To visualize this behavior, click the block, change the parameter value, and click "OK". The mask initialization code executes a "whos" command, but variable "complexGainVal" is not visible in the mask workspace.

If you execute the "whos" command in the MATLAB command window, you will see the variable "complexGainVal".

## Organize Mask Initialization and Callbacks in a MATLAB File

You can organize mask initialization and mask callback code in a separate MATLAB® class file. By using a separate MATLAB file you can:

- Organize all mask callbacks and initialization code in a single MATLAB file.
- Use code debugging capabilities such as breakpoints in MATLAB Editor.
- Reduce the memory footprint of the masks since the callbacks are stored in a MAT file instead of in the memory.
- Edit the mask callback code using either Mask Editor or MATLAB Editor.

### Explore the Model

This example model implements the equation  $y = u \cdot \text{gain} + \text{bias}$  through mask initialization and callbacks. There are three mask parameters, `gain`, `bias`, and `EnableBias`. The value of `EnableBias` is set by selecting or clearing the `Enable Bias` check box. In the mask initialization section, the value of `EnableBias` is retrieved from the mask workspace, if it is not selected, then the value of `bias` is set to 0. In the mask parameter callback section, if `EnableBias` is selected, then the property `MaskEnables` of all the parameters are set to on, otherwise the `MaskEnables` property of all parameters are set to on except `Enable Bias` parameter. In the mask control callback section, you can set the `MaskEnables` property for all parameters to on clicking the **Reset Visibility** button.

```
open_system("slexMaskCallbackFileExample.slx");
```

## Mask Callback File

This example shows the usage of a MATLAB callback file to author mask callbacks (mask initialization, parameter callbacks and dialog control callbacks).

This example shows how to author mask initialization code, parameter and dialog control callbacks in a MATLAB class file.

## Author Mask Callback Code in MATLAB File

You can organize mask initialization and callback code in a single MATLAB file. Name of the callback file and the name of the class that the function belongs to must be the same. For example, if the name of the callback file is `mask_cb_file_example` then the name of the class file is `mask_cb_file_example`. The MATLAB file must be created in the MATLAB path.

```

1 classdef mask_cb_file_example
2
3     I methods(Static)
4
5         % Following properties are available for function argument 'maskInitContext'
6         % - BlockHandle
7         % - MaskObject
8         % - MaskWorkspace - Use get/set APIs to work with mask workspace.
9
10        function MaskInitialization(maskInitContext)
11            blkHandle = maskInitContext.BlockHandle; % Block Handle of this block
12            maskObj = maskInitContext.MaskObject; % Mask object of this masked block
13            maskWorkspace = maskInitContext.MaskWorkspace; % Use this to work with mask workspace
14
15            disp('Mask initialization triggered');
16
17            % Get value of 'enableBias' parameter using mask workspace get() API.
18            enableBiasValue = maskWorkspace.get('enableBias');
19
20            if ~enableBiasValue
21                % Set 'BiasValue' parameter value to 0 using mark workspce set() API.
22                maskWorkspace.set('biasValue',0);
23

```

## Write Mask Initialization Code

In this example, the mask initialization code sets the `biasValue` to 0 if the parameter **EnableBias** is cleared.

To view the mask initialization written for this example, right-click Masked Block Using a Mask Callback File. > In the context menu, click **Mask > Edit Mask**. On the **Code** tab, the `mask_cb_file_example` file contains the initialization and callback code for the model.

The mask initialization function should be in the following format:

```

function MaskInitialization(maskInitContext)
    blkHandle = maskInitContext.BlockHandle; % Block Handle of this block
    maskObj = maskInitContext.MaskObject; % Mask object of this masked block
    maskWorkspace = maskInitContext.MaskWorkspace; % Use this to work with mask workspace

    disp('Mask initialization triggered');

    % Get value of 'EnableBias' parameter using mask workspace get() API.
    enableBiasValue = maskWorkspace.get('EnableBias');

    if ~enableBiasValue
        % Set 'BiasValue' parameter value to 0 using mark workspce set() API.
        maskWorkspace.set('biasValue',0);
    end
end

```

- The method that executes the mask initialization code must be static.
- Mask initialization function must be named as `MaskInitialization`.

- Input argument to the mask initialization function is a `struct` with these properties:

`BlockHandle`: Handle of the block.

`MaskObject`: Mask object of the masked block.

`MaskWorkspace`: Use this property to access the mask workspace:

```
maskWorkspace = maskInitContext.MaskWorkspace;
```

**Note:** The properties of the input argument of the initialization function are case sensitive.

- Use `set` and `get` methods along with the `maskworkspace` property to set and retrieve the values of `MaskWorkspace` variables.

### Write Mask Parameter Callback Code

In this example, the parameter callback code is written to enable the parameters on selecting or clearing the **Enable Bias**.

```
function EnableBias(callbackContext)
    % Block Handle of this block
    blkHandle = callbackContext.BlockHandle;
    % Parameter object for 'EnableBias'.
    parameterObj = callbackContext.ParameterObject;

    disp('EnableBias callback triggered');

    % Set the 'MaskEnables' property for each parameters
    if strcmp(get_param(blkHandle, 'EnableBias'), 'on')
        set_param(blkHandle, 'MaskEnables', {'on', 'on', 'on'});
    else
        set_param(blkHandle, 'MaskEnables', {'on', 'on', 'off'});
    end
end
```

- The function name of the parameter callback must be same as the parameter name.
- Input argument to the mask parameter callback function is a `struct` with these properties.

`BlockHandle`: Block handle of the block.

`MaskObject`: Mask object of the masked block or the dialog control object of the dialog control.

- Use `set_param` and `get_param` to set and retrieve the values of parameters.

### Write Mask Dialog Control Callback

In this example, the dialog control callback code is written to enable all the mask parameters on clicking the **ResetVisibility** button in the mask dialog control.

The control callback code should be in the following format:

```
function ResetVisibility(callbackContext)
    % Block Handle of this block
    blkHandle = callbackContext.BlockHandle;
    % Dialog Control object for 'ResetVisibility'.
    resetButtonObj = callbackContext.DialogControlObject;
```

```

disp('ResetVisibility button callback triggered');

% Reset mask enables.
set_param(blkHandle, 'MaskEnables', {'on', 'on', 'on'});
end

```

- The function name of the control callback must be same as the name of the property set by the dialog box control.
- Input argument to the mask control callback function is a struct with these properties.

BlockHandle: Block handle of the block.

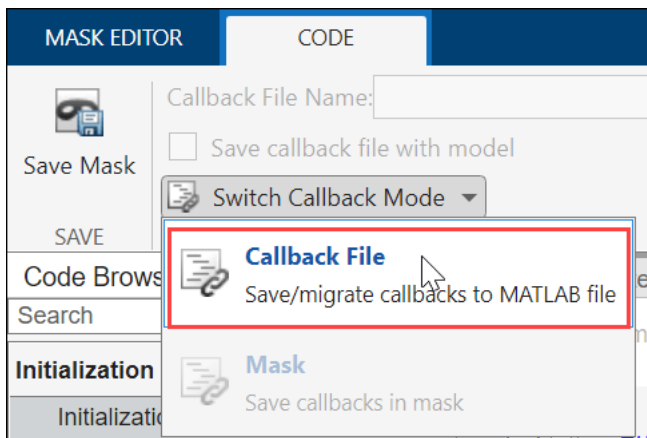

DialogControlObject: Dialog control object of the dialog control.

- Use `set_param` and `get_param` to set and retrieve the values of parameters.

### Migrate Existing Callback Code to MATLAB File

You can migrate existing callback code to MATLAB file. The template of the code is migrated but you will have to inspect the mask initialization code and make corrections before executing it. For example, you must modify the code to set and get values of variables from the mask workspace in the mask initialization section using the `set` and `get` methods.

To migrate the existing callback code, right-click the masked block, from the context menu select, **Mask > Edit Mask**. In the **Code** tab, click **Switch Callback Mode** and select callback file.

In the dialog box, click **Yes** to migrate the existing callback and save. Click **No**, to save mask callbacks in a separate MATLAB file and you do not want to migrate. Save the mask to save the callback file.

**Note:** If you do not wish to store the mask callback in a separate MATLAB file and if you want to store the mask callback in the mask object, go to **Mask Editor**, click **Code > Switch Callback Mode > select Mask**.

### Save Callback File with the Model

You can also package the callback file along with the model. Use the option **Save callback file with model** in the toolstrip. You must also save the model to package the callback file along with the model.

**Note:** To edit the callback file saved with the model, you must load the model. Use the **Open** option in the toolstrip to open the callback file in MATLAB editor.

# Creating Custom Blocks

## Types of Custom Blocks

### In this section...

“MATLAB Function Blocks” on page 43-2

“MATLAB System Blocks” on page 43-2

“Subsystem Blocks” on page 43-3

“C Caller Block” on page 43-3

“C Function Block” on page 43-3

“S-Function Blocks” on page 43-3

“Masked Blocks” on page 43-4

### MATLAB Function Blocks

A MATLAB Function block allows you to use the MATLAB language to define custom functionality. These blocks are a good starting point for creating a custom block if:

- You have an existing MATLAB function that models the custom functionality.
- You find it easier to model custom functionality using a MATLAB function than using a Simulink block diagram.
- The custom functionality does not include continuous or discrete dynamic states.

You can create a custom block from a MATLAB function using one of the following types of MATLAB function blocks.

- The Interpreted MATLAB Function block allows you to use a MATLAB function to define a SISO block.
- The MATLAB Function block allows you to define a custom block with multiple inputs and outputs that you can deploy to an embedded processor.
- The Fcn block allows you to use a MATLAB expression to define a single-input, single-output (SISO) block.

Each of these blocks has advantages in particular modeling applications. For example, you can generate code from models containing MATLAB Function blocks, whereas you cannot generate code for models containing a Fcn block.

### MATLAB System Blocks

A MATLAB System block allows you to use System objects written with the MATLAB language to define custom functionality. These blocks are a good starting point for creating a custom block if:

- You have an existing System object that models the custom functionality.
- You find it easier to model custom functionality using the MATLAB language than using a Simulink block diagram.
- The custom functionality includes discrete dynamic states.

## Subsystem Blocks

Subsystem blocks allow you to build a Simulink diagram to define custom functionality. These blocks serve as a good starting point for creating a custom block if:

- You have an existing Simulink diagram that models custom functionality.
- You find it easier to model custom functionality using a graphical representation rather than using handwritten code.
- The custom functionality is a function of continuous or discrete system states.
- You can model the custom functionality using existing Simulink blocks.

Once you have a Simulink subsystem that models the required behavior, you can convert it into a custom block by:

- 1 Masking the block to hide the block contents and provide a custom block dialog box.
- 2 Placing the block in a library to prohibit modifications and allow for easily updating copies of the block.

For more information, see “Custom Libraries” and “Create Block Masks”.

## C Caller Block

The C Caller block allows you to integrate C code into Simulink blocks. These blocks serve as a good starting point for creating a custom block if:

- You have existing C code that models custom functionality.
- Your C functions do not read or write global/static variables.
- You want blocks to easily integrate with other Simulink features, such as Simulink Coverage, Simulink Test, and Simulink Coder.
- You are not modeling dynamic systems.

## C Function Block

The C Function block allows you to integrate C code into Simulink blocks. These blocks serve as a good starting point for creating a custom block if:

- You have existing C code that models custom functionality.
- You want to call multiple C functions from the block, or call C functions conditionally.
- You want to include C code to preprocess and postprocess data before and after calling C functions.
- You want to specify different code for simulation and code generation.
- You are not modeling dynamic systems with continuous states.

## S-Function Blocks

S-function blocks allow you to write MATLAB, C, or C++ code to define custom functionality. These blocks serve as a good starting point for creating a custom block if:

- You have existing MATLAB, C, or C++ code that models custom functionality.
- You use continuous or discrete dynamic states or other system behaviors that require access to the S-function API.
- You cannot model the custom functionality using existing Simulink blocks.

You can create a custom block from an S-function using one of the following types of S-function blocks.

- The Level-2 MATLAB S-Function block allows you to write your S-function using the MATLAB language. (See “Write Level-2 MATLAB S-Functions”). You can debug a MATLAB S-function during a simulation using the MATLAB debugger.
- The S-Function block allows you to write your S-function in C or C++, or to incorporate existing code into your model using a C MEX wrapper. (See “Implement C/C++ S-Functions”).
- The S-Function Builder block assists you in creating a C MEX S-function or a wrapper function to incorporate legacy C or C++ code. (See “Implement C/C++ S-Functions”).
- The Legacy Code Tool transforms existing C or C++ functions into C MEX S-functions. (See “Integrate C Functions Using Legacy Code Tool”).

The S-function target in the Simulink Coder product automatically generates a C MEX S-function from a graphical subsystem. If you want to build your custom block in a Simulink subsystem, but implement the final version of the block in an S-function, you can use the S-function target to convert the subsystem to an S-function. See “Use S-Function Target for Model or Subsystem” (Simulink Coder) in the Simulink Coder User's Guide for details and limitations on using the S-function target.

## Masked Blocks

You can customize any block by adding a mask to it. A mask is a custom interface to the block. You can customize a block using a mask in many ways, such as:

- Change the block appearance.
- Hide some or all of the parameters from the user of the block.
- Customize block parameters.

To learn more about masked blocks, see “Create Block Masks”.

## Comparison of Custom Block Functionality

In this section...
"Model State Behavior" on page 43-6
"Simulation Performance" on page 43-6
"Code Generation" on page 43-8
"Multiple Input and Output Ports" on page 43-9
"Speed of Updating the Simulink Diagram" on page 43-9
"Callback Methods" on page 43-10
"Comparing MATLAB S-Functions to MATLAB Functions for Code Generation" on page 43-11
"Expanding Custom Block Functionality" on page 43-11

When creating a custom block, consider:

- Does the block model continuous or discrete state behavior on page 43-6?
- Is the simulation performance on page 43-6 important?
- Do you need to generate code on page 43-8 for a model containing the custom block?

This table shows how each custom block type addresses the three concerns.

### Modelling Considerations

Custom Block Type	Model State Dynamics on page 43-6	Simulation Performance on page 43-6	Code Generation on page 43-8
Interpreted MATLAB Function	No	Less fast	Not supported
Level-2 MATLAB S-Function	Yes	Less fast	Requires a TLC file
MATLAB Function	No	Fast	Supported with exceptions
MATLAB System	Yes	Fast	Supported with exceptions
S-Function	Yes	Fast	Requires a TLC file or non-inline S-Function support
C Caller	No	Fast	Supported
C Function	Yes	Fast	Supported
S-Function Builder	Yes	Fast	Supported
Simulink Function	Yes	Fast	Supported
Subsystem	Yes	Fast	Supported
Fcn	No	Very fast	Supported

For detailed design of custom blocks, consider:

- Does the custom block need multiple input and output ports on page 43-9?
- What are the callback methods on page 43-10 to communicate with the Simulink engine and which custom blocks let you implement all or a subset of these callback methods?

- How important is the effect of the custom block on the speed of updating the Simulink diagram on page 43-9?

## Model State Behavior

You need to model the state behavior for a block that requires some or all of its previous outputs to compute its current outputs. See “State variables” for more information.

Custom Block Type	Notes
Fcn, Interpreted MATLAB Function, C Caller	Does not allow you to model state behavior.
MATLAB Function, C Function	Allows you to model a discrete state using persistent variables.
Level-2 MATLAB S-Function	Allows you to model both continuous and discrete state behavior using the <code>ContStates</code> or <code>Dwork</code> run-time object methods in combination with block callback methods. For a list of supported methods, see “Level-2 MATLAB S-Function Callback Methods” in “Write Level-2 MATLAB S-Functions”.
MATLAB System	Allows you to model discrete state behavior using <code>DiscreteState</code> properties of the <code>System</code> object, in combination with block callback methods. This block uses <code>System</code> object methods for callback methods: <code>mdlOutputs</code> ( <code>stepImpl</code> , <code>outputImpl</code> ), <code>mdlUpdate</code> ( <code>updateImpl</code> ), <code>mdlInitializeConditions</code> ( <code>resetImpl</code> ), <code>mdlStart</code> ( <code>setupImpl</code> ), <code>mdlTerminate</code> ( <code>releaseImpl</code> ). For more information see “What Are System Objects?”.
C MEX S-Function, S-Function Builder	Allows you to model both continuous and discrete state behavior in combination with block callback methods. For more information, see “Callback Methods for C MEX S-Functions”
Simulink Function	Communicates directly with the engine. You can model the state behavior using appropriate blocks from the continuous and discrete Simulink block libraries. When multiple calls to this function originate from different callers, the state values are also persistent between these calls. For more information, see “Call a Simulink Function Block from Multiple Sites” on page 10-156.
Subsystem	Communicates directly with the engine. You can model the state behavior using appropriate blocks from the continuous and discrete Simulink block libraries.

## Simulation Performance

For most applications, all custom block types provide satisfactory simulation performance. Use the Simulink profiler to get the actual performance indication. See “How Profiler Captures Performance Data” on page 34-5 for more information.

The two categories of performance indication are the interface cost and the algorithm cost. The interface cost is the time it takes to move data from the Simulink engine into the block. The algorithm cost is the time it takes to perform the algorithm that the block implements.

Custom Block Type	Notes
Fcn	Has the highest simulation performance. The block is tightly integrated with the Simulink engine and optimized for simulation and code generation.

Custom Block Type	Notes
Interpreted MATLAB Function	<p>Has a slower performance due to the interface, but has the same algorithm cost as a MATLAB function.</p> <p>When block data (such as inputs and outputs) is accessed or returned from an Interpreted MATLAB Function block, the Simulink engine packages this data into MATLAB arrays. This packaging takes additional time and causes a temporary increase in memory during communication. If you pass large amounts of data across this interface, such as frames or arrays, the performance can be substantially slow.</p> <p>Once the data has been converted, the MATLAB execution engine executes the algorithm. As a result, the algorithm cost is the same as for MATLAB function.</p>
Level-2 MATLAB S-Function	<p>Incurs the same algorithm costs as the Interpreted MATLAB Function block, but with a slightly higher interface cost. Since MATLAB S-Functions can handle multiple inputs and outputs, the packaging is more complicated than for the Interpreted MATLAB Function block. In addition, the Simulink engine calls the MATLAB execution engine for each block method you implement, whereas the Interpreted MATLAB Function block calls the MATLAB execution engine only for the <b>Outputs</b> method.</p>
MATLAB Function	<p>Performs simulation through code generation and incurs the same interface cost as other Simulink built-in blocks.</p> <p>The algorithm cost of this block is harder to analyze because of the block's implementation. On average, a function for this block and the MATLAB function run at about the same speed.</p> <p>If the MATLAB Function block has code that uses <code>coder.extrinsic</code> to call out to the MATLAB execution engine, it incurs all the costs that the MATLAB S-Function or Interpreted MATLAB Function block incur. Calling out to the MATLAB execution engine from a MATLAB Function block produces a warning to prevent you from doing so unintentionally.</p> <p>To reduce the algorithm cost, you can disable debugging for all MATLAB Function blocks.</p>
MATLAB System	<p>In the interpreted execution mode, performance is similar to that of the Level-2 MATLAB S-function because the model simulates the block using the MATLAB execution engine. In the code generation mode, performance is similar to that of the MATLAB Function because the model simulates the block using the generated code. For more information, see the MATLAB Function entry in this table.</p>
C Caller, C Function	<p>First time model simulation with could be slower due to parsing and building of the custom code. To speed up the simulation after the first compile, from <b>Configuration parameters</b>, select <b>Faster Builds</b> for faster compile and select <b>Faster Runs</b> for faster simulation.</p>
C MEX S-Function	<p>Simulates via the compiled code and incurs the same interface cost as Simulink built-in blocks. The algorithm cost depends on the complexity of the S-Function.</p>
S-Function Builder	<p>This block only builds an S-Function from the specifications and C code you supply. You can also use this block as a wrapper for the generated S-Function in models. The algorithm cost of this block compared to C MEX S-Function is incurred only from the wrapper.</p>

Custom Block Type	Notes
Simulink Function, Subsystem	<p>If included in a library, introduces no interface or algorithm costs beyond what would normally be incurred if the block existed as a regular subsystem in the model.</p> <p>Performance is proportional to the complexity of the algorithm implemented in the subsystem. If the subsystem is contained in a library, some cost is incurred when Simulink loads any unloaded libraries the first time the diagram is updated or readied for simulation. If all referenced library blocks remain unchanged, Simulink does not subsequently reload the library. Compiling the model becomes faster than if the model did not use libraries.</p>

## Code Generation

You need code generation if your model is part of a bigger system. Not all custom block types support code generation with Simulink Coder.

Custom Block Type	Notes
Fcn	Supports code generation.
Interpreted MATLAB Function	Does not support code generation.
C Caller, C Function	Supports code generation.
Level-2 MATLAB S-Function	Generates code only if you implement the algorithm using a Target Language Compiler (TLC) function. In accelerated and external mode simulations, you can choose to execute the S-Function in the interpretive mode by calling back to the MATLAB execution engine without implementing the algorithm in TLC. If the MATLAB S-Function is <code>SimViewingDevice</code> , the Simulink Coder product automatically omits the block during code generation.
MATLAB Function, MATLAB System	Supports code generation. However, if your block calls out to the MATLAB execution engine, it will build with the Simulink Coder product only if the calls to the MATLAB execution engine do not affect the block outputs. Under this condition, the Simulink Coder product omits these calls from the generated C code. This feature allows you to leave visualization code in place, even when generating embedded code.
C MEX S-Function, S-Function Builder	<p>Both supports code generation.</p> <ul style="list-style-type: none"> <li>For non-inlined S-Functions, the Simulink Coder product uses the C MEX function during code generation.</li> <li>In the case of C MEX S-Functions, if you need to either inline the S-Function or create a wrapper for handwritten code, you must write a TLC file for the S-Function.</li> <li>In the case of S-Function Builder, you can choose the Generate wrapper TLC option to automatically generate a TLC file.</li> </ul> <p>See “S-Functions and Code Generation” (Simulink Coder) for more information.</p>
Simulink Function	Supports code generation.

Custom Block Type	Notes
Subsystem	Supports code generation as long as the blocks contained within the subsystem support code generation. For more information, see “Subsystems” (Simulink Coder).

## Multiple Input and Output Ports

These types of custom blocks support multiple input and output ports.

Custom Block Type	Notes
Fcn, Interpreted MATLAB Function	Supports only a single input and a single output port.
MATLAB Function	Supports multiple input and output ports, including bus signals. See “How Structure Inputs and Outputs Interface with Bus Signals” on page 49-65 for more information.
MATLAB System	Supports multiple input and output ports, including bus signals. In addition, you can modify the number of input and output ports based on system object properties using the <code>getNumInputs</code> and <code>getNumOutputs</code> methods.
C Caller, C Function	Supports multiple input and output ports, including bus signals.
Level-2 MATLAB S-Function, C MEX S-Function, S-Function Builder	Supports multiple input and output ports. In addition, you can modify the number of input and output ports based on user-defined parameters. The C MEX S-Function and S-Function Builder support bus signals.
Simulink Function	Supports multiple input and output ports, including bus signals.
Subsystem	Supports multiple input and output ports, including bus signals. In addition, you can modify the number of input and output ports based on user-defined parameters. See “Self-Modifiable Linked Subsystems” on page 44-18 for more information.

## Speed of Updating the Simulink Diagram

Simulink updates the diagram before every simulation and when requested by the user. Every block introduces some overhead into the diagram update process.

Custom Block Type	Notes
Fcn, Interpreted MATLAB Function	Low diagram update cost.
MATLAB Function, C Caller, C Function	Simulation is performed through code generation, so this blocks can take a significant amount of time when first updated. However, because code generation is incremental, Simulink does not repeatedly update the block if the block and the signals connected to it have not changed.
MATLAB System	Faster than MATLAB Function because code is not generated to update the diagram. Since, code generation is incremental, Simulink does not repeatedly update the block if the block and the signals connected to it have not changed.

Custom Block Type	Notes
C MEX S-Function, Level-2 MATLAB S-Function	Incurs greater costs than other Simulink blocks only if it overrides methods executed when updating the diagram. If these methods become complex, they can contribute significantly to the time it takes to update the diagram. For a list of methods executed when updating the diagram, see the process view in “Simulink Engine Interaction with C S-Functions”. When updating the diagram, Simulink invokes all relevant methods in the model initialization phase up to, but not including, <code>mdlStart</code> .
Simulink Function, Subsystem	The speed is proportional to the complexity of the algorithm implemented in the subsystem. If the subsystem is contained in a library, some cost is incurred when Simulink loads any unloaded libraries the first time the diagram is updated or readied for simulation. If all referenced library blocks remain unchanged, Simulink does not subsequently reload the library. Compiling the model becomes faster than if the model does not use libraries.

## Callback Methods

Simulink blocks communicate with the Simulink engine through block callback methods, which fully specify the behavior of blocks (except the Simulink Function block). Each custom block type allows you to implement a different set of callback methods. To learn how blocks interact with Simulink engine, see “Simulink Engine Interaction with C S-Functions”. This table uses “S-Function Callback Methods” names as equivalents.

Custom Block Type	Notes
Fcn, Interpreted MATLAB Function, MATLAB Function, C Caller	All create a <code>mdlOutputs</code> method to calculate the value of outputs given the value of inputs. You cannot implement any other callback methods using one of these blocks and, therefore, cannot model state behavior.
C Function	Allows implementation of start, output, and terminate callback methods. Allows modeling of discrete states with persistent data.
Level-2 MATLAB S-Function	Allows implementation of a larger subset of callback methods, including methods you can use to model continuous and discrete states. For a list of supported methods, see “Level-2 MATLAB S-Function Callback Methods” in “Write Level-2 MATLAB S-Functions”.
MATLAB System	Uses System object methods for callback methods: <code>mdlOutputs</code> ( <code>stepImpl</code> , <code>outputImpl</code> ), <code>mdlUpdate</code> ( <code>updateImpl</code> ), <code>mdlInitializeConditions</code> ( <code>resetImpl</code> ), <code>mdlStart</code> ( <code>setupImpl</code> ), <code>mdlTerminate</code> ( <code>releaseImpl</code> ). For more information, see “Simulink Engine Interaction with System Object Methods” on page 50-26
C MEX S-Function	Allows implementation of a complete set of callback methods.
S-Function Builder	Allows implementation of <code>mdlOutputs</code> , <code>mdlDerivatives</code> and <code>mdlUpdate</code> .
Simulink Function	Packaged as a standalone function. Any caller to this function becomes part of one of the callback methods based on the caller’s location.
Subsystem	Communicates directly with the engine. You can model state behaviors using appropriate blocks from the continuous and discrete Simulink block libraries.

## Comparing MATLAB S-Functions to MATLAB Functions for Code Generation

MATLAB S-functions and MATLAB functions for code generation have some fundamental differences.

- The Simulink Coder product can generate code for both MATLAB S-functions and MATLAB functions for code generation. However, MATLAB S-functions require a Target Language Compiler (TLC) file for code generation. MATLAB functions for code generation do not require a TLC file.
- MATLAB S-functions can use any MATLAB function whereas MATLAB functions for code generation are a subset of the MATLAB language. For a list of supported functions for code generation, see “Functions and Objects Supported for C/C++ Code Generation” on page 54-2.
- MATLAB S-functions can model discrete and continuous state dynamics whereas MATLAB functions for code generation cannot model state dynamics.

## Expanding Custom Block Functionality

You can expand the functionality of any custom block using callbacks and MATLAB graphics.

Block callbacks perform user-defined actions at specific points in the simulation. For example, the callback can load data into the MATLAB workspace before the simulation or generate a graph of simulation data at the end of the simulation. You can assign block callbacks to any of the custom block types. For a list of available callbacks and more information on how to use them, see “Block Callbacks” on page 4-59.

App Designer, the MATLAB graphical user interface development environment, provides tools for easily creating custom user interfaces. See “App Building” for more information on using App Designer.

```

### How to Design a Custom Block

In general, use the following process to design a custom block:

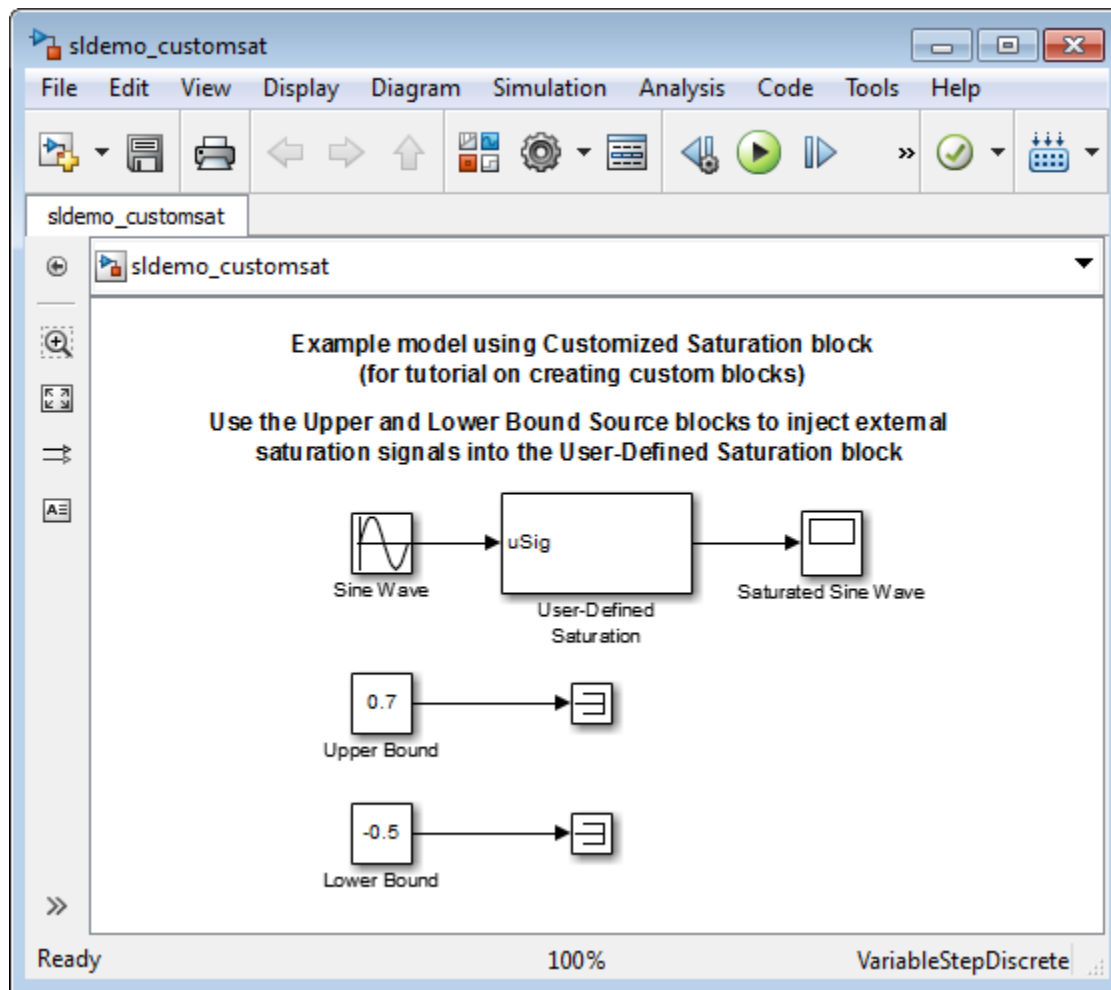

- 1 “Defining Custom Block Behavior” on page 43-14
- 2 “Deciding on a Custom Block Type” on page 43-14
- 3 “Placing Custom Blocks in a Library” on page 43-18
- 4 “Adding a User Interface to a Custom Block” on page 43-19

Suppose you want to create a customized saturation block that limits the upper and lower bounds of a signal based on either a block parameter or the value of an input signal. In a second version of the block, you want the option to plot the saturation limits after the simulation is finished. The following tutorial steps you through designing these blocks. The library `ex_customsat_lib` contains the two versions of the customized saturation block.

The example model `sldemo_customsat` uses the basic version of the block.

## Defining Custom Block Behavior

Begin by defining the features and limitations of your custom block. In this example, the block supports the following features:

- Turning on and off the upper or lower saturation limit.
- Setting the upper and/or lower limits via a block parameters.
- Setting the upper and/or lower limits using an input signal.

It also has the following restrictions:

- The input signal under saturation must be a scalar.
- The input signal and saturation limits must all have a data type of double.
- Code generation is not required.

## Deciding on a Custom Block Type

Based on the custom block features, the implementation needs to support the following:

- Multiple input ports
- A relatively simple algorithm
- No continuous or discrete system states

Therefore, this tutorial implements the custom block using a Level-2 MATLAB S-function. MATLAB S-functions support multiple inputs and, because the algorithm is simple, do not have significant overhead when updating the diagram or simulating the model. See “Comparison of Custom Block Functionality” on page 43-5 for a description of the different functionality provided by MATLAB S-functions as compared to other types of custom blocks.

### Parameterizing the MATLAB S-Function

Begin by defining the S-function parameters. This example requires four parameters:

- The first parameter indicates how the upper saturation limit is set. The limit can be off, set via a block parameter, or set via an input signal.
- The second parameter is the value of the upper saturation limit. This value is used only if the upper saturation limit is set via a block parameter. In the event this parameter is used, you should be able to change the parameter value during the simulation, i.e., the parameter is tunable.
- The third parameter indicates how the lower saturation limit is set. The limit can be off, set via a block parameter, or set via an input signal.
- The fourth parameter is the value of the lower saturation limit. This value is used only if the lower saturation limit is set via a block parameter. As with the upper saturation limit, this parameter is tunable when in use.

The first and third S-function parameters represent modes that must be translated into values the S-function can recognize. Therefore, define the following values for the upper and lower saturation limit modes:

- 1 indicates that the saturation limit is off.
- 2 indicates that the saturation limit is set via a block parameter.
- 3 indicates that the saturation limit is set via an input signal.

### Writing the MATLAB S-Function

After you define the S-function parameters and functionality, write the S-function. The template `msfuntmpl.m` provides a starting point for writing a Level-2 MATLAB S-function. You can find a completed version of the custom saturation block in the file `custom_sat.m`. Open this file before continuing with this tutorial.

This S-function modifies the S-function template as follows:

- The `setup` function initializes the number of input ports based on the values entered for the upper and lower saturation limit modes. If the limits are set via input signals, the method adds input ports to the block. The `setup` method then indicates there are four S-function parameters and sets the parameter tunability. Finally, the method registers the S-function methods used during simulation.

```
function setup(block)

% The Simulink engine passes an instance of the Simulink.MSFcnRunTimeBlock
% class to the setup method in the input argument "block". This is known as
% the S-function block's run-time object.
```

```

% Register original number of input ports based on the S-function
% parameter values

try % Wrap in a try/catch, in case no S-function parameters are entered
    lowMode = block.DialogPrm(1).Data;
    upMode = block.DialogPrm(3).Data;
    numInPorts = 1 + isequal(lowMode,3) + isequal(upMode,3);
catch
    numInPorts=1;
end % try/catch
block.NumInputPorts = numInPorts;
block.NumOutputPorts = 1;

% Setup port properties to be inherited or dynamic
block.SetPreCompInpPortInfoToDynamic;
block.SetPreCompOutPortInfoToDynamic;

% Override input port properties
block.InputPort(1).DatatypeID = 0; % double
block.InputPort(1).Complexity = 'Real';

% Override output port properties
block.OutputPort(1).DatatypeID = 0; % double
block.OutputPort(1).Complexity = 'Real';

% Register parameters. In order:
% -- If the upper bound is off (1) or on and set via a block parameter (2)
%    or input signal (3)
% -- The upper limit value. Should be empty if the upper limit is off or
%    set via an input signal
% -- If the lower bound is off (1) or on and set via a block parameter (2)
%    or input signal (3)
% -- The lower limit value. Should be empty if the lower limit is off or
%    set via an input signal
block.NumDialogPrms = 4;
block.DialogPrmsTunable = {'Nontunable','Tunable','Nontunable', ...
    'Tunable'};

% Register continuous sample times [0 offset]
block.SampleTimes = [0 0];

%% -----
%% Options
%% -----
% Specify if Accelerator should use TLC or call back into
% MATLAB script
block.SetAccelRunOnTLC(false);

%% -----
%% Register methods called during update diagram/compilation
%% -----

block.RegBlockMethod('CheckParameters', @CheckPrms);
block.RegBlockMethod('ProcessParameters', @ProcessPrms);
block.RegBlockMethod('PostPropagationSetup', @DoPostPropSetup);
block.RegBlockMethod('Outputs', @Outputs);
block.RegBlockMethod('Terminate', @Terminate);
%end setup function

```

- The CheckParameters method verifies the values entered into the Level-2 MATLAB S-Function block.

```

function CheckPrms(block)

lowMode = block.DialogPrm(1).Data;
lowVal = block.DialogPrm(2).Data;
upMode = block.DialogPrm(3).Data;
upVal = block.DialogPrm(4).Data;

% The first and third dialog parameters must have values of 1-3
if ~any(upMode == [1 2 3]);
    error('The first dialog parameter must be a value of 1, 2, or 3');
end

```

```

end
if ~any(lowMode == [1 2 3]);
    error('The first dialog parameter must be a value of 1, 2, or 3');
end

% If the upper or lower bound is specified via a dialog, make sure there
% is a specified bound. Also, check that the value is of type double
if isequal(upMode,2),
    if isempty(upVal),
        error('Enter a value for the upper saturation limit.');
```

```

    end
    if ~strcmp(class(upVal), 'double')
        error('The upper saturation limit must be of type double.');
```

```

    end
end

if isequal(lowMode,2),
    if isempty(lowVal),
        error('Enter a value for the lower saturation limit.');
```

```

    end
    if ~strcmp(class(lowVal), 'double')
        error('The lower saturation limit must be of type double.');
```

```

    end
end

% If a lower and upper limit are specified, make sure the specified
% limits are compatible.
if isequal(upMode,2) && isequal(lowMode,2),
    if lowVal >= upVal,
        error('The lower bound must be less than the upper bound.');
```

```

    end
end
end

```

```
%end CheckPrms function
```

- The `ProcessParameters` and `PostPropagationSetup` methods handle the S-function parameter tuning.

```
function ProcessPrms(block)
```

```
%% Update run time parameters
block.AutoUpdateRuntimePrms;
```

```
%end ProcessPrms function
```

```
function DoPostPropSetup(block)
```

```
%% Register all tunable parameters as runtime parameters.
block.AutoRegRuntimePrms;
```

```
%end DoPostPropSetup function
```

- The `Outputs` method calculates the block's output based on the S-function parameter settings and any input signals.

```
function Outputs(block)
```

```
lowMode    = block.DialogPrm(1).Data;
upMode     = block.DialogPrm(3).Data;
sigVal     = block.InputPort(1).Data;
lowPortNum = 2; % Initialize potential input number for lower saturation limit
```

```
% Check upper saturation limit
if isequal(upMode,2), % Set via a block parameter
    upVal = block.RuntimePrm(2).Data;
elseif isequal(upMode,3), % Set via an input port
    upVal = block.InputPort(2).Data;
    lowPortNum = 3; % Move lower boundary down one port number
else
    upVal = inf;
```

```

end

% Check lower saturation limit
if isequal(lowMode,2), % Set via a block parameter
    lowVal = block.RuntimePrm(1).Data;
elseif isequal(lowMode,3), % Set via an input port
    lowVal = block.InputPort(lowPortNum).Data;
else
    lowVal = -inf;
end

% Assign new value to signal
if sigVal > upVal,
    sigVal = upVal;
elseif sigVal < lowVal,
    sigVal=lowVal;
end

block.OutputPort(1).Data = sigVal;

%end Outputs function

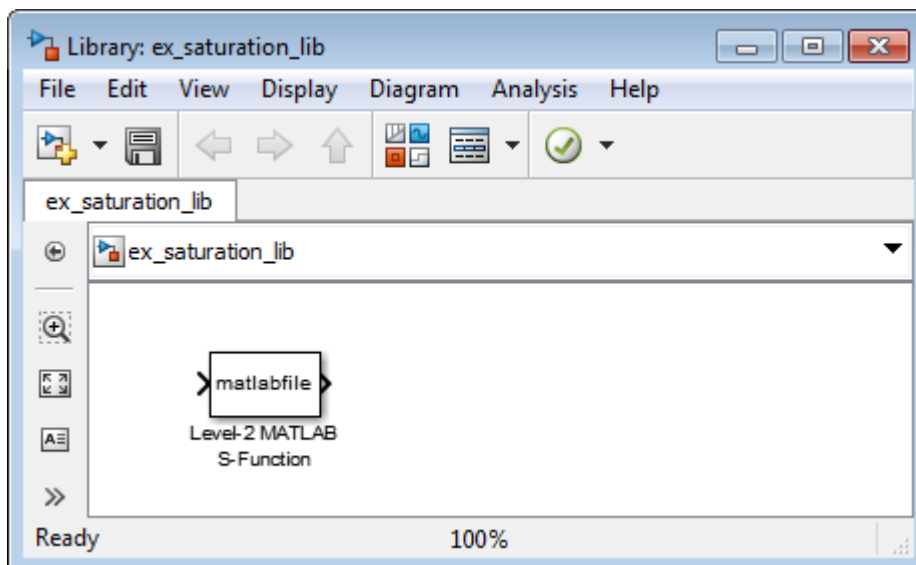

```

## Placing Custom Blocks in a Library

Libraries allow you to share your custom blocks with other users, easily update the functionality of copies of the custom block, and collect blocks for a particular project into a single location. If your custom block requires a bus as an interface, you can share the bus object with library users by creating the bus object in a data dictionary and attaching the dictionary to the library (See “Attach Data Dictionary to Custom Libraries” on page 79-36).

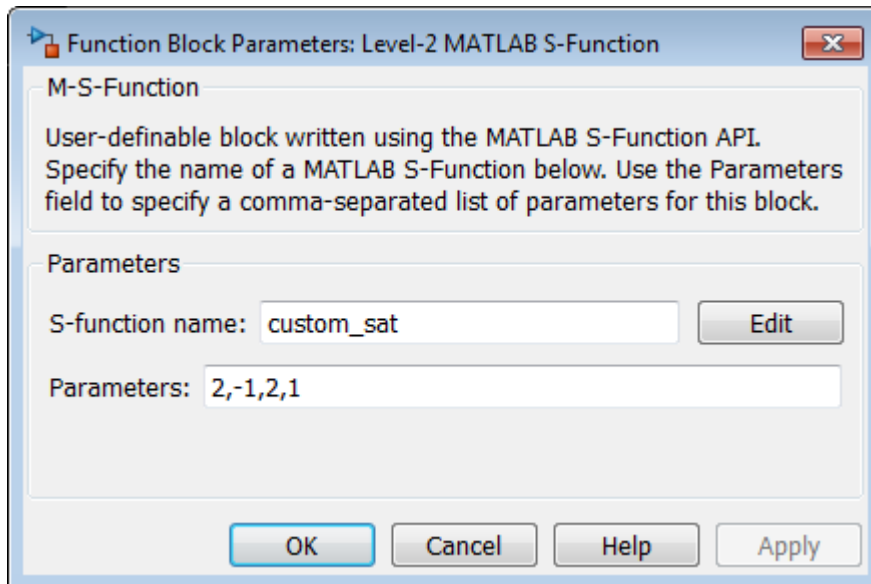

This example places the custom saturation block into a library.

- 1 In the Simulink Editor, in the **Simulation** tab, select **New > Library**.
- 2 From the User-Defined Functions library, drag a Level-2 MATLAB S-Function block into your new library.

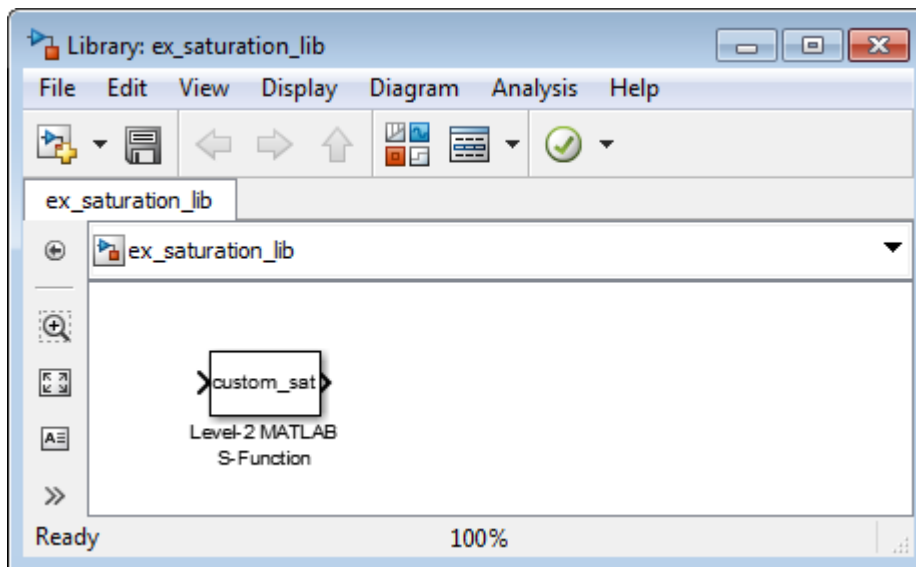

- 3 Save your library with the filename `saturation_lib`.
- 4 Double-click the block to open its Function Block Parameters dialog box.

- 5 In the **S-function name** field, enter the name of the S-function. For example, enter `custom_sat`. In the **Parameters** field enter `2, -1, 2, 1`.

- 6 Click **OK**.

You have created a custom saturation block that you can share with other users.

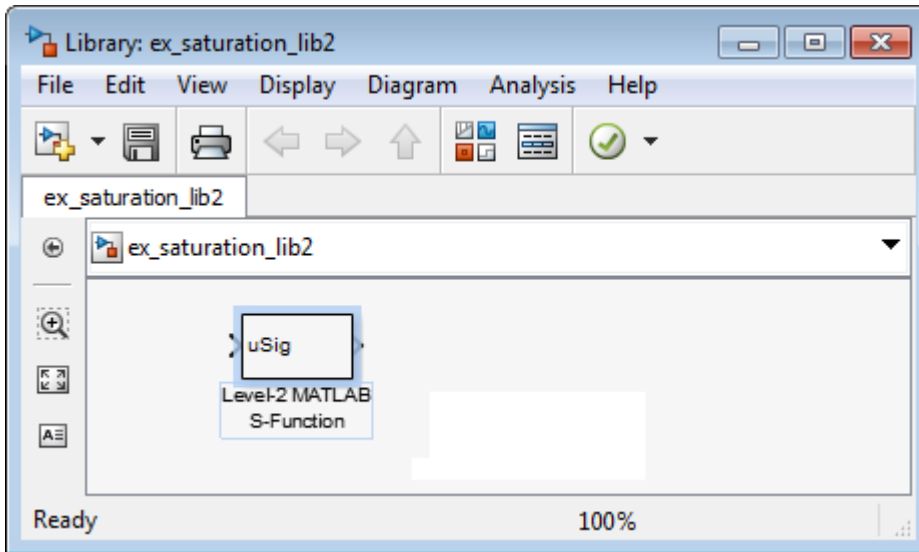

You can make the block easier to use by adding a customized user interface.

## Adding a User Interface to a Custom Block

You can create a block dialog box for a custom block using the masking features of Simulink. Masking the block also allows you to add port labels to indicate which ports corresponds to the input signal and the saturation limits.

- 1 Open the library `saturation_lib` that contains the custom block you created,
- 2 Right-click the Level-2 MATLAB S-Function block and select **Mask > Create Mask**.
- 3 On the **Icon & Ports** pane in the **Icons drawing commands** box, enter `port_label('input',1,'uSig')`, and then click **Apply**.

This command labels the default port as the input signal under saturation.

- 4 In the **Parameters & Dialog** pane, add four parameters corresponding to the four S-Function parameters. For each new parameter, drag a popup or edit control to the **Dialog box** section, as shown in the table. Drag each parameter into the Parameters group.

Type	Prompt	Name	Evaluate	Tunable	Popup options	Callback
popup	Upper boundary :	upMode	✓		No limit Enter limit as parameter Limit using input signal	customsat_callback('upperbound_callback', gcb)
edit	Upper limit:	upVal	✓	✓	N/A	customsat_callback('upperparam_callback', gcb)

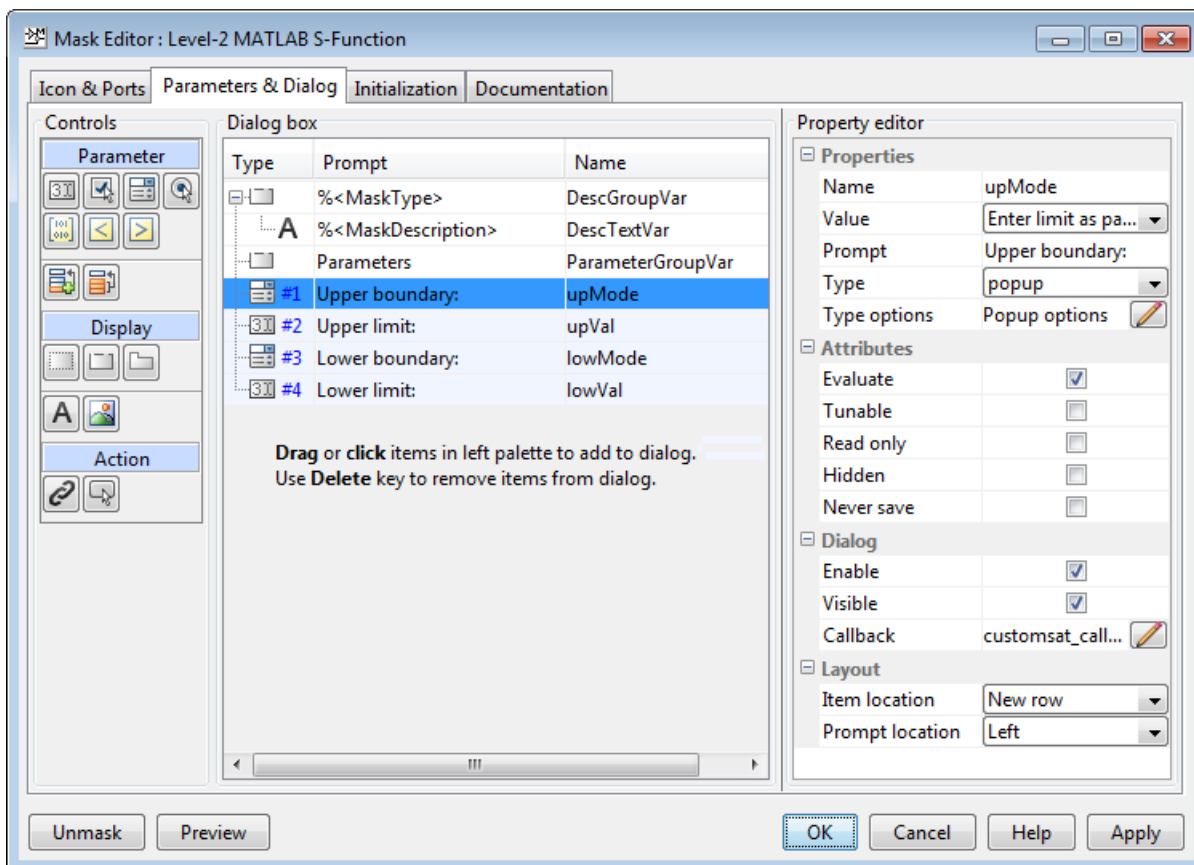

Type	Prompt	Name	Evaluate	Tunable	Popup options	Callback
popup	Lower boundary :	lowMode	✓		No limit Enter limit as parameter Limit using input signal	customsat_callback('lowerbound_callback', gcb)

Type	Prompt	Name	Evaluate	Tunable	Popup options	Callback
edit	Lower limit:	lowVal	✓	✓	N/A	customsat_callback('lowerparam_callback', gcb)

The MATLAB S-Function script `custom_sat_final.m` contains the mask parameter callbacks. Find `custom_sat_final.m` in your working folder to define the callbacks in this example. This MATLAB script has two input arguments. The first input argument is a character vector indicating which mask parameter invoked the callback. The second input argument is the handle to the associated Level-2 MATLAB S-Function block.

The figure shows the completed **Parameters & Dialog** pane in the Mask Editor.

5 In the **Initialization** pane, select the **Allow library block to modify its contents** check box. This setting allows the S-function to change the number of ports on the block.

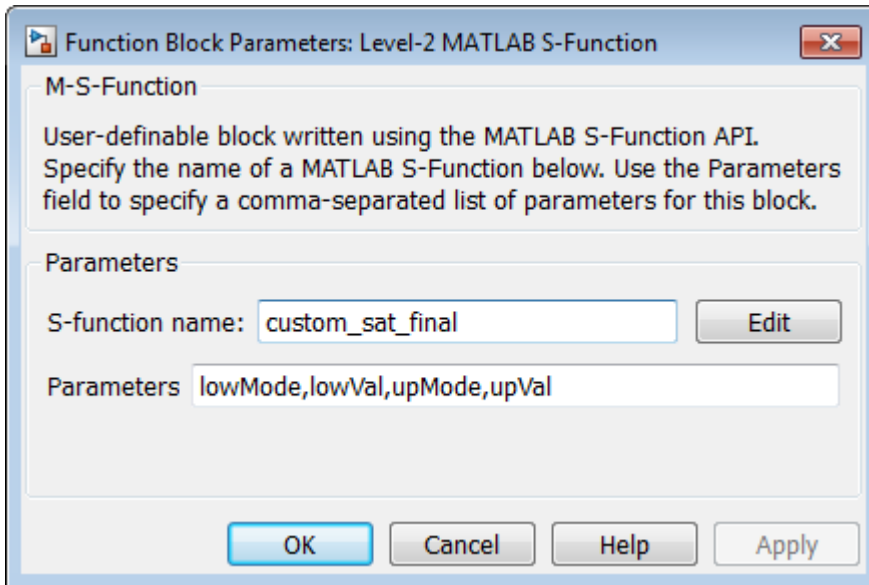

6 In the **Documentation** pane:

- In the **Mask type** field, enter  
Customized Saturation
- In the **Mask description** field, enter

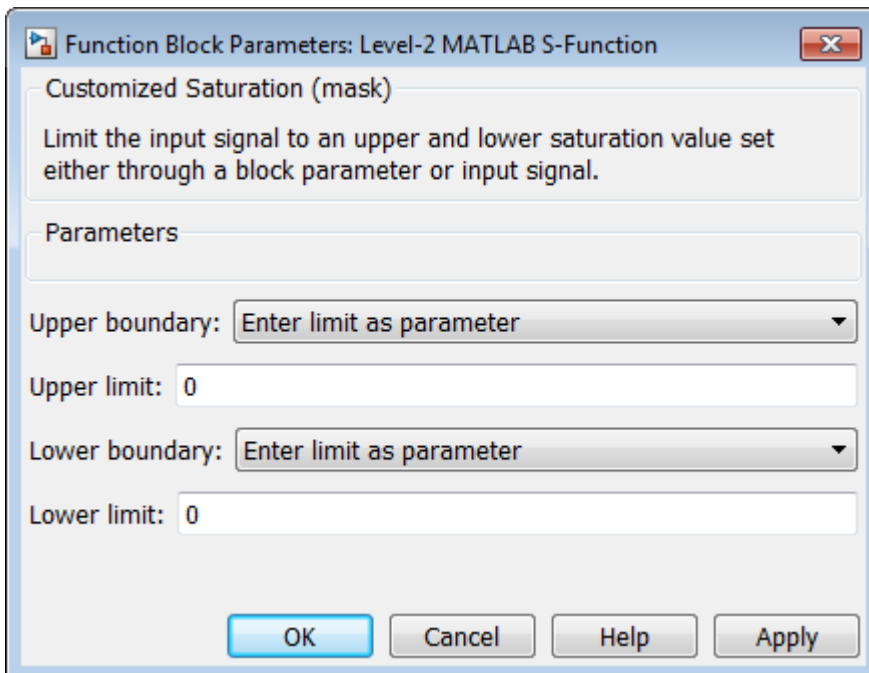

Limit the input signal to an upper and lower saturation value set either through a block parameter or input signal.

- 7 Click **OK**.
- 8 To map the S-function parameters to the mask parameters, right-click the Level-2 MATLAB S-Function block and select **Mask > Look Under Mask**.
- 9 Change the **S-function name** field to `custom_sat_final` and the **Parameters** field to `lowMode, lowVal, upMode, upVal`.

The figure shows the Function Block Parameters dialog box after the changes.

- 10 Click **OK**. Save and close the library to exit the edit mode.
- 11 Reopen the library and double-click the customized saturation block to open the masked parameter dialog box.

To create a more complicated user interface, place a MATLAB graphics user interface on top of the masked block. The block `OpenFcn` invokes the MATLAB graphics user interface, which uses calls to `set_param` to modify the S-function block parameters based on settings in the user interface.

### Writing the Mask Callback

The function `customsat_callback.m` contains the mask callback code for the custom saturation block mask parameter dialog box. This function invokes local functions corresponding to each mask parameter through a call to `feval`.

The following local function controls the visibility of the upper saturation limit's field based on the selection for the upper saturation limit's mode. The callback begins by obtaining values for all mask parameters using a call to `get_param` with the property name `MaskValues`. If the callback needed the value of only one mask parameter, it could call `get_param` with the specific mask parameter name, for example, `get_param(block, 'upMode')`. Because this example needs two of the mask parameter values, it uses the `MaskValues` property to reduce the calls to `get_param`.

The callback then obtains the visibilities of the mask parameters using a call to `get_param` with the property name `MaskVisibilities`. This call returns a cell array of character vectors indicating the visibility of each mask parameter. The callback alters the values for the mask visibilities based on the selection for the upper saturation limit's mode and then updates the port label text.

The callback finally uses the `set_param` command to update the block's `MaskDisplay` property to label the block's input ports.

```
function customsat_callback(action,block)
% CUSTOMSAT_CALLBACK contains callbacks for custom saturation block

% Copyright 2003-2007 The MathWorks, Inc.

%% Use function handle to call appropriate callback
feval(action,block)

%% Upper bound callback
function upperbound_callback(block)

vals = get_param(block,'MaskValues');
vis = get_param(block,'MaskVisibilities');
portStr = {'port_label('input',1,'uSig')}';
switch vals{1}
    case 'No limit'
        set_param(block,'MaskVisibilities',[vis(1);{'off'};vis(3:4)]);
    case 'Enter limit as parameter'
        set_param(block,'MaskVisibilities',[vis(1);{'on'};vis(3:4)]);
    case 'Limit using input signal'
        set_param(block,'MaskVisibilities',[vis(1);{'off'};vis(3:4)]);
        portStr = [portStr;{'port_label('input',2,'up')}'];
end
if strcmp(vals{3},'Limit using input signal'),
    portStr = [portStr;{'port_label('input','',num2str(length(portStr)+1), ...
        'low')}'];
end
set_param(block,'MaskDisplay',char(portStr));
```

The final call to `set_param` invokes the `setup` function in the MATLAB S-function `custom_sat.m`. Therefore, the `setup` function can be modified to set the number of input ports based on the mask parameter values instead of on the S-function parameter values. This change to the `setup` function keeps the number of ports on the Level-2 MATLAB S-Function block consistent with the values shown in the mask parameter dialog box.

The modified MATLAB S-function `custom_sat_final.m` contains the following new `setup` function. If you are stepping through this tutorial, open the file.

```

%% Function: setup =====
function setup(block)

% Register original number of ports based on settings in Mask Dialog
ud = getPortVisibility(block);
numInPorts = 1 + isequal(ud(1),3) + isequal(ud(2),3);

block.NumInputPorts = numInPorts;
block.NumOutputPorts = 1;

% Setup port properties to be inherited or dynamic
block.SetPreCompInPortInfoToDynamic;
block.SetPreCompOutPortInfoToDynamic;

% Override input port properties
block.InputPort(1).DatatypeID = 0; % double
block.InputPort(1).Complexity = 'Real';

% Override output port properties
block.OutputPort(1).DatatypeID = 0; % double
block.OutputPort(1).Complexity = 'Real';

% Register parameters. In order:
% -- If the upper bound is off (1) or on and set via a block parameter (2)
%    or input signal (3)
% -- The upper limit value. Should be empty if the upper limit is off or
%    set via an input signal
% -- If the lower bound is off (1) or on and set via a block parameter (2)
%    or input signal (3)
% -- The lower limit value. Should be empty if the lower limit is off or
%    set via an input signal
block.NumDialogPrms = 4;
block.DialogPrmsTunable = {'Nontunable','Tunable','Nontunable','Tunable'};

% Register continuous sample times [0 offset]
block.SampleTimes = [0 0];

%% -----
%% Options
%% -----
% Specify if Accelerator should use TLC or call back into
% MATLAB script
block.SetAccelRunOnTLC(false);

%% -----
%% Register methods called during update diagram/compilation
%% -----

block.RegBlockMethod('CheckParameters', @CheckPrms);
block.RegBlockMethod('ProcessParameters', @ProcessPrms);
block.RegBlockMethod('PostPropagationSetup', @DoPostPropSetup);
block.RegBlockMethod('Outputs', @Outputs);
block.RegBlockMethod('Terminate', @Terminate);
%endfunction

```

The `getPortVisibility` local function in `custom_sat_final.m` uses the saturation limit modes to construct a flag that is passed back to the `setup` function. The `setup` function uses this flag to determine the necessary number of input ports.

```

%% Function: Get Port Visibilities =====
function ud = getPortVisibility(block)

ud = [0 0];

vals = get_param(block.BlockHandle,'MaskValues');
switch vals{1}
    case 'No limit'
        ud(2) = 1;
    case 'Enter limit as parameter'
        ud(2) = 2;
    case 'Limit using input signal'
        ud(2) = 3;
end

```

```

end
switch vals{3}
case 'No limit'
    ud(1) = 1;
case 'Enter limit as parameter'
    ud(1) = 2;
case 'Limit using input signal'
    ud(1) = 3;
end

```

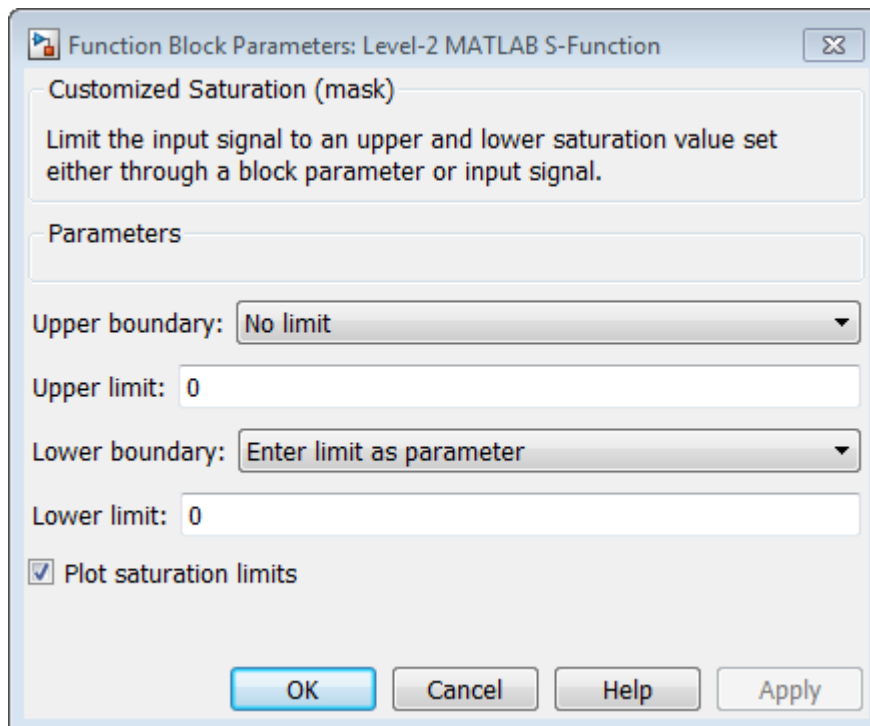

## Adding Block Functionality Using Block Callbacks

The User-Defined Saturation with Plotting block in `ex_customsat_lib` uses block callbacks to add functionality to the original custom saturation block. This block provides an option to plot the saturation limits when the simulation ends. The following steps show how to modify the original custom saturation block to create this new block.

- 1 Add a check box to the mask parameter dialog box to toggle the plotting option on and off.
  - a Right-click the Level-2 MATLAB S-Function block in `saturation_lib` and select **Mask + Create Mask**.
  - b On the Mask Editor **Parameters** pane, add a fifth mask parameter with the following properties.

Prompt	Name	Type	Tunable	Type options	Callback
Plot saturation limits	plotcheckbox	checkbox	No	NA	customsat_callback('plotsaturation',gcb)

- c Click **OK**.

- 2 Write a callback for the new check box. The callback initializes a structure to store the saturation limit values during simulation in the Level-2 MATLAB S-Function block UserData. The MATLAB script `customsat_plotcallback.m` contains this new callback, as well as modified versions of the previous callbacks to handle the new mask parameter. If you are following through this example, open `customsat_plotcallback.m` and copy its local functions over the previous local functions in `customsat_callback.m`.

```

%% Plotting checkbox callback
function plotsaturation(block)

% Reinitialize the block's userdata
vals = get_param(block,'MaskValues');
ud = struct('time',[],'upBound',[],'upVal',[],'lowBound',[],'lowVal',[]);

if strcmp(vals{1},'No limit'),
    ud.upBound = 'off';
else
    ud.upBound = 'on';
end

if strcmp(vals{3},'No limit'),
    ud.lowBound = 'off';
else
    ud.lowBound = 'on';
end

set_param(gcb, 'UserData',ud);

```

- 3 Update the MATLAB S-function Outputs method to store the saturation limits, if applicable, as done in the new MATLAB S-function `custom_sat_plot.m`. If you are following through this example, copy the Outputs method in `custom_sat_plot.m` over the original Outputs method in `custom_sat_final.m`

```

%% Function: Outputs =====
function Outputs(block)

lowMode    = block.DialogPrm(1).Data;
upMode     = block.DialogPrm(3).Data;
sigVal     = block.InputPort(1).Data;
vals = get_param(block.BlockHandle,'MaskValues');
plotFlag = vals{5};
lowPortNum = 2;

% Check upper saturation limit
if isequal(upMode,2)
    upVal = block.RuntimePrm(2).Data;
elseif isequal(upMode,3)
    upVal = block.InputPort(2).Data;
    lowPortNum = 3; % Move lower boundary down one port number
else
    upVal = inf;
end

% Check lower saturation limit
if isequal(lowMode,2),
    lowVal = block.RuntimePrm(1).Data;
elseif isequal(lowMode,3)
    lowVal = block.InputPort(lowPortNum).Data;
else
    lowVal = -inf;
end

% Use userdata to store limits, if plotFlag is on
if strcmp(plotFlag,'on');
    ud = get_param(block.BlockHandle,'UserData');
    ud.lowVal = [ud.lowVal;lowVal];
    ud.upVal = [ud.upVal;upVal];
    ud.time = [ud.time;block.CurrentTime];
    set_param(block.BlockHandle,'UserData',ud)

```

```

end

% Assign new value to signal
if sigVal > upVal,
    sigVal = upVal;
elseif sigVal < lowVal,
    sigVal=lowVal;
end

block.OutputPort(1).Data = sigVal;

%endfunction

```

- 4** Write the function `plotsat.m` to plot the saturation limits. This function takes the handle to the Level-2 MATLAB S-Function block and uses this handle to retrieve the block's `UserData`. If you are following through this tutorial, save `plotsat.m` to your working folder.

```

function plotSat(block)

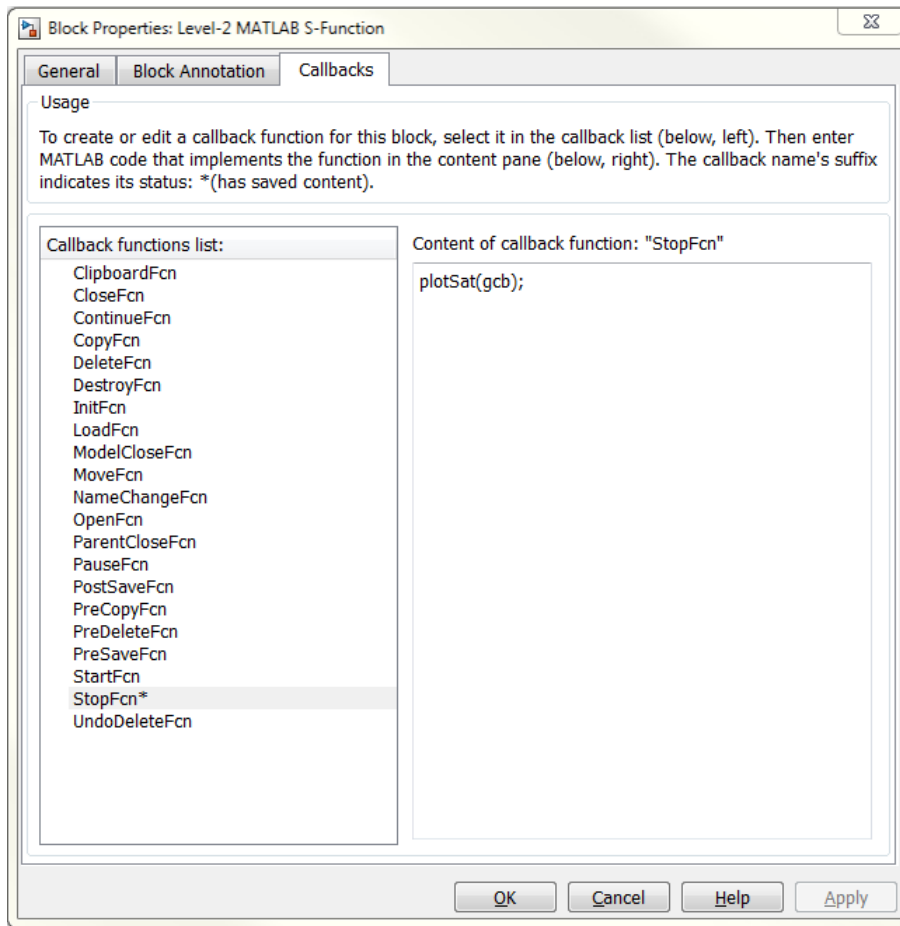

% PLOTSAT contains the plotting routine for custom_sat_plot
% This routine is called by the S-function block's StopFcn.

ud = get_param(block,'UserData');
fig=[];
if ~isempty(ud.time)
    if strcmp(ud.upBound,'on')
        fig = figure;
        plot(ud.time,ud.upVal,'r');
        hold on
    end
    if strcmp(ud.lowBound,'on')
        if isempty(fig),
            fig = figure;
        end
        plot(ud.time,ud.lowVal,'b');
    end
    if ~isempty(fig)
        title('Upper bound in red. Lower bound in blue.')
    end
end

% Reinitialize userdata
ud.upVal=[];
ud.lowVal=[];
ud.time = [];
set_param(block,'UserData',ud);
end

```

- 5** Right-click the Level-2 MATLAB S-Function block and select **Properties**. The Block Properties dialog box opens. On the **Callbacks** pane, modify the `StopFcn` to call the plotting callback as shown in the following figure, then click **OK**.

## Integrate Python GPS Text Message Parsing Algorithms in Simulink

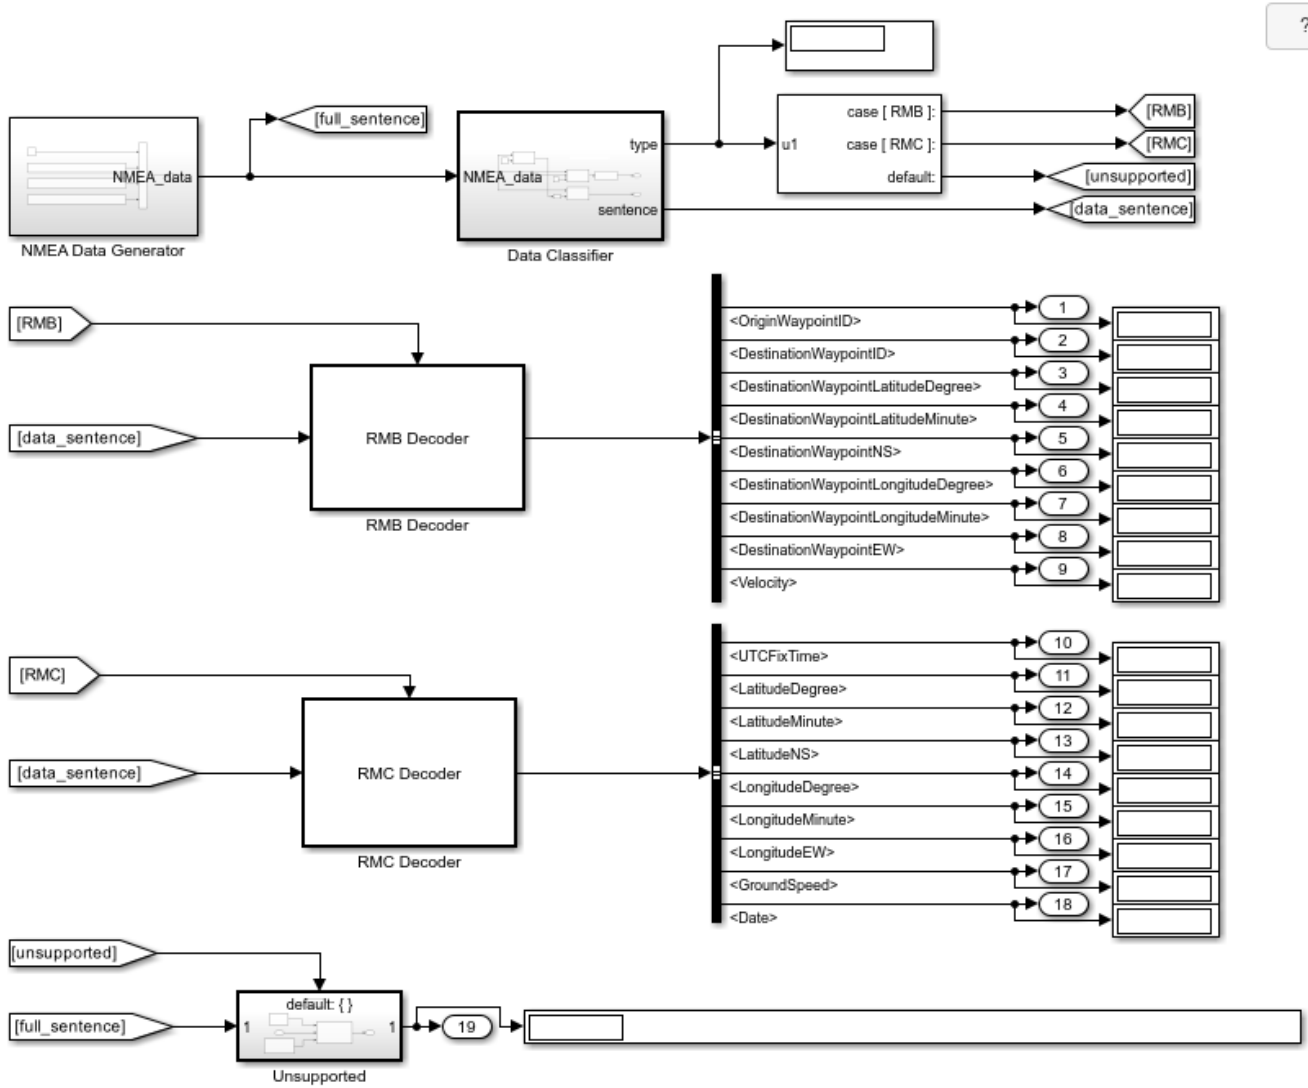

This example shows how to parse text messages in NMEA GPS format using Simulink® string blocks and Python®. NMEA sentences are used for communication between marine devices, and the model in the example decodes RMB and RMC sentences in NMEA. RMB is the sentence for the recommended navigation data for GPS. RMC is the sentence for the recommended minimum data for GPS sentences.

In the model, you can choose to decode RMB and RMC sentences using Simulink or by incorporating Python code. This example explains the details of incorporating Python for decoding. For more information about the model and using Simulink® blocks for decoding, see “Simulink Strings” on page 72-43. For more on using Python in MATLAB®, see “Access Python Modules from MATLAB - Getting Started”.

MATLAB supports the reference implementation of Python, often called CPython. If you are on a Mac or Linux® platform, you already have Python installed. If you are using Windows®, you need to install a distribution, such as those found at <https://www.python.org/downloads>. For more information, see “Configure Your System to Use Python”.

### Explore the Model

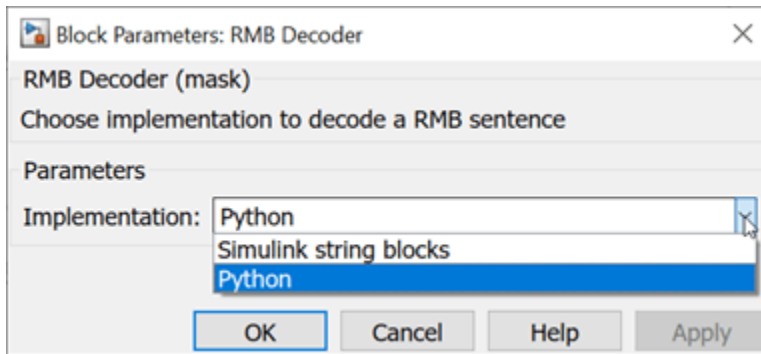

In the model, the subsystem named `NMEA Data Generator` generates data and sends the data to the subsystem named `Data Classifier`. The `Data Classifier` classifies the sentences as RMB, RMC, or unsupported. The sentences are then sent to `RMB Decoder`, `RMC decoder`, or `Unsupported`, depending on their type.

Copyright 2022 The MathWorks, Inc.

### Model RMB and RMC Decoders Using Python or Simulink String Blocks

If you double-click the block named RMB Decoder, you can choose to model the decoder using Simulink string blocks or Python code.

Look under the mask. Observe that when you select Python, the decoder is modeled by using a MATLAB System block.

Open the source code. Observe that the Python code to decode the message is incorporated into the `setupImpl` and `stepImpl` functions.

```
function setupImpl(obj)
    py.importlib.import_module('RMBDecode');
end

function y = stepImpl(obj,sentence)
    % convert sentence to python string
    pstr = py.str(sentence);

    % call python module for string processing
    plist = py.RMBDecode.parseRMBSentence(pstr);

    % assign python list elements to Simulink bus
    y.Status = string(plist{1});
    y.Error = str2double(string(plist{2}));
    y.ErrorDirection = string(plist{3});
    y.OriginWaypointID = uint16(str2double(string(plist{4})));
    y.DestinationWaypointID = uint16(str2double(string(plist{5})));
    y.DestinationWaypointLatitudeDegree = uint16(str2double(string(plist{6})));
    y.DestinationWaypointLatitudeMinute = str2double(string(plist{7}));
    y.DestinationWaypointNS = string(plist{8});
    y.DestinationWaypointLongitudeDegree = uint16(str2double(string(plist{9})));
    y.DestinationWaypointLongitudeMinute = str2double(string(plist{10}));
    y.DestinationWaypointEW = string(plist{11});
```

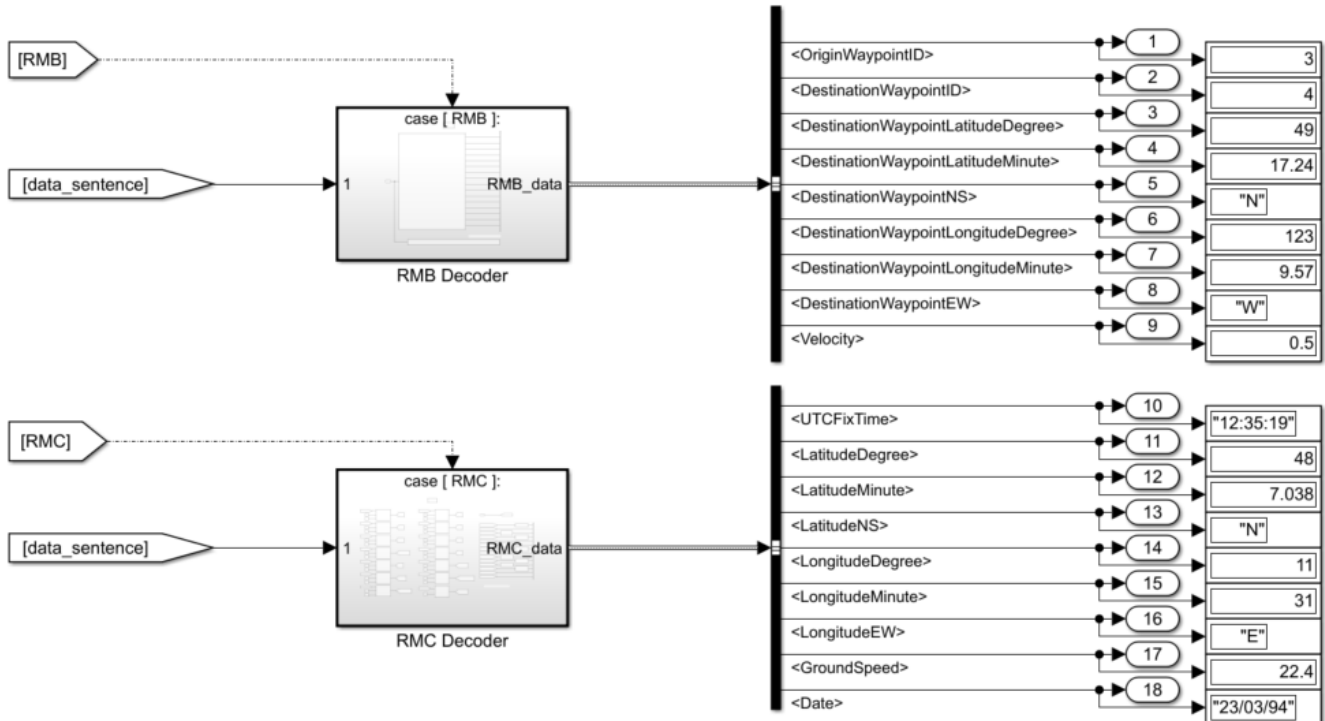

```

y.RangeToDestination = str2double(string(plist{12}));
y.TrueBearing = str2double(string(plist{13}));
y.Velocity = str2double(string(plist{14}));
y.ArrivalAlarm = string(plist{15});
y.Checksum = string(plist{16});
end

```

**Simulate Model and Review Results**

Simulate the model and observe the decoded RMB and RMC sentences.

## Create Custom Library

You can create your own library and, optionally, add it to the Simulink **Library Browser**. You save a library as a `.slx` file similar to the way you save a model. However, you cannot simulate in a library, and a library becomes locked for editing each time you close it. You must unlock a library before you make changes to it. See “Lock and Unlock Libraries” on page 44-6.

- 1 From the Simulink start page, select **Blank Library** and click **Create Library**.

---

**Note** The Library Browser only supports libraries. You cannot display the contents of a model in the Library Browser.

---

- 2 (Optional) Define data types to be used on block interfaces in a Simulink data dictionary. Then, attach the data dictionary to the library. Library users automatically gain access to the data contained in the dictionary when they drag a block from the library into their model.
- 3 Add blocks to the new library. Make the changes you want to the blocks, such as changing block parameters, adding masks, or adding blocks to subsystems.

Subsystem names in a library hierarchy must be unique. For example, do not create a hierarchy such as `Subsystem_Name1/Subsystem_Name2/Subsystem_Name1`.

- 4 Add annotations or images. Right-click the ones you want to appear in the library in the Library Browser and select **Show in Library Browser**.
- 5 If you plan to add the library to the Library Browser, you can order the blocks and annotations in your library. By default, they appear alphabetically in the Library Browser, with subsystems first, then blocks, and then annotations. The user of your library can use the Library Browser context menu to choose between viewing them in alphabetical order or the order you specified. When the user selects this option, the order in which they appear in your library determines the order they appear on the grid in the library in the Library Browser.
- 6 If you want the library to appear in the Library Browser, enable the `EnableLBRepository` library property before you save the library.

```
set_param(gcs, 'EnableLBRepository', 'on');
```

- 7 Save the library.

Where you save the library depends on how you plan to use it. If you want to add it to the Library Browser, save it to a folder on the MATLAB path or add the location to the MATLAB path. Otherwise, save it to a location where the models that use the blocks can access it.

If you want the library to appear in the Library Browser, you must also create a function `slblocks` on your MATLAB path that adds the library to the browser. For an example that shows complete steps for adding a library to the browser, see “Add Libraries to Library Browser” on page 44-8.

---

**Note** To update the Library Browser with your custom libraries, right-click anywhere in the Library Browser library list and select **Refresh Library Browser**. Refreshing the Library Browser also updates the quick insert menu to include the blocks in custom libraries currently in effect. The quick insert menu lets you add blocks to a model without leaving the canvas. Click the canvas and start typing to add blocks from the quick insert menu.

---

## Data Dictionary for Custom Libraries

When you define data types — such as bus and enumeration types — to be used on block interfaces, you can make these data types available to users by storing them in a data dictionary that is attached to the library. When a user drags a block from the library into their model, the model automatically gains access to the data contained in the dictionary.

- 1 Create a data dictionary.
- 2 In the dictionary, define bus objects, enumeration types, or other data objects that you will use for the interface definitions of your library blocks.
- 3 Attach the dictionary as an external data source for your library programmatically by using `set_param` or in the UI by using the **External Data** tab in the Library Properties dialog box. The Model Explorer displays the attached dictionary and its content as an external data source for the library.
- 4 To save the data dictionary specifications, save the library.

The types that you defined in the library are now available to you while developing library blocks. See “Attach Data Dictionary to Custom Libraries” on page 79-36.

## Blocks for Custom Libraries

Your library can contain the blocks you need, configured for your purposes. Subsystems, masked blocks, and charts in your library become linked blocks as instances in the model and stay updated if you change them in your library. Knowing about custom blocks is also useful when you create a library. See “Design and Create a Custom Block” on page 43-12.

You can create blocks in custom libraries with settings for specific purposes.

### Create a Sublibrary

If your library contains many blocks, you can group the blocks into subsystems or separate sublibraries. To create a sublibrary, you create a library of the sublibrary blocks and reference the library from a Subsystem block in the parent library.

- 1 In the library you want to add a sublibrary to, add a Subsystem block.
- 2 Inside the Subsystem block, delete the default input and output ports.
- 3 If you want, create a mask for the subsystem that displays text or an image that conveys the sublibrary purpose.
- 4 In the subsystem block properties, set the `OpenFcn` callback to the name of the library you want to reference.

To learn more about masks, see “Create a Simple Mask” on page 42-7.

### Prevent Library Block from Linking to Instance

You can configure a library block so the instances created from it are not linked blocks and are instead copies. Set the block’s `CopyFcn` callback.

```
set_param(gcbh, 'LinkStatus', 'none');
```

### Include Block Description in Linked Block

To add a description that appears in the linked block, mask the library block and add the description in the **Documentation** pane of the mask. Descriptions added to the library block through the block's properties do not appear on the linked block.

### Configure Block with Keywords for Quick Insert

You can add one or more keywords to a block in your library. The keyword lets you add the block to your model from the quick insert menu by entering the keyword or the block name.

For example, suppose you have a custom Gain block in your library. You can add the keyword **My Gain** to the block. Then, you can add the block to your model by entering **My Gain** at the quick insert menu.

---

**Note** You cannot add keywords to the blocks from **Commonly Used Blocks** as they are a place to view frequently used blocks from various libraries. If you want to add keywords to a block available in **Commonly Used Blocks**, make sure that you set it in the library where the block is defined.

---

To add the keyword to the block in your library, use `set_param` with the `'BlockKeywords'` parameter. You can use a character vector, string scalar, or string array as the value. For example:

```
set_param(gcb, 'BlockKeywords', {"My Gain", "Your Gain"})
set_param(gcb, 'BlockKeywords', 'My Integrator')
```

---

**Note** The supported special characters in keywords are '&', '(', ')', '+', '@', '!'.  

---

**Note** The quick insert menu also supports searching for blocks in languages other than English by using internationalized keywords.  

---

### Configure Subsystems with OpenFcn Callback for Library Browser

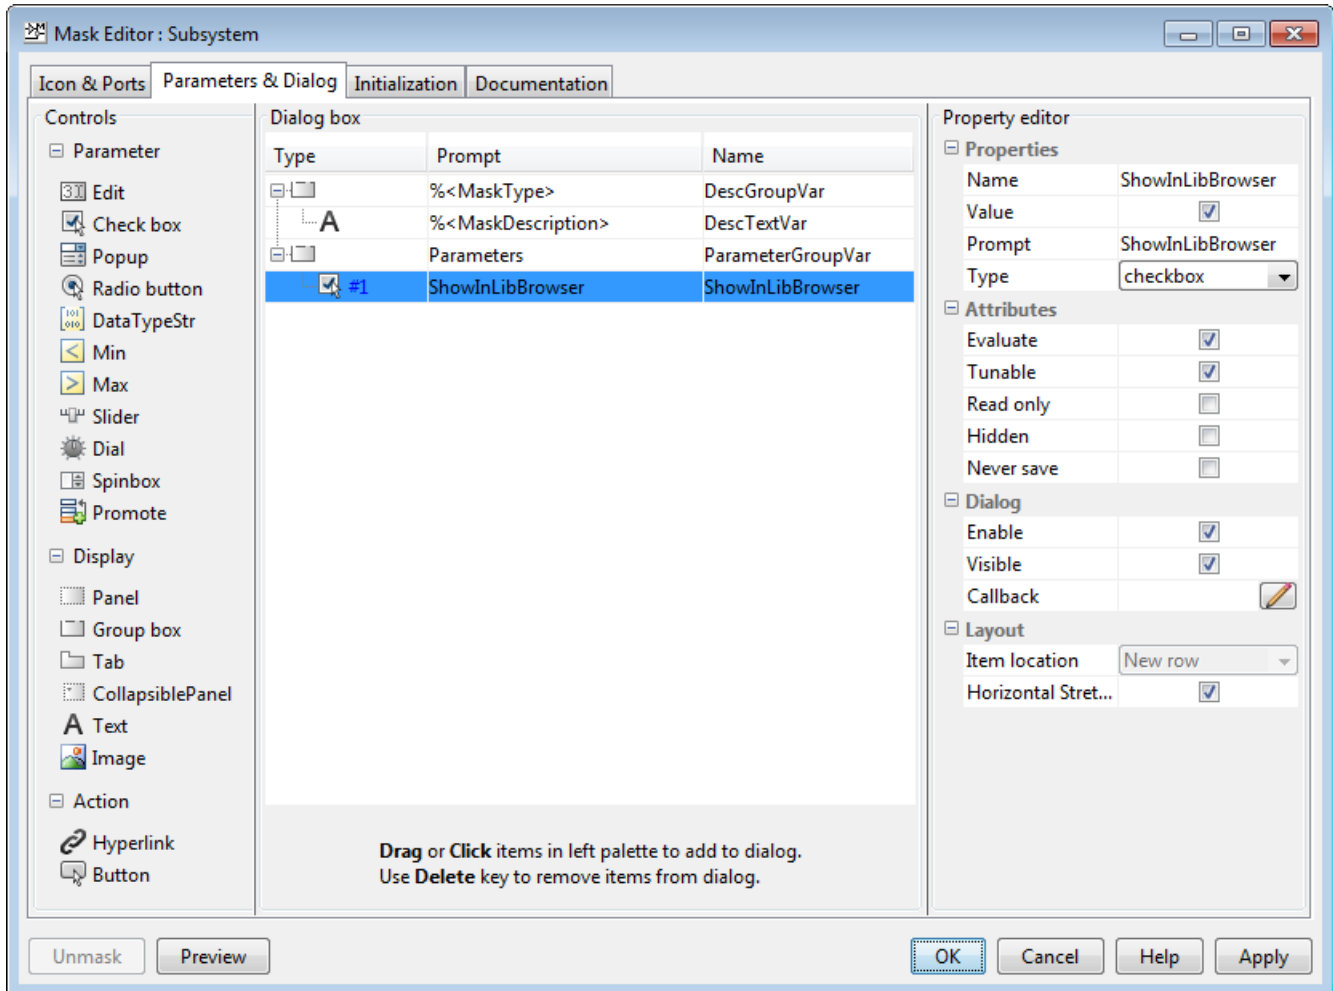

A common use of a Subsystem block in a custom library is to set the `OpenFcn` callback property to open a library, creating a library hierarchy. However, you can use the `OpenFcn` callback property of a Subsystem block for other purposes, for example to run MATLAB code or to open a link.

If a Subsystem block in a library is empty and its `OpenFcn` callback contains code that performs an action other than point to a library, then you need to add a `'ShowInLibBrowser'` mask parameter to the subsystem to have it appear in the Library Browser.

- 1 Right-click the subsystem and select **Mask > Create Mask**. If the block already has a mask, select **Edit Mask** instead.

- 2 In the Mask Editor **Parameters & Dialog** tab, on the **Controls** pane, click **Check box**.
- 3 In the **Dialog box** pane, set the prompt and name for the new check box to **ShowInLibBrowser** and click **OK**.

## Annotations in Custom Libraries

You can add annotations in your custom library and optionally have them appear in the Library Browser. For example, you can add an annotation that documents the library. You can also add annotations that the user of your library can add to their model from the Library Browser. Annotations can contain text and images or display an equation. Annotations can also perform an action when clicked. Learn more about annotations in “Annotate Models” on page 1-78.

You can add callout lines from annotations to blocks in your library. However, the callouts do not appear in the Library Browser.

If you want the annotation to appear in the Library Browser, after you add it to your library, right-click it and select **Show in Library Browser**. If you want a description to appear in a tooltip when the user hovers over the annotation in the Library Browser, add the description to the annotation programmatically. At the MATLAB command prompt, enter:

```
set_param(annotationHandle,'Description','descriptionText')
```

To get the annotation handle, use `find_system`. This example gets all the annotations in the library `mylib`:

```
ann = find_system('mylib','FindAll','on','Type','annotation');
```

To get a specific annotation, turn on regular expression search and specify part of the annotation text with the `'Name'` argument:

```
ann = find_system('mylib2','FindAll','on','RegExp',...  
'on','Type','annotation','Name','matchingText');
```

“Add Libraries to Library Browser” on page 44-8 includes instructions for adding an annotation that appears in the Library Browser.

## Lock and Unlock Libraries

When you close a library, it becomes locked for editing. When you next open it, unlock it if you want to make changes to it. Click the lock badge in the lower-left corner of the library to unlock it. Additionally, if you try to modify a locked library, a message prompts you to unlock it.

You can unlock a library programmatically. At the MATLAB command prompt, enter:

```
set_param('library_name','Lock','off');
```

To lock the library programmatically, enter:

```
set_param('library_name','Lock','on');
```

## Prevent Disabling of Library Links

By default, a user of the blocks in your library can disable the link to library blocks. If you want to control editing of linked blocks and prevent the block user from disabling links, you can lock links to your library. Locking library links prevents the user from making any changes to the block instances.

- In your library, on the **Library** tab, click **Lock Links**.

To understand how the block user interacts with blocks from locked libraries, see “Lock Links to Blocks in a Library” on page 44-24.

## Add Libraries to Library Browser

This example shows how to create a block library and add it to the Simulink **Library Browser**. This example also shows how to add a sublibrary.

To specify information about your library, you create a function named `slblocks`.

### Add Library to Library Browser

- 1 On the Simulink start page, in the search box, type `library`. Select **Blank Library**, then click **Create Library**.

---

**Note** The Library Browser only supports libraries. You cannot display the contents of a model in the Library Browser.

---

- 2 Add a Gain block to the library.
- 3 In the MATLAB Command Window, enter this command to set the `EnableLBRepository` library property to `'on'`. Your library will appear in the Library Browser only if this property is enabled when you save your library.

```
set_param(gcs, 'EnableLBRepository', 'on');
```

- 4 Save the library in a folder on the MATLAB path. For this example, name the library `mylib`.
- 5 In the MATLAB Current Folder Browser, open the folder that contains `mylib`, then, in the MATLAB Toolstrip, click **New Script**.
- 6 In the MATLAB Editor that opens, add this function, which specifies that the library `mylib` should appear in the Library Browser with the name **My Library**.

```
function blkStruct = slblocks
% This function specifies that the library 'mylib'
% should appear in the Library Browser with the
% name 'My Library'

    Browser.Library = 'mylib';
    % 'mylib' is the name of the library

    Browser.Name = 'My Library';
    % 'My Library' is the library name that appears
    % in the Library Browser

    blkStruct.Browser = Browser;
```

- 7 Save the function as `slblocks.m`.

---

**Note** You can save the function as an `.m` or `.mlx` file. You cannot save the function as a P-code file.

---

- 8 To open the Library Browser, in the Simulink Toolstrip, click **Library Browser**.
- 9 To see the new library in the Library Browser, right-click the library list and select **Refresh Library Browser**.

The figure shows the example library `mylib` with the Library Browser name **My Library**.

**Note** If you save your library without setting 'EnableLBRepository' to 'on', a message appears at the top of the Library Browser.

Click **Fix** and respond to the prompt as appropriate.

## Add Sublibrary to Library Browser

Follow these steps to add a sublibrary named `mylib2` to your `mylib` library.

- 1 Create a library named `mylib2`. Add some blocks to it.
- 2 In the MATLAB Command Window, set the `EnableLBRepository` library property to 'on' for the new library.
 

```
set_param(gcs, 'EnableLBRepository', 'on');
```
- 3 Save `mylib2` to the folder that contains `mylib`.
- 4 Add a Subsystem block to the `mylib` library.
- 5 Remove the input and output ports from the subsystem by deleting the Inport and Outport blocks inside the subsystem.
- 6 Name the Subsystem block `My Sublibrary`.
- 7 To link the Subsystem block to the sublibrary, set the `OpenFcn` callback to `mylib2` by using the Property Inspector.

- 8 Save mylib.
- 9 To see the new sublibrary in the Library Browser, right-click the library list and select **Refresh Library Browser**.

The figure shows the example sublibrary mylib2 with the Library Browser name **My Sublibrary**.

Because of the callback you created, expanding **My Sublibrary** displays the contents of the mylib2 library.

## Specify Library Order in Library List

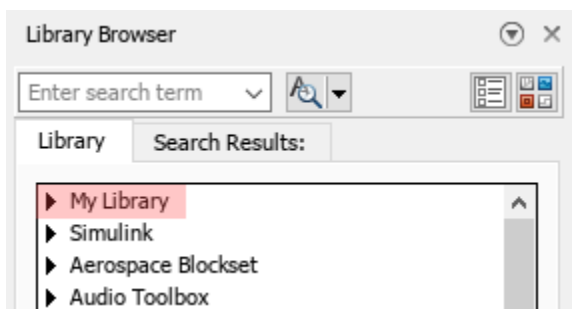

You can specify the order of your library relative to the other libraries in the list by adding a `sl_customization.m` file to the MATLAB path and setting the sort priority of your library. For example, to see your library at the top of the list, you can set the sort priority to `-2`. By default, the sort priority of the Simulink library is `-1`. The other libraries have a sort priority of `0` by default, and these libraries appear below the Simulink library. Libraries with the same sort priority appear in alphabetical order.

This sample content of the `sl_customization.m` file places the new library at the top of the list of libraries.

```
function sl_customization(cm)
% Change the order of libraries in the Simulink Library Browser.
cm.LibraryBrowserCustomizer.applyOrder({'My Library',-2});
end
```

To make the customization take effect immediately, in the MATLAB Command Window, enter:

```
sl_refresh_customizations
```

## Linked Blocks

### In this section...

“Rules for Linked Blocks” on page 44-13

“Linked Block Terminology” on page 44-13

When you add a masked library block or a Subsystem block from a library to a Simulink model, a referenced instance of the library block is created. Such referenced instance of a library block is called a linked block and contains link or path to the parent library block. The link or path allows the linked block to update when the library block is updated.

To optimize the performance, the child blocks (and the parameters) of a linked block are not saved with the Simulink model. When such a model is loaded and viewed, the child blocks are referenced from the parent library. If you change the parameter value of a child block of such a linked block, the changed information is saved as linked data in the model.

To locate the parent library block of a linked block, right-click the block and select **Library Link > Go To Library Link** (Ctrl + L). This option is available only for the blocks that are linked and not for the Simulink built-in blocks. To prevent unintentional disabling of library links, use the locked links option on the library. For more information, see “Lock Links to Blocks in a Library” on page 44-24.

**Note** The tooltip for a linked block shows the name of the referenced masked library block.

When you edit a library block (either in Simulink Editor or at the command line), Simulink updates the changes in the linked blocks. The outdated links are updated when you:

- Simulate or update the model.
- Use the `find_system` command.
- On the **Modeling** tab, select **Update Model > Refresh Blocks** (or press **Ctrl+K**).
- Load the model or library (only the visible links are updated).
- Use `get_param` to query the link status of the block (see “Control Linked Block Programmatically” on page 44-34).

You can use the `LinkStatus` parameter or the `StaticLinkStatus` parameter to query the link status.

- `LinkStatus`: First updates the linked block and then returns the link status.
- `StaticLinkStatus`: Returns the link status without updating the linked block.

Selective usage of `StaticLinkStatus` over `LinkStatus` can result in better Simulink performance. For more information on `StaticLinkStatus` and `LinkStatus`, see “Control Linked Block Programmatically” on page 44-34.

## Rules for Linked Blocks

- You can change the values of a linked block parameter (including the existing mask) in the mask dialog box.
- To allow the library block initialization code to change the values of a linked block parameter, select the **Allow library block to modify its contents** check box in the **Initialization** pane of the library block.
- It is not recommended to set callback parameters for a linked block.
- If the reference library block of a linked block is a subsystem, you can make nonstructural changes such as changing the parameter value of the linked subsystem. To make structural changes to a linked block, disable the link of the linked block from its library block (See “Disable or Break Links to Library Blocks” on page 44-22).

## Linked Block Terminology

Terminology	Definition
Parent library block	Library block from which the linked blocks are referenced.
Linked block	Reference instance of a library block that contains links or path to its parent library block.
Locked links	Prevents unintentional modification of a linked block. For more information, see “Lock Links to Blocks in a Library” on page 44-24.
Disabled links	Library links that are temporarily disconnected from their parent library block. For more information, see “Disable or Break Links to Library Blocks” on page 44-22.
Restore links	Restores the disabled link of a linked block to their parent library block. For more information, see “Restore Disabled Links” on page 44-26.
Break links	Permanently breaks the link of a linked block from its parent library block. For more information, see “Disable or Break Links to Library Blocks” on page 44-22.
Self-modifiable links	Linked block with the ability to have structural changes in a linked Subsystem block. For more information, see “Self-Modifiable Linked Subsystems” on page 44-18.
Parameterized links	Created when the parameter values of a linked block are modified using the MATLAB command prompt. For more information, see “Parameterized Links and Self-Modifiable Linked Subsystems” on page 44-15.
Forwarding Tables	Maps the old library block path to new library block path. For more information, see “Maintain Compatibility of Library Blocks Using Forwarding Tables” on page 44-37.

<b>Terminology</b>	<b>Definition</b>
Transformation function	Corrects the mismatch of parameters in the <code>InstanceData</code> of the new and old library links to ensure that the library links continue to work. For more information, see “Maintain Compatibility of Library Blocks Using Forwarding Tables” on page 44-37.

**See Also**`find_system`**More About**

- “Choose Among Types of Model Components” on page 23-4
- “Display Library Links” on page 44-20
- “Control Linked Block Programmatically” on page 44-34
- “Fix Unresolved Library Links” on page 44-32

## Parameterized Links and Self-Modifiable Linked Subsystems

You can use the MATLAB command prompt to change the value of a parameter in a linked block. Such parameter changes on the linked block result in parameterized links.

Similarly, you can also modify the structure of a linked Subsystem block without changing the parent library block. Such changes can be applied using the mask initialization code and is called self-modifiable linked subsystem.

### Parameterized Links

A parameterized link is created when you change the parameter values of the child blocks of a masked subsystem linked block.

A parameterized link allows you to have a different parameter value for the linked block and the parent library block. For such library blocks, the link to the parent block is still retained.

---

**Note** Changing the mask value of a parent library block does not create a parameterized link.

---

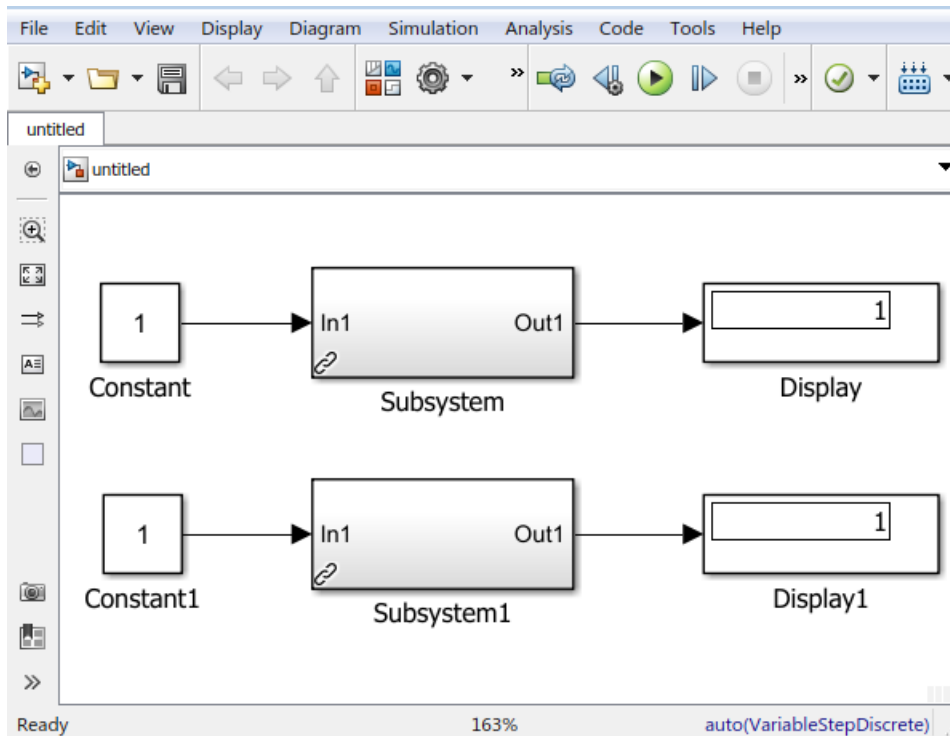

For example, you can use the `set_param` command to set a parameter value in the child blocks of a linked subsystem block. The `set_param` command overrides the parameter values of the child blocks of the subsystem linked block. Thus, differentiating the child block value from its parent library block and creating a parameterized link.

Consider a Subsystem library block (see “Subsystem Library Block” on page 44-15) that contains a Gain block within with its parameter value as 1.

### Subsystem Library Block

Use this Subsystem block as a linked block in a model.

You can modify the parameter values of the child blocks of the linked block without changing the value of the parent library block. For example, you can change the parameter value of the Gain block within the Subsystem linked block.

To change the Gain parameter value of the Gain block within the Subsystem linked block to 100, sequentially type these commands at MATLAB command prompt:

```
pathName = [modelName, '/Gain_Subsystem1/Gain'];
set_param(pathName, 'Gain', '100')
```

A parameterized link is now created, overriding the parameter value (see “Parameterized Linked Block” on page 44-17). Similarly, change the Gain parameter value of the Subsystem1 linked block.

### Parameterized Linked Block

When you save a model containing a parameterized link, Simulink saves the changes to a local copy of the Subsystem with the path to the parent library. When you reopen the model, Simulink copies the library block into the loaded model and applies the saved changes.

**Note** To view the parameterized changes on a block, right-click the block, and on the context menu, select **View Changes**. The **Link changes** dialog box opens displaying the list of modified blocks. You can also use this dialog box to remove parameterized changes from a block.

## Identifying Parameterized Links

A parameterized link displays these identifications:

- The link badge of a parameterized link contains a black link with a red star icon, . For more information, see “Display Library Links” on page 44-20.
- The tooltip of a parameterized linked block displays **Modified parameter in link**.

- Block dialog box of a linked Subsystem block contains **parameterized link**.

## Self-Modifiable Linked Subsystems

---

**Tip** We recommend using variant blocks over self-modifiable linked subsystems.

---

A self-modifiable linked subsystem is a linked block with the ability to have structural changes in the subsystem without disabling the link. A self-modifiable linked subsystem is created when you use a library block containing a self-modifiable mask as a linked block. You can use the mask initialization code to change the structural contents.

For more information, see “Dynamic Masked Subsystem” on page 42-38 and Self-Modifiable Mask on page 44-19.

## See Also

### More About

- “Linked Blocks” on page 44-12
- “Disable or Break Links to Library Blocks” on page 44-22
- “Restore Disabled Links” on page 44-26

## Create a Self-Modifiable Library Block

A self-modifiable linked block is created when you add a self-modifiable masked subsystem block from the library to your model. Such linked blocks allow structural changes within the subsystem block.

You can observe that in this example, if you change the 'Time domain' on the mask dialog box, the block within the Subsystem is replaced accordingly. For example, if you select the 'Time domain' as 'Discrete', the continuous integrator block is replaced with a discrete integrator block and vice-versa.

This dynamic change in the structure of the self-modifiable linked block is controlled using the MATLAB code that is added in the Initialization pane of the Mask Editor.

The structural changes take place only if the option 'Allow library block to modify its contents' available on the Initialization pane is selected.

```
open_system('self_modifiable_mask_example');
```

## Display Library Links

Each linked block has a link badge associated with it. The badge makes it easier to identify the linked block in a model and also displays its link status.

To control the display of library link badges in a Simulink model, on the **Debug** tab, select **Information Overlays** and then one of these options:

- **Hide All Links** — Displays no links.
- **Disabled Links** — Displays only disabled links (the default for new models).
- **User-Defined Links** — Displays only links to user libraries.
- **Show All Links** — Displays all links.

If activated, link badges are displayed at the bottom left corner of a linked block. You can right-click the link badge to access link menu options.

The color and icon of the link badge indicates the status of the link.

Link Badge	Status
Black links 	Active link
Gray separated links 	Inactive link
Black links with a red star icon 	Active and modified (parameterized link)
White links, black background 	Locked link

- “Disable or Break Links to Library Blocks” on page 44-22
- “Restore Disabled Links” on page 44-26

## Disable or Break Links to Library Blocks

Structural changes in a model include addition or deletion of blocks or adding ports while non-structural changes include changes in parameter value.

A linked block does not allow structural changes to it. You can disable the link of a linked block from its parent library block and perform required modifications. A disabled linked block behaves like a local instance of a block and allows you to make structural and nonstructural changes.

To disable a link, right-click the linked block and select **Library Link > Disable Link**. The **Disable Link** menu choice is made available only if the parent block of the linked block is disabled. If the menu option is grayed out, you must disable the link of the parent block first.

Alternatively, you can right-click the link icon in the graph on the bottom left corner of the canvas and click **Disable Link**. This action recursively disables the links of all the blocks up in the hierarchy.

To prevent unintentional disabling of a linked block, you can lock its links to the library. To lock a link, in the Library window, on the **Library** tab, click **Lock Links**. You can later choose to unlock the locked link by clicking **Links Locked**.

---

**Note** Simulink offers to disable the library links (unless the link is locked) when you try to make structural changes to a block that contains active library links.

Do not use `set_param` to make structural changes to an active link. The result of this type of change is undefined.

---

A disabled link of a linked block can be restored. For more information, see “Restore Disabled Links” on page 44-26.

Disabled links can cause merge conflicts and failure to update all instances of the same model component. In a hierarchy of links, you can accidentally disable all links without being aware of it, and only restore one link while leaving others disabled.

### Break Links

You can permanently break links to the parent library. Before you break a library link, the link must first be disabled. When you break a link, the linked block is converted to a standalone block, and you cannot detect what the block linked to previously.

To break a link, use any of these options:

- For disabled links, right-click the linked block and select **Library Link > Break Link**.
- To copy and break links to multiple blocks simultaneously, select multiple blocks and then drag. The locked links are ignored and not broken.
- When you save the model, you can break links by supplying arguments to the `save_system` command. For more information, see `save_system`.

---

**Note**

- Some models can contain blocks from third-party libraries or optional Simulink block sets. Breaking the link for such models does not guarantee that you can run the model standalone. It is possible that a library block invokes functions supplied with the library and hence can run only if the library is installed on the system running the model.
  - Breaking a link can cause a model to fail when you install a new version of the library on a system. For example, if a model block invokes a function that is supplied from a library. If you break the link for such a block, the function can no longer be invoked from the model, causing simulation to fail. To avoid such problems, avoid breaking links to libraries.
- 

**See Also**

“Linked Blocks” on page 44-12 | “Restore Disabled Links” on page 44-26

## Lock Links to Blocks in a Library

You can lock links to a library. Lockable library links prevent unintentional disabling of these links. Lockable libraries ensure robust usage of mature stable libraries.

To lock links to a library, in the Library window, on the **Library** tab, click **Lock Links**. The link from the linked block to its parent library is now locked. When you refresh the model, you see a change in the link badge. The locked link badges have a black background.

Locked linked block links cannot be disabled from the parent library block. Such links can only be disabled from the command line by changing the LinkStatus to inactive. For more information, see “Control Linked Block Programmatically” on page 44-34.

The context menu of a locked linked block displays **Locked Library Link** and not **Library Link**. Also notice that the only enabled option on this menu is **Go To Library Block**.

If you open a locked linked block, the window title displays **Locked Link: *blockname***. The bottom left corner shows a lock icon and a link badge. You can also hover over the link badge to view lock information.

To unlock links from the Library window, on the **Library** tab, click **Links Locked**. If the library is locked, the option to lock or unlock the links is disabled. You must unlock the library to enable the option.

### Rules for Locked Links

- Locked links cannot be edited. If you try to make a structural change to a locked link (such as editing the diagram), you see a message that you cannot modify the link because it is either locked or inside another locked link.
- The mask and block parameter dialogs are disabled for blocks inside locked links. For a resolved linked block with a mask, its parameter dialog is always disabled.
- You cannot parameterize locked links in the Model Editor.

- When you copy a block, the library status determines the status of a link (locked or not). If you copy a block from a library with locked links, the link is locked. If you later unlock the library links, any existing linked blocks do not change to unlocked links until you refresh the links.
- If you use sublibraries, when you lock links to a library, lock links to the sublibraries.

## **See Also**

## **More About**

- “Linked Blocks” on page 44-12

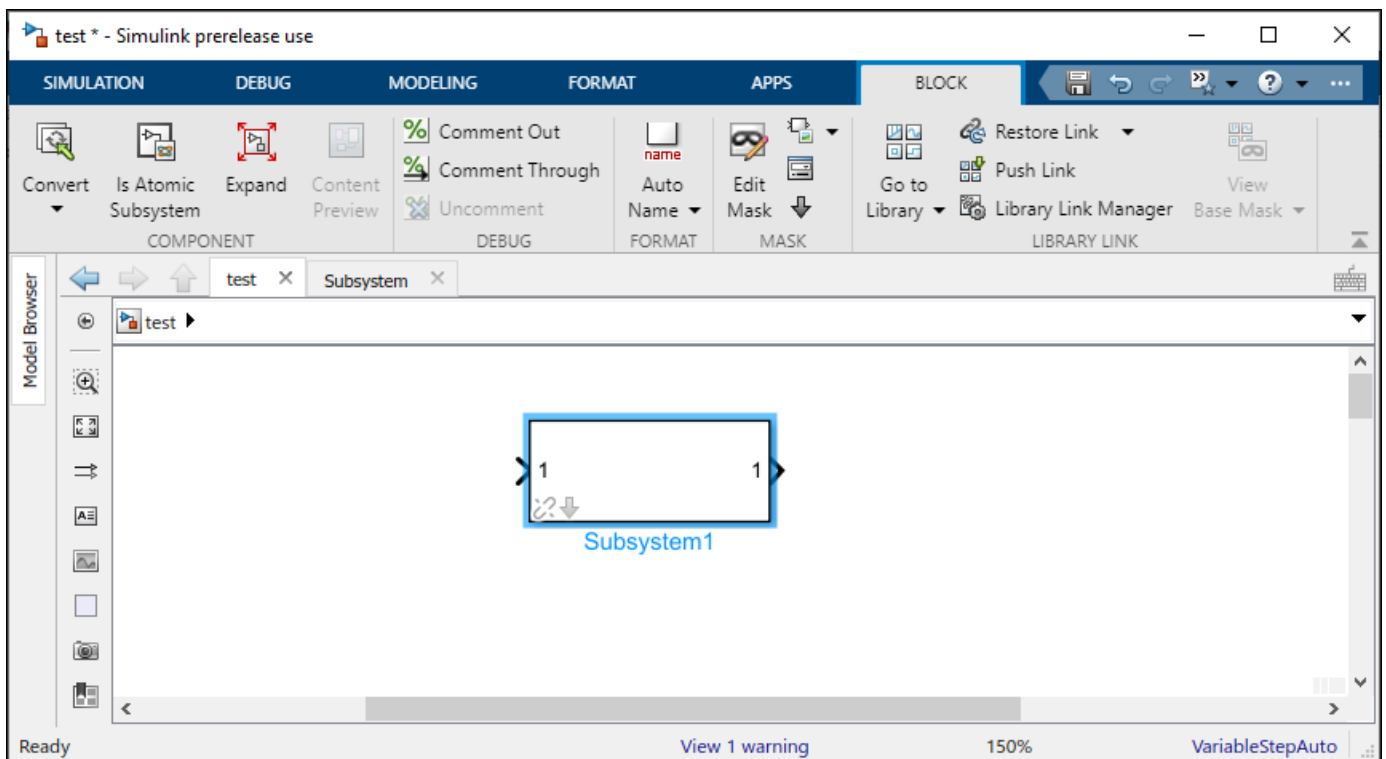

## Restore Disabled Links

You can restore a disabled linked block or push a linked block value to the parent library block either individually or hierarchically.

### Restore Disabled Links Individually

When you push or restore a disabled block in individual mode, the disabled or edited block is pushed to or restored from the library, preserving the changes inside the block without acting on the hierarchy. All other links are unaffected. You can restore or push individual disabled blocks in three ways:

- Select the disabled linked block and in the Simulink toolstrip, on the **Subsystem Block** tab, select **Push Link** or **Restore Link**.

- Right-click a disabled linked block and from the context menu, select **Library Links** and click **Push Link** to push the changes or **Restore Link** to restore the values from the parent library block.
- Right-click the link badge on the bottom-left corner of a disabled linked block and from the context menu, click **Push Links** to push the changes or **Restore Link** to restore the values from the parent library block.

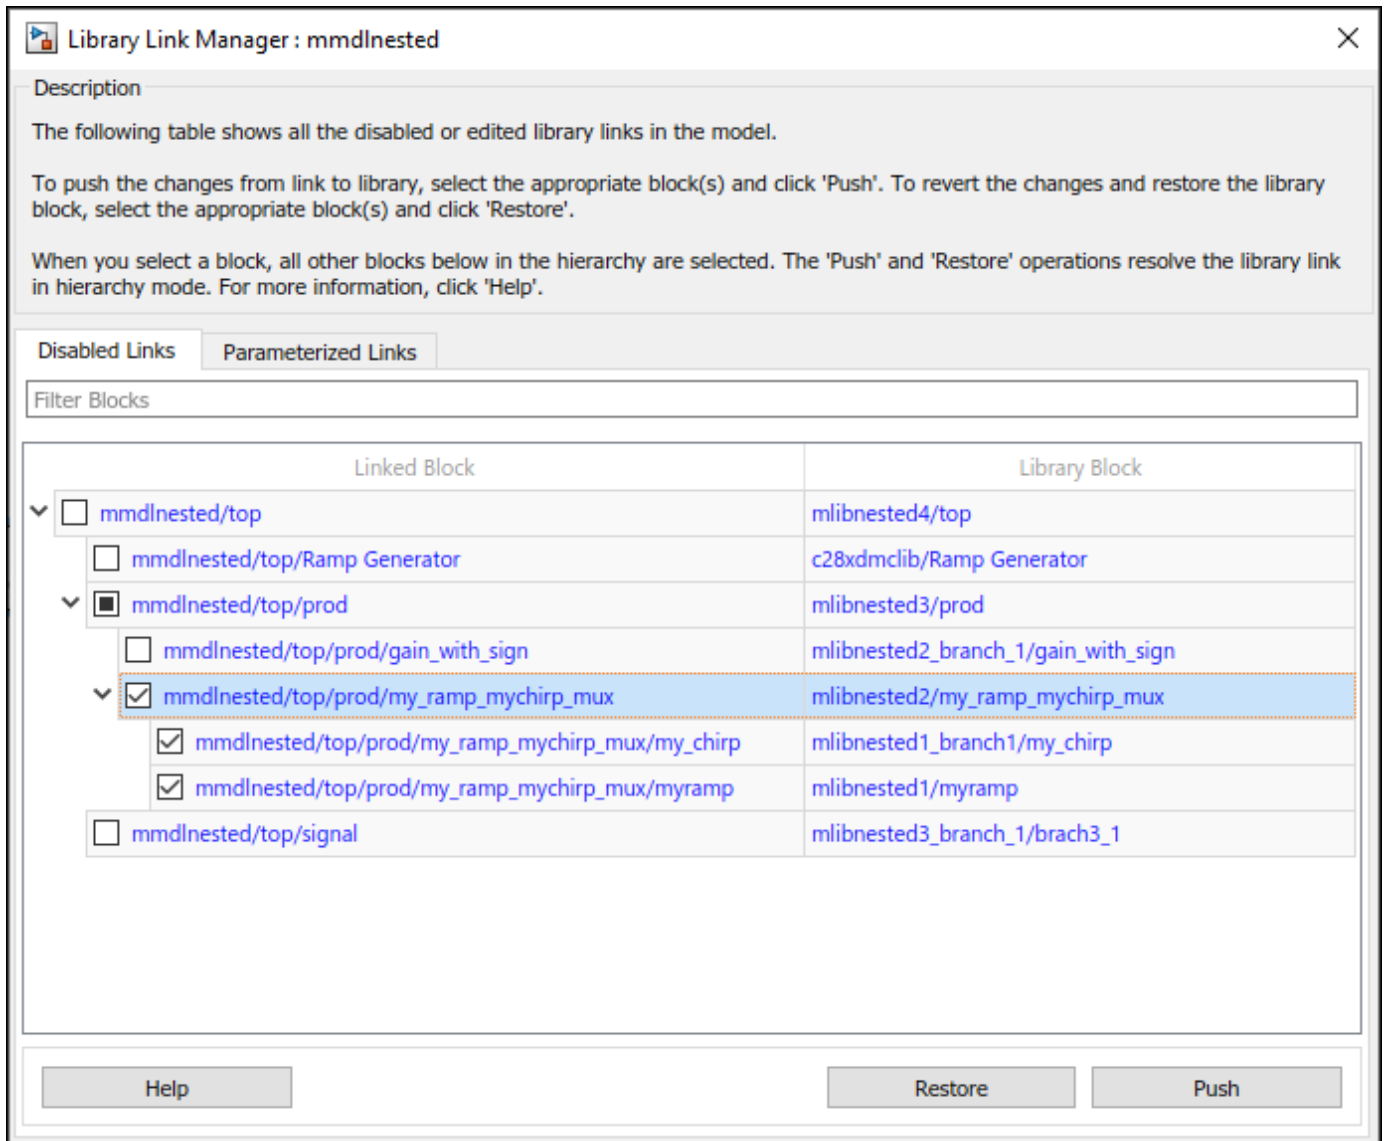

## Restore Disabled Links Hierarchically

When you push or restore disabled links in the hierarchy mode, the operation is applied to the whole hierarchy of links. To push or restore in hierarchy mode, use the Library Link Manager tool. The Library Link Manager displays all the disabled and parameterized linked blocks in the model.

You can launch the Library Link Manager in two ways:

- In the Simulink toolstrip, on the **Modeling** Tab, under the **System Design** section, click **Library Link Manager**.
- or
- Select any disabled linked block and in the Simulink toolstrip, on the **Subsystem Block** tab, click **Library Link Manager**.

The Library Link Manager window appears. It has two tabs showing disabled Links and parameterized links in the model. By default, the **Disabled Links** tab is selected.

The table shows two columns where the **Linked Block** column displays the list of linked blocks that have disabled links and the **Library Block** column displays the parent library block of the corresponding linked blocks.

To push or restore disabled blocks,

- 1 Select the disabled block or blocks as per your requirement.
- 2 Click **Push** to replace the version of the block in the library with the version in the model or **Restore** to replace the version of the linked block in the model with the version in the library.

You can use the **Filter Blocks** field to filter the displayed linked blocks based on your preference. This is useful when you have a huge number of blocks in the model.

## Pushing or Restoring Link Hierarchies

Pushing a hierarchy of disabled links affects the disabled links inside and outside the hierarchy for a given link. If you push changes from a disabled link in the middle of a hierarchy, the inside links are pushed and the outside links are restored if unchanged. This operation does not affect outer (parent) links with changes unless you also explicitly selected them for push. The Library Link Manager starts to push from the lowest inside links and then moves up in the hierarchy.

For examples:

- 1 Link A contains link B and both have changes.
  - Push A. The Links Tool pushes both A and B.
  - Push B. The Links Tool pushes B and not A.
- 2 Link A contains link B. A has no changes, and B has changes.
  - Push B. The Links Tool pushes B and restores A. When parent links are unmodified, they are restored.

If you have a hierarchy of parameterized links, the Library Links Manager can manipulate only the top level.

---

**Tip** To compare files and view structural changes, in the **Modeling** tab, select **Compare > Compare Models**.

## Restore Parameterized Links

A parameterized link is created when you change the parameter values of the child blocks of a masked subsystem linked block. You can choose to push the new values from the linked block to the parent block or restore the linked block with values from the parent block. You can push or restore parameterized links using the Library Links Manager.

To restore or push parameterized links:

- 1 Select the parameterized link and in the Simulink toolstrip, on the **Subsystem Block** tab, click **Library Link Manager**.

The Library Link manager opens. Click the **Parameterized Links** tab to display all the parameterized link in the model.

The table has the following columns:

- **Block** - Displays the block name.
  - **Parameter** - The name of the parameter in the block.
  - **Parameterized Value** - The changed value of any edited parameter in the model.
  - **Library Value** - The original value of the parameter in the parent library block.
- 2 Select the blocks you want to push or restore.
  - 3 Click **Push** to replace the value of the block in the library with the parameterized value in the model or **Restore** to replace the version of the linked block in the model with the version in the library.

## Fix Unresolved Library Links

If Simulink is unable to find either the library block or the source library on your MATLAB path during a linked block update, the link becomes unresolved. Simulink changes the appearance of these blocks.

### Install Missing Product

Simulink helps you find and install missing products that a model needs to run.

- Blocks are labeled with missing products (for example, **SimEvents not installed**).
- Tooltips include the name of the missing product.
- Diagnostic messages provide links to open the Add-On Explorer and install any missing products.
- When you double-click the block, the dialog box provides a link to open the Add-On Explorer and install any missing products.

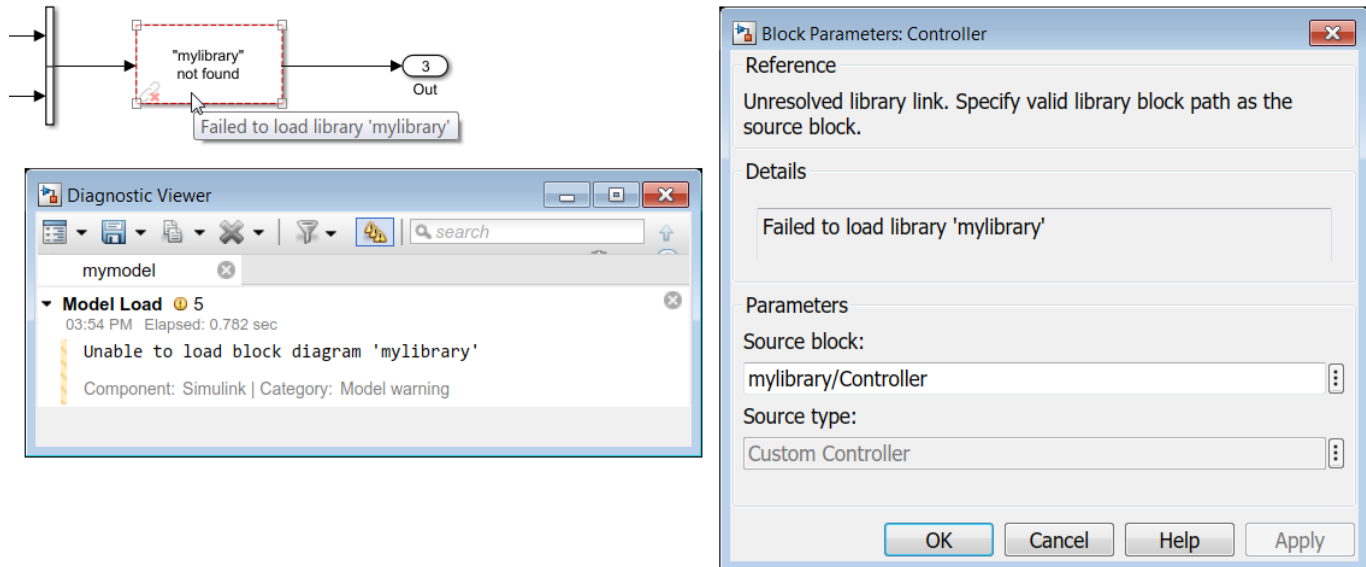

### Resolve Path to Source Block

If Simulink is unable to find the library, you can fix the unresolved link using one of these methods:

- Fix the reference to point to the correct location of the library block. Double-click the block to open its dialog box. Then, correct the path of the library block in the **Source block** text box and click **OK**.

- Delete the unresolved block and copy the library block back into your model.
- Add the folder that contains the required library to the MATLAB path. Then, on the **Modeling** tab, click **Update Model**.

## Specify Unresolved Block Details for Custom Libraries

You can customize the description that appears in the dialog box for an unresolved link to a custom library. Use the `set_param` function to set the `libraryinfo` property of the library. For example, this command customizes the description to include a URL.

```
set_param(library1, 'libraryinfo', 'https://www.mathworks.com');
```

Here, `library1` is the name of the library for which you want to change the description, and `libraryinfo` is the property that provides the description of the unresolved link.

## Control Linked Block Programmatically

### Linked Block Information

Use the `libinfo` command to get information about the linked blocks in the model. `libinfo` also provides information about the parent library blocks of a linked block.

For example, here is a model with linked blocks:

“Mask a Variant Subsystem” on page 42-82

When you execute the `libinfo(gcb)` command on this block:

```
Block: 'slexMaskVariantExample/VariantSubsystem2' %Linked block
      Library: 'slexMaskingVariants_libraryblock' %Parent library block
      ReferenceBlock: 'slexMaskingVariants_libraryblock/VariantSubsystem2'
      LinkStatus: 'resolved' %Link status
```

The `ReferenceBlock` property gives the path of the library block to which a block links. You can change this path programmatically by using the `set_param` command. For example:

```
set_param('slexMaskVariantExample/VariantSubsystem2','ReferenceBlock','slexMaskVariantExample2/VariantSubsystem')
```

Here, `slexMaskVariantExample/VariantSubsystem2` is the original library block path and `slexMaskVariantExample2/VariantSubsystem` is the new library block path.

---

**Note** It is not recommended to change the properties of a referenced block by using the `set_param` command in the mask initialization code or callback code of the same block. For such modeling patterns, you can use Variant blocks or use the `ReferenceBlock` parameter on the callback code or the mask initialization code of the parent block of the reference block.

---

### Lock Linked Blocks

Use the `LockLinksToLibrary` command to lock or unlock a linked block in a library from the command line. When you set the value of `LockLinksToLibrary` to `on`, the linked block links to the library are locked.

```
set_param('MyLibraryName', 'LockLinksToLibrary', 'on') %Lock links
```

```
set_param('MyLibraryName', 'LockLinksToLibrary', 'off') %Unlock links
```

### Link Status

All blocks have a `LinkStatus` parameter and a `StaticLinkStatus` parameter to indicate whether the block is a linked block.

Use `get_param(gcb, 'StaticLinkStatus')` to query the link status without updating the linked blocks. You can use `StaticLinkStatus` to query the status of a linked block that is either active or outdated.

Use `get_param` to send a query to get the value of the `LinkStatus`.

Get LinkStatus Value	Description
none	Block is not a linked block.
resolved	Resolved link.
unresolved	Unresolved link.
implicit	Block resides in library block and is itself not a link to a library block. Suppose that A is a link to a subsystem in a library that contains the Gain block. If you open A and select the Gain block, <code>get_param(gcb, 'LinkStatus')</code> returns <code>implicit</code> .
inactive	Disabled link.

Use `set_param` to set the `LinkStatus`.

Set LinkStatus Value	Description
none	Breaks link. Use <code>none</code> to break a link, for example, <code>set_param(gcb, 'LinkStatus', 'none')</code> .
<code>breakWithoutHierarchy</code>	Breaks links in place without breaking the nested parent hierarchy of link. For example, <code>set_param(gcb, 'LinkStatus', 'breakWithoutHierarchy')</code> .
inactive	Disables link. Use <code>inactive</code> to disable a link, for example, <code>set_param(gcb, 'LinkStatus', 'inactive')</code> .
restore	Restores an inactive or disabled link to a library block and discards any changes made to the local copy of the library block. For example, <code>set_param(gcb, 'LinkStatus', 'restore')</code> replaces the selected block with a link to a library block of the same type. It discards any changes in the local copy of the library block.  <code>restore</code> is equivalent to <code>Restore Individual</code> in the Links Tool.
propagate	Pushes any changes made to the disabled link to the library block and re-establishes its link. <code>propagate</code> is equivalent to <code>Push Individual</code> in the Links Tool.
restoreHierarchy	Restores all disabled links in the hierarchy with their corresponding library blocks. <code>restoreHierarchy</code> is equivalent to <code>Restore</code> in hierarchy mode in the Links Tool.
propagateHierarchy	Pushes all links with changes in the hierarchy to their libraries. <code>propagateHierarchy</code> is equivalent to <code>Push</code> in the <b>Hierarchy</b> mode of the Links Tool. See “Restore Disabled Links” on page 44-26.

#### Note

- When you use `get_param` to query the link status of a block, the outdated block links also resolve.
- Using the `StaticLinkStatus` command to query the link status when `get_param` is being used in the callback code of a child block is recommended. `StaticLinkStatus` command does not resolve any outdated links.

If you call `get_param` on a block inside a library link, Simulink resolves the link wherever necessary. Executing `get_param` can involve loading part of the library and executing callbacks.

## Maintain Compatibility of Library Blocks Using Forwarding Tables

Forwarding Table allow you to check that the changes to blocks in a library do not break the model if you have saved the model with an older version of the library block. Forwarding tables help you to maintain compatibility of library blocks when you change the path or name of the library, or add, remove, or rename the parameters in the library block. For more information see, “Create Custom Library” on page 44-2.

Create a forwarding table entry for mapping old library blocks to new library blocks. When you open the model, the links to the old library block are updated automatically without losing data or functionality. Forwarding tables are executed when you open a model, close a model, or when you execute the `add_block` or `replace_block` command.

Create a forwarding table entry when you:

- Rename a block.
- Move a block from one library to another library.
- Add or remove parameters from the block.
- Split the functionality of a block.

### Forwarding Table Entry for a Renamed Block

Consider an example where the block name in a library `testlib` is renamed from `ss1` to `ss2`.

- 1 Open the locked library `Lib1`.
- 2 In the Library window, on the **Library** tab, click **Locked Library**. The library is now unlocked for editing.
- 3 On the **Modeling** tab, click **Library Properties**. The **Library Properties** dialog box opens.
- 4 Click the **Forwarding Table** tab.
- 5 Click Add New entry. A new row is added in the forwarding table.
- 6 Specify the name of the old block in **Old Block Path** and the corresponding new block path in the **New Block Path**. If you do not know the path, select the block in the model and click **Get gcb** button. The path of the block is automatically populated in the respective columns.

The mapping of the old path to new path is created in the forwarding table. Now, open a model that contains links to the library. The links to the old library blocks in the model are updated automatically. You can use the search bar above the table to filter the table contents. You can sort the columns in ascending or descending order. You can also group columns by their values.

### Assign Version Numbers to Library Blocks

In the **Version** column, you can specify a version number for the library block.

If the old block name is the same as new block name, the forwarding table populates the version number automatically. The initial value of the library version `LibraryVersion` is derived from the `ModelVersion` property of the library at the time the library link is created. Any subsequent updates to the library block will update the library version to match the model version of the library.

The version number:

- Must be a numeric value.
- Must be of the format `<major_version>. <minor_version>` when the old and the new block paths are the same.
- Must not have more than one dot notation. For example, a version number of 1.3 is acceptable. A version number 1.3.1 is not acceptable.
- Format is not critical when you use a forwarding table to move a library block from one library to another.

### Move Block from One Library to Another

Consider an example where a block `ss1` is moved from `testlib1` to `testlib2`. The forwarding table entry in this case is shown here:

## Add or Remove Parameters from the Block

Consider an example where the **Gain** parameter of `ss1` in library `testlib` is removed, and two other parameters `Initial condition` and `Delay length` are added to it.

To handle this change we use a transformation function. A transformation function corrects the mismatch of parameters between the new and old library links, which ensures that the library links continue to work. You can define a transformation function using a `.m` function file on MATLAB path, then call the function in the **Transformation Function** column of the **Forwarding Table**.

A linked block contains an instance of the block parameters in the form of name-value arguments to instantiate the block. This instance data is passed to transformation function as `InstanceData` along with forwarding entry. This data is stored as `struct` fields.

When you create versions of a library block, parameters are added or removed from the `InstanceData`. In this example, the `InstanceData` before removal of the **Gain** parameter and after the addition of initial condition and delay length looks like this

### Before:

```
'RTWMemSecFuncInitTerm' 'Inherit from model'
'RTWMemSecFuncExecute' 'Inherit from model'
```

```
'RTWMemSecDataConstants' 'Inherit from model'
'RTWMemSecDataInternal' 'Inherit from model'
'RTWMemSecDataParameters' 'Inherit from model'
'ContentPreviewEnabled' 'on'
'Gain' '0'
```

**After:**

```
'RTWMemSecFuncInitTerm'      'Inherit from model'
'RTWMemSecFuncExecute'      'Inherit from model'
'RTWMemSecDataConstants'    'Inherit from model'
'RTWMemSecDataInternal'     'Inherit from model'
'RTWMemSecDataParameters'   'Inherit from model'
'ContentPreviewEnabled'     'on'
'DelayLength'               '1'
'InitialCondition'          '0'
```

This is the syntax for transformation function.

```
function outData = TransformationFcn(inData)
```

In this function syntax:

- `inData` is a structure with fields `ForwardingTableEntry` and `InstanceData`. `ForwardingTableEntry` is also a structure.
- • The `ForwardingTableEntry` has the old name, new name, old path, and new path of a block. Refer to the code to access the members of the `ForwardingTableEntry`.
- `outData` is a structure with fields `NewInstanceData` and `NewBlockPath`.

To add or remove parameters from a block:

- 1 Obtain the instance data and the forwarding table entry.
- 2 Extract the list of name-value pair and block names.
- 3 Get the old and new block names.
- 4 Check if the old and new block names are same. If so, then extract the versions of the block.
- 5 Check if the old version is 1.1 and the new version is 1.2. Then, remove the `Gain` parameter and add the parameters `Delay length` and `Initial condition`.

---

**Note** You can have only one transformation function for one library or block. However, you can have multiple functions.

---

To add or remove parameters, use this transformation function.

```
function [outData] = txFcnTestlib(inData)
    outData.NewBlockPath = '';
    outData.NewInstanceData = [];

    % Get linked block instance data and forwarding entry for which
    % function is called
    instanceData = inData.InstanceData;
    forwardingTableEntry = inData.ForwardingTableEntry;

    % Get list of name value pair and block names
```

```

[ParamNames{1:length(instanceData)}] = instanceData.Name;

% Get old and new block paths or simply names
oldName = forwardingTableEntry('__slOldName__');
newName = forwardingTableEntry('__slNewName__');

% If block names are same and its subsys block in the lib
if strcmp(oldName, newName)
    % Get old and new block versions from forwarding table
    oldVer = forwardingTableEntry('__slOldVersion__');
    newVer = forwardingTableEntry('__slNewVersion__');

    % Each forwarding entry with different version can have separate
    % entry. Here, for one single entry in forwarding table i.e.
    % 1.2->1.3 or 1.3->2.0, we have separate transformation making one
    % TX Fcn for one library or block.
    if strcmp(oldName, 'testlib/ssl')
        % Forwarding with same block name ssl
        if oldVer == '1.1' && newVer == '1.2'
            % Remove gain param
            if (ismember('Gain',ParamNames))
                for (i = 1:length(instanceData))
                    if (strcmp(instanceData(i).Name,'Gain') == true)
                        instanceData(i) = [];
                        break;
                    end
                end
            end
        end

        % Add delay length param
        if (ismember('DelayLength',ParamNames))
            for (i = 1:length(instanceData))
                if (strcmp(instanceData(i).Name,'Value') == true)
                    instanceData(i).Value = '5';
                    break;
                end
            end
        else
            instanceData(end+1).Name = 'DelayLength';
            instanceData(end).Value = '1';
        end

        % Add initial condition param
        if (ismember('InitialCondition',ParamNames))
            for (i = 1:length(instanceData))
                if (strcmp(instanceData(i).Name,'InitialCondition') == true)
                    instanceData(i).Value = '0';
                    break;
                end
            end
        else
            instanceData(end+1).Name = 'InitialCondition';
            instanceData(end).Value = '0';
        end
    elseif (oldVer == '1.2' && newVer == '1.3')
        % Do version 1.2 to 1.3 specific changes
    elseif (oldVer == '1.3' && newVer == '2.0')
        % Do version 1.3 to 2.0 specific changes
    end
end

```

```

        else
            % Do default changes not applicable to any version if
            % required
        end
    elseif strcmp(oldName, 'testlib/ss2')
        % Forwarding for block ss2 with version upgrade
    end
elseif strcmp(oldName, 'testlib/oldblk') && strcmp(newName, 'testlib2/newblk')
    % Block moved to new library or just block is renamed within same
    % library, no version is checked here. Do transformation is
    % required i.e. is block has been modified while renaming or moving
    % to new lib.
elseif strcmp(oldName, 'testlib/blkX') && isempty(newName)
    % We are splitting the block into 2 different blocks. Hence, kept
    % newName empty in fwd table. Using one of the block param from its
    % instance data (which is name-value pair of all block params) to
    % decide how and what to divide.

    % Get the index of param we are interested in i.e. param X
    i = find(contains({instanceData.Name}, 'X'), true);

    % Based on its value, do block splitting
    switch (instanceData(i).Value)
        case 'op1'
            newName = 'newlibX/blkX';
            % Remove existing param or add new param or modify existing
            % params etc.
        case 'op2'
            newName = 'newlibY/blkX';
        otherwise
            newName = oldName;
    end
end

% Return new instance data and new block path
outData.NewInstanceData = instanceData;
outData.NewBlockPath = newName;
end

```

## Split Block Functionality

Splitting the functionality of a block involves adding, removing, or modifying the existing parameter of the block and adding it to the new block. To split the functionality of a block:

- 1 Leave the newName argument empty.
- 2 Get the index and value of the parameter.
- 3 Split the block based on its value.
- 4 Return the NewBlockPath with the updated InstanceData if required.

## Create Mask Parameter Aliases

If you rename a mask parameter, you must ensure that the existing MATLAB scripts that use the old parameter names, continues to work. To check compatibility, you can create an alias for a mask parameter name. An alias allows you to change the name of a mask parameter in a library block without having to recreate links to the block in existing models.

Consider a masked block that contains an **Edit** parameter. The mask parameter name for this **Edit** parameter is `p1`.

```
MaskObj = Simulink.Mask.get(gcb);
hEdit = MaskObj.getParameter('p1');
```

```
hEdit=
% MaskParameter with properties:
```

```
    Type: 'edit'
TypeOptions: {0x1 cell}
    Name: 'p1'
    Prompt: 'p1'
    Value: '0'
    Evaluate: 'on'
    Tunable: 'on'
NeverSave: 'off'
    Hidden: 'off'
    Enabled: 'on'
    Visible: 'on'
    ToolTip: 'on'
    Callback: ''
    Alias: ''
```

Notice that the **Edit** mask parameter does not have an alias. To add an alias for the mask parameter, set a value for the **Alias** mask parameter property.

```
MaskObj.Alias = 'pa'
```

You can either use the mask parameter name or the alias to do a function call on the mask parameter. For example, you can either use `set_param(gcb, 'p1, '10)` (mask parameter name) or `set_param(gcb, 'pa, '10)` (mask parameter alias) to set a value for the **Edit** mask parameter.

# Integrating Custom C/C++ Code

---

## Debug Custom C/C++ Code

When you integrate custom C/C++ code into your model, you can debug your code from within Simulink by launching an external debugger and setting breakpoints in your custom code. This option applies to custom code specified in the **Simulation Target** pane of the Model Configuration Parameters dialog box. You can integrate this custom code into your model using any of these blocks:

- C Caller
- C Function
- MATLAB Function
- MATLAB System
- Stateflow chart

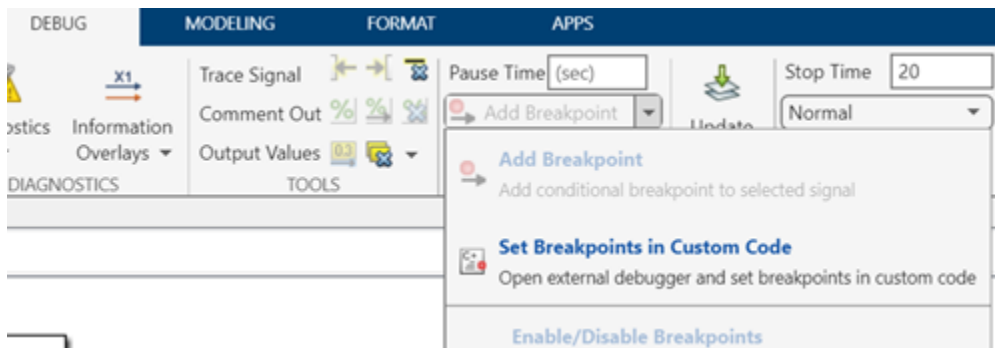

**Note** To debug custom code, the **Import custom code** check box in the **Simulation Target** pane of the Model Configuration Parameters dialog must be selected. This parameter is selected by default.

This table gives information about debugger support.

Operating System	Supported Debuggers
Windows	Microsoft Visual Studio® IDE.
	Visual Studio Code with MinGW® GDB. Requires installation of MATLAB Coder Interface for Visual Studio Code Debugging support package. See <a href="https://www.mathworks.com/matlabcentral/fileexchange/103555">https://www.mathworks.com/matlabcentral/fileexchange/103555</a> .
macOS	LLDB.
	Visual Studio Code with LLDB. Requires installation of MATLAB Coder Interface for Visual Studio Code Debugging support package. See <a href="https://www.mathworks.com/matlabcentral/fileexchange/103555">https://www.mathworks.com/matlabcentral/fileexchange/103555</a> .
Linux	GNU® Data Display Debugger (DDD).
	Visual Studio Code with GDB. Requires installation of MATLAB Coder Interface for Visual Studio Code Debugging support package. See <a href="https://www.mathworks.com/matlabcentral/fileexchange/103555">https://www.mathworks.com/matlabcentral/fileexchange/103555</a> .

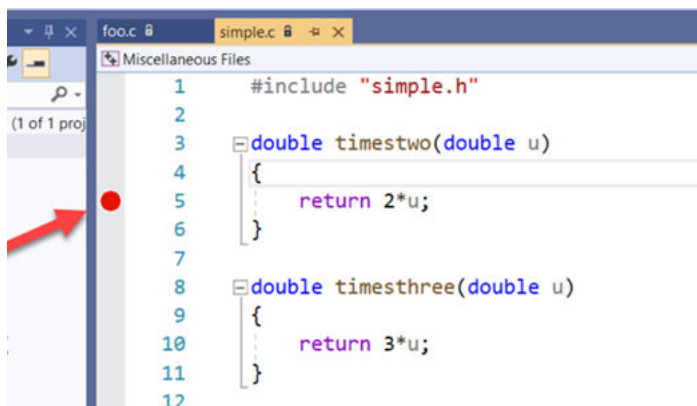

To select a compiler to use with C or C++ code, execute the command `mex -setup C` or `mex -setup C++`.

To launch the external debugger, on the **Debug** tab of the Simulink toolstrip, in the **Breakpoints** section, click the arrow to the right of the **Add Breakpoint** button. From the menu, select **Set Breakpoints in Custom Code**.

Debugging is supported only when simulating in normal or accelerated mode and only in normal mode for referenced models. If debugging is not supported, the button to launch the debugger is disabled.

Once the debugger is launched, you can set breakpoints in your custom code.

When you simulate your model, the simulation pauses when it reaches a breakpoint in the custom code. Note that when the simulation is paused during debugging, the simulation time step display at the bottom of the Simulink window may not be up-to-date.

To end a debugging session, first detach the active process from the debugger, then close the debugger window.

**Caution** Do not kill the process attached to the debugger. Issuing a `kill` command from the process in which the debugger is running can cause MATLAB to stop running, and you can lose work.

**Note** On Linux or Mac OS platforms, do not close the debugger before issuing a `detach` command from the process in which the debugger is running.

**Note** To use the Microsoft Visual Studio debugger in in-process mode, you must set the value of the Windows registry key `HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Control\Session Manager\DebuggerMaxModuleMsgs` to 4096 or greater.

To obtain the current value of `DebuggerMaxModuleMsgs`, execute this command in MATLAB.

```
winqueryreg('HKEY_LOCAL_MACHINE','SYSTEM\CurrentControlSet\Control\Session Manager','DebuggerMaxModuleMsgs')
```

If this registry key does not exist yet, this command will produce an error.

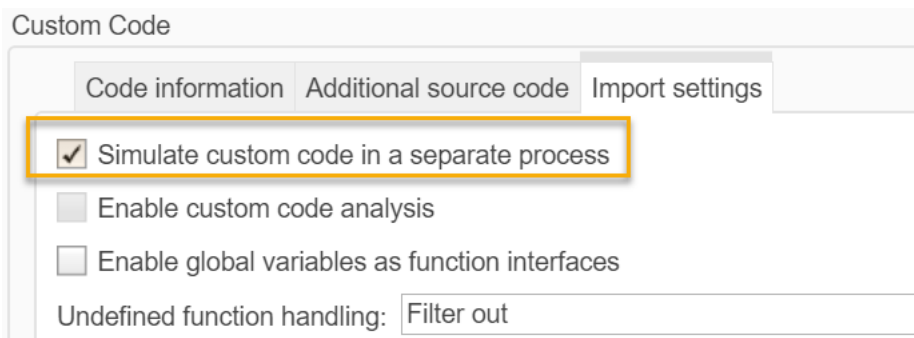

If this key does not exist or is set to a lower number than 4096, use this procedure to set it:

- 1 Start the Registry Editor.
- 2 Locate this subkey in the registry, and click **Session Manager**:  
`HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Control\Session Manager`
- 3 In the list of entries on the right, if `DebuggerMaxModuleMsgs` exists, go to step 6. Otherwise, continue to step 4.
- 4 On the Registry Editor window, select **Edit > New > DWORD Value**.
- 5 In the list of entries on the right, change the new value name to `DebuggerMaxModuleMsgs` and press **Enter**.
- 6 Right-click the `DebuggerMaxModuleMsgs` entry name and select **Modify**.
- 7 In the Edit DWORD Value dialog, in the **Value data** field, enter 4096. For the **Base** value, select **Decimal**. Click **OK**.
- 8 Close the Registry Editor.
- 9 Reboot your machine.

## In-Process and Out-of-Process Simulation

When simulating a model containing custom C or C++ code, you have the option to run the custom code in a separate process outside of MATLAB. This process is called *out-of-process simulation*. This option may be useful when debugging your custom code. By running in a separate process, problems with the custom code do not cause MATLAB to crash, and you can more easily debug and resolve such problems. Problems can arise due to unexpected exceptions in the custom code or errors in the interface between Simulink and the custom code.

To enable out-of-process simulation, in the Model Configuration Parameters dialog box, in the **Simulation Target** pane, on the **Import settings** tab, select **“Simulate custom code in a separate process”**.

If **Simulate custom code in a separate process** is not selected, that is, if you are using *in-process simulation*, then when you launch an external debugger, the entire MATLAB process attaches to the debugger. This action could cause the debugger to take more time to launch. Debugging is generally faster with out-of-process simulation.

Debugging with out-of-process simulation is not supported on Mac OS, and not all custom code functions are supported in out-of-process simulation. Note that simulation time is generally faster with in-process simulation.

When you simulate a model out-of-process, if you encounter a run-time exception, Simulink gives you the option to launch the external debugger. For example, this model contains a C Caller block that calls the function `adder()`, which accesses an object called `adderObj`. Before calling the function, the object must be created, which you can do by calling `initAdder()` from the **Initialize code** specified on the **Additional source code** tab of the **Simulation Target** pane of the Model Configuration Parameters dialog box.

```

#include "myAdder.hpp"

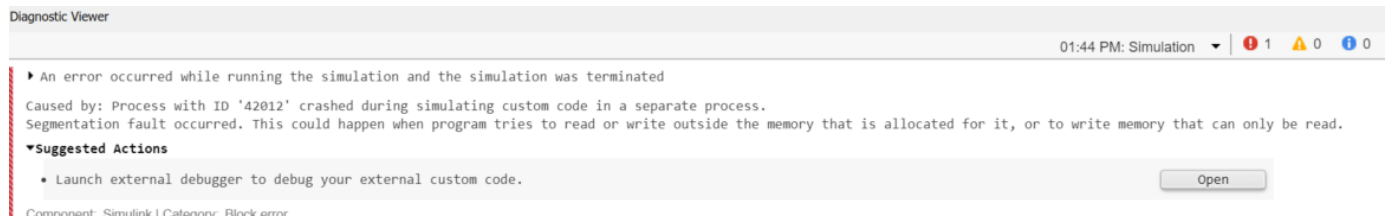

static Adder* adderObj = nullptr;

int Adder::add_one(int increment)
{
    for (int i = 0; i < increment; i++)
    {
        val = val + 1;
    }
    return val;
}

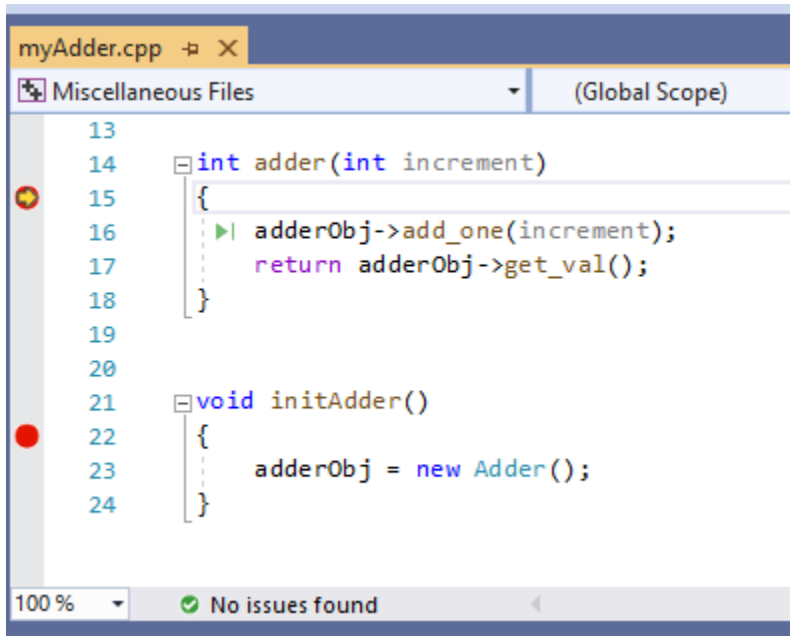

int adder(int increment)
{
    adderObj->add_one(increment);
    return adderObj->get_val();
}

void initAdder()
{
    adderObj = new Adder();
}
  
```

If `initAdder()` is not called before `adder()`, then `adder()` attempts to access an uninitialized pointer, which causes a run-time exception. During in-process simulation, this exception can cause MATLAB to crash when you simulate the model. However, with out-of-process simulation, simulating the model produces an error message within Simulink.

You can then click **Open** to launch your external debugger and resolve the issue that caused the error.

After the debugger launches, it restarts the simulation and stops at the breakpoints of custom function entries automatically.

“Debug Custom Code” on page 46-11

“Generate Code from Model” on page 46-11

“Limitations” on page 46-11

You can integrate new or existing C code into Simulink using the C Caller block. To create custom blocks in your Simulink models, the C Caller block allows you to call external C functions specified in external source code and libraries. The advantages of the C Caller block are:

- Automated integration of simple C functions including functions defined under namespace
- Integration with Simulink Coverage, Simulink Test, and Simulink Design Verifier
- Integration with Simulink Coder

The C Caller block and the C Function block allow you to bring C algorithms into Simulink. To model dynamic systems, use the S-Function Builder instead. Next steps describe the workflow to integrate C code into Simulink using the C Caller block.

---

**Note** C99 is the standard version of C language supported for custom C code integration into Simulink.

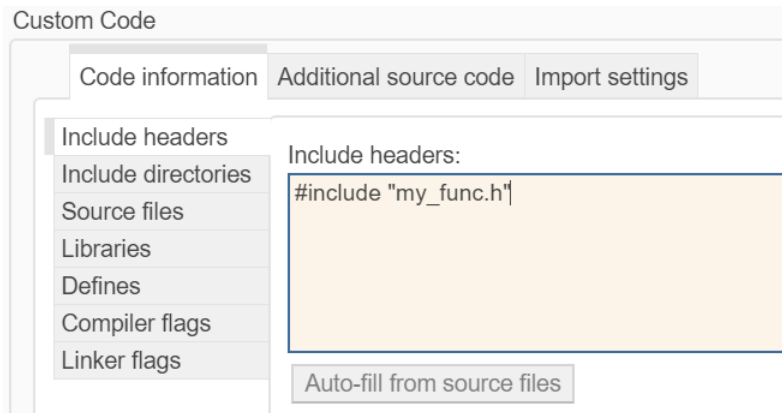

---

### Specify Source Code and Dependencies

Specify your external source code file that contains your C functions.

- 1 From Simulink toolstrip, open the **Configuration Parameters**.
- 2 In the left pane, select **Simulation Target**.
- 3 Select **Include headers** and enter the name of your header file with the `#include` tag.

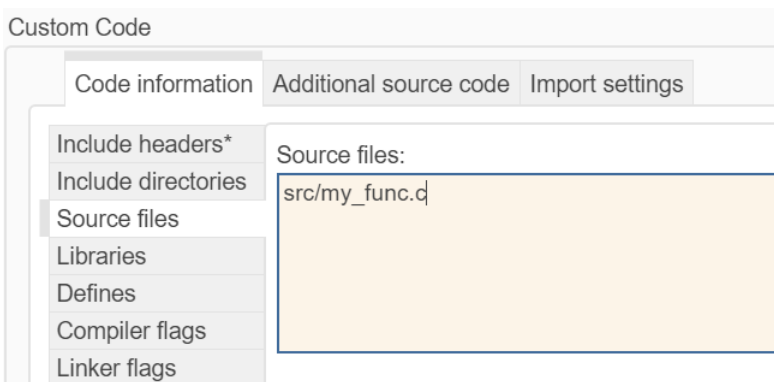

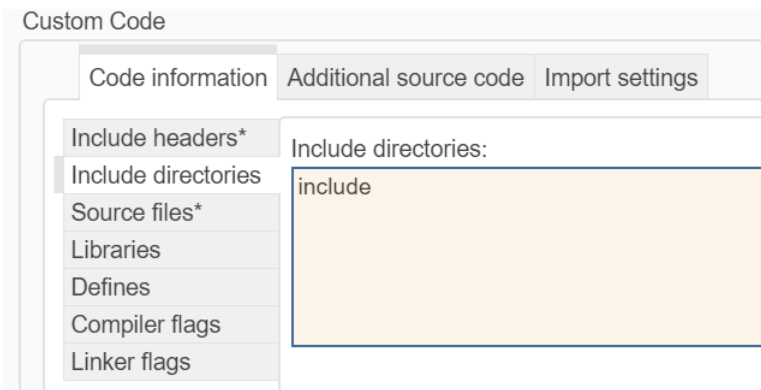

The directories and file paths can be absolute and relative file paths to model directories or to the current working directory. See “Specify Relative Paths to Your Custom Code” (Stateflow).

**Tip** After you have entered information for **Source files** in the next step, you can click **Auto-fill from source files** to have the header file name filled in automatically, using information contained in your source files.

- 4 Select **Source files** and enter the path and the name of the source file. If the model and the source files are in different directories, enter the directory that contains the source file before the file name.

- 5 Select **Include directories**, and enter the folders where additional build information, such as header files, are stored.

To verify that your custom code can be parsed and built successfully, click **Validate**.

**Note** If your header file declares a function but your source files do not define the function, by default the function is not visible in the C Caller block dialog. You can set the **Undefined function handling** parameter in Configuration Parameters to specify other behaviors in this situation, including throwing an error, generating a stub function, or ignoring the condition.

**Note** To use a C Caller block in a For Each subsystem or with continuous sample time, or to optimize the use of the block in conditional input branch execution, the custom code function called by the block must be deterministic, that is, always producing the same outputs for the same inputs. Identify which custom code functions are deterministic by using the **Deterministic functions** and **Specify by function** parameters in the **Simulation target** pane. For a conditional input branch execution example, see “Use C Caller Block with Conditional Execution” on page 46-13.

## N-D Array Handling

Simulink can pass N-D array data to custom code functions in C Caller blocks, and receive data from such blocks. When you do so, you must specify the correct array layout to achieve the intended results. See **Default function array layout** and **Exception by function**. For examples of the use of array data with C Caller blocks, see “Use Custom Image Filter Algorithms as Reusable Blocks in Simulink” and “Call a Legacy Lookup Table Function Using C Caller block” on page 47-27.

You can specify the order of how matrix data is handled in your C functions. Matrix data passed to and from your C functions is converted if necessary to the array layout you specify. If the array layout is not specified, the matrix data is passed through the C function in the same order of your Simulink data, and computational errors may occur due to row-column major disagreement. Ensure that you follow the same default function array layout for all Simulink data.

- **Column-Major** — The C function handles input array data in column-major order. Suppose that you have a 3-by-3 matrix. In the C function, this matrix is accessed in this sequence: first column, second column, and third column.
- **Row-Major** — The C function handles input array data in row-major order. Suppose that you have a 3-by-3 matrix. In the C function, this matrix is accessed in this sequence: first row, second row, and third row.
- **Any** — The C function is indifferent to the layout of input array data. This would be the case if, for example, the function performs only element-wise operations on the data.
- **Not specified** — The C function makes no assumption about the layout of input array data. Compared to the **Any** setting, you can generate code only in column-major setting. Attempting to generate code in row-major setting produces an error. See **Array layout**. Select this option only if needed for compatibility with older models.

To learn more about the row-major and column-major array layouts in Simulink, see “Default function array layout”.

- 1 Select an array layout option under **Default function array layout**.
- 2 If you need to apply a specific array layout to some of the functions in your code, click **Exception by function** to select these functions.
- 3 Click **Apply** to accept your changes.

If your C functions accept only scalar and/or vector inputs, the **Default function array layout** setting has no effect.

## Call C Caller Block and Specify Ports

You can start your custom C code integration into Simulink by typing `C Caller` in the Simulink canvas. Alternatively, drag a C Caller block from the User-Defined Functions library onto the canvas. Double-click the block to open the Block Parameters dialog box to see the names of your functions and port specifications.

- 1 Click on the Refresh button  to import your source code and its dependencies.
- 2 Your C functions are displayed under **Function Name**. If you do not see your full list of functions, click on the  to reimport your source code.
- 3 To view function definitions in the source file, click the . The source code for the selected function is displayed in the MATLAB Editor. If the source code is not available, the function declaration in the header file is displayed.
- 4 To change source files and their dependencies, or to define and select function array layouts, click the custom code settings button  to open the **Simulation Target** pane in Model Configuration Parameters.

## Map C Function Arguments to Simulink Ports

You can map C function arguments from your source code to Simulink ports using the **Port specification** table in the C Caller block or by creating a `FunctionPortSpecification` object through the command line. In your source code, the header file includes the C function arguments to be connected to Simulink ports.

```
extern void mean_filter(const unsigned char* src,
                      unsigned char* dst,
                      unsigned int width, unsigned int height,
                      unsigned int filterSize);
```

The **Port specification** table shows the details of your arguments and how they connect to your C Caller block in Simulink.

▼ Port specification:

Name	Scope	Label	Type	Size
src	Input	src	uint8	-1
dst	Output	dst	uint8	size(src)
width	Constant	size(src,2)	uint32	1
height	Constant	size(src,1)	uint32	1
filterSize	Parameter	filterSize	uint32	1

The table has these columns:

### Name

Specifies the name of input and output arguments. **Name** is the function argument or parameter name as defined in your C functions from source code. This column is for reference purposes only.

### Scope

Specifies how C function arguments map to the Simulink scope. Your arguments have default scopes depending on the function definition, and you can change the scopes depending your function definition in the source code.

Simulink Scope	Scope to Block Mapping
Input	Block input port
Output	Block output port
InputOutput	Block input and output port
Global	Not applicable
Parameter	Block tunable parameter
Constant	Constant value

For an argument passed by pointer, when the argument has a constant qualifier definition such as `const double *u`, the argument can only be an input or a parameter. When there is no constant qualifier, the argument is an `InputOutput` by default, and you can change it to an `Input`, `Output`, or `Parameter` scope. In the case of an `Input` or `Parameter` scope, ensure that the C function does not modify the memory pointed to by the pointer. If the argument is of an `Output` scope, every element pointed to by this pointer should be reassigned in every call for the function.

C Argument	Simulink Scope
Function return	Output
double u	Input, Parameter, Constant

C Argument	Simulink Scope
double *u double u[] double u[][2] double u[2][3]	InputOutput (default), Output, Input, Parameter
const double *u const double u[] const double u[][2] const double u[2][3]	Input (default), Parameter

Use the `InputOutput` scope to map an input passed by a pointer in your C functions. Ports created using an `InputOutput` scope have the same name for input and output ports. The `InputOutput` scope enables reuse of buffer for input and output ports. This may optimize the memory use depending on the signal size and the block layout.

To map a C function argument to an `InputOutput` scope, define the variable as a pointer in your function.

```
extern void mean_filter(unsigned char* src,
                      unsigned int width, unsigned int height,
                      unsigned int filterSize);
```

Then set the scope to `InputOutput` in the **Port Specification** table and assign the resulting function output to the input variable in the custom function.

▼ Port specification:

Name	Scope	Label	Type	Size
src	InputOutput	src	uint8	-1
width	Constant	size(src,2)	uint32	1
height	Constant	size(src,1)	uint32	1
filterSize	Parameter	filterSize	uint32	1

You can use global variables in your custom code, mapping them to the appropriate Simulink scope. To enable the use of global variables in your model, select “Enable global variables as function interfaces” from **Model Settings > Configuration Parameters > Simulation Target**. You can map the global variables to an `Input`, `Output`, `InputOutput` or `Global` scope on the C Caller block. The availability of these scopes depend on the use of the global variable in your custom code.

A `Global` scope enables you to transfer data between custom code and the C Caller block and lets you use the global variable during calculations on the block. Values transferred using `Global` scope

are not visible on the block interface. This table shows example code snippets and their default and available ports.

Example Code	Simulink Scope
<pre>double data;  void foo(void) {     int temp = data; }</pre>	<p>Global variable data only reads the variable data. Available scopes are:</p> <p>Input (default)</p> <p>Global</p>
<pre>double data;  void bar(void) {     data = 0; }</pre>	<p>Data is written to a global variable. Available scopes are:</p> <p>Output (default)</p> <p>Global</p> <p>InputOutput</p>
<pre>double data;  void foo2(void) {     data = data + 1; }</pre>	<p>Data is both read and written on a global variable. Available scopes are:</p> <p>Global (default)</p> <p>InputOutput</p> <p>Output</p>

### Label

Indicates the label for the corresponding argument in a Simulink block. By default, your argument label is the same as the argument name, unless you change it. Change the **Scope** to configure the options for the port labels.

Scope	Simulink Port Label
Input, Output	Port name
InputOutput	Port name in both input and output ports
Global	Port name and global variable name
Parameter	Parameter name
Constant	<p>Expression for the constant value.</p> <p>size expressions using input argument names, for example <code>size(in1,1)</code></p>

### Type

Specifies the data type of the argument. Data types in the C function must match equivalent data types in Simulink. This table shows the supported C data types you can use in the C Caller block, and the equivalent Simulink data types.

<b>C Argument Data Type</b>	<b>Simulink Data Type</b>
signed char/unsigned char	int8/unit8
char	int8 or uint8, depending on the compiler
int/unsigned int*	int32/unit32
short/unsigned short*	int16/unit16
long/unsigned long*	int32/unit32 or int64/unit64, depending on the operating system
long long/unsigned long long*	int64/unit64
float	single
double	double
int8_t/uint8_t*	int8/unit8
int16_t/unit16_t*	int16/unit16
int32_t/unit32_t*	int32/unit32
int64_t/unit64_t*	int64/unit64
bool	boolean
typedef struct {...} AStruct**	Bus: AStruct
typedef enum {...} AnEnum**	Enum: AnEnum
* If the C Caller takes an integer type, for example, int16_t, you can modify it to a fixed-point type with matching base type, for example to fixdt(1, 16, 3).	
** The C Caller sync button prompts you to import struct or enum types used by a C function as Simulink bus and enumeration types.	

## Size

Specifies the data dimensions in the argument.

<b>C Argument Dimensions</b>	<b>Simulink Port Dimensions</b>
double u	scalar (1)
double u[]	inherited (-1) (default)
double u[][2]	If the argument is for an output port, its size must be specified and cannot be inherited, unless the argument is mapped to an InputOutput scope or the model configuration parameter <b>Simulate custom code in a separate process</b> is selected.
double *u	inherited (-1) (default)  If the argument is for an output port, its size must be specified and cannot be inherited, unless the argument is mapped to an InputOutput scope or the model configuration parameter <b>Simulate custom code in a separate process</b> is selected.  For global variables, size is scalar (1).

C Argument Dimensions	Simulink Port Dimensions
double u[2][3]	Size is [2, 3].

## Create a FunctionPortSpecification Object and Edit C Caller Block Properties

To change **Port Specification** table properties programmatically, you can create a `FunctionPortSpecification` object and modify its properties. To create a `FunctionPortSpecification` object for a selected C Caller block in a model, type in the command line:

```
myCCallerConfigObj = get_param(gcb, 'FunctionPortSpecification')
```

```
myCCallerConfigObj =
```

```
FunctionPortSpecification with properties:
```

```

    CPrototype: 'real_T add(real_T u1, real_T u2);'
  InputArguments: [1x2 Simulink.CustomCode.FunctionArgument]
  ReturnArgument: [1x1 Simulink.CustomCode.FunctionArgument]
  GlobalArguments: [1x0 Simulink.CustomCode.FunctionArgument]
```

The `CPrototype` property is read-only, and shows the declaration of C function input variables. The `InputArgument` and `ReturnArgument` properties create a `FunctionArgument` object that you can further edit its properties according to the rules defined for **Port Specification** table above. See `FunctionPortSpecification` to learn more.

To modify the global arguments in a C Caller block, create a handle to the `GlobalArguments` object using `getGlobalArg` and modify its properties.

## Create a Custom C Caller Library

It is recommended to create a library model to group your C Caller blocks and keep your models organized. You can also link a data dictionary to the library to hold custom types defined in your code. Using a library model is especially useful when you have multiple models or a model reference hierarchy that uses custom C code.

- 1 Open a new library model. On the **Simulation** tab, select **New > Library**.
- 2 On the **Modeling** tab, under **Design**, click **Simulation Custom Code**.
- 3 Select C or C++ in the **Language** option, depending on your code, and ensure the **Import custom code** box is selected.
- 4 Follow the instructions in “Specify Source Code and Dependencies” on page 46-2 to add your source files and their dependencies.
- 5 Create C Caller blocks to call C functions.
- 6 To insert a block from your library model to a Simulink model, simply drag the block into your model.

You can also create a library of C Caller blocks from your custom code using the Simulink Code Importer. See “Import Custom C/C++ Code Using the Simulink Code Importer”.

## Debug Custom Code

You can debug your code from within Simulink by launching an external debugger and setting breakpoints in your custom code. For more information, see “Debug Custom C/C++ Code” on page 45-2.

## Generate Code from Model

The C Caller supports code generation. In the code generated from your model, each execution of a C Caller block corresponds to a call to the external C function associated with the block. In order to build the generated code, the **Code Generation > Custom Code** pane of the Model Configuration Parameters must be populated with the correct information regarding the custom code. See “Model Configuration Parameters: Code Generation Custom Code” (Simulink Coder).

## Limitations

- **Initialization/Termination of Custom Code Settings** — If you need to allocate and deallocate memory for your custom code, insert `allocate` and `deallocate` in the **Initialize function** and **Terminate function** fields of custom code settings, or use a C Function block.
- **Complex Data Support** — The C Caller block does not support complex data types in Simulink.
- **Variable Arguments** — Variable arguments in C are not supported, for example, `int sprintf(char *str, const char *format, ...)`.
- **C++ Syntax** — The C Caller block does not support native C++ syntax directly. You need to write a C function wrapper to interface with C++ code.

To test models that include C Caller blocks, see “Test Integrated C Code” (Simulink Test).

---

**Note** If a model has custom code, after the model is updated or run, the `slprj` folder may be locked due to the loaded custom code simulation executable file. The folder cannot be deleted when it is locked. To unload the executable file and unlock the `slprj` folder, use the `clear mex` command. See `clear`.

## Use C Caller Block with Conditional Execution

This example shows how to use a C Caller block with conditional execution. The example model contains two C Caller blocks whose outputs are input branches into a Switch block. Each C Caller block calls one of the custom C code functions `sort_ascend()` and `sort_descend()`. Only one of the values from the input branches is passed to the output side of the Switch block. A C Function block with the same settings can also be used in place of a C Caller block to call these custom code functions.

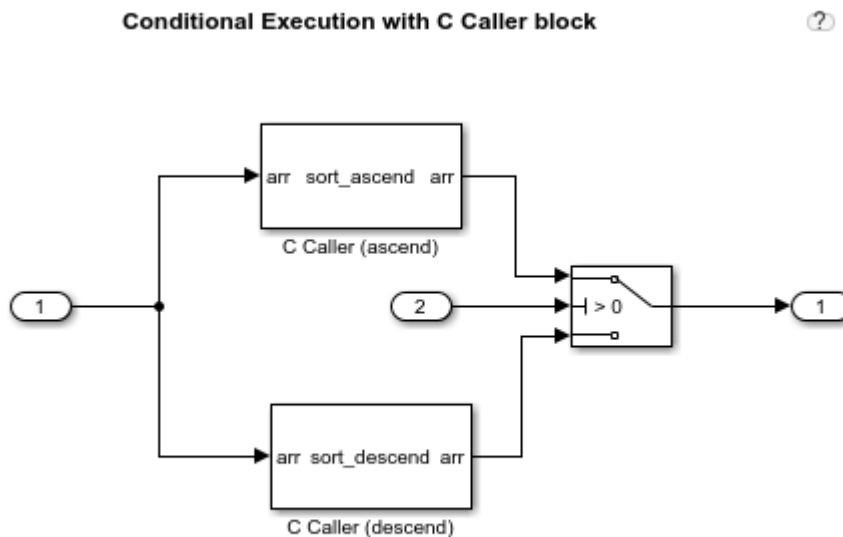

This example illustrates the following concepts:

- Calling custom C code from a Simulink® block in a conditional execution context.
- Configuring deterministic functions by function in custom code.

### Examine the Model

This model calls custom code through a C Caller block that is connected to an input branch of a Switch block.

```
open_system('slexCCallerConditional');
% Create a temporary folder for the build and inspection process.
currentDir=pwd;
[~,cgDir]=rtwdemodir();
```

Copyright 2020 The MathWorks, Inc.

### Generate Code

The custom code functions in this model have not been identified as deterministic functions. When code is generated from the model, both C functions are executed during simulation and in the generated code, even though the Switch block requires the output of only one of the functions.

```
slbuild(bdroot);
cfile = fullfile(cgDir,'slexCCallerConditional_grt_rtw','slexCCallerConditional.c');
rtwdemodbtype(cfile,'/* Model step', '/* Matfile logging', 1, 0);
```

```
### Starting build procedure for: slexCCallerConditional
### Successful completion of build procedure for: slexCCallerConditional
```

Build Summary

Top model targets built:

Model	Action	Rebuild Reason
slexCCallerConditional	Code generated and compiled.	Code generation information file does not exist

```
1 of 1 models built (0 models already up to date)
Build duration: 0h 1m 7.0044s
```

```
/* Model step function */
void slexCCallerConditional_step(void)
{
    real_T rtb_CCallerascend[6];
    real_T rtb_CCallerdescend[6];
    int32_T i;

    /* CCaller: '<Root>/C Caller (ascend)' incorporates:
     * Inport: '<Root>/In2'
     */
    for (i = 0; i < 6; i++) {
        rtb_CCallerascend[i] = slexCCallerConditional_U.In2[i];
    }

    sort_ascend(&rtb_CCallerascend[0], 6);

    /* End of CCaller: '<Root>/C Caller (ascend)' */

    /* CCaller: '<Root>/C Caller (descend)' incorporates:
     * Inport: '<Root>/In2'
     */
    for (i = 0; i < 6; i++) {
        rtb_CCallerdescend[i] = slexCCallerConditional_U.In2[i];
    }

    sort_descend(&rtb_CCallerdescend[0], 6);

    /* End of CCaller: '<Root>/C Caller (descend)' */
    for (i = 0; i < 6; i++) {
        /* Switch: '<Root>/Switch' incorporates:
         * Inport: '<Root>/In1'
         */
        if (slexCCallerConditional_U.In1 > 0.0) {
            /* Outport: '<Root>/Out3' */
            slexCCallerConditional_Y.Out3[i] = rtb_CCallerascend[i];
        } else {
            /* Outport: '<Root>/Out3' */
            slexCCallerConditional_Y.Out3[i] = rtb_CCallerdescend[i];
        }
    }
}
```

```

    /* End of Switch: '<Root>/Switch' */
}

```

## Specify Custom Code Deterministic Functions

Open the Configuration Parameters dialog box.

In the **Simulation Target** pane, set **Deterministic functions** to **By Function**. Click **Specify by function** and add the functions `sort_ascend` and `sort_descend` to the list. This action tells the model that the specified custom code functions have deterministic behavior, that is, the same input values to the functions always give the same outputs. If a function is set to be deterministic, it does not need to be called if it is in the input branch corresponding to a false value of the Switch block.

```
configset.highlightParameter(bdroot, 'DefaultCustomCodeDeterministicFunctions');
set_param(bdroot, 'DefaultCustomCodeDeterministicFunctions', 'ByFunction');
set_param(bdroot, 'CustomCodeDeterministicFunctions', 'sort_ascend,sort_descend');
```

### Generate Code Again

Now that you have specified the deterministic functions, the generated code is more efficient because only the C Caller block in the true branch of the Switch block is executed. The same efficiency applies when you simulate the model in Simulink.

```
slbuild(bdroot);
cfile = fullfile(cgDir, 'slexCCallerConditional_grt_rtw', 'slexCCallerConditional.c');
rtwdemodbtype(cfile, '/* Model step', '/* Matfile logging', 1, 0);
close_system(bdroot, 0);
```

```
### Starting build procedure for: slexCCallerConditional
### Successful completion of build procedure for: slexCCallerConditional
```

Build Summary

“Specify Simulation or Code Generation Code” on page 47-5

“Specify Declaration for Target-Specific Function for Code Generation” on page 47-6

You can call and integrate your external C code into Simulink models using C Function blocks. C Function blocks allow you to call external C code and customize the integration of your code using the **Output Code**, **Start Code**, **Initialize Conditions Code**, and **Terminate Code** panes in the block parameters dialog. Use the C Function block to:

- Call functions from external C code including functions defined under namespace, and customize the code for your Simulink models.
- Preprocess data to call a C function and postprocess data after calling the function.
- Specify different code for simulation and code generation.
- Call multiple functions.
- Initialize and work with persistent data cached in the block.
- Allocate and deallocate memory.

Use the C Function block to call external C algorithms into Simulink that you want to modify. To call a single C function from a Simulink model, use the C Caller block. To integrate dynamic systems that have continuous states or state changes, use the S-Function block.

---

**Note** C99 is the standard version of C language supported for custom C code integration into Simulink.

---

The following examples use C Function blocks to calculate the sum and mean of inputs.

### Write External Source Files

Begin by creating the external source files.

- 1 Create a header file named `data_array.h`.

```
/* Define a struct called dataArray */
typedef struct dataArray_tag {
    /* Define a pointer called pData */
    const double* pData;
    /* Define the variable length */
    int length;
} dataArray;

/* Function declaration */
double data_sum(dataArray data);
```

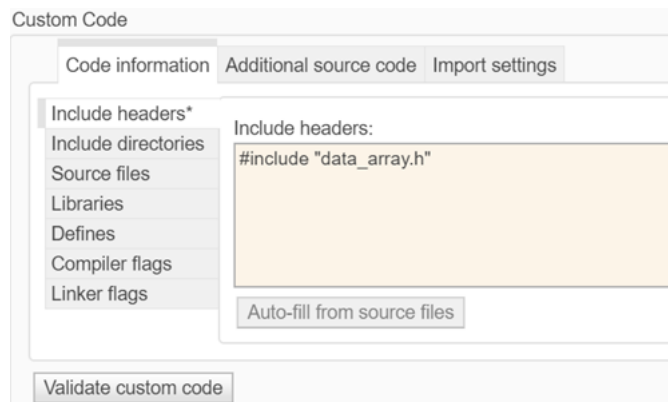

- 2 In the same folder, create a new file, `data_array.c`. In this file, write a C function that calculates the sum of input numbers.

```
#include "data_array.h"

/* Define a function that takes in a struct */
double data_sum(DataArray data)
{
    /* Define 2 local variables to use in the function */
    double sum = 0.0;
    int i;
    /* Calculate the sum of values */
    for (i = 0; i < data.length; i++) {
        sum = sum + data.pData[i];
    }
    /* Return the result to the block */
    return sum;
}
```

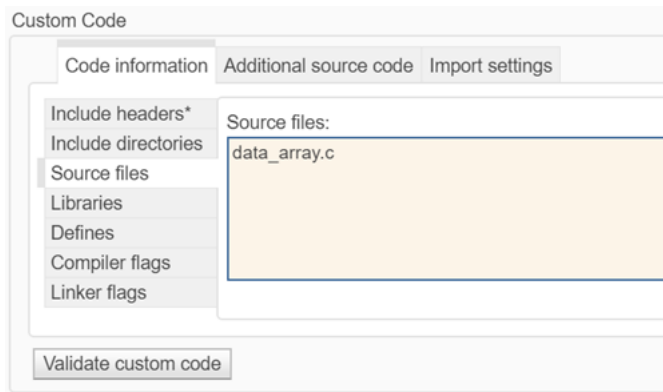

## Enter the External Code Into Simulink

- 1 Create a new, blank model and add a C Function block. The C Function block is in the **User-Defined Functions** library of the Library Browser.
- 2 Double-click the C Function block to open the block dialog. Click  to open the Model Configuration Parameters dialog. In the **Simulation Target** pane, define your header file under **Include headers** on the **Code information** tab.

**Tip** After you have entered information for **Source file** in the next step, you can click **Auto-fill from Source files** to have the header file name filled in automatically, using information contained in your source files.

- 3 Define the source file under **Source files** on the **Code Information** tab. To verify that your custom code can be parsed and built successfully, click **Validate custom code**.

**Note** To use a C Function block in a For Each subsystem or with continuous sample time, or to optimize the use of the block in conditional input branch execution, all custom code functions called by the block must be deterministic, that is, always producing the same outputs for the same inputs. Identify which custom code functions are deterministic by using the **Deterministic functions** and **Specify by function** parameters in the **Simulation target** pane. If the block references any custom code global variables, then **Deterministic functions** must set to All in order for the block to be used in a For Each subsystem, in conditional input branch execution, or with continuous sample time.

For an example showing a C Function block in a For Each subsystem, see “Use C Function Block Within For Each Subsystem” on page 47-36.

- 4 In the **Output Code** pane of the C Function block parameters dialog, write the code that the block executes during simulation. In this example, the external C function computes a sum. In the **Output Code** pane, write code that calls the `data_array.c` function to compute the sum, then computes the mean.

```
/* declare the struct dataArr */
dataArray dataArray;
/* store the length and data coming in from the input port */
dataArray.pData = &data[0];
dataArray.length = length;

/* call the function from the external code to calculate sum */
sum = data_sum(dataArr);

/* calculate the mean */
mean = sum / length;
```

You can specify code that runs at the start of a simulation and at the end of a simulation in the **Start Code** and **Terminate Code** panes.

- 5 Use the **Symbols** table to define the symbols used in the code in the block. Add or delete a symbol using the **Add** and **Delete** buttons. Define all symbols used in the **Output Code**, **Start Code**, **Initialize Conditions Code**, and **Terminate Code** panes to ensure that ports display correctly.

▼ Symbols:

Add Delete

Name	Scope	Label	Type	Size	Port
data	Input	inData	double	-1	1
length	Constant	size(data)	int32	1	-
mean	Output	mean	double	1	2
sum	Output	sum	double	1	1

In the **Symbols** table, for each symbol used in the code in the block, define the **Name**, **Scope**, **Label**, **Type**, **Size**, and **Port**, as appropriate.

Close the block parameters dialog. After filling in the data in the table, the C Function block now has one input port and two output ports with the labels specified in the table.

- 6 Add a Constant block to the Simulink canvas that will be the input to the C Function block. In the Constant block, create a random row array with 100 elements. To display the results, attach display blocks to the outputs of the C Function block.

## Specify Simulation or Code Generation Code

You can specify different **Output Code** for simulation and code generation for the C Function block by defining `MATLAB_MEX_FILE`. For example, to specify code that only runs during the model simulation, use the following.

```
#ifdef MATLAB_MEX_FILE
/* Enter simulation code */
#else
/* Enter code generation code */
#endif
```

## Specify Declaration for Target-Specific Function for Code Generation

For code generation purposes, if you do not have the external header file with the declaration of a function (such as a target-specific device driver) that you want to call from the C Function block, you can include a declaration with the correct signature in the **Output Code** pane of the block. This action creates a function call to the expected function when code is generated, as in the following example:

```
#ifndef MATLAB_MEX_FILE
extern void driverFcnCall(int16_T in, int16_T * out);
driverFcnCall(blockIn, &blockOut);
#endif
```

### More About

- “Debug Custom C/C++ Code” on page 45-2

## Interface with C++ Classes Using C Function Block

You can use code that you specify in a C Function block to interface directly with C++ classes defined in your custom code.

- Instantiate an object of a C++ class defined in your custom code.
- Read and write to public data members of the class object.
- Call public class methods (class member functions) of the object.

This example demonstrates the use of a C Function block with C++ classes.

### Create Source Code Files

Before introducing your custom code, select C++ as the custom code language. In the Model Configuration Parameters, on the **Simulation Target** pane, set **Language** to C++.

Next, create the header and source files. Create a header file named `adder.h` that defines a C++ class `adder` and its methods.

```
#ifndef _ADDER_CPP_
#define _ADDER_CPP_

class adder {
private:
    int int_state;
public:
    adder();
    adder(int init_value);
    int add_one(int increment);
    int get_val();
};

#endif /* _ADDER_CPP_ */
```

Implement the class and its methods in a source file. Create the source file, `adder.cpp`.

```
#include "adder.h"

adder::adder()
{
    int_state = 0;
}

adder::adder(int init_value)
{
    int_state = init_value;
}

int adder::add_one(int increment)
{
    int_state += increment;
    return int_state;
}
```

```
int adder::get_val()
{
    return int_state;
}
```

## Configure the C Function Block

To instantiate an object of a C++ class defined in the custom code in your model:

- 1 Add a C Function block to the model.
- 2 Double-click the C Function block to open it.
- 3 Define the header and source files:

a

Click the Configure custom code settings button  to open the Configuration Parameters window. In the **Simulation Target** pane, in the **Code information tab**, under **Include headers**, define the header file by entering `#include "adder.h"`.

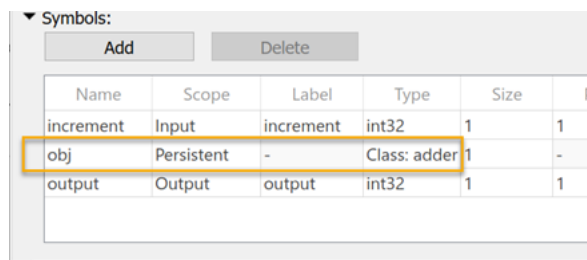

b In the **Code Information** tab, under **Source files**, define the source file by entering `adder.cpp`.

For more information, see “Enter the External Code Into Simulink” on page 47-3.

- 4 Define the class object. In the block dialog, in the **Symbols** table, click **Add** to define a symbol.
- 5 Specify the symbol properties. Set the **Scope** of the symbol to **Persistent**, set the name of the object in the **Name** column, set the symbol **Type** by using the following format:

Class: `<ClassName>`

For example, this **Symbols** table instantiates an object of the `adder` class named `obj`. The `int_state` property of `obj` is initialized with the default value of zero.

Name	Scope	Label	Type	Size	P
increment	Input	increment	int32	1	1
obj	Persistent	-	Class: adder	1	-
output	Output	output	int32	1	1

To pass arguments to the class constructor, enclose those arguments in parentheses, separated by commas, following the symbol name in the **Name** field.

`ObjectName(Argument1,Argument2,...)`

You can use literal constants as well as expressions with **Parameter** and **Constant** symbols defined in the **Symbols** table for the argument specification. Such expressions can use C syntax, including expressions like `&p` and `p[0]`, where `p` is a **Parameter** or **Constant** symbol. Overloaded class constructors are supported.

For example, this **Symbols** table instantiates an object of the `adder` class named `obj`, and initializes the `int_state` property of the object with the value of 10 by passing that value to the constructor.

▼ Symbols:

Add Delete

Name	Scope	Label	Type	Size	Port
increment	Input	increment	int32	1	1
obj(10)	Persistent	-	Class: adder	1	-
output	Output	output	int32	1	1

Simulink creates the object at the start of simulation and destroys the object when simulation ends. During simulation, the object is cached in the block as a block state like other Persistent symbols. You cannot explicitly call the class constructor or destructor from the block.

You can use the **Output Code** and other code in the block to read and write to public data members of the class object and to call public class methods of the object. Overloaded methods and operators are supported, as are static methods. Default arguments for class methods are supported if they are specified in the header file that defines the class.

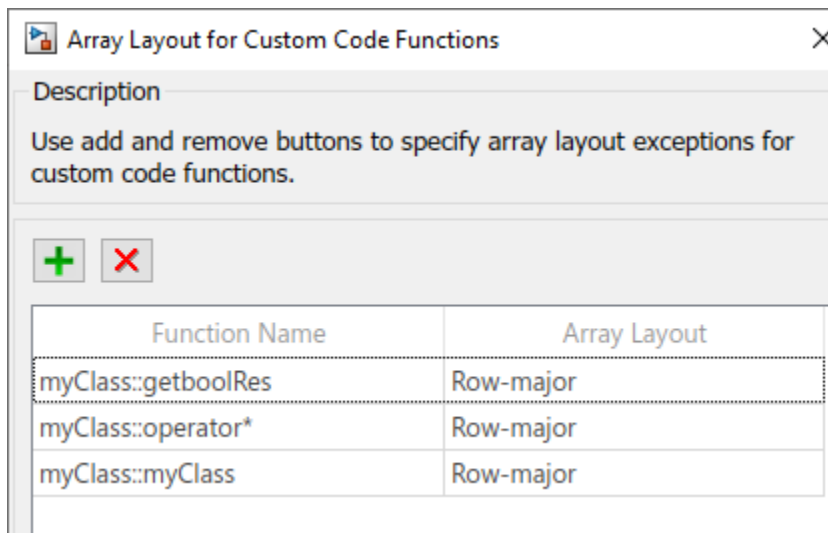

Use **Start Code** or **Initialize Conditions Code** to initialize data members and **Terminate Code** to call cleanup methods. The class object is created before the **Start Code** executes and is destroyed after the **Terminate Code** executes. To access properties and methods, use dot notation.

```
PropertyValue = ClassObjectName.PropertyName;
ReturnValue = ClassObjectName.MethodName(Arguments);
```

In the **Output Code**, the block invokes the `add_one` method of `obj`. The block passes the block input as an argument to the method and sends the return value to the block output.

If a class constructor or other class method receives multidimensional array data from Simulink or passes such data to Simulink, you must specify the correct array layout to achieve the intended results, as for any other custom code function. See “N-D Array Handling” on page 46-4. To indicate the array layout of a class method in the dialog box for **Exception by function**, for the **Function Name**, use the syntax `ClassName::MethodName`.

## Limitations

The C Function block cannot be used to directly access all C++ classes. These types of classes are not supported:

- Template classes
- Standard Template Library (STL) containers
- Classes with private constructors and destructors

In such cases, you can access C++ class data members and methods indirectly by writing and calling a C-style wrapper function. For an example, see “Call C++ Class Methods Using a C-style Wrapper Function from a C Function Block” on page 47-31.

Expressions used for constructor arguments are limited to literal constants and `Parameter` and `Constant` symbols. Such expressions may not call other functions or access global variables.

The C Function block cannot call overloaded functions that are not class methods.

These actions are not supported in the code in the C Function block:

- Copying and assigning a class object
- Passing a class object to a function or method, either by value or by reference
- Explicitly calling a class constructor or destructor
- Defining a class
- Accessing class static data members
- Accessing multidimensional data members of a class

## Modify States of a C Function Block Using Persistent Symbols

This example shows a unit delay system where a C Function block takes in a sine wave signal and delays its output by a specified sample period.

```
open_system('CFunctionPersistentExample');
```

An initial value, specified as a parameter, is cached in the block as persistent data in the **Start Code** pane.

In the **Output Code** pane, a calculation is done on this state. A new input is passed to the block as the next state at the next time step.

Output Code

```
y = state * 0.1;
state = u;
```

The **Symbols** table defines the attributes of the symbols used in the code. Note that the scope of the `initialValue` symbol is specified as `Parameter`, so its value can be changed using the block dialog. The state is defined as having `Persistent` scope. This value changes at each time step.

▼ Symbols:

Name	Scope	Label	Type	Size	Port
initialValue	Parameter	Initial Value	double	1	1
state	Persistent	-	double	1	-
u	Input	u	double	1	1
y	Output	y	double	1	1

### Blocks

C Function

## Change Values of Signals Using C Function Block and Buses

This example shows how to use buses with a C Function block. In this example two Constant blocks supply values. These signals are combined using a Bus Creator block. Code in the C Function block changes the values of these signals. Using a Bus Selector block, the values are displayed separately in two Display blocks.

```
open_system('mCFunction_BusWithoutCStruct')
```

The **Output Code** pane contains code that changes the values of the signals.

```
Output Code
out.a = data.a * 2;
out.b = data.b + 3;
```

Add the symbols used in the code to the **Symbols** table. To use buses with a C Function block, set the **Type** of the symbol to Bus: SimpleBus.

▼ Symbols:

Add Delete

Name	Scope	Label	Type	Size	Port
data	Input	data	Bus: SimpleBus	1	1
out	Output	out	Bus: SimpleBus	1	1

### Blocks

C Function

## Access Elements of a Matrix Using Output Code in a C Function Block

This example shows how to access elements of a matrix from a C Function block using the **Output Code** pane.

```
open_system('mMatrixColumnSumOutputCode')
```

Elements in each column of the input matrix are accessed and added to calculate a sum for each column.

### Output Code

```
int r, c;

for (c = 0; c < 3; c++) {
    y[c] = 0;
    for (r = 0; r < 3; r++) {
        y[c] += u[r][c];
    }
}
```

You must define all symbols used in code on the **Symbols** table of the Block Parameters. To set the size of the input matrix, specify size as [ r c ]. r corresponds to the number of rows in the input matrix and c corresponds to the number of columns in the input matrix.

▼ Symbols:

Add Delete

Name	Scope	Label	Type	Size	Port
u	Input	u	double	[3 3]	1

### Blocks

C Function

## Use External Functions with Matrix Input in a C Function Block

This example shows how to pass a matrix input to a C Function block and do row-major operations using external custom code.

```
open_system('mMatrixColumnSumExternalCode');
```

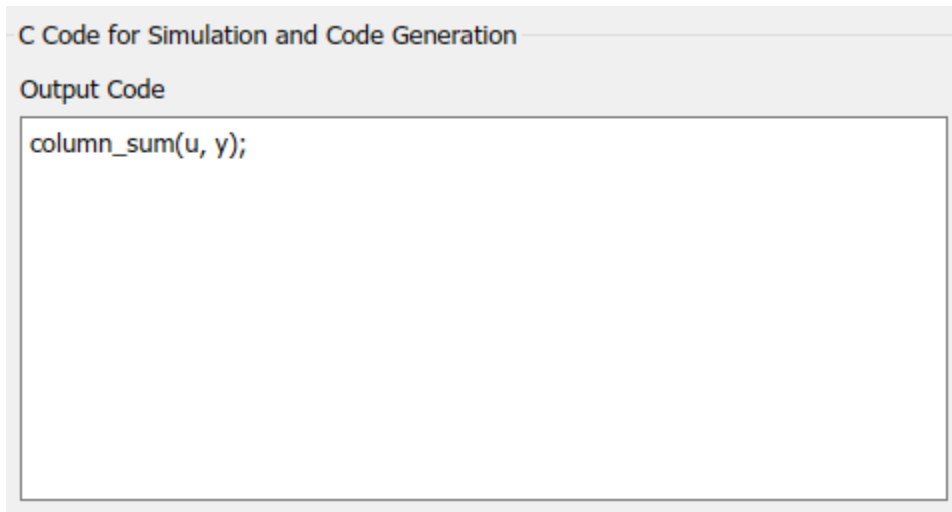

In this example, a matrix input is used by external custom code to calculate the sum of the each column of the matrix and the results are passed to the output block. The external function accesses input array `arr` as row-major using `arr[r][c]`.

```
matrixsum.c x +
#include "matrixsum.h"

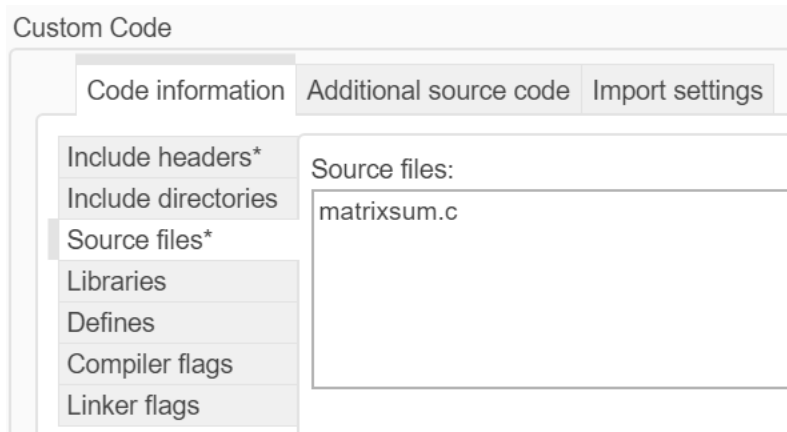

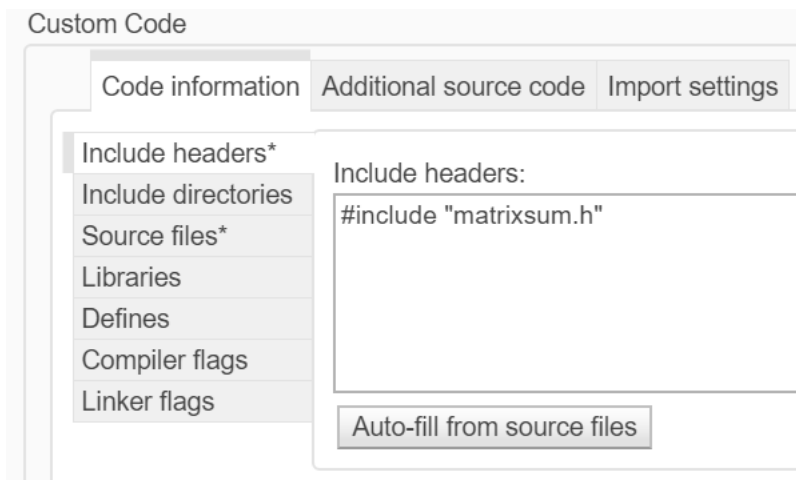

void column_sum(real_T arr[3][3], real_T sum[3])
{
    int r, c;

    for (c = 0; c < 3; c++) {
        sum[c] = 0;
        for (r = 0; r < 3; r++) {
            sum[c] += arr[r][c];
        }
    }
}
```

The custom code is called in the **Output Code** pane of the C Function block.

The external source and header files are specified on the **Configuration Parameters > Simulation Target** pane.

For the matrix input, the size of the input symbol on the matrix table is specified as  $[r \ c]$ , where  $r$  corresponds to the number of rows in the matrix input and  $c$  corresponds to the number of columns.

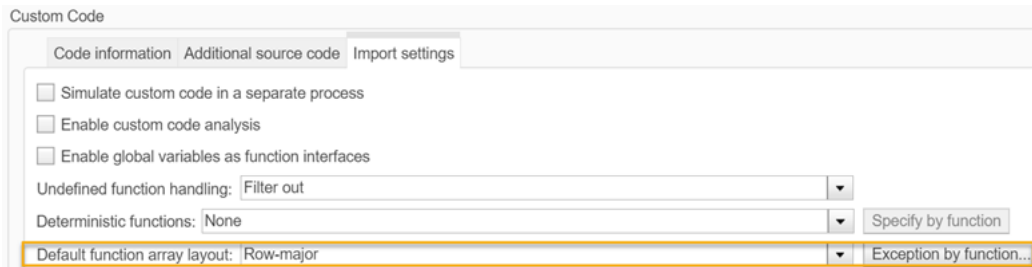

▼ Symbols:

Add Delete

Name	Scope	Label	Type	Size	Port
u	Input	u	double	[3 3]	1
y	Output	y	double	3	1

### Specify the Default Function Array Layout

The external C function accesses input array  $a \ r$  using row-major layout. To ensure the validity of calculations with MATLAB, go to **Default Function Array Layout** under **Configuration Parameters > Simulation Target** and select Row-major.

## Define an Alias Type in a C Function Block

This example shows how to specify alias data types in a C Function block. The model reads in a source and header file from the **Configuration Parameters > Simulation Target** pane. Calculations are performed using the functions in the source file.

```
Simulink.importExternalCTypes('multiply_func.h');
open_system('mCFunction_AliasType');
```

### Define an Alias type in the header file

To define an alias type in your C source code to be used in your C Function block, use the `typedef` keyword. In this example, a double alias is defined as `typedef double doubleAlias` in the `multiply_func.h` file.

### Specify the alias types in the C Function block

You must define your symbols in the **Symbols** table of the C Function block parameters. Define the symbols in the block as alias types by entering the alias type in the **Type** column of the **Symbols** table.

▼ Symbols:

Add Delete

Name	Scope	Label	Type	Size	Port
u	Input	u	doubleAlias	1	1
y	Output	y	doubleAlias	1	1

**Blocks**  
C Function

## Use Enumerated Data in a C Function Block

This example shows how to define and use enumerated data in a C Function block. In this example, a series of traffic lights are defined in an Enumerated Constant block using the Data Type Assistant. The code that controls the traffic lights is written in the **Output Code** pane of the C Function block dialog. In the **Symbols** table, the data types of the block inputs and outputs are defined as Enum: *classname*. In this example, the enumerations are defined in the class TrafficLightColor\_t, so the type is defined as Enum: TrafficLightColor\_t.

```
open_system('CFunctionEnum')
```

### Output Code to Switch Traffic Lights

#### Output Code

```
switch(u) {
  case RED:
    out = GREEN;
    break;
  case YELLOW:
    out = RED;
    break;
  case GREEN:
    out = YELLOW;
    break;
  default:
    out = UNKNOWN;
}
```

## Symbols Table to Define Enumerations

▼ Symbols:

Add Delete

Name	Scope	Label	Type	Size	Port
out	Output	out	Enum: TrafficLightColor_t	1	1
u	Input	u	Enum: TrafficLightColor_t	1	1

### Objects

SymbolSpec | Symbol

### Blocks

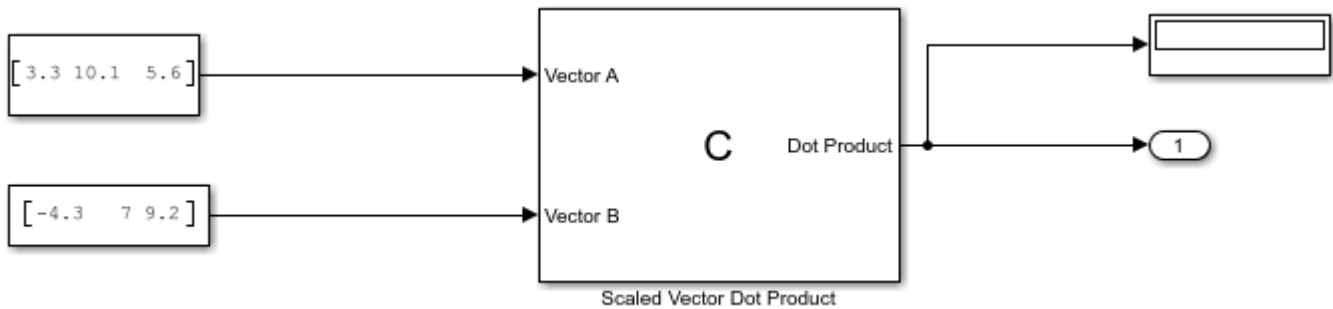

C Function

## Use Inherited Sizes in a C Function Block

This example shows how to use a C Function block to compute a scaled vector dot product from two input vectors. In this example, the C Function block takes two row vectors as inputs with inherited sizes. The block scales the data using parameters. The vector dimension, which is used to define loop indices in the C code, is defined as a constant. The block calculates the dot product, and displays the results.

```
open_system('CFunctionVectorDotProduct');
```

In the C Function Block Parameters dialog, the **Output Code** pane contains the code that performs the vector dot product calculations on the two input vectors.

```
Output Code

int i;
dotProduct = 0;
for(i = 0; i < vectorDimension; ++i){
    dotProduct = dotProduct + (scaleA*vectorA[i] * scaleB*vectorB[i]);
}
```

You must define all symbols used in the code in the **Symbols** table of the Block Parameters. To specify that the sizes of the input vectors are inherited, specify -1 in the **Size** field of the table. The symbols `scaleA` and `scaleB` are defined as parameters of the block. These parameters appear on the block parameter mask. The definitions of all symbols used in this example are shown in the following table.

Name	Scope	Label	Type	Size	Port
dotProduct	Output	Dot Product	double	1	1
scaleA	Parameter	Scale A by	double	1	1
scaleB	Parameter	Scale B by	double	1	2
vectorA	Input	Vector A	double	-1	1
vectorB	Input	Vector B	double	-1	2
vectorDim...	Constant	size(vecto...	int32	1	-

### Blocks

C Function

## Call a Legacy Lookup Table Function Using C Caller block

This example shows how to use the C Caller block to call legacy C functions that implement N-dimensional table lookups.

In this example the legacy C functions are defined in `lookupTable.h`, and implemented in `directLookupTableND.c`. The type definitions used in this example can be found in `your_types.h`.

To enable calling the C functions from the C Function block, in the model, specify the header file and the source file in the **Configuration Parameters > Simulation Target** pane. The prototype of the legacy function being called in this example is:

```
FLT directLookupTableND(const FLT *tableND, const UINT32 nbDims, const UINT32 *tableDims, const UINT32 *tableIdx)
```

where FLT is a type definition to a floating-point type, and UINT32 is a type definition to an unsigned 32-bit integer.

- `const FLT *tableND` - Table
- `const UINT32 nbDims` - Dimensionality of the table
- `const UINT32 *tableDims` - Size of the table
- `const UINT32 *tableIdx` - Table index

In the C Caller block, `tableND` and `tableDims` are mapped to C Caller block parameters, `nbDims` is a block constant, and `tableIdx` is the input to the block. The value returned by the legacy C function is the output of the block.

```
model = 'slexCCallerLookupTable';  
open_system(model);  
sim(model);  
slcc('clearCustomCodeModules');
```

This demonstration illustrates how the C Caller Block is used to call legacy functions that implement N-dimensional table lookups

Copyright 2019 The MathWorks, Inc.

## Start and Terminate Actions Within a C Function Block

This example shows how to use the C Function block to integrate legacy C functions that have start and terminate actions.

In this example, the legacy C functions are defined in `fault.h`, and implemented in `fault.c`.

To enable calling the C functions from the C Function block, in the model, specify the header file and the source file in the **Configuration Parameters > Simulation Target** pane. This model opens a log file, writes data to it, and then closes the log file. The `openLogFile` function is called in the **Start Code** section and the `closeLogFile` function is called in the **Terminate Code** section of the C Function block. In the **Output Code** section, the `incAndLogFaultCounter` function is called. The prototype of the legacy functions are:

- `void* openLogFile()`
- `closeLogFile(void* fid)`
- `incAndLogFaultCounter(void *fid, unsigned int counter, double time)`

where, `void *fid` is a file pointer, `unsigned int counter` is the fault counter, and `double time` indicates the time.

In this example the ports of the C Function block are configured as follows:

- The file pointer returned by `openLogFile` function and the fault counter are persistent symbols of the C Function block.
- The input of the C Function block is mapped to time.

```
model = 'slexCFunctionStartTerm';
open_system(model);
sim(model);
slcc('clearCustomCodeModules');
```

This demonstration illustrates how the C Function Block is used to call legacy functions that have start and terminate actions

Start Code → call `openLogFile()` → open the file 'slex\_CFunction\_fault.log' for logging faults  
 Output Code → call `incAndLogFaultCounter()` → increment the fault counter and append one line in the log file  
 Terminate Code → call `closeLogFile()` → close the logging file

**- run the model and edit the generated logging file 'slex\_CFunction\_fault.log'**

Copyright 2019 The MathWorks, Inc.

## Call C++ Class Methods Using a C-style Wrapper Function from a C Function Block

This example shows how to use the C Function block to call C++ class methods using a C-style wrapper function. For some C++ classes, such as template classes, the C Function block does not support direct instantiation of class objects or calling of class methods, so it is necessary to use C wrapper functions. See “Interface with C++ Classes Using C Function Block” on page 47-7. For an example of a C Function block accessing C++ class members and methods directly, see “Call C++ Class Methods Directly from a C Function Block” on page 47-33.

In this example, the C-style wrapper functions are declared in `adder_wrapper.h` and implemented in `adder_wrapper.cpp`.

To run this example model, you must configure MATLAB® to use a C++ compiler. This can be done using the `mex -setup` command, and selecting a C++ compiler.

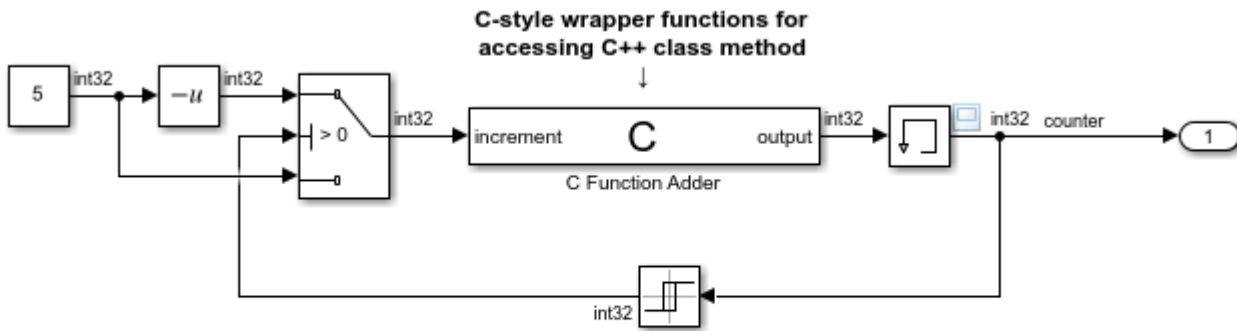

To enable calling of the C functions from the C Function block, in the model, specify the header file and the source file in the **Simulation Target** pane of the Model Configuration Parameters dialog. In this model the custom code header file `adder_template.h` defines an `adder` class template along with the class member functions. The header file `adder_wrapper.h` contains declarations of C-style wrapper functions which are called in the C Function block. The prototypes of the C-style wrapper functions are:

- `void *createAdder()`
- `void deleteAdder(void *obj)`
- `int adderOutput(void *obj, int increment)`

where `void *obj` is the class object handle and `increment` is an input used by the `adder` function.

The `createAdder` function is called in the **Start Code** section of the C Function block dialog to construct an object of the `adder` class. The `deleteAdder` function is called in the **Terminate Code** section to destruct the `adder` class object. In the **Output Code** section, the `adderOutput` function is called. In this example the ports of the C Function block are configured as follows:

- The `adder` class object, `obj`, return by the `createAdder` function, is a Persistent symbol of the C Function block.
- The input of the C Function block is mapped to `increment`.
- The output of the C Function block is mapped to the return value of the `adderOutput` function.

**NOTE:**

For this demo to run you must go to the MATLAB command prompt and enter: `>> mex -setup` then select a C++ compiler.

C Function

## Call C++ Class Methods Directly from a C Function Block

This example shows how to use the C Function block to call C++ class methods. In this example, a C++ class and its methods are defined in `adder_cpp.h` and implemented in `adder_cpp.cpp`.

To run this example model, you must configure MATLAB® to use a C++ compiler. This can be done using the `mex -setup C++` command, and selecting a C++ compiler.

To enable access to the C++ class from the C Function block, in the model, specify the header file and the source file in the **Configuration Parameters > Simulation Target** pane. In this model, the custom code header file `adder_cpp.h` declares an `adder` class along with the class methods.

In the **Output Code** section, the class method is called. In this example, the ports of the C Function block are configured as follows:

- The `adder` class object `adderObj` is a persistent symbol of the C Function block, which instantiates the class object for use in the block. The object is destroyed at the end of simulation.
- The input of the C Function block is mapped to `increment`, which is an input argument to the class method `add_one`.
- The output of the C Function block is mapped to `output`, which receives the return value of the class method `add_one`.

### NOTE:

For this demo to run you must go to the MATLAB command prompt and enter: `>> mex -setup C++` then select a C++ compiler.

## Call Legacy Lookup Table Functions Using C Function Block

This example shows how to use the C Function block to call legacy C functions that implement n-dimensional table lookups.

In this example the legacy C functions are defined in `lookupTable.h`, and implemented in `directLookupTableND.c`. The type definitions used in this example can be found in `your_types.h`.

In the model, the header file and the source file are specified in **Model Configuration Parameters > Simulation Target**. Now the C function can be called in the C Function block. The prototype of the function being called in this example is:

```
FLT directLookupTableND(const FLT *tableND, const UINT32 nbDims, const UINT32 *tableDims, const UINT32 *tableIdx)
```

where `FLT` is a type definition to a floating-point type, and `UINT32` is a type definition to an unsigned 32-bit integer.

This example defines two macro functions that use the function `directLookupTableND`, which are called using the C Function blocks. They are:

- `DirectLookupTable3D` - 3D lookup table
- `DirectLookupTable4D` - 4D lookup table

Both these functions take the following input arguments:

- `const FLT *tableND` - Table
- `const UINT32 *tableDims` - Size of the table
- `const UINT32 *tableIdx` - Table index

where the `tableND` and `tableDims` are mapped to C Function block parameters and `tableIdx` is the input to the block. The value returned by the legacy C function is the output of the block.

```
model = 'slexCFunctionLookupTable';  
open_system(model);  
evalc('sim(model)');  
slcc('clearCustomCodeModules');
```

This demonstration illustrates how the C Function block is used to call legacy functions that implement N-dimensional table lookups

Copyright 2020 The MathWorks, Inc.

## Use C Function Block Within For Each Subsystem

This example shows how to use a C Function block within a For Each subsystem. The example passes a vector signal into the For Each subsystem, which repeats execution of the C Function block on each element of the input signal and concatenates the results. The C Function block calls the custom code function `customSaturateFcn()`, which implements a saturation algorithm and outputs a clipped version of the input signal. A C Caller block with the same settings can also be used in place of a C Function block in a For Each subsystem.

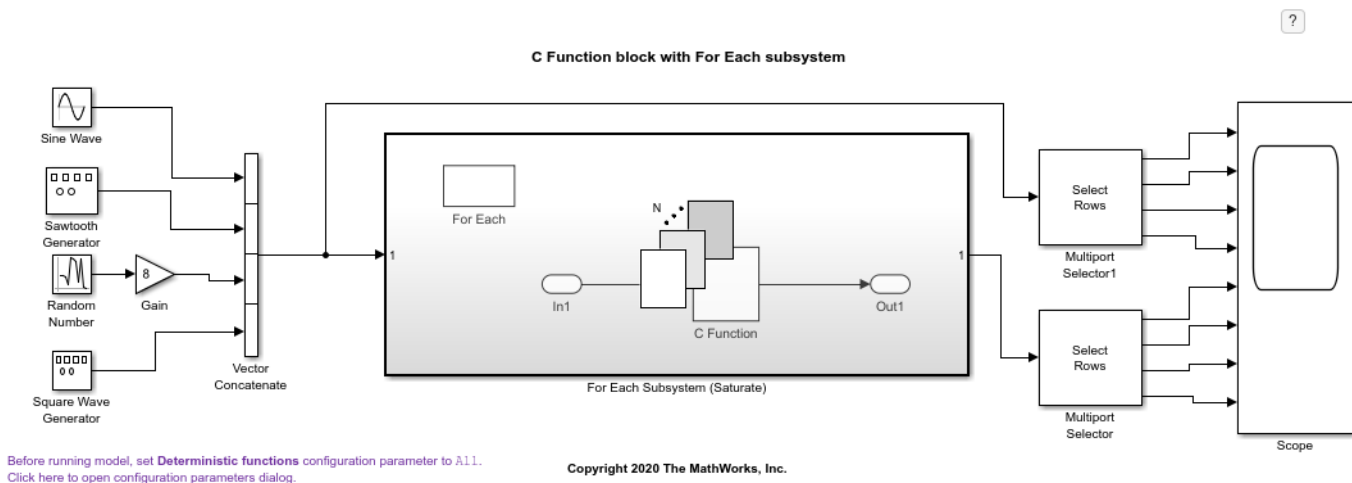

This example illustrates the following concepts:

- Calling a C function from a Simulink® block inside a For Each subsystem.
- Configuring deterministic functions in custom code.

### Examine the Model

This model calls custom code from a For Each subsystem. When the model runs, the scope displays the output.

```
open_system('slexCFunctionForEach');
```

### Identify Custom Code Deterministic Functions

Open the Configuration Parameters dialog box.

In the **Simulation Target** pane, set the value of **Deterministic functions** to All. This setting tells the model that all custom code functions have deterministic behavior, that is, the same input values to the function always give the same outputs. If a custom code function is specified as deterministic, it can be safely called from a C Function or C Caller block inside a For Each subsystem. If not all custom code functions are deterministic, specific functions can be set to be deterministic with the **By Function** option. If a For Each subsystem contains a C Function or C Caller block that calls a custom code function that is not specified as deterministic, Simulink produces an error.

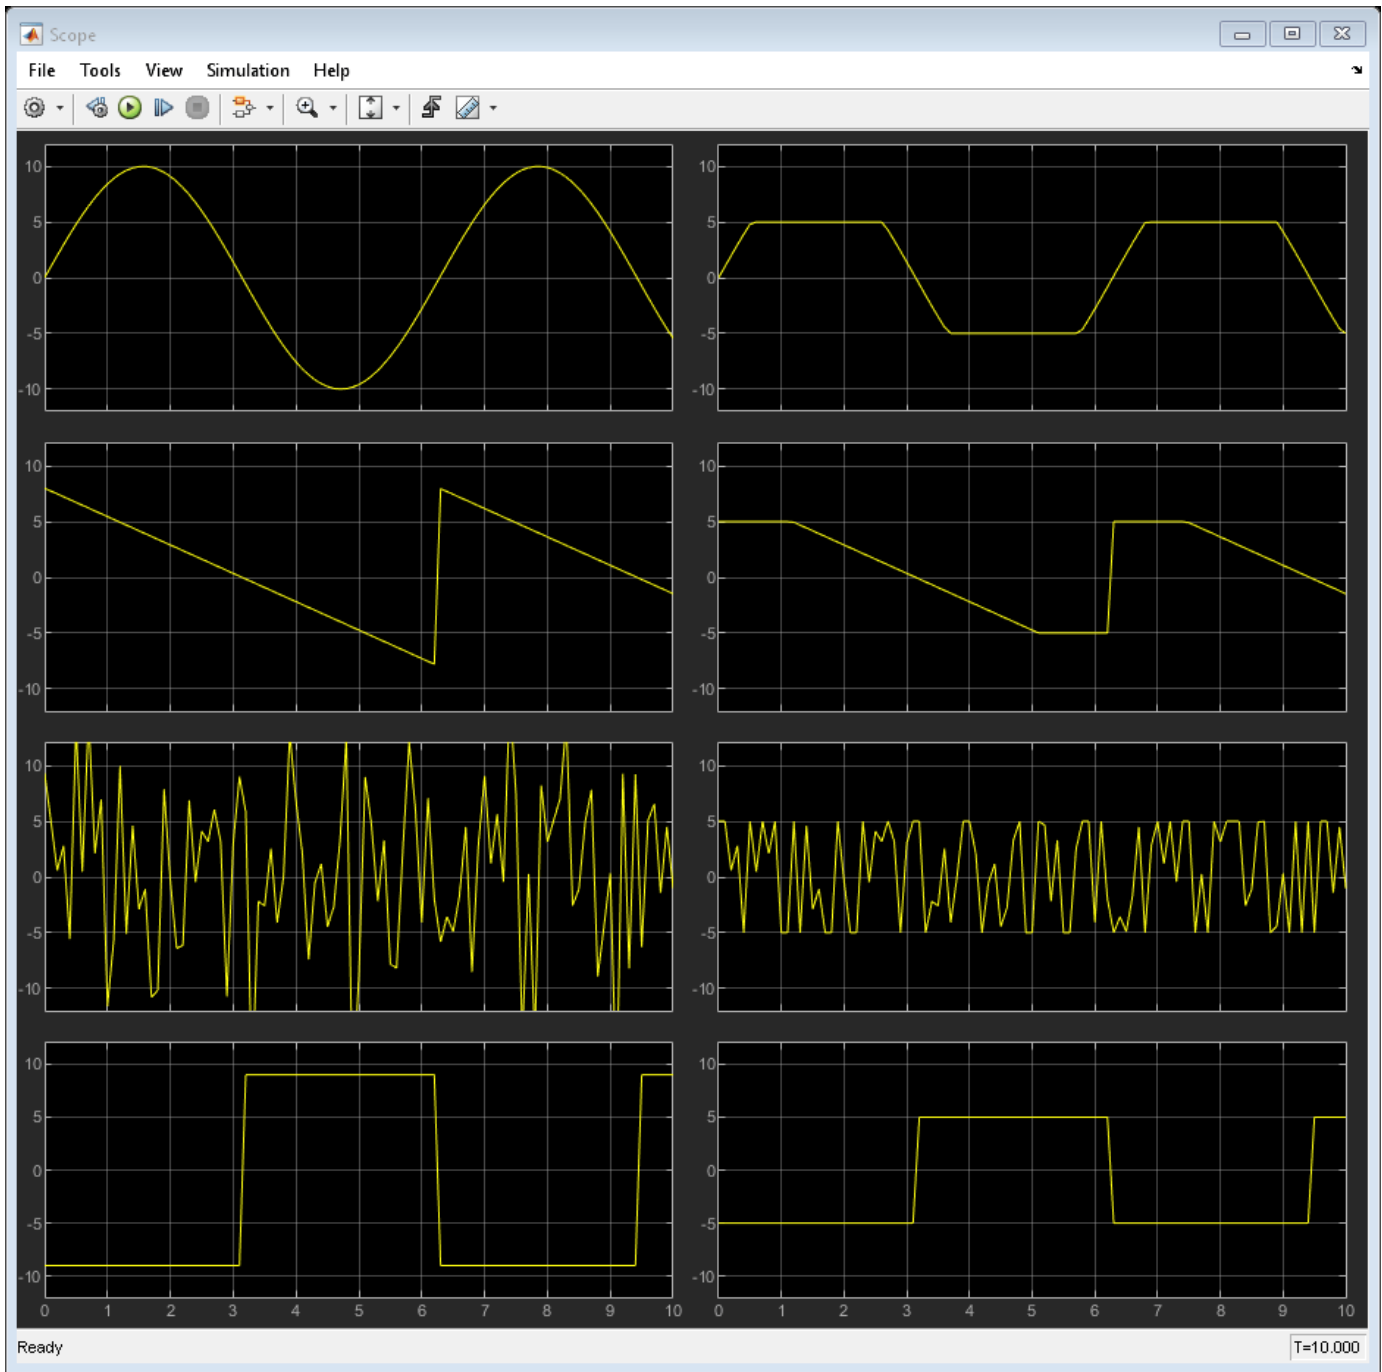

```
configset.highlightParameter(bdroot,'DefaultCustomCodeDeterministicFunctions');  
set_param(bdroot,'DefaultCustomCodeDeterministicFunctions','All');
```

### Simulate the Model

Simulate the model and view the results.

```
sim(bdroot);  
open_system('slexCFunctionForEach/Scope');
```

# Simulink Code Importer

---

## Import Custom Code Using the Simulink Code Importer Wizard

This example uses C code for a heat pump controller to show how to use the Simulink® Code Importer wizard to import custom C/C++ code into a Simulink library. The example also shows how to perform the equivalent actions using the Simulink Code Importer command-line interface in MATLAB®. For more information, see “Import Custom C/C++ Code Using the Simulink Code Importer”.

### Heat Pump Controller Custom Code

These C code source and header files contain the complete code for the heat pump controller.

The source files are in the `src` directory:

- `tempController.c`
- `utils.c`

The header files are in the `include` directory:

- `tempController.h`
- `utils.h`
- `controllerTypes.h`

The file `tempController.c` contains the algorithm for the custom C code for a heat pump unit. The `Controller` function in that file uses the room temperature (`Troom_in`) and the set temperature (`Tset`) as inputs. The output is a `pump_control_bus` type structure with signals that control the fan, the heat pump, and the direction of the heat pump (heat or cool). The `pump_control_bus` structure has these fields: `fan_cmd`, `pump_cmd`, and `pump_dir`. The `pump_control_bus` structure type is defined in the file `controllerTypes.h`.

This table summarizes the output of the `Controller` algorithm.

Temperature Condition	System State	Fan Command	Pump Command
$ T_{room\_in} - T_{set}  < \Delta T_{fan}$	Idle	0	0
$\Delta T_{fan} \leq  T_{room\_in} - T_{set}  < \Delta T_{pump}$	Fan only	1	0
$ T_{room\_in} - T_{set}  \geq \Delta T_{pump}$ and $T_{set} < T_{room\_in}$	Cooling	1	1
$ T_{room\_in} - T_{set}  \geq \Delta T_{pump}$ and $T_{set} > T_{room\_in}$	Heating	1	1

The `Controller` function uses two utility functions, `absoluteTempDifference` and `pumpDirection`, which are defined in the `utils.c` file. The `absoluteTempDifference` function returns the absolute difference between `Tset` and `Troom_in` as a double. The `pumpDirection` function returns one of these `PumpDirection` type enum values.

Temperature Condition	Pump Direction
$T_{set} < T_{room\_in}$	COOLING
$T_{set} > T_{room\_in}$	HEATING

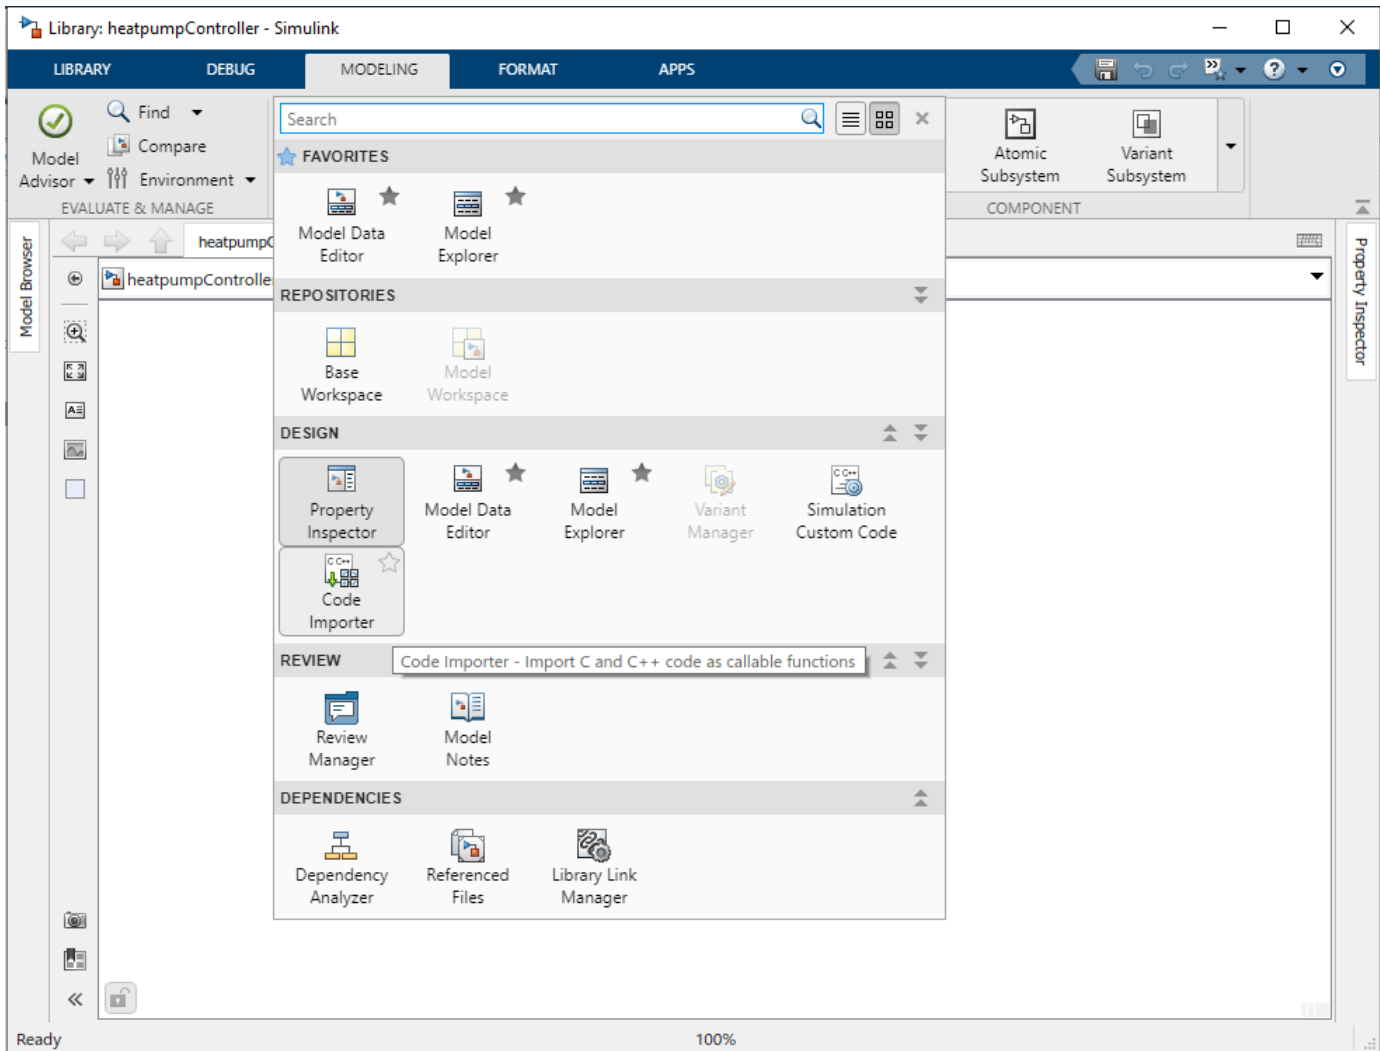

The `PumpDirection` enum type is defined in the file `controllerTypes.h`.

## Open the Code Importer Wizard

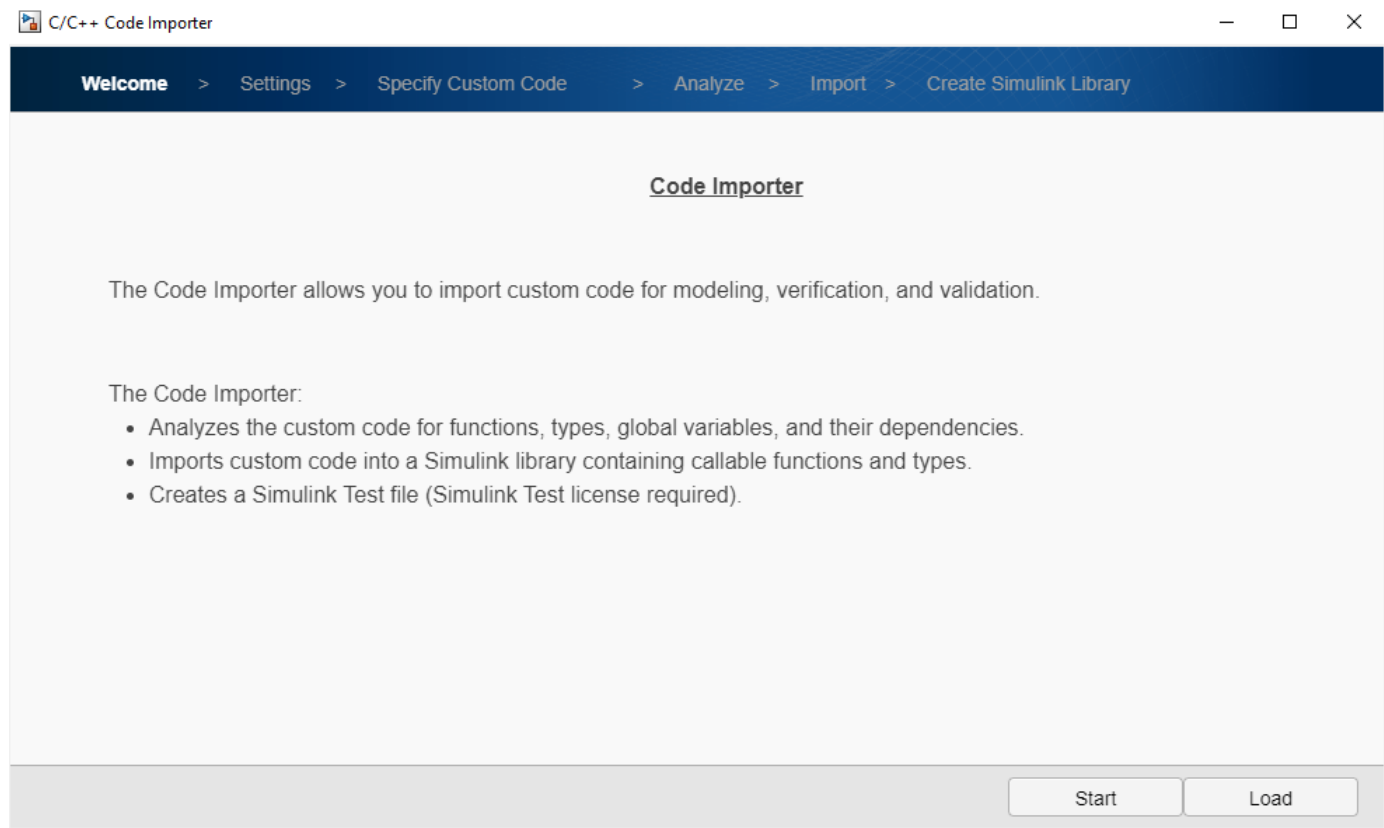

To open the Code Importer wizard, create an empty Simulink library where the `src` and `include` folders are located and save it. For this example, the library is saved as `heatpumpController`.

Then, on the **Modeling** tab, select **Design > Code Importer**.

## Specify the Simulink Library

Once the **Welcome** page loads, click **Start** to begin the import process.

On the **Settings** page:

- 1 The **Simulink library file name** is auto-populated with the saved library name, in this case, `heatpumpController`.
- 2 The **Output folder** is auto-populated with location of the saved Simulink library.

Optionally, select **Add generated library to the Simulink Library Browser** to create an `slblocks.m` file.

The `slblocks.m` file is used to add the generated library into the Simulink library browser. For more information, see “Add Library to Library Browser” on page 44-8.

Click **Next** to continue.

Note: The following MATLAB code is equivalent to this step.

```
obj = Simulink.CodeImporter('heatpumpController');
obj.LibraryFileName = 'heatpumpController';
obj.OutputFolder = '$pwd$'; %This evaluates to the pwd
```

### Specify the Custom Code to Import

On the **Specify Custom Code** page:

- 1 For **Language**, select C.
- 2 For **Interface headers**, specify the required header files. For this example, specify tempController.h.
- 3 For **Source files**, specify the required source files. For this example, specify the tempController.c and utils.c files location in the src folder as .\src\tempController.c; .\src\utils.c.
- 4 For **Include directories**, specify the required include directories. For this example, specify .\include.

Then, click **Next**.

Click **Next** on the **Analyze** page.

Note: The following code is equivalent to this step.

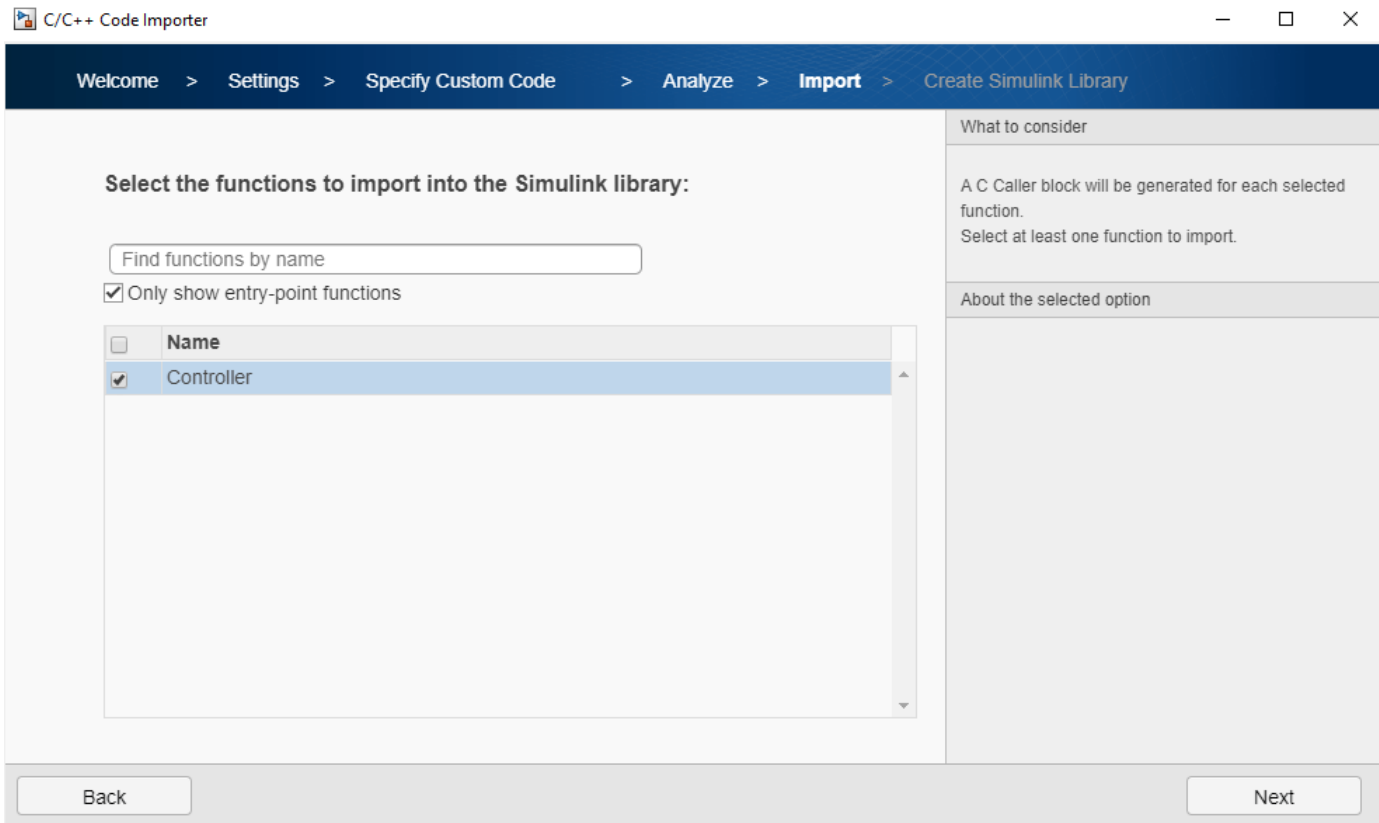

```
% The src and include directories should be located in pwd
obj.CustomCode.InterfaceHeaders = 'tempController.h';
obj.CustomCode.Language = 'C';
obj.CustomCode.SourceFiles = {'.\src\tempController.c', '.\src\utils.c'};
obj.CustomCode.IncludePaths = '.\include';
```

```
% Analyze the specified custom code
obj.parse();
```

### Specify Import Settings

#### Specify Functions to Import

On the **Import** page, select the functions to import into the Simulink library. For this example, select Controller. Then, click **Next**.

### Set the Block Port Specifications

For each function selected on the previous page, the wizard generates a function port specification. The selected ports are used for the generated C Caller block.

In this example, the port specification table lists the formal arguments `Tset`, `Troom_in`, and `out` for the `Controller` function.

Change the label of the `out` argument to `control_out`. Click **Next**.

Note: The following code is equivalent to this step.

```
% Requires a successful obj.parse() to get the function objects
fcnObj = obj.ParseInfo.getFunctions();

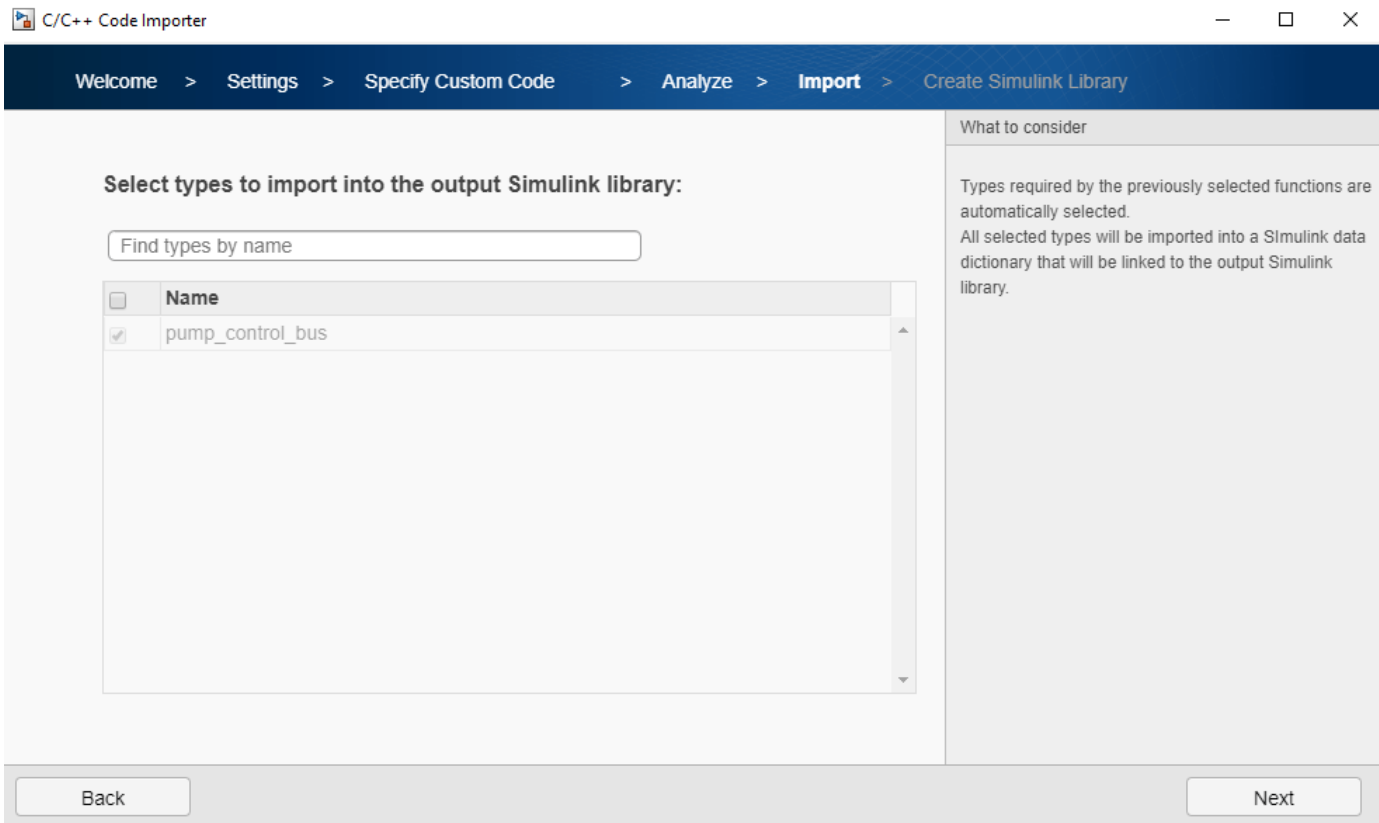

%fcnObj =
%
% Function with properties:
%
%         Name: "Controller"
%       CPrototype: "pump_control_bus Controller(real_T Tset, real_T Troom_in);"
% PortSpecification: [1x1 Simulink.CodeImporter.SimulinkPortSpecification]
%         IsEntry: 1
%         IsDefined: 1
%         IsStub: 0
%       ArrayLayout: NotSpecified
%       IsDeterministic: 0

fcnObj.PortSpecification.ReturnArgument.Label = 'control_out';
```

## Specify Types to Import

Next, select the types to import into Simulink. If a type is required by the functions you selected for import, it is selected and dimmed. For this example, `pump_control_bus` is required. The wizard creates a Simulink data dictionary containing this type and links the dictionary to the generated library.

Click **Next**.

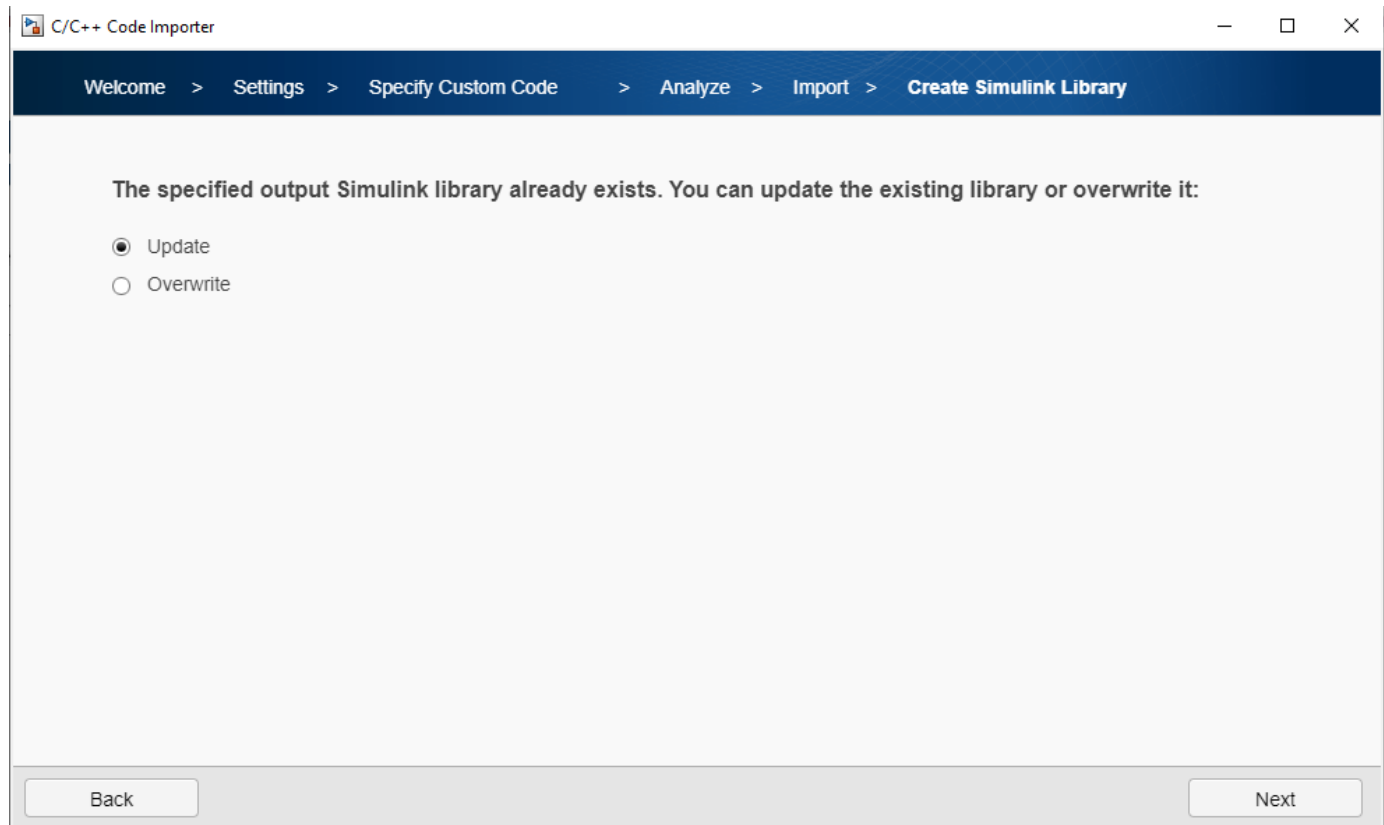

## Specify Library Update Setting

Since this example uses a saved Simulink library, this page allows you to confirm the update operation to be performed on the library.

- 1 Select **Overwrite** to remove any existing blocks and create new C Caller blocks for the selected custom code functions.
- 2 Select **Update** to preserve existing blocks and add new C Caller blocks for the selected custom code functions.

For this example, select **Update**, then click **Next**.

### Create Test Harness

This option is available only if you have a Simulink Test™ license.

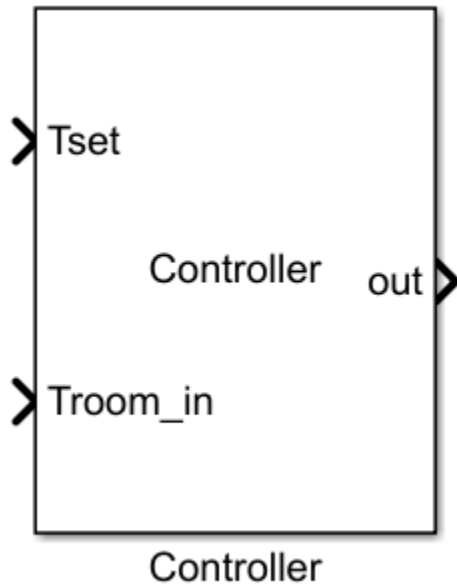

To test the imported custom code function using Simulink Test Manager, select **Automatically create test harness for all imported functions**. Each block in the created library will be attached to an internal test harness.

For this example, select **Skip**. Click **Next** to generate the Simulink library.

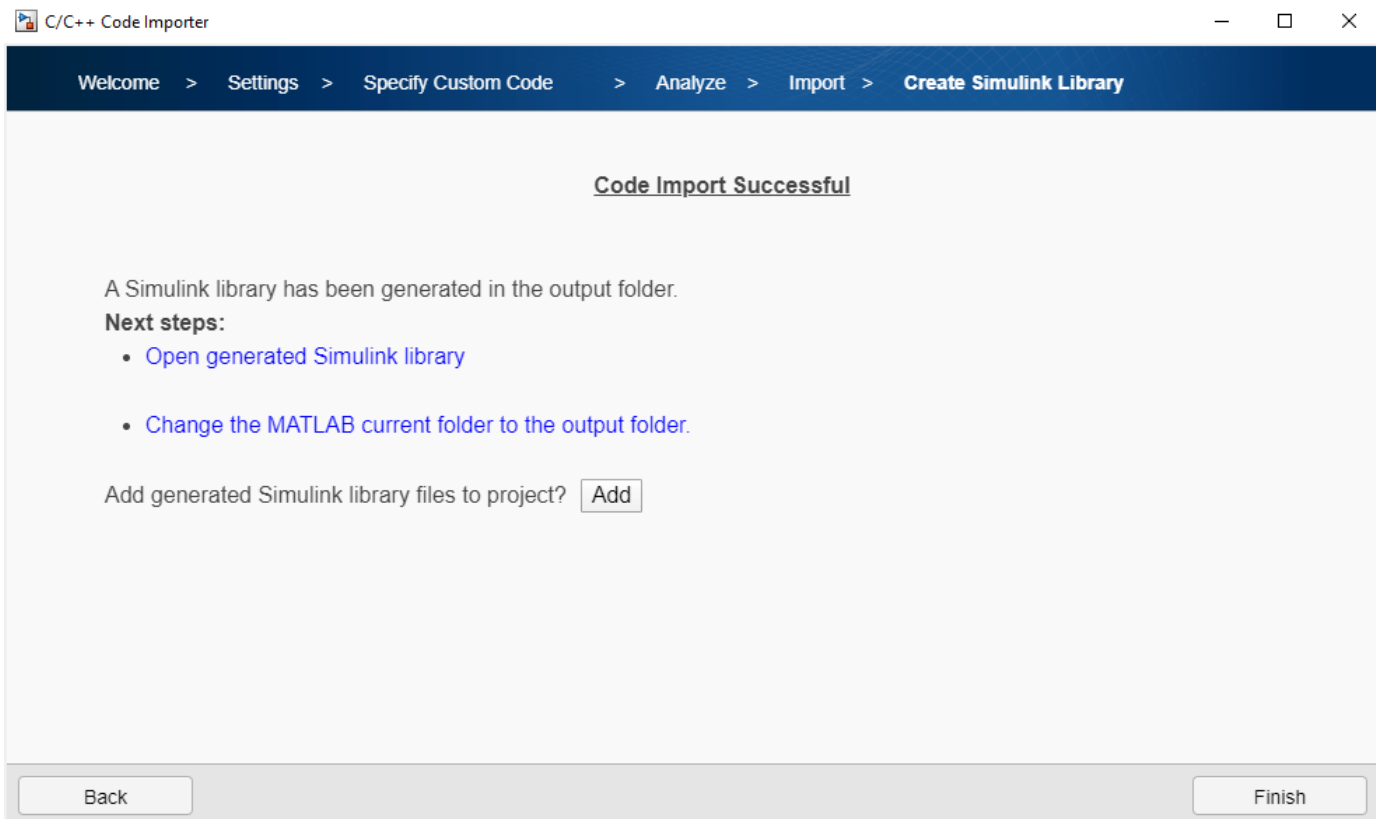

After the code imports, the wizard creates a library attached to a Simulink data dictionary that defines `pump_control_bus` as a `Simulink.Bus` object.

Note: The following code is equivalent to this step.

```
% Requires Simulink Test license to generate the test harness
obj.Options.CreateTestHarness = true;
obj.import('Functions', 'Controller', ...
          'Types', 'pump_control_bus', ...
          'Overwrite', 'off');
```

If you have an existing project file (PRJ file), you can select **Add**, select the desired project file, and add the generated file to that project.

Click **Finish** to close the wizard.

When you click **Finish**, select whether to save the current import settings to a JSON file. You can use this file to load the Code Importer wizard with the current import settings.

## Implement MATLAB Functions in Simulink with MATLAB Function Blocks

MATLAB Function blocks enable you to define custom functions in Simulink models by using the MATLAB language. MATLAB Function blocks support C/C++ code generation from Simulink Coder and Embedded Coder.

Use these blocks when:

- You have an existing MATLAB function that models custom functionality, or it is easy for you to create such a function.
- Your model requires custom functionality that is not or cannot be captured in the Simulink graphical language.
- You find it easier to model custom functionality by using a MATLAB function than by using a Simulink block diagram.
- The custom functionality that you want to model does not include continuous or discrete dynamic states. To model dynamic states, use S-functions. See “Create and Configure MATLAB S-Functions”.

### Calculate Mean and Standard Deviation with a MATLAB Function Block

This example starts with a model that includes a MATLAB Function block and guides you through how to customize the block to calculate the mean and standard deviation for a vector of values.

#### Open the Model

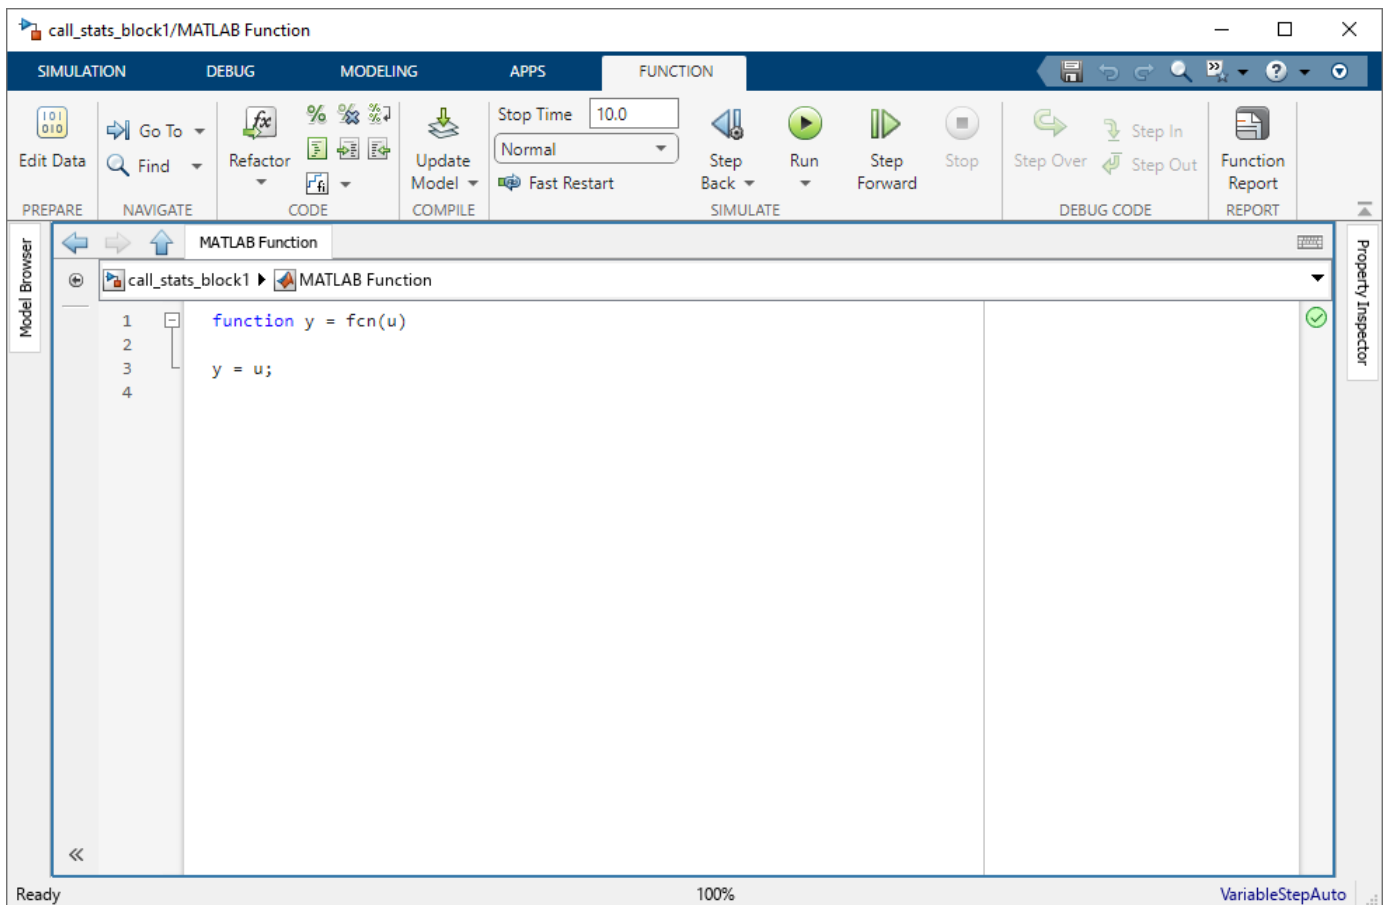

The model `call_stats_block1` includes an empty MATLAB Function block and the blocks you need for the example. Open the model.

#### Program the MATLAB Function Block

Program the block to calculate the mean and standard deviation for a vector of values.

- 1 To open the **MATLAB Function Block Editor**, double-click the MATLAB Function block. A default function appears in the **MATLAB Function Block Editor** with two variables: one input and one output argument.

- 2 Define the function inputs and outputs by editing the function declaration statement:

```
function [mean, stdev] = stats(vals)
```

This statement defines a function called `stats` with three variables. The statement defines an input argument, `vals`, and two output arguments, `mean` and `stdev`.

- 3 On a new line after the function declaration statement, add the following code:

```
% Calculates a statistical mean and a standard
% deviation for the values in vals.

len = length(vals);
mean = avg(vals, len);
stdev = sqrt(sum(((vals-avg(vals, len)).^2))/len);
plot(vals, "-+");
```

```
function mean = avg(array, size)
mean = sum(array)/size;
```

- 4 Exit the block. The block updates the port names. The function outputs `mean` and `stdev` correspond to block output ports **mean** and **stdev** and the function input `vals` corresponds to the block input port **vals**.
- 5 Complete the connections to the MATLAB Function block as shown.

- 6 Save the model as `call_stats_block2`.

## Check Properties for MATLAB Function Block Variables

You can check and manage properties for variables in MATLAB Function blocks. See “Create and Define MATLAB Function Block Variables” on page 49-31. In this example, verify that the input argument `vals` inherits its type and size properties:

- 1 Double-click the MATLAB Function block.
- 2 Open the **Symbols** pane and the Property Inspector. In the **Function** tab, click **Edit Data**.

The **Symbols** pane displays the variable names in the **Name** column. The **Type** column determines the function argument port assignment and where it appears in the function declaration statement. In this example, `vals` is assigned to an input port. `mean` and `stdev` are assigned to output ports. If you change the **Type** entry for either variable, the function declaration statement also changes.

- 3 Check the properties for `vals`. In the **Symbols** pane, click the row for `vals`. The Property Inspector updates to show the properties for `vals`. The **Scope** property matches the **Type** column.

Only some properties can be inherited: **Size**, **Unit**, **Complexity**, and **Type**. Variables indicate that they inherit these properties when **Size** is `-1`, **Unit** is `inherit`, **Complexity** is `Inherited`, and **Type** is `Inherit`: `Same as Simulink`. In this example, `vals` uses these values for **Size** and **Type**.

Check the other MATLAB Function block variables by selecting them in the **Symbols** pane.

By default, newly defined input and output variables inherit their size, unit, complexity, and type. If you want the variables to use a specific size, unit, or type, you can specify these properties explicitly. For example, enter `[2 3]` in the **Size** property to specify the variable as a 2-by-3 matrix. For more information, see “Define and Modify Variable Data Types” on page 49-44 and “Specify Size of MATLAB Function Block Variables” on page 49-52.

## Build the Function

After you enter code in a MATLAB Function block, you can check the code for errors and build the function. See “Debug MATLAB Function Blocks” on page 49-14.

When you build a model, MATLAB uses a compiler to compile your MATLAB function block code. If you have multiple MATLAB-supported compilers installed on your system, you can change the default compiler using the `mex -setup` command. See “Change Default Compiler”. To see a list of supported

compilers, open Supported and Compatible Compilers, click the tab that corresponds to your operating system, find the **Simulink Product Family** table, and go to the **For Model Referencing, Accelerator mode, Rapid Accelerator mode, and MATLAB Function blocks** column.

In Simulink, click **Run** to simulate the model. The software builds the MATLAB Function block when it builds the model and outputs the data from the function to the two Display blocks.

## Prepare the Block for Code Generation

To generate standalone C/C++ code from a model that contains MATLAB Function blocks, use Simulink Coder or Embedded Coder.

### Select a Supported Compiler for Simulation and Code Generation Builds

To see a list of supported compilers, open Supported and Compatible Compilers, click the tab that corresponds to your operating system, find the **Simulink Product Family** table, and go to the **Simulink Coder** column.

### Generate Code for the MATLAB Function Block

If you have a license for Simulink Coder or Embedded Coder, you can generate code from the model. To generate code:

- 1 In the `call_stats_block2` model, double-click the MATLAB Function block.
- 2 Open the Simulink Coder or Embedded Coder app.
- 3 On the **C Code** tab, **Build** to compile and build the example model.

If you get an error related to the `Variable-step` solver, open the Configuration Parameters window, then click **Solver** in the left pane. Under **Solver selection**, set **Type** to `Fixed-step` and generate code again. To learn more about the differences between fixed-step and variable-step solvers, see “Fixed-Step Versus Variable-Step Solvers” on page 3-6.

- “Configure MATLAB Function Blocks Programmatically” on page 49-7

## External Websites

- Mass-Spring-Damper Systems (MathWorks Teaching Resources)

## Configure MATLAB Function Blocks Programmatically

### In this section...

“Call MATLAB Function Objects” on page 49-7  
 “Programmatically Configure Block Properties” on page 49-7  
 “Access Block Inputs, Outputs, and Properties” on page 49-7  
 “Programmatically Access MATLAB Function Reports” on page 49-8

You can programmatically adjust and inspect the properties of MATLAB Function blocks. You can also access the content in MATLAB function reports programmatically.

### Call MATLAB Function Objects

After adding a MATLAB Function block to your model, you can use these objects to configure the block:

- Use a `MATLABFunctionConfiguration` object to query and modify the properties of the block. Identify the block by using a block path or calling the `gcb` function.
- Use a `Stateflow.EMChart` object to access the inputs, outputs, and properties of the block. Identify the block by navigating the hierarchy of Stateflow API objects.

### Programmatically Configure Block Properties

Consider the model `call_stats_block2` in “Implement MATLAB Functions in Simulink with MATLAB Function Blocks” on page 49-3. You can access the `MATLABFunctionConfiguration` object for the MATLAB Function block in this model by calling the `get_param` function:

```
config = get_param("call_stats_block2/MATLAB Function", ...
    "MATLABFunctionConfiguration");
```

To query or modify the properties, use dot notation with your object name:

```
config.UpdateMethod
```

```
ans =
```

```
    'Inherited'
```

```
config.Description = "Calculate the mean and standard deviation for a vector of values.";
```

To see a list of the properties you can modify, see `MATLABFunctionConfiguration`.

### Access Block Inputs, Outputs, and Properties

To modify the inputs, outputs, and properties of the MATLAB Function block, access its `Stateflow.EMChart` object by calling the `find` function for the `Simulink.BlockDiagram` object of the current system.

```
bd = get_param(gcs, "Object");
block = find(bd, "-isa", "Stateflow.EMChart", ...
    Path="call_stats_block2/MATLAB Function");
```

To query or modify the properties, use dot notation with your object name:

```
block.ChartUpdate
```

```
ans =
```

```
'INHERITED'
```

```
block.Description = "Calculate the mean and standard deviation for a vector of values.";
```

The `Stateflow.EMChart` object gives you access to additional properties that are not available in the `MATLABFunctionConfiguration` object. For example, to create a table of the block inputs and outputs, enter:

```
info = get([block.Inputs;block.Outputs],{"Name","Scope","Port"});
T = table(info(:,2),cell2mat(info(:,3)), ...
    VariableNames = ["Scope","Port"], ...
    RowNames = info(:,1));
T.Scope = categorical(T.Scope)
```

```
T =
```

```
3x2 table
```

	Scope	Port
<b>vals</b>	Input	1
<b>mean</b>	Output	1
<b>stdev</b>	Output	2

## Programmatically Access MATLAB Function Reports

You can access MATLAB function reports by calling these functions on `MATLABFunctionConfiguration` objects:

- `openReport` opens the MATLAB function report for the block.
- `closeReport` closes the MATLAB function report for the block.
- `getReport` returns a `MATLABFunctionReport` object for the block. You can query report information from this object by accessing its `Functions` property, which is an array of `coder.Function` objects. See `coder.Function` Properties (MATLAB Coder).

For example, to create a custom report that lists the functions and variables in the MATLAB Function block in the `call_stats_block2` model, follow these steps:

- 1 Access the `MATLABFunctionConfiguration` object for the MATLAB Function block.

```
config = get_param("call_stats_block2/MATLAB Function", ...
    "MATLABFunctionConfiguration");
```

- 2 Create a `MATLABFunctionReport` object for the MATLAB Function block.

```
report = getReport(config);
```

- 3 Access the `coder.Function` objects in the report.

```
functions = report.Functions;
```

**4** Create a custom report.

```

for i = 1:numel(functions)
    fprintf("Function %s uses these variables:\n", functions(i).Name)
    variables = functions(i).Variables;
    for j = 1:numel(variables)
        fprintf("%d. %s -- %s\n", j, variables(j).Name, variables(j).Scope)
    end
    fprintf("\n")
end

```

```
Function stats uses these variables:
```

```

1. mean -- Output
2. stdev -- Output
3. vals -- Input
4. len -- Local

```

```
Function avg uses these variables:
```

```

1. mean -- Output
2. array -- Input
3. size -- Input

```

---

**Note** The `MATLABFunctionReport` object does not contain information about errors and warnings. To find errors and warnings in a MATLAB Function block, open the report or use the debugger in the **MATLAB Function Block Editor**. For more information, see “Debug MATLAB Function Blocks” on page 49-14.

## Code Generation Readiness Tool

The code generation readiness tool screens MATLAB code for features and functions that code generation does not support. The tool provides a report that lists the source files that contain unsupported features and functions. It is possible that the tool does not detect all code generation issues. Under certain circumstances, it is possible that the tool can report false errors. Therefore, before you generate code, verify that your code is suitable for code generation by generating a MEX function.

The code generation readiness tool does not report functions that the code generator automatically treats as extrinsic. Examples of such functions are `plot`, `disp`, and `figure`.

### Issues Tab

The screenshot displays the Code Generation Readiness Tool interface. At the top, a warning icon is followed by the text "2 Code generation readiness issues - Code might require changes". Below this, it indicates "2 Unsupported functions" and "2 Files analyzed". On the right, there is a dropdown menu for "Language C/C++ (MATLAB Coder)" and links for "Refresh" and "Edit".

The main area is divided into "Issues" and "Files" tabs. Under the "Issues" tab, two issues are listed:

- Unsupported function: `hascycles` (1)
- Unsupported function: `isdag` (1)

Below the list, a detailed view of the "Unsupported function: `hascycles`" is shown. At the bottom, a code editor window for "foo2.m" displays the following code:

```

1 function [tf1,tf2] = foo2(source,target)
2   G = digraph(source,target);
3   tf1 = hascycles(G);
4   tf2 = isdag(G);
5   end
6

```

Red squiggly lines under the function names `hascycles` and `isdag` indicate the tool's detection of unsupported functions. A red exclamation mark icon is visible in the right margin of the code editor.

On the **Issues** tab, the tool displays information about:

- MATLAB syntax issues. These issues are reported in the MATLAB editor. To learn more about the issues and how to fix them, use the Code Analyzer.
- Unsupported MATLAB function calls, language features, and data types.

You can also:

- View your MATLAB code inside the Code Generation Readiness Tool. When you select an issue, the part of your MATLAB code that caused this issue gets highlighted.
- Group the readiness results either by issue or by file.
- Select the language that the code generation readiness analysis uses.
- Refresh the code generation readiness analysis if you updated your MATLAB code.
- Export the analysis report either as plain text file or as a `coder.ScreenerInfo` object in the base workspace.

## Files Tab

**2 Code generation readiness issues - Code might require changes**

Language **C/C++ (MATLAB Coder)** [Refresh](#) [Edit](#)

2 Unsupported functions  
2 Files analyzed

Issues Files  Show MathWorks functions

foo1  
  foo2

Unsupported function: **hascycles**

foo2.m

```

1 function [tf1,tf2] = foo2(source,target)
2   G = digraph(source,target);
3   tf1 = hascycles(G);
4   tf2 = isdag(G);
5   end
6

```

If the code that you are checking calls functions in other MATLAB code files, the **Files** tab shows the call dependency between these files. If you select **Show MathWorks Functions**, the report also lists the MathWorks functions that your function calls.

## Check Code Using the Code Generation Readiness Tool

<b>In this section...</b>
“Run Code Generation Readiness Tool at the Command Line” on page 49-13
“Run the Code Generation Readiness Tool From the Current Folder Browser” on page 49-13

### Run Code Generation Readiness Tool at the Command Line

- 1 Navigate to the folder that contains the file that you want to check for code generation readiness.
- 2 At the MATLAB command prompt, enter:

```
coder.screener('filename')
```

The **Code Generation Readiness** tool opens for the file named `filename`, provides a code generation readiness score, and lists issues that must be fixed prior to code generation.

### Run the Code Generation Readiness Tool From the Current Folder Browser

- 1 In the current folder browser, right-click the file that you want to check for code generation readiness.
- 2 From the context menu, select **Check Code Generation Readiness**.

The **Code Generation Readiness** tool opens for the selected file and provides a code generation readiness score and lists issues that must be fixed prior to code generation.

## Debug MATLAB Function Blocks

### In this section...

“Debug an Example Function” on page 49-14  
 “Set Conditions on Breakpoints” on page 49-16  
 “Watch Function Variables During Simulation” on page 49-17  
 “Check for Data Range Violations” on page 49-19  
 “Debug MATLAB Function Blocks in Initialize Function and Terminate Function Blocks” on page 49-19

You can use the **MATLAB Function Block Editor** to debug MATLAB Function block code. The **MATLAB Function Block Editor** includes some of the same debugging tools available in the MATLAB editor. To debug MATLAB Function block code, set at least one breakpoint and run the simulation.

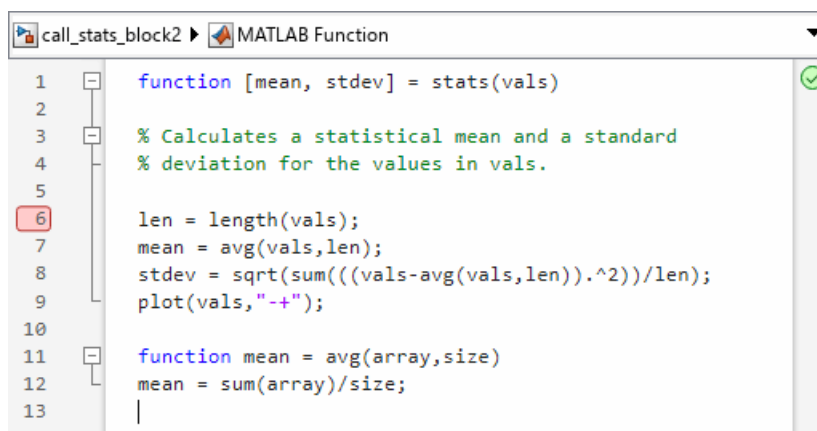

### Debug an Example Function

This example uses the model `call_stats_block2`, which you create in “Implement MATLAB Functions in Simulink with MATLAB Function Blocks” on page 49-3. To debug the MATLAB Function block code in this model:

- 1 Open the `call_stats_block2` model. Double-click the MATLAB Function block to open the editor.
- 2 In the **MATLAB Function Block Editor**, click the line number to the left of the line:

```
len = length(vals);
```

The line number is highlighted in red, which indicates the breakpoint.

The screenshot shows the MATLAB Function Block Editor for the model `call_stats_block2`. The editor displays the following code:

```

1 function [mean, stdev] = stats(vals)
2
3 % Calculates a statistical mean and a standard
4 % deviation for the values in vals.
5
6 len = length(vals);
7 mean = avg(vals,len);
8 stdev = sqrt(sum(((vals-avg(vals,len)).^2))/len);
9 plot(vals,"-+");
10
11 function mean = avg(array,size)
12 mean = sum(array)/size;
13

```

Line 6 is highlighted in red, indicating a breakpoint. A green checkmark is visible in the top right corner of the editor window.

- 3 Simulate the model.

The simulation pauses when execution reaches the breakpoint. A green arrow points to where the simulation has paused.

```

call_stats_block2 ▸ MATLAB Function
1  function [mean, stdev] = stats(vals)
2
3  % Calculates a statistical mean and a standard
4  % deviation for the values in vals.
5
6  len = length(vals);
7  mean = avg(vals,len);
8  stdev = sqrt(sum(((vals-avg(vals,len)).^2))/len);
9  plot(vals,"-+");
10
11 function mean = avg(array,size)
12 mean = sum(array)/size;
13

```

- 4 On the **Function** tab, click **Step Over** to advance execution.

The execution advances to the next line of `stats`, which calls the local function `avg`.

- 5 On the **Function** tab, click **Step In**.

Execution advances to the local function `avg`. Once you are in a local function, you can use the **Step Over** or **Step In** commands to advance execution. If the local function calls another local function, use **Step In** to enter it. If you want to execute the remaining lines of the local function, use **Step Out**.

- 6 Click **Step Over** to execute the only line in `avg`.
- 7 Click **Step Over** to return to the function `stats`.

Execution advances to the line after the call to `avg`.

- 8 Click **Step Over** twice to calculate the `stdev` and to execute the `plot` function.

The `plot` function executes in MATLAB:

- 9 Click **Continue** to continue executing the model.

If you return to the model, the computed values of `mean` and `stdev` appear in the Display blocks.

- 10 In the **MATLAB Function Block Editor**, click **Stop** to stop the simulation.

---

**Note** You can debug MATLAB Function blocks in Normal and Accelerator modes. However, if you simulate a model in Accelerator mode that uses a MATLAB Function block in a model reference, the parent model simulation ignores the breakpoints.

---

## Set Conditions on Breakpoints

You can enter a MATLAB expression as a condition on a breakpoint inside a MATLAB Function block. Simulation then pauses on that breakpoint only when the condition is true. To set a conditional breakpoint, in the **MATLAB Function Block Editor**, right-click the line number to the left of a line of code and select **Set Conditional Breakpoint**, and enter the condition in the dialog box. You can use any valid MATLAB expression as a condition. This expression can include numerical values and any data that is in scope at the breakpoint.

To add or modify a condition on an existing breakpoint, right-click the breakpoint and select **Set/Modify Condition**.

## Watch Function Variables During Simulation

You can use several tools to track the variable values of the function while you simulate a MATLAB Function block.

### Watch Function Variables in the Code

To view the value of a variable in the function of a MATLAB Function block during simulation in the code:

- 1 Add a breakpoint to the **MATLAB Function Block Editor**.
- 2 Run the model.
- 3 When the simulation pauses, point to a variable name. A tooltip displays the current variable value.

For example, to watch the variable `stdev` during simulation, point to `len` in the code.

The screenshot shows a MATLAB Function Block Editor with a breakpoint set at line 6. The code is as follows:

```

5
6 len = length(vals);
7 mean = avg(vals, len);
8 stdev = sqrt(sum((vals-avg(vals, len)).^2)/len);
9 vals, "-+");
10
11 function mean = avg(array, size)
12 mean = sum(array)/size;
13

```

A tooltip is displayed over the variable `len` on line 8, showing its current value as 4.

### Watch Function Variables in the Symbols Pane

To view the value of a variable in the **Symbols** pane in a MATLAB Function block during simulation:

- 1 Open the **Symbols** pane. In the **Function** tab, click **Edit Data**.
- 2 Add a breakpoint to the **MATLAB Function Block Editor**.
- 3 Run the model.
- 4 When the simulation pauses, the **Symbols** pane updates with the values at the breakpoint. If the variable is an array, the **Value** column displays the dimension and data type of the variable. Point to the **Value** column to see the values.

For example, to view the variable `vals` during simulation, point to the value of `vals` in the **Value** column.

### Watching Function Variables with the Command Line Debugger

You can view the values for a function variable in the Command Window during simulation. When you reach a breakpoint, enter the name of a variable at the `debug>>` prompt to see its value.

```
debug>> stdev
```

```
1.1180
```

```
debug>>
```

You can also enter these commands in the command window while debugging:

Command	Description
<code>dbcont</code>	Continue execution to next breakpoint.
<code>dbquit</code>	Quit debugging and terminate the simulation.
<code>dbstep [in   out]</code>	Advance to next program step after a breakpoint is encountered. Step over or step into/out of a MATLAB local function.
<code>help</code>	Display help for command line debugging.
<code>print &lt;var&gt;</code>	Display the value of the variable <code>var</code> in the current scope. If <code>var</code> is a vector or matrix, you can also index into <code>var</code> . For example, <code>var(1,2)</code> .
<code>save</code>	Saves all variables in the current scope to the specified file. Follows the syntax of the MATLAB <code>save</code> command. To retrieve variables from the MATLAB base workspace, use <code>load</code> command after simulation completes.
<code>&lt;var&gt;</code>	Equivalent to <code>print &lt;var&gt;</code> if the variable is in the current scope.
<code>who</code>	Display the variables in the current scope.
<code>whos</code>	Display the size and class (type) of all variables in the current scope.

If you enter other commands at the `debug>>` prompt, the results execute in the workspace of the MATLAB Function block. To issue a command in the MATLAB base workspace, use the `evalin` command with the first argument "base" followed by the second argument command, for example, `evalin("base", "whos")`. You cannot define or change variables at the `debug>>` prompt.

## Display Size Limits

The **MATLAB Function Block Editor** does not display the contents of matrices that have more than two dimensions or more than 200 elements. For matrices that exceed these limits, the **MATLAB Function Block Editor** displays the shape and base type only.

## Check for Data Range Violations

MATLAB Function blocks check inputs and outputs for data range violations when the input or output values enter or leave the blocks. To enable data range violation checking, open the Configuration Parameters window, click **Diagnostics > Data Validity**, and set **Simulation range checking** to error or warning.

## Specify a Data Range

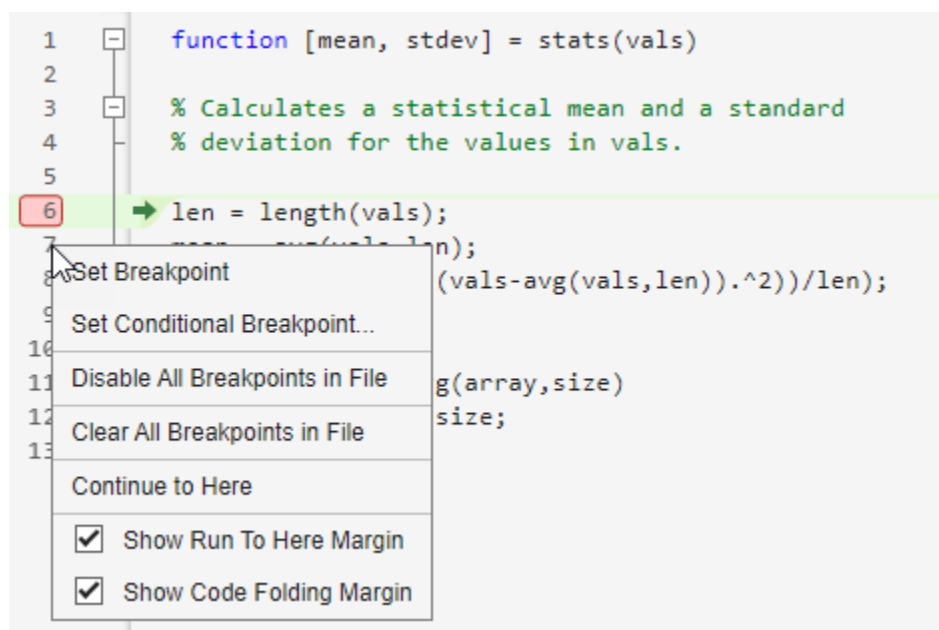

To specify a range for input and output variables, in the **MATLAB Function Block Editor**:

- 1 In the **Symbols** pane, click the variable of interest.
- 2 In the Property Inspector, in the **Properties** tab, adjust the **Limit range** property by entering the desired values for **Minimum** and **Maximum**.

## Debug MATLAB Function Blocks in Initialize Function and Terminate Function Blocks

When you use MATLAB Function blocks in Initialize Function or Terminate Function blocks, you cannot use the buttons in the **Debug Code** section to navigate through breakpoints. You must use the command line debugger or the line number context menu options.

To use the line number context menu. In the **MATLAB Function Block Editor**, add a breakpoint and run the simulation. During simulation, right-click any of the line numbers after the breakpoint and click **Continue to Here**.

## Prevent Algebraic Loop Errors in MATLAB Function, Chart, and Truth Table Blocks

You can use MATLAB Function, Chart, and Truth Table blocks in feedback loops in your model if you apply certain settings. You can also use these blocks with synchronous subsystems enabled by the State Control block. To prevent algebraic loop or synchronous semantic errors, apply these restrictions.

Block	Restrictions
Chart	Use Moore charts to prevent an algebraic loop. In the Property Inspector, set the <b>State Machine Type</b> to <b>Moore</b> . Moore charts prevent algebraic loops by ensuring that outputs depend only on the current state.
MATLAB Function	<p>Nondirect feedthrough semantics prevent algebraic loop errors by ensuring that outputs depend only on the current state. To enable nondirect feedthrough, clear the <b>Allow direct feedthrough</b> property.</p> <p>When <b>Allow direct feedthrough</b> is selected, do not:</p> <ul style="list-style-type: none"> <li>• Call imported functions.</li> <li>• Define output function-call events.</li> <li>• Define or use persistent variables.</li> </ul> <p>When you follow these guidelines, you allow the Simulink solver to try to solve resultant algebraic loops.</p>
Truth Table	<p>Do not:</p> <ul style="list-style-type: none"> <li>• Call imported functions.</li> <li>• Define local or output function-call events.</li> <li>• Define local or data store memory data.</li> <li>• Define or use persistent variables.</li> </ul> <p>When you follow these guidelines, you allow the Simulink solver to try to solve resultant algebraic loops.</p>

## Manage Function Call Outputs of a MATLAB Function Block

A function call output is an event on the output port of a MATLAB Function block that causes a Function-Call Subsystem or Stateflow chart in the model to execute. See “Using Function-Call Subsystems” on page 10-50. You can add function call outputs to MATLAB Function blocks and configure the function call outputs by using the **Symbols** pane and Property Inspector or the Model Explorer.

After creating a function call output, you need to call the function call output in the MATLAB Function block code.

### Create Function Call Outputs

To create function call outputs, use the **Symbols** pane or the Model Explorer.

To use the **Symbols** pane:

- 1 Open the **MATLAB Function Block Editor**. In the **Function** tab, click **Edit Data**.
- 2 Click the Create Event button  and select **Add Function Call Output**.

To delete the function call output, right-click the function call output name and select **Delete**.

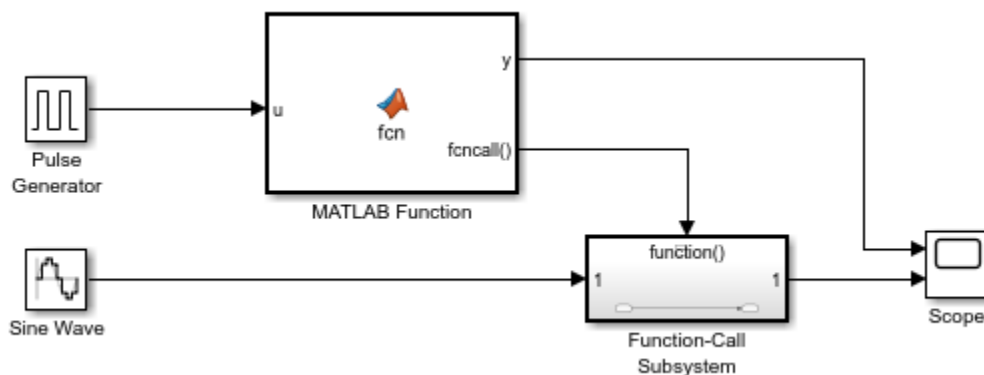

To use the Model Explorer:

- 1 Open the Model Explorer. In the **Modeling** tab, in the **Design** section, click **Model Explorer**.
- 2 In the **Model Hierarchy** pane, select the MATLAB Function block.
- 3 Click **Add > Function Call Output** or the Add Function Call Output button .

To delete a function call output, select the function call output and click **Edit > Delete** or the Delete button .

### Enable a Function-Call Subsystem with a MATLAB Function Block

This example uses a MATLAB Function block with a function call output to trigger a subsystem.

When the signal from the Pulse Generator block equals 1, the MATLAB Function block executes the function call output. The block then continues to execute the function call output at each major time step. Double-click the MATLAB Function block to open the code.

```
function y = fcn(u)
y = u;
if u == 1
    fcncall()
end
```

The function-call subsystem allows the signal from the Sine Wave block to propagate when the function-call triggers. When the function call is not triggered, the subsystem outputs the last propagated value. Run the model and open the Scope block to see the outputs.

## Considerations When Triggering Function-Call Subsystems

If a MATLAB Function block triggers a function-call subsystem and outputs a signal to the same function-call subsystem, the signal to the function-call subsystem is delayed by one time step compared to the function call. At the moment of the function call output, the function-call subsystem

sees the previous MATLAB Function block output port value even if the output data has been updated within the block MATLAB code.

If **Allow direct feedthrough** is cleared, MATLAB Function blocks with function call outputs can cause unexpected results. When **Allow direct feedthrough** is disabled, the triggered subsystem receives the function call during model update, and therefore the function call output executes later than required. To avoid these issues, enable **Allow direct feedthrough** when using function call outputs. For more information, see “Use Nondirect Feedthrough in a MATLAB Function Block” on page 49-129.

## Set Function Call Output Properties

To adjust function call output properties, use the **Symbols** pane and Property Inspector or the Model Explorer.

To edit the properties by using the **Symbols** pane and Property Inspector, specify the function call output and open the Property Inspector by using one of these approaches:

- In the **Function** tab, click **Edit Data**. In the **Symbols** pane, select the function call output.
- In the **Symbols** pane, right-click the function call output name and click **Inspect**.
- In the **Symbols** pane, select the function call output. In the **Modeling** tab, in the **Design Data** section, click **Property Inspector**.

To edit the properties by using Model Explorer, click a function call output.

You can modify the following properties.

### Name

Specifies the name of the function call output. Use the naming conventions used in MATLAB. You can only set this property in the **Symbols** pane or Model Explorer.

### Port

Specifies the index of the port associated with the function call output. Function call output ports are numbered sequentially after output ports.

### Description

Specifies the description of the function call output.

### Document link

Specifies the link to documentation for the function call output. You can enter a URL address or a MATLAB command that displays documentation, such as an HTML file or text in the MATLAB Command Window. When you click the **Document link** link, the MATLAB Function block evaluates the link and displays the documentation.

## Manage the Input Trigger of a MATLAB Function Block

An input trigger is an input that executes the MATLAB Function block when activated. See “Using Triggered Subsystems” on page 10-18. You can add one input trigger to each MATLAB Function block and configure the input trigger by using the **Symbols** pane and Property Inspector or the Model Explorer.

### Create an Input Trigger

To create an input trigger, use the **Symbols** pane or the Model Explorer.

To use the **Symbols** pane:

- 1 Open the **MATLAB Function Block Editor**. In the **Function** tab, click **Edit Data**.
- 2 Click the Create Event button  and select **Add Trigger**.

To delete the input trigger, right-click the input trigger name and select **Delete**.

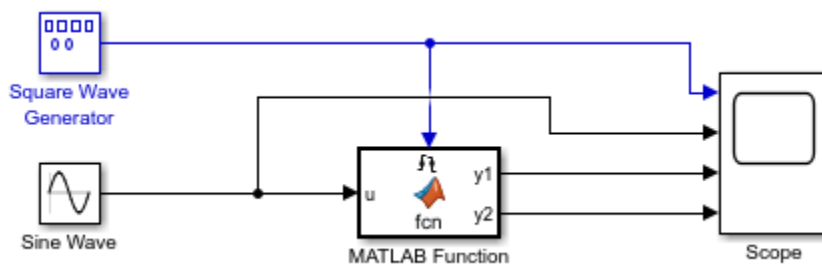

To use the Model Explorer:

- 1 Open the Model Explorer. In the **Modeling** tab, in the **Design** section, click **Model Explorer**.
- 2 In the **Model Hierarchy** pane, select the MATLAB Function block.
- 3 Click **Add > Trigger** or the Add Trigger button .

To delete the input trigger, select the input trigger output and click **Edit > Delete** or the Delete button .

### Enable a MATLAB Function Block with an Input Trigger

This example uses a MATLAB Function block that is controlled by an either input trigger.

When the signal from the Square Wave Generator block rises or falls below 0, the MATLAB Function block executes. Double-click the MATLAB Function block to open the code.

```
function [y1,y2] = fcn(u)
```

```
y1 = u;  
y2 = u - 1;
```

The MATLAB Function block outputs the last propagated value until the block triggers again. Run the model and open the Scope block to see the outputs.

## Set Input Trigger Properties

To adjust the input trigger properties, use the **Symbols** pane and Property Inspector or the Model Explorer.

To edit the properties by using the **Symbols** pane and Property Inspector, specify the input trigger and open the Property Inspector by using one of these approaches:

- In the **Function** tab, click **Edit Data**. In the **Symbols** pane, select the input trigger.
- In the **Symbols** pane, right-click the input trigger name and click **Inspect**.
- In the **Modeling** tab, in the **Design Data** section, click **Property Inspector**. In the **Symbols** pane, select the input trigger.

To edit the properties by using the Model Explorer, click the input trigger.

You can modify the following properties.

**Name**

Specifies the name of the input trigger. Use the naming conventions used in MATLAB. You can only set this property in the **Symbols** pane or Model Explorer.

**Port**

Specifies the index of the port associated with the input trigger. The property is read-only. Because you can only add one trigger to a MATLAB Function block, this property is always 1.

**Trigger**

Specifies the type of event that triggers the MATLAB Function block. You can select one of the following types:

Trigger Event	Description
Rising	The trigger signal executes the MATLAB Function block when the signal rises from a negative or zero value to a positive value or from a negative value to zero.
Falling	The trigger signal executes the MATLAB Function block when the signal falls from a positive or zero value to a negative value or from a positive value to zero..
Either	The trigger signal executes the MATLAB Function block when the control signal is either Rising or Falling.
Function call	A trigger signal from a block that outputs function-call events executes the MATLAB Function block.

**Description**

Specifies the description of the input trigger.

**Document link**

Specifies the link to the documentation for the input trigger. You can enter a URL address or a MATLAB command that displays documentation, such as an HTML file or text in the MATLAB Command Window. When you click the **Document link** link, the MATLAB Function block evaluates the link and displays the documentation.

**Related Examples**

- “Debug MATLAB Function Blocks” on page 49-14
- “Implement MATLAB Functions in Simulink with MATLAB Function Blocks” on page 49-3
- “Triggered Subsystems”

- “Create and Define MATLAB Function Block Variables” on page 49-31

## Create and Define MATLAB Function Block Variables

MATLAB Function blocks use variables to manage simulation data. Variables can represent data for block inputs, outputs, parameters, or from Data Store Memory. You can create or delete variables in the MATLAB Function block code, the **Symbols** pane, or the Model Explorer. Then you can set the properties of the variables in the Property Inspector or Model Explorer.

### Create and Delete MATLAB Function Block Variables

You can create or delete MATLAB Function block variables in the function code, by using the **Symbols** pane, or Model Explorer.

To create or delete variables in the MATLAB Function block code, double-click the MATLAB Function block to open the **MATLAB Function Block Editor**. When you specify new input and output arguments, the MATLAB Function block automatically assigns the arguments to the respective input or output port. Similarly, you can remove arguments from the block by deleting them and updating or saving the model.

To use the **Symbols** pane, double-click the MATLAB Function block to open the **MATLAB Function Block Editor**. Then use one of these approaches:

- In the **Function** tab, click **Edit Data**.
- the **Modeling** tab, in the **Design** section, click **Symbols Pane**.

Add variables by clicking the Create Data button . Delete variables by right-clicking the variable and clicking **Delete**.

To use the Model Explorer, in the **Modeling** tab, in the **Design** section, click **Model Explorer**. In the **Model Hierarchy** pane, expand the model tree view and select the MATLAB Function block. Add variables by clicking **Add > Data** or the Add Data button . Delete variables by selecting the variable and clicking **Edit > Delete** or the Delete button .

If you do not use the variable in the code, the **Symbols** pane shows the Unused Symbol icon  next to the variable name.

### Set General Variable Properties

You can modify the properties of a variable by using the **Symbols** pane and the Property Inspector or by using the Model Explorer.

To edit the properties by using the **Symbols** pane and Property Inspector, use of one of these approaches:

- In the **Function** tab, click **Edit Data**. In the **Symbols** pane, select the variable.
- In the **Symbols** pane, right-click a variable name and click **Inspect**.
- In the **Modeling** tab, in the **Design Data** section, click **Property Inspector**. In the **Symbols** pane, select the variable.

To edit the properties by using Model Explorer, click a variable, then edit the properties in the **General** tab.

### Name

Specifies the name of the variable. Use the same naming conventions used in MATLAB. You can also modify this property in the **Symbols** pane directly.

Changing the name in the **Symbols** pane only adjusts variables in the function declaration statement, and does not change the name of the variable used throughout the body of the code. If you want to adjust the variable throughout the code, enter the **Name** property in the **Symbols** pane and press **Shift + Enter**.

### Scope

Specifies where the variable resides in memory relative to its parent. This property determines the functionality of the variable. You can also modify this property in the **Type** column of the **Symbols** pane. You can set **Scope** to one of these values:

Scope	Description
Parameter	The variable resides in a variable of the same name in the MATLAB workspace, the model workspace, or in the workspace of a masked subsystem that contains this block. If a variable of the same name exists in more than one of the workspaces visible to the block, the block uses the variable closest to the block in the workspace hierarchy. The <b>Symbols</b> pane indicates the variable has <b>Scope</b> set to Parameter with the Parameter Data icon  . For more information, see “Model Workspaces” on page 72-113.
Input	The variable is an input signal to the MATLAB Function block. The <b>Symbols</b> pane indicates the variable has <b>Scope</b> set to Input with the Input Data icon  .
Output	The variable is an output signal of the MATLAB Function block. The <b>Symbols</b> pane indicates the variable has <b>Scope</b> set to Output with the Output Data icon  .
Data Store Memory	The variable resides in a Data Store Memory block in the model. The <b>Symbols</b> pane indicates the variable has <b>Scope</b> set to Data Store Memory with the Data Store Memory icon  . For more information, see “Retrieve Data From Data Store Memory Blocks” on page 49-95.

For more information, see “Check Properties for MATLAB Function Block Variables” on page 49-5 and “Configure MATLAB Function Block Parameter Variables” on page 49-54.

**Port**

Specifies the index of the port associated with the variable. This property applies only to variables with the **Scope** property set to **Input** or **Output**.

**Data must resolve to signal object**

Specifies that the variable resolves to a Simulink signal object. This property applies only to variables with the **Scope** property set to **Output**. This property appears only if you set the configuration parameter **Signal resolution** to a value other than **None**. For more information, see “Symbol Resolution” on page 72-126.

**Size**

Specifies the size of the variable. This property can be a scalar value or a MATLAB vector of values. **Size** defaults to  $-1$ , which means that the size is inherited. For more information, see “Inherit Size from Simulink” on page 49-52. This property does not apply to variables with the **Scope** property set to **Data Store Memory**. See “Specify Size of MATLAB Function Block Variables” on page 49-52.

**Variable size**

Specifies whether the size of the variable can change or is fixed. This property applies only to variables with the **Scope** property set to **Output**. For more information, see “Declare Variable-Size MATLAB Function Block Variables” on page 49-76.

Input variables inherit size variability from their corresponding signals. Variables in both the input and output of the function declaration statement also automatically inherit size variability.

This property appears only if the MATLAB Function block property **Support variable-size arrays** is enabled. See “Support variable-size arrays” on page 49-37.

**Tunable**

Specifies whether the parameter used as the source of this variable data is tunable. For more information, see “Tunable Parameters” on page 10-85. This property applies only to variables with the **Scope** property set to **Parameter**. Clear this option if the parameter must be a constant expression, such as for toolbox functions supported for code generation. For more information, see “Functions and Objects Supported for C/C++ Code Generation” on page 54-2.

**Complexity**

Specifies real or complex variables. Set **Complexity** to one of the following values:

<b>Complexity</b>	<b>Description</b>
Inherited	Variable inherits complexity based on the <b>Scope</b> property. Input and output variables inherit complexity from the Simulink signals connected to the associated input or output ports. Parameter variables inherit complexity from the specified parameter.
Off	Variable is a real number.
On	Variable is a complex number.

This property does not apply to variables with the **Scope** property set to **Data Store Memory**.

### Type

Specifies the data type for the variable. You can specify the data type by:

- Selecting a built-in type from the **Type** property.
- Entering an expression in the **Type** property that evaluates to a data type. See “About Data Types in Simulink” on page 72-2.
- Using the Data Type Assistant to specify the **Mode** property, then specifying the data type based on that mode.

---

**Note** To display the Data Type Assistant, click the Show data type assistant button .

For more information, see “Define and Modify Variable Data Types” on page 49-44. This property does not apply to variables with the **Scope** property set to **Data Store Memory**.

### Unit (e.g., m, m/s<sup>2</sup>, N\*m)

Specifies the physical units for the variable. By default, this property is set to inherit the unit from the Simulink signal on the corresponding input or output port. See “Specify Units in MATLAB Function Blocks” on page 9-6. The property applies only to variables with the **Scope** property set to **Input** or **Output**.

## Set Limit Range Properties

You can set the range of acceptable values for variables in the **Limit range** section of the Property Inspector or Model Explorer. The MATLAB Function block uses this range to validate the data as it enters or leaves the block. You can enter an expression or parameter that evaluates to a numeric scalar. Specify the range by using two properties. These properties apply only to variables with the **Scope** property set to **Input** or **Output**

### Minimum

The smallest value allowed for the variable during simulation. The default value is `-inf`.

### Maximum

The largest value allowed for the variable during simulation. The default value is `inf`.

## Set Description Properties

You can modify the description properties of a variable by using the Property Inspector or the Model Explorer. In the Model Explorer, click a variable, then edit the properties in the **Description** tab. In the Property Inspector, edit the properties in the **Info** tab.

### Save final value to base workspace

Specifies if the MATLAB Function block assigns the value of the variable to a variable of the same name in the MATLAB base workspace after simulation. This property applies only to variables with the **Scope** property set to **Input** or **Output**. This property appears only in the Model Explorer.

**Description**

Specifies the description of the variable.

**Document link**

Specifies the link to the documentation for the variable. You can enter a URL address or a MATLAB command that displays documentation, such as an HTML file or text in the MATLAB Command Window. When you click the **Document link** link, the MATLAB Function block evaluates the link and displays the documentation.

**See Also**

**MATLAB Function Block Editor**

**Related Examples**

## Specify MATLAB Function Block Properties

You can specify how a MATLAB Function block interfaces with a Simulink model by setting the block properties in the Property Inspector or Model Explorer.

To specify properties in the Property Inspector, open the Property Inspector. In the **Modeling** tab, in the **Design** section, select **Property Inspector**. Click the block to show the properties in the Property Inspector.

To specify properties in the Model Explorer, click the **Modeling** tab. In the **Design** section, select **Model Explorer**. In the **Model Hierarchy** pane, expand the model tree view, select the MATLAB Function block, and edit the properties in the **MATLAB Function** pane.

### MATLAB Function Block Properties

You can adjust the following properties in the Model Explorer or by navigating to the **Properties** tab of the Property Inspector.

#### Update method

Specifies the method used for activating the MATLAB Function block.

Update Method	Description
Inherited (default)	Input from the Simulink model activates the MATLAB Function block.  If you define an input trigger, the MATLAB Function block executes in response to a Simulink signal or function-call event on the trigger port. If you do not define an input trigger, the MATLAB Function block implicitly inherits triggers from the model. These implicit events are the sample times (discrete or continuous) of the signals that provide inputs to the block.  If you define data inputs, the MATLAB Function block samples at the rate of the fastest data input. If you do not define data inputs, the MATLAB Function block samples at the rate defined by the execution behavior of the parent subsystem.
Discrete	Sample the MATLAB Function block using the rate you specify in the <b>Sample time</b> property of the MATLAB Function block. The MATLAB Function block generates an implicit event at regular time intervals that correspond to the specified rate. Note that other blocks in the model can have different sample times.
Continuous	Sample the MATLAB Function block at each major time step of the simulation, as well as at intermediate time points requested by the Simulink solver.

#### Saturate on integer overflow

Specifies how the MATLAB Function block handles overflow conditions during integer operations.

Setting	Action When Overflow Occurs
Enabled (default)	Saturates an integer by setting it to the maximum positive or negative value allowed by the word size. This setting matches MATLAB behavior.

Setting	Action When Overflow Occurs
Disabled	Generates a run-time error in simulation mode. For Simulink Coder code generation, the behavior depends on your C language compiler.

---

**Note** The **Saturate on integer overflow** option is relevant only for integer arithmetic. It has no effect on fixed-point or double-precision arithmetic.

---

When you enable **Saturate on integer overflow**, MATLAB adds additional checks during simulation to detect integer overflow or underflow. Therefore, it is more efficient to disable this option if you are sure that integer overflow and underflow does not occur in your MATLAB Function block code.

Note that the code generated by Simulink Coder does not check for integer overflow or underflow and, therefore, may produce unpredictable results when **Saturate on integer overflow** is disabled. In this situation, simulate your model to test for overflow and underflow before generating code.

### Support variable-size arrays

Specifies if the MATLAB Function block supports input and output data that varies in dimension during simulation. When you enable this property, you can enable variable-size outputs by enabling the **Variable size** property on output variables. For more information, see “Declare Variable-Size MATLAB Function Block Variables” on page 49-76 and “Variable size” on page 49-33.

### Allow direct feedthrough

Specifies if the MATLAB Function block supports direct feedthrough semantics, so that the output of the block is controlled directly by the value of an input. When you disable **Allow direct feedthrough**, nondirect feedthrough semantics ensure that outputs rely only on the current state of the block. Using nondirect feedthrough enables you to use MATLAB Function blocks in a feedback loop and prevent algebraic loops. For more information, see “Use Nondirect Feedthrough in a MATLAB Function Block” on page 49-129.

### Interpret output column vectors as one-dimensional data

Specifies if the output of a column vector evaluates as one-dimensional data.

- If you enable this property, the block converts output column vectors of size  $N$ -by-1 to one-dimensional signals with a signal size equal to  $N$ .
- If you disable this property, the block outputs column vectors of size  $N$ -by-1 as signals with a signal size equal to  $N$ -by-1.

---

**Note** Before R2021b, MATLAB Function blocks always converted output column vectors to one-dimensional signals.

---

### Treat dimensions of length 1 as fixed size

Specifies if variables with at least one dimension of length 1 are fixed size. When this property is enabled, the block sets variables that are variable size with a dimension of 1 to fixed size. When this property is disabled, variables in the block that have the **Variable size** property enabled are always variable size. Prior to R2023a, the block treats variables with at least one dimension of length 1 as fixed size.

This property only affects output variables that have the **Variable size** property enabled. See “Variable size” on page 49-33.

## Fixed-Point Properties

You can adjust fixed-point properties for the MATLAB Function block in the Model Explorer or by navigating to the **Fixed-point properties** section in the **Properties** tab of the Property Inspector.

### Treat these inherited Simulink signal types as fi objects

Specifies whether to treat inherited fixed-point and integer signals as Fixed-Point Designer **fi** objects. For more information, see “Ways to Construct **fi** Objects” (Fixed-Point Designer).

- When you select **Fixed-point**, the MATLAB Function block treats all fixed-point inputs as Fixed-Point Designer **fi** objects.
- When you select **Fixed-point & Integer**, the MATLAB Function block treats all fixed-point and integer inputs as Fixed-Point Designer **fi** objects.

### MATLAB Function **fimath**

Specifies **fimath** properties for the MATLAB Function block. The **fimath** on a MATLAB Function block behaves as a global **fimath** (Fixed-Point Designer) for the contents of the MATLAB Function block. The block associates the **fimath** properties in **MATLAB Function **fimath**** with all fixed-point and integer input signals to the MATLAB Function block that you choose to treat as **fi** objects. Constructing **fi** objects in the MATLAB Function block introduces additional considerations.

- If no **fimath** is associated with a **fi** object when it is constructed, then the **fi** constructor uses the default **fimath** settings regardless of the properties in **MATLAB Function **fimath****. However, if you perform additional operations on the **fi** object after it is constructed, the object will adopt the properties in **MATLAB Function **fimath****.
- If you specify a **fimath** in the **fi** constructor, then that **fimath** is obeyed when quantizing the value in the **fi** constructor. Any **fimath** settings not specified in the **fi** constructor use the specified properties in **MATLAB Function **fimath****.

You can select one of these options:

Setting	Description
<b>Same as MATLAB</b>	The block uses the same <b>fimath</b> properties as the current default <b>fimath</b> . The edit box is dimmed and displays the current global <b>fimath</b> in read-only form.
<b>Specify other</b>	<p>You can specify your own <b>fimath</b> object in the edit box. You can do so in one of two ways:</p> <ul style="list-style-type: none"> <li>• Constructing the <b>fimath</b> object inside the edit box.</li> <li>• Constructing the <b>fimath</b> object in the MATLAB or model workspace and then entering its variable name in the edit box. If you use this option and plan to share your model with others, define the variable in the model workspace.</li> </ul> <p>For more information, see “<b>fimath</b> Object Construction” (Fixed-Point Designer) and “Fixed-Point Data Types with MATLAB Function Block” (Fixed-Point Designer).</p>

## Description and Document Link Properties

You can set description and document link properties for the MATLAB Function block in the Model Explorer or by navigating to the **Info** tab of the Property Inspector.

### Description

Specifies the description of the MATLAB Function block. You can enter a brief description and comments.

### Document link

Specifies the link to the documentation for the data argument. You can enter a URL address or a MATLAB command that displays documentation, such as an HTML file or text in the MATLAB Command Window. When you click the **Document link** link, the MATLAB Function block evaluates the link and displays the documentation.

## Programmatically Specify Block Properties

You can specify MATLAB Function block properties programmatically by retrieving the `MATLABFunctionConfiguration` or `Stateflow.EMChart` objects of the block. For more information, see “Configure MATLAB Function Blocks Programmatically” on page 49-7.

## MATLAB Function Reports

### In this section...

“Open a MATLAB Function Report” on page 49-40  
 “Analyze MATLAB Source Code” on page 49-40  
 “View Error and Warning Messages” on page 49-41  
 “View MATLAB Variables” on page 49-41  
 “Report Limitations” on page 49-43

When you simulate, update, or generate code from a Simulink model that contains MATLAB Function blocks or Stateflow charts with MATLAB functions, Simulink generates a report for each MATLAB function in your model. The report provides type information for the variables and expressions in your functions, which can help you find the sources of errors and warnings.

Stateflow produces one report for each Stateflow chart, regardless of the number of MATLAB functions it contains.

If you have identical MATLAB Function blocks in your model, a single report is generated for the identical blocks.

### Open a MATLAB Function Report

To open a MATLAB function report, use one of these methods:

- Open the MATLAB function. On the **Function** tab, click **Function Report**.
- Simulate or update the model. If a compilation error occurs, in the **Diagnostic Viewer** window, select the report link.
- For MATLAB Function blocks, call the `openReport` function on the `MATLABFunctionConfiguration` object associated with the block. For more information, see “Programmatically Access MATLAB Function Reports” on page 49-8.

**Note** The first time that you open the MATLAB function report, Simulink automatically updates your model. If you make subsequent changes to the MATLAB code in the block, you must update your model before you reopen the report. Otherwise, the report does not reflect your changes. From the **Modeling** tab, select **Update Model**, or use the **Ctrl+D** keyboard shortcut. If you are in the **MATLAB Function Block Editor**, update the model by using the **Ctrl+Shift+D** keyboard shortcut instead.

### Analyze MATLAB Source Code

In the **MATLAB Source** pane, the **Function List** view organizes functions by the file that contains them. To visualize functions according to the call structure, use the **Call Tree** view.

The MATLAB function report is read-only. To edit a function, select the name of the function in the **MATLAB Source** pane and click **Open in Editor**.

To view a MATLAB function in the code pane, click the name of the function in the **MATLAB Source** pane. In the code pane, when you pause on a variable or expression, a tooltip displays information

about its size, type, and complexity. Additionally, syntax highlighting helps you to identify MATLAB syntax elements and certain code generation attributes, such as whether a function is extrinsic or whether an argument is constant.

### Extrinsic Functions

The report identifies an extrinsic function with purple text. The tooltip indicates that the function is extrinsic.

The screenshot shows a MATLAB function report for 'callMyExtrinsic'. The code is as follows:

```

Function: callMyExtrinsic
1 function z = callMyExtrinsic(a,b)
2 %#codegen
3 coder.extrinsic('myExtrinsic');
4 z = 0;
5 z = myExtrinsic(a,b);
6 disp(z);
7 end
8

```

The call to `myExtrinsic(a,b)` on line 5 is highlighted in purple. A tooltip titled 'EXPRESSION INFO' is displayed over it, showing:

myExtrinsic(a,b)	
Size:	1 × 1
Class:	mxArray
myExtrinsic is an extrinsic function.	

### Constant Arguments

Orange text indicates a compile-time constant argument to an entry-point function or a specialized function. The tooltip includes the constant value.

The screenshot shows a MATLAB function report for 'myadd'. The code is as follows:

```

Function: myadd
1 function c = myadd(a,b)
2 c = a + b;
3 end

```

The argument `a` in the function signature on line 1 is highlighted in orange. A tooltip titled 'CONSTANT INFO' is displayed over it, showing:

a	
Size:	1 × 1
Class:	double
Complex:	No
Value:	2

Knowing the value of a constant argument helps you to understand the generated function signatures. It also helps you to see when code generation creates function specializations for different constant argument values.

To export the value to a variable in the workspace, click the Export icon .

### View Error and Warning Messages

To view errors and warnings, in the bottom pane of the report, open the **All Messages** tab. To highlight the source code for an error or warning, click the message. It is a best practice to address the first message in the list because subsequent errors and warnings are often related to the first message.

### View MATLAB Variables

To view information about the variables for the selected MATLAB function, in the bottom pane of the report, open the **Variables** tab.

The variables table shows:

- Class, size, and complexity
- Properties of fixed-point types

This information helps you to understand type propagation and identify type mismatch errors.

### Visual Indicators on the Variables Tab

This table describes the symbols, badges, and other indicators in the variables table.

Column in the Variables Table	Indicator	Description
Name	expander	Variable has elements or properties that you can see by clicking the expander.
Name	{:}	Homogenous cell array (all elements have the same properties).
Name	{n}	nth element of a heterogeneous cell array.
Class	v > n	v is reused with a different class, size, and complexity. The number n identifies a reuse with a unique set of properties. When you pause on a renamed variable, the report highlights only the instances of this variable that share the class, size, and complexity. See “Reuse the Same Variable with Different Properties” on page 56-10.
Size	:n	Variable-size array with an upper bound of n.
Size	:?	Variable-size array with no upper bound.
Size	italics	Variable-size array whose dimensions do not change size during execution.
Class	sparse prefix	Sparse array.
Class	complex prefix	Complex number.
Class		Fixed-point type.  To see the fixed-point properties, click the badge.

## Report Limitations

- The variables table does not show the individual elements of `varargin` and `varargout`.
- The report does not show full information for unrolled loops. It displays data types of one arbitrary iteration.
- The report does not show information about dead code.

## Define and Modify Variable Data Types

### In this section...

“Specify Variable Data Types” on page 49-44

“Inheriting Data Types” on page 49-45

“Built-In Data Types” on page 49-45

“Fixed-Point Designer Data Type Properties” on page 49-46

“Specify Data Types with Expressions” on page 49-50

When you create variables in a MATLAB Function block, you can use the **Type** property to set the data type. Variables can inherit their data types, or be set to built-in, fixed-point, or enumerated data types. Variables can also be nonvirtual buses. By default, MATLAB Function block variables inherit their data type.

For more information on creating variables, see “Create and Define MATLAB Function Block Variables” on page 49-31.

### Specify Variable Data Types

You can specify the data types by using the **Symbols** pane and Property Inspector, or the Model Explorer.

To specify the data type using the **Symbols** pane and Property Inspector:

- 1 Double-click the MATLAB Function block to open the **MATLAB Function Block Editor**.
- 2 Open the **Symbols** pane. In the **Function** tab, click **Edit Data**.
- 3 Select the variable.
- 4 In the Property Inspector, in the **Properties** tab, select the data type from the **Type** property.

To specify the data type of a variable by using the Model Explorer:

- 1 Open the Model Explorer. In the **Modeling** tab, in the **Design** section, click **Model Explorer**.
- 2 In the **Model Hierarchy** pane select the MATLAB Function block.
- 3 Click the variable you want to modify.
- 4 Select the data type from the **Type** property.

In the Model Explorer, you can also filter the data type options. In the **General** tab, click the Show data type assistant button  to display the Data Type Assistant parameters. Then, choose an option from the **Mode** parameter. Based on the mode you select, specify the data type:

Mode	What to Specify
Inherit (default)	The inherited data depends on the <b>Scope</b> property: <ul style="list-style-type: none"> <li>• If <b>Scope</b> is <b>Input</b>, the data type is inherited from the input signal on the designated port.</li> <li>• If <b>Scope</b> is <b>Output</b>, the data type is inherited from the output signal on the designated port.</li> <li>• If <b>Scope</b> is <b>Parameter</b>, the data type is inherited from the associated parameter, which can be defined in the Simulink masked subsystem or the MATLAB workspace.</li> </ul>
Built in	Select from a list of built-in data types.
Fixed point	Specify the fixed-point data properties.
Enumerated	Enter the name of a <code>Simulink.IntEnumType</code> object that you define in the base workspace. See “Code Generation for Enumerations” on page 49-87.
Bus Object	In the <b>Bus object</b> field, enter the name of a <code>Simulink.Bus</code> object to define the properties of a MATLAB structure. You must define the bus object in the base workspace. See “How Structure Inputs and Outputs Interface with Bus Signals” on page 49-65.  <b>Note</b> You can click the <b>Edit</b> button to create or modify <code>Simulink.Bus</code> objects by using the Simulink Type Editor. See “Attach Bus Signals to MATLAB Function Blocks” on page 49-60.
Expression	Enter an expression that evaluates to a data type.

## Inheriting Data Types

MATLAB Function block variables can inherit their data types, including fixed point types, from their connected signals. To make a variable inherit a data type, set the **Type** property to **Inherit: Same as Simulink**.

An argument can also inherit complexity from the signal connected to it. To inherit complexity, set the **Complexity** property to **Inherited**.

After you build the model, the **CompiledType** column of the Model Explorer gives the actual type inherited from Simulink. If the expected type matches the inferred type, inheritance is successful.

## Built-In Data Types

In the Model Explorer, when you expand the Data Type Assistant and set **Mode** to **Built in**, you can set **Type** to these built-in data types. The built-in data types are:

Data Type	Description
double	64-bit double-precision floating point
single	32-bit single-precision floating point

Data Type	Description
half	A half-precision data type occupies 16 bits of memory, but its floating-point representation enables it to handle wider dynamic ranges than integer or fixed-point data types of the same size. See “The Half-Precision Data Type in Simulink” (Fixed-Point Designer).
int64	64-bit signed integer
int32	32-bit signed integer
int16	16-bit signed integer
int8	8-bit signed integer
uint64	64-bit unsigned integer
uint32	32-bit unsigned integer
uint16	16-bit unsigned integer
uint8	8-bit unsigned integer
boolean	Boolean
string	String scalar

## Fixed-Point Designer Data Type Properties

To represent variables as fixed-point numbers in MATLAB Function blocks, you must install Fixed-Point Designer.

You can set the following fixed-point properties:

### Signedness

Select whether you want the fixed-point variable to be **Signed** or **Unsigned**. Signed variables can represent positive and negative quantities. Unsigned variables represents positive values only. The default is **Signed**.

### Word length

Specify the size, in bits, of the word that will hold the quantized integer. Large word sizes represent large quantities with greater precision than small word sizes. Word length can be any integer between 0 and 128 bits. The default is 16.

### Scaling

Specify the method for scaling your fixed-point variable to avoid overflow conditions and minimize quantization issues. You can select these scaling modes:

Scaling Mode	Description
Binary point (default)	<p>The Data Type Assistant displays the <b>Fraction Length</b> parameter, which specifies the binary point location.</p> <p>Binary points can be positive or negative integers. A positive integer moves the binary point left of the rightmost bit by that amount. For example, an entry of 2 sets the binary point in front of the second bit from the right. A negative integer moves the binary point further right of the rightmost bit by that amount, as in this example:</p> <p>The default is 0.</p>
Slope and bias	<p>The Data Type Assistant displays the <b>Slope</b> and <b>Bias</b> parameters:</p> <ul style="list-style-type: none"> <li>• Slope can be any positive real number. The default is 1.0.</li> <li>• Bias can be any real number. The default value is 0.0.</li> </ul> <p>You can enter slope and bias as expressions that contain parameters defined in the MATLAB workspace.</p>

---

**Note** Use binary-point scaling whenever possible to simplify the implementation of fixed-point numbers in generated code. Operations with fixed-point numbers that use binary-point scaling are performed with simple bit shifts and eliminate the expensive code implementations required for separate slope and bias values.

---

### Data type override

Specify whether the data type override setting is `Inherit` or `Off`. For more information, see “Data Type Override with MATLAB Function Block” (Fixed-Point Designer).

### Calculate Best-Precision Scaling

Have Simulink automatically calculate best-precision values for both `Binary point` and `Slope and bias` scaling, based on the **Minimum** and **Maximum** properties you specify.

To automatically calculate best precision scaling values:

- 1 Specify the **Minimum** or **Maximum** properties.
- 2 Click **Calculate Best-Precision Scaling**.

Simulink calculates the scaling values, then displays them in either the **Fraction length**, or the **Slope** and **Bias** fields.

---

**Note** The **Minimum** and **Maximum** properties do not apply to variables with the **Scope** property set to `Constant` or `Parameter`. The software cannot calculate best-precision scaling for these kinds of variables.

---

### Fixed-point details

Displays information about the fixed-point variable that is defined in the Data Type Assistant:

- Minimum and Maximum show the same values that you specify in the **Minimum** and **Maximum** properties.
- Representable minimum, Representable maximum, and Precision show the minimum value, maximum value, and precision that the fixed-point variable can represent.

**Data data**

General Description

Mode: Fixed point Signedness: Signed Word length: 16

Scaling: Binary point Fraction length: 0

Data type override: Inherit Calculate Best-Precision Scaling

Fixed-point details

Representable maximum:	32767
Maximum:	10000
Minimum:	-20
Representable minimum:	-32768

Precision: 1 Refresh Details

Unit (e.g., m, m/s<sup>2</sup>, N\*m): SI, English, ...

inherit

Limit range

Minimum: -20 Maximum: 10000

Revert Help Apply

If the value of a field cannot be determined without first compiling the model, the **Fixed-point details** subpane shows the value as Unknown. The values displayed by the **Fixed-point details** subpane do not automatically update if you change the values that define the fixed-point variable. To update the values shown in the **Fixed-point details** subpane, click **Refresh Details**.

Clicking **Refresh Details** does not modify the variable. It changes only the display. To apply the displayed values, click **Apply** or **OK**.

The **Fixed-point details** subpane indicates issues resulting from the fixed-point variable specification. For example, this figure shows two issues.

The screenshot shows the 'Data data' configuration window with the 'Description' tab selected. The variable name is 'data', scope is 'Input', and port is '1'. The type is 'fixdt(1,16,0)'. The 'Data Type Assistant' shows 'Mode' as 'Fixed point', 'Signedness' as 'Signed', 'Word length' as '16', 'Scaling' as 'Binary point', and 'Fraction length' as '0'. The 'Fixed-point details' section shows the following values:

Representable maximum:	32767	
Maximum:	50000	Outside representable range by 17233 (17233 x precision)
Minimum:	MySymbol	Cannot evaluate
Representable minimum:	-32768	
Precision:	1	

The 'Unit' is set to 'inherit' and the 'Limit range' shows a minimum of 'MySymbol' and a maximum of '50000'. A 'Refresh Details' button is visible next to the precision value.

The row labeled **Maximum** indicates that the value specified by the **Maximum** property is not representable by the fixed-point variable. To correct the issue, make one of these modifications so the fixed-point data type can represent the maximum value:

- Decrease the value in the **Maximum** property.
- Increase **Word length**.
- Decrease **Fraction length**.

The row labeled **Minimum** shows the message `Cannot evaluate` because evaluating the expression `MySymbol`, specified by the **Minimum** property, does not return a numeric value. When an

expression does not evaluate successfully, the **Fixed-point details** subpane shows the unevaluated expression (truncating to 10 characters as needed) in place of the unavailable value. To correct this issue, define `MySymbol` in the base workspace to provide a numeric value.

If you click **Refresh Details**, the issue indicator and description are removed and the value of `MySymbol` appears in place of the unevaluated text.

## Specify Data Types with Expressions

You can specify the types of MATLAB Function block variables as expressions by using the Model Explorer or the Property Inspector.

To use the Model Explorer, set the **Mode** property to `Expression`. In the **Type** property, replace `<data type expression>` with an expression that evaluates to a data type.

To use the Property Inspector, double-click the **Type** property, clear the contents, and enter an expression.

You can use the following expressions:

- Alias type from the MATLAB workspace, as described in `Simulink.AliasType`.
- `fixdt` function to create a `Simulink.NumericType` object describing a fixed-point or floating-point data type.
- `type` operator, to base the type on previously defined data.

For example, suppose you want to designate the workspace variable `myDataType` as an alias for a single data type to use as an expression in the **Type** property of an MATLAB Function block input variable. Create an instance of the `Simulink.AliasType` class and set its `BaseType` property by entering these commands:

```
myDataType = Simulink.AliasType;
myDataType.BaseType = "single";
```

In the Property Inspector, enter the data type alias name, `myDataType`, as the value in the **Type** property.

u	
Properties	Info
Scope	Input
Port	1
Size	-1
Type	myDataType

**Note** MATLAB Function blocks do not support code generation if one of the variables uses an alias type and is variable size. This limitation does not apply to input or output variables. For more information on defining variable-size variables and generating code with them, see “Declare Variable-Size MATLAB Function Block Variables” on page 49-76 and “Code Generation for Variable-Size Arrays” on page 58-2.

**See Also****MATLAB Function Block Editor****Related Examples**

- “Specify Size of MATLAB Function Block Variables” on page 49-52
- “Configure MATLAB Function Block Parameter Variables” on page 49-54
- “Create and Define MATLAB Function Block Variables” on page 49-31

## Specify Size of MATLAB Function Block Variables

### In this section...

“Inherit Size from Simulink” on page 49-52

“Customize Variable Sizes” on page 49-52

You can specify the size of the variables in MATLAB Function blocks with the **Symbols** pane and Property Inspector, or with the Model Explorer. MATLAB Function blocks can use scalars, vectors, or matrices. For more information about creating, deleting, and setting properties for variables, see “Create and Define MATLAB Function Block Variables” on page 49-31 and “Define and Modify Variable Data Types” on page 49-44. You can set a variable to inherit the size or manually specify the size.

### Inherit Size from Simulink

The size defaults to -1, which means that the variable inherits its size based on the value of the **Scope** property:

Scope	Description
Input	Inherits size from the Simulink signal connected to the associated input port.
Output	Inherits size from the Simulink signal connected to the associated output port.
Parameter	Inherits size from the associated Simulink or MATLAB parameter. See “Configure MATLAB Function Block Parameter Variables” on page 49-54.

Variables with the **Scope** property set to **Data Store Memory** always inherit their size.

### Customize Variable Sizes

You can also manually set the size of variables to a scalar, vector, or matrix. To specify the size as a scalar, set **Size** to 1 or clear the parameter. To specify the size as a vector or a matrix, enter a row vector with positive integers in `[row column]` format. For example, to define a column vector of size 6, set the **Size** property to `[6 1]`. To define a row vector of size 5, set the **Size** property to `[1 5]`. To define a matrix of data size 3-by-3, set the **Size** property to `[3 3]`.

**Note** Prior to R2021b, MATLAB Function blocks output column vectors as one-dimensional data. In R2021b and later, MATLAB Function blocks retain their dimensionality by default. To maintain the old behavior, clear the **Interpret output column vectors as one-dimensional data** property in the Property Inspector or Model Explorer. Once you clear this property, you can then use a single integer in **Size** to define the size of an output column vector size. See “Interpret output column vectors as one-dimensional data” on page 49-37.

You can also set the **Size** property with an expression. The expressions can include:

- Numeric constants

- Arithmetic operators, restricted to +, -, \*, and /
- Names of variables with the **Scope** property set to **Parameter**
- Calls to the MATLAB functions `min`, `max`, and `size`

These expressions must output a positive integer or two positive integers entered in [row column] format. Otherwise, the specified size produces an error at model compilation. For example, consider a MATLAB Function block with variables `k`, `x`, and `y` that all have the **Scope** property set to **Parameter**. Here, `k` is a positive integer and `x` and `y` are matrices. If you create new variables for the block, you can define the **Size** property with any of the following expressions:

```
k+1  
size(x)  
min(size(y))
```

### Simulation and Size Matching

After you build the model, the **CompiledSize** column in the Model Explorer displays the actual size used in the simulation. If the value of the **Size** property is not -1 and does not match the actual size, a mismatch error occurs during model compilation.

### See Also

**MATLAB Function Block Editor**

### More About

- “Configure MATLAB Function Block Parameter Variables” on page 49-54
- “Define and Modify Variable Data Types” on page 49-44

## Configure MATLAB Function Block Parameter Variables

You can use parameter variables in MATLAB Function blocks to use variables defined in the MATLAB workspace, model workspace, a masked subsystem workspace, or a Simulink data dictionary as input arguments. Simulink searches for and selects variables used by parameter variables by using the same rules for symbol resolution. See “Symbol Resolution” on page 72-126. If a variable of the same name exists in more than one of the workspaces visible to the block, the block uses the variable closest to the block in the workspace hierarchy. If the MATLAB Function block is in a masked subsystem, the block uses the variable in the subsystem workspace. Otherwise, the block uses the variable in the model workspace, followed by using the variable in the MATLAB base workspace and in an associated Simulink data dictionary, in that order.

To define parameter variables, use the **Symbols** pane, Property Inspector, or the Model Explorer. Set the **Scope** property of the selected variable to **Parameter**. Parameter variables do not create block ports. For more information about defining variables in MATLAB Function blocks, see “Create and Define MATLAB Function Block Variables” on page 49-31.

### Control Parameter Variables with Masks

You can directly assign values to parameter variables in a MATLAB Function block by adding a mask to the block, creating a parameter in the mask, and giving the parameter the same name as the parameter variable. For more information about creating masks for blocks, see “Masking Fundamentals” on page 42-3. After you mask the block, you can adjust the parameter variable properties by using the Property Inspector.

#### Adjust Parameter Variable Example

This example uses a masked MATLAB Function block with a parameter variable.

The MATLAB function multiplies the parameter variable `const` by the value of the Sine Wave block signal. Click the arrow icon on the MATLAB Function block to view the code.

```
function y = fcn(u, const)
y = const*u;
```

You can adjust the value of `const` by double-clicking the MATLAB Function block. The block mask defines the **Set sine wave multiplier** parameter, which you can edit in the Mask Editor. The

MATLAB Function block defines `const` as data with **Scope** set to **Parameter** in the Property Inspector. You can see this property in the Property Inspector when you select `const` in the **Symbols** pane.

The parameter variable and the mask parameter must have the same name. In this example, changing the parameter variable name without changing the mask parameter name causes an error. If you are using a non-tunable parameter, ensure that the **Tunable** property is cleared in the Property Inspector.

## Control Parameter Variables in Workspaces

If you want multiple MATLAB Function blocks to access the same variable in a model, you can define the variable in the model workspace and add parameter variables to each MATLAB function that points to that variable. You can define the variable directly in the model workspace, load the variable in a MAT-file or MATLAB file, or create the variable with custom MATLAB code. For more information, see “Specify Source for Data in Model Workspace” on page 72-115.

If you want to use the variable in MATLAB Function blocks in multiple models, you can define the variable in the MATLAB base workspace by defining the variable in the Command Window or by

loading a MAT-file. MATLAB Function blocks access variables defined in the MATLAB workspace until you close MATLAB.

You can also define variables using a Simulink data dictionary. For more information, see “What Is a Data Dictionary?” on page 79-2.

## Resolve Signal Objects for Output Variables

### In this section...

“Implicit Signal Resolution” on page 49-57

“Eliminating Warnings for Implicit Signal Resolution in the Model” on page 49-57

“Disabling Implicit Signal Resolution for a MATLAB Function Block” on page 49-57

“Forcing Explicit Signal Resolution for an Output Signal” on page 49-57

### Implicit Signal Resolution

MATLAB Function blocks participate in signal resolution with Simulink signal objects. By default, output variables from MATLAB Function blocks become associated with Simulink signal objects of the same name during a process called *implicit signal resolution*.

By default, implicit signal resolution generates a warning when you update the chart in the Simulink model. The following sections show you how to manage implicit signal resolution at various levels of the model hierarchy. See “Symbol Resolution” on page 72-126 and “Explicit and Implicit Symbol Resolution” on page 72-128 for more information.

### Eliminating Warnings for Implicit Signal Resolution in the Model

To enable implicit signal resolution for all signals in a model, but eliminate the attendant warnings, follow these steps:

- 1 In the Simulink Editor, in the **Modeling** tab, click **Model Settings**.  
The Configuration Parameters dialog appears.
- 2 In the left pane of the Configuration Parameters dialog, under Diagnostics, select **Data Validity**.  
Data Validity configuration parameters appear in the right pane.
- 3 In the Signal resolution field, select **Explicit and implicit**.

### Disabling Implicit Signal Resolution for a MATLAB Function Block

To disable implicit signal resolution for a MATLAB Function block in your model, follow these steps:

- 1 In the Simulink Editor, in the **Modeling** tab, click **Model Settings**.  
The Configuration Parameters dialog appears.
- 2 In the left pane of the Configuration Parameters dialog, under Diagnostics, select **Data Validity**.  
Data Validity configuration parameters appear in the right pane.
- 3 In the Signal resolution field, select **Explicit only** or **None**.

### Forcing Explicit Signal Resolution for an Output Signal

To force signal resolution for an output signal in a MATLAB Function block, follow these steps:

- 1** In the Simulink model, right-click the signal line connected to the output that you want to resolve and select **Properties** from the context menu.
- 2** In the Signal Properties dialog, enter a name for the signal that corresponds to the signal object.
- 3** Select the **Signal name must resolve to Simulink signal object** check box and click **OK**.

## Types of Structures in MATLAB Function Blocks

In MATLAB Function blocks, you can define structure data as inputs or outputs that interact with bus signals. MATLAB Function blocks also support arrays of buses. You can also define structures inside MATLAB functions that are not part of MATLAB Function blocks.

The following table summarizes how to create different types of structures in MATLAB Function blocks:

Scope	How to Create	Details
Input	Create structure data with scope of <b>Input</b> .	You can create structure data as inputs or outputs in the top-level MATLAB function for interfacing to other environments. See “Create Structures in MATLAB Function Blocks” on page 49-68.
Output	Create structure data with scope of <b>Output</b> .	
Local	Create a local variable implicitly in a MATLAB function.	See “Define Scalar Structures for Code Generation” on page 59-4.
Persistent	Declare a variable to be persistent in a MATLAB function.	See <b>persistent</b> .
Parameter	Create structure data with scope of <b>Parameter</b> .	See “Define and Use Structure Parameters” on page 49-74.

Structures in MATLAB Function blocks can contain fields of any type and size, including mux signals, buses, and arrays of structures.

## Attach Bus Signals to MATLAB Function Blocks

### Structures in a MATLAB Function Block

This example shows how to use structures in a MATLAB Function block to read and write to Simulink® bus signals.

In this model, a MATLAB Function block receives a bus signal using the structure `inbus` at input port 1. The block outputs two bus signals: structure `outbus` at output port 1 and structure `outbus1` at output port 2. The input signal comes from the Bus Creator block `MainBusCreator`, which bundles signals `ele1`, `ele2`, and `ele3`. The signal `ele3` is the output of another Bus Creator block `SubBusCreator`, which bundles the signals `a1` and `a2`. The structures `outbus` and `outbus1` connect to Bus Selector blocks that, in turn, connect to Display blocks.

To explore the MATLAB function `fcn`, double-click the MATLAB Function block. Notice that the code implicitly defines a local structure variable `mystruct` using the `struct` function, and uses this local structure variable to initialize the value of the first output, `outbus`. It initializes the second output, `outbus1`, to the value of field `ele3` of structure `inbus`.

### Structure Definitions in Example

Here are the definitions of the structures in the MATLAB Function block in the example, as they appear in the **Symbols** pane and the Property Inspector:

## Bus Objects Define Structure Inputs and Outputs

Each structure input and output must be defined by a `Simulink.Bus` object in the base workspace. See “Create Structures in MATLAB Function Blocks” on page 49-68. This means that the structure shares the same properties as the bus object, including number, name, type, and sequence of fields. In this example, the following bus objects define the structure inputs and outputs:

Name	Data Type	Complexity	Dimensions	Dimensionality
ele1	double	real	1	Fixed
ele2	single	real	1	Fixed
ele3(SubBus)	SubBus	real	1	Fixed

The Simulink.Bus object MainBus defines structure input inbus and structure output outbus. The Simulink.Bus object SubBus defines structure output outbus1. Based on these definitions, inbus and outbus have the same properties as MainBus and, therefore, reference their fields by the same names as the fields in MainBus, using dot notation (see “Index Substructures and Fields” on page 49-67). Similarly, outbus1 references its fields by the same names as the fields in SubBus. Here are the field references for each structure in this example:

Structure	First Field	Second Field	Third Field
inbus	inbus.ele1	inbus.ele2	inbus.ele3
outbus	outbus.ele1	outbus.ele2	outbus.ele3
outbus1	outbus1.a1	outbus1.a2	—

### Write Buses From Data Store Memory to a MATLAB Function Block

This example shows how to use bus data stored in a data store as an input to a MATLAB Function block.

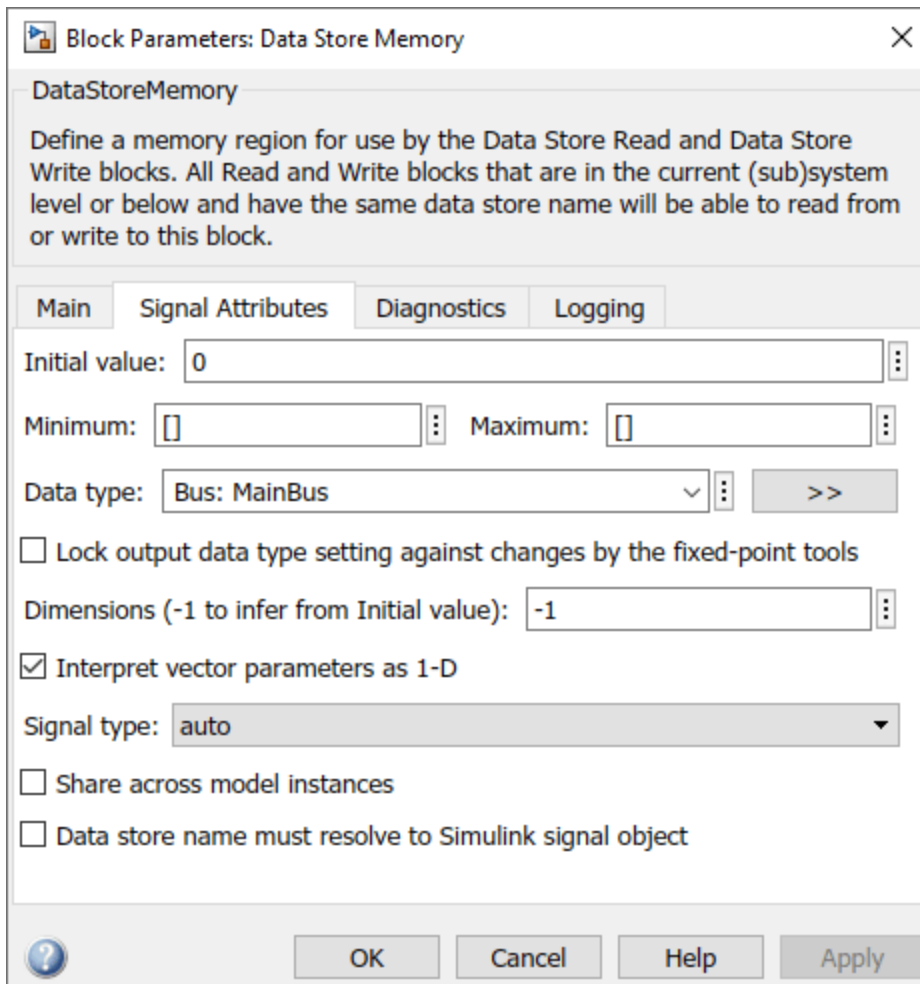

## Capture the Bus Data in a Data Store Memory Block

In this example, the Bus Creator block `MainBusCreator` creates a bus called `MainBus` because the **Output data type** parameter is `Bus: MainBus`. The Data Store Write block then writes the bus data to a data store named `inbus`, which the **Data store name** parameter specifies.

To store the bus data from the Data Store Write block, the model includes a Data Store Memory block. In the Data Store Memory block, the **Data store name** parameter is `inbus`, the name of the data store defined by the Data Store Write block. The **Data type** parameter is `Bus: MainBus`, the data type specified by the `MainBusCreator` block.

## Define the Data Store Memory Variable

To capture the data store in a variable, the MATLAB Function block uses variables that have the **Scope** property set to `Data Store Memory`. The function then defines the variable as a global variable with the name of the data store, which is `inbus`. Double-click the MATLAB Function block to examine the code.

```
function [outbus, outbus1] = fcn
global inbus;
```

```
substruct.a1 = inbus.ele3.a1;
substruct.a2 = int8([1 2;3 4]);

mystruct = struct('ele1',20.5, 'ele2', single(100), 'ele3', substruct);

outbus = mystruct;
outbus.ele3.a2 = 2*(substruct.a2);

outbus1 = inbus.ele3;
```

You can adjust the properties of the data store memory variable in the **Symbols** pane, Property Inspector, or the Model Explorer.

## How Structure Inputs and Outputs Interface with Bus Signals

Buses in a Simulink model appear inside the MATLAB Function block as structures; structure outputs from the MATLAB Function block appear as buses in Simulink models. When you create structure inputs, the MATLAB Function block determines the type, size, and complexity of the structure from the input signal. When you create structure outputs, you must define their type, size, and complexity in the MATLAB function.

You connect structure inputs and outputs from MATLAB Function blocks to any bus signal, including:

- Blocks that output bus signals — such as Bus Creator blocks
- Blocks that accept bus signals as input — such as Bus Selector and Gain blocks
- S-Function blocks
- Other MATLAB Function blocks

You can use global bus type data in Data Store Memory blocks with MATLAB Function blocks. For more information on using buses and Data Store Memory, see “Data Stores with Buses and Arrays of Buses” on page 78-22.

### Working with Virtual and Nonvirtual Buses

MATLAB Function blocks supports nonvirtual buses only (see “Composite Interface Guidelines” on page 81-2). For MATLAB Function block bus inputs, incoming virtual bus signals are converted to nonvirtual buses.

## Rules for Defining Structures in MATLAB Function Blocks

Follow these rules when defining structures in MATLAB Function blocks:

- For each structure input or output in a MATLAB Function block, you must define a `Simulink.Bus` object in the base workspace to specify its type.
- MATLAB Function blocks support nonvirtual bus outputs but do not support virtual bus outputs.

## Index Substructures and Fields

As in MATLAB, you index substructures and fields structures in MATLAB Function blocks by using dot notation. However, for code generation from MATLAB, you must reference field values individually (see “Structure Definition for Code Generation” on page 59-2).

For example, in the “Structures in a MATLAB Function Block” on page 49-60 example, the MATLAB function uses dot notation to index fields and substructures:

```
function [outbus, outbus1] = fcn(inbus)
%#codegen
substruct.a1 = inbus.ele3.a1;
substruct.a2 = int8([1 2;3 4]);

mystruct = struct('ele1',20.5,'ele2',single(100),
                 'ele3',substruct);

outbus = mystruct;
outbus.ele3.a2 = 2*(substruct.a2);

outbus1 = inbus.ele3;
```

The following table shows how the code generation software resolves symbols in dot notation for indexing elements of the structures in this example:

Dot Notation	Symbol Resolution
substruct.a1	Field a1 of local structure substruct
inbus.ele3.a1	Value of field a1 of field ele3, a substructure of structure inputinbus
inbus.ele3.a2(1,1)	Value in row 1, column 1 of field a2 of field ele3, a substructure of structure input inbus

## Create Structures in MATLAB Function Blocks

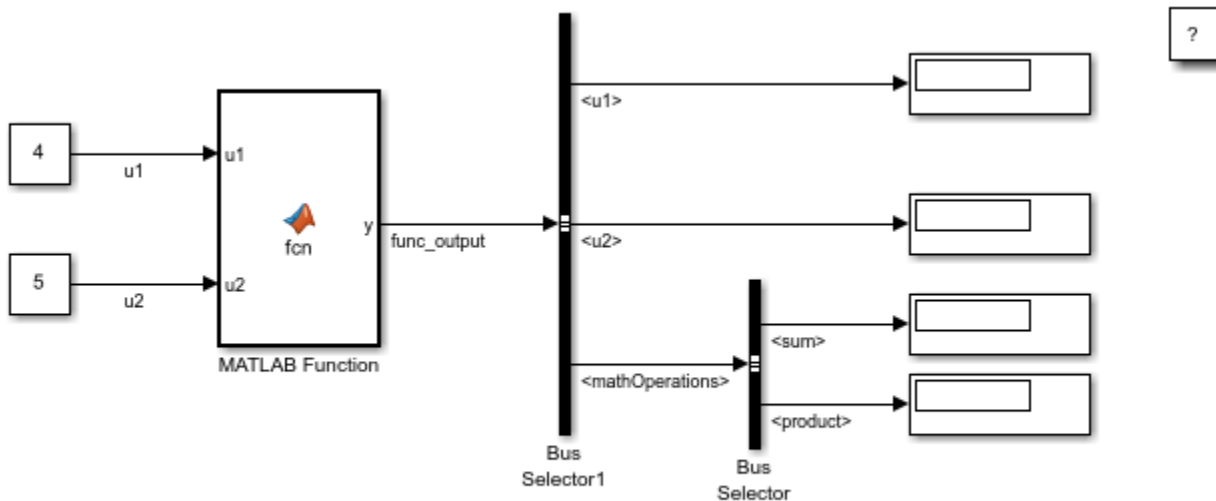

Here is the workflow for creating a structure in a MATLAB Function block:

- 1 Decide on the type (or scope) of the structure (see “Types of Structures in MATLAB Function Blocks” on page 49-59).
- 2 Based on the scope, follow these guidelines for creating the structure:

For Structure Scope:	Follow These Steps:
Input	<p><b>a</b> Create a <code>Simulink.Bus</code> object in the base workspace to define the structure input.</p> <p><b>b</b> Add data to the MATLAB Function block, as described in “Create and Define MATLAB Function Block Variables” on page 49-31. The data should have the following properties</p> <ul style="list-style-type: none"> <li>• <b>Scope</b> = Input</li> <li>• <b>Type</b> = Bus: &lt;object name&gt;</li> </ul> <p>For &lt;object name&gt;, enter the name of the <code>Simulink.Bus</code> object that defines the structure input</p> <p>See “Rules for Defining Structures in MATLAB Function Blocks” on page 49-66.</p>
Output	<p><b>a</b> Create a <code>Simulink.Bus</code> object in the base workspace to define the structure output.</p> <p><b>b</b> Add data to the MATLAB Function block with the following properties:</p> <ul style="list-style-type: none"> <li>• <b>Scope</b> = Output</li> <li>• <b>Type</b> = Bus: &lt;object name&gt;</li> </ul> <p>For &lt;object name&gt;, enter the name of the <code>Simulink.Bus</code> object that defines the structure output</p> <p><b>c</b> Define and initialize the output structure implicitly as a variable in the MATLAB function, as described in “Structure Definition for Code Generation” on page 59-2.</p> <p><b>d</b> Make sure the number, type, and size of fields in the output structure variable definition match the properties of the <code>Simulink.Bus</code> object.</p>
Local	Define the structure implicitly as a local variable in the MATLAB function, as described in “Structure Definition for Code Generation” on page 59-2. By default, local variables in MATLAB Function blocks are temporary.
Persistent	Define the structure implicitly as a persistent variable in the MATLAB function.
Parameter	<p><b>a</b> Create a structure variable in the base workspace.</p> <p><b>b</b> Add data to the MATLAB Function block with the following properties:</p> <ul style="list-style-type: none"> <li>• <b>Name</b> = same name as the structure variable you created in step 1.</li> <li>• <b>Scope</b> = Parameter</li> </ul> <p>See “Define and Use Structure Parameters” on page 49-74.</p>

## Use Nonvirtual Buses with MATLAB Function Blocks

In this example model, the MATLAB Function block includes MATLAB code that creates a structure. If a MATLAB Function block outputs a structure, then you must use a Simulink.Bus object to define the bus output.

Copyright 2017-2019 The MathWorks, Inc.

To see the structure definition, double-click the MATLAB Function block.

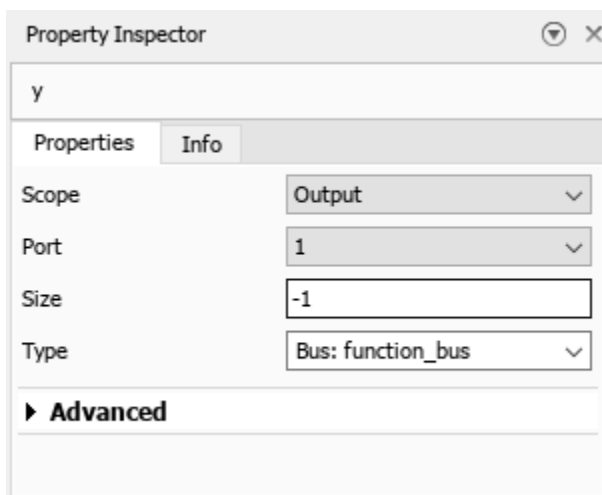

```
function y = fcn(u1,u2)

y.u1 = u1;
y.u2 = u2;
y.mathOperations.sum = u1+u2;
y.mathOperations.product = u1*u2;
```

Open the Type Editor and expand the Bus object definition that represents the structure.

Name	Type
function_bus	
u1	double
u2	double
mathOperations	<b>Bus: subBus</b>
sum	double
product	double
subBus	
sum	double
product	double

To see how the Bus object defines the bus output for the MATLAB Function block, in the MATLAB Function block, in the Function tab, click **Edit Data**. In the **Symbols** pane, click **y**. The output **Type** is defined as the Bus object named `function_bus` in the Property Inspector.

## Assign Values to Structures and Fields

You can assign values to any structure, substructure, or field in a MATLAB Function block. Here are the guidelines:

Operation	Conditions
Assign one structure to another structure	You must define each structure with the same number, type, and size of fields, either as <code>Simulink.Bus</code> objects in the base workspace or locally as implicit structure declarations (see “Create Structures in MATLAB Function Blocks” on page 49-68).
Assign one structure to a substructure of a different structure and vice versa	You must define the structure with the same number, type, and size of fields as the substructure, either as <code>Simulink.Bus</code> objects in the base workspace or locally as implicit structure declarations.
Assign an element of one structure to an element of another structure	The elements must have the same type and size.

For example, the following table presents valid and invalid structure assignments based on the specifications for the model described in “Attach Bus Signals to MATLAB Function Blocks” on page 49-60:

Assignment	Valid or Invalid?	Rationale
<code>outbus = mystruct;</code>	Valid	Both <code>outbus</code> and <code>mystruct</code> have the same number, type, and size of fields. The structure <code>outbus</code> is defined by the <code>Simulink.Bus</code> object <code>MainBus</code> and <code>mystruct</code> is defined locally to match the field properties of <code>MainBus</code> .
<code>outbus = inbus;</code>	Valid	Both <code>outbus</code> and <code>inbus</code> are defined by the same <code>Simulink.Bus</code> object, <code>MainBus</code> .
<code>outbus1 = inbus.ele3;</code>	Valid	Both <code>outbus1</code> and <code>inbus.ele3</code> have the same type and size because each is defined by the <code>Simulink.Bus</code> object <code>SubBus</code> .
<code>outbus1 = inbus;</code>	Invalid	The structure <code>outbus1</code> is defined by a different <code>Simulink.Bus</code> object than the structure <code>inbus</code> .

## Initialize Matrix Using a Nontunable Structure Parameter

This example shows how to use a nontunable structure parameter input to output a matrix in a MATLAB Function block. Open the model, `matrix_struct_param_model`.

In this example, the model uses a pre-load callback that defines a structure, `p`, in the base workspace. `p` has two fields, `rows` and `cols`. To view the callback, in the **Modeling** tab, click **Model Settings > Model Properties**. In the **Callbacks** tab, click **PreLoadFcn**.

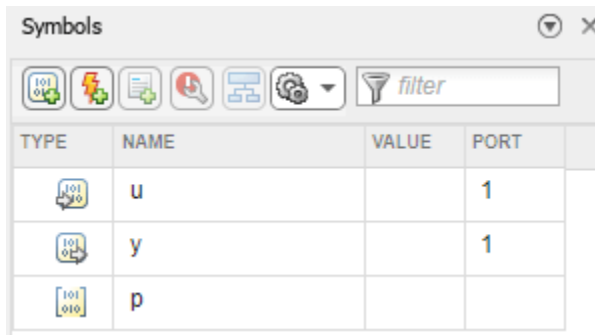

### View the MATLAB Function Block and Variable Properties

Open the MATLAB Function block. The function uses the block input `u` and the parameter `p` to define the matrix output `y`. The function adds the value of the input variable `u` to each element of an empty matrix with a size determined by the fields of `p`. The function uses this MATLAB code:

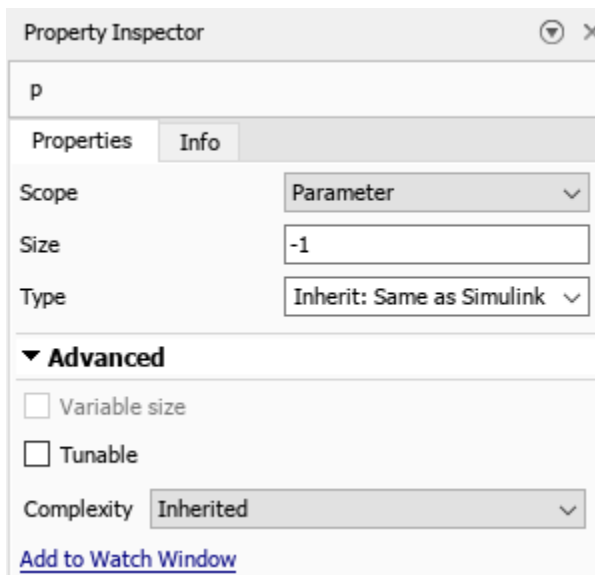

```
function y = fcn(u, p)
y = zeros(p.rows,p.cols) + u;
```

In the **Function** tab, click **Edit Data** to open the Property Inspector and the **Symbols** pane. `p` is a parameter variable, and therefore does not have a port. See “Configure MATLAB Function Block Parameter Variables” on page 49-54. Instead, it uses the values from the base workspace variable `p` defined in the callback.

TYPE	NAME	VALUE	PORT
	u		1
	y		1
	p		

Click p to view the properties in the Property Inspector. The Scope property of p is Parameter and the **Tunable** property is cleared.

Property Inspector

p

Properties Info

Scope Parameter

Size -1

## Define and Use Structure Parameters

### In this section...

“Defining Structure Parameters” on page 49-74

“FIMATH Properties of Nontunable Structure Parameters” on page 49-74

### Defining Structure Parameters

To define structure parameters in MATLAB Function blocks, follow these steps:

- 1 Define and initialize a structure variable

A common method is to create a structure in the base workspace.

- 2 Use the **Symbols** pane and the Property Inspector to add data in the MATLAB Function block with the following properties:

Property	What to Specify
Name	Enter same name as the structure variable you defined in the base workspace
Scope	Select Parameter
Tunable	Leave checked if you want to change (tune) the value of the parameter during simulation; otherwise, clear to make the parameter nontunable and preserve the initial value during simulation
Type	Select Inherit: Same as Simulink

### FIMATH Properties of Nontunable Structure Parameters

FIMATH properties for nontunable structure parameters containing fixed-point values are based on the initial values of the structure. They do *not* come from the FIMATH properties specified for fixed-point input signals to the parent MATLAB Function block. (These FIMATH properties appear in the properties dialog box for MATLAB Function blocks.)

## Limitations of Structures and Buses in MATLAB Function Blocks

- Structures in MATLAB Function blocks support a subset of the operations available for MATLAB structures (see “Structures”).
- You cannot use structures that contain cell arrays or classes for Simulink signals, parameters, or data store memory.
- You cannot use variable-size data with arrays of buses (see “Group Nonvirtual Buses in Arrays of Buses” on page 81-71).

### See Also

MATLAB Function

## Declare Variable-Size MATLAB Function Block Variables

MATLAB Function blocks support variables that change size during simulation if the **Support variable-size array** block property is enabled. See “Support variable-size arrays” on page 49-37. However, only variables that you specify as variable size can change in size during simulation. Depending on the scope, you can set variables as variable size by using the **MATLAB Function Block Editor**, by using the `coder. varsize` function, or by inheriting size variability from the connected block signal. For more information about scope, see “Scope” on page 49-32.

### Output Variables

By default, output variables are not variable size. To specify an output as variable size:

- 1 Double-click the MATLAB Function block to open the **MATLAB Function Block Editor**.
- 2 Open the **Symbols** pane and the Property Inspector. In the **Function** tab, click **Edit Data**.
- 3 In the **Symbols** pane, select the output variable.
- 4 In the Property Inspector, in the **Properties** tab, select the **Variable size** property.
- 5 In the **Size** property, specify the size as the upper bound. For example, to specify a 2-by-4 matrix as the largest acceptable size, enter [2 4]. See “Customize Variable Sizes” on page 49-52.

### Other Scope Types

Input variables inherit size from their attached signals. Therefore, you do not explicitly define input variables as variable size. Input variables can also be unbounded. For more information on creating variable-size signals, see “Variable-Size Signal Basics” on page 82-2.

If the variable is not an input or output variable, define the variable by using the `coder. varsize` function. See “Define Variable-Size Data Explicitly by Using `coder. varsize`” on page 58-11.

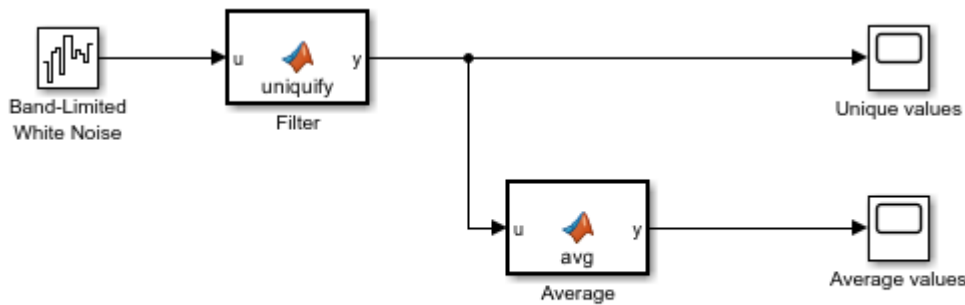

### Use a Variable-Size Signal in a Filtering Algorithm

This example uses a variable-size vector to store the values of a white noise signal.

The size of the vector can vary at run time because the functions prune the signal values by:

- Filtering out signal values that are not unique to within a specified tolerance of each other.
- Averaging every two signal values and outputting only the resulting means.

In this model, a Band-Limited White Noise block generates a set of normally distributed random values as the source of a white noise signal. The MATLAB Function block `Filter` filters out signal values that are not unique to within a specified tolerance of each other. Then, the MATLAB Function block `Average` outputs the average of a specified number of unique signal values. The Scope blocks display the output from the `Filter` and `Average` blocks. Open the model to see the configuration.

Copyright 2009-2021 The MathWorks, Inc.

### Inspect the Source Signal

Open the Band-Limited White Noise block to view the properties of the source signal. The size of the **Noise power** parameter defines the size of the array that holds the signal values. This array is a 1-by-9 vector of double values.

**Parameters**

**Noise power:**

**Sample time:**

**Seed:**

Interpret vector parameters as 1-D

### Inspect the Filter MATLAB Function Block

Open Filter to inspect the filtering function. Filter filters out unique signal values that are not within a tolerance of 0.2 of each other. The function calls an external MATLAB® function file, `emldemo_uniquetol.m`, to filter the signal values. The function passes the 1-by-9 vector of white noise signal values as the first argument and the tolerance value as the second argument.

```
function y = uniquify(u)
y = emldemo_uniquetol(u,0.2);
```

Open the MATLAB function file `emldemo_uniquetol.m` to view the code for the external function, `emldemo_uniquetol`. `emldemo_uniquetol` returns the filtered values of `A` in an output vector `B` so that  $\text{abs}(B(i) - B(j)) > \text{tol}$  for all  $i$  and  $j$ .

```
function B = emldemo_uniquetol(A,tol)
%#codegen

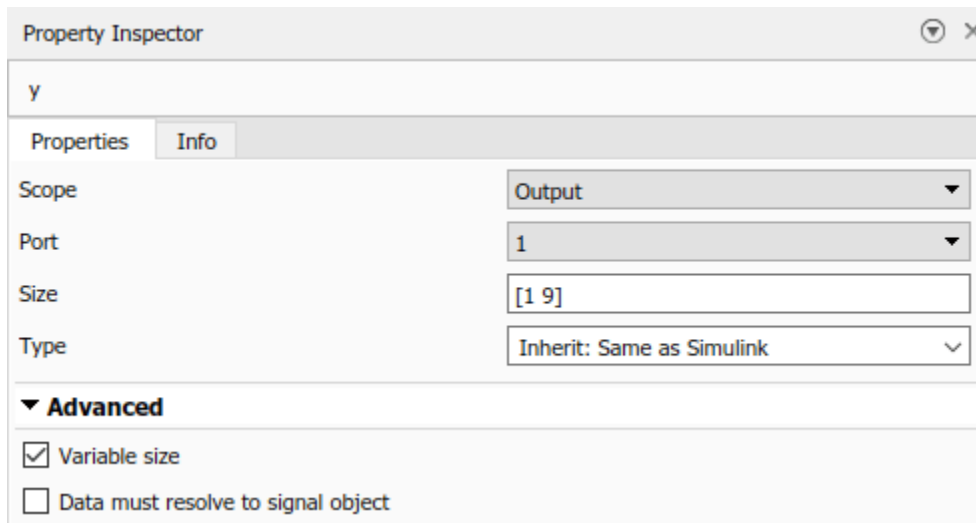

A = sort(A);
B = A(1);
```

```

k = 1;
for i = 2:length(A)
    if abs(A(k) - A(i)) > tol
        B = [B A(i)];
        k = i;
    end
end
end

```

At each time step, the Band-Limited White Noise block generates a different set of random values for A, and `emldemo_uniquetol` may produce a different number of output signals in B. Therefore, y must be variable size. In order for y to be variable size, you must enable the **Variable size** property. In this example, **Variable size** is enabled for y. In Filter, open the **Symbols** pane and Property Inspector. In the **Function** tab, click **Edit Data**. In the **Symbols** pane, click y to view the properties in the Property Inspector. For variable-size outputs, you must specify the **Size** property as the maximum-size upper bound. In the example, **Size** is [1 9].

### Inspect the Average MATLAB Function Block

Average averages the values filtered by Filter by following these conditions:

- If the number of signals is greater than 1 and divisible by 2, then Average averages every consecutive pair of values.
- If the number of signals is greater than 1 but not divisible by 2, then Average drops the first value and averages the remaining consecutive pairs.
- If there is exactly one signal, then Average returns the value unchanged.

Open Average to view the code.

```

function y = avg(u)
if numel(u) == 1
    y = u;
else
    k = numel(u)/2;
    if k ~= floor(k)
        u = u(2:numel(u));
    end
end

```

```
    y = emldemo_navg(u,2);  
end
```

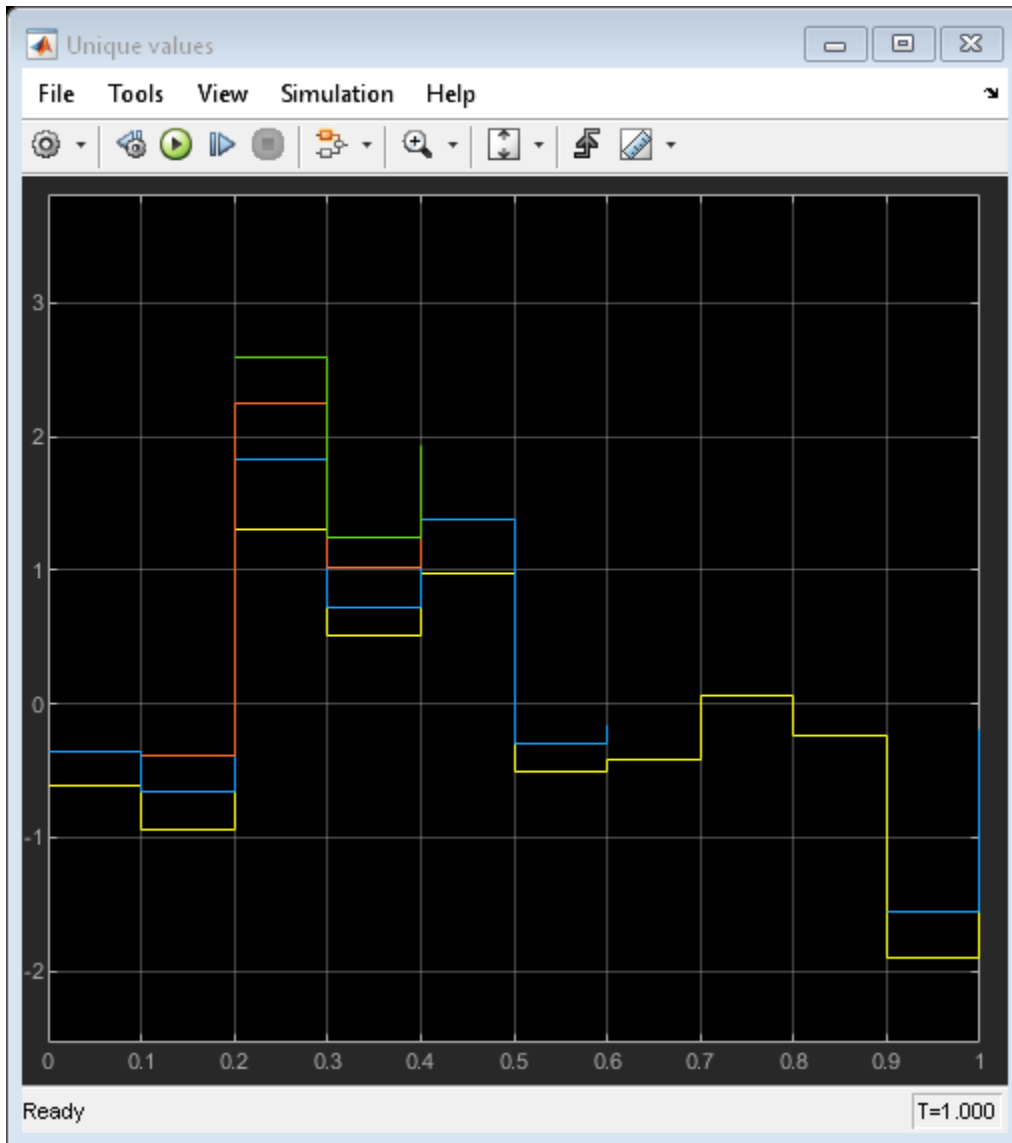

The `avg` function calls the external MATLAB function `emldemo_navg` to calculate the average of every two consecutive signal values.

```
function B = emldemo_navg(A,n)  
%#codegen  
  
assert(n>=1 && n<=numel(A));  
  
B = zeros(1,numel(A)/n);  
k = 1;  
for i = 1 : numel(A)/n  
    B(i) = mean(A(k + (0:n-1)));  
    k = k + n;  
end
```

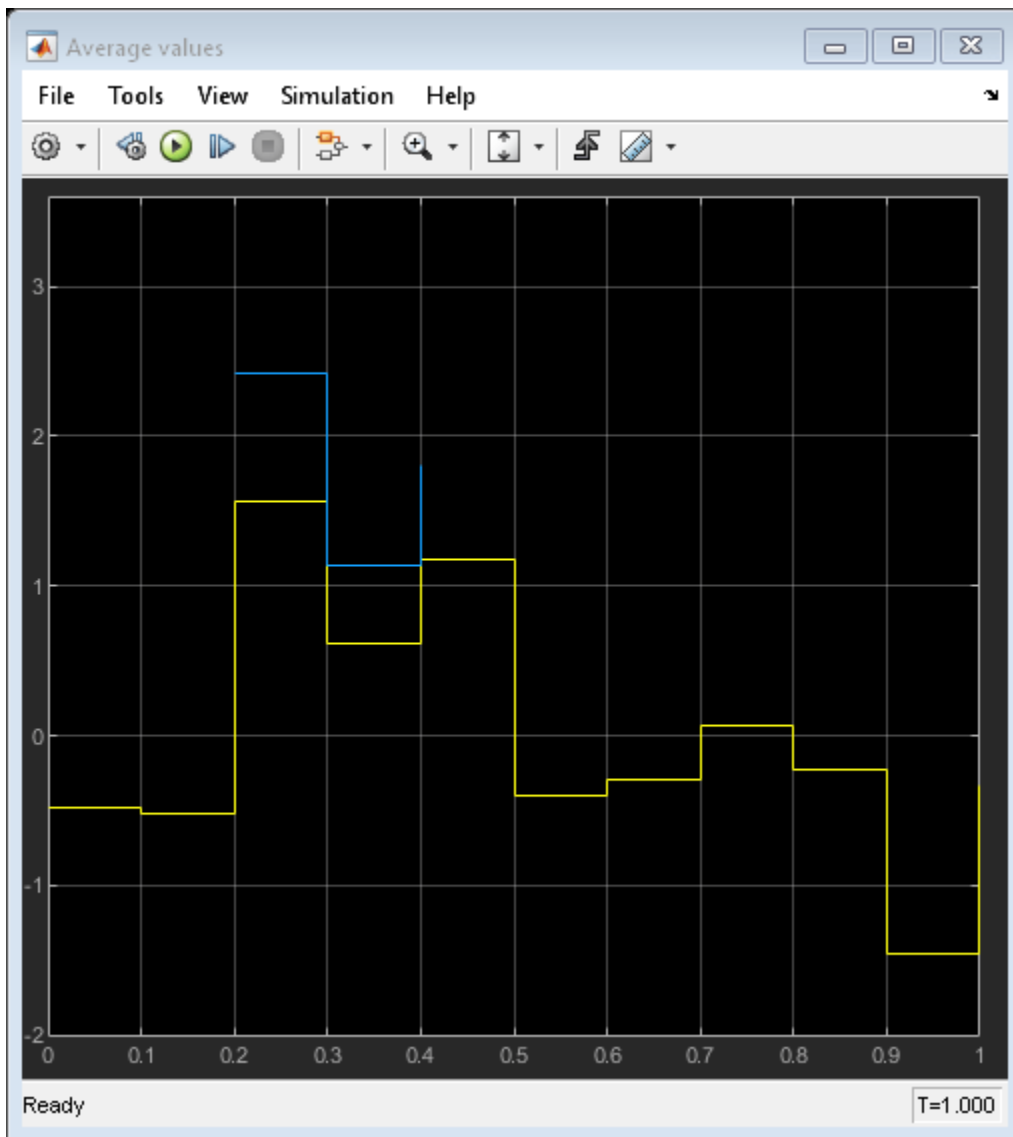

Both `u` and `y` are variable size. You do not need to explicitly define `u` as variable size, because `u` is an input. The output `y` is declared as a variable-size vector because the number of elements varies depending on the size provided by `u`. Inspect the properties of `y` to confirm that it is variable size.

### Simulate the Model

Simulate the model to view the results in each Scope block. `Filter` outputs a variable number of signal values each time it executes.

Average outputs a variable number of signal values each time it executes. The block returns approximately half the number of the unique values.

## Control Memory Allocation for Variable-Size Arrays in a MATLAB Function Block

Dynamic memory allocation allocates memory on the heap as needed at run time, instead of allocating memory statically on the stack. You can use dynamic memory allocation for arrays inside a MATLAB Function block.

You cannot use dynamic memory allocation for:

- Input and output signals. Variable-size input and output signals must have an upper bound.
- Parameters or global variables. Parameters and global variables must be fixed-size.
- Fields of bus arrays. Bus arrays cannot have variable-size fields.
- Discrete state properties of System objects associated with a MATLAB System block.

Dynamic memory allocation is beneficial when:

- You do not know the upper bound of an array.
- You do not want to allocate memory on the stack for large arrays.

Dynamic memory allocation and the freeing of this memory can result in slower execution of the generated code. To control the use of dynamic memory allocation for variable-size arrays in a MATLAB Function block, you can:

- Provide upper bounds for variable-size arrays on page 49-82.
- Disable dynamic memory allocation for MATLAB Function blocks on page 49-82.
- Modify the dynamic memory allocation threshold on page 49-82.

### Provide Upper Bounds for Variable-Size Arrays

For an unbounded variable-size array, the code generator allocates memory dynamically on the heap. For a bounded variable-size array, if the size, in bytes, is less than the dynamic memory allocation threshold, the code generator allocates memory statically on the stack. To avoid dynamic memory allocation, provide upper bounds for the array dimensions so that the size of the array, in bytes, is less than the dynamic memory allocation threshold. See “Specify Upper Bounds for Variable-Size Arrays” on page 58-7.

### Disable Dynamic Memory Allocation for MATLAB Function Blocks

By default, dynamic memory allocation for MATLAB Function blocks is enabled for GRT-based targets and disabled for ERT-based targets. To change the setting, in the Configuration Parameters dialog box, clear or select **Dynamic memory allocation in MATLAB functions**.

If you disable dynamic memory allocation, you must provide upper bounds for variable-size arrays.

### Modify the Dynamic Memory Allocation Threshold

Instead of disabling dynamic memory allocation for all variable-size arrays, you can use the dynamic memory allocation threshold to specify when the code generator uses dynamic memory allocation.

Use the dynamic memory allocation threshold to:

- Disable dynamic memory allocation for smaller arrays. For smaller arrays, static memory allocation can speed up generated code. However, static memory allocation can lead to unused storage space. You can decide that the unused storage space is not a significant consideration for smaller arrays.
- Enable dynamic memory allocation for larger arrays. For larger arrays, when you use dynamic memory allocation, you can significantly reduce storage requirements.

The default value of the dynamic memory allocation threshold is 64 kilobytes. To change the threshold, in the Configuration Parameters dialog box, set the **Dynamic memory allocation threshold in MATLAB functions** parameter.

To use dynamic memory allocation for all variable-size arrays, set the threshold to 0.

- “Use Dynamic Memory Allocation for Variable-Size Arrays in a MATLAB Function Block” on page 49-84

## Use Dynamic Memory Allocation for Variable-Size Arrays in a MATLAB Function Block

This example shows how to use dynamic memory allocation for variable-size arrays in a MATLAB Function block. Dynamic memory allocation allocates memory on the heap as needed at run time, instead of allocating memory statically on the stack. Dynamic memory allocation is beneficial when:

- You do not know the upper bound of an array.
- You do not want to allocate memory on the stack for large arrays.

You can use dynamic memory allocation only for arrays that are local to the MATLAB Function block.

You cannot use dynamic memory allocation for:

- Input and output signals. Variable-size input and output signals must have an upper bound.
- Parameters or global variables. Parameters and global variables must be fixed-size.
- Fields of bus arrays. Bus arrays cannot have variable-size fields.
- Discrete state properties of System objects associated with a MATLAB System block.

### Create Model

Create this Simulink model that has a MATLAB Function block with an unbounded variable-size array.

- 1 Create a Simulink model `mymodel`.
- 2 Add a MATLAB Function block to the model.
- 3 In the MATLAB Function block, add this code:

```
function s = myfcn(n)
Z = rand(1,n);
s = sum(Z);
end
```

- 4 Add a Constant block to the left of the MATLAB Function block.
- 5 Add an Outport block to the right of the MATLAB Function block.
- 6 Connect the blocks.

### Configure Model for Dynamic Memory Allocation

Make sure that you configure the model to use dynamic memory allocation for variable-size arrays in MATLAB Function blocks. In the Configuration Parameters dialog box, in the **Simulation Target > Advanced parameters** category, make sure that:

- The **Dynamic memory allocation in MATLAB functions** check box is selected.
- The **Dynamic memory allocation threshold in MATLAB functions** parameter has the default value 65536.

## Simulate Model Using Dynamic Memory Allocation

- 1 Simulate the model.
- 2 In the MATLAB Function Editor, to open the MATLAB function report, click **Function Report**.

The variables tab shows that Z is a 1-by-? array. The colon (:) indicates that the second dimension is variable size. The question mark (?) indicates that the second dimension is unbounded.

Simulation must use dynamic memory allocation for Z because the second dimension of Z does not have an upper bound.

## Use Dynamic Memory Allocation for Bounded Arrays

When an array is unbounded, the code generator must use dynamic memory allocation. If an array is bounded, the code generator uses dynamic memory allocation only if the array size, in bytes, is greater than or equal to the dynamic memory allocation threshold. The default value for this threshold is 65536.

Dynamic memory has a run-time performance cost. By controlling its use, you can improve execution speed.

If you make Z a bounded variable-size array with a size that is greater than the threshold, the code generator uses dynamic memory allocation for Z. For example:

- 1 In `mymodel`, modify `myfcn` so that Z has an upper bound of 500.

```
function s = myfcn(n)
assert(n < 500);
Z = rand(1,n);
s = sum(Z);
end
```

- 2 Simulate the model.

In the MATLAB function report, you see that Z is a 1-by-500 array. It is variable size with an upper bound of 500.

- 3 Lower the dynamic memory allocation to a value less than or equal to 4000, which is the size, in bytes, of Z. In the Configuration Parameters dialog box, in the **Simulation Target > Advanced parameters** category, set the **Dynamic memory allocation threshold in MATLAB functions** parameter to 4000.
- 4 Simulate the model.

The code generator uses dynamic memory allocation because the size of Z is equal to the dynamic memory allocation threshold, 4000.

## Generate C Code That Uses Dynamic Memory Allocation

If you have Simulink Coder, you can generate C code for this model. Then, you can see how the code generator represents dynamically allocated arrays.

- 1 Configure the model to use a fixed-step solver. In the Configuration Parameters dialog box, in the **Solver** pane, under **Solver selection**:
  - For **Type**, select **Fixed-step**.
  - For **Solver**, select **discrete (no continuous states)**.
- 2 Configure the model to create and use a code generation report. In the Configuration Parameters dialog box, in the **Code Generation > Report** pane, select **Create code generation report** and **Open report automatically**.
- 3 Edit the code in the MATLAB Function block so that it looks like this code:

```
function s = myfcn(n)
Z = rand(1,n);
s = sum(Z);
end
```

Z is an unbounded variable-size array.

- 4 Make sure that the model is configured for dynamic memory allocation:
  - The **Dynamic memory allocation in MATLAB functions** check box is selected.
  - The **Dynamic memory allocation threshold in MATLAB functions** parameter has the default value 65536.
- 5 Build the model.
- 6 In the code generation report, open `mymodel.c`. You can tell that the code generator used dynamic memory allocation for Z because you see the `emxArray` type `emxArray_real_T_mymodel_T` and `emxArray` utility functions, such as `mymodel_emxInit_real_T`. The code generator uses an `emxArray` type for variables whose memory is dynamically allocated. The generated code uses the `emxArray` utility functions to manage the `emxArrays`.

If you have Embedded Coder, you can customize the identifiers for `emxArray` types and the utility functions. See “Identifier Format Control” (Embedded Coder).

## Code Generation for Enumerations

Enumerations represent a fixed set of named values. Enumerations help make your MATLAB code and generated C/C++ code more readable. For example, the generated code can test equality with code such as `if (x == Red)` instead of using `strcmp`. To generate C/C++ code, you must have Simulink Coder.

When you use enumerations in a MATLAB Function block, adhere to these restrictions:

- Calls to methods of enumeration classes are not supported.
- Passing strings or character vectors to constructors of enumerations is not supported.
- For members of `uint32` enumerations, code generation supports values that are less than or equal to `intmax("int32")`.
- For a MATLAB Function block, you can import an externally defined type by using `Simulink.defineIntEnumType` or you can define an enumeration class. The enumeration class must derive from one of these base types: `Simulink.IntEnumType`, `int8`, `uint8`, `int16`, `uint16`, `int32`, or `uint32`. See “Define Enumerations for MATLAB Function Blocks” on page 49-87.
- You can use only a limited set of operations on enumerations. See “Allowed Operations on Enumerations” on page 49-88.
- Use enumerations with functions that support enumerated types for code generation. See “MATLAB Toolbox Functions That Support Enumerations” on page 49-89.

### Define Enumerations for MATLAB Function Blocks

You can define enumerations for MATLAB Function blocks in two ways:

- To import an externally defined enumeration, use the `Simulink.defineIntEnumType` function. See “Import Enumerations Defined Externally to MATLAB” on page 73-9.
- In a class definition file, define an enumerated type. For example:

```
classdef PrimaryColors < Simulink.IntEnumType
    enumeration
        Red(1),
        Blue(2),
        Yellow(4)
    end
end
```

If you define an enumerated type in a class definition file, the class must derive from one of these base types: `Simulink.IntEnumType`, `int8`, `uint8`, `int16`, `uint16`, or `int32`. Then, you can exchange enumerated data between MATLAB Function blocks and other Simulink blocks in a model.

If you use Simulink Coder to generate C/C++ code, you can use the enumeration class base type to control the size of an enumerated type in generated C/C++ code. You can:

- Represent an enumerated type as a fixed-size integer that is portable to different targets.
- Reduce memory usage.
- Interface with legacy code.
- Match company standards.

The base type determines the representation of the enumerated type in generated C/C++ code.

If the base type is `Simulink.IntEnumType`, the code generator produces a C enumeration type. Consider the following MATLAB enumerated type definition:

```
classdef LEDcolor < Simulink.IntEnumType
    enumeration
        GREEN(1),
        RED(2)
    end
end
```

This enumerated type definition results in the following C code:

```
typedef enum {
    GREEN = 1,
    RED
} LEDcolor;
```

For built-in integer base types, the code generator produces a `typedef` statement for the enumerated type and `#define` statements for the enumerated values. Consider the following MATLAB enumerated type definition:

```
classdef LEDcolor < int16
    enumeration
        GREEN(1),
        RED(2)
    end
end
```

This enumerated type definition results in the following C code:

```
typedef int16_T LEDcolor;

#define GREEN ((LEDcolor)1)
#define RED ((LEDcolor)2)
```

To customize the code generated for an enumerated type, see “Customize Simulink Enumeration” on page 73-6.

## Allowed Operations on Enumerations

For code generation, you are restricted to the operations on enumerations listed in this table.

Operation	Example	Notes
assignment operator: =		—
relational operators: < > <= >= == ~=	xon == xoff	Code generation does not support using == or ~= to test equality between an enumeration member and a string array, a character array, or a cell array of character arrays.
cast operation	double(LEDcolor.RED)	—

Operation	Example	Notes
conversion to character array or string	<pre>y = char(LEDcolor.RED); y1 = cast(LEDcolor.RED,'char'); y2 = string(LEDcolor.RED);</pre>	<ul style="list-style-type: none"> <li>You can convert only compile-time scalar valued enumerations. For example, this code runs in MATLAB, but produces an error in code generation:  <pre>y2 = string(repmat(LEDcolor.RED,1,2));</pre></li> <li>The code generator preserves enumeration names when the conversion inputs are constants. For example, consider this enumerated type definition:  <pre>classdef AnEnum &lt; int32     enumeration         zero(0),         two(2),         otherTwo(2)     end end</pre> Generated code produces "two" for  <pre>y = string(AnEnum.two)</pre> and "otherTwo" for  <pre>y = string(AnEnum.two)</pre></li> </ul>
indexing operation	<pre>m = [1 2] n = LEDcolor(m) p = n(LEDcolor.GREEN)</pre>	—
control flow statements: if, switch, while	<pre>if state == sysMode.ON     led = LEDcolor.GREEN; else     led = LEDcolor.RED; end</pre>	—

## MATLAB Toolbox Functions That Support Enumerations

For code generation, you can use enumerations with these MATLAB toolbox functions:

- cast
- cat
- char
- circshift
- enumeration
- fliplr
- flipud
- histc
- intersect
- ipermute

- `isequal`
- `isequaln`
- `isfinite`
- `isinf`
- `ismember`
- `isnan`
- `issorted`
- `length`
- `permute`
- `repmat`
- `reshape`
- `rot90`
- `setdiff`
- `setxor`
- `shiftdim`
- `sort`
- `sortrows`
- `squeeze`
- `string`
- `union`
- `unique`

MATLAB Function

## **Related Examples**

- “Implement MATLAB Functions in Simulink with MATLAB Function Blocks” on page 49-3
- “Add Enumerated Inputs, Outputs, and Parameters to a MATLAB Function Block” on page 49-91

## Add Enumerated Inputs, Outputs, and Parameters to a MATLAB Function Block

When you add enumerated inputs, outputs, or parameters to a MATLAB Function block, follow these guidelines:

- For inputs, inherit the type from the enumerated type of the connected Simulink signal or specify the enumeration explicitly.
- For outputs, specify the enumerated type explicitly.
- For tunable parameters, specify the enumerated type explicitly. For nontunable parameters, derive the properties from an enumerated parameter in a parent Simulink masked subsystem or enumerated variable defined in the MATLAB base workspace.

To add enumerated data to a MATLAB Function block:

- 1 In the **Symbols** pane, click the Create Data button . In the **Name** field, enter a name for the enumerated data.

For parameters, the name must match the enumerated masked parameter or workspace variable name.

- 2 In the Property Inspector, in the **Type** field, specify an enumerated type.
  - For an explicit enumerated type, set **Type** to Enum: <class name>. Replace <class name> with the name of an enumerated data type that you defined in a MATLAB file on the MATLAB path.

The **Complexity** field is not visible because enumerated data types do not support complex values.

- For inputs, to inherit the enumerated type from a connected Simulink signal, set **Type** to Inherit: Same as Simulink.

## Enumerations in a MATLAB Function Block

This example shows how MATLAB Function blocks exchange enumerated data with other Simulink blocks. The model uses enumerations to represent the modes of a device that controls the colors of an LED display. The MATLAB Function block receives an enumerated input signal that represents the mode. The enumerated output signal represents the color that the LED displays.

Copyright 2009-2022 The MathWorks, Inc.

In this model, the Step block provides the source of the on/off signal. This block outputs an initial value of 0 (off) and, after 10 seconds, steps up to a value of 1 (on). A pair of Data Type Conversion

blocks convert this signal from type `double` to type `int32`, and then from `int32` to the enumerated type `switchmode`. The parameters in the second Data Type Conversion block have these settings:

- Output minimum: [ ]
- Output maximum: [ ]
- Output data type: Enum:switchmode

The MATLAB Function block evaluates the enumerated input state to determine the value of the enumerated output `ledval`. `state` inherits its enumerated type `switchmode` from the incoming Simulink signal, while `ledval` has the type Enum:led. Finally, a Display block displays the value of `ledval`.

### View the Enumeration Class Definitions

The `switchmode` enumeration represents the allowed modes for the input to the MATLAB Function block.

```
classdef switchmode < Simulink.IntEnumType
    enumeration
        OFF(0),
        ON(1),
    end
end
```

The `led` enumeration represents the colors that the MATLAB Function block outputs.

```
classdef led < Simulink.IntEnumType
    enumeration
        GREEN(1),
        RED(8),
    end
end
```

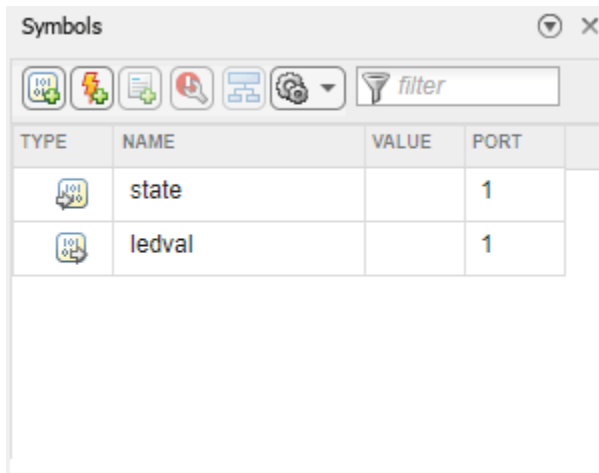

Both enumeration classes inherit from the built-in type `Simulink.IntEnumType` and reside on the MATLAB path.

### Inspect the MATLAB Function Block

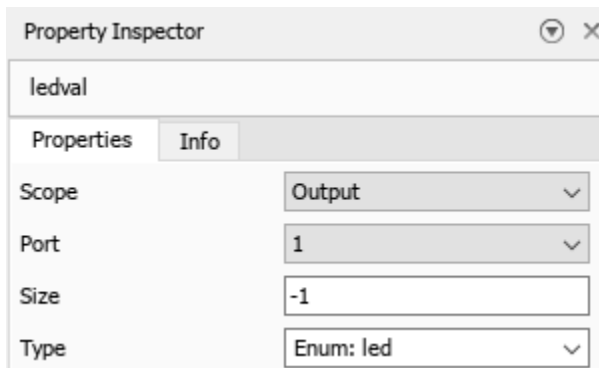

Open the MATLAB Function block. The function `checkState` uses enumerations to activate an LED display based on the state of a device. The function lights a green LED display to indicate the ON state and a red LED display to indicate the OFF state.

```
function ledval = checkState(state)
    if state == switchmode.ON
        ledval = led.GREEN;
    else
        ledval = led.RED;
    end
```

In the **Function** tab, click **Edit Data** to view the enumerated inputs and outputs specified in the MATLAB Function block. The **Symbols** pane displays the input `state` and the output `ledval`.

When using enumerations for outputs, you must explicitly refer to the enumeration class definition in the **Type** property of the variable. Click either of the variable names to view the properties in the Property Inspector. In this example, the **Type** property for `state` is `Inherit: Same as Simulink`. The **Type** property for `ledval` is `Enum: led`.

### Simulate the Model

When you simulate the model, the Display block displays the state of the LED display. If you simulate the model for less than 10 seconds, the state is OFF and the Display block displays RED. If you simulate the model for more than 10 seconds, the state is ON and the Display block displays GREEN.

## Use Global Data in MATLAB Function Blocks

### In this section...

“Use Global Data from Data Store Memory Blocks” on page 49-94

“Use Global Data from Simulink.Signal Objects” on page 49-94

“Choose How to Store Global Data” on page 49-95

“Retrieve Data From Data Store Memory Blocks” on page 49-95

“Retrieve Data From Simulink.Signal Objects Example” on page 49-97

“Using Data Store Diagnostics to Detect Memory Access Issues” on page 49-99

You can reference globally defined data in MATLAB Function blocks by defining global variables in the function code. Use global variables if:

- You have multiple MATLAB functions that use global variables and you want to call these functions from MATLAB Function blocks.
- You add a MATLAB Function block to an existing model that uses global data, and you want to avoid cluttering your model with additional inputs and outputs.
- You want to scope the visibility of data to parts of the model.

In Simulink, you store global data using either Data Store Memory blocks or `Simulink.Signal` objects. For more information, see “Local and Global Data Stores” on page 78-2.

### Use Global Data from Data Store Memory Blocks

To define global data with a Data Store Memory block and use the data in a MATLAB Function block, or in code that this block calls:

- 1 Declare a global variable in your MATLAB Function block or in the code that the MATLAB Function block calls.
- 2 In the MATLAB Function block, set the **Scope** property of the global variable to **Data Store Memory**. For more information on how to define variables in MATLAB Function blocks, see “Create and Define MATLAB Function Block Variables” on page 49-31.
- 3 In the model, create a Data Store Memory block. Assign the **Data store name** parameter to the same name as the global variable.
- 4 In the Data Store Memory, set the **Initial value**, **Data type**, and **Signal type** parameters. The data type cannot be inherited, and the signal type must be real or complex.

Data Store Memory blocks scope the data to the model. You must add a Data Store Memory block to the model for each global data. Data Store Memory blocks do not support MATLAB value classes or variable-size data.

### Use Global Data from Simulink.Signal Objects

To define global data with a `Simulink.Signal` object and use the data in a MATLAB Function block or in the code that this block calls:

- 1 Declare a global variable in your MATLAB Function block, or in the code that the MATLAB Function block calls.

- 2 In the MATLAB Function block, set the **Scope** property of the global variable to **Data Store Memory**. For more information on how to define variables in MATLAB Function blocks, see “Create and Define MATLAB Function Block Variables” on page 49-31.
- 3 In the model workspace or base workspace, create a `Simulink.Signal` object. Assign the `Simulink.Signal` object to a variable with the same name as the global variable.
- 4 Set the `DataType`, `InitialValue`, and `Dimensions` properties of the `Simulink.Signal` object. The data type cannot be inherited, and the signal type must be real or complex.

You can scope `Simulink.Signal` objects to the model or base workspace. You can define the `Simulink.Signal` objects in the Model Explorer or load them from a MAT-file.

## Choose How to Store Global Data

How you store global data depends on the number and scope of your global variables. This table describes when to use Data Store Memory blocks or `Simulink.Signal` objects.

How You Use Global Data	Solution
A single model that does not use a referenced model must define a small number of global variables.	Data Store Memory blocks.
A single model that does not use a referenced model must define a large number of global variables.	<code>Simulink.Signal</code> objects defined in the model workspace.
You share global data between multiple models, including referenced models.	<code>Simulink.Signal</code> objects defined in the base workspace.

## Retrieve Data From Data Store Memory Blocks

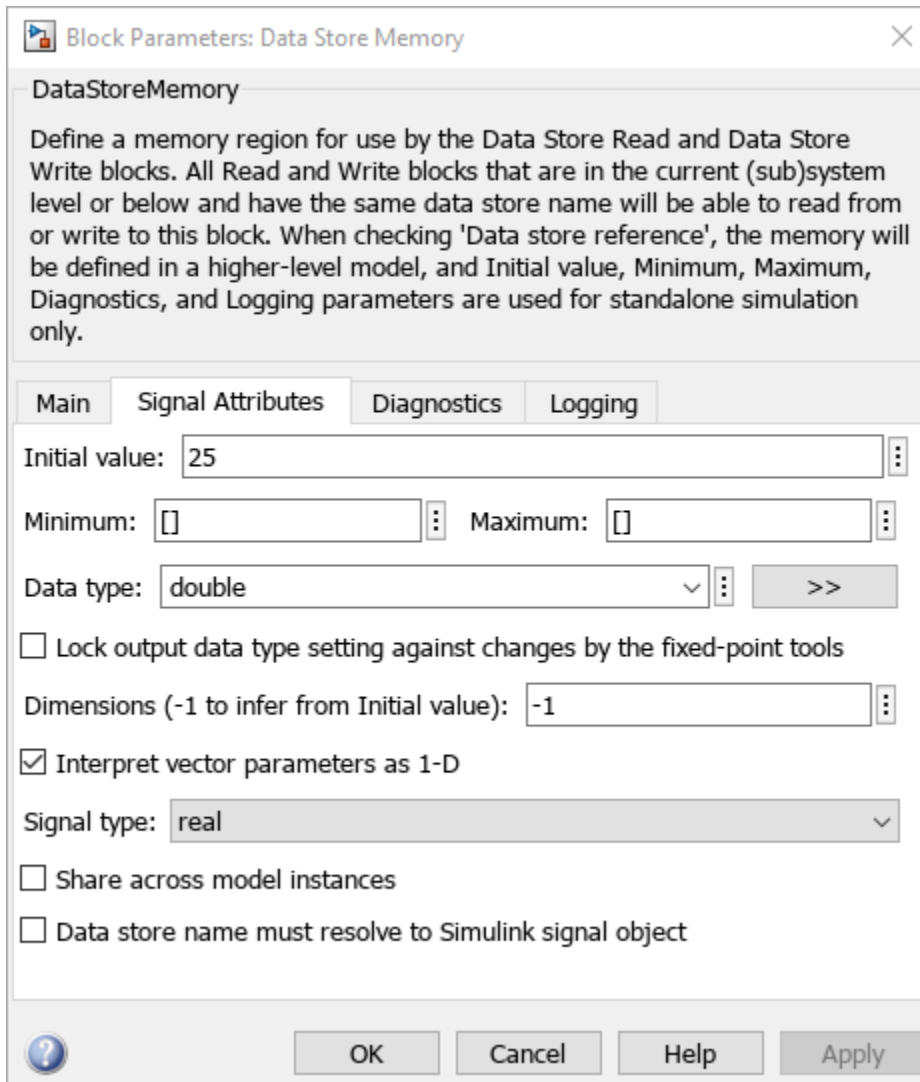

This example shows how a MATLAB Function block can use global data stored in a Data Store Memory block.

Copyright 2022, The MathWorks, Inc.

## View the Data Store Memory Block Parameters

Open the Data Store Memory block to view the parameters. On the **Main** tab, note that the **Data store name** parameter is **A**. Open the **Signal Attributes** tab. In this example, the **Initial value** parameter is **25**, the **Data type** parameter is **double**, and the **Signal type** parameter is **real**.

To use global data in the MATLAB Function block, you cannot set these parameters to auto or inherited.

### Inspect the MATLAB Function Block

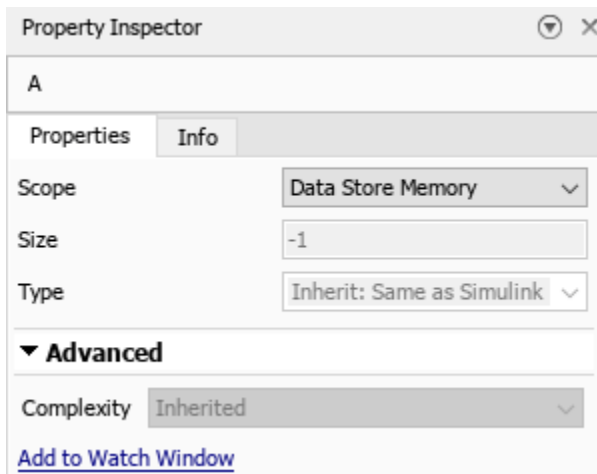

Open the MATLAB Function block. The function code declares a global variable **A**, which matches the name of the Data Store Memory block **Data store name** parameter. The block adds 1 to **A** during each execution by using this code:

```
function y = fcn
    global A;
    A = A+1;
    y = A;
```

Ensure that the variable **A** uses data store memory from the block:

- 1 In the **Function** tab, in the **Prepare** section, click **Edit Data**.
- 2 In the **Symbols** pane, select the variable **A**. The properties display in the Property Inspector.

- 3 Ensure the **Scope** property is Data Store Memory.

### Simulate the Model

Run the model. The block execution occurs at each major time step. The final output of the MATLAB Function block is 76.

## Retrieve Data From Simulink.Signal Objects Example

This example shows how a MATLAB Function block can use the global data stored in a `Simulink.Signal` object.

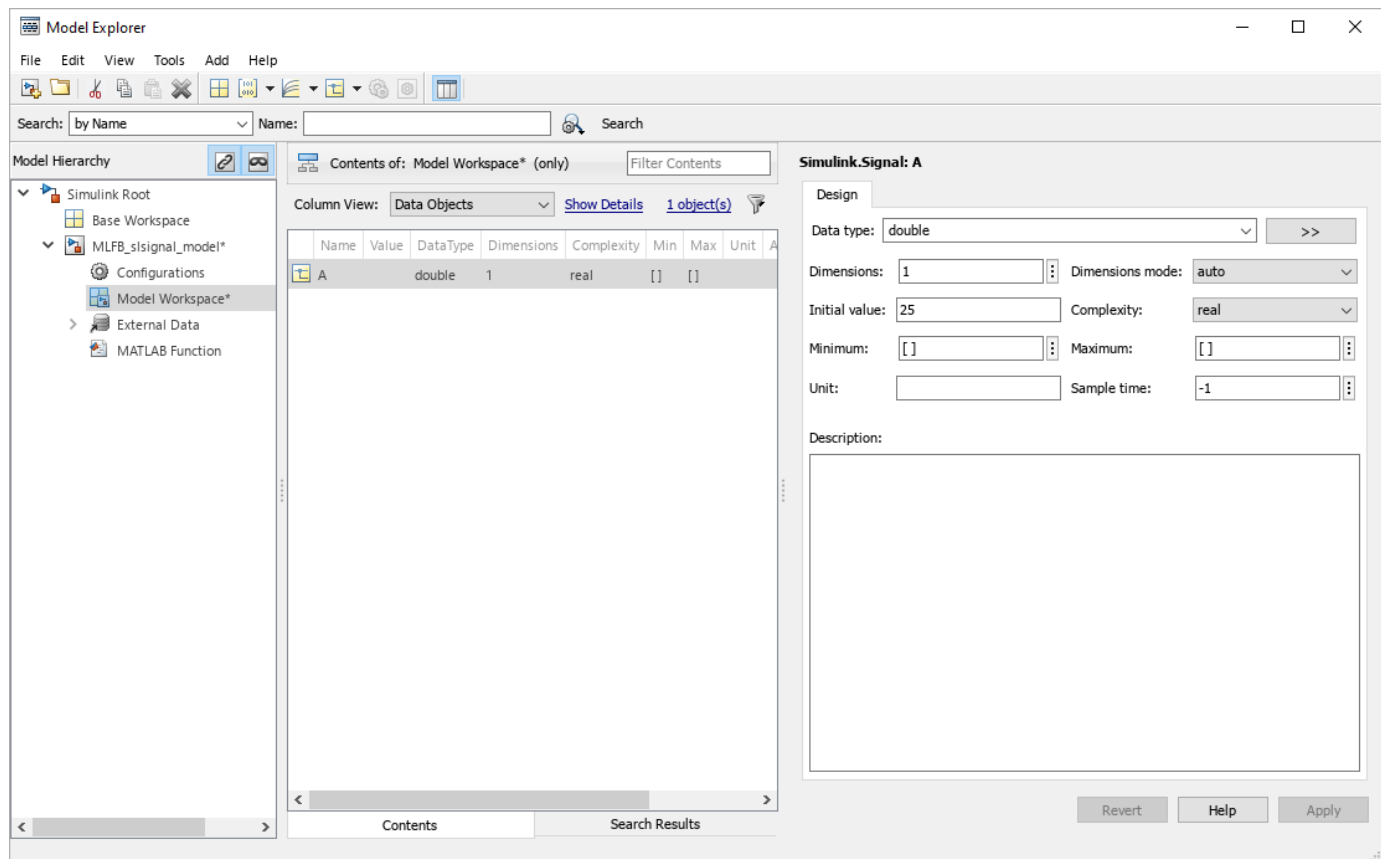

Copyright 2022, The MathWorks, Inc.

### View the Simulink.Signal Object Properties

View the properties of the `Simulink.Signal` object:

- 1 Open the Model Explorer. In the **Modeling** tab, in the **Design** section, click **Model Explorer**.
- 2 In the left pane, expand the `MLFB_slsignal_model` and click **Model Workspace**. The middle pane displays the data in the model workspace.
- 3 Click the `Simulink.Signal` object A. In the right pane, the Model Explorer displays the properties of A. In this example, **Data type** is `double`, **Dimensions** is 1, **Initial value** is 25, and **Complexity** is `real`.

To use global data in the MATLAB Function block, you cannot set these properties to **auto** or **inherited**.

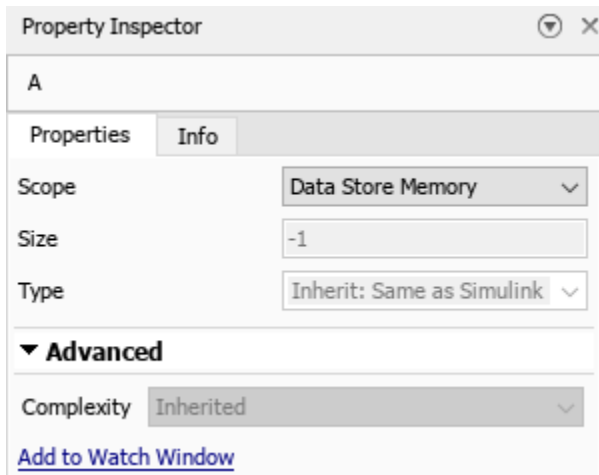

### Inspect the MATLAB Function Block

Open the MATLAB Function block. The function code declares a global variable A, which matches the name of the Data Store Memory block **Data store name** parameter. The block adds 1 to A during each execution by using this code:

```
function y = fcn
    global A;
    A = A+1;
    y = A;
```

Ensure that the variable A uses data store memory from the object:

- 1 In the **Function** tab, in the **Prepare** section, click **Edit Data**.
- 2 In the **Symbols** pane, select the variable A. The properties display in the Property Inspector.
- 3 Ensure the **Scope** property is Data Store Memory.

### Simulate the Model

Run the model. The block execution occurs at each major time step. The final output of the MATLAB Function block is 76.

## Using Data Store Diagnostics to Detect Memory Access Issues

If you use Data Store Memory blocks, you can avoid problems with data stores by configuring your model to provide run-time and compile-time diagnostics. The Configuration Parameters window and the Parameters window display diagnostics for the Data Store Memory block. For more information on using data store diagnostics, see “Data Store Diagnostics” on page 78-3.

---

**Note** If you pass data store memory arrays to functions, optimizations such as `A = foo(A)` might result in the code generation software marking the entire contents of the array as read or written even though only some elements were accessed.

---

## Initialize Persistent Variables in MATLAB Functions

A persistent variable is a local variable in a MATLAB function that retains its value in memory between calls to the function. If you generate code from your model, you must initialize a persistent variable for your MATLAB functions. For more information, see `persistent`.

When using MATLAB functions that contain persistent variables in Simulink models, you should follow these guidelines:

- Initialize the persistent variables in functions only by accessing constants.
- Ensure the control flow of the function does not depend on whether the initialization occurs.

If you do not follow these guidelines, several conditions produce an initialization error:

- MATLAB Function blocks with persistent variables where the **Allow direct feedthrough** property is cleared
- MATLAB Function blocks with persistent variables in models with State Control blocks where **State control** is set to Synchronous
- Stateflow charts that implement Moore machine semantics and that use MATLAB functions with persistent variables

For example, the function `fcn` below uses a persistent variable, `n`. `fcn` violates both guidelines. The initial value of `n` depends on the input `u` and the `return` statement interrupts the normal control flow of the function. Consequently, this code produces an error when used in a model that has one of the conditions described above.

```
function y = fcn(u)
    persistent n

    if isempty(n)
        n = u;
        y = 1;
        return
    end

    y = n;
    n = n + u;
end
```

To prevent the error, initialize the persistent variable by setting it to a constant value and removing the `return` statement. This modified version of `fcn` initializes the persistent variable without producing an error:

```
function y = fcn(u)
    persistent n

    if isempty(n)
        n = 1;
    end

    y = n;
    n = n + u;
end
```

## MATLAB Function Block with No Direct Feedthrough

This model contains a MATLAB Function block that uses the first version of `fcn`, described previously. The MATLAB Function block input is a square wave, which is provided by a Sign and Sine Wave block. The MATLAB Function block adds the value of `u` to the persistent variable `n` at each time step.

Simulate the model. The simulation returns an error because:

- The initial value of the persistent variable `n` depends on the input `u`.
- The `return` statement interrupts the normal control flow of the function.
- The **Allow direct feedthrough** property of the MATLAB Function block is cleared.

Modify the MATLAB Function block code, as shown in the corrected version of `fcn`. Simulate the model again.

## State Control Block in Synchronous Mode

This model contains a MATLAB Function block that uses the first version of fcn, described previously. The MATLAB Function block input is a square wave, which is provided by a Sign and Sine Wave block. The MATLAB Function block adds the value of  $u$  to the persistent variable  $n$  at each time step. The model contains a State Control block where **State control** is set to Synchronous.

Simulate the model. The simulation returns an error because:

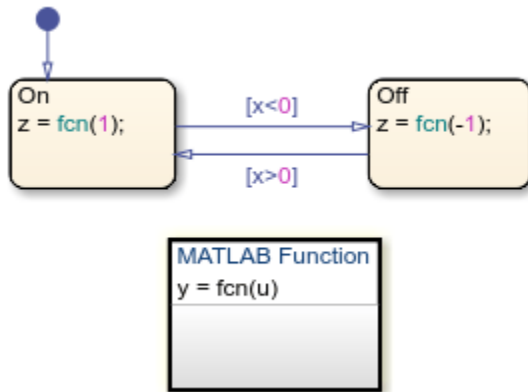

- The initial value of the persistent variable  $n$  depends on the input  $u$ .
- The return statement interrupts the normal control flow of the function.
- The model contains a State Control block where **State control** is set to **Synchronous**.

Modify the MATLAB Function block code, as shown in the corrected version of `fcn`. Simulate the model again.

## Stateflow Chart Implementing Moore Semantics

This model contains a Stateflow Chart with a MATLAB function that uses the first version of `fcn`, described previously. The MATLAB function adds the value (1 or -1) determined by the active state to the persistent variable  $n$  at each time step.

Simulate the model. The simulation returns an error because:

- The initial value of the persistent variable `n` depends on the input `u`.
- The return statement interrupts the normal control flow of the function.
- The chart implements Moore semantics.

Modify the MATLAB function code, as shown in the corrected version of `fcn`. Simulate the model again.

## Run Simulations and Generate Code with Masked Library Subsystems Containing MATLAB Function Blocks

This example shows how to use a masked library subsystem that contains a MATLAB Function block to run simulations and generate C code. Edits to the function code, the subsystem, or the mask properties affect all instances of the block in the model, while changes to the mask parameter affect only the selected block. Use masked library blocks if you need duplications of custom blocks that can generate code. For more information, see “Create Custom Library” on page 44-2 and “Design and Create a Custom Block” on page 43-12.

Copyright 2021-2022, The MathWorks, Inc.

### Navigate the Model

The masked subsystem contains a MATLAB Function block that uses the `conv` function to calculate the convolution of two input vectors. The mask parameter **shape** allows you to change the normalization weight to `full`, `same`, or `valid`. The block calculates the convolution using this MATLAB® code:

```
function c = my_conv(a, b, shape)
if shape == 1
    c = conv(a, b, "full");
elseif shape == 2
    c = conv(a, b, "same");
```

```

else
    c = conv(a, b, "valid");
end

```

In this model, the **shape** parameter of the top instance of the block is set to `full`, the middle instance is set to `same`, and the bottom instance is set to `valid`. Run the simulation to calculate the convolution of the vectors and display their values in the Display blocks.

The two top block instances output different vector sizes because each block calculates the convolution with a different weight. Change the **shape** parameter in any of the blocks and simulate again to see the output change.

### Generate C Code From the Model

If you have a license for Embedded Coder® or Simulink® Coder™, you can generate code from this example without changing the parameters or the blocks. However, MATLAB Function blocks support code generation for only a restricted subset of MATLAB functions. For more information, see “Functions and Objects Supported for C/C++ Code Generation” (MATLAB Coder).

If the parameters and inputs are identical for multiple instances of the library blocks, you can generate code with reusable functions that represent each identical MATLAB Function block. You can enable this behavior by right-clicking the MATLAB Function block, clicking **Block Parameters (Subsystem)**, and then opening the **Code Generation** tab. Set **Function packaging** to **Reusable function**. For more information, see “Generate Reusable Code from Library Subsystems Shared Across Models” (Simulink Coder).

Generate code by opening the Embedded Coder or Simulink Coder apps and clicking **Generate Code**. This model generates unique C functions for each block instance. To produce reusable functions, set the **shape** parameter to `full` for each library subsystem instance and generate code. The generated code reuses logic for the `my_conv_filter` and `my_conv_filter1` instances because they have the same block inputs and mask parameter value.

```

/*
 * Output and update for atomic system:
 *   '<S1>/MATLAB Function'
 *   '<S2>/MATLAB Function'
 */
void MLFB_model_MATLABFunction(const real_T rtu_a[2], const
    real_T rtu_b[5], real_T rty_c[6])
{
    int32_T b_k;
    int32_T i;
    for (i = 0; i < 6; i++) {
        rty_c[i] = 0.0;
    }

    for (i = 0; i < 2; i++) {
        for (b_k = 0; b_k < 5; b_k++) {
            int32_T tmp;
            tmp = i + b_k;
            rty_c[tmp] += rtu_a[i] * rtu_b[b_k];
        }
    }
}

```

The `my_conv_filter2` instance uses a different function because it uses different inputs.

```
/* Output and update for atomic system: '<S3>/MATLAB Function' */
void MLFB_model_MATLABFunction_p(const real_T rtu_a[3], const
real_T rtu_b[3], real_T rty_c[5])
{
    int32_T i;
    for (i = 0; i < 5; i++) {
        rty_c[i] = 0.0;
    }

    for (i = 0; i < 3; i++) {
        rty_c[i] += rtu_b[i] * rtu_a[0];
        rty_c[i + 1] += rtu_b[i] * rtu_a[1];
        rty_c[i + 2] += rtu_b[i] * rtu_a[2];
    }
}
```

## Include MATLAB Code as Comments in Generated Code

If you have a Simulink Coder license, you can include MATLAB source code as comments in the code generated for a MATLAB Function block. Including this information in the generated code enables you to:

- Correlate the generated code with your source code.
- Understand how the generated code implements your algorithm.
- Evaluate the quality of the generated code.

When you select the **MATLAB source code as comments** parameter, the generated code includes:

- The source code as a comment immediately after the traceability tag. When you enable traceability and generate code for ERT targets (requires an Embedded Coder license), the traceability tags are hyperlinks to the source code. For more information on traceability for the MATLAB Function block, see “Use Traceability in MATLAB Function Blocks” (Embedded Coder).

For examples and information on the location of the comments in the generated code, see “Location of Comments in Generated Code” on page 49-109.

- The function help text in the function body in the generated code. The function help text is the first comment after the MATLAB function signature. It provides information about the capabilities of the function and how to use it.

---

**Note** With an Embedded Coder license, you can also include the function help text in the function banner of the generated code. For more information, see “Including MATLAB user comments in Generated Code” on page 49-111.

---

### How to Include MATLAB Code as Comments in the Generated Code

To include MATLAB source code as comments in the code generated for a MATLAB Function block:

- 1 In the model, in the **Modeling** tab, click **Model Settings**.
- 2 In the **Code Generation > Comments** pane, select **MATLAB source code as comments** and click **Apply**.

### Location of Comments in Generated Code

The automatically generated comments containing the source code appear after the traceability tag in the generated code as follows.

```
/* '<S2>:1:18' for y = 1 : 2 : (HEIGHT-4) */
```

Selecting the **Stateflow object comments** parameter generates the traceability comment '`<S2>:1:18`'. Selecting the **MATLAB source code as comments** parameter generates the `for y = 1 : 2 : (HEIGHT-4)` comment.

### Straight-Line Source Code

The comment containing the source code precedes the generated code that implements the source code statement. This comment appears after any comments that you add that precede the generated

code. The comments are separated from the generated code because the statements are assigned to function outputs.

#### MATLAB Code

```
function [x y] = straightline(r,theta)
%#codegen
% Convert polar to Cartesian
x = r * cos(theta);
y = r * sin(theta);
```

#### Commented C Code

```
/* MATLAB Function 'straightline': '<S1>:1' */
/* Convert polar to Cartesian */
/* '<S1>:1:4' x = r * cos(theta); */
/* '<S1>:1:5' y = r * sin(theta); */
straightline0_Y.x = straightline0_U.r * cos(straightline0_U.theta);

/* Output: '<Root>/y' incorporates:
 * Inport: '<Root>/r'
 * Inport: '<Root>/theta'
 * MATLAB Function Block: '<Root>/straightline'
 */
straightline0_Y.y = straightline0_U.r * sin(straightline0_U.theta);
```

#### If Statements

The comment for the `if` statement immediately precedes the code that implements the statement. This comment appears after any comments that you add that precede the generated code. The comments for the `elseif` and `else` clauses appear immediately after the code that implements the clause, and before the code generated for statements in the clause.

#### MATLAB Code

```
function y = ifstmt(u,v)
%#codegen
if u > v
    y = v + 10;
elseif u == v
    y = u * 2;
else
    y = v - 10;
end
```

#### Commented C Code

```
/* MATLAB Function 'MLFcn': '<S1>:1' */
/* '<S1>:1:3' if u > v */
if (MLFcn_U.u > MLFcn_U.v) {
    /* Output: '<Root>/y' */
    /* '<S1>:1:4' y = v + 10; */
    MLFcn_Y.y = MLFcn_U.v + 10.0;
} else if (MLFcn_U.u == MLFcn_U.v) {
    /* Output: '<Root>/y' */
    /* '<S1>:1:5' elseif u == v */
    /* '<S1>:1:6' y = u * 2; */
    MLFcn_Y.y = MLFcn_U.u * 2.0;
} else {
```

```

/* Output: '<Root>/y' */
/* '<S1>:1:7' else */
/* '<S1>:1:8' y = v - 10; */
MLFcn_Y.y = MLFcn_U.v - 10.0;

```

### For Statements

The comment for the `for` statement header immediately precedes the generated code that implements the header. This comment appears after any comments that you add that precede the generated code.

#### MATLAB Code

```

function y = forstmt(u)
%#codegen
y = 0;
for i=1:u
    y = y + 1;
end

```

#### Commented C Code

```

/* MATLAB Function 'MLFcn': '<S1>:1' */
/* '<S1>:1:3' y = 0; */
rtb_y = 0.0;

/* '<S1>:1:5' for i=1:u */
for (i = 1.0; i <= MLFcn_U.u; i++) {
    /* '<S1>:1:6' y = y + 1; */
    rtb_y++;
}

```

### While Statements

The comment for the `while` statement header immediately precedes the generated code that implements the statement header. This comment appears after any comments that you add that precede the generated code.

### Switch Statements

The comment for the `switch` statement header immediately precedes the generated code that implements the statement header. This comment appears after any comments that you add that precede the generated code. The comments for the `case` and `otherwise` clauses appear immediately after the generated code that implements the clause, and before the code generated for statements in the clause.

## Including MATLAB user comments in Generated Code

MATLAB user comments include the function help text and other comments. The function help text is the first comment after the MATLAB function signature. It provides information about the capabilities of the function and how to use it. You can include the MATLAB user comments in the code generated for a MATLAB Function block.

- 1 In the model, on the **Modeling** tab, click **Model Settings**.
- 2 In the **Code Generation > Comments** pane, select MATLAB user comments (Embedded Coder) and click **Apply**.

## Limitations of MATLAB Source Code as Comments

The MATLAB Function block has the following limitations for including MATLAB source code as comments.

- You cannot include MATLAB source code as comments for:
  - MathWorks toolbox functions
  - P-code
  - Simulation targets
  - Stateflow Truth Table blocks
- The appearance or location of comments can vary depending on the following conditions:
  - Comments might still appear in the generated code even if the implementation code is eliminated, for example, due to constant folding.
  - Comments might be eliminated from the generated code if a complete function or code block is eliminated.
  - For certain optimizations, the comments might be separated from the generated code.
  - The generated code always includes legally required comments from the MATLAB source code, even if you do not choose to include source code comments in the generated code.

## Integrate C Code by Using the MATLAB Function Block

### In this section...

“Call C Code from a Simulink Model” on page 49-113

“Use `coder.ceval` in an Example MATLAB Function Block” on page 49-113

“Control Imported Bus and Enumeration Type Definitions” on page 49-116

If you have C code that you want to use in your Simulink model, you can call external C code to the model using a MATLAB Function block. MATLAB Function blocks call C code using MATLAB commands. You can also generate code from models with MATLAB Function blocks that call external C code.

### Call C Code from a Simulink Model

To call external C code in a Simulink model, follow these steps:

- 1 Identify the source (.c) and header (.h) files that contain the C code you want to use in your model.
- 2 Insert a MATLAB Function block into your model.
- 3 In the MATLAB Function block, use the `coder.ceval` function to call the C code. To pass data by reference, use `coder.ref`, `coder.rref`, or `coder.wref`.
- 4 Specify the C source and header files in the **Simulation Target** pane of the Configuration Parameters window. Include the header file using double quotations, for example, `#include "program.h"`. If you need to access C source and header files outside your working folder, list the path in the **Simulation Target** pane, in the **Include Directories** text box.

Alternatively, use the `coder.cinclude` and `coder.updateBuildInfo` functions to specify source and header files in your MATLAB code. To develop an interface to external code, you can use the `coder.ExternalDependency` class. To see which workflow is supported, see “Import custom code”.

- 5 Test your Simulink model and ensure it functions correctly.
- 6 If you have a Simulink Coder license, you can generate code for targets. To use the same source and header files for code generation, open Configuration Parameters, navigate to the **Code Generation > Custom Code** pane, and enable **Use the same custom code settings as Simulation Target**. You can also specify different source and header files.

To conditionalize your code to execute different commands for simulation and code generation, you can use the `coder.target` function.

### Use `coder.ceval` in an Example MATLAB Function Block

This example shows how to call the simple C program `doubleIt` from a MATLAB Function block.

- 1 Create the source file `doubleIt.c` in your current working folder.

```
#include "doubleIt.h"

double doubleIt(double u)
{
```

```

    return(u*2.0);
}

```

- 2 Create the header file `doubleIt.h` in your current working folder.

```

#ifndef MYFN
#define MYFN

double doubleIt(double u);

#endif

```

- 3 Create a new Simulink model. Save it as `myModel`.

- 4 In the Library Browser, navigate to the **Simulink > User-Defined Functions** library, and add a MATLAB Function block to the model.

- 5 Double-click the block to open the **MATLAB Function Block Editor**. Enter code that calls the `doubleIt` program:

```

function y = callingDoubleIt(u)

y = 0.0;
y = coder.ceval("doubleIt",u);

```

- 6 Connect a Constant block that has a value of 3.5 to the input port of the MATLAB Function block.

- 7 Connect a Display block to the output port.

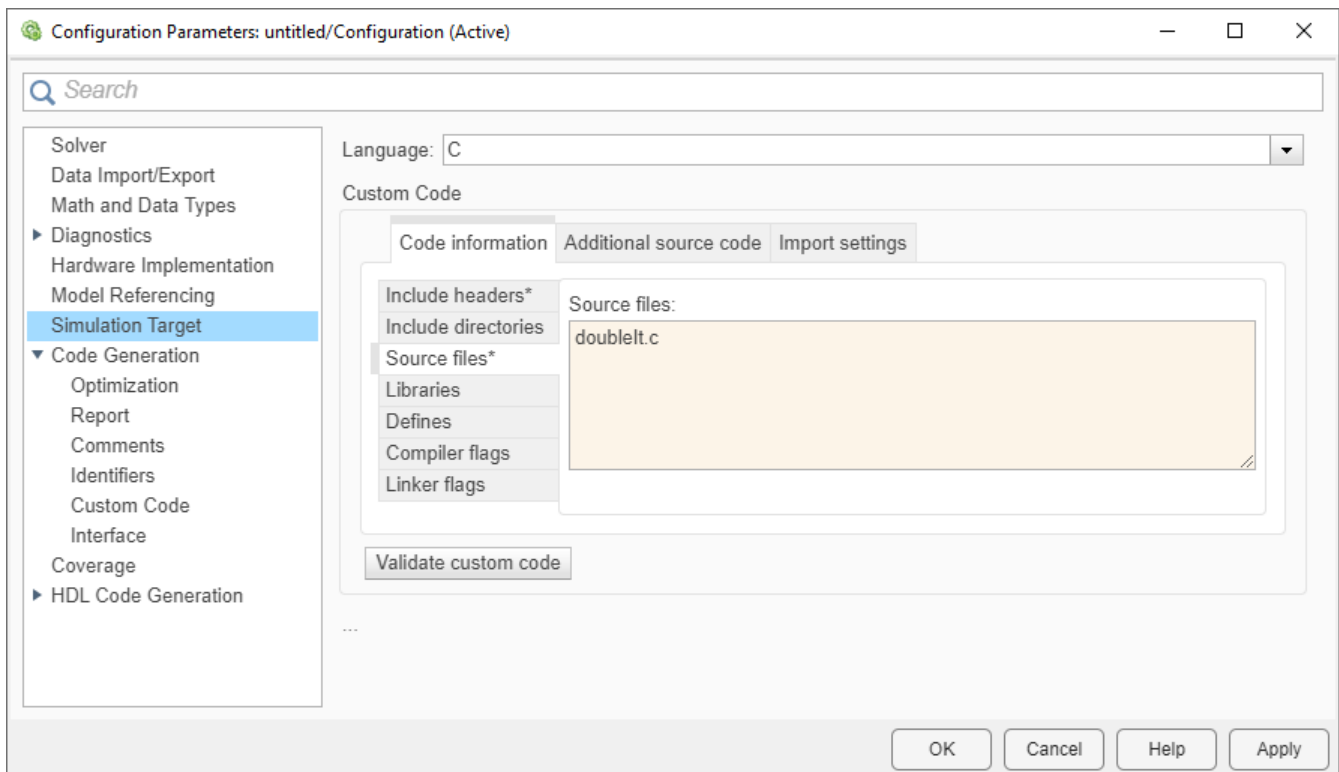

- 8 Open the Configuration Parameters window, and navigate to the **Simulation Target** pane.

- 9 In the **Code information** tab, click **Include headers**, then enter `#include "doubleIt.h"`.

**10** Click the **Source files** tab and enter `doubleIt.c`. Click **OK**.

**11** Run the simulation. The value 7 appears in the Display block.

## Control Imported Bus and Enumeration Type Definitions

When you call external C code by using MATLAB Function blocks or Stateflow, you can control the type definitions for imported buses and enumerations in your model. Simulink can generate type definitions for you, or you can supply a header file containing the type definitions. You can control this behavior by toggling the **Generate typedefs for imported bus and enumeration types** parameter. To find this parameter, open the Configuration Parameters window, navigate to the **Simulation Target** pane, and expand the **Advanced parameters** section.

To configure Simulink to automatically generate type definitions, enable **Generate typedefs for imported bus and enumeration types**. To include a custom header file that defines the enumeration and bus types, clear **Generate typedefs for imported bus and enumeration types** and list the header file in the **Header file** text box.

## Control Run-Time Checks

### In this section...

“Types of Run-Time Checks” on page 49-117  
 “When to Disable Run-Time Checks” on page 49-117  
 “How to Disable Run-Time Checks” on page 49-117

### Types of Run-Time Checks

In simulation, the code generated for your MATLAB Function block includes the following run-time checks:

- Memory integrity checks

These checks detect violations of memory integrity in code generated for MATLAB Function blocks and stop execution with a diagnostic message.

---

**Caution** For safety, these checks are enabled by default. Without memory integrity checks, violations result in unpredictable behavior.

---

- Responsiveness checks in code generated for MATLAB Function blocks

These checks enable periodic checks for Ctrl+C breaks in the generated code. Enabling responsiveness checks also enables graphics refreshing.

---

**Caution** For safety, these checks are enabled by default. Without these checks, the only way to end a long-running execution might be to terminate MATLAB.

---

### When to Disable Run-Time Checks

Generally, generating code with run-time checks enabled results in more lines of generated code and slower simulation than generating code with the checks disabled. Disabling run-time checks usually results in streamlined generated code and faster simulation, with these caveats:

Consider disabling:	Only if:
Memory integrity checks	You are sure that your code is safe and that all array bounds and dimension checking is unnecessary.
Responsiveness checks	You are sure that you will not need to stop execution of your application using Ctrl+C.

### How to Disable Run-Time Checks

MATLAB Function blocks enable run-time checks by default, but you can disable them explicitly for all MATLAB Function blocks in your Simulink model. Follow these steps:

- 1 Open your MATLAB Function block.

- 2 In the **MATLAB Function Block Editor**, select **Simulation Target**.
- 3 In the Configuration Parameters dialog box, clear the **Ensure memory integrity** or **Ensure responsiveness** check boxes, as applicable, and click **Apply**.

## Call MATLAB Function Files in MATLAB Function Blocks

The example model uses a MATLAB Function block to estimate the location of a moving object by calling a MATLAB® function file on the path. The model then plots this prediction data against the actual location of the object with another MATLAB Function block. The example then allows you to generate code from the MATLAB Function block that calls the MATLAB function file.

Copyright 2021 The MathWorks, Inc.

### Simulate the Model

The model takes the position data of an object stored in a MAT-file and runs the data through a tracking algorithm. The MATLAB Function block labeled Tracking calls a separate MATLAB function file, `ex_kalman_f.m`, to execute the tracking algorithm. In the model, double-click the Tracking block to see the code that calls `ex_kalman_f.m`.

```
function y = kalman(u)
y = ex_kalman_f(u);
end
```

Open `ex_kalman_f.m` to view the algorithm. `ex_kalman_f.m` uses a Kalman filter algorithm to track the location of the object. The algorithm uses two persistent variables. `x_est` stores the state between time steps and `p_ext` stores the covariance. The algorithm uses these persistent variables to calculate the estimated location of the object at every time step as the output `y`.

```
function y = ex_kalman_f(z)
%#codegen

% Initialize state transition matrix
dt = 1;
A = [ 1 0 dt 0 0 0;...
      0 1 0 dt 0 0;...
      0 0 1 0 dt 0;...
      0 0 0 1 0 dt;...
      0 0 0 0 1 0 ;...
      0 0 0 0 0 1 ];

% Measurement matrix
H = [ 1 0 0 0 0 0; 0 1 0 0 0 0 ];
Q = eye(6);
R = 1000 * eye(2);
```

```

% Initial conditions
persistent x_est p_est
if isempty(x_est)
    x_est = zeros(6, 1);
    p_est = zeros(6, 6);
end
% Predicted state and covariance
x_prd = A * x_est;
p_prd = A * p_est * A' + Q;

% Estimation
S = H * p_prd' * H' + R;
B = H * p_prd';
klm_gain = (S \ B)';

% Estimated state and covariance
x_est = x_prd + klm_gain * (z - H * x_prd);
p_est = p_prd - klm_gain * H * p_prd;

% Compute the estimated measurements
y = H * x_est;
end

```

MATLAB Function block code, and the function files the block calls, must be supported for code generation. Unlike the MATLAB Function block, MATLAB files called by the MATLAB Function block require the `%%codegen` directive to find code violations that would result in errors during code generation. In this example, `ex_kalman_f.m` does not have any violations.

After Simulink® calculates the estimated location of the object, the Visualizing block plots the actual and estimated locations of the object by using the MATLAB `plot` function.

```

function plot_me(y,z)

persistent h
if isempty(h)
    h = figure;
    hold;
end

N = size(z,2);
title("Trajectory of object [blue] its Kalman estimate[green]");
xlabel("horizontal position");
ylabel("vertical position");

for i = 1:N
    plot(y(1,i), y(2,i), "bx-");
    plot(z(1,i), z(2,i), "go-");
    axis([-1.1, 1.1, -1.1, 1.1]);
    pause(0.02);
end
end

```

Run the model to watch the data during simulation.

### Generate C Code

If you have a license for Embedded Coder® or Simulink Coder™, you can generate C code from MATLAB Function blocks that do not include extrinsic functions. In this example, you cannot generate C code from the Visualizing block because it includes `plot` and `figure`, which MATLAB treats as extrinsic functions. For more information, see “Use MATLAB Engine to Execute a Function Call in Generated Code” (MATLAB Coder). However, you can generate C code for the Tracking block. To generate C code for the Tracking block, right-click the block and click **C/C++ Code > Build This Subsystem**.

### Limitations

- The simulation time in this model must match the size of the position data array. If the input data size changes, you must manually adjust the simulation time.
- This model can only estimate the location of a moving point. For more sophisticated motion estimation capabilities, consider using “Computer Vision Toolbox”.
- You cannot call the function of a MATLAB Function block elsewhere, including in the code of the block that defines the function or other MATLAB Function blocks. For example, if the function of a MATLAB Function block is named `foo` and contains a call to a function `foo` in its body, the block

function does not make a recursive call to itself, but attempts to find and call `foo.m` in the current folder or on the path.

## Interface with Row-Major Data in MATLAB Function Block

Array layout can be important for integration, usability, and performance. Simulink uses column-major layout by default, as does the MATLAB Function block. However, many devices, sensors, and libraries use row-major array layout for their data. You can apply your model directly to this data by using the `coder.ceval` function with row-major layout in a MATLAB Function block.

Array layout can also affect performance. Many algorithms perform memory access more efficiently for one specific array layout.

### Row-Major Layout in Simulation and Code Generation

For the MATLAB Function block, you can specify row-major array layout inside the block. This specification occurs at the function level and does not alter the array layout of the model outside of the function. The array layout that you specify inside the MATLAB Function block applies to both simulation and C/C++ code generation. See “Specify Array Layout in Functions and Classes” on page 57-19.

For C/C++ code generation using Simulink Coder and Embedded Coder software, you can specify array layout at the model level, which is supported by MATLAB Function blocks. For more information on controlling array layout at the model level, see “Code Generation of Matrices and Arrays” (Simulink Coder). The model code generation setting for array layout has no effect for simulation. See Array layout (Simulink Coder). For examples of using row-major layout in MATLAB Function block for code generation, see “Generate Row-Major Code for Model That Contains a MATLAB Function Block” (Simulink Coder).

For the MATLAB Function block, the array layout specification at the function level takes precedence over the array layout specification of the model. However, for global and persistent variables, the array layout specification of the model takes precedence.

### Array Layout Conversions

MATLAB and Simulink store data in column-major layout by default. The software automatically inserts array layout conversions as needed when you specify different array layouts in different functions and at different boundaries.

For example, when you simulate a model or generate code for a model that uses column-major layout, and the model contains a MATLAB Function block that uses row-major layout, then the software converts the block input data to row-major and the block output data back to column-major, as needed. Array layout conversions can affect performance. For more information on performance considerations for array layout, see “Code Design for Row-Major Array Layout” on page 57-23.

### Array Layout and Algorithmic Efficiency

For certain algorithms, row-major layout provides more efficient memory access. Consider this function for adding two matrices. The algorithm performs the addition through explicit row and column traversal.

```
function [S] = addMatrix(A,B)
coder.rowMajor;
S = zeros(size(A));
for row = 1:size(A,1)
```

```

    for col = 1:size(A,2)
        S(row,col) = A(row,col) + B(row,col);
    end
end

```

If you use this code in a MATLAB Function block, code generation results in this C code for the function:

```

...
/* generated code for addMatrix using row-major */
for (row = 0; row < 20; row++) {
    for (col = 0; col < 10; col++) {
        S[col + 10 * row] = A[col + 10 * row] + B[col + 10 * row];
    }
}
...

```

The arrays are indexed by the generated code using the formula:

```
[col + 10 * row]
```

Because the arrays are stored in row-major layout, adjacent memory elements are separated by single column increments. The *stride length* for the algorithm is equal to one. The stride length is the distance in memory elements between consecutive memory accesses. A shorter stride length provides more efficient memory access.

Using column-major layout for the data results in a longer stride length and less efficient memory access. To see this comparison, consider the generated C code for `addMatrix` that uses column-major layout:

```

...
/* generated code for addMatrix using column-major */
for (row = 0; row < 20; row++) {
    for (col = 0; col < 10; col++) {
        S[row + 20 * col] = A[row + 20 * col] + B[row + 20 * col];
    }
}
...

```

In column-major layout, the column elements are contiguous in memory in the generated code. Adjacent memory elements are separated by single row increments and indexed by the formula:

```
[row + 20 * col]
```

However, the algorithm iterates through the columns in the inner for-loop. Therefore, the column-major C code must make a stride of 20 elements for each consecutive memory access.

The array layout that provides the most efficient memory access depends on the algorithm. For this algorithm, row-major layout of the data provides more efficient memory access. The algorithm traverses over the data row by row. Row-major storage is therefore more efficient.

## Row-Major Layout for N-Dimensional Arrays

You can use row-major layout for N-dimensional arrays. When an array is stored in row-major layout, the elements from the last (rightmost) dimension or index are contiguous in memory. In column-major layout, the elements from the first (leftmost) dimension or index are contiguous.

Consider the example function `addMatrix3D`, which accepts three-dimensional inputs.

```
function [S] = addMatrix3D(A,B)
coder.rowMajor;
S = zeros(size(A));
for i = 1:size(A,1)
    for j = 1:size(A,2)
        for k = 1:size(A,3)
            S(i,j,k) = A(i,j,k) + B(i,j,k);
        end
    end
end
end
```

The code generator produces this C code:

```
...
/* row-major layout */
for (i = 0; i < 20; i++) {
    for (j = 0; j < 10; j++) {
        for (k = 0; k < 5; k++) {
            S[(k + 5 * j) + 50 * i] = A[(k + 5 * j) + 50 * i]
            + B[(k + 5 * j) + 50 * i];
        }
    }
}
...
```

In row-major layout, adjacent memory elements are separated by single increments of the last index, `k`. The inner for-loop iterates over adjacent elements separated by only one position in memory.

Remove the `coder.rowMajor` call and generate C code that uses column-major layout:

```
...
/* column-major layout */
for (i = 0; i < 20; i++) {
    for (j = 0; j < 10; j++) {
        for (k = 0; k < 5; k++) {
            S[(i + 20 * j) + 200 * k] = A[(i + 20 * j) + 200 * k]
            + B[(i + 20 * j) + 200 * k];
        }
    }
}
...
```

In column-major layout, adjacent elements are separated by single increments of the first index, `i`. The inner for-loop now iterates over adjacent elements separated by 200 positions in memory. The long stride length can cause performance degradation due to cache misses.

Because the algorithm iterates through the last index, `k`, in the inner for-loop, the stride length is much longer for the generated code that uses column-major layout. For this algorithm, row-major layout of the data provides more efficient memory access.

## Specify Array Layout in External Function Calls

To call external C/C++ functions that expect data stored with a specific layout, use `coder.ceval` with the `layout` syntax. If you do not use this syntax, the external function inputs and outputs are assumed to use column-major layout by default.

Consider an external C function designed to use row-major layout called `myCFunctionRM`. To integrate this function into your code, call the function using the `'-layout:rowMajor'` or `'-row'` option. This option ensures that the input and output arrays are stored in row-major order. The code generator automatically inserts array layout conversions as needed.

```
coder.ceval('-layout:rowMajor','myCFunctionRM',coder.ref(in),coder.ref(out))
```

Within a MATLAB function that uses row-major layout, you may seek to call an external function designed to use column-major layout. In this case, use the `'-layout:columnMajor'` or `'-col'` option.

```
coder.ceval('-layout:columnMajor','myCFunctionCM',coder.ref(in),coder.ref(out))
```

You can perform row-major and column-major function calls in the same code. Consider the function `myMixedFn1` as an example:

```
function [E] = myMixedFn1(x,y)
%#codegen
coder.rowMajor;
% specify type of return arguments for ceval calls
D = zeros(size(x));
E = zeros(size(x));

% include external C functions that use row-major & column-major
coder.cinclude('addMatrixRM.h');
coder.updateBuildInfo('addSourceFiles', 'addMatrixRM.c');
coder.cinclude('addMatrixCM.h');
coder.updateBuildInfo('addSourceFiles', 'addMatrixCM.c');

% call C function that uses row-major order
coder.ceval('-layout:rowMajor','addMatrixRM', ...
    coder.rref(x),coder.rref(y),coder.wref(D));

% call C function that uses column-major order
coder.ceval('-layout:columnMajor','addMatrixCM', ...
    coder.rref(x),coder.rref(D),coder.wref(E));
end
```

The external files are:

### **addMatrixRM.h**

```
extern void addMatrixRM(const double x[200], const double y[200], double z[200]);
```

### **addMatrixRM.c**

```
#include "addMatrixRM.h"

void addMatrixRM(const double x[200], const double y[200], double z[200])
{
    int row;
```

```

int col;

/* add two matrices */
for (row = 0; row < 20; row++) {
    /* row by row */
    for (col = 0; col < 10; col++) {
        /* each element in current row */
        z[col + 10 * row] = x[col + 10 * row] + y[col + 10 * row];
    }
}
}

```

**addMatrixCM.h**

```
extern void addMatrixCM(const double x[200], const double y[200], double z[200]);
```

**addMatrixCM.c**

```

#include "addMatrixCM.h"

void addMatrixCM(const double x[200], const double y[200], double z[200])
{
    int row;
    int col;

    /* add two matrices */
    for (row = 0; row < 20; row++) {
        /* row by row */
        for (col = 0; col < 10; col++) {
            /* each element in current row */
            z[row + 20 * col] = x[row + 20 * col] + y[row + 20 * col];
        }
    }
}

```

## Code and Integration Limitations for MATLAB Function Blocks

Because MATLAB Function blocks rely on MATLAB Coder and Stateflow infrastructure, you must:

- Declare functions as extrinsic to use functions that are not supported for code generation.
- Follow the data definition guidelines.
- Set blocks to use nondirect feedthrough to use the block in a feedback loop.

Additionally, after you assign properties to a variable, you cannot redefine its class, size, or complexity elsewhere in the function body, with some exceptions.

### Use Supported Functions

When you simulate a model that contains a MATLAB Function block, the software generates binary code or C/C++ MATLAB executable (MEX) code from the block and integrates this code with the model. The MATLAB Function block uses the same infrastructure as MATLAB Coder, which you use to generate C/C++ code from MATLAB code outside of Simulink.

Because the MATLAB Function block relies on code generation technology to compile and simulate, C/C++ code generation limitations for MATLAB Coder also apply to MATLAB Function blocks. As a result, you can only use MATLAB language features that are supported for C/C++ code generation in MATLAB Function block code if you declare them as extrinsic. For a list of functions supported for code generation, see “Functions and Objects Supported for C/C++ Code Generation” on page 54-2. For supported language features, see “MATLAB Language Features Supported for C/C++ Code Generation” on page 53-23.

### Use Extrinsic Functions

You can still use the functions that are not supported in simulation by declaring them as extrinsic with `coder.extrinsic`. Functions that you declare as extrinsic execute in the MATLAB workspace during model simulation.

For example, if you want to use `patch` to plot data with a MATLAB Function block, define the function as an extrinsic function by using `coder.extrinsic`:

```
coder.extrinsic("patch");
```

After you declare the extrinsic function, you can use the function in the code below the declaration.

The MATLAB Function block automatically treats some plotting functions, such as `plot` and `axis`, as extrinsic. You do not have to explicitly declare them as extrinsic functions by using `coder.extrinsic`.

Extrinsic functions are omitted from generated standalone code. Therefore, do not use extrinsic functions when generating standalone code if they affect block outputs. For more information, see “Resolution of Function Calls for Code Generation” on page 69-2 and “Use the `coder.extrinsic` Construct” on page 69-7.

### Prepare Variables for Code Generation

To generate efficient standalone code, you must define data types differently than you normally would when running your code in MATLAB. See “Data Definition Considerations for Code Generation” on page 57-2.

After you assign properties to a variable, you cannot redefine its class, size, or complexity elsewhere in the function body, with some exceptions. See “Reassignment of Variable Properties” on page 56-9.

## Use Nondirect Feedthrough in a MATLAB Function Block

In Simulink blocks, *direct feedthrough* means that the value of an input port signal directly controls the output of a block. In nondirect feedthrough, the value of the output signal does not depend on the value of the input signal in at least one function during the simulation.

By default, MATLAB Function blocks enable direct feedthrough. If you disable direct feedthrough, the Simulink semantics ensure that outputs rely only on current state. Using nondirect feedthrough enables you to use MATLAB Function blocks in a feedback loop and prevent algebraic loops.

To use nondirect feedthrough:

- Enable function inlining of the MATLAB Function block by using `coder.inline` in the top-level function body.
- Open the properties for the MATLAB Function block and clear **Allow direct feedthrough**. For more information, see “Specify MATLAB Function Block Properties” on page 49-36.

### Limitations of Nondirect Feedthrough

When **Allow direct feedthrough** is cleared, do not program outputs to rely on inputs or updated persistent variables. For example, do not use this:

```
counter = counter + 1;      % update state
output = counter;         % compute output based on updated state
```

Instead, use this code:

```
output = counter;         % compute output based on current state
counter = counter + 1;    % update state
```

For more information, see “Initialize Persistent Variables in MATLAB Functions” on page 49-100.

You also cannot call custom code functions in MATLAB Function blocks because it is not possible to enforce that the outputs of custom code functions depend only on the current state. Calling a custom code function in a MATLAB Function block triggers an error.

Additionally, MATLAB Function blocks with function call outputs can cause unexpected results. When **Allow direct feedthrough** is disabled, the triggered subsystem receives function calls during the model update phase, and therefore the function call output executes later than required. To avoid these issues, enable **Allow direct feedthrough** when using function call outputs.

# MATLAB System Block

## In this section...

“Why Use the MATLAB System Block?” on page 50-3

“Choosing the Right Block Type” on page 50-3

“System Objects” on page 50-3

“Interpreted Execution or Code Generation” on page 50-4

“Default Input Signal Attributes” on page 50-4

“MATLAB System Block Limitations” on page 50-4

“MATLAB System and System Objects Examples” on page 50-5

## Why Use the MATLAB System Block?

System objects let you implement algorithms using the MATLAB language. The MATLAB System block enables you to use System objects in Simulink.

The MATLAB System block lets you:

- Share the same System object in MATLAB and Simulink
- Dedicate integration of System objects with Simulink
- Unit test your algorithm in MATLAB before using it in Simulink
- Customize dialog box customization
- Simulate efficiently with better initialization
- Handle states
- Customize block icons with port labels
- Access two simulation modes

## Choosing the Right Block Type

There are several mechanisms for including MATLAB algorithms in Simulink, such as:

- MATLAB System block
- MATLAB Function block
- Interpreted MATLAB Function block
- Level-2 MATLAB S-Function block

For help on choosing the right block, see “Comparison of Custom Block Functionality” on page 43-5.

## System Objects

Before you use a MATLAB System block, you must have a System object to associate with the block. A System object is a specialized kind of MATLAB class. System objects are designed specifically for implementing and simulating dynamic systems with inputs that change over time.

For more information on creating System objects, see “Customize System Objects for Simulink”.

**Note** To use your System object in the Simulink environment, it must have a constructor that you can call with no arguments. By default, the System object constructor has this capability and you do not need to define your own constructor. However, if you create your own System object constructor, you must be able to call it with no arguments.

System objects exist in other MATLAB products. MATLAB System block supports only the System objects written in the MATLAB language. In addition, if a System object has a corresponding Simulink block, you cannot implement a MATLAB System block for it.

## Interpreted Execution or Code Generation

You can use MATLAB System blocks in Simulink models for simulation via interpreted execution or code generation.

- With interpreted execution, the model simulates the block using the MATLAB execution engine.
- With code generation, the model simulates the block using code generation (requires the use of the subset of MATLAB code supported for code generation). For a list of supported functions, see “Functions and Objects Supported for C/C++ Code Generation” on page 54-2.

## Default Input Signal Attributes

If a MATLAB System block has one or more inputs that are unconnected to another block’s output port or connected to a port that has underspecified attributes, the default input signal attributes for the unspecified attributes are:

Data Attribute	Default
Data Type	double
Size	[1 1] scalar
Complexity	real

## MATLAB System Block Limitations

These capabilities are currently not supported.

Category	Limitation Description	Workaround
System Objects	Tunable logical and character vector properties of the System object are nontunable parameters in the MATLAB System block.	—
Data Types	<ul style="list-style-type: none"> <li>• The MATLAB System block does not support virtual buses as input or output.</li> <li>• System objects cannot use user-defined opaque data types.</li> </ul>	—

Category	Limitation Description	Workaround
Sample Time	Cannot use MATLAB System blocks to model continuous time or multirate systems.	—
Linearizations	Cannot use Jacobian based linearization.	—
Global Variables	Global variables defined in the model Configuration Parameters <b>Simulation Target &gt; Custom Code</b> pane and referenced by the System object are not shared with Stateflow and the MATLAB Function block.	Turn on the <b>Import custom code option</b> in the <b>Simulation Target</b> pane of the Configuration Parameters dialog box.
Debugging	MATLAB debugging for code-generation-based simulation.	Set the MATLAB System block <b>Simulate using</b> parameter to <b>Interpreted execution</b> , and then debug. When you are done, set <b>Simulate using</b> back to <b>Code generation</b> .
Fixed-Point Tool	The Fixed-Point Tool does not return design min/max, min/max logging, and autoscaling information for MATLAB System blocks.	—
Model coverage analysis (Simulink Coverage software)	Simulink Coverage cannot perform model analysis for MATLAB System block with <b>Simulate using</b> parameter set to <b>Interpreted execution</b> .	—

## MATLAB System and System Objects Examples

For examples of MATLAB System and System objects, see:

Example	Description
“Illustration of Law of Large Numbers”	This example shows how to use MATLAB System blocks to illustrate the law of large numbers. Due to the use of MATLAB functions not supported for code generation, the example uses propagation methods and interpreted execution.
“Using Buses with MATLAB System Blocks”	This example shows how to use MATLAB System blocks with nonvirtual buses at input or output. Due to the use Simulink buses, the example uses propagation methods. The example defines the bus types in the MATLAB base workspace using model callbacks.

## Implement a MATLAB System Block

Implement a block and assign a System object to it. You can then explore the block to see the effect.

- 1 Create a new model and add the MATLAB System block from the User-Defined Functions library.

- 2 In the block dialog box, from the **New** list, select **Basic**, **Advanced**, or **Simulink Extension** if you want to create a new System object from a template. Modify the template according to your needs and save the System object.
- 3 Enter the full path name for the System object in the **System object name**. Click the list arrow. If valid System objects exist in the current folder, the names appear in the list.

The MATLAB System block icon and port labels update to those of the corresponding System object. For example, suppose you selected a System object named `lmsSysObj` in your current folder. The block updates as shown in the figure:

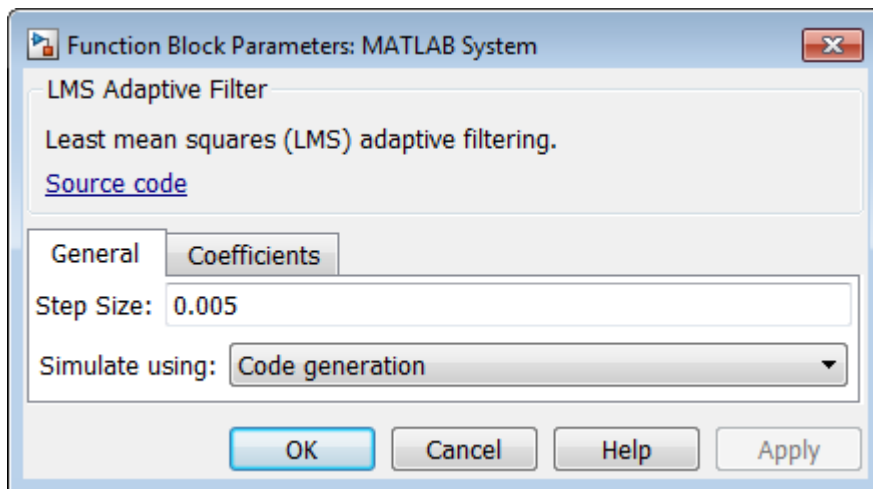

---

**Note** After you associate the block with a System object class name, you cannot assign a new System object using the same MATLAB System block dialog box. Instead, right-click the MATLAB System block, select **Block Parameters (MATLABSystem)** and enter a new class name in **System object name**.

---

### Understanding the MATLAB System Block

- 1 Double-click the block. The MATLAB System block dialog box reflects the System object parameters. The dialog box usually includes a **Source code** link that leads to the System object class file. For example:

The **Source code** link appears if the System object uses MATLAB language. It does not appear if you have:

- Converted the System object to P-code
  - Overridden the default behavior using the `getHeaderImpl` method
- 2 Click **Source code** and observe that the public and active properties in the System object appear in the MATLAB System block dialog box as block parameters.
  - 3 Select how you want the model to simulate the block using the **Simulate using** parameter. (This parameter appears at the bottom of each MATLAB System block if there is only one tab, or the bottom of the first of multiple tabs.)

## Change Blocks Implemented with System Objects

To implement a block with another System object, right-click the MATLAB System block and select **Block Parameters (MATLABSystem)**. Then, use the block dialog box to identify a new class name in **System object name**. For more information, see “Implement a MATLAB System Block” on page 50-7.

## Call Simulink Functions from MATLAB System Block

A Simulink function is a graphical representation of a computational unit in the Simulink environment. Once you create the Simulink function, it can be executed by any computational unit and can be called in multiple places. You can only call a Simulink function inside the `stepImpl`, `outputImpl`, or `updateImpl` method of a System object. See “Simulink Functions Overview” on page 10-133 for more information on Simulink function.

---

**Note** Interpreted mode is not supported for a model that contains a MATLAB System block calling a Simulink function.

---

### Create a Simulink Function Block

Set up a Simulink Function block that implements a simple function such as  $y = 2 * u$ .

- 1 Open a new model from **Simulink Editor** and add a Simulink Function block by typing Simulink function on Simulink canvas.
- 2 When **Function prototype** window opens, type `y = timestwo_func(u)` as the function definition. This indicates that you define a function called `timestwo_func` that takes `u` as the input argument and produces `y` as the output argument. Alternatively, define the function name from Simulink Function block parameters.
- 3 Double-click the Simulink Function block and observe that a Trigger Port function block appears as well as an input and an output argument block.
- 4 Double-click the Trigger Port block in the Simulink Function block, and observe that the **Function visibility** is set to `scoped`. To learn more about `scoped` Simulink functions, see “Scoped, Global, and Port-Scoped Simulink Function Blocks Overview” on page 10-168.
- 5 Add a Gain block and set its value to 2. Connect it with the input and output argument block. Click **Navigate Up to Parent** to return to the main model.

---

**Note** To determine which Simulink function a MATLAB System block is calling, turn on the function tracing lines. In the **Debug** tab, select **Information Overlays > Function Connectors**.

---

### Create a MATLAB System Block and Define System Object

Drag a MATLAB System block into the model and implement a System object to this block.

- 1 Add a MATLAB System block to your Simulink model.
- 2 In the block dialog box, from the New list, select **Basic**. This opens a basic System object template for you to type your code.
- 3 To subclass an object from `matlab.System`, replace `Untitled` with the name of your System object. For this example, name it `SimulinkFcnCaller`.
- 4 In the `stepImpl` method of your System object, declare the Simulink function using `getSimulinkFunctionNamesImpl`.

See an example of the System object code below. To learn more about how to write a System object, see “Define Basic System Objects”.

```
classdef SimulinkFcnCaller < matlab.System
    % Public, tunable properties
```

```

% SimulinkFcnCaller calls a Simulink function from a
% MATLAB System block to multiply the signal's value by 2.

methods(Access = protected)

    function y = stepImpl(obj,u)
        % Implement algorithm. Calculate y as a function of input u and
        % discrete states.
        y = timestwo_func(u);
    end
    function names = getSimulinkFunctionNamesImpl(obj)
        % Use 'getSimulinkFunctionNamesImpl' method to declare
        % the name of the Simulink function that will be called
        % from the MATLAB System block's System object code.
        names = {'timestwo_func'};
    end
end
end

```

- 5 Save the file and name it SimulinkFcnCaller.m.

## Call a Simulink Function in a Subsystem from a MATLAB System Block

The hierarchy of the Simulink Function block affects the function calls in the System object. For example, if the Simulink function is defined at a higher hierarchy in the Simulink model, the function is defined for all blocks in that hierarchy. If the Simulink function is defined at a lower hierarchy, you need to qualify the Subsystem and the function name. For example, suppose you have a Subsystem that contains a Simulink Function block at the same level as a MATLAB System block. When a Simulink Function block is placed in a subsystem, the function name is not visible to the outside the subsystem. You can call the Simulink Function block by qualifying the function name using the Subsystem name in your System object. To qualify the Subsystem and the function name follow these steps:

- 1 In the `stepImpl` method of your System object code, call the Simulink function using dot notation. For example, in the code `y = Subsystem1.timestwo_func(u)`, `Subsystem1` corresponds to the Subsystem, and `timestwo_func` corresponds to the Simulink function name.
- 2 Similarly, declare the Subsystem and the Simulink function in the `getSimulinkFunctionNamesImpl` method using the dot notation. The System object code shows the `timestwo` example written for a Simulink function defined at a lower hierarchy than the MATLAB System block.

```

classdef SimulinkFcnCallerQualified < matlab.System

    % SimulinkFcnCallerQualified calls a Simulink function embedded in a Subsystem
    % from a MATLAB System block, and multiplies the signal's value by 2.

    methods(Access = protected)

        function y = stepImpl(obj,u)
            % Use the '.' notation to call a scoped Simulink function from
            % a Simulink Function block.
            % Subsystem1 corresponds to the block name, where
            % timestwo_func is the Simulink function name.
            y = Subsystem1.timestwo_func(u);
        end

        function names = getSimulinkFunctionNamesImpl(obj)
            % Use the 'getSimulinkFunctionNamesImpl' method with the '.'
            % notation to declare the name of a Simulink function in
            % MATLAB System block's System object code.
            names = {'Subsystem1.timestwo_func'};
        end
    end
end

```

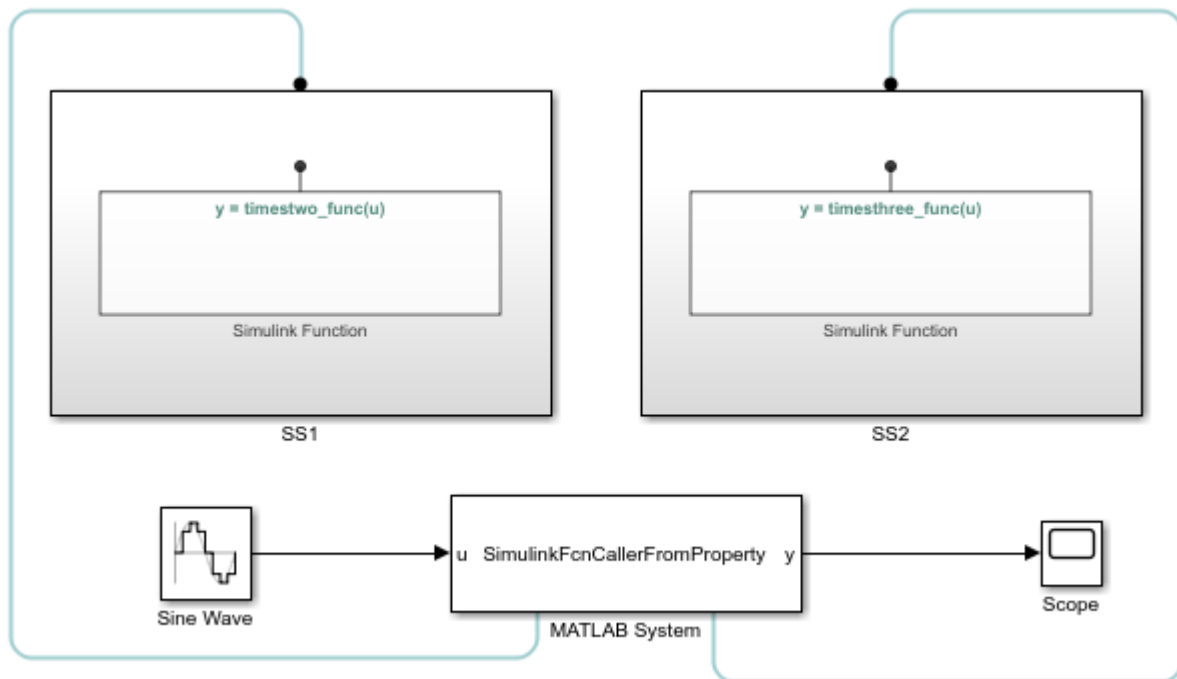

- 3 Save the System object file and name it `SimulinkFcnCallerQualified.m`.

## Call Simulink Functions from a MATLAB System Block

This example shows two Simulink® Functions conditionally called by a MATLAB System block using the nontunable properties of the System object®.

The MATLAB System block calls one of the Simulink functions inside two different subsystems, depending on the value of the signal coming from the Sine Wave block. If the value of the signal is less than 10, the MATLAB System block calls the `timestwo_func` Simulink Function inside the SS1 subsystem. If the value is larger than 10, it calls the `timesthree_func` in the SS2 subsystem.

Function names are defined as nontunable properties, are switched from string to functions using the `str2func` function. Then, these functions are declared as properties in the `getSimulinkFunctionNamesImpl` method.

### See Also

`getSimulinkFunctionNamesImpl`

## Specify Sample Time for MATLAB System Block

The sample time of a block is a parameter that indicates when the block produces an output, and eventually updates its internal state. To specify sample time for a MATLAB System block, implement the `getSampleTimeImpl` method with a call to `createSampleTime`. To query the MATLAB System block for current sample time and simulation time, use the `getSampleTime` and `getCurrentTime` methods. For more information, see “Specify Sample Time for MATLAB System Block System Objects” on page 50-110.

### Types of Sample Time for MATLAB System Block

If you use discrete sample time on page 7-19 in simulation, Simulink only calculates the output of a simulation for each of the fixed time intervals. To specify discrete sample time, in the `createSampleTime`, set 'Type' to 'Discrete' and set the 'SampleTime' property.

When the sample time is inherited on page 7-20, Simulink determines the best sample time for the block based on the block's role within the model. To specify inherited sample time, in the `createSampleTime`, set 'Type' to 'Inherited'. When using inherited sample time, you can alter or error out on specific sample times by specifying the 'AlternatePropagation' or 'ErrorOnPropagation' Name-Value pair.

In fixed-in-minor-step on page 7-20 sample time, Simulink does not execute the block at the minor time steps, the updates only occur at the major time steps. To specify the fixed-in-minor time step, in the `createSampleTime`, set 'Type' to 'Fixed In Minor Step'.

To use controllable on page 7-21 sample time, configure a block to specify controllable sample time with a resolution  $T_{base}$ , where  $T_{base}$  is the smallest allowable time interval between block executions. A block using controllable sample time can be dynamically set to execute at  $n$  multiples of  $T_{base}$ , then the block's next execution is

$$T_{next} = n T_{base} + T$$

To specify  $T_{base}$  in MATLAB System block, in the `createSampleTime`, set 'Type' to 'Controllable' and set the 'TickTime' property to  $T_{base}$ . You can set the  $n$  in your MATLAB System block using `setNumTicksUntilNextHit`.

For more information on types of sample time, see “Types of Sample Time” on page 7-19. To see an example on how to control the sample time of the MATLAB System block using System object methods, see “Specify Sample Time for MATLAB System Block System Objects” on page 50-110.

### See Also

`getSampleTimeImpl` | `getSampleTime` | `getCurrentTime` | `createSampleTime` | `setNumTicksUntilNextHit`

## Change Block Icon and Port Labels

To change the icon appearance of your block, you must add specific methods to your System object. For example, to define port labels, implement `getInputNamesImpl` and `getOutputNamesImpl`.

- 1 To define the icon, implement the `getIconImpl` method.
- 2 To define the port labels, implement `getInputNamesImpl` to change the input and `getOutputNamesImpl` to change the output port labels.

If you do not implement these methods, by default the System object uses the input and output port names from the `stepImpl` method. If you are using nondirect feedthrough, by default the System object uses the input names from `updateImpl` and the output port names from `outputImpl`.

## Modify MATLAB System Block Dialog

You can change the MATLAB System block dialog in two ways.

- Implement the `getPropertyGroupsImpl` method in the System object code of the MATLAB System block. Inside the method, implement the following classes.

Description	matlab.system.display Method
Define header text for property group.	<code>matlab.system.display.Header</code>
Group properties together.	<code>matlab.system.display.Section</code>
Group properties into a separate tab.	<code>matlab.system.display.SectionGroup</code>

- Use the Mask Editor user interface. For more information, see “Customize System Object Dialog Box Using Mask Editor” on page 50-60.

## Change the MATLAB System Block Icon to an Image

You can change the image of MATLAB System block in MATLAB Editor. For a list of accepted image files, see `image`. To use an existing image file for the MATLAB System block:

- 1 Double-click your MATLAB System block.
- 2 In the block dialog box, click the **Source code**. The MATLAB Editor that contains the System object code opens.
- 3 In the MATLAB Editor, from the **System Block** drop-down list, select **Add Image Icon**.
- 4 In the **Add image icon** dialog window, click **Browse** to select an image of your choice.
- 5 Click **OK** to insert the corresponding code for the `getIconImpl` method in your System object.

For more information, see “Customize System Block Appearance” on page 50-56.

## Nonvirtual Buses and MATLAB System Block

The MATLAB System block supports nonvirtual buses as input and output signals. The corresponding System object input or output must be a MATLAB structure whose fields match those defined by the nonvirtual bus. If the System object output is a MATLAB structure, it must define propagator methods. In addition, the `getOutputDataTypeImpl` method must return the name of the corresponding bus object. This bus object must exist in the base workspace or a data dictionary linked to the model.

---

**Note** If the output is the same bus type as the input, do not use the `propagatedInputDataType` method to obtain the name of the bus object. Instead, you must return the name of the bus object directly.

---

## Use System Objects in Feedback Loops

If your algorithm needs to process nondirect feedthrough data through the System object, use the `isInputDirectFeedthroughImpl`, `outputImpl`, and `updateImpl` methods. These methods process nondirect feedthrough data through a System object.

Most System objects use direct feedthrough, where the object's input is needed to generate the output. For these direct feedthrough objects, the `step` method calculates the output and updates the state values. For nondirect feedthrough, however, the object's output depends on internal states and not directly on the inputs. The inputs, or a subset of the inputs, are used to update the object states. For these objects, calculating the output is separated from updating the state values. This enables you to use an object as a feedback element in a feedback loop.

This example shows how to implement a delay object with nondirect feedthrough.

- 1 In MATLAB, select **New > System object > Basic**.
- 2 Select **Insert Method** and implement the `outputImpl` and `updateImpl` methods.

`outputImpl` calculates outputs from states and/or inputs. `updateImpl` updates state values from inputs.

When implementing the `outputImpl` method, do not access the System object inputs for which the direct feedthrough flag is false.

- 3 If the System object supports code generation and does not use propagation, Simulink can automatically infer the direct feedthrough settings from the System object MATLAB code. However, if the System object does not support code generation, the default `isInputDirectFeedthroughImpl` method returns false (no direct feedthrough). In this case, override this method to specify nondirect feedthrough behavior.

The processing of the nondirect feedthrough changes the way that the software calls the System object methods within the context of the Simulink engine.

## Simulation Modes

### Interpreted Execution vs. Code Generation

You can use MATLAB System block in Simulink models for simulation via interpreted execution or code generation. Implementing a MATLAB System block with a valid System object class name enables the **Simulate using** parameter. This parameter appears at the bottom of the MATLAB System block dialog if there is only one tab, or the bottom of the first of multiple tabs. Use the **Simulate using** parameter to control how the block simulates. The table describes how to choose the right value for your purpose.

- With interpreted execution, the model simulates the block using the MATLAB execution engine.

---

**Note** With interpreted execution, if you set the **Use division for fixed-point net slope computation** parameter to On or Use division for reciprocals of integers only in the Configuration Parameters dialog box, you might get unoptimized numeric results. These bad numeric results are because MATLAB code does not support this parameter.

---

- With code generation, the model simulates the block using code generation, using the subset of MATLAB code supported for code generation.

Action	Select	Pros	Cons
Upon first model run, simulate and generate code for MATLAB System using only the subset of MATLAB functions supported for code generation. Choosing this option causes the simulation to run the generated code.	Code generation (default)	Potentially better performance.	System object is limited to the subset of MATLAB functions supported for code generation. Simulation may start more slowly.
Simulate model using all supported MATLAB functions. Choosing this option can slow simulation performance.	Interpreted execution	System object can contain any supported MATLAB function. Faster startup time.	Potentially slower performance. If the MATLAB functions in the System object do not support code generation, the System object must contain propagation methods.

To take advantage of faster performance, consider using propagation methods in your System object. For more information, see “Add and Implement Propagation Methods” on page 50-29.

---

**Note** If a Simulink model is setup to simulate in Normal mode and if you use MATLAB System block via code generation individual MATLAB System blocks can take advantage of the acceleration via code generation. If the Simulink model is setup to simulate in accelerator or any of the other target modes, MATLAB System block's **Simulate using** parameter does not have any effect. There is only one exception. If the model is setup to simulate in Accelerator mode and you use MATLAB System block with interpreted execution mode, the block will run in interpreted execution mode.

---

## Simulation Using Code Generation

While simulating and generating code for one or more simulation targets (in this case, System object blocks), the model displays status messages in the bottom left of the Simulink Editor window. A model can have multiple copies of the same MATLAB System block. Blocks are considered the same if they,

- Use the same System object.
- Have inputs and tunable parameters that have identical signals, data types, and complexities.
- Have nontunable parameters that have the same value.

When the model has multiple copies of the same block, the software does not regenerate the code for each block. It reuses the code from the first time that code was generated for one of these blocks. The status messages reflect this and does not show status messages for each of these blocks.

When the code generation process is complete, Simulink creates a MEX-file for the generated code.

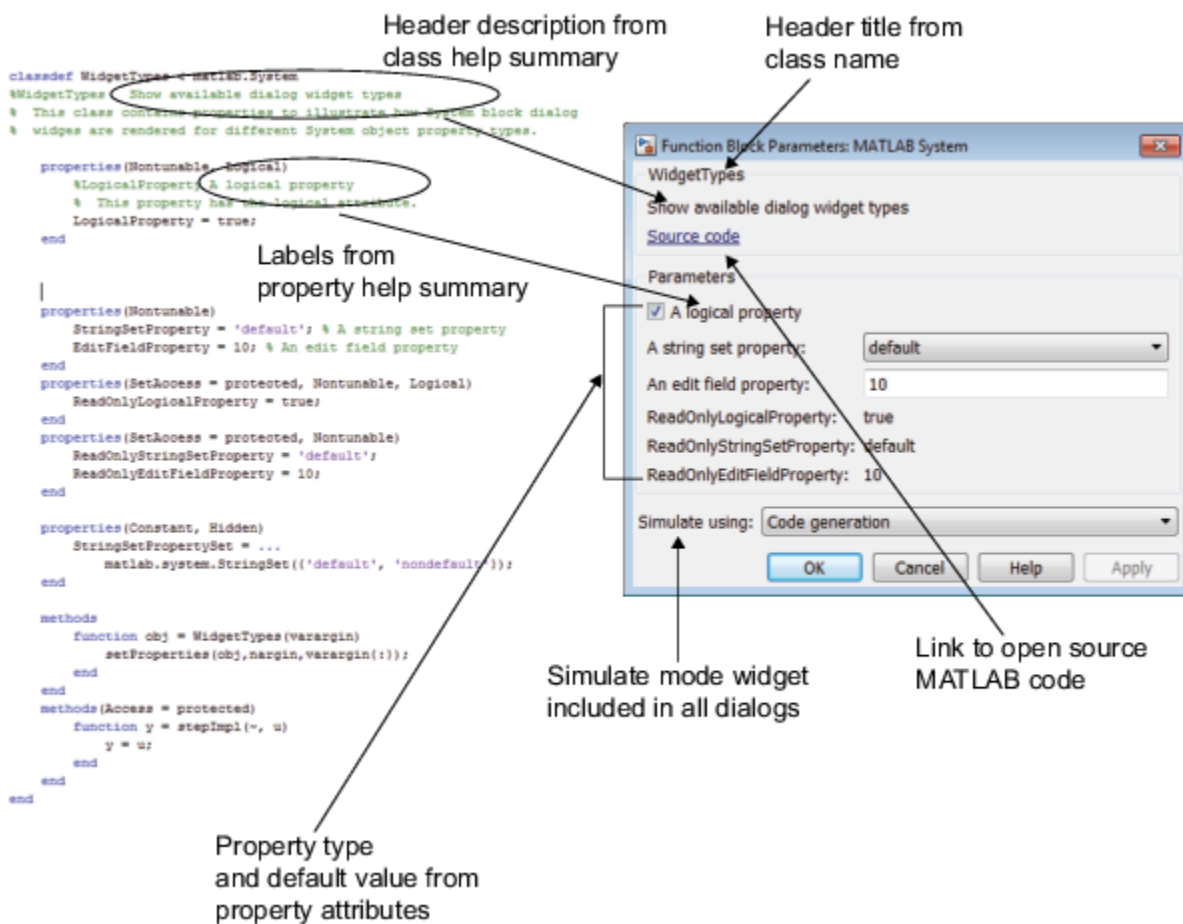

## Mapping System Object Code to MATLAB System Block Dialog Box

The System object source code controls the appearance of the block dialog box. This section maps the System object code to the block dialog box. This example code snippet uses two System objects, one that uses default System object to block dialog box mapping, and one that uses a custom mapping.

**Note** You can also change the appearance of a MATLAB System block dialog box using the Mask Editor. For more information, see “Customize System Object Dialog Box Using Mask Editor” on page 50-60.

### System Object to Block Dialog Box Default Mapping

The following figure shows how the source code corresponds to the dialog box elements when you do not customize the dialog using the `getHeaderImpl` or `getPropertyGroupsImpl` methods. (The link to open the source code and the **Simulate using** parameter appear on all MATLAB System block dialog boxes.)

The Delay block from the example model snippet uses a System object that draws the dialog box using the default mapping. This block has one input and one output.

This block uses a System object that has direct feedthrough set to false (nondirect feedthrough). This setting means that the System object does not directly use the input to compute the output, enabling the model to use this block safely in a feedback system without introducing an algebraic loop. For more information on nondirect feedthrough, see “Use System Objects in Feedback Loops” on page 50-17.

For an example of a custom block dialog box, see “System Object to Block Dialog Box Custom Mapping” on page 50-21.

## System Object to Block Dialog Box Custom Mapping

The LMS Adaptive block is an example of a block with a custom header and property groups. The System object code uses the `getHeaderImpl` and `getPropertyGroupsImpl` methods from `matlab.System` to customize these block dialog elements.

The LMS Adaptive Filter block estimates the coefficients of an unknown system (formed by the Unknown System and Delay blocks). Its inputs are the desired signal and the actual signal. Its outputs are the estimated signal and the vector norm of the error in the estimated coefficients. It uses the `lmsSysObj` System object.

```

classdef lmsSysObj < matlab.System & matlab.system.mixin.CustomIcon
%lmsSysObj Least mean squares (LMS) adaptive filtering.

methods(Static, Access=protected)

function header = getHeaderImpl
header = matlab.system.display.Header(...
'Title', 'LMS Adaptive Filter');
end

function groups = getPropertyGroupsImpl
firstGroup = matlab.system.display.SectionGroup(...
'Title', 'General', ...
'PropertyList', {'Mu'});

secondGroup = matlab.system.display.SectionGroup(...
'Title', 'Coefficients', ...
'PropertyList', {'TrueCoefficients', 'NumCoeff'});

groups = [firstGroup, secondGroup];
end
end

properties
% Mu Step Size
Mu = 0.005;
end
    
```

Header description from class help summary

Specified header title overrides class name

Tabs from SectionGroups

Label from product help summary

The source code for this System object also defines two input and output ports for the block.

```

function num = getNumInputsImpl(~)
num = 2;
end

function num = getNumOutputsImpl(~)
num = 2;
end

function icon = getIconImpl(~)
icon = sprintf('LMS Adaptive\nFilter');
end

function [name1, name2] = getInputNamesImpl(~)
name1 = 'Desired';
name2 = 'Actual';
end

function [name1, name2] = getOutputNamesImpl(~)
name1 = 'Output';
name2 = 'EstError';
end
    
```

## Considerations for Using System Objects in Simulink

### In this section...

“Variable-Size Signals” on page 50-24  
“Tunable Parameters” on page 50-24  
“System Objects as Properties” on page 50-24  
“Default Property Values” on page 50-25  
“System Objects in For Each Subsystems” on page 50-25  
“Input Validation” on page 50-25

There are differences in how you can use System objects in a MATLAB System block in Simulink versus using the same object in MATLAB. You see these differences when working with variable-size signals and tunable parameters and when using System objects as properties.

### Variable-Size Signals

To use variable-size signals in a System object, you must implement propagation methods. In particular, use the `isOutputFixedSizeImpl` method to specify if an output is variable-size or fixed-size. This method is needed for interpreted execution and code generation simulation methods.

### Tunable Parameters

Simulink registers public tunable properties of a System object as tunable parameters of the corresponding MATLAB System block. If a System object property is tunable, it is also tunable in the MATLAB System block. At runtime, you can change the parameter using one of the following approaches. The change applies at the top of the simulation loop.

- At the MATLAB command line, use the `set_param` to change the parameter value.
- In the Simulink editor, edit the MATLAB System block dialog box to change the parameter value, and then update the block diagram.

You cannot change public tunable properties from System object internal methods such as `stepImpl`.

During simulation, setting an invalid value on a tunable parameter causes an error message and stops simulation.

### System Objects as Properties

The MATLAB System block allows a System object to have other System objects as public or private properties. However:

- System objects and other MATLAB objects stored as public properties are read only. As a result, you cannot set the value of the parameter, you can only get the value of a parameter.
- System objects stored as property values appear dimmed in the MATLAB System block dialog box.

## Default Property Values

MATLAB does not require that objects assign default values to properties. However, in Simulink, if your System object has properties with no assigned default values, the associated dialog box parameter requires that the value data type be a built-in Simulink data type.

## System Objects in For Each Subsystems

To use the MATLAB System block within a For Each Subsystem block, implement the `supportsMultipleInstanceImpl` method. This method should return `true`. The MATLAB System block clones the System object for each For Each Subsystem iteration.

## Input Validation

In Simulink, use the `validateInputsImpl` method to validate only attributes (size, data type, and complexity) of the input. Do not use this method to validate the value of the input.

## **Simulink Engine Interaction with System Object Methods**

### **Simulink Engine Phases Mapped to System Object Methods**

This diagram shows a process view of the order in which the MATLAB System block invokes System object methods within the context of the Simulink engine.

### Initialization

Note the following:

- Simulink calls the `stepImpl`, `outputImpl`, and `updateImpl` methods multiple times during simulation at each time step. Simulink typically calls other methods once per simulation.
- The Simulink engine calls the `isOutputFixedSizeImpl`, `getDiscreteStateSpecificationImpl`, `isOutputComplexImpl`, `getOutputDataTypeImpl`, and `getOutputSizeImpl` when using propagation methods.
- Simulink calls `saveObjectImpl` and `loadObjectImpl` for saving and restoring the model operating point, the Simulation Stepper, and Fast Restart.
- Default implementations save and restore all properties with public access, including `DiscreteState`.

## Add and Implement Propagation Methods

### In this section...

“When to Use Propagation Methods” on page 50-29

“Implement Propagation Methods” on page 50-29

### When to Use Propagation Methods

Propagation methods define output specifications. Use them when the output specifications cannot be inferred directly from the inputs during Simulink model compilation.

Consider using propagation methods in your System object when:

- The System object requires access to all MATLAB functions that do not support code generation, which means that you cannot generate code for simulation. You must use propagation methods in this case and the interpreted execution mode for simulation. Code generation modes will not be supported.
- You want to use variable-size signals.
- You do not care whether code is generated, but you want to improve startup performance. Use propagation methods to specify information for the inputs and outputs, enabling quicker startup time.

At startup, the Simulink software tries to evaluate the input and output ports of the model blocks for signal attribute propagation. In the case of MATLAB System blocks, if the software cannot perform this evaluation, it displays a message prompting you to add propagation methods to the System object.

### Implement Propagation Methods

Simulink evaluates the uses of the propagation methods to evaluate the input and output ports of the MATLAB System block for startup.

Each method has a default implementation, listed in the **Default Implementation Should Suffice if** column. If your System object does not use the default implementation, you must implement a version of the propagation method for your System object.

Description	Propagation Method	Default Implementation Should Suffice if	Example
Gets dimensions of output ports. The associated method is <code>getOutputSize</code> .	<code>getOutputSizeImpl</code>	<ul style="list-style-type: none"> <li>• Only one input</li> <li>• Only one output</li> <li>• An input size that is the same as the output size</li> </ul>	<ul style="list-style-type: none"> <li>• Analysis and Plot block in “Illustration of Law of Large Numbers”</li> </ul>

Description	Propagation Method	Default Implementation Should Suffice if	Example
Gets data types of output ports. The associated method is <code>getOutputDataType</code> .	<code>getOutputDataTypeImpl</code>	<ul style="list-style-type: none"> <li>• Only one input</li> <li>• Only one output</li> <li>• Output data type always the same as the input data type</li> </ul>	<ul style="list-style-type: none"> <li>• Analysis and Plot block in “Illustration of Law of Large Numbers”</li> </ul>
Indicates whether output ports are complex or not. The associated method is <code>isOutputComplex</code> .	<code>isOutputComplexImpl</code>	<ul style="list-style-type: none"> <li>• Only one input</li> <li>• Only one output</li> <li>• Output complexity always the same as th input complexity</li> </ul>	<ul style="list-style-type: none"> <li>• Analysis and Plot block in “Illustration of Law of Large Numbers”</li> </ul>
Whether output ports are fixed size. ## Share Data with Other Blocks

### In this section...

“Setup Working Environment to Share System Object Data with Other Blocks” on page 50-31

“Data Sharing with the MATLAB System Block” on page 50-31

“Choose How to Store Shared Data” on page 50-32

“How to Use Data Store Memory Blocks for the MATLAB System Block” on page 50-33

“How to Set Up Simulink.Signal Objects” on page 50-34

“Using Data Store Diagnostics to Detect Memory Access Issues” on page 50-36

“Limitations of Using Shared Data in MATLAB System Blocks” on page 50-36

“Use Shared Data with P-Coded System Objects” on page 50-36

Share data between MATLAB System and other blocks using the `global` keyword and the Data Store Memory block or `Simulink.Signal` object. You might need to use global data with a MATLAB System block if:

- You have an existing model that uses a large amount of global data, you are adding a MATLAB System block to this model, and you want to avoid cluttering your model with additional inputs and outputs.
- You want to scope the visibility of data to parts of the model.

### Setup Working Environment to Share System Object Data with Other Blocks

This example opens up a directory containing the following files required for this topic.

- 1 `ex_globalsys_objmatrix1.slx`
- 2 `ex_globalsys_simulink_signal_share.slx`

### Data Sharing with the MATLAB System Block

In Simulink, you store global data using data store memory. You implement data store memory using either Data Store Memory blocks or `Simulink.Signal` objects. How you store global data depends on the number and scope of your global variables.

#### Scoping Rules for Shared Data in MATLAB System Blocks

The MATLAB System block uses these scoping rules:

- If you use the same name for both Data Store Memory block and `Simulink.Signal` object, Data Store Memory block scopes the data to the model.
- A global variable resolves hierarchically to the closest Data Store Memory block with the same name in the model. The same global variable appearing in two different MATLAB System blocks might resolve to different Data Store Memory blocks depending on the hierarchy of the model. You can use this ability to scope the visibility of data to a subsystem.

## Using Shared Data in MATLAB System Blocks

MATLAB System blocks support data store memory for:

- MATLAB structures (buses)
- Enumerated data types

## How to Use Data Sharing with the MATLAB System Block

To use shared data in your MATLAB System block:

- 1 Declare a global variable in the System object that you associate with the MATLAB System block.

You can use the `global` keyword in these methods of the System object:

- `stepImpl`
  - `outputImpl`
  - `updateImpl`
- 2 Add a Data Store Memory block or `Simulink.Signal` object that has the same name as the global variable in the System object.

To share data between referenced models using the `Simulink.Signal` object, define the `Simulink.Signal` object in the base workspace and use the same global variable name as in the MATLAB System block.

## Choose How to Store Shared Data

You can use Data Store Memory blocks or `Simulink.Signal` objects to store shared data.

Type of Data	Global Data Storage Method	Related Links
A small number of global variables in a single model that does not use model reference.	Data Store Memory blocks.  <b>Note</b> Using Data Store Memory blocks scopes the data to the model.	"How to Use Data Store Memory Blocks for the MATLAB System Block" on page 50-33
A large number of global variables in a single model that does not use model reference.	<code>Simulink.Signal</code> objects defined in the model workspace. <code>Simulink.Signal</code> objects offer these advantages: <ul style="list-style-type: none"> <li>• You do not have to add numerous Data Store Memory blocks to your model.</li> <li>• You can load the <code>Simulink.Signal</code> objects in from a MAT-file.</li> </ul>	"How to Set Up <code>Simulink.Signal</code> Objects" on page 50-34

Type of Data	Global Data Storage Method	Related Links
Data shared between multiple models (including referenced models).	Simulink.Signal objects defined in the base workspace  <b>Note</b> If you use Data Store Memory blocks as well as Simulink.Signal, note that using Data Store Memory blocks scopes the data to the model.	"How to Set Up Simulink.Signal Objects" on page 50-34

## How to Use Data Store Memory Blocks for the MATLAB System Block

- 1 Declare a global keyword in the System object methods that support globals. For example:  

```
global A;
```
- 2 Add a MATLAB System block to your model.
- 3 Double-click the MATLAB System block and associate the System object.
- 4 Add a Data Store Memory block to your model and set:
  - a **Data store name** to match the name of the global variable in your MATLAB System block code.
  - b **Data type** to an explicit data type.  
 The data type cannot be auto.
  - c **Signal type**.
  - d **Initial value**.

The initial value of the Data Store Memory block cannot be unspecified.

### Use Data Store Memory with the MATLAB System Block

This model demonstrates how a MATLAB System block uses the global data stored in Data Store Memory block B. The MATLAB System block is associated with the `globalSysObjMatrix1` System object. To see the completed model, open the `ex_globalSys_objmatrix1` model.

- 1 Drag these blocks into a new model:
  - MATLAB System
  - Data Store Memory
  - Display

- 2 Create a System object to associate with the MATLAB System block. To start, from the MATLAB System block, create a Basic System object template file.
- 3 In MATLAB Editor, create a System object with code like the following. Save the System object as `globalSysObjMatrix1.m`. The System object modifies B each time it executes.

```
classdef globalSysObjMatrix1 < matlab.System
    % Global/DSM support scalar example

    methods(Access = protected)
        function setupImpl(obj)
            % Perform one-time calculations, such as computing constants
        end

        function y = stepImpl(obj)
            global B;
            B(:,1)= B(:,1)+100;
            y = B;
        end
    end
end
```

- 4 Double-click the MATLAB System block and associate the `globalSysObjMatrix1` System object with the block.
- 5 In the model, double-click the Data Store Memory block B.
- 6 In the Signal Attributes tab, enter an initial value, for example:  
[74 75 5 1;22 23 24 32;33 44 55 22]
- 7 Simulate the model.

The MATLAB System block reads the initial value of global data stored in B and updates the value of B each time it executes. This model executes for five time steps.

- 8 Save and close your model.

## How to Set Up Simulink.Signal Objects

Create a `Simulink.Signal` object in the model workspace.

---

**Tip** Create a `Simulink.Signal` object in the base workspace to use the global data with multiple models.

---

- 1 In the Model Explorer, navigate to `model_name` > **Model Workspace** in the **Model Hierarchy** pane.

Select **Add > Simulink Signal**.

2 Ensure that these settings apply to the `Simulink.Signal` object:

a Set **Data type** to an explicit data type.

The data type cannot be auto.

b Set **Dimensions** to be fully specified.

The signal dimensions cannot be -1 or inherited.

c Set the **Complexity**.

d Specify an **Initial value**.

The initial value of the signal cannot be unspecified.

e Set **Name** to the name of the global variable.

### Use a `Simulink.Signal` Object with a MATLAB System Block

This simple model demonstrates how a MATLAB System block uses a `Simulink.Signal` with signal B. The MATLAB System block is associated with the `globalSysObjScalar` System object. To see the completed model, open the `ex_globalsys_simulink_signal_share` model.

1 Drag these blocks into a new model:

- MATLAB System
- Display

2 Create a System object to associate with the MATLAB System block. To start, from the MATLAB System block, create a Basic System object template file.

3 In MATLAB Editor, create a System object. Save the System object as `globalSysObjScalar.m`. The System object modifies B each time it executes.

```
classdef globalSysObjScalar < matlab.System
    % Global/DSM support scalar example

    methods(Access = protected)
        function setupImpl(obj)
            % Perform one-time calculations, such as computing constants
        end

        function y = stepImpl(obj)
            global B;
            B= B+100;
            y = B;
        end
    end
end
```

4 Double-click the MATLAB System block and associate the `globalSysObjScalar` System object with the block.

- 5 From the model, on the **Modeling** tab, click **Model Explorer**.
- 6 In the left pane of the Model Explorer, select the model workspace for this model.

The **Contents** pane displays the data in the model workspace.

- 7 In the Model Explorer, in the **Model Hierarchy** pane, navigate to *model\_name* > **Model Workspace**. In the **Contents** pane, set **Name** to B.
- 8 Navigate back to *model\_name* > **Model Workspace**.
  - Select **Add > Simulink Signal**.
  - Make these settings for the Simulink.Signal object:

Attribute	Value
Data type	double
Complexity	real
Dimensions	1
Initial value	25

- 9 Simulate the model.

The MATLAB System block reads the initial value of global data stored in B and updates the value of B each time it executes. The model runs for five time steps.

- 10 Save and close your model.

## Using Data Store Diagnostics to Detect Memory Access Issues

You can configure your model to provide run-time and compile-time diagnostics to avoid problems with data stores. Diagnostics are available in the Configuration Parameters dialog box and the Parameters dialog box for the Data Store Memory block. These diagnostics are available for Data Store Memory blocks only, not for Simulink.Signal objects. For more information on using data store diagnostics, see “Data Store Diagnostics” on page 78-3.

## Limitations of Using Shared Data in MATLAB System Blocks

The MATLAB System block does not support data store memory for variable-sized data

## Use Shared Data with P-Coded System Objects

If the System object is P-code, you must implement the `getGlobalNamesImpl` method to provide the global variable names you use in the System object. For example:

```
classdef GlobalSysObjMatrix < matlab.System
    % Matrix DSM support: Increment first row by 1 at each time step
    methods (Access = protected)
        function y = stepImpl(obj)
```

```
        global B;  
        B(1,:) = B(1, :)+1;  
        y = B;  
    end  
  
        function globalNames = getGlobalNamesImpl(~)  
        globalNames = {'B'};  
        end  
    end  
end
```

## Troubleshoot System Objects in Simulink

### In this section...

“Class Not Found” on page 50-38  
“Error Invoking Object Method” on page 50-38  
“Performance” on page 50-38

### Class Not Found

The MATLAB System block **System object name** parameter requires that you enter the full path to the System object class. In addition:

- Check that the System object class is on your MATLAB path.
- Check capitalization to make sure it matches.
- Check that the class name is a supported System object.
- Do not include the file extension.

### Error Invoking Object Method

The MATLAB System block supports only System objects written in the MATLAB language. If the software can identify an alternative block, it suggests that block in the error message, for example:

This message indicates that there is an existing dedicated and optimized block that you should use.

### Performance

For fastest performance, set the block **Simulate using** parameter to **Code generation**. This setting allows the MATLAB System block to run as fast as it can. The parameter is set to this value by default.

This setting causes a slower startup time, as the software generates C code and creates a MEX-file from it. However, after code generation, later simulations have better performance. When the block uses generated code to simulate, performance is typically better than simulation without generated code.

In some cases, the implementation of your System object does not allow you to generate code, which requires you to set **Simulate using** to **Interpreted execution**. For example, your System object can require MATLAB functions beyond the subset supported for code generation. In this case, use

propagation methods to specify the block input and output port information. The MATLAB System block then propagates this signal attribution information.

## Customize MATLAB System Block Dialog

This example shows you how to customize the block dialog for a MATLAB System block.

### System objects

System objects allow you to implement algorithms using MATLAB. System objects are a specialized kind of MATLAB object, designed specifically for implementing and simulating dynamic systems with inputs that change over time.

After you define a System object, you can include it in a Simulink model using a MATLAB System block.

### Model Description

This example contains a MATLAB System block that implements the System object `CustomDialog`. Use the MATLAB System block dialog box to modify properties of the System object. This example shows how to customize the prompt for a property and how to create check boxes, lists, groups, tabs, and buttons in the dialog box.

### Customizing the Block Dialog

Double Click on MATLAB System Block to Open Dialog

Copyright 2018 The MathWorks, Inc.

### System Object Class Definition

You can access MATLAB source code used by the MATLAB System block by clicking the "Source Code" hyperlink from the block dialog. The System object `CustomDialog` implements the `getPropertyGroupsImpl` and `getHeaderImpl` methods that are used to customize the appearance of the block dialog and organize the System object properties.

- 1 `PropertyDefault` - Property with no customization
- 2 `PropertyCustomPrompt` - Property with custom prompt
- 3 `PropertyEnum` - Enumeration property with a finite list of options
- 4 `PropertyLogical` - Property validation with `logical` to create check box
- 5 `PropertyInDifferentTab` - Property shown on a different tab of the dialog box

The `getPropertyGroupsImpl` method uses the `matlab.system.display.Section` and `matlab.system.display.SectionGroup` classes to create property sections and tabs in the dialog box. `getPropertyGroupsImpl` also creates a button in the "Group 2" section which calls the `visualize` method of the System object.

```
classdef CustomDialog < matlab.System
% CustomDialog Customize System block dialog

    properties
        PropertyDefault = 10
        % For PropertyDefault, with no comment above, property name is used
```

```
% as prompt

% PropertyCustomPrompt Use comment above property for custom prompt
PropertyCustomPrompt = 20

% PropertyEnum Use enumeration to limit values to finite list
PropertyEnum (1,1) ColorValues = ColorValuesEnum.blue

% PropertyInDifferentTab Use getPropertyGroupsImpl to create tabs
PropertyInDifferentTab = 30
end

properties(Nontunable)
% PropertyLogical Use logical property validation to create a checkbox
% Logical properties need to be Nontunable for use in Simulink
PropertyLogical (1,1) logical = true
end

methods(Access = protected)
function y = stepImpl(~, u)
    y = u;
end
end

methods (Static, Access = protected)
function groups = getPropertyGroupsImpl
% Use getPropertyGroupsImpl to create property sections in the
% dialog. Create two sections with titles "Group1" and
% "Group2". "Group1" contains PropertyDefault and
% PropertyCustomPrompt. "Group2" contains PropertyEnum,
% PropertyLogical, and a Visualize button.
    group1 = matlab.system.display.Section(...
        'Title', 'Group 1', ...
        'PropertyList', {'PropertyDefault', 'PropertyCustomPrompt'});

    group2 = matlab.system.display.Section(...
        'Title', 'Group 2', ...
        'PropertyList', {'PropertyEnum', 'PropertyLogical'});

% Add a button that calls back into the visualize method
    group2.Actions = matlab.system.display.Action(@(actionData,obj)...
        visualize(obj,actionData), 'Label', 'Visualize');

    tab1 = matlab.system.display.SectionGroup(...
        'Title', 'Tab 1', ...
        'Sections', [group1, group2]);

    tab2 = matlab.system.display.SectionGroup(...
        'Title', 'Tab 2', ...
        'PropertyList', {'PropertyInDifferentTab'});

    groups = [tab1, tab2];
end

function header = getHeaderImpl
    header = matlab.system.display.Header(mfilename('class'), ...
        'Title', 'AlternativeTitle', ...
        'Text', 'Customize dialog header using getHeaderImpl method.');
```

```
        end
    end

    methods
        function visualize(obj, actionData)
            % Use actionData to store custom data
            f = actionData.UserData;
            if isempty(f) || ~ishandle(f)
                f = figure;
                actionData.UserData = f;
            else
                figure(f); % Make figure current
            end

            d = 1:obj.PropertyCustomPrompt;
            plot(d);
        end
    end
end
```

## Break Algebraic Loops

This example shows how to create a MATLAB System block that can break an algebraic loop in the model.

### System objects

System objects allow you to implement algorithms using MATLAB. System objects are a specialized kind of MATLAB object, designed specifically for implementing and simulating dynamic systems with inputs that change over time.

After you define a System object, you can include it in a Simulink model using a MATLAB System block.

### Model Description

This example has a MATLAB System block that is used in a feedback loop in the model. The feedback loop is used to accumulate input values and the result is displayed in the Scope block. The feedback in the model creates an algebraic loop. To solve the algebraic loop, Simulink needs a block that has nondirect feedthrough. Blocks that have nondirect feedthrough are used in the feedback loops to break algebraic loops. This block can produce an output in the current time step without receiving the input first. In this example, MATLAB System block has nondirect feedthrough.

### Breaking Algebraic Loops

Copyright 2018 The MathWorks, Inc.

The MATLAB System block uses the System object `UnitDelayNondirect` that implements a unit delay. The output shows how the feedback loop accumulates the input signal values.

### System Object Class Definition

You can access MATLAB source code used by the MATLAB System block by clicking the "Source Code" hyperlink from the block dialog. The `UnitDelayNondirect` System object implements the `resetImpl`, `outputImpl`, and `updateImpl` methods. The System object has one property called `State`.

- `resetImpl` initializes the `State` property to 0.
- `outputImpl` returns the value stored in `State`. This System object has nondirect feedthrough because `outputImpl` does not use any inputs.
- `updateImpl` uses the inputs to update `State`.

```
classdef UnitDelayNondirect < matlab.System
% UnitDelayNondirect Delay input by one time step

properties(DiscreteState)
```

```
        State
    end

    methods(Access = protected)
        function resetImpl(obj)
            obj.State = 0; % Initialize states
        end
        function y = outputImpl(obj, ~)
            y = obj.State; % Output current state
            % Input is not used in this method
        end
        function updateImpl(obj,u)
            obj.State = u; % Update state with input
        end
    end
end
```

## Customize MATLAB System Block Appearance

This example shows how to customize the appearance of the MATLAB System block.

### System objects

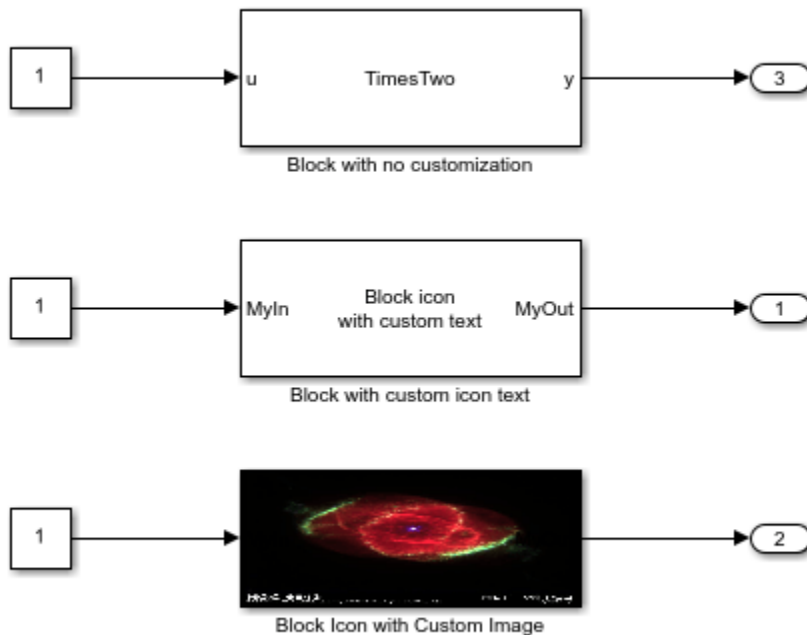

System objects allow you to implement algorithms using MATLAB. System objects are a specialized kind of MATLAB object, designed specifically for implementing and simulating dynamic systems with inputs that change over time.

After you define a System object, you can include it in a Simulink model using a MATLAB System block.

### Model Description

There are three MATLAB System blocks in this model. The first block does not have any customization for block appearance and by default shows the name of the System object on the block. The port labels for this block are obtained from the name of the arguments in the `stepImpl` method of the System object. Second block shows custom text and custom port labels on the block icon. The third block shows a custom block icon image.

### Customizing the Block Icon and Ports

Copyright 2018 The MathWorks, Inc.

### System Object Class Definition

You can access MATLAB source code used by the MATLAB System block by clicking the "Source Code" hyperlink from the block dialog. The `TimesTwo` System object used in the first block has no

customization and implements only the `stepImpl` method. The `CustomBlockIconExample` System object implements the following methods for customizing block appearance.

- `getInputNamesImpl` - Customize input port labels
- `getOutputNamesImpl` - Customize output port labels
- `getIconImpl` - Display text or an image on the block

The System object has a `DisplayImage` property to choose between text and image for display on the block.

### TimesTwo System object

```
classdef TimesTwo < matlab.System
%TimesTwo Multiply input by 2
% obj = TimesTwo returns a System object, obj, that
% multiplies its input by two.

    methods(Access = protected)
        function y = stepImpl(~, u)
            y = 2 * u;
        end
    end
end
```

### CustomBlockIconExample System object

```
classdef CustomBlockIconExample < matlab.System
% SystemObjectBlockIconExample Customize Block Icon

    properties(Nontunable)
        % DisplayImage Select to display image as block icon
        DisplayImage (1,1) logical = false
    end

    methods(Access = protected)
        function y = stepImpl(~, u)
            y = u;
        end
        function inputName = getInputNamesImpl(~)
            inputName = "MyIn";
        end
        function outputName = getOutputNamesImpl(~)
            outputName = "MyOut";
        end
        function icon = getIconImpl(obj)
            % Return text or image to be displayed on the block icon
            % Use array of strings to display multiple lines of text
            if obj.DisplayImage
                % Display image
                icon = matlab.system.display.Icon('slexngc6543aPix.jpg');
            else
                % Display text
                icon = ["Block icon", "with custom text"];
            end
        end
    end
end
```

```
    end  
end
```

## Implement a Simple Algorithm

This example shows how to use a simple System object™ in Simulink® with the MATLAB System block.

### System Objects

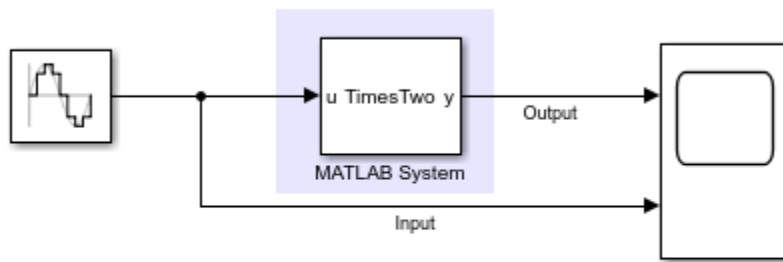

System objects allow you to implement algorithms using MATLAB®. System objects are a specialized kind of MATLAB object, designed specifically for implementing and simulating dynamic systems with inputs that change over time.

After you define a System object, you can include it in a model using a MATLAB System block.

### Open and Simulate the Model

This model has a MATLAB System block that uses the System object `TimesTwo` that multiplies the input by two. The input to the MATLAB System block is provided by the Sine Wave block. The Scope block displays the output along with the input. When you run the model, you can see in the Scope block that the input to MATLAB System block is multiplied by two.

### Basic MATLAB System Block

Copyright 2018 The MathWorks, Inc.

### System Object Class Definition

You can access MATLAB source code used by the MATLAB System block by clicking the Source Code hyperlink in the Block Parameters dialog box. The System object implements only the `stepImpl` method. The algorithm does not need any properties or additional methods.

```
classdef TimesTwo < matlab.System
%TimesTwo Multiply input by 2
% obj = TimesTwo returns a System object, obj, that
% multiplies its input by two.

    methods(Access = protected)
        function y = stepImpl(~, u)
            y = 2 * u;
        end
    end
end
```

### MATLAB System Block Icon and Dialog Box

The MATLAB System block displays the name of the System object `TimesTwo` on the block and uses the input and output variable names from the `stepImpl` method of the `TimesTwo` class as port labels. If you open the MATLAB System Block Parameters dialog box by double clicking the block, the dialog box shows title as `TimesTwo` and the description `Multiply input by 2`. The title comes from the name of the System object, and the description is created from the class help summary in the System object.

## Specify Output Characteristics of MATLAB System Block

This example shows how to specify output size, data type and complexity of a MATLAB System block.

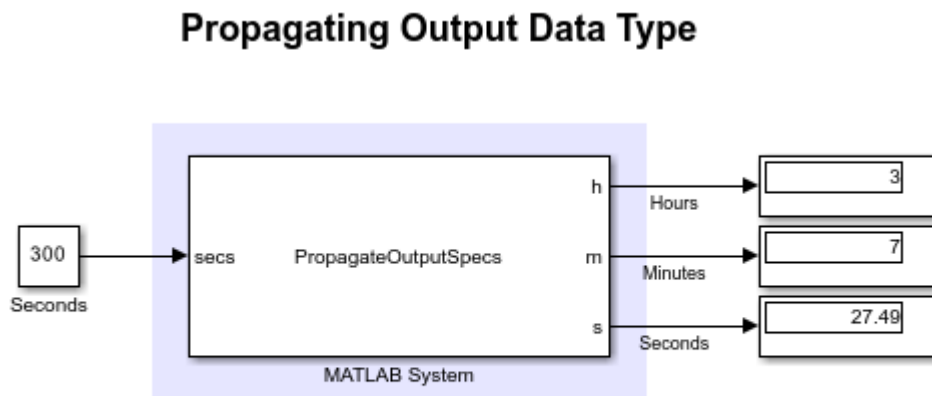

### System objects

System objects allow you to implement algorithms using MATLAB. System objects are a specialized kind of MATLAB object, designed specifically for implementing and simulating dynamic systems with inputs that change over time.

After you define a System object, you can include it in a Simulink model using a MATLAB System block.

### Model Description

This example has a MATLAB System block that adds input number of seconds to the current time and produces the resulting hours, minutes and seconds as outputs. The output values from each output port are displayed in the Display blocks.

Copyright 2018 The MathWorks, Inc.

This example, shows how to specify output size, data type and complexity of a System object. You specify the output properties when MATLAB System block cannot infer them automatically. The MATLAB System block uses the System object `PropagateOutputSpecs` that implements methods to propagate input data type, size and complexity.

### System Object Class Definition

You can access MATLAB source code used by the MATLAB System block by clicking the "Source code" hyperlink from the block dialog. The System object `PropagateOutputSpecs` implements the `stepImpl` method that adds the input value in seconds to current time and outputs the resulting hours, minutes and seconds. The `stepImpl` method uses `datetime` function to calculate its output. Since `datetime` function is not supported for code generation, MATLAB System block cannot infer the output specifications automatically. The System object implements the following methods to specify output properties:

- `getOutputSizeImpl` - Specify output size
- `getOutputDataTypeImpl` - Specify output data type
- `isOutputComplexImpl` - Specify output complexity
- `isOutputFixedSizeImpl` - Specify whether output can be variable-size

```
classdef PropagateOutputSpecs < matlab.System
% PropagateOutputSpecs Propagation in Simulink

    methods(Access = protected)
        function [h, m, s] = stepImpl(~, secs)
            % Add input hours, minutes and seconds to current time
            d = datetime;
            d = d + seconds(secs);
            h = hour(d);
            m = minute(d);
            s = second(d);
        end

        function [o1, o2, o3] = getOutputSizeImpl(obj)
            % Return size for output port to be same as input port
            inSize = propagatedInputSize(obj, 1);
            o1 = inSize;
            o2 = inSize;
            o3 = inSize;
        end

        function [o1, o2, o3] = getOutputDataTypeImpl(obj)
            % Return data type for output port to be same as input port
            inType = propagatedInputDataType(obj, 1);
            o1 = inType;
            o2 = inType;
            o3 = inType;
        end

        function [o1, o2, o3] = isOutputComplexImpl(~)
            % Return output port complexity to be real
            o1 = false;
            o2 = false;
            o3 = false;
        end

        function [o1, o2, o3] = isOutputFixedSizeImpl(~)
            % Return true for each output port with fixed size
            o1 = true;
            o2 = true;
            o3 = true;
        end
    end
end
```

## Customize System Block Appearance

### In this section...

“Specify Input and Output Names” on page 50-56

“Add Text to Block Icon” on page 50-57

“Add Image to Block Icon” on page 50-58

### Specify Input and Output Names

Specify the names of the input and output ports of a System object-based block implemented using a MATLAB System block.

Use `getInputNamesImpl` and `getOutputNamesImpl` to specify the names of the input port as “source data” and the output port as “count.”

If you do not specify the `getInputNamesImpl` and `getOutputNamesImpl` methods, the object uses the `stepImpl` method input and output variable names for the input and output port names, respectively. If the `stepImpl` method uses *varargin* and *varargout* instead of variable names, the port names default to empty character vectors.

```
methods (Access = protected)
    function inputName = getInputNamesImpl(~)
        inputName = 'source data';
    end

    function outputName = getOutputNamesImpl(~)
        outputName = 'count';
    end
end
```

### Complete Class Definition with Named Inputs and Outputs

```
classdef MyCounter < matlab.System

    % MyCounter Count values above a threshold

    properties
        Threshold = 1
    end
    properties (DiscreteState)
        Count
    end

    methods
        function obj = MyCounter(varargin)
            setProperties (obj,nargin,varargin{:});
        end
    end

    methods (Access = protected)
        function setupImpl(obj)
            obj.Count = 0;
        end
        function resetImpl(obj)
```

```

        obj.Count = 0;
    end
    function y = stepImpl(obj,u)
        if (u > obj.Threshold)
            obj.Count = obj.Count + 1;
        end
        y = obj.Count;
    end
    function inputName = getInputNamesImpl(~)
        inputName = 'source data';
    end
    function outputName = getOutputNamesImpl(~)
        outputName = 'count';
    end
end
end
end

```

## Add Text to Block Icon

Add text to the block icon of a System object-based block implemented using a MATLAB System block.

- 1 Subclass from custom icon class.

```
classdef MyCounter < matlab.System & matlab.system.mixin.CustomIcon
```

- 2 Use `getIconImpl` to specify the block icon as `New Counter` with a line break between the two words.

```

methods (Access = protected)
    function icon = getIconImpl(~)
        icon = {'New', 'Counter'};
    end
end
end

```

### Complete Class Definition File with Defined Icon

```

classdef MyCounter < matlab.System & ...
    matlab.system.mixin.CustomIcon

    % MyCounter Count values above a threshold

    properties
        Threshold = 1
    end
    properties (DiscreteState)
        Count
    end

    methods
        function obj = MyCounter(varargin)
            setProperties(obj, nargin, varargin{:});
        end
    end

    methods (Access = protected)
        function setupImpl(obj)
            obj.Count = 0;
        end
    end
end

```

```

end
function resetImpl(obj)
    obj.Count = 0;
end
function y = stepImpl(obj,u)
    if (u > obj.Threshold)
        obj.Count = obj.Count + 1;
    end
    y = obj.Count;
end
function icon = getIconImpl(~)
    icon = {'New', 'Counter'};
end
end
end
end

```

## Add Image to Block Icon

Define an image on the block icon of a System object-based block implemented using a MATLAB System block.

- 1 Subclass from custom icon class.

```
classdef MyCounter < matlab.System & matlab.system.mixin.CustomIcon
```

- 2 Use `getIconImpl` method to call the `matlab.system.display.Icon` class and specify the image.

```

methods (Access = protected)
    function icon = getIconImpl(~)
        icon = matlab.system.display.Icon('counter.png');
    end
end
end

```

## Complete Class Definition File with Icon Image

```

classdef MyCounter < matlab.System & ...
    matlab.system.mixin.CustomIcon

    % MyCounter Count values above a threshold

    properties
        Threshold = 1
    end
    properties (DiscreteState)
        Count
    end

    methods
        function obj = MyCounter(varargin)
            setProperties(obj,nargin,varargin{:});
        end
    end

    methods (Access = protected)
        function setupImpl(obj)
            obj.Count = 0;
        end
    end
end

```

```
function resetImpl(obj)
    obj.Count = 0;
end
function y = stepImpl(obj,u)
    if (u > obj.Threshold)
        obj.Count = obj.Count + 1;
    end
    y = obj.Count;
end
function icon = getIconImpl(~)
    icon = matlab.system.display.Icon('counter.png');
end
end
end
```

## Customize System Object Dialog Box Using Mask Editor

The Mask Editor provides a robust way of customizing a System Object dialog box. To employ the use of the Mask Editor, you must first define block parameters in a System Object file. On launch from the System Object toolstrip, Mask Editor pre-populates block parameters from the System Object file. You cannot add or delete block parameters from the Mask Editor.

In the Mask Editor, you can use a rich set of graphical controls such as buttons, list control, images or hyperlinks to enhance a dialog box. You can change the value, position, layout, prompt, and properties of existing block parameters. You can change the type of a block parameter to a compatible type.

### Build System Object Dialog Box Using Mask Editor

Follow these steps to create a dialog box for the MATLAB System block using the Mask Editor.

#### Initialize Block Parameters in System Object File

This example customizes the dialog box for a MATLAB System block called `MaskEditorDialogBox`. To begin with, you must initialize block parameters in the System Object class of `MaskEditorDialogBox` to later edit in the Mask Editor.

```
classdef MaskEditorDialogBox < matlab.System
    % Initialize block dialog parameters.

    % Public, tunable properties
    properties
        %InitialTestValue Initial Test Value
        InitialTestValue = 0

        %FinalTestValue Final Test Value
        FinalTestValue = 32

        UpperLimit = 10

        %LowerLimit Lower Limit
        LowerLimit = 4
    end

    % Public Nontunable
    properties(Nontunable)
        %IC1 First initial condition
        IC1 = 0

        %IC2 Second initial condition
        IC2 = 40

        %IC3 Third initial condition
        IC3 = 95

        %EnforceUpperLimit Enforce Upper Limit
        EnforceUpperLimit (1,1) logical = true
    end
end
```

end

Run the following commands to open the dialog box resulting from the code.

```
load_system('MaskEditorBlockDialog')
open_system('MaskEditorBlockDialog/MATLAB System')
```

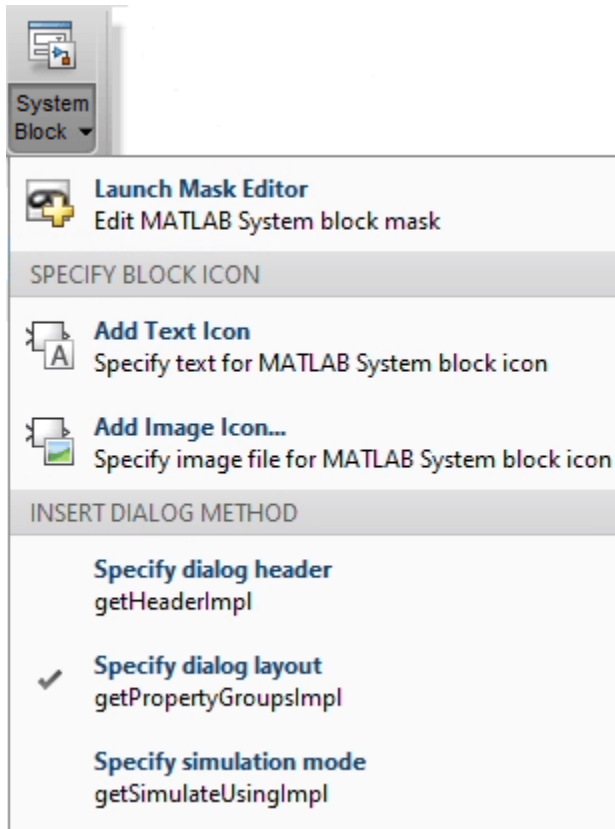

### Launch Mask Editor

Keep the dialog box for the `MaskEditorDialogBox` block open so that you can refer to it while making changes in the Mask Editor. You can also click the **System Block > Launch Mask Editor > Parameters and Dialog > Preview Dialog** button from the System Object toolbar to view the dialog box as it stands currently.

Launch the Mask Editor in one of three ways.

- Select **System Block > Launch Mask Editor** from the System object toolstrip.

- Right-click the corresponding MATLAB System block and select **Mask > Edit Mask**.
- Select the corresponding MATLAB System block and press **Ctrl + M**.

The Mask Editor displays the parameters initialized in the `MaskEditorDialogBox` System object class. Change the appearance of the dialog box from the Mask Editor in one of the following ways.

- Create a new tab container.
- Move parameters between containers.
- Change the layout of parameters.
- Change parameter type.
- Change the prompts for parameters and containers.

In addition, you can also add other display widgets such as buttons, list control, images, or hyperlinks to a dialog box. These widgets are not dependent on block parameters.

### Create a New Tab Container

In the Mask Editor, create a new tab called **Additional Properties** above the existing **Parameters** group box container:

- Navigate to the **Parameters and Dialog** pane of the Mask Editor.
- Drag the **Tab Container** control from the **Container** pane on the left, to the location above the row with the prompt **Parameters**.

Type	Prompt	Name
MaskEditorDialogBox	MaskEditorDialogBox	DescGroupVar
A	Initialize block dialog parame...	DescTextVar
	Source code	SourceCodeLink
	(N/A)	Container4
Parameters	Parameters	SectionGroup1_Section1
Parameter   Edit	Initial Test Value:	InitialTestValue
#2	Final Test Value:	FinalTestValue
#3	UpperLimit:	UpperLimit
#4	Lower Limit:	LowerLimit
#5	First initial condition:	IC1
#6	Second initial condition:	IC2
#7	Third initial condition:	IC3
<input checked="" type="checkbox"/> #8	Enforce Upper Limit	EnforceUpperLimit
	(N/A)	SectionGroup1_Section2
#9	Simulate using:	SimulateUsing

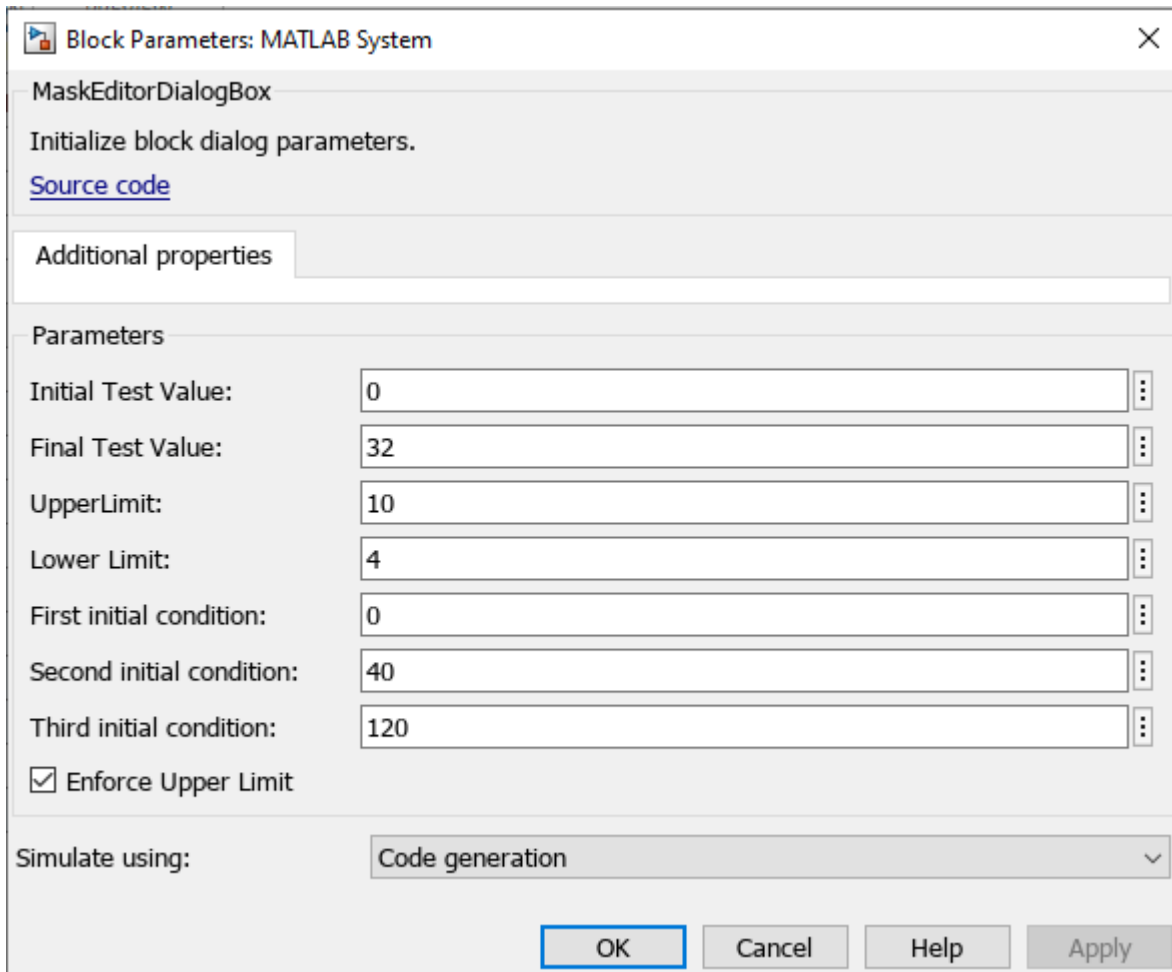

- A new row is created above the **Parameters** group box container. Enter the **Name** as **SectionGroup0\_Section1**.

Type	Prompt	Name
MaskEditorDialogBox	MaskEditorDialogBox	DescGroupVar
A	Initialize block dialog parame...	DescTextVar
	Source code	SourceCodeLink
	(N/A)	SectionGroup0_Section1
Parameters	Parameters	SectionGroup1_Section1
#1	Initial Test Value:	InitialTestValue
#2	Final Test Value:	FinalTestValue
#3	UpperLimit:	UpperLimit
#4	Lower Limit:	LowerLimit
#5	First initial condition:	IC1
#6	Second initial condition:	IC2
#7	Third initial condition:	IC3
<input checked="" type="checkbox"/> #8	Enforce Upper Limit	EnforceUpperLimit
	(N/A)	SectionGroup1_Section2
#9	Simulate using:	SimulateUsing

- Click on the newly created row and select **Tab** in the **Container** pane on the left. A new tab is created within the tab container. In the **Prompt** column, enter the prompt text as **Additional Properties**. Enter the **Name** as **Tab1**.

Type	Prompt	Name
▼ [icon]	MaskEditorDialogBox	DescGroupVar
A	Initialize block dialog parame...	DescTextVar
[link icon]	Source code	SourceCodeLink
▼ [folder icon]	(N/A)	SectionGroup0_Section1
[folder icon]	Additional properties	Tab1
▼ [icon]	Parameters	SectionGroup1_Section1
[text icon] #1	Initial Test Value:	InitialTestValue
[text icon] #2	Final Test Value:	FinalTestValue
[text icon] #3	UpperLimit:	UpperLimit
[text icon] #4	Lower Limit:	LowerLimit
[text icon] #5	First initial condition:	IC1
[text icon] #6	Second initial condition:	IC2
[text icon] #7	Third initial condition:	IC3
[checkbox icon] #8	Enforce Upper Limit	EnforceUpperLimit
▼ [icon]	(N/A)	SectionGroup1_Section2
[text icon] #9	Simulate using:	SimulateUsing

- Press **Save Mask** and check the dialog box of the block. A new tab with the title **Additional Properties** is created.

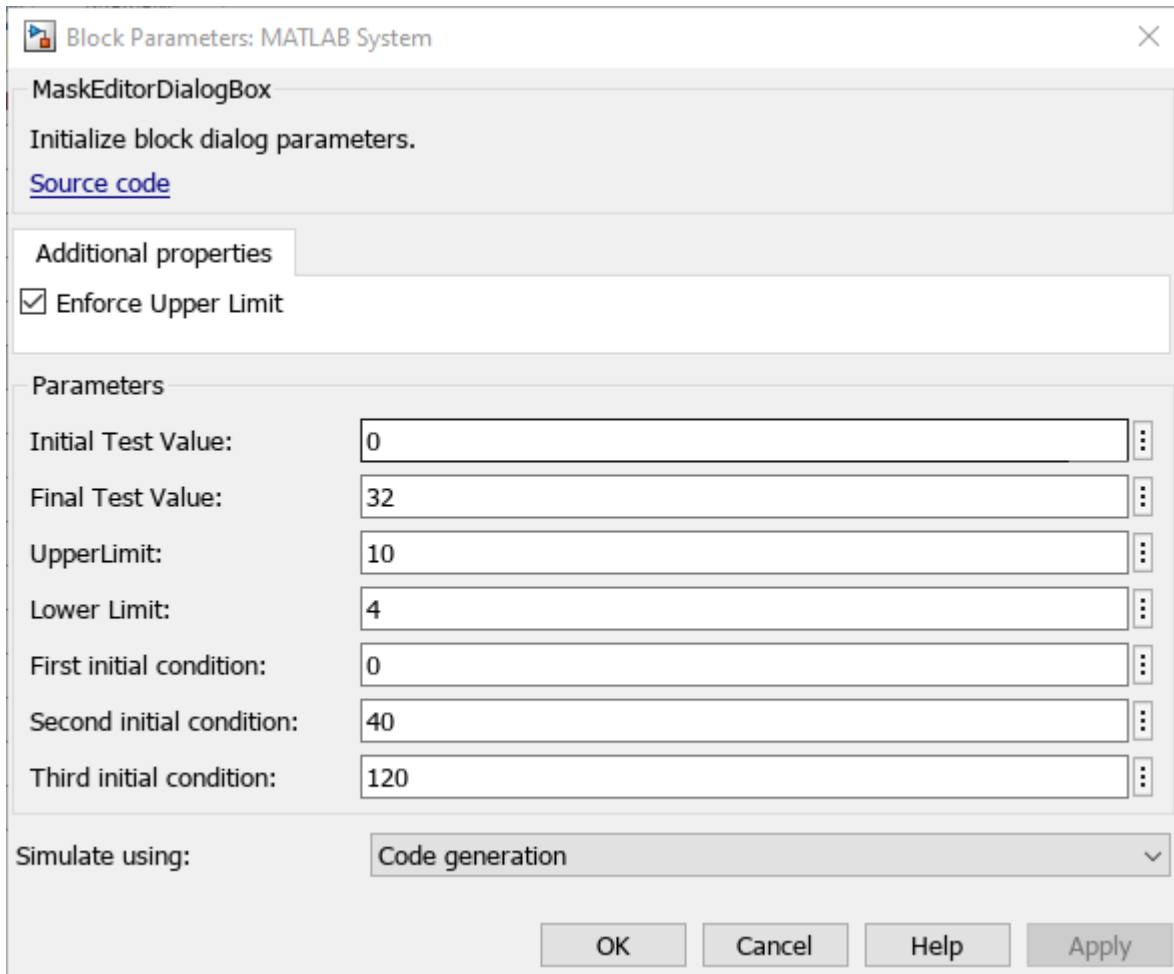

### Move Parameters Between Containers

In the Mask Editor, move the existing parameter named **EnforceUpperLimit** to the newly created tab:

- Drag the row containing the parameter named **EnforceUpperLimit** onto the **Tab1** row.
- Release the row containing the **EnforceUpperLimit** parameter so that it snaps to position below the **Tab1** row. Press **Save Mask**.

▼ 	(N/A)	SectionGroup0_Section1
▼ 	Additional properties	Tab1
<input checked="" type="checkbox"/> #1	Enforce Upper Limit	EnforceUpperLimit
▼ 	Parameters	SectionGroup1_Section1
 #2	Initial Test Value:	InitialTestValue
 #3	Final Test Value:	FinalTestValue
 #4	UpperLimit:	UpperLimit
 #5	Lower Limit:	LowerLimit
 #6	First initial condition:	IC1
 #7	Second initial condition:	IC2
 #8	Third initial condition:	IC3
▼ 	(N/A)	SectionGroup1_Section2
 #9	Simulate using:	SimulateUsing

- This action causes the **Enforce Upper Limit** check box to move to the **Additional Properties** tab of the dialog box.

### Change the Layout of Parameters

In the Mask Editor, change a layout property for the **IC3** text box. For example, you can change the location of the text prompt label:

- Click on the **IC3** row in the **Parameters and Dialog** pane.
- In the **Property Editor** pane on the right, under **Layout**, select **top** from the **Prompt Location** list. Press **Save Mask**.

LAYOUT	
Row Location	new
Prompt Location	top
Horizontal Stretch	<input checked="" type="checkbox"/>

- In the dialog box, the **Third initial condition:** text box label moves from the left of the text box to the top.

### Change Parameter Type

In the Mask Editor, change the type of the **IC3** text box to **dial**, and define the minimum and maximum values:

- Click on the **IC3** row in the **Parameters and Dialog** pane.
- In the **Property Editor** pane on the right, under **Properties**, select **dial** from the **Type** list.
- Enter 0 as the **Minimum** value and 100 as the **Maximum** value. Select **Linear** from the **Scale** drop-down list. Press **Save Mask**.
- In the dialog box, the **IC3** text box is converted to a dial with the minimum and maximum values at either end. Choose the required value by rotating the dial.

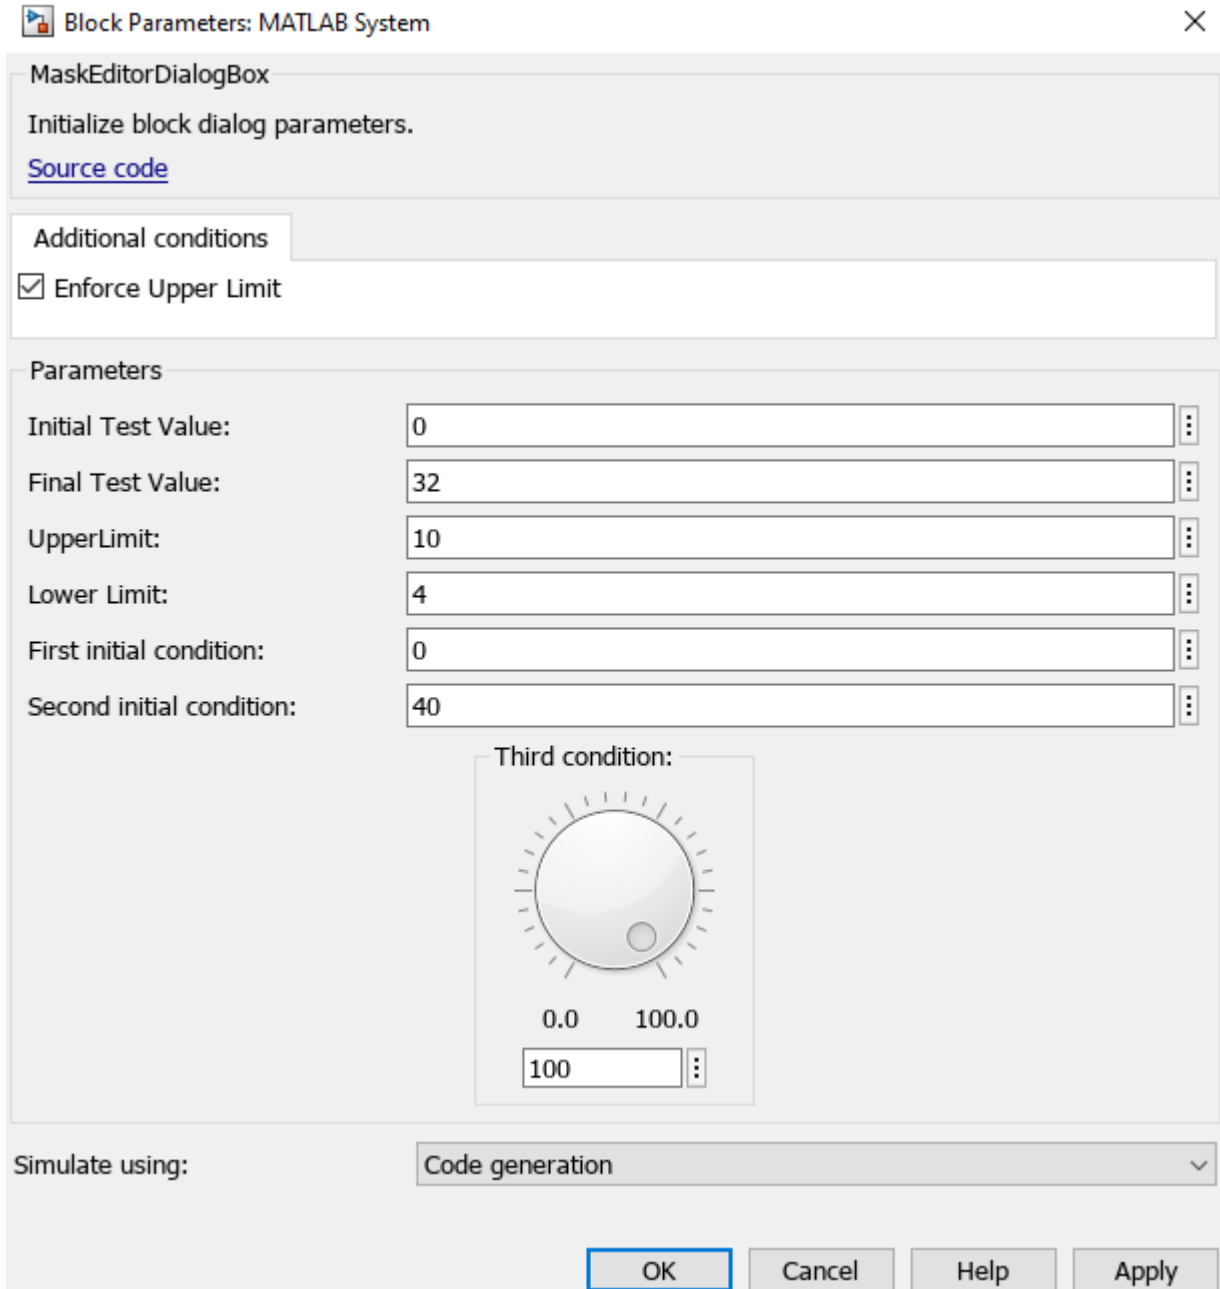

### Change Parameter and Container Prompts

In the Mask Editor, change the prompt of the **IC3** text box and the **Additional Properties** tab to new strings:

- Double-click on the text in the **Prompt** column of the **Tab1** row in the **Parameters and Dialog** pane. Edit the prompt text to **Additional Conditions**.
- Double-click on the text in the **Prompt** column of the **IC3** row in the **Parameters and Dialog** pane. Edit the prompt text to **Third Condition:**
- The text labels are changed to the new strings in the dialog box.

### Migrate Existing Dialog Box Customizations to Mask Editor

If you previously customized your MATLAB System dialog box using the `getPropertyGroupsImpl` function, then you can migrate all the customizations to the Mask Editor:

- 1 Launch the Mask Editor. The Mask Editor displays the most recent dialog controls and layout as programmed in the `getPropertyGroupsImpl` function.
- 2 Continue work on the dialog box customizations, if required.
- 3 When done, click **Save Mask** to complete the migration. On saving the mask, the following changes occur:

- The **getPropertyGroupsImpl** function is removed from the body of the System Object file.
- The dialog customizations of the **getPropertyGroupsImpl** function are moved to a new XML file with the name format: `sysObjectName_mask.xml`.
- The `sysObjectName_mask.xml` file is stored in the same location as the System Object file.

In this way, the **getPropertyGroupsImpl** function is migrated to the `sysObjectName_mask.xml` file. When the Mask Editor is invoked next, Simulink loads all dialog customizations from the `sysObjectName_mask.xml` file.

## Customize System Block Dialog Box Using System object

### In this section...

“Define Block Dialog Tabs, Sections, and Order of Properties” on page 50-71

“Define Property Sections” on page 50-74

“Add Header Description” on page 50-76

“Control Simulation Type in MATLAB System Block” on page 50-77

“Add Custom Button to MATLAB System Block” on page 50-78

You can customize the dialog box for a MATLAB System block by adding properties and methods in the corresponding System object. You can add tabs, organized properties into groups and sections, add block descriptions, simulation type control, and add custom buttons.

**Note** From R2022b, you can use the Mask Editor to design a MATLAB System dialog box. You can also migrate existing dialog box customizations to the Mask Editor. This capability eliminates the need to develop or maintain the `getPropertyGroupsImpl` method in a System object file. For more information, see “Customize System Object Dialog Box Using Mask Editor” on page 50-60.

### Define Block Dialog Tabs, Sections, and Order of Properties

This example customizes the block dialog box for the `MultipleGroupsWithTabs` MATLAB System block by specifying property display names and modifying the `getPropertyGroupImpl` method.

#### Change Property Label

To change the property label that appears on the dialog box, add comments before each property in this format `%PropertyName Block Dialog Label` with no space between the comment and the property name. For example, to display the `StartValue` property as **Start Value**, specify:

```
%StartValue Start Value
StartValue = 0
```

The `MultipleGroupsWithTabs` System object in this example relabels each property for display in the MATLAB System block dialog.

#### Organize Dialog Box

The `MultipleGroupsWithTabs` System object class defines a `getPropertyGroupsImpl` method. Inside the `getPropertyGroupsImpl` method, this example defines two tabs (section groups) and three parameter groupings (sections).

```
classdef MultipleGroupsWithTabs < matlab.System
    % MultipleGroupsWithTabs Customize block dialog with multiple tabs and parameter groups.

    % Public, tunable properties
    properties
        %StartValue Start Value
        StartValue = 0
    end
end
```

```

    %EndValue End Value
    EndValue = 10

    Threshold = 1

    %BlockLimit Limit
    BlockLimit = 55
end
% Public Nontunable
properties(Nontunable)
    %IC1 First initial condition
    IC1 = 0

    %IC2 Second initial condition
    IC2 = 10

    %IC3 Third initial condition
    IC3 = 100

    %UseThreshold Use threshold
    UseThreshold (1,1) logical = true
end

methods (Static, Access = protected)
    function groups = getPropertyGroupsImpl
        % Section to always display above any tabs.
        alwaysSection = matlab.system.display.Section(...
            'Title', '', 'PropertyList', {'BlockLimit'});

        % Group with no sections
        initTab = matlab.system.display.SectionGroup(...
            'Title', 'Initial conditions', ...
            'PropertyList', {'IC1', 'IC2', 'IC3'});

        % Section for the value parameters
        valueSection = matlab.system.display.Section(...
            'Title', 'Value parameters', ...
            'PropertyList', {'StartValue', 'EndValue'});

        % Section for the threshold parameters
        thresholdSection = matlab.system.display.Section(...
            'Title', 'Threshold parameters', ...
            'PropertyList', {'Threshold', 'UseThreshold'});

        % Group with two sections: the valueSection and thresholdSection sections
        mainTab = matlab.system.display.SectionGroup(...
            'Title', 'Main', ...
            'Sections', [valueSection, thresholdSection]);

        % Return an array with the group-less section, the group with
        % two sections, and the group with no sections.
        groups = [alwaysSection, mainTab, initTab];
    end
end
end

```

### Resulting Dialog Box

```
load_system('ShowSystemBlockDialog')
open_system('ShowSystemBlockDialog/MATLAB System')
```

## Define Property Sections

This example customizes the block dialog box for a MATLAB System block by specifying property display names and modifying the `getPropertyGroupImpl` method. This customization is demonstrated with the System object `AddPropertySections`.

### Change Property Labels

To change the property label that appears on the dialog box, add comments before each property in this format `%PropertyName Block Dialog Label` with no space between the percent sign and the property name. For example, to display the `UseAlpha` property as **Use alpha**, specify:

```
%UseAlpha Use alpha
UseAlpha = 0
```

The `AddPropertySections` System object included with this example relabels properties for display in the MATLAB System block dialog.

### Organize Dialog Box

To organize the properties on the dialog box, the `AddPropertySections` System object class defines a `getPropertyGroupsImpl` method. Inside the `getPropertyGroupsImpl` method, this example defines two sections, each with two properties.

```

classdef AddPropertySections < matlab.System
    % AddPropertySections Customized dialog with two parameter sections

    % Public, tunable properties
    properties
        %NumberOfShapes Number of shapes
        NumberOfShapes = 10

        Alpha = 0.75
    end

    % Public, nontunable properties
    properties(Nontunable)
        Coloring (1, 1) {mustBeMember(Coloring,["red","blue","green"])} = "red"

        %UseAlpha Use alpha
        UseAlpha (1,1) logical = false
    end

    methods (Static, Access = protected)
        function groups = getPropertyGroupsImpl
            % Section for the value parameters
            valueSection = matlab.system.display.Section(...
                'Title', 'Shape parameters',...
                'PropertyList',{'NumberOfShapes', 'Coloring'});

            % Section for the threshold parameters
            shadingSection = matlab.system.display.Section(...
                'Title', 'Shading parameters',...
                'PropertyList',{'UseAlpha', 'Alpha'});

            % Return an array with the two sections.
            groups = [valueSection, shadingSection];
        end
    end
end
end

```

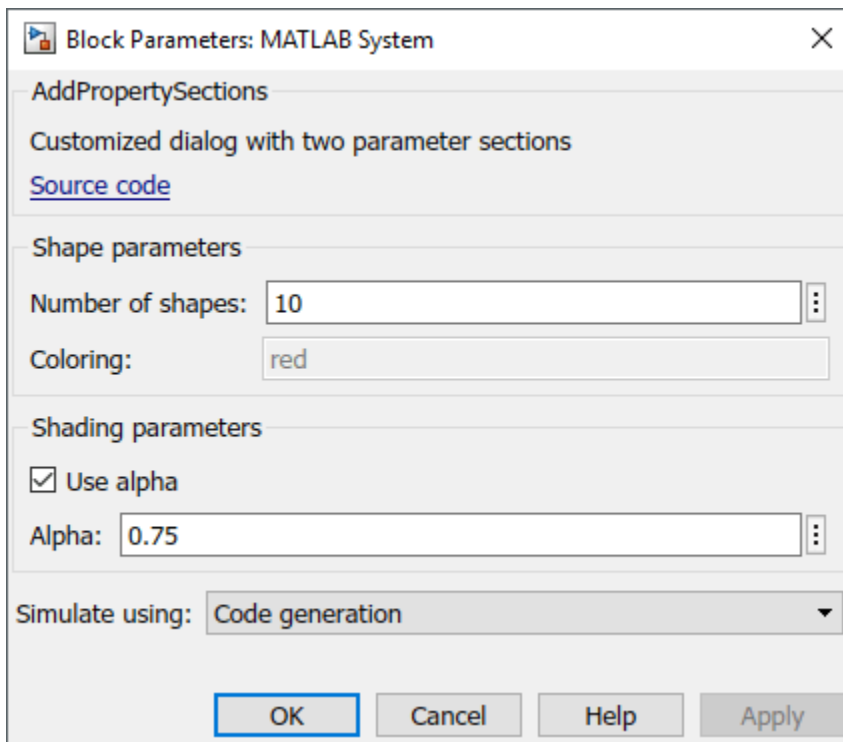

### Resulting Dialog Box

```

load_system('CustomSystemBlockDialog')
open_system('CustomSystemBlockDialog/MATLAB System')

```

## Add Header Description

Add a header panel to a MATLAB System block by adding the `getHeaderImpl` method to your System object.

Use `getHeaderImpl` to specify a panel title and text for the `MyCounter` System object. If you do not specify the `getHeaderImpl`, the block does not display any title or text for the panel.

As for all `Impl` methods, set the `getHeaderImpl` method access to `protected` because the method is only called internally.

```
methods (Static, Access = protected)
    function header = getHeaderImpl
        header = matlab.system.display.Header('MyCounter', ...
            'Title', 'My Enhanced Counter');
    end
end
```

## Complete Class Definition

```
classdef MyCounter < matlab.System

    % MyCounter Count values

    properties
        Threshold = 1
    end
    properties (DiscreteState)
        Count
    end
end
```

```

methods (Static, Access = protected)
    function header = getHeaderImpl
        header = matlab.system.display.Header('MyCounter',...
            'Title','My Enhanced Counter',...
            'Text', 'This counter is an enhanced version. ');
    end
end

methods (Access = protected)
    function setupImpl(obj,u)
        obj.Count = 0;
    end
    function y = stepImpl(obj,u)
        if (u > obj.Threshold)
            obj.Count = obj.Count + 1;
        end
        y = obj.Count;
    end
    function resetImpl(obj)
        obj.Count = 0;
    end
end
end

```

## Control Simulation Type in MATLAB System Block

Specify a simulation type and whether the **Simulate using** parameter appears on the Simulink MATLAB System block dialog box. The simulation options are 'Code generation' and 'Interpreted mode'.

If you do not include the `getSimulateUsingImpl` method in your class definition file, the System object allows both simulation modes and defaults to 'Code generation'. If you do not include the `showSimulateUsingImpl` method, the **Simulate using** parameter appears on the block dialog box.

You must set the `getSimulateUsingImpl` and `showSimulateUsingImpl` methods to static and the access for these methods to protected.

Use `getSimulateUsingImpl` to specify that only interpreted execution is allowed for the System object.

```

methods(Static,Access = protected)
    function simMode = getSimulateUsingImpl
        simMode = 'Interpreted execution';
    end
end

```

### Complete Class Definition

```

classdef PlotRamp < matlab.System
    % Display a button to launch a plot figure.

    properties (Nontunable)
        RampLimit = 10;
    end

    methods(Static, Access=protected)

```

```

function group = getPropertyGroupsImpl
    group = matlab.system.display.Section(mfilename('class'));
    group.Actions = matlab.system.display.Action(@(~,obj)...
        visualize(obj),'Label','Visualize');
end

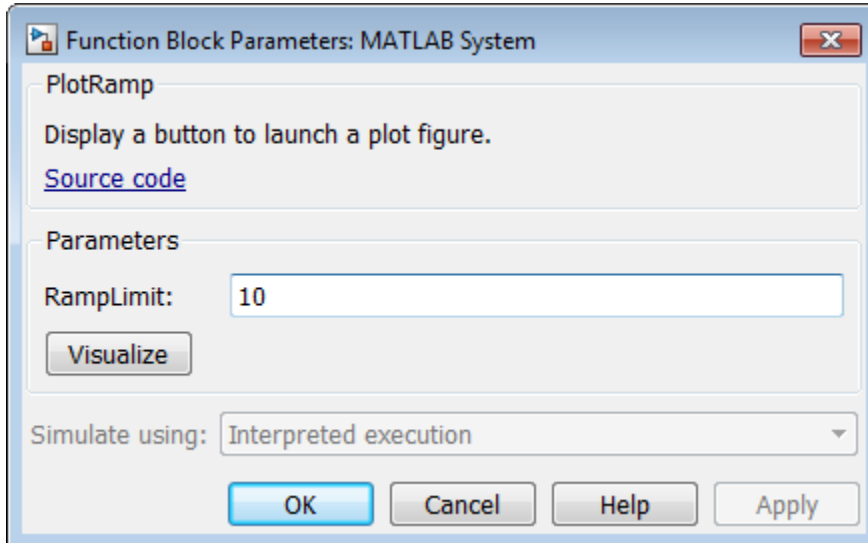

function simMode = getSimulateUsingImpl
    simMode = 'Interpreted execution';
end

methods
function obj = ActionDemo(varargin)
    setProperties(obj,nargin,varargin{:});
end

function visualize(obj)
    figure;
    d = 1:obj.RampLimit;
    plot(d);
end
methods(Static,Access = protected)
end
end
end

```

The resulting dialog box with the **Simulate using** parameter:

## Add Custom Button to MATLAB System Block

Add a button to the MATLAB System block dialog box. This button opens a figure that plots a ramp function.

Use `matlab.system.display.Action` to define the MATLAB function or code associated with a button in the MATLAB System block dialog box. The example also shows how to set button options and use an `actionData` object input to store a figure handle. This part of the code example uses the

same figure when the button is clicked multiple times, rather than opening a new figure for each button click.

```

methods(Static,Access = protected)
    function group = getPropertyGroupsImpl
        group = matlab.system.display.Section(mfilename('class'));
        group.Actions = matlab.system.display.Action(@(actionData,obj)...
            visualize(obj,actionData),'Label','Visualize');
    end
end

methods
    function obj = ActionDemo(varargin)
        setProperties(obj,nargin,varargin{:});
    end

    function visualize(obj,actionData)
        f = actionData.UserData;
        if isempty(f) || ~ishandle(f)
            f = figure;
            actionData.UserData = f;
        else
            figure(f); % Make figure current
        end

        d = 1:obj.RampLimit;
        plot(d);
    end
end

```

### Complete Class Definition File for Dialog Button

Define a property group and a second tab in the class definition file.

```

classdef PlotRamp < matlab.System
    % Display a button to launch a plot figure.

    properties (Nontunable)
        RampLimit = 10;
    end

    methods(Static,Access = protected)
        function group = getPropertyGroupsImpl
            group = matlab.system.display.Section(mfilename('class'));
            group.Actions = matlab.system.display.Action(@(actionData,obj)...
                visualize(obj,actionData),'Label','Visualize');
        end
    end

    methods
        function obj = ActionDemo(varargin)
            setProperties(obj,nargin,varargin{:});
        end

        function visualize(obj,actionData)
            f = actionData.UserData;
            if isempty(f) || ~ishandle(f)
                f = figure;
            end
        end
    end
end

```

```
        actionData.UserData = f;  
    else  
        figure(f); % Make figure current  
    end  
  
    d = 1:obj.RampLimit;  
    plot(d);  
end  
end  
end
```

The resulting dialog box with the **Visualize** button:

## More About

- “Using ~ as an Input Argument in Method Definitions”

## Specify Output

### In this section...

“Set Output Size” on page 50-81  
 “Set Fixed- or Variable-Size Output” on page 50-82  
 “Set Output Data Type” on page 50-84  
 “Set Output Complexity” on page 50-87  
 “Set Discrete State Output Specification” on page 50-88

Sometimes, Simulink cannot infer the output characteristics of your System object during model compilation. To give Simulink more information about the System object output, use these methods.

### Set Output Size

Specify the size of a System object output using the `getOutputSizeImpl` method. Use this method when Simulink cannot infer the output size from the inputs during model compilation. For instance, when the System object has multiple inputs or outputs or has variable-sized output.

For variable-size inputs, the propagated input size from `propagatedInputSizeImpl` differs depending on the environment.

- MATLAB — When you first run an object, it uses the actual sizes of the inputs.
- Simulink — The maximum of all the input sizes is set before the model runs and does not change during the run.

Subclass from the `matlab.System` base class.

```
classdef CounterReset < matlab.System
```

Use the `getOutputSizeImpl` method to specify the output size.

```
methods (Access = protected)
    function sizeout = getOutputSizeImpl(~)
        sizeout = [1 1];
    end
end
```

View the method in the complete class definition file.

```
classdef CounterReset < matlab.System
    % CounterReset Count values above a threshold

    properties
        Threshold = 1
    end

    properties (DiscreteState)
        Count
    end

    methods (Access = protected)
        function setupImpl(obj)
            obj.Count = 0;
        end
    end
end
```

```

end

function y = stepImpl(obj,u1,u2)
    % Add to count if u1 is above threshold
    % Reset if u2 is true
    if (u2)
        obj.Count = 0;
    elseif (any(u1 > obj.Threshold))
        obj.Count = obj.Count + 1;
    end
    y = obj.Count;
end

function resetImpl(obj)
    obj.Count = 0;
end

function [sz,dt,cp] = getDiscreteStateSpecificationImpl(~,name)
    if strcmp(name,'Count')
        sz = [1 1];
        dt = 'double';
        cp = false;
    else
        error(['Error: Incorrect State Name: ', name.']);
    end
end

function dataout = getOutputDataTypeImpl(~)
    dataout = 'double';
end

function sizeout = getOutputSizeImpl(~)
    sizeout = [1 1];
end

function cplxout = isOutputComplexImpl(~)
    cplxout = false;
end

function fixedout = isOutputFixedSizeImpl(~)
    fixedout = true;
end

function flag = isInputSizeMutableImpl(~,idx)
    if idx == 1
        flag = true;
    else
        flag = false;
    end
end
end
end
end

```

## Set Fixed- or Variable-Size Output

Specify the System object output is fixed-size. Fixed-size output is always the same size, while variable-size output can be different size vectors.

Simulink cannot infer the output size for variable-size output. To avoid errors, implement `isOutputFixedSizeImpl` and `getOutputSizeImpl`.

`isOutputFixedSizeImpl` accepts System object handle and returns an array of flags. Array size is equal to the size of the output ports. The value of the flags and their meanings are:

- `true` — the output size is fixed (output port on MATLAB System block creates fixed-size signal)
- `false` — the output size is variable (output port on MATLAB System block creates variable-size signal)

Subclass from the `matlab.System` base class.

```
classdef CounterReset < matlab.System
```

Use the `isOutputFixedSizeImpl` method to specify that the output is fixed size.

```
methods (Access = protected)
    function fixedout = isOutputFixedSizeImpl(~)
        fixedout = true;
    end
end
```

View the method in the complete class definition file.

```
classdef CounterReset < matlab.System
    % CounterReset Count values above a threshold

    properties
        Threshold = 1
    end

    properties (DiscreteState)
        Count
    end

    methods (Access = protected)
        function setupImpl(obj)
            obj.Count = 0;
        end

        function y = stepImpl(obj,u1,u2)
            % Add to count if u1 is above threshold
            % Reset if u2 is true
            if (u2)
                obj.Count = 0;
            elseif (any(u1 > obj.Threshold))
                obj.Count = obj.Count + 1;
            end
            y = obj.Count;
        end

        function resetImpl(obj)
            obj.Count = 0;
        end

        function [sz,dt,cp] = getDiscreteStateSpecificationImpl(~,name)
            if strcmp(name,'Count')
                sz = [1 1];
                dt = 'double';
                cp = false;
            else

```

```

        error(['Error: Incorrect State Name: ', name.']);
    end
end
function dataout = getOutputDataTypeImpl(~)
    dataout = 'double';
end
function sizeout = getOutputSizeImpl(~)
    sizeout = [1 1];
end
function cplxout = isOutputComplexImpl(~)
    cplxout = false;
end
function fixedout = isOutputFixedSizeImpl(~)
    fixedout = true;
end
function flag = isInputSizeMutableImpl(~, idx)
    if idx == 1
        flag = true;
    else
        flag = false;
    end
end
end
end
end

```

## Set Output Data Type

Specify the data type of a System object output using the `getOutputDataTypeImpl` method. A second example shows how to specify a gain object with bus output. Use this method when Simulink cannot infer the data type from the inputs during model compilation or when you want different input and output data types. If you want bus output, also use the `getOutputDataTypeImpl` method. To use bus output, you must define the bus data type in the base workspace and you must include the `getOutputDataTypeImpl` method in your class definition file.

For both examples, subclass from the `matlab.System` base class.

```
classdef DataTypeChange < matlab.System
```

Specify, in your class definition file, how to control the output data type from a MATLAB System block. Use the `getOutputDataTypeImpl` method to change the output data type from double to single, or propagate the input as a double. It also shows how to cast the data type to change the output data type in the `stepImpl` method, if necessary.

```

methods (Access = protected)
    function out = getOutputDataTypeImpl(obj)
        if obj.Quantize == true
            out = 'single';
        else
            out = propagatedInputDataType(obj, 1);
        end
    end
end
end

```

```
classdef DataTypeChange < matlab.System
```

```

    properties(Nontunable)
        Quantize = false;
    end

```

```

end

methods(Access = protected)
function y = stepImpl(obj,u)
    if obj.Quantize == true
        % Cast for output data type to differ from input.
        y = single(u);
    else
        % Propagate output data type.
        y = u;
    end
end

function out = getOutputDataTypeImpl(obj)
    if obj.Quantize == true
        out = 'single';
    else
        out = propagatedInputDataType(obj,1);
    end
end
end
end
end
end

```

This model shows propagated double data type.

This model shows the result of changing the data type from double to single. The Display block shows the effect of quantizing the data.

The block mask for the MATLAB System block includes an edit field to switch between using propagation (**Quantize** = false) and switching from double to single (**Quantize** = true).

Use the `getOutputDataTypeImpl` method to specify the output data type as a bus. Specify the bus name in a property.

```
properties(Nontunable)
    OutputBusName = 'bus_name';
end

methods (Access = protected)
    function out = getOutputDataTypeImpl(obj)
        out = obj.OutputBusName;
    end
end
```

View the method in the complete class definition file. This class definition file also includes code to implement a custom icon for this object in the MATLAB System block

```
classdef busGain < matlab.System
% busGain Apply a gain of two to bus input.

    properties
        GainK = 2;
    end

    properties(Nontunable)
        OutputBusName = 'bus_name';
    end

    methods (Access=protected)
        function out = stepImpl(obj,in)
            out.a = obj.GainK * in.a;
            out.b = obj.GainK * in.b;
        end

        function out = getOutputSizeImpl(obj)
            out = propagatedInputSize(obj, 1);
        end

        function out = isOutputComplexImpl(obj)
            out = propagatedInputComplexity(obj, 1);
        end
    end
end
```

```

function out = getOutputDataTypeImpl(obj)
    out = obj.OutputBusName;
end

function out = isOutputFixedSizeImpl(obj)
    out = propagatedInputFixedSize(obj,1);
end
end
end

```

## Set Output Complexity

Specify whether a System object output is complex or real using the `isOutputComplexImpl` method. Use this method when Simulink cannot infer the output complexity from the inputs during model compilation.

Subclass from the `matlab.System` base class.

```
classdef CounterReset < matlab.System
```

Use the `isOutputComplexImpl` method to specify that the output is real.

```

methods (Access = protected)
    function cplxout = isOutputComplexImpl(~)
        cplxout = false;
    end
end

```

View the method in the complete class definition file.

```

classdef CounterReset < matlab.System
    % CounterReset Count values above a threshold

    properties
        Threshold = 1
    end

    properties (DiscreteState)
        Count
    end

    methods (Access = protected)
        function setupImpl(obj)
            obj.Count = 0;
        end

        function y = stepImpl(obj,u1,u2)
            % Add to count if u1 is above threshold
            % Reset if u2 is true
            if (u2)
                obj.Count = 0;
            elseif (any(u1 > obj.Threshold))
                obj.Count = obj.Count + 1;
            end
            y = obj.Count;
        end
    end
end

```

```

function resetImpl(obj)
    obj.Count = 0;
end

function [sz,dt,cp] = getDiscreteStateSpecificationImpl(~,name)
    if strcmp(name,'Count')
        sz = [1 1];
        dt = 'double';
        cp = false;
    else
        error(['Error: Incorrect State Name: ', name.']);
    end
end

function dataout = getOutputDataTypeImpl(~)
    dataout = 'double';
end

function sizeout = getOutputSizeImpl(~)
    sizeout = [1 1];
end

function cplxout = isOutputComplexImpl(~)
    cplxout = false;
end

function fixedout = isOutputFixedSizeImpl(~)
    fixedout = true;
end

function flag = isInputSizeMutableImpl(~,idx)
    if idx == 1
        flag = true;
    else
        flag = false;
    end
end
end
end

```

## Set Discrete State Output Specification

Specify the size, data type, and complexity of a discrete state property using the `getDiscreteStateSpecificationImpl` method. Use this method when your System object has a property with the `DiscreteState` attribute and Simulink cannot infer the output specifications during model compilation.

Subclass from the `matlab.System` base class.

```
classdef CounterReset < matlab.System
```

Use the `getDiscreteStateSpecificationImpl` method to specify the size and data type. Also specify the complexity of a discrete state property `Count`, which is used in the counter reset example.

```

function [sz,dt,cp] = getDiscreteStateSpecificationImpl(~,name)
    if strcmp(name,'Count')
        sz = [1 1];
        dt = 'double';
        cp = false;
    else
        error(['Error: Incorrect State Name: ', name.]);
    end
end

```

```

end
end

```

View the method in the complete class definition file.

```

classdef CounterReset < matlab.System
    % CounterReset Count values above a threshold

    properties
        Threshold = 1
    end

    properties (DiscreteState)
        Count
    end

    methods (Access = protected)
        function setupImpl(obj)
            obj.Count = 0;
        end

        function y = stepImpl(obj,u1,u2)
            % Add to count if u1 is above threshold
            % Reset if u2 is true
            if (u2)
                obj.Count = 0;
            elseif (any(u1 > obj.Threshold))
                obj.Count = obj.Count + 1;
            end
            y = obj.Count;
        end

        function resetImpl(obj)
            obj.Count = 0;
        end

        function [sz,dt,cp] = getDiscreteStateSpecificationImpl(~,name)
            if strcmp(name,'Count')
                sz = [1 1];
                dt = 'double';
                cp = false;
            else
                error(['Error: Incorrect State Name: ', name.']);
            end
        end

        function dataout = getOutputDataTypeImpl(~)
            dataout = 'double';
        end

        function sizeout = getOutputSizeImpl(~)
            sizeout = [1 1];
        end

        function cplxout = isOutputComplexImpl(~)
            cplxout = false;
        end

        function fixedout = isOutputFixedSizeImpl(~)
            fixedout = true;
        end

        function flag = isInputSizeMutableImpl(~,idx)

```

```
        if idx == 1
            flag = true;
        else
            flag = false;
        end
    end
end
end
end
```

## Set Model Reference Discrete Sample Time Inheritance

Disallow model reference discrete sample time inheritance for a System object. The System object defined in this example has one input, so by default, it allows sample time inheritance. To override the default and disallow inheritance, the class definition file for this example includes the `allowModelReferenceDiscreteSampleTimeInheritanceImpl` method, with its output set to `false`.

```
methods (Access = protected)
    function flag = ...
        allowModelReferenceDiscreteSampleTimeInheritanceImpl(obj)
        flag = false;
    end
end
```

View the method in the complete class definition file.

```
classdef MyCounter < matlab.System

    % MyCounter Count values

    properties
        Threshold = 1;
    end

    properties (DiscreteState)
        Count
    end

    methods (Static, Access = protected)
        function header = getHeaderImpl
            header = matlab.system.display.Header('MyCounter',...
                'Title','My Enhanced Counter',...
                'Text','This counter is an enhanced version.');
        end
    end

    methods (Access = protected)
        function flag = ...
            allowModelReferenceDiscreteSampleTimeInheritanceImpl(obj)
            flag = false
        end
        function setupImpl(obj,u)
            obj.Count = 0;
        end
        function y = stepImpl(obj,u)
            if (u > obj.Threshold)
                obj.Count = obj.Count + 1;
            end
            y = obj.Count;
        end
        function resetImpl(obj)
            obj.Count = 0;
        end
    end
end
```

```
end  
end
```

## Use Update and Output for Nondirect Feedthrough

Implement nondirect feedthrough for a System object by using the `updateImpl`, `outputImpl`, and `isInputDirectFeedthroughImpl` methods. In nondirect feedthrough, the outputs depend only on the internal states and properties of the object, rather than the input at that instant in time. You use these methods to separate the output calculation from the state updates of a System object. Implementing these two methods overrides the `stepImpl` method. These methods enable you to use the object in a feedback loop and prevent algebraic loops.

### Subclass from the `matlab.System` Class

To use the `updateImpl`, `outputImpl`, and `isInputDirectFeedthroughImpl` methods, you must subclass from the `matlab.System`.

```
classdef IntegerDelaySysObj < matlab.System
```

### Implement Updates to the Object

Implement an `updateImpl` method to update the object with previous inputs.

```
methods (Access = protected)
    function updateImpl(obj,u)
        obj.PreviousInput = [u obj.PreviousInput(1:end-1)];
    end
end
```

### Implement Outputs from Object

Implement an `outputImpl` method to output the previous, not the current input.

```
methods (Access = protected)
    function [y] = outputImpl(obj,~)
        y = obj.PreviousInput(end);
    end
end
```

### Implement Whether Input Is Direct Feedthrough

Implement an `isInputDirectFeedthroughImpl` method to indicate that the input is nondirect feedthrough.

```
methods (Access = protected)
    function flag = isInputDirectFeedthroughImpl(~,~)
        flag = false;
    end
end
```

### Complete Class Definition File with Update and Output

```
classdef intDelaySysObj < matlab.System
    % intDelaySysObj Delay input by specified number of samples.

    properties
        InitialOutput = 0;
    end
    properties (Nontunable)
        NumDelays = 1;
    end
end
```

```
end
properties (DiscreteState)
    PreviousInput;
end

methods (Access = protected)
    function validatePropertiesImpl(obj)
        if ((numel(obj.NumDelays)>1) || (obj.NumDelays <= 0))
            error('Number of delays must be > 0 scalar value.');
```

```
        end
        if (numel(obj.InitialOutput)>1)
            error('Initial Output must be scalar value.');
```

```
        end
    end

    function setupImpl(obj)
        obj.PreviousInput = ones(1,obj.NumDelays)*obj.InitialOutput;
    end

    function resetImpl(obj)
        obj.PreviousInput = ones(1,obj.NumDelays)*obj.InitialOutput;
    end

    function [y] = outputImpl(obj,~)
        y = obj.PreviousInput(end);
    end

    function updateImpl(obj, u)
        obj.PreviousInput = [u obj.PreviousInput(1:end-1)];
    end

    function flag = isInputDirectFeedthroughImpl(~,~)
        flag = false;
    end
end
end
```

## Enable For Each Subsystem Support

Enable For Each subsystem support by using a System object in a Simulink For Each subsystem. Include the `supportsMultipleInstanceImpl` method in your class definition file. This method applies only when the System object is used in Simulink via the MATLAB System block.

Use the `supportsMultipleInstanceImpl` method and have it return `true` to indicate that the System object supports multiple calls in a Simulink For Each subsystem.

```
methods (Access = protected)
    function flag = supportsMultipleInstanceImpl(obj)
        flag = true;
    end
end
```

View the method in the complete class definition file.

```
classdef RandSeed < matlab.System
% RANDSEED Random noise with seed for use in For Each subsystem

    properties (DiscreteState)
        count;
    end

    properties (Nontunable)
        seed = 20;
        useSeed (1,1) logical = false;
    end

    methods (Access = protected)
        function y = stepImpl(obj,u1)
            % Initial use after reset/setup
            % and use the seed
            if (obj.useSeed && ~obj.count)
                rng(obj.seed);
            end
            obj.count = obj.count + 1;
            [m,n] = size(u1);
            % Uses default rng seed
            y = rand(m,n) + u1;
        end

        function setupImpl(obj)
            obj.count = 0;
        end
        function resetImpl(obj)
            obj.count = 0;
        end

        function flag = supportsMultipleInstanceImpl(obj)
            flag = obj.useSeed;
        end
    end
end
```

```
end  
end
```

## Define System Object for Use in Simulink

### In this section...

“Develop System Object for Use in MATLAB System Block” on page 50-97

“Define Block Dialog Box for Plot Ramp” on page 50-97

### Develop System Object for Use in MATLAB System Block

You can develop a System object for use in a System block and interactively preview the block dialog box. This feature requires Simulink.

With the **System Block** editing options, the MATLAB Editor inserts predefined code into the System object. This coding technique helps you create and modify your System object faster and increases accuracy by reducing typing errors.

Using these options, you can also:

- View and interact with the block dialog box design using **System Block > Launch Mask Editor > Preview Dialog** as you define the System object.
- Add dialog box customization methods. If the block dialog box is open when you make changes, the block dialog design preview updates the display on saving the file.
- Add icon methods. However, these elements display only on the MATLAB System block in Simulink, not in the **Preview Dialog**.

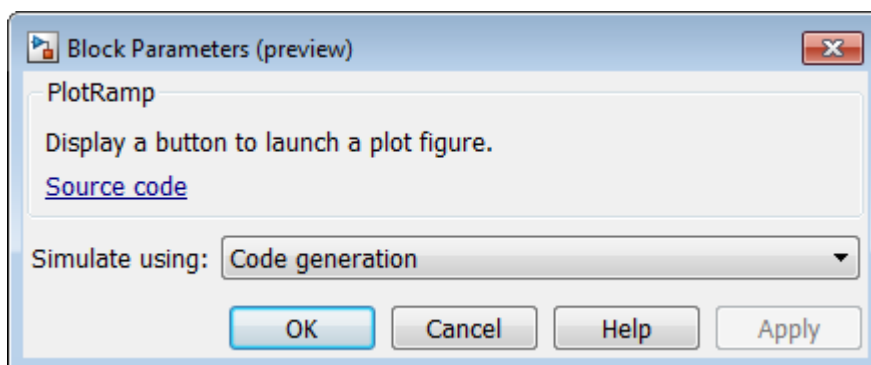

### Define Block Dialog Box for Plot Ramp

- 1 Create a System object using the menu option **New > System Object > Simulink Extension**.
- 2 Name the System object `PlotRamp` and save the file. This name becomes the block dialog box title.
- 3 Delete the comment at the beginning of the file and replace it with the block description.

```
% Display a button to launch a plot figure.
```

This comment becomes the block parameters dialog box description, under the block title.

- 4 Select **System Block > Launch Mask Editor > Preview Dialog**. The block dialog box displays as you develop the System object.

- 5 Add a ramp limit by selecting **Insert Property > Numeric**. Then change the property name and set the value to 10.

```
properties (Nontunable)
    RampLimit = 10;
end
```

- 6 Locate the `getPropertyGroupsImpl` method using the **Analyze** button.

```
function group = getPropertyGroupsImpl
    % Define property section(s) for System block dialog
    group = matlab.system.display.Section(mfilename('class'));
end
```

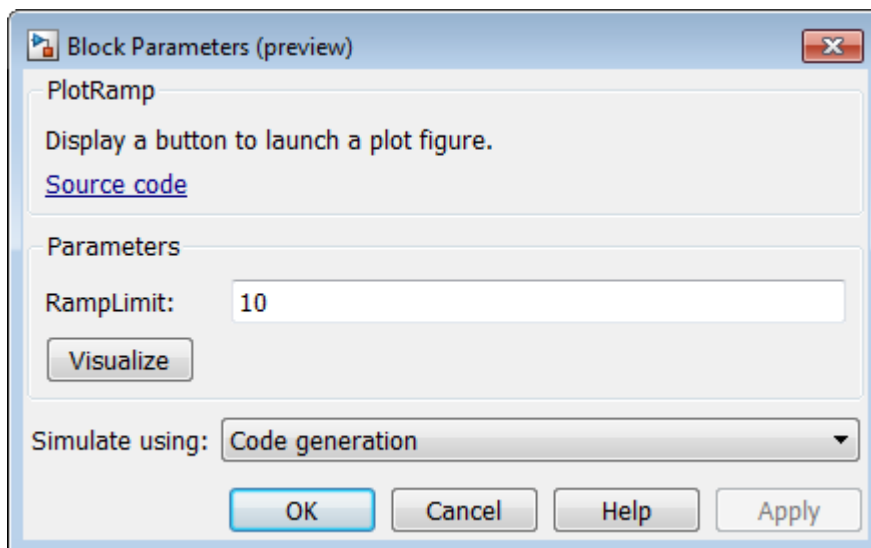

- 7 Create the group for the **Visualize** action.

```
function group = getPropertyGroupsImpl
    % Define property section(s) for System block dialog
    group = matlab.system.display.Section(mfilename('class'));
    group.Actions = matlab.system.display.Action(@(~,obj)...
        visualize(obj), 'Label', 'Visualize');
end
```

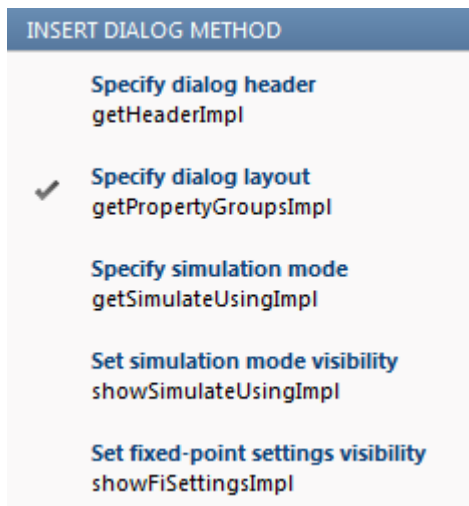

- 8 Add a function that adds code to display the **Visualize** button on the dialog box.

```
methods
    function visualize(obj)
        figure;
        d = 1:obj.RampLimit;
        plot(d);
    end
end
```

- 9 As you add elements to the System block definition, save your file. Observe the effects of your code additions to the System block definition.

The **System Block** menu also displays checks next to the methods included in your file.

- 10** Delete any unused methods in the template or modify the methods to further customize the System object and System block. The class definition file now has all the code necessary for the PlotRamp System object.

```
classdef PlotRamp < matlab.System
    % Display a button to launch a plot figure.

    properties (Nontunable)
        RampLimit = 10;
    end

    methods(Static, Access=protected)
        function group = getPropertyGroupsImpl
            group = matlab.system.display.Section(mfilename('class'));
            group.Actions = matlab.system.display.Action(@(~,obj)...
                visualize(obj), 'Label', 'Visualize');
        end
    end

    methods
        function visualize(obj)
            figure;
            d = 1:obj.RampLimit;
            plot(d);
        end
    end
end
```

After you complete your System block definition, save it, and then load it into a MATLAB System block in Simulink.

## Use Global Variables in System Objects

Global variables are variables that you can access in other MATLAB functions or Simulink blocks.

### System Object Global Variables in MATLAB

For System objects that are used only in MATLAB, you define global variables in the System object class definition files in the same way that you define global variables in other MATLAB code (see “Global Variables”).

### System Object Global Variables in Simulink

For System objects that are used in the MATLAB System block in Simulink, you also define global variables as you do in MATLAB. However, to use global variables in Simulink, if you have declared global variables in methods called by `stepImpl`, `updateImpl`, or `outputImpl`, you must declare global variables in the `stepImpl`, `updateImpl`, or `outputImpl` method, respectively.

You set up and use global variables for the MATLAB System block in the same way as you do for the MATLAB Function block (see “Data Stores” and “Use Global Data in MATLAB Function Blocks” on page 49-94). Like the MATLAB Function block, you must also use variable name matching with a Data Store Memory block to use global variables in Simulink.

For example, this class definition file defines a System object that increments the first row of a matrix by 1 at each time step. If the file is P-coded, you must include `getGlobalNamesImpl`.

```
classdef GlobalSysObjMatrix < matlab.System
    methods (Access = protected)
        function y = stepImpl(obj)
            global B;
            B(1,:) = B(1, :)+1;
            y = B;
        end

        % Include getGlobalNamesImpl only if the class file is P-coded.
        function globalNames = getGlobalNamesImpl(~)
            globalNames = {'B'};
        end
    end
end
```

This model includes the `GlobalSysObjMatrix` object in a MATLAB System block and the associated Data Store Memory block.

- “Define System Object with Block Customizations” on page 50-104
- “Define System object with Nondirect Feedthrough” on page 50-106

A System object is a component you can use to create your system in MATLAB. You can write the code in MATLAB and use that code to create a block in Simulink. To define your own System object, you write a class definition file, which is a text-based MATLAB file that contains the code defining your object. See “Integrate System Objects Using MATLAB System Block”.

#### Define System Object with Block Customizations

Create a System object for use in Simulink. The example performs system identification using a least mean squares (LMS) adaptive filter.

Create a class definition text file to define your System object. The code in this example creates a least mean squares (LMS) filter and includes customizations to the block icon and dialog box appearance.

---

**Note** Instead of manually creating your class definition file, you can use the **New > System Object > Simulink Extension** menu option to open a template. This template includes customizations of the System object for use in the Simulink MATLAB System block. You edit the template file, using it as a guideline, to create your own System object.

---

On the first line of the class definition file, specify the name of your System object and subclass from `matlab.System`. The `matlab.System` base class enables you to use all the basic System object methods and specify the block input and output names, title, and property groups.

Add the appropriate basic System object methods to set up, reset, set the number of inputs and outputs, and run your algorithm. See the reference pages for each method and the full class definition file below for the implementation of each of these methods.

- Use the `setupImpl` method to perform one-time calculations and initialize variables.
- Use the `stepImpl` method to implement the block's algorithm.
- Use the `resetImpl` method to reset the state properties or `DiscreteState` properties.
- Use the `getNumInputsImpl` and `getNumOutputsImpl` methods to specify the number of inputs and outputs, respectively.

Add the appropriate methods to define the appearance of the MATLAB System block in Simulink. See the reference pages for each method and the full class definition file below for the implementation of each of these methods.

- Use the `getHeaderImpl` method to specify the title and description to display on the block dialog box.
- Use the `getPropertyGroupsImpl` method to specify groups of properties to display on the block dialog box.
- Use the `getIconImpl` method to specify the text to display on the block icon.
- Use the `getInputNamesImpl` and `getOutputNamesImpl` methods to specify the labels to display for the block input and output ports.

The full class definition file for the least mean squares filter is:

```
classdef lmsSysObj < matlab.System
    % lmsSysObj Least mean squares (LMS) adaptive filtering.
    % #codegen

    properties
        % Mu Step size
        Mu = 0.005;
    end

    properties (Nontunable)
        % Weights Filter weights
        Weights = 0;
        % N Number of filter weights
        N = 32;
    end

    properties (DiscreteState)
        X;
        H;
    end

    methods (Access = protected)
        function setupImpl(obj)
            obj.X = zeros(obj.N,1);
            obj.H = zeros(obj.N,1);
        end

        function [y, e_norm] = stepImpl(obj,d,u)
            tmp = obj.X(1:obj.N-1);
            obj.X(2:obj.N,1) = tmp;
        end
    end
end
```

```

    obj.X(1,1) = u;
    y = obj.X'*obj.H;
    e = d-y;
    obj.H = obj.H + obj.Mu*e*obj.X;
    e_norm = norm(obj.Weights'-obj.H);
end

function resetImpl(obj)
    obj.X = zeros(obj.N,1);
    obj.H = zeros(obj.N,1);
end

end

% Block icon and dialog customizations
methods (Static, Access = protected)
    function header = getHeaderImpl
        header = matlab.system.display.Header(...
            'lmsSysObj', ...
            'Title', 'LMS Adaptive Filter');
    end

    function groups = getPropertyGroupsImpl
        upperGroup = matlab.system.display.SectionGroup(...
            'Title','General',...
            'PropertyList',{'Mu'});

        lowerGroup = matlab.system.display.SectionGroup(...
            'Title','Coefficients', ...
            'PropertyList',{'Weights','N'});

        groups = [upperGroup,lowerGroup];
    end
end

methods (Access = protected)
    function icon = getIconImpl(~)
        icon = sprintf('LMS Adaptive\nFilter');
    end
    function [in1name, in2name] = getInputNamesImpl(~)
        in1name = 'Desired';
        in2name = 'Actual';
    end
    function [out1name, out2name] = getOutputNamesImpl(~)
        out1name = 'Output';
        out2name = 'EstError';
    end
end
end
end

```

### Define System object with Nondirect Feedthrough

Create a System object for use in Simulink. The example performs system identification using a least mean squares (LMS) adaptive filter and uses feedback loops.

Create a class definition text file to define your System object. The code in this example creates an integer delay and includes feedback loops, and customizations to the block icon. For information on

feedback loops, see “Use System Objects in Feedback Loops” on page 50-17. This example implements a System object that you can use for nondirect feedthrough.

On the first line of the class definition file, subclass from `matlab.System`. The `matlab.System` base class enables you to use all the basic System object methods and specify the block input and output names, title, and property groups.

Add the appropriate basic System object methods to set up and reset the object and set and validate the properties. Since this object supports nondirect feedthrough, you do not implement the `stepImpl` method. You implement the `updateImpl` and `outputImpl` methods instead. See the reference pages for each method and the full class definition file below for the implementation of each of these methods.

- Use the `setupImpl` method to initialize some of the object’s properties.
- Use the `resetImpl` method to reset the property states.
- Use the `validatePropertiesImpl` method to check that the property values are valid.

Add the following class methods instead of the `stepImpl` method to specify how the block updates its state and its output. See the reference pages and the full class definition file below for the implementation of each of these methods.

- Use the `outputImpl` method to implement code to calculate the block output.
- Use the `updateImpl` method to implement code to update the block’s internal states.
- Use the `isInputDirectFeedthroughImpl` method to specify that the block is not direct feedthrough. Its inputs do not directly affect its outputs.

Add the `getIconImpl` method to define the block icon when it is used in Simulink via the MATLAB System block. See the reference page and the full class definition file below for the implementation of this method.

The full class definition file for the delay is:

```
classdef intDelaySysObj < matlab.System
    % intDelaySysObj Delay input by specified number of samples.
    % #codegen

    properties
        % InitialOutput Initial output
        InitialOutput = 0;
    end

    properties (Nontunable)
        % NumDelays Number of delays
        NumDelays = 1;
    end

    properties (DiscreteState)
        PreviousInput;
    end

    methods (Access = protected)
        function setupImpl(obj, ~)
            obj.PreviousInput = ones(1,obj.NumDelays)*obj.InitialOutput;
        end
    end
end
```

```

function [y] = outputImpl(obj, ~)
    % Output does not directly depend on input
    y = obj.PreviousInput(end);
end

function updateImpl(obj, u)
    obj.PreviousInput = [u obj.PreviousInput(1:end-1)];
end

function flag = isInputDirectFeedthroughImpl(~,~)
    flag = false;
end

function validatePropertiesImpl(obj)
    if ((numel(obj.NumDelays)>1) || (obj.NumDelays <= 0))
        error('Number of delays must be positive non-zero ...
            scalar value.');
```

```

    end
    if (numel(obj.InitialOutput)>1)
        error('Initial output must be scalar value.');
```

```

    end
end

function resetImpl(obj)
    obj.PreviousInput = ones(1,obj.NumDelays)*obj.InitialOutput;
end

function icon = getIconImpl(~)
    icon = sprintf('Integer\nDelay');
```

```

end
end
end

```

## Test New System Objects in MATLAB

- 1 Create an instance of your new System object. For example, create an instance of the `lmsSysObj`.
 

```
s = lmsSysObj;
```
- 2 Run the object multiple times with different inputs. Doing this step tests for syntax errors and other possible issues before you add it to Simulink. For example,

```

desired = 0;
actual = 0.2;
s(desired,actual);

```

## Add System Objects to Your Simulink Model

### System Objects in the MATLAB Function Block

You can include System object code in Simulink models with the MATLAB Function block. Your function can include one or more System objects. Portions of your system may be easier to implement in the MATLAB environment than directly in Simulink. Many System objects have Simulink block counterparts with equivalent functionality. Before writing MATLAB code to include in a Simulink model, check for existing blocks that perform the desired operation.

**System Objects in the MATLAB System Block**

You can include individual System objects that you create with a class definition file into Simulink with the MATLAB System block. This option is one way to add your own algorithm blocks into your Simulink models.

Add your System objects to your Simulink model by using the MATLAB System block as described in “Mapping System Object Code to MATLAB System Block Dialog Box” on page 50-20.

For information, see “Integrate System Objects Using MATLAB System Block”.

## Specify Sample Time for MATLAB System Block System Objects

This example shows how to control the sample time of the MATLAB System block using System object™ methods.

Inside the class definition, use the System object sample time methods to configure the sample time and modify the System object behavior based on the current simulation time. If you want to use inherited sample time, you do not need to specify a sample time in your System object definition.

### Specify Sample Time

To specify the sample time, implement the `getSampleTimeImpl` method and create a sample time specification object with `createSampleTime`.

In this example, a property `SampleTimeTypeProp` is created to assign the sample time based on different property values. The `getSampleTimeImpl` method creates a sample time specification based on the `SampleTimeTypeProp` property. The `getSampleTimeImpl` method returns the sample time specification object `sts` created by `createSampleTime`.

```

18     methods(Access = protected)
19         function sts = getSampleTimeImpl(obj)
20             switch char(obj.SampleTimeTypeProp)
21                 case 'Inherited'
22                     sts = createSampleTime(obj,'Type','Inherited');
23                 case 'InheritedNotControllable'
24                     sts = createSampleTime(obj,'Type','Inherited',...
25                         'AlternatePropagation','Controllable');
26                 case 'InheritedErrorConstant'
27                     sts = createSampleTime(obj,'Type','Inherited',...
28                         'ErrorOnPropagation','Constant');
29                 case 'FixedInMinorStep'
30                     sts = createSampleTime(obj,'Type','Fixed In Minor Step');
31                 case 'Discrete'
32                     sts = createSampleTime(obj,'Type','Discrete',...
33                         'SampleTime',obj.SampleTime, ...
34                         'OffsetTime',obj.OffsetTime);
35                 case 'Controllable'
36                     sts = createSampleTime(obj,'Type','Controllable',...
37                         'TickTime',obj.TickTime);
38             end
39         end

```

### Query Simulation Time and Sample Time

Use the `getSampleTime` and `getCurrentTime` methods to query the MATLAB System block for the current sample time and simulation time, respectively. `getSampleTime` returns a sample time specification object with properties describing the sample time settings.

```

40
41     function [Count, Time, SampleTime] = stepImpl(obj,u)
42         Count = obj.Count + u;
43         obj.Count = Count;
44         Time = getCurrentTime(obj);

```

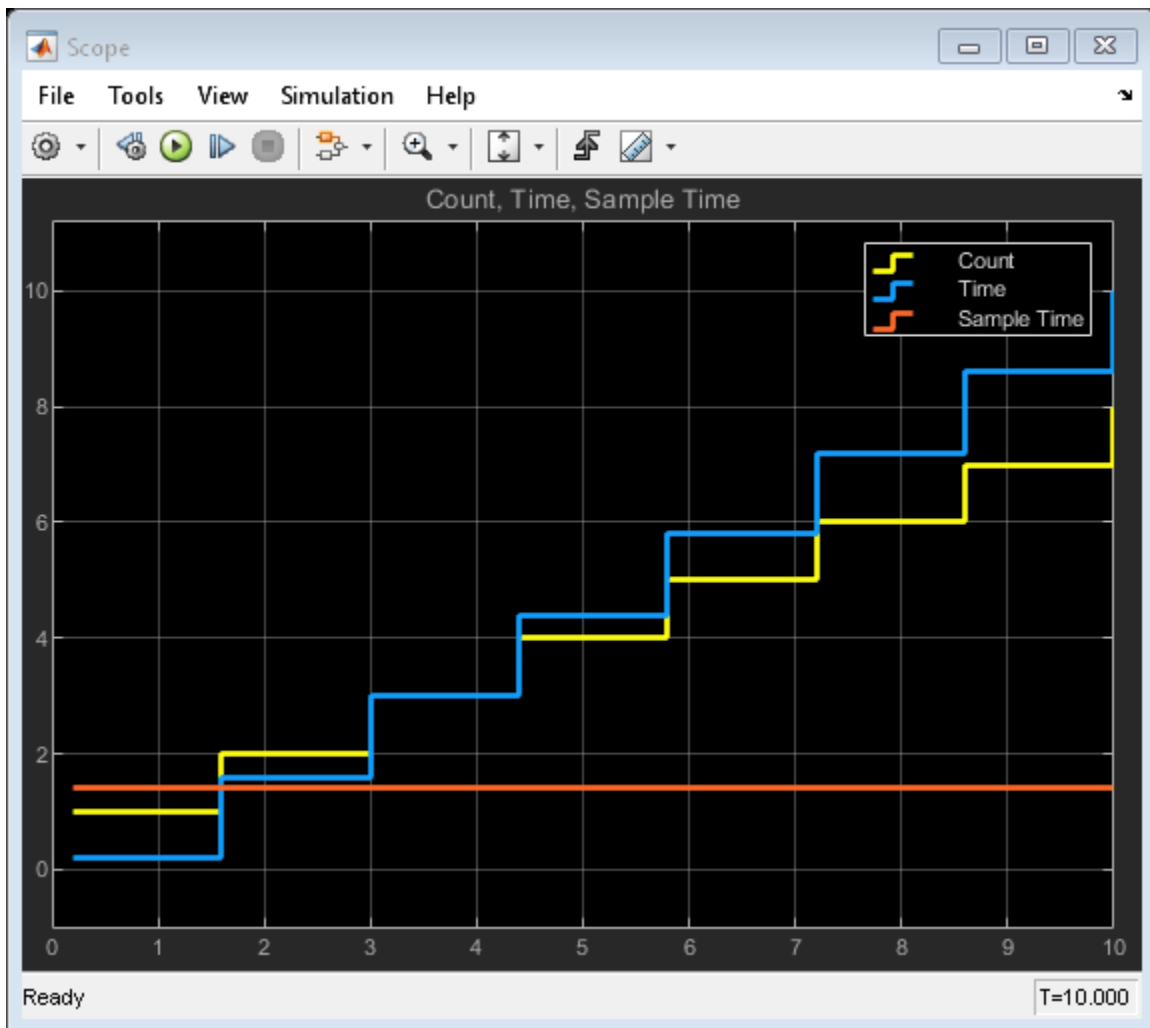

```
45         sts = getSampleTime(obj);
46         if strcmp(sts.Type, 'Controllable')
47             setNumTicksUntilNextHit(obj,obj.Count);
48         end
49         SampleTime = sts.SampleTime;
50     end
```

### Behavior in Simulink

Include this System object in a MATLAB System block.

In the scope, you can see the effects of the sample time changes to the block.

### Full Class Definition

Full class definition of the CountTime System object.

```

classdef CountTime < matlab.System
    % Counts Hits and Time

    properties(Nontunable)
        SampleTime = 1.4; % Sample Time
        OffsetTime = 0.2; % Offset Time
        TickTime = 0.1;
        SampleTimeTypeProp (1,:) char {mustBeMember(SampleTimeTypeProp, ...
            {'Discrete','FixedInMinorStep','Controllable',...
            'Inherited','InheritedNotControllable',...
            'InheritedErrorConstant'})} = 'Discrete'
    end

    properties(DiscreteState)
        Count
    end

```

```

methods(Access = protected)
function sts = getSampleTimeImpl(obj)
    switch char(obj.SampleTimeTypeProp)
        case 'Inherited'
            sts = createSampleTime(obj, 'Type', 'Inherited');
        case 'InheritedNotControllable'
            sts = createSampleTime(obj, 'Type', 'Inherited', ...
                'AlternatePropagation', 'Controllable');
        case 'InheritedErrorConstant'
            sts = createSampleTime(obj, 'Type', 'Inherited', ...
                'ErrorOnPropagation', 'Constant');
        case 'FixedInMinorStep'
            sts = createSampleTime(obj, 'Type', 'Fixed In Minor Step');
        case 'Discrete'
            sts = createSampleTime(obj, 'Type', 'Discrete', ...
                'SampleTime', obj.SampleTime, ...
                'OffsetTime', obj.OffsetTime);
        case 'Controllable'
            sts = createSampleTime(obj, 'Type', 'Controllable', ...
                'TickTime', obj.TickTime);
    end
end

function [Count, Time, SampleTime] = stepImpl(obj,u)
    Count = obj.Count + u;
    obj.Count = Count;
    Time = getCurrentTime(obj);
    sts = getSampleTime(obj);
    if strcmp(sts.Type, 'Controllable')
        setNumTicksUntilNextHit(obj, obj.Count);
    end
    SampleTime = sts.SampleTime;
end

function setupImpl(obj)
    obj.Count = 0;
end

function resetImpl(obj)
    % Initialize / reset discrete-state properties
    obj.Count = 0;
end

function flag = isInactivePropertyImpl(obj,prop)
    flag = false;
    switch char(obj.SampleTimeTypeProp)
        case {'Inherited', ...
            'InheritedNotControllable', ...
            'FixedInMinorStep'}
            if any(strcmp(prop,{'SampleTime', 'OffsetTime', 'TickTime'}))
                flag = true;
            end
        case 'Discrete'
            if any(strcmp(prop,{'TickTime'}))
                flag = true;
            end
        case 'Controllable'

```

```
        if any(strcmp(prop,{'SampleTime','OffsetTime'}))
            flag = true;
        end
    end
end
end
end
```

## Create Moving Average Filter Block with System Object

This example shows how to extend the `movingAverageFilter` System object™ for use in Simulink™. To use a System object in Simulink, include the System object in a MATLAB System block.

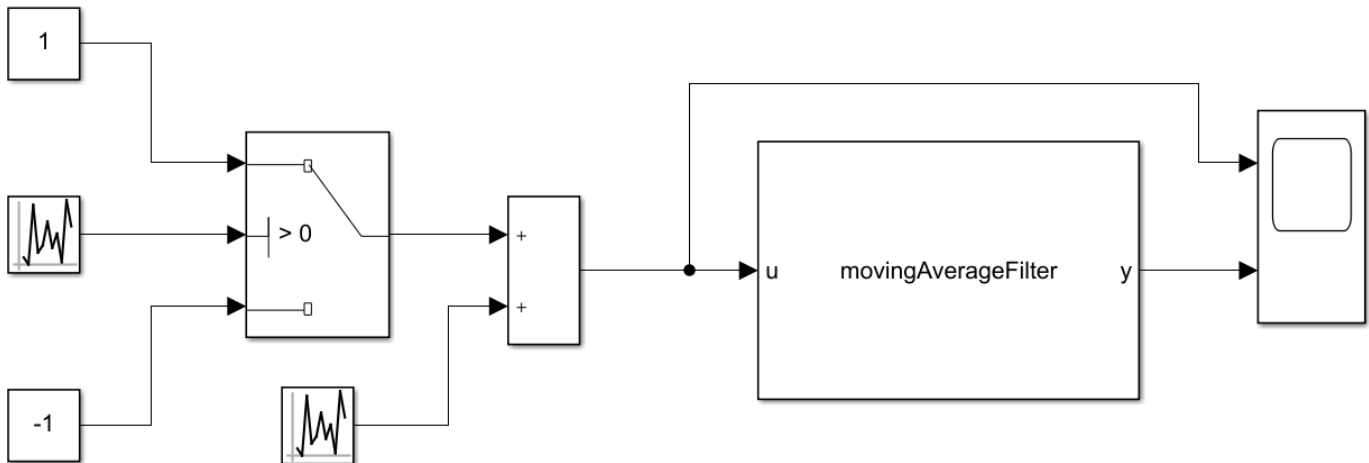

### movingAverageFilter System Object

This example extends the `movingAverageFilter` System object built in “Create Moving Average System Object”. The `movingAverageFilter` System object computes the unweighted mean of a specified number of previous inputs. Use the `WindowLength` property to specify how many previous samples to use.

### Use in Simulink

The object is already ready to use in Simulink. Create a Simulink model and add a MATLAB System block. Specify `movingAverageFilter` as the System object name. For example, this model uses the moving average filter to eliminate noise from a signal.

```
model = 'movingaveragefilter_sl';
open_system(model);
```

The block dialog window shows the public, tunable parameters:

### Customize MATLAB System Block

Optionally, you can customize the block appearance and block dialog for a MATLAB System block by adding methods to the System object.

#### Add Simulink Block Icon Customization Method

By default the block icon shows the name of the System object, in this case `movingAverageFilter`. Customize the Moving Average Filter block icon with a cleaner name. In the **Editor** toolstrip, select the **System Block** dropdown button, then select **Add Text Icon**. The `getIconImpl` method is added to `movingAverageFilter`. Inside `getIconImpl`, set `icon` equal to the string array `["Moving", "Average", "Filter"]`;

```
function icon = getIconImpl(~)
    % Define icon for the System block.
    icon = ["Moving", "Average", "Filter"];
end
```

#### Customize Block Dialog

You can also customize the block dialog by adding methods and comments to the System object. For details about block dialog customization, see “Customize System Block Appearance” on page 50-56. In this example, rename the `WindowLength` property in the dialog box and add a method to customize the description.

By default, all public properties appear as parameters in the block dialog with their property names. In this example, add comments before the `WindowLength` property so that it appears as **Moving window length** in the dialog. Add a comments above the property in the form: `PropertyName Name in dialog`

```
% WindowLength Moving window length
WindowLength (1,1){mustBeInteger,mustBePositive} = 5
```

To specify the header and description in the block dialog, in the toolstrip select **System Block > Specify Dialog Header**. This option adds the `getHeaderImpl` method to `movingAverageFilter`. Modify the call to `matlab.system.display.Header` to this:

```
methods(Access = protected, Static)
    function header = getHeaderImpl
```

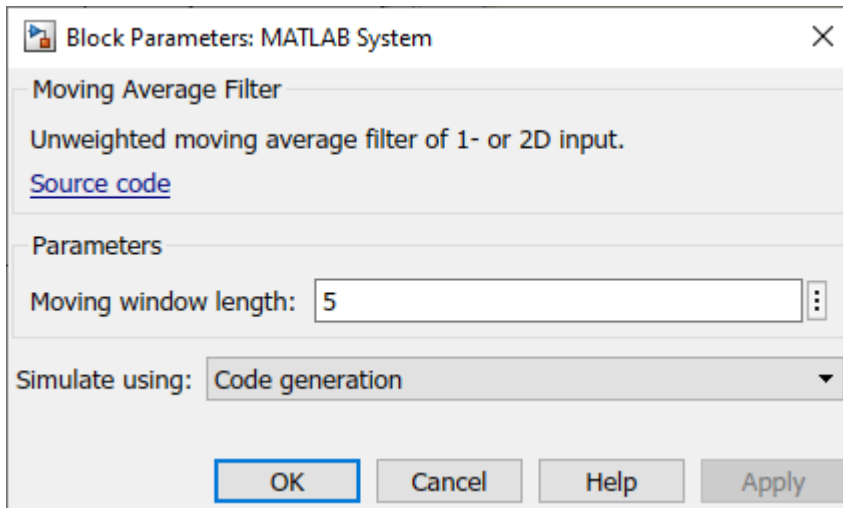

```

% Define header panel for System block dialog
header = matlab.system.display.Header('movingAverageFilter',...
    'Title','Moving Average Filter',...
    'Text','Unweighted moving average filter of 1- or 2D input.');
```

end

end

You can see a preview of the block dialog by clicking the button in the toolbar above **System Block**.

### Customized Block in Simulink

This is the block with the added customizations:

```

model = 'movingaveragefilter_sl_extended';
open_system(model);
```

To see the completed System object with the Simulink customization methods, type:

```
edit movingAverageFilter_extended.m
```

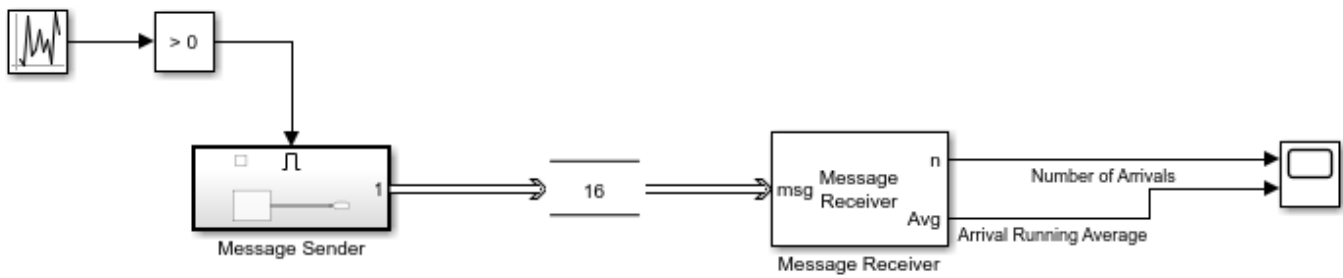

## Process Message Payload Using MATLAB System Block

This example shows how to send, receive, and process messages using the MATLAB System block. Use System objects to author blocks to model custom behavior to send and receive messages and manipulate the message payload.

### Load and Open the Model

Open the model of the Message Send and Receive system. This model contains a random number generator as a data source. Based on that data, the Message Sender sends a message with a sine wave payload to a queue block. The queue block stores the messages, and the Message Receiver converts the message back to data.

```
open_system('slexMessageArrivalExample');
```

### Use getInterfaceImpl System Object API to Specify Message Ports

`getInterfaceImpl` is used in this example to specify the input and output message ports in the MATLAB System block for both the Message Sender and the Message Receiver. For the Message Sender, `getInterfaceImpl` is used to define the output of the MATLAB System block as a message. This action prompts the System object to create a message output. For the Message Receiver, `getInterfaceImpl` is used to define the input of the System object as a message and the output as data.

```
%Function to send messages
function interface = getInterfaceImpl(~)
    import matlab.system.interface.*;
    interface = Output("Out1", Message);
end

%Function to receive messages and output as data
function interface = getInterfaceImpl(obj)
    import matlab.system.interface.*;
    interface = [Input("In1", Message), ...
                Output("Out1", Data), Output("out2", Data)];
end
```

### Set the Propagators and Sample time

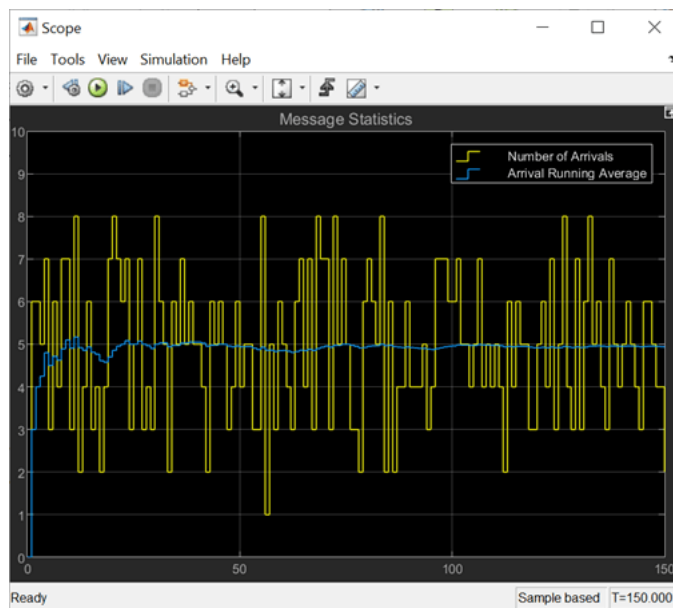

The following four propagators need to be set in the Message Sender: `getOutputSizeImpl`, `getOutputDataTypeImpl`, `isOutputComplexImpl`, `isOutputFixedSizeImpl`.

In this example, the message queue has a maximum capacity of 16 messages. The random number generator has a sample time of 0.1. The receiver has a sample time of 1. The Message Receiver sample time is set in the MATLAB System block using the `getSampleTimeImpl` API.

```
function sts = getSampleTimeImpl(obj)
    sts = createSampleTime(obj, 'Type', 'Discrete', ...
        'SampleTime', obj.SampleTime);
end
```

### Simulate the Model and Review Results

The Scope block displays the results. These results show that as you run more simulations, the random number generator produces a number greater than zero 50% of the time, as expected.

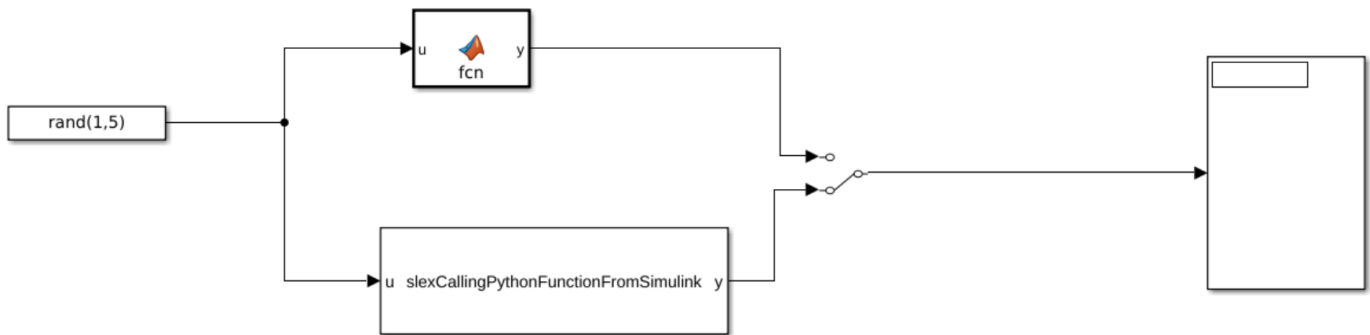

## Call Python Function Using MATLAB Function and MATLAB System Block

This example shows how to call a Python® function in Simulink® that sorts random numbers using a Python® sorting function and two different blocks: the MATLAB Function block and MATLAB System block. For more on using Python in MATLAB®, see “Access Python Modules from MATLAB - Getting Started”.

MATLAB supports the reference implementation of Python, often called CPython. If you are on a Mac or Linux® platform, you already have Python installed. If you are using Windows®, you need to install a distribution, such as those found at <https://www.python.org/downloads>. For more information, see “Configure Your System to Use Python”.

### Use Python Functions in Simulink Model

This model contains a random number generator that outputs a 1x5 double containing numbers from 0 to 1, a MATLAB Function and a MATLAB System block that sorts the numbers, and a manual switch that leads to a Display block.

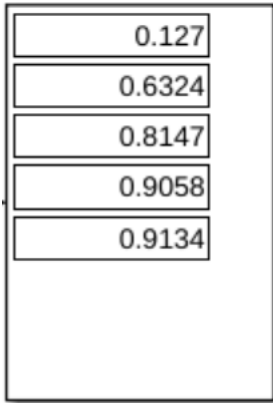

The MATLAB Function block calls the `py.sorted` function from Python and outputs a 1x5 double sorted list, as seen below in the code snippet.

```
function y = fcn(u)
    % Sort values of 'u'
    coder.extrinsic('py.sorted');
    ytmp = py.sorted(u);
end
```

The MATLAB System block calls the `py.sorted` function as part of `stepImpl` and outputs a 1x5 double sorted list as seen below in the code snippet.

```
function y = stepImpl(~,u)
    % Implement algorithm. Calculate y as a function of input u and
    % discrete states.
    y = py.sorted(u);
    y = cellfun(@double,cell(y));
end
```

Running this model using the MATLAB Function block or MATLAB System block yields a sorted list of the numbers generated in the random number generator block. An example of this can be seen below.

## Convert Moving Target MATLAB Code to a Simulink Model

This example shows you how to convert MATLAB algorithms to a Simulink model using a moving target example. The conversion allows you to build models containing MATLAB and Simulink components. This example uses MATLAB code for target creation and deletion then shows you how to convert that functionality into Simulink.

### Moving Target MATLAB Code

Open Script

This example uses MATLAB to create, move, visualize, and delete targets. Two different MATLAB packages generate two separate target databases. The target creator is a System object<sup>®</sup> since it requires the use of states. The target database is a global database. The target checker, which determines if the target is out of range and deletes the target if it is, is a System object because it requires the use of states. The target position updater is a simple algorithm and is therefore a MATLAB function. The target visualizer is a System object and requires the use of states.

For this example, an `initDB` function is used to initialize the global database and create the Target Struct. Then, the targets are created using the `Target Creator` function and the `Target Creation info Package`. The out-of-range targets are then deleted. The target range is 5 for this example, so any target greater than 5 is deleted, and the remaining target positions are updated. This process is looped over 100 times and visualized as it runs.

TargetIllustrationScript;

## Moving Target Simulink Model

Open this model

```
open_system('slexTargetIllustrationModel.slx')
```

The MATLAB script can be converted into a Simulink model that has the same functionality. The Target Database is converted to a DSM using the Model PostLoadFcn and Simulink.Bus.createObject. Convert the Target Creation info Package to a Simulink Function. The target creator, target deleter, and target viewer are each converted into a MATLAB System block since they use System objects in MATLAB. The target viewer also uses a Display block to visualize the targets as the simulation runs. The target updater is converted into a MATLAB Function block since it is a simple MATLAB function that does not use System objects or states. The number of time steps in the loop corresponds with the stop time in the toolbar.

The target creator uses scoped functions in the MATLAB code to call the target creation packages. Use the getGlobalNamesImpl and getSimulinkFunctionNamesImpl APIs in Simulink to declare the function names for the Target Creator System object. These functions declare the target creation package position and velocity names in the target creation package so the package can be called by the System objects in Simulink.

To run the model, click Run. After the model compiles, it produces a visualization just like in the MATLAB code.

```
sim('slexTargetIllustrationModel.slx');
```

## Common Conversions of MATLAB Code to Simulink Behavior

The following list shows some cases of MATLAB code mapping to Simulink blocks and functions. Note: this list is not comprehensive.

- `struct` — Bus
- Array of `struct` — Array of buses
- Global — Data Store Memory
- Function — MATLAB Function block
- System object — MATLAB System block
- System object calls to external functions — System block calls to Simulink functions
- Scheduling algorithm — Stateflow® chart
- Top-level loop (for example: "`for t = 1:0.1:10`") — Simulink start time, stop time, and time step
- Parameter tuning in MATLAB algorithms — Simulink tunable parameters
- Iteration over an array — For-each subsystem
- `if-else` loop — If block and if-action subsystem
- Switch-case statement — Switch Case block and Switch Case Action Subsystem block
- `while` loop — While Iterator block
- Global resource access (for example - database, file handle, communication port, hardware device) — Data Store Memory or Simulink Functions
- Persistent variables — Discrete states in System object or `persistent` keyword in MATLAB Function block
- Dynamic array — Variable-size (bounded now, unbounded in the future)
- Fixed-point `fi` object — Simulink fixed-point
- Cell array — Use `struct` to represent uniform cell array

## Integrate Python Algorithms to Parse NMEA GPS Messages Using Python Importer

This example shows how to use Python® Importer to import a Python package containing algorithms to parse NMEA GPS messages into Simulink®.

In the baseline model `ex_nmea_gps_data_parser_simulink.slx`, built-in Simulink blocks are used to decode RMB and RMC sentences. For more information about the model and using Simulink blocks, see “Parse NMEA GPS Text Message” on page 72-55. This example uses Python Importer to generate custom MATLAB System blocks from Python packages that implement RMB and RMC decoding. The generated custom blocks replace the built-in Simulink blocks in the baseline model.

To call Python modules in MATLAB, you must have a compatible version of Python installed. For more information on supported Python versions and setting up your system to use Python in MATLAB, see “Configure Your System to Use Python”.

### Explore Baseline Model

In the baseline model, the subsystem named `NMEA Data Generator` generates data and sends the data to the subsystem named `Data Classifier`. The `Data Classifier` subsystem classifies the sentences as RMB, RMC, or unsupported. The sentences are then sent to `RMB Decoder`, `RMC decoder`, or `Unsupported`, depending on their type. The `RMB Decoder` and `RMC Decoder` subsystems contain `RMBDecoder` and `RMCDecoder` blocks that are built-in Simulink blocks implementing RMB and RMC decoding, respectively.

```
open_system('ex_nmea_gps_data_parser_simulink');
```

### Use Python Importer to Integrate Python Functions into Simulink

1. Open Python Importer as a standalone application and click **Start**.

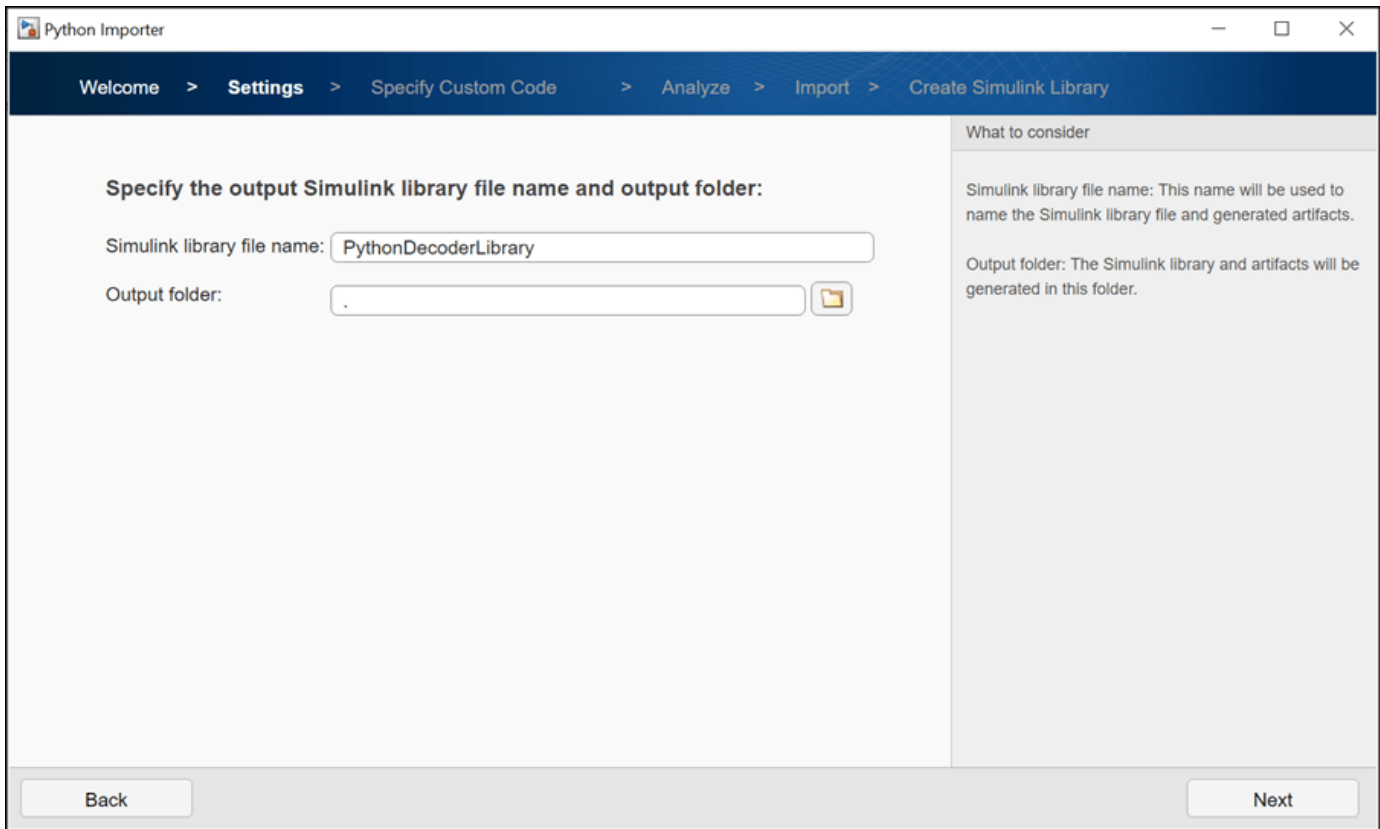

```
obj = Simulink.PythonImporter;  
obj.view();
```

For more information on Python Importer, see “Import Python Code to Simulink Using Python Importer Wizard” on page 89-6.

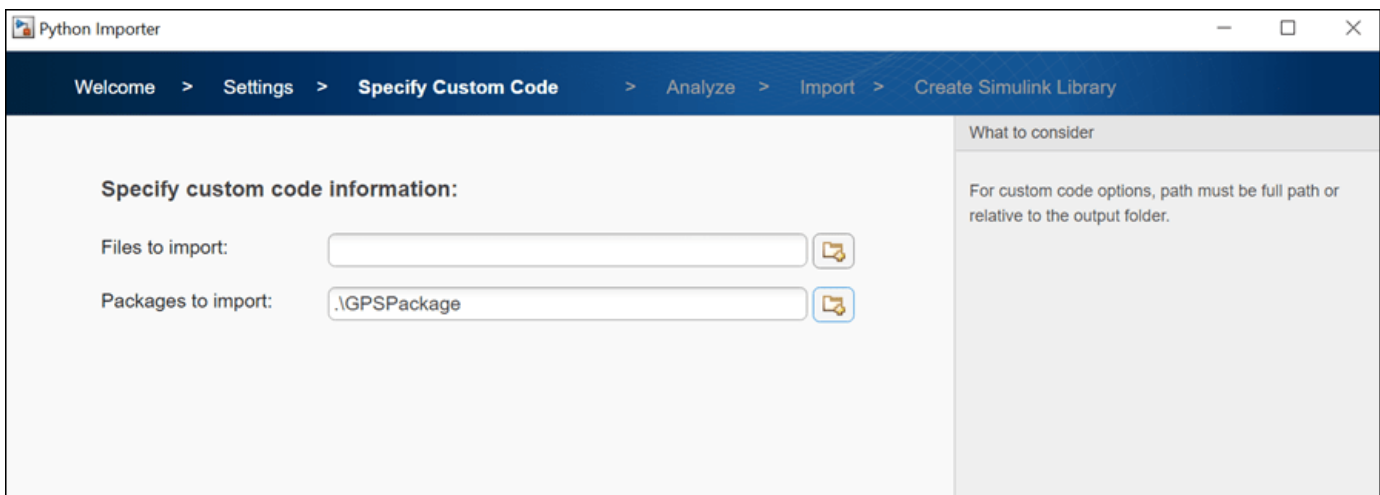

Load the bus objects used for this example.

```
load('pyNMEABuses.mat');
```

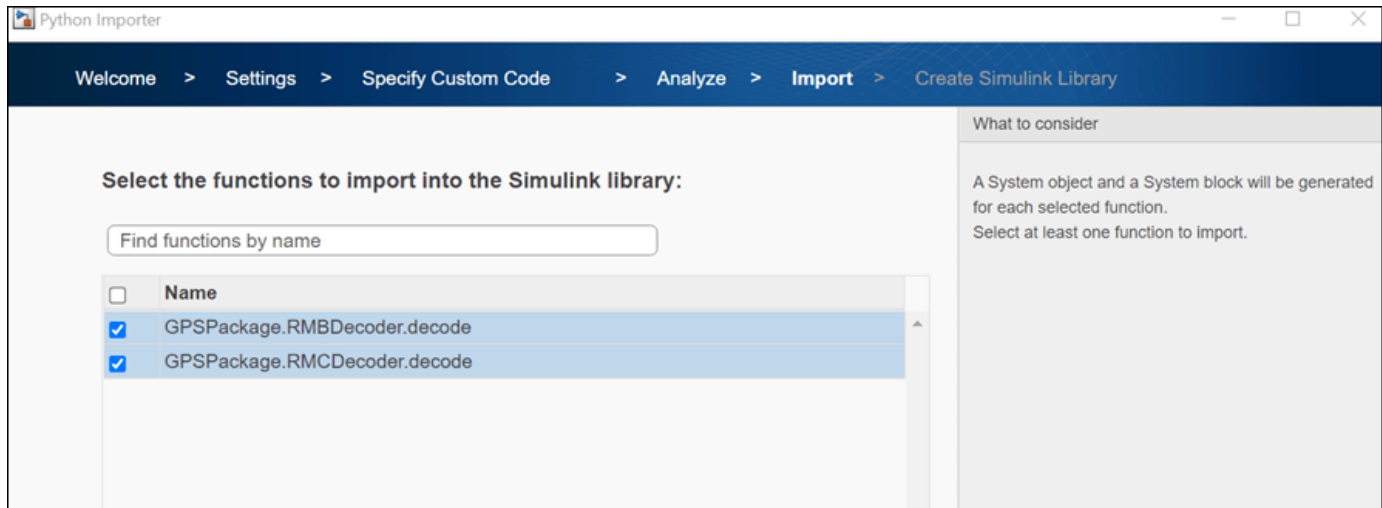

2. On the **Settings** page, in **Simulink library file name** box, specify the library file name. In the **Output folder** box, specify the path of folder where you want the Simulink library and artifacts to be located. Click **Next**.

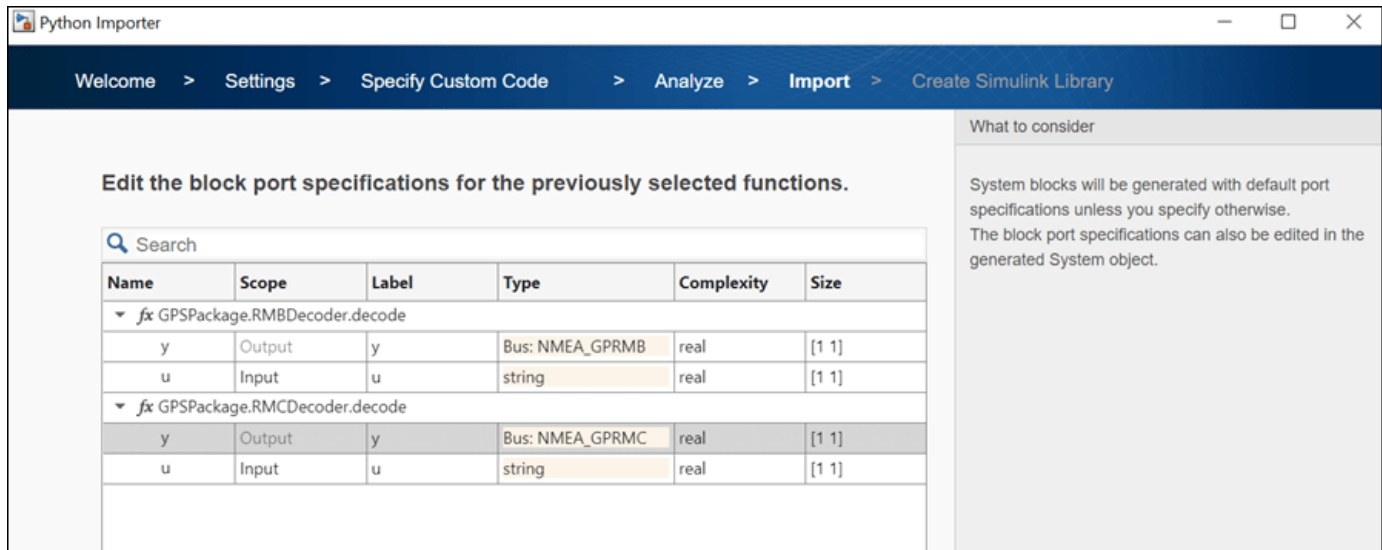

3. On the **Specify Custom Code** page, in the **Packages to Import** box, specify GPSPackage folder. The GPSPackage folder contains a Python package that defines modules that implement RMB and RMC decoding using python. Click **Next**.

4. On the **Import** page, select the **GPSPackage.RMBDecoder.decode** and **GPSPackage.RMCDecoder.decode** functions for import. Click **Next**.

5. Specify the data type of input as `string` for both the functions. For the **GPSPackage.RMBDecoder.decode** function, specify data type of the output as `Bus: NMEA_GPRMB`. For the **GPSPackage.RMCDecoder.decode** function, specify data type of the output as `Bus: NMEA_GPRMC` for . Click **Next**.

6. On the **Create Simulink Library** page, check the specification of the library to be generated. Click **Next** to generate the library.

7. The Python Importer generates a custom Simulink library containing MATLAB System blocks for the selected functions. Click **Finish**.

Open the library containing the generated blocks.

```
open_system("PythonImporterDecoderLibrary.slx");
```

8. In the baseline model, replace the RMBDecoder and RMCDecoder blocks with the generated GPSPackage\_RMBDecoder\_decode and GPSPackage\_RMCDecoder\_decode blocks, respectively.

Open this model to explore the implementation of the generated blocks in place of the built-in Simulink blocks for decoding GPS messages.

```
open_system("ex_nmea_gps_data_parser_py");
```

# Manage and Create a Blockset Using Blockset Designer

---

- “Create a Blockset Project” on page 51-2
- “Create and Organize Block Artifacts” on page 51-14
- “Publish the Created Blockset” on page 51-18

## Create a Blockset Project

### In this section...

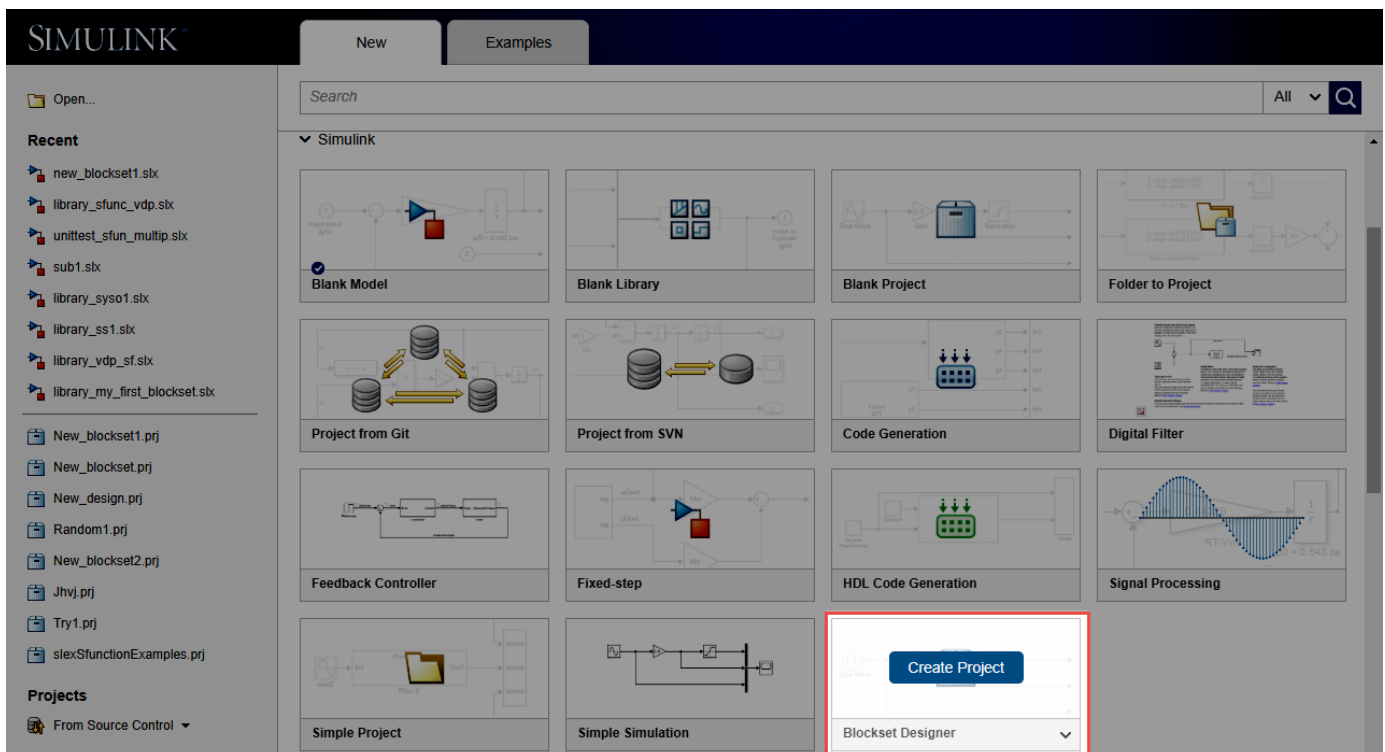

- “Create a New Blockset Project” on page 51-2
- “Create a Project from an Existing Blockset” on page 51-9
- “Blockset Project File Structure” on page 51-12

A blockset is a collection of blocks organized in Simulink libraries for a purpose. The blocks could be part of a standalone library or may be part of an extensive project.

The Blockset Designer is a Projects-based tool that allows you to create, group and manage custom blocks. After creating different blocks, you can add tests, document your blocks, and run Model Advisor checks. If your model contains any S-function or S-function Builder blocks, you can build them using the interface. In addition, you can import your existing blocksets, and set up a Blockset Designer project. You can create new Subsystem, MATLAB System, S-function, and S-function Builder blocks using the Blockset Designer.

### Create a New Blockset Project

- 1 Open the Simulink start page, and pause on Blockset Designer, and click **Create Project**.

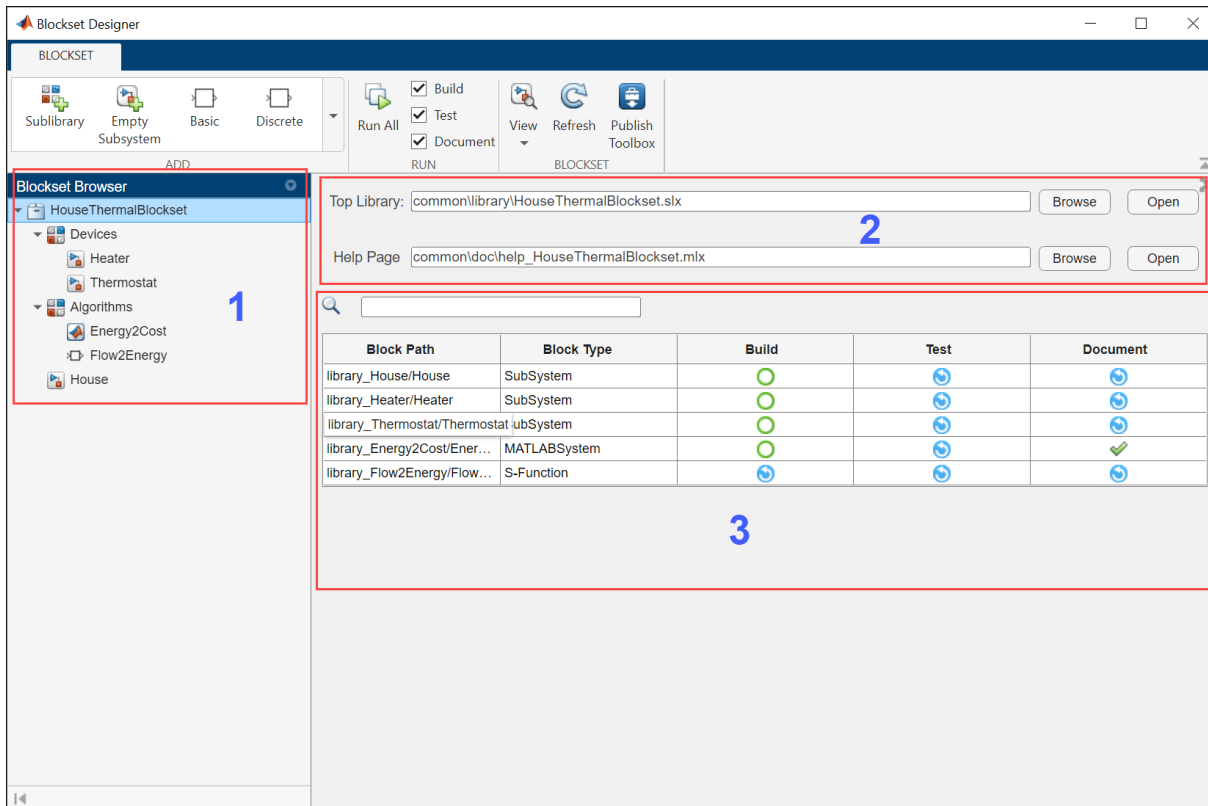

- 2 Specify a name for your project. Note that when you start typing a name for your project, a new folder is automatically created for you in the directory `username\MATLAB\Projects\<foldername>`. If you would like to specify an existing project folder, click the **Browse** button.

If you create a new folder, click **OK** to create a new project folder. Confirm this action by clicking **Yes**.

- 3 Now you are directed to the Blockset Designer project user interface. You are looking at the project at the blockset level. In a Blockset Designer project, the  icon represents the blockset you are working on.

The Blockset Designer consists of these components at the blockset level:

1 — The Blockset Browser panel shows the organization of the blocks and sublibraries in the project. When you add a new block or a new sublibrary to your blockset, it will show up in this tree. You can also use this tree to switch between the sublibrary and block control menus.

2 — The **Top Library** corresponds to the `Browser.Library` in the library information file `slblocks.m`, which is the entry point to the blockset. Click **Open** to display the location of the top library. Click **Browse** to change the top library for the blockset. Note that if you change the top library, `slblocks.m` updates accordingly, and your blockset project is reloaded based on the new top library. See “Add Libraries to Library Browser” on page 44-8 to learn more about `slblocks.m`

3 — The status table shows the status of the blocks and their artifacts. For more information on the status table, see “Create and Organize Block Artifacts” on page 51-14.

### Add a New Sublibrary

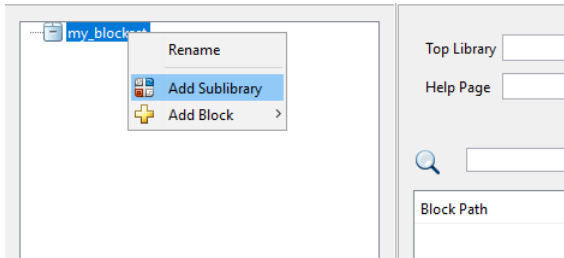

Start building your blockset project by adding a sublibrary. Sublibraries enable you to organize and

manage your blocks. In your blockset project, the  icon represents the sublibraries. You can add a new sublibrary to your blockset using in these ways:

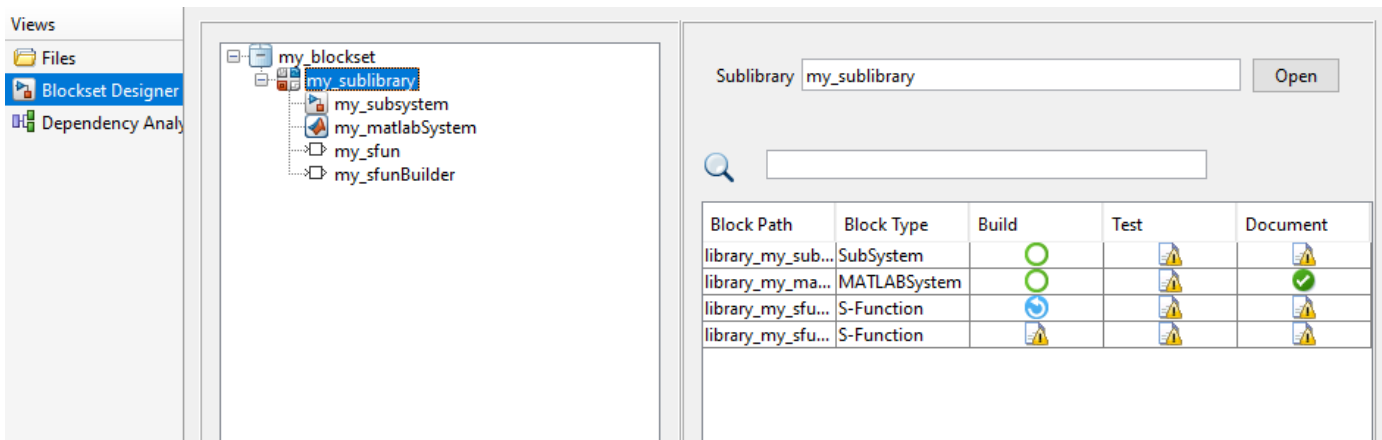

- 1 From the toolstrip, select the **Sublibrary** button.

- 2 Click the blockset from the blockset tree, and from the context menu, select **Sublibrary**.

- 3 Name your sublibrary and close the window. After creating sublibraries, click one of them and see the changes in the working area. Observe that on the top right of the working area, you see **Sublibrary** instead of the **Top Library** and the **Help Page**.

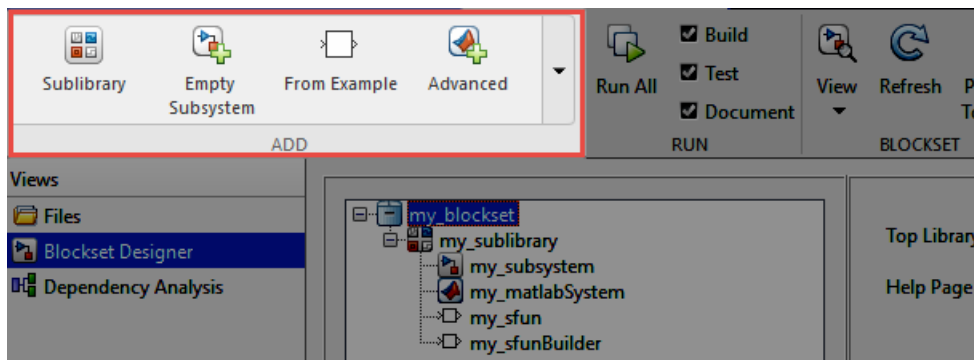

- 4 Click **Open** on the right to open the library model constructed from your sublibrary. This library model contains all blocks from the selected sublibrary.

### Add a New Block

Blockset Designer supports many custom blocks.

- You can add a new block to your blockset project from the **ADD** menu on the toolbar

- Alternatively, when you select the blockset or the sublibrary, open the context menu and click **Add Block**.

You can create these blocks in the Blockset Designer:

- C MEX S-function blocks in basic, discrete, continuous templates. You can also create a C MEX S-function from an existing example.

- Subsystem block
- MATLAB System block with basic, advanced, and Simulink Extension System object templates.

- S-functions created using the S-function Builder.

The working area changes according to the blocks added to your project. For a Subsystem block, you see block properties such as the block path and type, **Test**, and **Documentation** in the working area.

When you click a MATLAB System block from the blockset tree, you can edit the System object code and add **Test** using the working area. To add documentation for a MATLAB System block, add comments in the System object code, and they are automatically added to block documentation for you.

If you have an S-function or a S-function Builder block in your blockset project, you can monitor the block properties, build and edit your S-function code, build the script, add test and document to your block.

Note that when you add an S-function to your Blockset Designer project, you need to write the code for your S-function and build it before adding test. To learn more about how to build S-functions using the Blockset Designer, see “S-Function Related Artifacts” on page 51-16.

Besides the blocks mentioned above, you can add and customize other available Simulink library blocks in the project, but you cannot do any operations such as adding test or documentation.

When you are finished creating your project, you can add:

- Test, or a test suite for your blocks.
- Documentation for your sublibraries and/or for your blocks.

See “Create and Organize Block Artifacts” on page 51-14 for more information.

## Create a Project from an Existing Blockset

Using the Blockset Designer, you can organize blocks, and add tests and documentation to your blocks and blockset. To import your blockset and create a new Blockset Designer project:

- 1 Open the Simulink Start Page. Under **Simulink** select Blockset Designer, and click **Create Project**
- 2 In the New Project dialog box, enter a project name, browse to select the folder containing your files, and click **OK**.

- 3 In the Welcome to your project dialog box, click **Set Up Project** to continue.

- 4 In the Set Up Project (Step 1 of 3) dialog box, choose folders to add to the project path. When you open the project, these folders are added to your MATLAB search path, and removed when you close the project. Add project folders and subfolders to the project path to ensure that you have access to `slblocks.m` and related libraries. `slblocks.m` contains all information about the top library in your project. To learn more, see “Add Libraries to Library Browser” on page 44-8. To add all project folders, select **Add with Subfolders** and then the project folder containing all your subfolders. Click **Next**.

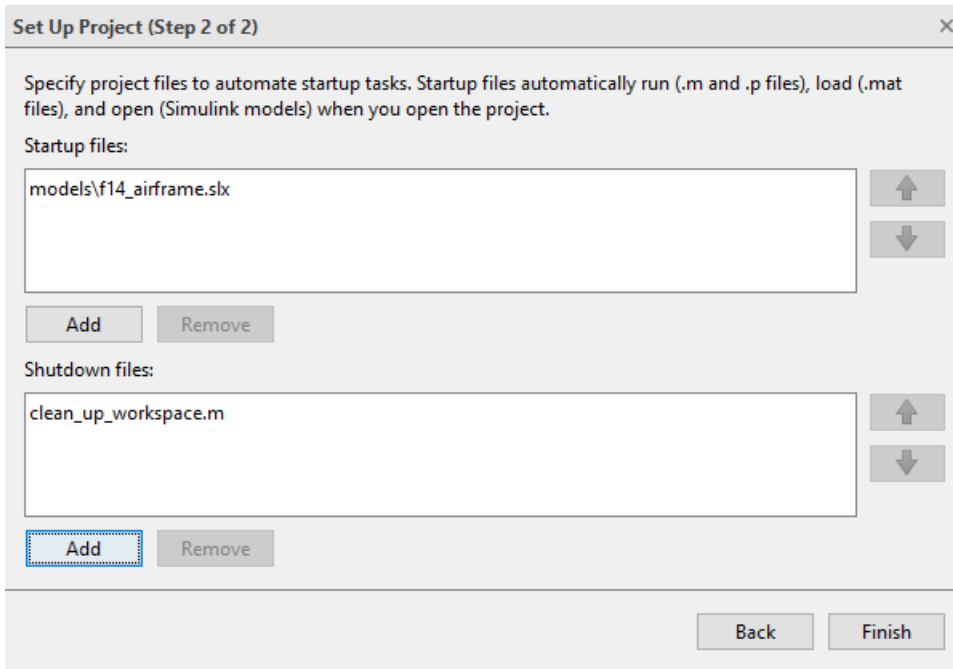

- 5 In the Set Up Project (Step 2 of 3) dialog box, optionally specify startup and shutdown files.
- Use startup files to configure settings when you open the project. Startup files automatically run (.m and .p files), load (.mat files), or open (Simulink models) when you open the project.

- Use shutdown files to specify MATLAB code to run as the project shuts down. You do not need to use shutdown files to close models when you close a project, because it automatically closes any project models that are open, unless they are dirty. The project prompts you to save or discard changes.

Click **Add** to specify startup or shutdown files.

- 6 In the Set Up Project (Step 3 of 3) dialog box, specify a `slblocks.m` library information file for this blockset. This file contains information on your blockset settings, and the location of your top library. Without this file, your project cannot be set up properly. Click **Browse** to select the file.

- 7 Click **Finish** and a new project opens. The Blockset Designer automatically adds all your files to the project. During the import process, based on the top library, the Blockset Designer explores the hierarchy of the blockset, creates dedicated folders for each type of supported blocks, and adds the folders to project and search corresponding artifacts such as S-function MEX file, source files, and System object files for MATLAB System block automatically. See “Blockset Project File Structure” on page 51-12 for more information.

Now you can start adding more blocks to your project, or add test or documentation to your existing blocks in the project. To learn more about how to build, test and document your blocks, see “Create and Organize Block Artifacts” on page 51-14.

## Blockset Project File Structure

When you create a blockset project, either by creating a new blockset or importing an existing blockset, the Blockset Designer organizes your project in a certain file organization. This organization changes with the different type of blocks you have in your project. Use this table as a guide to determine which folders are created for each block. To see your blockset folder structure, click **Files** in the **Views** panel.

Block Type	Folder Name	Folder Contains
Subsystem	<b>doc</b>	Documentation source and html file for the documentation
	<b>library</b>	Library model for the block
	<b>unittest</b>	Unit test model, test suite, and input file for the test
MATLAB System	<b>library</b>	Library model for the block

Block Type	Folder Name	Folder Contains
	<b>sysobj</b>	The System object code for the MATLAB System block
	<b>unittest</b>	Unit test model, test suite, and input file for the test
S-function and S-function Builder	<b>build</b>	S-function build script
	<b>doc</b>	Documentation source and HTML file for the documentation
	<b>library</b>	Library model for the block
	<b>mex</b>	S-function MEX and code generation files
	<b>src</b>	S-function source files
	<b>unittest</b>	Unit test model, test suite, and input file for the test
Blockset Project (common)	<b>doc</b>	Documentation source and HTML file for the documentation
	<b>library</b>	Library model for the block
	<b>script</b>	<code>blocksetroot.m</code> file to return the blockset root folder

## See Also

S-Function | S-Function Builder | MATLAB System | Subsystem

## More About

- “Create and Organize Block Artifacts” on page 51-14
- “Publish the Created Blockset” on page 51-18

## Create and Organize Block Artifacts

After creating a new blockset or importing your existing blocksets, you can start adding artifacts. In Blockset Designer, there are different artifacts associated with different blocks:

- Subsystem blocks — You can add test and documentation.
- MATLAB System blocks — You can add test using the Blockset Designer working area. To document your blocks, add comments in the System object code.
- S-function and S-function Builder Blocks — You can build S-functions, add test and documentation.

Follow the status of your artifacts by checking the icons in the working area.

Icon	Artifact Status
	No files are specified for the artifact. To resolve, click <b>Create</b> or select an artifact from <b>Browse</b> .
	The artifact files have been updated but has not been run yet. To resolve, click <b>Run</b> in the toolbar for the desired artifact.
	No action needed for the shown status of this block. For example, you do not need to build a MATLAB System or a Subsystem block, and on the status table, <b>Build</b> column shows this icon.
	Build operation of the selected S-function block encountered an error. To resolve, check the S-function build report from the top right of the <b>Build</b> working area, or check your S-function code to resolve issues. See “S-Function Related Artifacts” on page 51-16 for more details.

### Add Tests to Blocks

To ensure that your custom blocks run seamlessly, you can add a test to your blocks. Blockset Designer gives you the capability to create a test harness automatically, or using you can bring in your own test suite.

 Test

Harness Model

Test Suite

To create a test model and a test suite automatically using Blockset Designer, click **Create**. Your test model opens automatically, investigate this model and verify that it matches your testing needs. Note

that you can only create one test using Blockset Designer, but you can add many tests using test suite. To write your test, open the MATLAB unit test file. This file is just a template for you create your test. If you are going to use the test harness the Blockset Designer created for you, make sure to uncomment the model file.

To bring in your own tests, browse and select your test model and click **Apply**. To bring your own test suite, browse to your test suite and click **Apply**.

To recreate a harness model, delete the contents of the **Harness model** and **Test Suite** and click **Apply**. Then, the **Create** button reappears.

### Check Blocks Using Model Advisor

Use **Model Advisor** functionalities to do further checks on your blocks. To use **Model Advisor**, you must have a test harness model for your block. Access it from **Check**, select **Model Advisor**. You can create a test model automatically using the steps above, or you can browse and select your own harness model.

To learn more about Model Advisor checks, see “Check Your Model Using the Model Advisor” on page 5-2.

### Run S-Function Checks

Use S-function Checks to analyze the quality of your S-functions. To use S-function checks, you must have a test harness model for your block. To run these checks, from **Check**, select **Run S-Function Checks** in Simulink toolstrip. The checks generate an S-function check report for your S-function. To learn more about S-function checks, see “Check S-Functions Using S-Function Analyzer APIs”.

## Document the Blocks

The Blockset Designer enables creating documentation for your custom blocks. To create documentation automatically, click **Create** in the **Document** part of the working area.

This creates a Live Editor file for you to write your documentation. After you complete your block documentation, save the Live Editor file. To produce an HTML file for your documentation, from the Simulink toolstrip, confirm that the Document check box is selected, and click **Run**.

## S-Function Related Artifacts

In the steps above, you already learned how to create a new S-function block. Here you learn how to build an S-function in a Blockset Designer project.

### Build S-Function Blocks

If you create your S-function as a new block:

- 1 Check the working area and observe that **S-Function File** and **S-Function Build Script** fields are already populated for your S-function.

- 2 To open the S-function code template, click **Open** next to the **S-Function File**. Write the code for your S-function and save your code. Close the MATLAB Editor.

To learn more about writing S-functions, see “Implement C/C++ S-Functions”. If you prefer to create a S-function automatically, see S-Function Builder.

- 3 Return to the Blockset Designer working area.

- 4 From the Blockset Designer toolstrip, confirm the **Build** check box is selected and click **Run** .

- 5 During the run, your S-function files are added to the project. A build report for your S-function that contains your S-function build status is generated. If you face any issues during build, check this report. You can reopen this report by clicking on the timestamp in the top right corner of **Build** section.
- 6 Return to the working area and observe that after build operation, an S-function MEX File is generated for this S-function block.

### Build S-Function Builder Blocks

- 1 After creating an S-function Builder block, the S-Function Builder dialog window automatically opens from the library model. Write your code in the panes of the S-function Builder dialog window.
- 2 Click **Build** on the top-right of the S-function Builder dialog window. This will build your S-function, create all S-function artifacts, and communicate with the Blockset Designer.
- 3 Click **Close** to return to Blockset Designer working area.

When you are finished adding and building Blockset Designer artifacts, you are ready to publish your project as a toolbox and share. For more information, see “Publish the Created Blockset” on page 51-18.

## **See Also**

S-Function | S-Function Builder | MATLAB System | Subsystem

## **More About**

- “Create a Blockset Project” on page 51-2
- “Publish the Created Blockset” on page 51-18

## Publish the Created Blockset

After you have added artifacts for your blocks in a Blockset Designer project, you can publish and share your project as a toolbox. To publish:

- 1 Click the blockset from the blockset tree, and click **Publish Toolbox** from the Simulink toolstrip.

The Blockset Designer collects your files in the project, and creates the **publish** folder in **Views > Files**. This folder contains all your files from the separate folders in the blockset project based on the dependency analysis, but now collected together under one folder. See “Dependency Analysis” to learn more about dependency analysis. The publish folder contains these folders and the associated content:

Folder Name	Contains
<b>doc</b>	<ul style="list-style-type: none"> <li>• All block documentation HTML files and blockset-level documentation XML files</li> <li>• <code>helpdoc.xml</code> and <code>info.xml</code> is generated to be used in toolbox documentation. See “Display Custom Documentation” for more information.</li> </ul>
<b>extra</b>	For all blocks: <ul style="list-style-type: none"> <li>• S-function source files and build scripts</li> <li>• Documentation source files</li> <li>• Test models, suites, and their generated input files</li> <li>• All other necessary files based on the dependency analysis, such as block icons.</li> </ul>
<b>library</b>	All library models in the blockset all files under <code>&lt;projectroot&gt;/common/library</code> . This includes library models of sublibraries, as well as the blockset project library model.
<b>mex</b>	All S-function mex files
<b>script</b>	<code>blocksetroot.m</code> file to return blockset root folder and all files under <code>&lt;projectroot&gt;/common/script</code> .
<b>sysobj</b>	All System object code for the MATLAB System blocks in the blockset project

If you have any other files that you would like to include in the publish, manually copy them to the publish folder.

Since the publish folder is added to project path by default, to avoid shadowing files in project, remove this folder from the project path or delete it after the publish process. If you make any changes to your blockset after publishing, click **Publish** again the move the updates files to the publish folder.

- 2 The **Toolbox Information** fields are populated with the project name, author, and description. Edit the information if needed.

- 3 To ensure that MATLAB detects installation components, review the toolbox contents from **Toolbox Files and Folders**. If you want to include files not already included in the project files, edit the **Exclude files and folders**.
- 4 Click **Package** from the toolstrip to package your toolstrip.

To save your toolbox and share it on the MATLAB Central File Exchange, select **Package and Share** from the **Package** menu at the top of the Package a Toolbox dialog box. This option generates a `.mltbx` file in your current MATLAB folder and opens a web page for your toolbox submission to the File Exchange. MATLAB populates the File Exchange submission form with information about the toolbox. Review and submit the form to share your toolbox on File Exchange.

To share your toolbox with others, use the `.mltbx` file. All files you added when you packaged the toolbox are included in the `.mltbx` file. When your toolbox is installed, `.mltbx` file manages the MATLAB path or other installation details.

To learn more about how to create and share toolboxes, and to see the details of the packaging user interface, see “Create and Share Toolboxes”.

# FMUs and Co-Simulation in Simulink

---

- “Import FMUs” on page 52-2
- “Implement an FMU Block” on page 52-5
- “Export a Model as a Tool-Coupling FMU” on page 52-14
- “Co-Simulation Execution” on page 52-18
- “Numerical Compensation” on page 52-20
- “Run Co-Simulation Components on Multiple Cores” on page 52-28
- “Simulink Community and Connection Partner Program” on page 52-34
- “FMU Block Calling Sequences” on page 52-35

## Import FMUs

Use the FMU block to import Functional Mockup Units (FMUs) into Simulink.

The FMU block automatically selects the FMU mode based on the existing FMU you want to import:

- **Co-Simulation** — Integrate FMUs that implement an FMI Co-Simulation interface. These FMUs can contain local solvers used for tool coupling.
- **Model Exchange** — Integrate FMUs that implement an FMI model exchange interface. These FMUs do not contain local solvers. Instead, these FMUs inherit solvers from Simulink.

This block supports FMI versions 1.0 and 2.0. For FMI version 2.0, if your FMU contains both Co-Simulation and Model Exchange elements, the block detects this state and prompts you to select the operation mode for the block.

You can use your FMU block as you do other Simulink blocks. The FMU block supports normal, rapid accelerator, and accelerator modes. Rapid accelerator mode is unsupported for FMU blocks with FMU logging.

This topic assumes that you provide a `.fmu` file.

### FMU XML File Directives

The default parameter values derive from the corresponding parameter `start` value defined in the FMU `ModelDescription.xml` file. A block parameter value overwrites the initial value of the corresponding parameter defined in the FMU binary implementation.

Simulink interprets these FMU tags accordingly.

FMU Tag	Simulink
ScalarVariable has attributes set as follows: <ul style="list-style-type: none"> <li>• <code>causality="none"</code> or <code>causality="internal"</code></li> <li>• <code>variability="parameter"</code></li> <li>• <code>start</code> value is defined</li> </ul>	Interprets <code>ScalarVariable</code> element as block parameter
<code>Real</code>	Interprets block parameter as edit field
<code>Integer</code>	Interprets block parameter as edit field
<code>Boolean</code>	Interprets block parameter as check box
<code>Enumeration</code>	Interprets block parameter as drop-down list
<code>String</code>	Interprets as UTF-8 encoded string

The FMU block supports the following encoding formats for the model description XML file:

- ISO-8859-1
- UTF-8
- UTF-16

## Additional Support and Limitations

Capability	FMI Version 2.0 Support	FMI Version 1.0 Support
Save model operating point to base workspace	✓	
Fast restart	✓	
Simulation Stepper	✓	
Solver Jacobian	✓	
Linearize models	✓	
Declare parameter as tunable and tune it during simulation	✓	
For Each subsystem blocks	✓ (Supported only when <code>canBeInstantiatedOnlyOncePerProcess</code> attribute is set to false in <code>modelDescription.xml</code> file)	
Parameters of type string	✓	✓
Rapid accelerator mode	✓	✓
Software-in-the-loop (SIL) and processor-in-the-loop (PIL) modes		
Code generation		Supports code generation target <code>slrealtime.tlc</code> in Co-Simulation mode. Does not support FMU blocks for Model Exchange mode. For more information, see “Apply Functional Mock-up Units by Using Simulink Real-Time” (Simulink Real-Time).
FMU export	✓	✓
Protected model export	✓	✓
Model coverage		
Simulink Design Verifier		
Model reference in accelerator mode	✓	✓

Simulink supports stepping back and forth, tuning parameters in between, and saving states for the FMU Import block as long as the FMU itself supports these features. FMU flags that it supports these

features by setting `canGetAndSetFMUstate` and `canSerializeFMUstate` fields in its model description XML to `true`.

## FMU Import Examples

Example	Description
"Import Co-Simulation FMU into Simulink"	This model shows how to use the FMU block to load an FMU file that supports Co-Simulation mode.
"Importing a Model Exchange FMU into Simulink"	This model shows how to use the FMU block to load an FMU file that supports Model Exchange mode.
"Simplify Interface for Structured Data with FMU Import Block"	This model shows how to use bus signals and structure parameters in an FMU block that supports Model Exchange mode.

## Implement an FMU Block

Implement a block and assign a functional mockup unit (FMU) to it. You can then explore the block to see the FMU. This example uses the FMU block with the vehicle FMU.

- 1 Create a model and add the FMU block.
- 2 In the block dialog box, enter the path name for an FMU file in the **FMU name** parameter and click **OK** or **Apply**. The file extension `.fmu` is optional.

The first time you click **OK** or **Apply**, the block identifies which FMU mode to set your FMU to, cosimulation or model exchange.

The block also creates a `slprj/_fmu/fmu_name` folder and unpacks the contents of the FMU file into this folder, which optionally include:

- `binaries` — FMU binary files
- `documentation` — FMU documentation HTML files
- `resources` — FMU source files
- `sources` — FMU source files
- Other supporting files, such as block mask and description files

The FMU block icon and port labels update to the labels of the corresponding FMU. After you associate the block with an FMU, if you want to change the FMU, right-click the FMU block, and select **Block Parameters**, and enter a new FMU name in **FMU name**. The section in this topic use the FMU from the “Simplify Interface for Structured Data with FMU Import Block” example.

### Explore the FMU Block

Double-click the block. Suppose that you entered an FMU named `fmuVehicA0B.fmu` from your current folder. The FMU block dialog box reflects the FMU parameters defined in the `fmuVehicA0B.fmu` file.

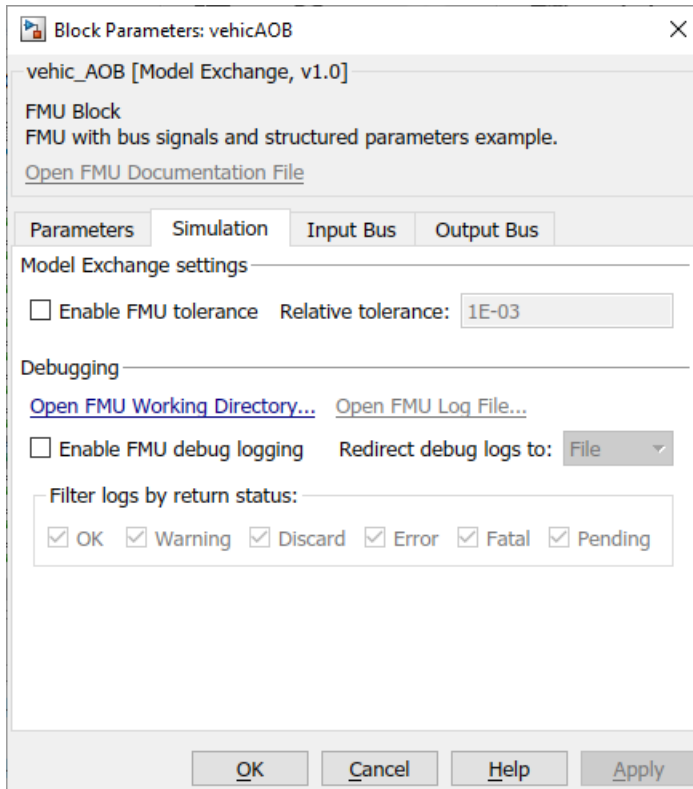

## Parameters Tab

Lists the FMU block parameters. Edit the values as necessary. You can edit the elements of a structure parameter by expanding the tree view.

## Simulation Tab

Enables logging and associated customizations.

- To enter a relative tolerance, select **Enable FMU tolerance** and set it.
- To determine the sample time of the block in the model, set **Communication step size**. To inherit the step size from the Simulink solver, set to -1. This option is available only if the FMU is a cosimulation FMU.
- To enable logging, select the **Enable FMU Debug Logging**.
- In **Redirect debug logs to**, select the destination for the logs.
  - File, saved to `slprj\_fmu\_logs_modelname\modelname_blockname.txt`
  - Display, displayed in the MATLAB Command Window.

If the **Enable FMU Debug Logging** check box is selected and the **Redirect debug logs to** parameter is set to **Display**, you cannot use the FMU block for cosimulation. For more information on cosimulation and multiple cores, see “Run Co-Simulation Components on Multiple Cores” on page 52-28

- In the **Filter logs by return status**, select the check box for the return status you want.

## Input and Output Bus Tabs

These two tabs list the input and output bus objects that the block defines.

In the **Bus Object Name** parameter, you can change the bus object names to match the bus objects defined in the workspace.

To create a bus object in the workspace:

```
fmudialog.createBusType(gcb)
```

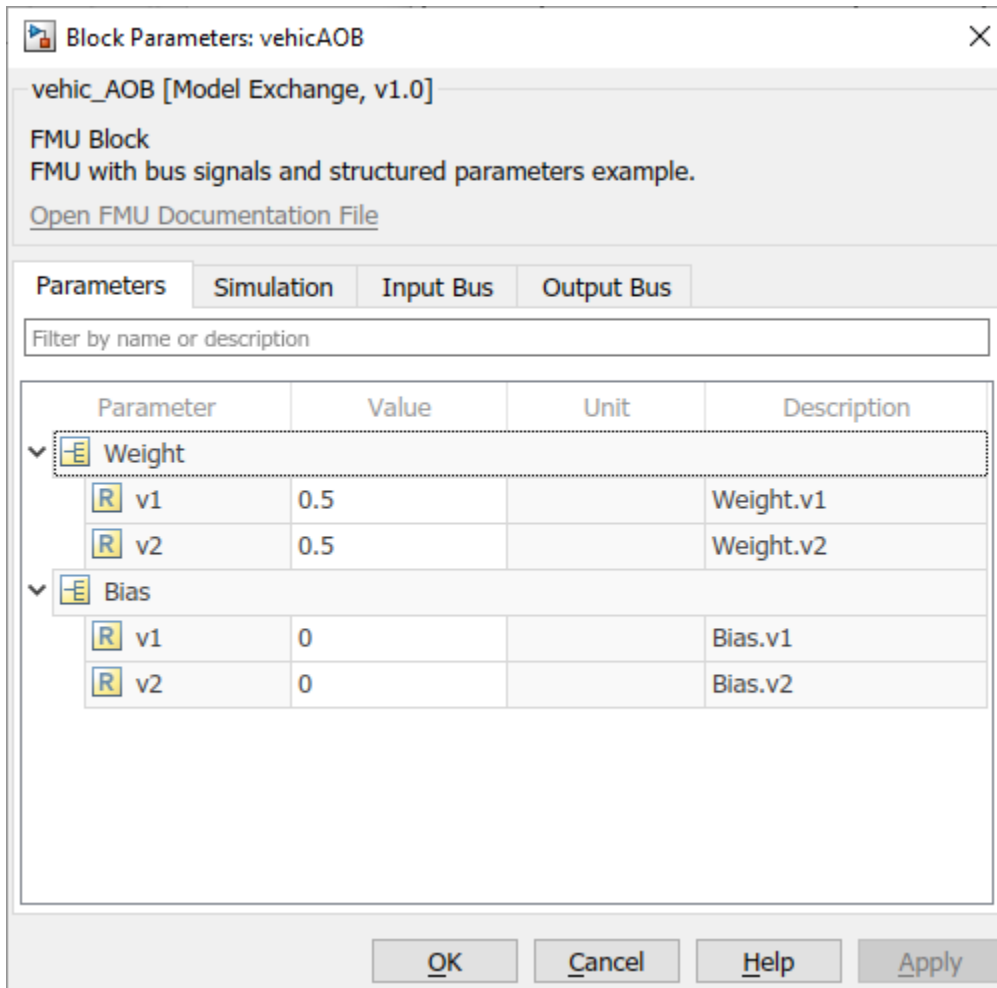

## Change Block Input, Output, Parameter and Internal Variable Structures

You can change the layout of FMU block input ports, output ports, and parameters with these parameters:

Parameter	Action	Settings
FMUInputMapping	Change hierarchy of input ports.	'Flat' — Separates input into individual signals.  'Structured' — Combines input into a structure of signals (bus).

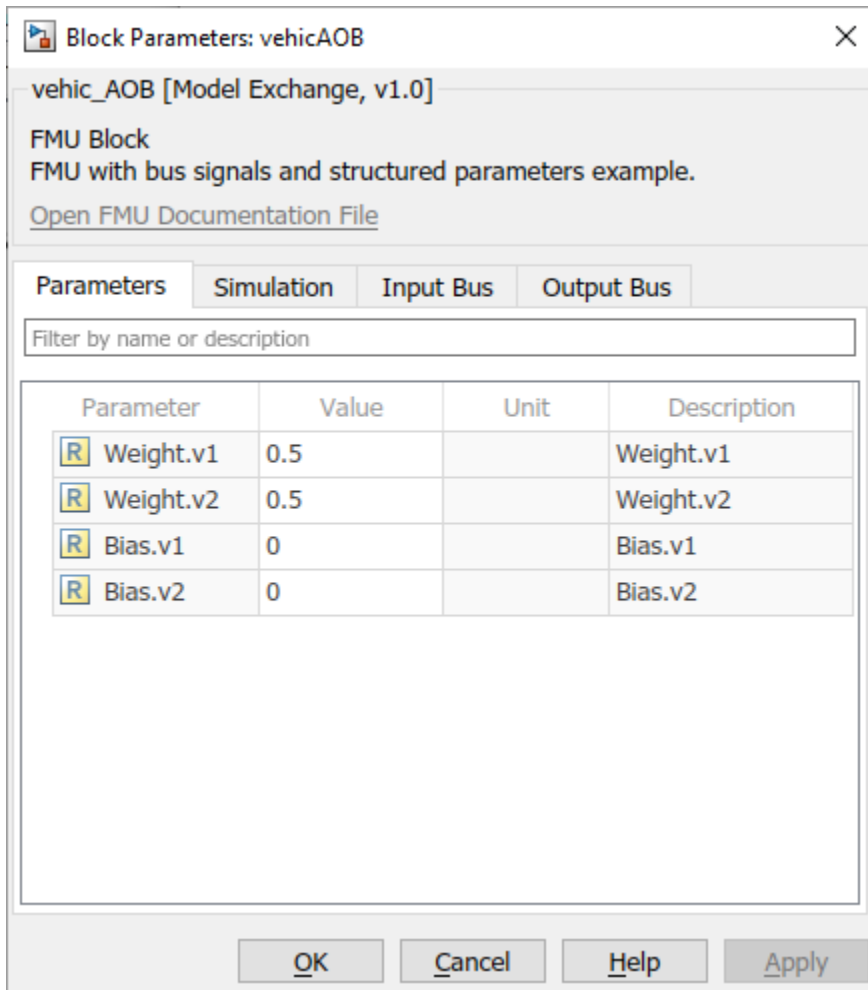

Parameter	Action	Settings
FMUOutputMapping	Change hierarchy of output ports.	'Flat' — Separates output into individual signals.  'Structured' — Combines output into a structure of signals (bus).
FMUParamMapping	Change hierarchy of parameters.	'Flat' — Separates parameters into individual parameters, listed by the parameter name and value.  'Structured' — Combines parameters into a structure of parameter values (struct).
FMUInternalMapping	Change hierarchy of internal variables	'Flat' — Separates internal variables into individual signals.  'Structured' — Combines internal variables into a structure of signals (bus).

Use the `get_param` and `set_param` functions to set these values. For example, assume a block parameter tab with a structure construct:

The parameters are contained in a struct. To list the parameters individually, set the FMUParamMapping property to 'Flat':

```
set_param(gcf, 'FMUParamMapping', 'Flat')
```

## Timing Considerations

You can set the sample time for the FMU block with the **Communication step size** parameter. This block sample time setting,  $t_C$ , like all Simulink blocks, must be an integer multiple of the model sample time,  $t_M$ . Simulink generates an error if the communication step size  $t_C$  is not a multiple of the model step size  $t_M$ .

The local step size of the FMU  $t_L$ , on the other hand, is part of the FMU specification and is known to the FMU only internally. For proper operation, the communication step size,  $t_C$  must also be an integer multiple of  $t_L$ . If the model sample time  $t_M$  or the block sample time  $t_C$  is incompatible with the FMU local step size  $t_L$ , the FMU may or may not produce an error at run time, depending on its implementation.

## Troubleshooting FMUs

If there are problems with using the FMU:

- Check the compliance of the FMU with the FMI standard. Use the FMU compliance checker.

- Select the **Enable FMU Debug Logging** check box on the FMU block Simulation tab.
- Contact the FMU supplier.

- FMI Standard

## Export a Model as a Tool-Coupling FMU

To integrate Simulink components into third-party software, export a Simulink model as a tool-coupling functional mockup unit (FMU). When a third-party tool runs the FMU, it checks out required licenses and starts a local installation of Simulink to start the model. Tool-coupling FMUs support the fixed-step and variable-step solvers that the FMU encapsulates.

Use a project to export an FMU. Open the model and select **New > Project > New Project from this Model** to create a project from a model.

You can export a FMU from a project interactively.

- 1 In the project, select **Share > Tool-Coupling FMU**.

- 2 Type in the **Copyright**, **Description**, and **FMU Icon** fields. Click **Save Settings and Export as** and provide a name.

The generated FMU includes model implementation, as well as the metadata provided during export.

```
<?xml version="1.0" encoding="utf-8"?>
<fmiModelDescription author="" copyright="" description="" fmiVersion="2.0"
  generationDateAndTime="2018-08-16T15:51:48Z"
  generationTool="Simulink (R2018b)"
  guid="5bd096be-a08d-020e-fc96-847aa21def5b"
  license=""
  modelName="vdpSlave"
  variableNamingConvention="structured"
  version="1.8">
```

You can also create and export a project to a FMU from the command line as follows:

```
>> p = slproject.create('vdpProject')
>> copyfile(which('vdp'), './vdpSlave.slx')
>> p.addFile('./vdpSlave.slx')
>> Simulink.fmuexport.ExportSimulinkProjectToFMU(p, 'vdpSlave.slx', '-fmuname', 'vdpFMU')
```

For more FMU export options from the command line, type:

```
help Simulink.fmuexport.ExportSimulinkProjectToFMU
```

The model must satisfy these conditions for exporting:

- Model must be in Normal or Accelerator simulation mode.
- Root input and output ports must be one of these numerical data types:
  - double
  - int32
  - Boolean
  - Simulink bus object, where all elements are double, int32, or Boolean
  - Simulink.AliasType, in which the base type resolves to double, int32 or Boolean

If the cosimulation component is an FMU exported from Simulink, the local sample time for that FMU is the sample time of the original model.

## Include Tunable Parameters for Tool-Coupling FMU

To include tunable parameters:

- 1 Open the model from the associated Simulink project.
- 2 From the Simulink model, click the **Modeling** tab and start Model Explorer.
- 3 Select Model Workspace and add a MATLAB variable or Simulink parameter.
- 4 For each parameter you add and want tunable, in the **Data Properties** or **Simulink.Parameter** pane, select the **Argument** check box.
- 5 Click **Apply**.
- 6 Reference the tunable parameters in the model.
- 7 Export the tool-coupling FMU.

## Use Protected Model to Conceal Content

The exported tool-coupling FMU is a zip package and contains the original Simulink project and model files in its resources folder. To protect your intellectual property, use protected model workflow. Save the model as a protected model and select the **Simulate** check box to conceal the contents. Create a new model with model reference block to load the SLXP file, and use this model as the main interface model when exporting to tool-coupling FMU. For more information, refer to “Protect Models to Conceal Contents” (Embedded Coder).

## Use the Exported Tool-Coupling FMU

The exported FMU requires a local installation of Simulink to run. The MATLAB version used for cosimulation must be the same as the MATLAB version where the FMU is exported. On Windows, the application that runs the FMU can check out the required licenses automatically. For other operating systems, apply these settings:

- On Linux:

```
setenv LD_LIBRARY_PATH ${LD_LIBRARY_PATH}:<InstallationFolder>/bin/glnxa64:<InstallationFolder>/bin/glnxa64
export LD_LIBRARY_PATH=${LD_LIBRARY_PATH}:<InstallationFolder>/bin/glnxa64:<InstallationFolder>/bin/glnxa64
```

- On Mac OS:

```
setenv DYLD_LIBRARY_PATH ${DYLD_LIBRARY_PATH}:<InstallationFolder>/bin/maci64:<InstallationFolder>/bin/maci64
export DYLD_LIBRARY_PATH=${DYLD_LIBRARY_PATH}:<InstallationFolder>/bin/maci64:<InstallationFolder>/bin/maci64
```

For Mac OS, due to System Integrity Protection (SIP), `setenv` command does not work for applications that starts new processes, such as MATLAB. Follow Append library path to "DYLD\_LIBRARY\_PATH" in MAC to set DYLD\_LIBRARY\_PATH to <InstallationFolder>/bin/maci64:<InstallationFolder>/extern/bin/maci64.

Before you can run the FMU, you must set up a MATLAB session from your operating system console. After you set up this session, start the third-party application and import the tool-coupling FMU. Each FMU instance requires a new MATLAB session.

### Start a Dedicated Session from MATLAB

If the application that imports the FMU runs a single instance of the FMU, you can use MATLAB to start a session.

```
>> shareMATLABForFMUCoSim
```

`shareMATLABForFMUCoSim` dedicates the current MATLAB session available for requests from the external tool to co-simulate an imported FMU. When an FMU is connected this session, the Simulink editor and Simulink project are loaded, and cosimulation starts automatically. You can use this session to pause, resume cosimulation, tune parameters, and plot signals from the command window while cosimulation is running. If cosimulation is finished, stopped by you, or interrupted by a runtime error, MATLAB closes, unloads the Simulink editor and Simulink project, and discards changes to the model. If an error occurs, it displays in the simulation tool that imports this FMU. Each session can connect to one FMU instance at the same time.

### Start a Dedicated Session from the Operating System

If the application that imports the FMU runs multiple FMU instances, you can use the operating system console to start dedicated MATLAB sessions. Run `matlabroot` in MATLAB to find out <matlabroot>.

Then, use <matlabroot>:

- On Windows:

```
<matlabroot>\toolbox\shared\fm_u_share\script\fm_u-matlab-setup.cmd [NumberOfMATLABSessions]
```

- On Linux and Mac OS:

```
<matlabroot>/toolbox/shared/fm_u_share/script/fm_u-matlab-setup [NumberOfMATLABSessions]
```

The input argument `NumberOfMATLABSessions` is an integer representing the number of MATLAB sessions to be launched when starting this script. If `NumberOfMATLABSessions` is not present, MATLAB sessions are not launched. Then, the program enters command-line interface mode and waits for a command.

See available commands by typing `help`:

```
> help
Command list:
quit - Close all shared MATLABs and exit.
list - List shared MATLABs.
start NUMBER_OF_MATLABS - Start NUMBER_OF_MATLABS more MATLABs.
stop NUMBER_OF_MATLABS - Stop NUMBER_OF_MATLABS MATLABs.
ignore - Stop asking about the hardware core count when launching MATLABs.
clean MATLAB_NUMBER - Clean up the MATLAB workspace for MATLAB #MATLAB_NUMBER. Use 0 for all MATLABs.
help - Print the command list.
```

Launch one session for each FMU to run concurrently. If there is a single FMU, type:

```
> start 1
```

If there are three FMUs running concurrently, type:

```
> start 3
```

Only one MATLAB management tool should be running on a single machine.

## Co-Simulation Execution

Simulink supports cosimulation between components with local solvers or involves external simulation tools. For example, cosimulation can involve an S-function implemented as a cosimulation gateway between Simulink and third-party tools or custom code. A cosimulation component can be a Functional Mockup Unit (FMU) in cosimulation mode imported to Simulink.

### Execution Timing

In Simulink simulation, the solver step size must be an integer divisor of each periodic, discrete block sample time. In other words, if a cosimulation component defines its own sample time, Simulink must communicate with the component at those time steps. Cosimulation can involve components whose time steps are determined internally and are not known to Simulink. The only information available to Simulink is the block sample time, either through the communication step size parameter of an FMU block, or the sample time definition in an S-function implementation. The block sample time determines the time steps Simulink must communicate with the cosimulation component. If the solver step size is not automatic, the communication step size must be an integer multiple of the solver step size.

If the cosimulation component internally uses a local solver, then this local solver should also be taken into account when determining the communication step size of the block. The step size of the local solver is not exposed to Simulink, and knowledge of the implementation is necessary to set the communication step size correctly. The behavior of cosimulation in case of a potential incompatibility also depends on this internal solver implementation.

## More About

- "Run Co-Simulation Components on Multiple Cores" on page 52-28
- "Identify co-simulation signals for numerical compensation"

## Numerical Compensation

Cosimulation signals typically represent continuous physical quantities that are discretized due to cosimulation. Data exchanges between cosimulation components such as C MEX S-functions and Co-Simulation FMU blocks can introduce numerical inaccuracies from signal delays. Use numerical compensation to improve numerical behavior for simulation involving components that use their own solver. Model Advisor includes a check that detects cosimulation components and advises numerical compensation.

### Numerical Compensation Prerequisites

Simulink automatically performs numerical compensation for cosimulation signals between cosimulation components. Simulink performs numerical compensation at the input of the destination block. A signal is automatically qualified for numerical compensation if its source port and destination port satisfy these conditions:

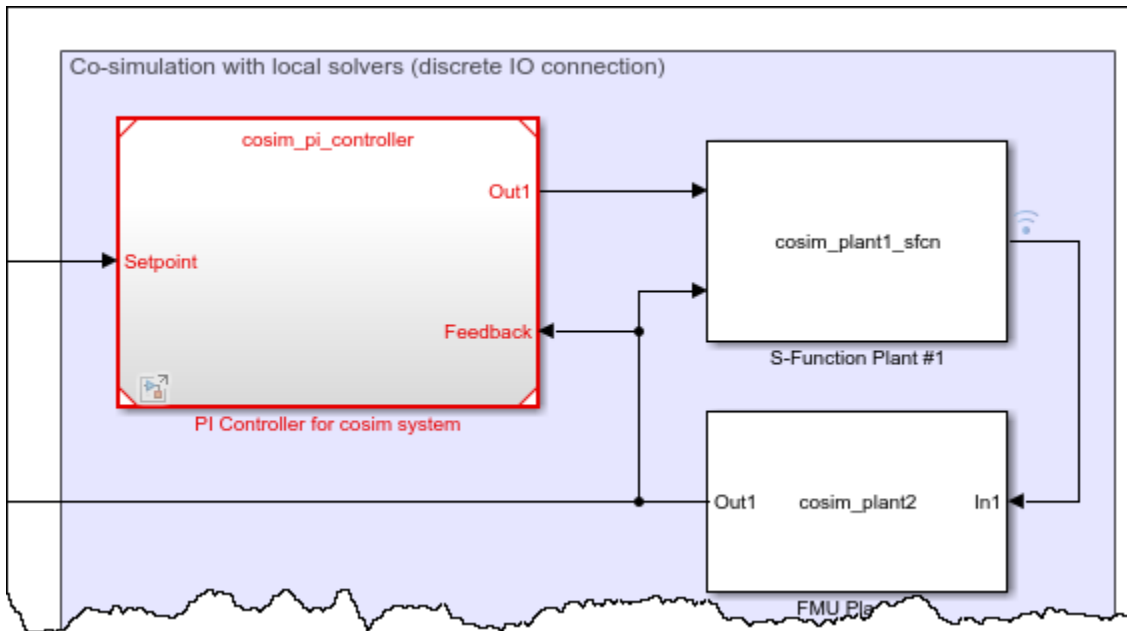

- The source port for the signal must satisfy these requirements:
  - S-Function
    - Output port data type is double
    - Output port sample time is periodic and discrete
    - Output port complexity is real
    - `ssSetOutputPortIsContinuousQuantity()` is set to `true` for the port
  - FMU
    - Output port data type is double
    - FMU is in cosimulation mode
    - Block sample time is periodic and discrete
    - Output port maps to a variable with `variability='continuous'` in `modelDescription.xml`
- The destination port for the signal must satisfy these requirements:
  - S-Function
    - Input port data type is double
    - Input port sample time is periodic and discrete
    - Input port complexity is real
    - `ssSetInputPortIsContinuousQuantity()` is set to `true` for this port
    - `ssSetInputPortDirectFeedThrough()` is set to `false` for this port
  - FMU
    - Input port data type is double
    - FMU is in cosimulation mode
    - Block sample time is periodic and discrete
    - Input port maps to a variable with `variability='continuous'` in `modelDescription.xml`

For an example of identifying cosimulation signals for numerical compensation, see “Using Numerical Compensation for Co-Simulation Integration” .

## Manage Numerical Compensation Options Using the Dialog

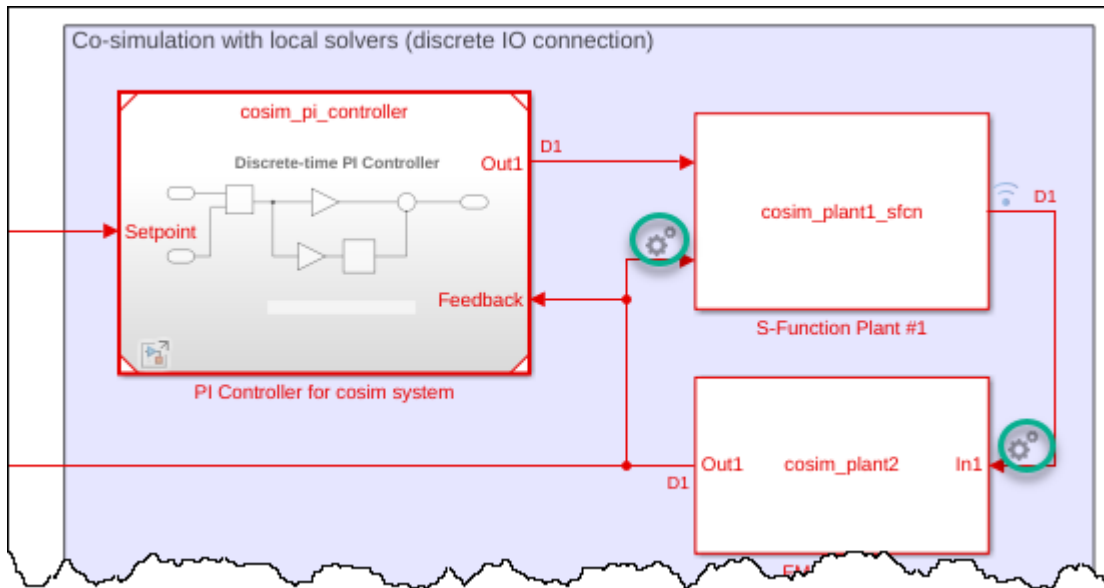

When Simulink detects signals that can have numerical compensation, the corresponding input ports display the  icon.

The `CoSimPIControllerPlantExample` example includes cosimulation signals that can have numerical compensation:

- 1 Open the `slexCoSimPIControllerPlantExample` model.  

```
openExample('slexCoSimPIControllerPlantExample')
```
- 2 Update the diagram. Simulink detects the signals that can have numerical compensation, and marks the corresponding ports with the  icon.

- 3 Adjust the parameters for automatic compensation using one of these methods:
- Right-click the icon and select **Co-simulation Numerical Compensation**.
  - Right-click the FMU or S-Function block and select **Co-simulation Numerical Compensation**.

**Note** The FMU block enables this option only if it is a block that can potentially support co-simulation, including these blocks:

- S-Function
- FMU Import
- MATLAB System
- Model
- Subsystem

The co-simulation compensation configuration dialog displays.

- On the **Input Signals** tab, select the port for which you want to adjust the automatic compensation.
- The **Continuous Quantity** column verifies if the component can support automatic numerical compensation.
- Double-click the **Request Compensation** column and select the automatic compensation.

Setting	Behavior	Icon
Auto	Enable automatic numerical compensation, allowing Simulink to detect if the port has a signal eligible for numerical compensation.  <b>Continuous Quantity</b> for both source and destination signal must be set to Yes.	
Off	Disable automatic numerical compensation. Icon appears with a red slash.  <b>Continuous Quantity</b> is ignored.	
Always	Force the port to be considered compliant for numerical compensation, even if the signal is not eligible for numerical compensation. This setting lets you add compensation without declaring it to be continuous.  <b>Continuous Quantity</b> is ignored.	

- 4 Adjust the parameters for compensation accuracy. Right-click the icon and select **Co-simulation Numerical Compensation**. The cosimulation compensation configuration dialog displays.
  - a On the **Input Signals** tab, select the port for which you want to adjust the calculation parameters, then click **Advanced compensation settings**:
    - **Extrapolation Method** — This method computes a compensated signal value for the current time step of simulation using extrapolation of simulation signal values generated from previous time steps. Select from the three types of extrapolations.
      - **Linear** is the default and uses signal values of the previous two time steps to linearly estimate the signal value for use in the current time step of simulation.
      - **Quadratic** uses signal values of the previous three time steps to fit the data to a quadratic polynomial.
      - **Cubic** uses signal values of the previous four time steps to fit the data to a cubic polynomial.

In the beginning of the simulation, when there is an insufficient number of past signal values, a lower-order extrapolation method is used automatically. Higher-order extrapolation methods use more past signal values to predict the current signal value and can improve accuracy of the prediction. However, high-order extrapolation methods can also be numerically unstable[1]. The best extrapolation method depends on the nature of the signal and its sample rate, as specified in the **Communication Step Size** parameter.

- **Signal correction coefficient** — This method further adjusts the extrapolated signal value based on past simulation results and past estimated signal values. A correction coefficient is offered for selection between 0 and 1, where 0 means no adjustment is made to the extrapolated signal value. The default setting for the correction coefficient is 1. For a given extrapolated signal at a given time step, the larger the signal correction coefficient is, the more the given extrapolated signal is adjusted.

**b**

If numerical compensation is not beneficial, disable it by left-clicking the  icon. When disabled, the icon appears with a red slash.

## Manage Numerical Compensation Options from the Command Line

If automatic compensation is not possible, you can manually enable numerical compensation using the `CoSimSignalCompensationMode` property.

The `CoSimSignalCompensationMode` property has these values:

Icon	Setting	Behavior
	'Auto'	Enable automatic numerical compensation, allowing Simulink to detect if the port has a signal eligible for numerical compensation.  <b>Continuous Quantity</b> for both source and destination signal must be set to Yes.
	'Auto_Off'	Disable automatic numerical compensation. Icon appears with a red slash.  <b>Continuous Quantity</b> is ignored.
	'Always'	Force the port to be considered numerical compensation compliant, even if the signal is not eligible for numerical compensation. This setting lets you add compensation without declaring it to be continuous.  <b>Continuous Quantity</b> is ignored.
	'Always_Off'	Disable forcing the port to be considered numerical compensation compliant.  <b>Continuous Quantity</b> is ignored.

For example, to disable numerical compensation for the first input port from the previous model:

- 1 Select the block for which you want to select the port for numerical compensation. For example, get all the port handles for the currently selected block S-Function Plant #1, gcb.

```
p = get_param(gcb, 'PortHandles')
```

This function returns all the ports for the currently selected block. For example,

```
p =
```

```
struct with fields:
```

```

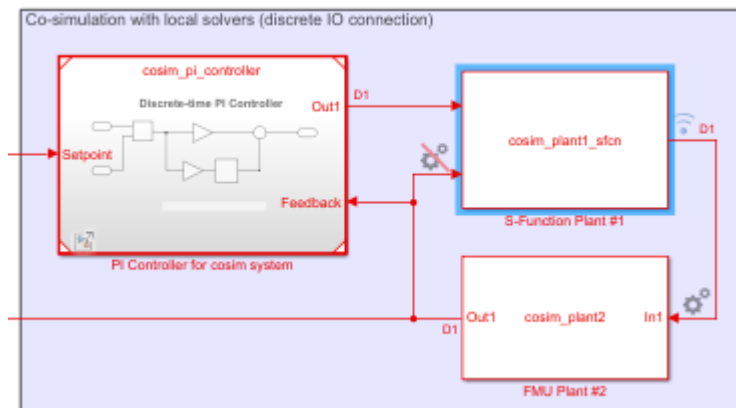

Inport: [79.0001 24.0001]
Output: 82.0001
Enable: []
Trigger: []
State: []
LConn: []
RConn: []
Ifaction: []
Reset: []
Event: []

```

- To disable numerical compensation for the first port:

```
set_param(p.Inport(2), 'CoSimSignalCompensationMode', 'Auto_Off')
```

The associated port appears with a red slash.

You can also set signal compensation parameters from the command line. The first step, again, is to obtain the port handles:

```
p = get_param(block, 'PortHandles')
```

Set the compensation parameters using the `CoSimSignalCompensationConfig` parameter, in this format:

```
set_param(p.Inport, 'CoSimSignalCompensationConfig', '{<CompensationParam>:<ParamValue>}' )
```

Find compensation parameter names and possible values in this table:

Compensation parameter	Parameter name	Parameter value	Default
ExtrapolationMethod	<b>Extrapolation method</b>	'LinearExtrapolation', 'QuadraticExtrapolation', or 'CubicExtrapolation'	'LinearExtrapolation'
CompensationCoefficient	<b>Signal correction coefficient</b>	Scalar between 0 and 1	1

For example, set the extrapolation method for the port:

```
set_param(p.Inport, 'CoSimSignalCompensationConfig', '{"ExtrapolationMethod":"LinearExtrapolation"
```

Set both the extrapolation method and the compensation coefficient:

```
set_param(p.Inport,'CoSimSignalCompensationConfig', '{"ExtrapolationMethod":"QuadraticExtrapolation", "CompensationCoefficient":"0.7"}'
```

## Numerical Compensation Limitations

- Nondouble nonreal signals, such as single, logical, complex, and bus signals cannot be compensated.
- Numerical compensation is not typically reliable when a rate transition exists between a source and destination component.
- Numerical compensation does not support code generation.
- Ensure that the compensated input port is a continuous quantity, especially if you override the behavior with the `Always` setting. Ideally, the input contributes to the integration process of the dynamic system, such as being integrated over time in the local solver, rather than being used as a discrete control signal, or being differentiated.
- If the Model block with local solver is turned on, no compensation is required at the input port.

## Run Co-Simulation Components on Multiple Cores

Simulink supports cosimulation between components using local solvers or that involves simulation tools. For example, cosimulation can involve an S-function implemented as a cosimulation gateway between Simulink and third-party tools or custom code. It can also involve an FMU in cosimulation mode imported to Simulink or a Model block in accelerator mode.

To improve performance, consider running models that contain cosimulation blocks (components) on multiple threads if:

- You are integrating multiple cosimulation components
- Integration at the component level is computationally intense

This topic assumes that you are familiar with multithreaded programming and concepts.

Simulink lets you run C MEX S-functions, Co-Simulation FMU blocks, and Model blocks configured for accelerator mode on multiple threads if they are threadsafe. Being threadsafe means that the block can work with multiple threads accessing shared data, resources, and objects without any conflicts.

You can also run a model on multiple threads if the model has a nondirect feedthrough block followed by a direct feedthrough block (see “Singlethreaded Versus Multithreaded Simulations” on page 52-28). Direct feedthrough means that the output port signal of a block is computed from the values of its input port signals in the same time step.

---

**Note** Multithreaded cosimulation for Level-2 MATLAB S-Function blocks is not supported.

---

By default, Simulink configures all models to run on multiple threads. If performance can be improved, Simulink automatically runs all models on multiple threads. However, not all models have cosimulation components that can run on multiple threads, and not all models benefit from running on multiple threads.

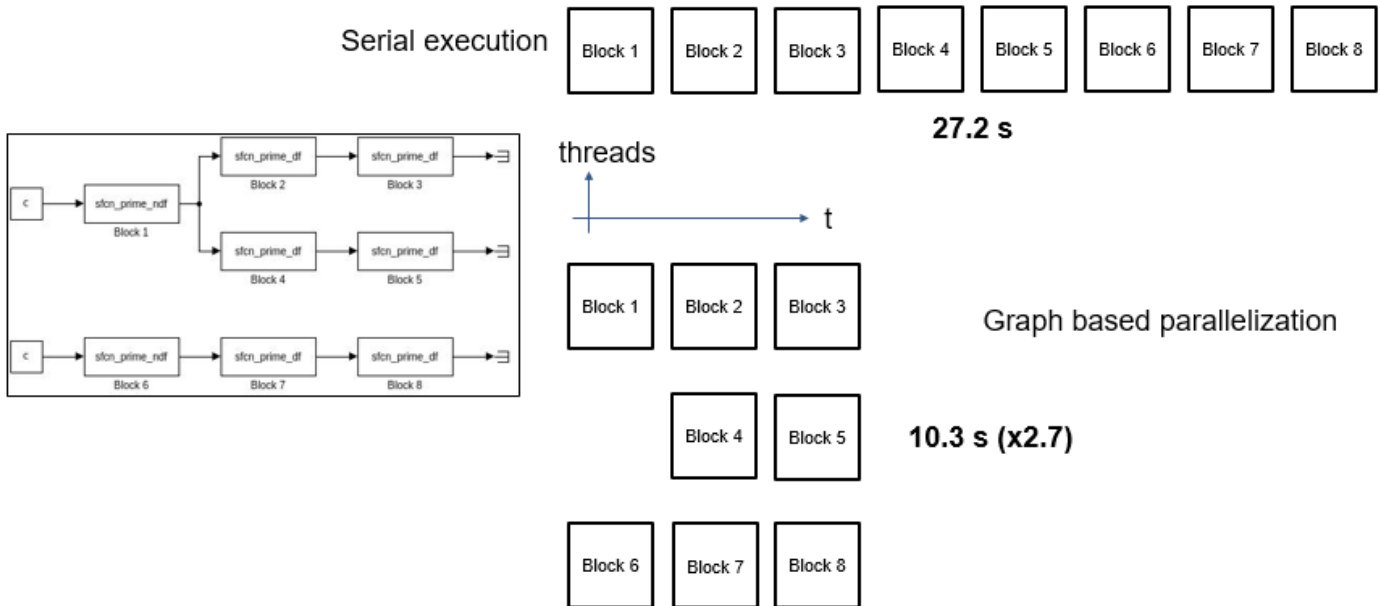

### Singlethreaded Versus Multithreaded Simulations

When evaluating a model for possible concurrencies in your system for multithread execution, Simulink uses a graph-based algorithm to analyze data dependencies among eligible blocks and form multiple task groups. This algorithm ensures that the different task groups:

- Have no data dependencies on each other
- Can execute in parallel using multiple cores

For example, Simulink might look for non-direct feedthrough blocks followed by direct feedthrough blocks. If the following direct feedthrough blocks depend only on a nondirect feedthrough block, the software can group the blocks in the same branch for parallel execution.

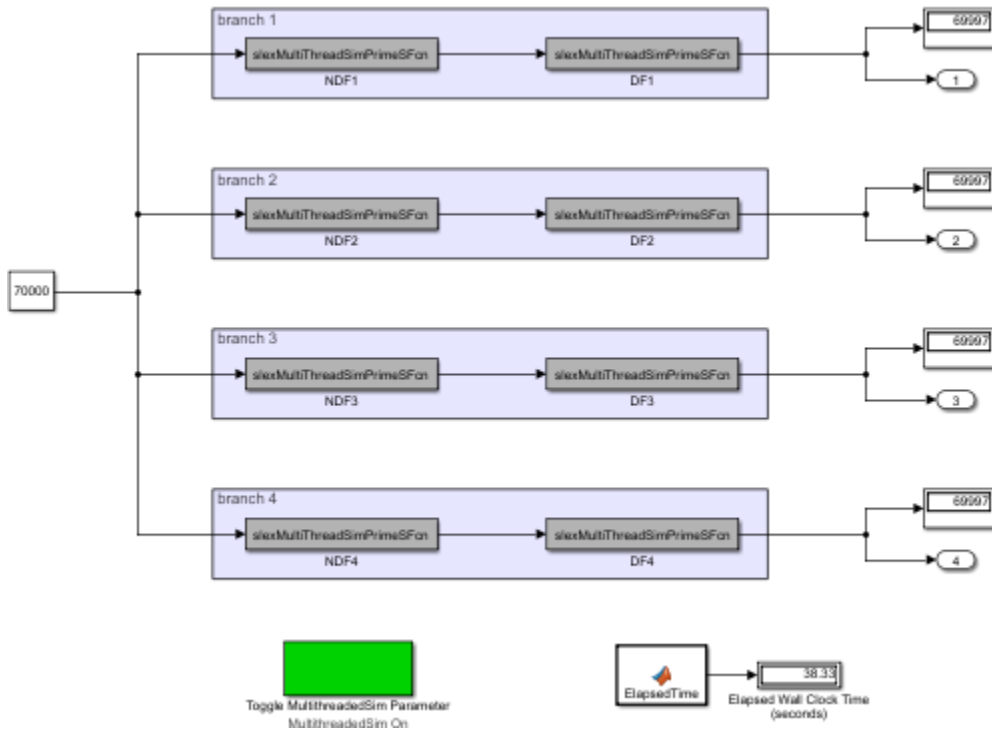

This example compares the serial execution of a series of blocks partitioned for parallel execution.

## Using Multithreaded Simulation to Speed up Simulation on Multiple Cores

Consider the Graph-Based Multithread Simulation example, which uses four nondirect feedthrough blocks followed by four direct feedthrough blocks. Direct feedthrough means that the output port signal of a block is computed from the values of its input port signals in the same time step.

Simulink analyzes the data dependencies and forms four branches. Each branch contains nondirect feedthrough blocks followed by direct feedthrough blocks. Then, Simulink uses multithreading to run those four branches. In this way, Simulink can speed up the simulation up to four times on a four or more core machine compared to a singlethreaded simulation on the same machine. You can manually measure the simulation of the model before and after changing the `MultithreadedSim` parameter.

This code shows how to measure simulation for the Graph-Based Multithreaded Simulation example:

```
openExample('slexGraphBasedMultiThreadSimExample');...
set_param(gcs, 'MultithreadedSim', 'off');
tic; sim('slexGraphBasedMultiThreadSimExample'); toc
```

Elapsed time is 39.406743 seconds.

```
set_param(gcs, 'MultithreadedSim', 'on');
tic; sim('slexGraphBasedMultiThreadSimExample'); toc
```

Elapsed time is 13.619744 seconds.

In this example, the speedup is almost three times (instead of four times) on a four core machine. This is due to the extra overhead introduced by the operating system thread context switch.

## Using the MultithreadedSim Parameter

You can specify that an entire model run on multiple threads, or specify that particular blocks run on multiple threads, using the `MultithreadedSim` parameter. Specify that an entire model runs on multiple threads if all the cosimulation blocks in the model are threadsafe. If some, but not all blocks, are threadsafe, identify only those blocks to run on multiple threads. The model and blocks use the `MultithreadedSim` parameter as follows:

Setting	Description
'auto' <sup>a</sup>	(Default) Let Simulink decide if the block can run on multiple threads.

Setting	Description
'off'	Disable the block or model from running on multiple threads.

<sup>a</sup> Starting in R2021a, when you open a model created in a previous release, Simulink interprets the 'on' setting to be the same as 'auto'.

Enabling the `MultithreadedSim` parameter does not mean that the block or model simulates on multiple threads. Simulation on multiple threads occurs when `MultithreadedSim` is enabled and:

- The block and/or model operate at a single rate.
- The block and/or model are threadsafe. (For example, they do not use static or global data).
- The block and/or model is exception-free. For S-function blocks, use the `ssSetOptions` function to set `SS_OPTION_EXCEPTION_FREE_CODE`.

Multithreading does not allow solver reset checks, and therefore skips over any use of the `ssSetSolverNeedsReset` and `ssBlockStateForSolverChangedAtMajorStep` functions. Conversely, in accelerator mode, if these functions are used or there are continuous states, multithreading is automatically turned off.

## Configuring S-Function Blocks to Run Single or Multithreaded

Whether an S-function block runs single or multithreaded depends on the `MultithreadedSim` parameter value and the `ssSetRuntimeThreadSafetyCompliance` function.

MultithreadedSim Setting	ssSetRuntimeThreadSafetyCompliance Setting	Single or Multithread
'auto'	<code>RUNTIME_THREAD_SAFETY_COMPLIANCE_UNKNOWN</code>	Single thread
'auto'	<code>RUNTIME_THREAD_SAFETY_COMPLIANCE_TRUE</code>	Multithread
'auto'	<code>RUNTIME_THREAD_SAFETY_COMPLIANCE_FALSE</code>	Single thread
'off'	—	The setting is ignored and the S-function block runs singlethreaded

## Co-Simulation on Multiple Threads Limitations and Guidelines

- The simulation runs on a single thread for accelerator and rapid accelerator modes. Multithreading is enabled when the simulation mode is normal.

Set model simulation mode to normal.

- There is no code generation for cosimulation components.
- Multithreading is not activated for blocks with constant sample time.
- Multithreading is not enabled when the Simulink debugger is on.

Turn off Simulink debugger.

- A block that depends on a non-thread-safe block cannot be multithreaded. Consider breaking the dependency, for example, by using a Unit Delay block.

### S-Function Block Limitations

- Must have a single rate.

Consider revising your model to break down multirate components into individual single-rate components.

- Multithreading is not enabled when an S-function has variable sample time.

Consider using a different sample time (see “Specify Sample Time” on page 7-10).

- Multithreading is not enabled when an S-function has continuous states and solver is fixed-step, which together trigger a continuous states consistency check. To disable continuous states consistency checks, use the `ssSetSkipContStatesConsistencyCheck` function.
- Must be thread safe — In `ssSetRuntimeThreadSafetyCompliance(SimStruct *S, int_T val)`, `val` must be `RUNTIME_THREAD_SAFETY_COMPLIANCE_TRUE`.

For more information, see “Guidelines for Writing Thread-Safe S-Functions”.

- Must be exception-free — In `ssSetOptions(SimStruct *S, uint_T options)`, `options` must include `SS_OPTION_EXCEPTION_FREE_CODE`.

For more information, see “Guidelines for Writing Thread-Safe S-Functions”.

- Multithreading is not enabled when the S-function Analyzer is on. Try multithreading in normal mode.
- Multithreading is not enabled when S-function has continuous sample time. Consider using a different sample time (see “Specify Sample Time” on page 7-10).
- Multithreading concurrently runs output and update methods. The block must have an output or update method.

### FMU Import Block Limitations

- Must be in cosimulation mode.

Consider switching FMU mode from Model Exchange to Co-Simulation.

- Must be thread-safe, for example, multiple FMUs must not access the same file at the same time.
- Multithreading is not enabled when FMU block logging displays in the MATLAB command window. Redirect FMU block logging to a file using:

```
set_param(blockName, 'FMUDebugLoggingRedirect', 'File')
```

- Multithreading is not supported when FMU is running out-of-process. To disable this setting, use:

```
set_param(blockName, 'DebugExecutionForFMUViaOutOfProcess', 'off')
```

### Model Block Limitations

- Multithreading is not enabled when a Model block has event ports.
- Cannot be inside a For Each Subsystem block.

Consider moving the Model block out of the For Each Subsystem block.

- Must be in accelerator mode.
- Must have single rate.

Consider revising your model to break down multirate components into individual single-rate components.

- Cannot use blocks with variable sample time.

Consider using a different sample time (see “Specify Sample Time” on page 7-10).

- Cannot have continuous states.
- Consider breaking the dependency between blocks, for example, by using a Unit Delay block.
- Must have a fixed-step solver.
- Cannot access any global data stores.
- Multithreading is not enabled when a model contains a Simulink Function block.
- Cannot use any Simulink functions or caller blocks.
- Cannot contain To File blocks. For more information, see “Save Simulation Data” on page 77-2.
- Cannot contain From File blocks.

Consider feeding data into the referenced model via an inport from the top-level model.

## Simulink Community and Connection Partner Program

Simulink supports the integration of multiple third-party functionalities, including apps, models, and toolboxes, from the Simulink community and commercial software tools.

For the integration of third-party functionality, this program includes:

- Simulink community — Provides direct access to all available Simulink apps, models, and toolboxes (Simulink community) using MATLAB Add-Ons. (To open the Add-On Explorer, go to the MATLAB Toolstrip and click **Add-Ons > get Add-Ons.**)
- Third-Party Products — The MathWorks Connections Program includes commercially offered products and services that complement MATLAB and Simulink.

## FMU Block Calling Sequences

During simulation of models containing FMU blocks, as Simulink passes through different Simulink engine phases, the FMU blocks call FMU Co-Simulation and Model Exchange methods for FMI Versions 1.0 and 2.0 (fmi\* and fmi2\* methods). This topic presents the FMI Standard call sequences in those phases.

This topic uses:

- fmiSetXXX (FMI Version 1.0) and fmi2SetXXX (FMI Version 2.0) to represent any of the methods: fmiSetReal/fmi2SetReal, fmiSetInteger/fmi2SetInteger, fmiSetBoolean/fmi2SetBoolean, or fmiSetString/fmi2SetString.
- fmiGetXXX (FMI Version 1.0) and fmi2GetXXX (FMI Version 2.0) to represent any of the methods: fmiGetReal/fmi2GetReal, fmiGetInteger/fmi2GetInteger, fmiGetBoolean/fmi2GetBoolean, or fmiGetString/fmi2GetString.

### Co-Simulation Call Sequence for FMI Version 1.0

These are the call orders for the FMI methods that the S-function callback methods call.

#### Setup Phase

At the end of compilation, the FMU block performs setup activities by calling these FMI methods:

- 1 fmiGetTypesPlatform
- 2 fmiGetVersion
- 3 fmiInstantiateModel
- 4 fmiSetTime
- 5 For variables with start values, fmiSetXXX

#### Initialization Phase

At the start of simulation, the FMU block sets up internal states and performs other initialization activities by calling the fmiSetXXX methods for tunable parameters.

#### Output Phase

During this phase, the FMU block computes outputs at the current time step by calling these FMI methods:

- 1 If the call is the first step:
  - a fmiSetXXX
  - b fmiInitialize
  - c If an event occurs, fmiEventUpdate
- 2 If the call is not the first step:
  - a fmiSetTime
  - b fmiSetXXX (for input)
  - c fmiSetContinuousStates

- d fmiCompletedIntegratorStep
  - e If an event occurs, fmiEventUpdate
- 3 For output, fmiGetXXX

### **Update Phase**

The FMU block computes states at the current time step and performs other major time step activities by calling the fmiSetXXX methods for input.

### **Derivatives Phase**

The FMU block computes derivatives of the FMU continuous states by calling these FMI methods:

- 1 fmiSetTime
- 2 fmiSetContinuousStates
- 3 fmiGetDerivatives

### **Zero-Crossing Signal Phase**

The FMU block computes the zero-crossing vector from the FMU event indicator by calling these FMI functions:

- 1 fmiSetTime
- 2 fmiSetContinuousStates
- 3 fmiGetEventIndicators

### **Termination Phase**

At the end of simulation, the FMU block performs activities before terminating the simulation by calling these FMI methods:

- 1 fmiTerminate
- 2 fmiFreeModelInstance

## **Model Exchange Call Sequence for FMI Version 1.0**

These are the call orders for the FMI methods that the S-function callback methods call.

### **Setup Phase**

At the end of compilation, the FMU block performs setup activities by calling these FMI functions:

- 1 fmiGetTypesPlatform
- 2 fmiGetVersion
- 3 fmiInstantiateModel
- 4 fmiSetTime
- 5 For variables with start values, fmiSetXXX

### **Initialization Phase**

At the start of simulation, the FMU block sets up internal states and performs other initialization activities by calling these fmiSetXXX methods for tunable parameters.

**Output Phase**

The FMU block computes outputs at the current time step by calling these FMI functions:

- 1 If the call is the first step:
  - a fmiSetXXX
  - b fmiInitialize
  - c If an event occurs, fmiEventUpdate
- 2 If the call is not the first step, fmiDoStep,
- 3 For output, fmiGetXXX

**Update Phase**

The FMU block computes states at the current time step and performs other major time step activities by calling the fmiSetXXX methods for input.

**Termination Phase**

At the end of simulation, the FMU block performs activities before terminating the simulation. This method calls these methods:

- 1 fmiTerminate
- 2 fmiFreeModelInstance

**Co-Simulation Call Sequence for FMI Version 2.0**

These are the call orders for the FMI methods that the S-function callback methods call.

**Setup Phase**

At the end of compilation, the FMU block performs setup activities by calling these FMI methods:

- 1 fmi2GetTypesPlatform
- 2 fmi2GetVersion
- 3 fmi2Instantiate
- 4 For variables with start values, fmi2SetXXX

**Initialization Phase**

At the start of simulation, the FMU block sets up internal states and performs other initialization activities by calling these FMI methods:

- 1 For variables with start values, fmi2SetXXX
- 2 fmi2SetupExperiment

**Output Phase**

During this phase, the FMU block computes outputs at the current time step by calling these FMI methods:

- 1 If the call is the first step:

- a `fmi2EnterInitializationMode`
  - b For input, `fmi2SetXXX`
  - c `fmi2InitializationMode`
- 2 If the call is not the first step, `fmi2DoStep`
- 3 For output, `fmi2GetXXX`

### **Update Phase**

During this phase, the FMU block computes states at the current time step and performs other major time step activities. This method calls the `fmi2SetXXX` for input.

### **Termination Phase**

At the end of simulation, the FMU block performs activities before terminating the simulation by calling these methods:

- 1 `fmi2Terminate`
- 2 `fmi2FreeModelInstance`

## **Model Exchange Call Sequence for FMI Version 2.0**

These are the call orders for the FMI methods that the S-function callback methods call.

### **Setup Phase**

At the end of compilation, the FMU block performs setup activities by calling these FMI methods:

- 1 `fmi2GetTypesPlatform`
- 2 `fmi2GetVersion`
- 3 `fmi2Instantiate`
- 4 For variables with start values, `fmi2SetXXX`

### **Initialization Phase**

At the start of simulation, the FMU block sets up internal states and performs other initialization activities by calling these FMI methods.

- 1 For tunable parameters, `fmi2SetXXX`
- 2 `fmi2SetupExperiment`

### **Output Phase**

The FMU block computes outputs at the current time step by calling these FMI methods:

- 1 If the call is the first step:
  - a `fmi2EnterIntializationMode`
  - b For input, `fmi2SetXXX`
  - c `fmi2ExitIntializationMode`
- 2 If the call is not the first step:

- a fmi1SetTime
- b For continuous input, fmi2SetXXX
- c fmi2SetContinuousStates
- d fmi2SetContinuousStates
- e fmi2CompletedIntegratorStep
- f If an event occurs:
  - i fmi2EnterEventMode
  - ii For input, fmi2SetXXX
  - iii fmi2NewDiscreteStates
  - iv fmi2EnterContinuousTimeMode
  - v If an event occurs:
    - A fmi2EnterEventMode
    - B For input, fmi2SetXXX
    - C fmi2NewDiscreteStates
    - D fmi2EnterContinuousTimeMode
- 3 For output, fmi2GetXXX

### Update Phase

The FMU block computes states at the current time step and performs other major time step activities by calling the fmi2SetXXX methods for input.

### Derivatives Phase

The FMU block computes derivatives of the FMU continuous states by calling these FMI methods:

- 1 fmi2SetTime
- 2 fmi2SetContinuousStates
- 3 fmi2GetEventIndicators

### Zero-Crossing Signal Phase

The FMU block computes the zero-crossing vector from the FMU event indicator by calling these FMI methods:

- 1 fmi2SetTime
- 2 fmi2SetContinuousStates
- 3 fmi2GetEventIndicators

### Termination Phase

At the end of simulation, the FMU block performs activities before terminating the simulation by calling these methods:

- 1 fmi2Terminate
- 2 fmi2FreeInstance

- “MATLAB Language Features Supported for C/C++ Code Generation” on page 53-23

## When to Generate Code from MATLAB Algorithms

Generating code from MATLAB algorithms for desktop and embedded systems allows you to perform your software design, implementation, and testing completely within the MATLAB workspace. You can:

- Verify that your algorithms are suitable for code generation
- Generate efficient, readable, and compact C/C++ code automatically, which eliminates the need to manually translate your MATLAB algorithms and minimizes the risk of introducing errors in the code.
- Modify your design in MATLAB code to take into account the specific requirements of desktop and embedded applications, such as data type management, memory use, and speed.
- Test the generated code and easily verify that your modified algorithms are functionally equivalent to your original MATLAB algorithms.
- Generate MEX functions to:
  - Accelerate MATLAB algorithms in certain applications.
  - Speed up fixed-point MATLAB code.
- Generate hardware description language (HDL) from MATLAB code.

## When Not to Generate Code from MATLAB Algorithms

Do not generate code from MATLAB algorithms for the following applications. Use the recommended MathWorks product instead.

To:	Use:
Deploy an application that uses handle graphics	MATLAB Compiler
Use Java	MATLAB Compiler SDK™
Use toolbox functions that do not support code generation	Toolbox functions that you rewrite for desktop and embedded applications
Deploy MATLAB based GUI applications on a supported MATLAB host	MATLAB Compiler
Deploy web-based or Windows applications	MATLAB Compiler SDK
Interface C code with MATLAB	MATLAB mex function

## Which Code Generation Feature to Use

To...	Use...	Required Product	To Explore Further...
Generate MEX functions for verifying generated code	codegen function	MATLAB Coder	Try this in “Accelerate MATLAB Algorithm by Generating MEX Function” (MATLAB Coder).
Produce readable, efficient, and compact code from MATLAB algorithms for deployment to desktop and embedded systems.	MATLAB Coder app	MATLAB Coder	Try this in “Generate C Code by Using the MATLAB Coder App” (MATLAB Coder).

## **Prerequisites for C/C++ Code Generation from MATLAB**

To generate C/C++ or MEX code from MATLAB algorithms, you must install the following software:

- MATLAB Coder product
- C/C++ compiler

## MATLAB Code Design Considerations for Code Generation

When writing MATLAB code that you want to convert into efficient, standalone C/C++ code, you must consider the following:

- Data types

C and C++ use static typing. To determine the types of your variables before use, MATLAB Coder requires a complete assignment to each variable.

- Array sizing

Variable-size arrays and matrices are supported for code generation. You can define inputs, outputs, and local variables in MATLAB functions to represent data that varies in size at run time.

- Memory

You can choose whether the generated code uses static or dynamic memory allocation.

With dynamic memory allocation, you potentially use less memory at the expense of time to manage the memory. With static memory, you get better speed, but with higher memory usage. Most MATLAB code takes advantage of the dynamic sizing features in MATLAB, therefore dynamic memory allocation typically enables you to generate code from existing MATLAB code without modifying it much. Dynamic memory allocation also allows some programs to compile even when upper bounds cannot be found.

Static allocation reduces the memory footprint of the generated code, and therefore is suitable for applications where there is a limited amount of available memory, such as embedded applications.

- Speed

Because embedded applications must run in real time, the code must be fast enough to meet the required clock rate.

To improve the speed of the generated code:

- Choose a suitable C/C++ compiler. Do not use the default compiler that MathWorks supplies with MATLAB for Windows 64-bit platforms.
- Consider disabling run-time checks.

By default, for safety, the code generated for your MATLAB code contains memory integrity checks and responsiveness checks. Generally, these checks result in more generated code and slower simulation. Disabling run-time checks usually results in streamlined generated code and faster simulation. Disable these checks only if you have verified that array bounds and dimension checking is unnecessary.

## Differences Between Generated Code and MATLAB Code

To convert MATLAB code to efficient C/C++ code, the code generator introduces optimizations that intentionally cause the generated code to behave differently, and sometimes produce different results, than the original source code.

Here are some of the differences:

- “Functions that have Multiple Possible Outputs” on page 53-7
- “Passing Input Argument Name at Run Time” (MATLAB Coder)
- “Empty Repeating Input Argument” (MATLAB Coder)
- “Output Argument Validation of Conditionally-Assigned Outputs” (MATLAB Coder)

- “Complex Numbers” on page 53-21
- “Converting Strings with Consecutive Unary Operators to double” on page 53-21
- “Display Function” (MATLAB Coder)

These differences are applicable for:

- MEX and standalone C/C++ code generation by using the `codegen` command or the MATLAB Coder app.

- Fixed-point code acceleration by generating MEX using the `fiaccl` command.
- MATLAB Function block simulation using Simulink.

When you run your generated `fiaccl` MEX, C/C++ MEX or standalone C/C++ code, run-time error checks can detect some of these differences. By default, run-time error checks are enabled for MEX code and disabled for standalone C/C++ code. To help you identify and address differences before you deploy code, the code generator reports a subset of the differences as potential differences (MATLAB Coder).

## Functions that have Multiple Possible Outputs

Certain mathematical operations, such as singular value decomposition and eigenvalue decomposition of a matrix, can have multiple answers. Two different algorithms implementing such an operation can return different outputs for identical input values. Two different implementations of the same algorithm can also exhibit the same behavior.

For such mathematical operations, the corresponding functions in the generated code and MATLAB might return different outputs for identical input values. To see if a function has this behavior, in the corresponding function reference page, see the **C/C++ Code Generation** section under **Extended Capabilities**. Examples of such functions include `svd` and `eig`.

## Passing Input Argument Name at Run Time

Suppose that `foo` is a function that uses name-value argument validation. When you call `foo` from another function `bar`, the code generator must be able to determine the names that you provide to `foo` at compile time.

If the argument names are passed at run time, code generation fails in most situations. See “Names Must Be Compile-Time Constants” (MATLAB Coder).

In certain situations, the code generator assigns the name that you passed to an optional positional or repeating input argument. In such situations, code generation succeeds with a warning and the generated code might produce results that are different from MATLAB execution. For example, consider this function:

```
function out = myNamedArg_warns(a,b)
out = local(a,b);
end

function out = local(varargin,args)
arguments (Repeating)
    varargin
end

arguments
    args.x
    args.y
end

if isfield(args,'x') && isfield(args,'y')
    out = args.x / args.y;
elseif isfield(args,'x')
    out = args.x;
```

```
else
    out = varargin{1};
end
end
```

### Behavior of MATLAB Execution

If you call `myNamedArg_warns` with `'x'` as the first input argument, MATLAB matches it against the first name-value argument of the function `local`.

```
myNamedArg_warns('x',5)
```

```
ans =
     5
```

By contrast, if you call `myNamedArg_warns` with `'z'` as the first input argument (that does not match with either name-value argument of `local`), MATLAB assigns the inputs into elements of `varargin`.

```
myNamedArg_warns('z',5)
```

```
ans =
    'z'
```

### Behavior of Generated Code

Attempt to generate a MEX by running the `codegen` command. Specify the type of the first argument to be a character scalar and the second argument to be a double scalar. Code generation succeeds with a warning.

```
codegen myNamedArg_warns -args {'x',2}
```

```
Warning: This argument is not constant, and therefore does not match against a name-value argument during code generation. Code generation might fail or produce results that do not agree with MATLAB. This warning is not known during code generation.
```

```
Warning in ==> myNamedArg_warns Line: 2 Column: 13
Code generation successful (with warnings): View report
```

Irrespective of whether you pass `'x'` or `'z'` as the first input argument, the generated MEX assigns it to the first cell of `varargin`.

```
myNamedArg_warns_mex('x',5)
```

```
ans =
    'x'
```

```
myNamedArg_warns_mex('z',5)
```

```
ans =
    'z'
```

### Workaround

To enable the code generator to match the first input against the name-value arguments of the function `local`, declare the first input to be a compile-time constant with value `'x'`. You can do this by using the `coder.Constant` function with the `-args` option of the `codegen` command.

```
codegen myNamedArg_warns -args {coder.Constant('x'),2}
```

```
Code generation successful.
```

Now, the behavior of the generated MEX agrees with MATLAB, although the MEX is unable to accept any value other than `'x'` for the first input.

```
myNamedArg_warns_mex('x',5)
```

```
ans =
```

```
5
```

```
myNamedArg_warns_mex('z',5)
```

```
Constant function parameter 'a' has a different run-time value than the compile-time value.
```

```
Error in myNamedArg_warns_mex
```

### Empty Repeating Input Argument

In code generation, if a repeating input argument (that is declared in an `arguments` block) is empty at run time, the size of that argument is  $0 \times 0$ . By contrast, in MATLAB execution, the size of an empty repeating input argument is  $1 \times 0$ .

For example, consider this function:

```
function out = testVararginSize
out = local;
end
```

```
function out = local(varargin)
arguments (Repeating)
    varargin
end
out = size(varargin);
end
```

Running `testVararginSize` in MATLAB returns  $[1 \ 0]$ . If you generate a MEX for `testVararginSize` and run the generated MEX, you get  $[0 \ 0]$ . However, iterating over elements of `varargin` by using `length(varargin)` or `numel(varargin)` produces the same behavior across MATLAB and code generation.

### Output Argument Validation of Conditionally-Assigned Outputs

The code generator validates an output argument if the argument is assigned a type during code generation. By contrast, MATLAB execution validates an output argument if the argument is assigned a value when the MATLAB function returns.

In most situations, this underlying behavioral difference does not cause your generated code to behave differently than MATLAB. Here is an example function for which you do see this difference:

```
function outerFunc(in)
innerFunc(in);
end

function out = innerFunc(inputVal)
arguments (Output)
    out {mustBePositive}
end
if inputVal
    out = inputVal;
end
end
```

In MATLAB, the execution of `func` succeeds for all double inputs. If the input is positive, `out` is assigned this positive value and the validator `mustBePositive` runs without assertion. If the input is negative or zero, `out` is not assigned and is not validated.

Attempt to generate code for `func`. Specify the input type to be a double scalar.

```
codegen outerFunc -args 0
```

```
Variable 'out' is not fully defined on some execution paths.
```

```
Error in ==> outerFunc Line: 7 Column: 5
Code generation failed: View Error Report
```

Because the variable `out` is assigned a double scalar value on one execution path, code generation assigns a double scalar type to `out` at compile time. The code generator then attempts to perform validation on `out` and discovers that it is not fully defined if the `if` condition fails.

## Writing to ans Variable

When you run MATLAB code that returns an output without specifying an output argument, MATLAB implicitly writes the output to the `ans` variable. If the variable `ans` already exists in the workspace, MATLAB updates its value to the output returned.

The code generated from such MATLAB code does not implicitly write the output to an `ans` variable.

For example, define the MATLAB function `foo` that explicitly creates an `ans` variable in the first line. The function then implicitly updates the value of `ans` when the second line executes.

```
function foo %#codegen
ans = 1;
2;
disp(ans);
end
```

Run `foo` at the command line. The final value of `ans`, which is 2, is displayed at the command line.

```
foo
```

```
2
```

Generate a MEX function from `foo`.

```
codegen foo
```

Run the generated MEX function `foo_mex`. This function explicitly creates the `ans` variable and assigns the value 1 to it. But `foo_mex` does not implicitly update the value of `ans` to 2.

```
foo_mex
```

```
1
```

## Logical Short-Circuiting

Suppose that your MATLAB code has the logical operators `&` and `|` placed inside square brackets (`[ ]`). For such code patterns, the generated code does not employ short-circuiting behavior for these logical operators, but some MATLAB execution employs short-circuiting behavior. See “Tips” and “Tips”.

For example, define the MATLAB function `foo` that uses the `&` operator inside square brackets in the conditional expression of an `if . . . end` block.

```
function foo
if [returnsFalse() & hasSideEffects()]
end
end
```

```
function out = returnsFalse
out = false;
end
```

```
function out = hasSideEffects
out = true;
disp('This is my string');
end
```

The first argument of the `&` operator is always `false` and determines the value of the conditional expression. So, in MATLAB execution, short-circuiting is employed and the second argument is not evaluated. So, `foo` does not call the `hasSideEffects` function during execution and does not display anything at the command line.

Generate a MEX function for `foo`. Call the generated MEX function `foo_mex`.

```
foo_mex
```

```
This is my string
```

In the generated code, short-circuiting is not employed. So, the `hasSideEffects` function is called and the string is displayed at the command line.

## Loop Index Overflow

Suppose that a `for`-loop end value is equal to or close to the maximum or minimum value for the loop index data type. In the generated code, the last increment or decrement of the loop index might cause the index variable to overflow. The index overflow might result in an infinite loop.

When memory integrity checks are enabled, if the code generator detects that the loop index might overflow, it reports an error. The software error checking is conservative. It might incorrectly report a loop index overflow. By default, memory-integrity checks are enabled for MEX code and disabled for

standalone C/C++ code. See “Why Test MEX Functions in MATLAB?” (MATLAB Coder) and “Generate Standalone C/C++ Code That Detects and Reports Run-Time Errors” (MATLAB Coder).

To avoid a loop index overflow, use the workarounds in this table.

Loop Conditions Causing the Potential Overflow	Workaround
<ul style="list-style-type: none"> <li>The loop index increments by 1.</li> <li>The end value equals the maximum value of the integer type.</li> </ul>	<p>If the loop does not have to cover the full range of the integer type, rewrite the loop so that the end value is not equal to the maximum value of the integer type. For example, replace:</p> <pre>N=intmax('int16') for k=N-10:N</pre> <p>with:</p> <pre>for k=1:10</pre>
<ul style="list-style-type: none"> <li>The loop index decrements by 1.</li> <li>The end value equals the minimum value of the integer type.</li> </ul>	<p>If the loop does not have to cover the full range of the integer type, rewrite the loop so that the end value is not equal to the minimum value of the integer type. For example, replace:</p> <pre>N=intmin('int32') for k=N+10:-1:N</pre> <p>with:</p> <pre>for k=10:-1:1</pre>
<ul style="list-style-type: none"> <li>The loop index increments or decrements by 1.</li> <li>The start value equals the minimum or maximum value of the integer type.</li> <li>The end value equals the maximum or minimum value of the integer type.</li> </ul>	<p>If the loop must cover the full range of the integer type, cast the type of the loop start, step, and end values to a bigger integer or to double. For example, rewrite:</p> <pre>M= intmin('int16'); N= intmax('int16'); for k=M:N     % Loop body end</pre> <p>as:</p> <pre>M= intmin('int16'); N= intmax('int16'); for k=int32(M):int32(N)     % Loop body end</pre>
<ul style="list-style-type: none"> <li>The loop index increments or decrements by a value not equal to 1.</li> <li>On the last loop iteration, the loop index is not equal to the end value.</li> </ul>	<p>Rewrite the loop so that the loop index in the last loop iteration is equal to the end value.</p>

## Indexing for Loops by Using Single Precision Operands

Suppose in your MATLAB code, you are indexing a `for` loop that has a colon operator, where at least one of the colon operands is a single type operand and the number of iterations is greater than `flintmax('single') = 16777216`. When all these conditions are true, code generation might generate run-time or compile-time errors because the generated code calculates different values for the loop index variable than the values that MATLAB calculates.

For example, consider this MATLAB code:

```
function j = singlePIndex
n = flintmax('single') + 2;
j = single(0);
for i = single(1):single(n)
    j = i;
end
end
```

This code snippet executes in MATLAB, but it causes a compile-time or run-time error because the value of the loop index variable, `i`, is calculated differently in the generated code. The code generator displays a compile-time or run-time error and stops code generation or execution to prevent this discrepancy.

To avoid this discrepancy, replace the single type operands with double type or integer type operands.

For more information on run-time errors, see “Generate Standalone C/C++ Code That Detects and Reports Run-Time Errors” (MATLAB Coder).

## Index of an Unentered for Loop

In your MATLAB code and generated code, after a `for` loop execution is complete, the value of the index variable is equal to its value during the final iteration of the `for` loop.

In MATLAB, if the loop does not execute, the value of the index variable is stored as `[]` (empty matrix). In generated code, if the loop does not execute, the value of the index variable is different than the MATLAB index variable.

- If you provide the `for` loop start and end variables at run time, the value of the index variable is equal to the start of the range. For example, consider this MATLAB code:

```
function out = indexTest(a,b)
for i = a:b
end
out = i;
end
```

Suppose that `a` and `b` are passed as `1` and `-1`. The `for` loop does not execute. In MATLAB, `out` is assigned `[]`. In the generated code, `out` is assigned the value of `a`, which is `1`.

- If you provide the `for` loop start and end values before compile time, the value of the index variable is assigned `[]` in both MATLAB and the generated code. Consider this MATLAB code:

```
function out = indexTest
for i = 1:-1
end
out = i;
end
```

In both MATLAB and the generated code, `out` is assigned `[]`.

## Character Size

MATLAB supports 16-bit characters, but the generated code represents characters in 8 bits, the standard size for most embedded languages like C. See “Encoding of Characters in Code Generation” on page 57-12.

## Order of Evaluation in Expressions

Generated code does not enforce the order of evaluation in expressions. For most expressions, the order of evaluation is not significant. For expressions that have side effects, the generated code might produce the side effects in a different order from the original MATLAB code. Expressions that produce side effects include those that:

- Modify persistent or global variables
- Display data to the screen
- Write data to files
- Modify the properties of handle class objects

In addition, the generated code does not enforce order of evaluation of logical operators that do not short circuit.

For more predictable results, it is good coding practice to split expressions that depend on the order of evaluation into multiple statements.

- Rewrite

```
A = f1() + f2();
```

as

```
A = f1();  
A = A + f2();
```

so that the generated code calls `f1` before `f2`.

- Assign the outputs of a multi-output function call to variables that do not depend on one another. For example, rewrite

```
[y, y.f, y.g] = foo;
```

as

```
[y, a, b] = foo;  
y.f = a;  
y.g = b;
```

- When you access the contents of multiple cells of a cell array, assign the results to variables that do not depend on one another. For example, rewrite

```
[y, y.f, y.g] = z{:};
```

as

```
[y, a, b] = z{:};
y.f = a;
y.g = b;
```

## Name Resolution While Constructing Function Handles

MATLAB and code generation follow different precedence rules for resolving names that follow the symbol @. These rules do not apply to anonymous functions. The precedence rules are summarized in this table.

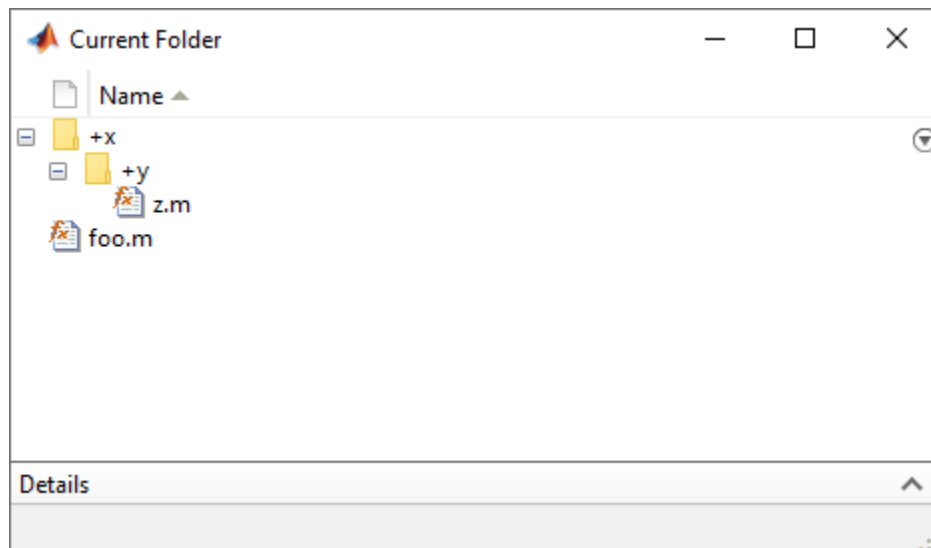

Expression	Precedence Order in MATLAB	Precedence Order in Code Generation
An expression that does not contain periods, for example @x	Nested function, local function, private function, path function	Local variable, nested function, local function, private function, path function
An expression that contains exactly one period, for example @x.y	Local variable, path function	Local variable, path function (Same as MATLAB)
An expression that contains more than one period, for example @x.y.z	Path function	Local variable, path function

If `x` is a local variable that is itself a function handle, generated code and MATLAB interpret the expression `@x` differently:

- MATLAB produces an error.
- Generated code interprets `@x` as the function handle of `x` itself.

Here is an example that shows this difference in behavior for an expression that contains two periods.

Suppose that your current working folder contains a package `x`, which contains another package `y`, which contains the function `z`. The current working folder also contains the entry-point function `foo` for which you want to generate code.

This is the definition for the file `foo`:

```
function out = foo
    x.y.z = @() 'x.y.z is an anonymous function';
    out = g(x);
end

function out = g(x)
    f = @x.y.z;
    out = f();
end
```

This is the definition for function `z`:

```
function out = z
    out = 'x.y.z is a package function';
end
```

Generate a MEX function for `foo`. Separately call both the generated MEX function `foo_mex` and the MATLAB function `foo`.

```
codegen foo
foo_mex
foo

ans =

    'x.y.z is an anonymous function'

ans =

    'x.y.z is a package function'
```

The generated code produces the first output. MATLAB produces the second output. Code generation resolves `@x.y.z` to the local variable `x` that is defined in `foo`. MATLAB resolves `@x.y.z` to `z`, which is within the package `x.y`.

## Termination Behavior

Generated code does not match the termination behavior of MATLAB source code. For example, if infinite loops do not have side effects, optimizations remove them from generated code. As a result, the generated code can possibly terminate even though the corresponding MATLAB code does not.

## Size of Variable-Size N-D Arrays

For variable-size N-D arrays, the `size` function might return a different result in generated code than in MATLAB source code. The `size` function sometimes returns trailing ones (singleton dimensions) in generated code, but always drops trailing ones in MATLAB. For example, for an N-D array `X` with dimensions `[4 2 1 1]`, `size(X)` might return `[4 2 1 1]` in generated code, but always returns `[4 2]` in MATLAB. See “Incompatibility with MATLAB in Determining Size of Variable-Size N-D Arrays” on page 58-18.

## Size of Empty Arrays

The size of an empty array in generated code might be different from its size in MATLAB source code. See “Incompatibility with MATLAB in Determining Size of Empty Arrays” on page 58-18.

## Size of Empty Array That Results from Deleting Elements of an Array

Deleting all elements of an array results in an empty array. The size of this empty array in generated code might differ from its size in MATLAB source code.

Case	Example Code	Size of Empty Array in MATLAB	Size of Empty Array in Generated Code
Delete all elements of an m-by-n array by using the colon operator (:).	<pre>coder.varsize('X',[4,4],[1,1]); X = zeros(2); X(:) = [];</pre>	0-by-0	1-by-0
Delete all elements of a row vector by using the colon operator (:).	<pre>coder.varsize('X',[1,4],[0,1]); X = zeros(1,4); X(:) = [];</pre>	0-by-0	1-by-0
Delete all elements of a column vector by using the colon operator (:).	<pre>coder.varsize('X',[4,1],[1,0]); X = zeros(4,1); X(:) = [];</pre>	0-by-0	0-by-1
Delete all elements of a column vector by deleting one element at a time.	<pre>coder.varsize('X',[4,1],[1,0]); X = zeros(4,1); for i = 1:4     X(i) = []; end</pre>	1-by-0	0-by-1

## Growing Variable-Size Column Cell Array That is Initialized as Scalar at Run Time

In MATLAB execution, if you grow a scalar cell array by using `{end+1}` indexing, the cell array grows along the second dimension and produces a row cell array. For example, define the function `growCell`:

```
function z = growCell(n, m)
for i = 1:m
    n{end+1} = m;
end
z = n;
end
```

Call `growCell` with example inputs:

```
growCell({2}, 3)
```

```
ans =
```

```
1×4 cell array
```

```
{[2]}    {[3]}    {[3]}    {[3]}
```

By contrast, in code generation, suppose that:

- You specify the cell array to be of variable-size column type (for example, `:Inf x 1`) at compile time, *and*
- Initialize this cell array as a scalar at run time.

In such situations, the generated code grows the scalar cell array along the first dimension and produces a column cell array. For example, generate MEX code for `growCell`. Specify the input `n` to be a `:Inf x 1` cell array with double as the underlying type. Specify the input `m` to be of double scalar type.

```
codegen growCell -args {coder.typeof({0}, [Inf 1], [1 0]), 1}
```

Code generation successful.

Run the generated MEX with the same inputs as before.

```
growCell_mex({2}, 3)
```

```
ans =
```

```
4x1 cell array
```

```
{[2]}
{[3]}
{[3]}
{[3]}
```

## Binary Element-Wise Operations with Single and Double Operands

If your MATLAB code contains a binary element-wise operation that involves a single type operand and a double type operand, the generated code might not produce the same result as MATLAB.

For such an operation, MATLAB casts both operands to double type and performs the operation with the double types. MATLAB then casts the result to single type and returns it.

The generated code casts the double type operand to single type. It then performs the operation with the two single types and returns the result.

For example, define a MATLAB function `foo` that calls the binary element-wise operation `plus`.

```
function out = foo(a,b)
out = a + b;
end
```

Define a variable `s1` of single type and a variable `v1` of double type. Generate a MEX function for `foo` that accepts a single type input and a double type input.

```
s1 = single(1.4e32);
d1 = -5.305e+32;
codegen foo -args {s1, d1}
```

Call both `foo` and `foo_mex` with inputs `s1` and `d1`. Compare the two results.

```
m1 = foo(s1,d1);
m1c = foo_mex(s1,d1);
m1 == m1c
```

```
ans =
    logical
     0
```

The output of the comparison is a logical 0, which indicates that the generated code and MATLAB produces different results for these inputs.

## Floating-Point Numerical Results

The generated code might not produce the same floating-point numerical results as MATLAB in these:

### When computer hardware uses extended precision registers

Results vary depending on how the C/C++ compiler allocates extended precision floating-point registers. Computation results might not match MATLAB calculations because of different compiler optimization settings or different code surrounding the floating-point calculations.

### For certain advanced library functions

The generated code might use different algorithms to implement certain advanced library functions, such as `fft`, `svd`, `eig`, `mldivide`, and `mrdivide`.

For example, the generated code uses a simpler algorithm to implement `svd` to accommodate a smaller footprint. Results might also vary according to matrix properties. For example, MATLAB might detect symmetric or Hermitian matrices at run time and switch to specialized algorithms that perform computations faster than implementations in the generated code.

### For implementation of BLAS library functions

For implementations of BLAS library functions, generated C/C++ code uses reference implementations of BLAS functions. These reference implementations might produce different results from platform-specific BLAS implementations in MATLAB.

## NaN and Infinity

The generated code might not produce exactly the same pattern of NaN and Inf values as MATLAB code when these values are mathematically meaningless. For example, if MATLAB output contains a NaN, output from the generated code should also contain a NaN, but not necessarily in the same place.

The bit pattern for NaN can differ between MATLAB code output and generated code output because the C99 language standard that is used to generate code does not specify a unique bit pattern for NaN across all implementations. Avoid comparing bit patterns across different implementations, for example, between MATLAB output and SIL or PIL output.

## Negative Zero

In a floating-point type, the value 0 has either a positive sign or a negative sign. Arithmetically, 0 is equal to -0, but some operations are sensitive to the sign of a 0 input. Examples include `rdivide`, `atan2`, `atan2d`, and `angle`. Division by 0 produces Inf, but division by -0 produces -Inf. Similarly, `atan2d(0, -1)` produces 180, but `atan2d(-0, -1)` produces -180.

If the code generator detects that a floating-point variable takes only integer values of a suitable range, then the code generator can use an integer type for the variable in the generated code. If the code generator uses an integer type for the variable, then the variable stores  $-0$  as  $+0$  because an integer type does not store a sign for the value  $0$ . If the generated code casts the variable back to a floating-point type, the sign of  $0$  is positive. Division by  $0$  produces  $\text{Inf}$ , not  $-\text{Inf}$ . Similarly, `atan2d(0, -1)` produces  $180$ , not  $-180$ .

There are other contexts in which the generated code might treat  $-0$  differently than MATLAB. For example, suppose that your MATLAB code computes the minimum of two scalar doubles  $x$  and  $y$  by using `z = min(x, y)`. The corresponding line in the generated C code might be `z = fmin(x, y)`. The function `fmin` is defined in the runtime math library of the C compiler. Because the comparison operation `0.0 == -0.0` returns `true` in C/C++, the compiler's implementation of `fmin` might return either `0.0` or `-0.0` for `fmin(0.0, -0.0)`.

## Code Generation Target

The `coder.target` function returns different values in MATLAB than in the generated code. The intent is to help you determine whether your function is executing in MATLAB or has been compiled for a simulation or code generation target. See `coder.target`.

## MATLAB Class Property Initialization

Before code generation, at class loading time, MATLAB computes class default values. The code generator uses the values that MATLAB computes. It does not recompute default values. If the property definition uses a function call to compute the initial value, the code generator does not execute this function. If the function has side effects such as modifying a global variable or a persistent variable, then it is possible that the generated code might produce different results than MATLAB. For more information, see “Defining Class Properties for Code Generation” on page 66-3.

## MATLAB Classes in Nested Property Assignments That Have Set Methods

When you assign a value to a handle object property, which is itself a property of another object, and so on, then the generated code can call set methods for handle classes that MATLAB does not call.

For example, suppose that you define a set of variables such that  $x$  is a handle object,  $pa$  is an object,  $pb$  is a handle object, and  $pc$  is a property of  $pb$ . Then you make a nested property assignment, such as:

```
x.pa.pb.pc = 0;
```

In this case, the generated code calls the set method for the object  $pb$  and the set method for  $x$ . MATLAB calls only the set method for  $pb$ .

## MATLAB Handle Class Destructors

The behavior of handle class destructors in the generated code can be different from the behavior in MATLAB in these situations:

- The order of destruction of several independent objects might be different in MATLAB than in the generated code.

- The lifetime of objects in the generated code can be different from their lifetime in MATLAB.
- The generated code does not destroy partially constructed objects. If a handle object is not fully constructed at run time, the generated code produces an error message but does not call the `delete` method for that object. For a System object, if there is a run-time error in `setupImpl`, the generated code does not call `releaseImpl` for that object.

MATLAB does call the `delete` method to destroy a partially constructed object.

For more information, see “Code Generation for Handle Class Destructors” on page 66-15.

## Variable-Size Data

See “Incompatibilities with MATLAB in Variable-Size Support for Code Generation” on page 58-17.

## Complex Numbers

See “Code Generation for Complex Data” on page 57-8.

## Converting Strings with Consecutive Unary Operators to double

Converting a string that contains multiple, consecutive unary operators to `double` can produce different results between MATLAB and the generated code. Consider this function:

```
function out = foo(op)
out = double(op + 1);
end
```

For an input value `--`, the function converts the string `--1` to `double`. In MATLAB, the answer is `NaN`. In the generated code, the answer is `1`.

## Display Function

Statements and expressions in MATLAB code that omit the semicolon implicitly invoke the `display` function. You can also explicitly invoke `display` as shown here:

```
display(2+3);

5
```

The MEX code generated for MATLAB code that invokes the `display` function preserves calls to this function and shows the output. In standalone code generated for targets that do not have access to MATLAB Runtime, implicit and explicit calls to `display` are removed. This includes calls to overridden class methods of `display`.

To display text in code generated for other targets, override the `disp` function in your MATLAB classes. For example:

```
%MATLAB Class

classdef foo
    methods
        function obj = foo
    end
```

```
        function disp(self)
            disp("Overridden disp");
        end
    end
end
```

**%Entry-point Function**

```
function callDisp
a = foo;
disp(a);
end
```

The generated code for the entry-point function is shown here:

```
/* Include Files */
#include "callDisp.h"
#include <stdio.h>

/* Function Definitions */
/*
 * Arguments      : void
 * Return Type    : void
 */
void callDisp(void)
{
    printf("%s\n", "Overridden disp");
    fflush(stdout);
}
```

### Function Handle Difference

Invoking `display` through a function handle in MATLAB prints the name of the variable as well. For example, running this function in MATLAB results in the following output:

```
function displayDiff
z = 10;
f = @display;
f(z)
end
```

```
z =

    10
```

However, the generated code for this snippet only outputs the value 10.

# MATLAB Language Features Supported for C/C++ Code Generation

## MATLAB Features That Code Generation Supports

Code generation from MATLAB code supports many major language features including:

- n-dimensional arrays (see “Array Size Restrictions for Code Generation” on page 57-13)
- matrix operations, including deletion of rows and columns
- variable-size data (see “Code Generation for Variable-Size Arrays” on page 58-2)
- subscripting (see “Incompatibility with MATLAB in Matrix Indexing Operations for Code Generation” on page 58-21)
- complex numbers (see “Code Generation for Complex Data” on page 57-8)
- numeric classes (see “Supported Variable Types” on page 56-13)
- double-precision, single-precision, and integer math
- enumerations (see “Code Generation for Enumerations” on page 49-87)
- fixed-point arithmetic
- program control statements `if`, `switch`, `for`, `while`, and `break`
- arithmetic, relational, and logical operators
- local functions
- persistent variables
- global variables
- structures (see “Structure Definition for Code Generation” on page 59-2)
- cell arrays (see “Cell Arrays”)
- tables (see “Code Generation for Tables” on page 64-2)
- timetables (see “Code Generation for Timetables” on page 65-2)
- characters (see “Encoding of Characters in Code Generation” on page 57-12)
- string scalars (see “Code Generation for Strings” on page 57-16)
- categorical arrays (see “Code Generation for Categorical Arrays” on page 61-2)
- `datetime` arrays (see “Code Generation for Datetime Arrays” on page 62-2)
- `duration` arrays (see “Code Generation for Duration Arrays” on page 63-2)
- sparse matrices (see “Code Generation for Sparse Matrices” on page 57-17)
- function handles (see “Function Handle Limitations for Code Generation” on page 67-2)
- anonymous functions (see “Code Generation for Anonymous Functions” on page 68-6)
- recursive functions (see “Code Generation for Recursive Functions” on page 69-12)
- nested functions (see “Code Generation for Nested Functions” on page 68-7)
- variable length input and output argument lists (see “Code Generation for Variable Length Argument Lists” on page 68-2)
- function argument validation (see “Generate Code for arguments Block That Validates Input and Output Arguments” on page 68-3)

- subset of MATLAB toolbox functions (see “Functions and Objects Supported for C/C++ Code Generation” on page 54-2)
- subset of functions and System objects in several toolboxes (see “Functions and Objects Supported for C/C++ Code Generation” on page 54-2)
- function calls (see “Resolution of Function Calls for Code Generation” on page 69-2)
- class aliasing
- MATLAB classes (see “MATLAB Classes Definition for Code Generation” on page 66-2)

## **MATLAB Language Features That Code Generation Does Not Support**

Code generation from MATLAB does not support the following frequently used MATLAB features (this list is not exhaustive):

- scripts
- GPU arrays

MATLAB Coder does not support GPU arrays. However, if you have GPU Coder™, you can generate CUDA® MEX code that takes GPU array inputs.

- `calendarDuration` arrays
- Java
- Map containers
- time series objects
- tall arrays
- `try/catch` statements
- `import` statements
- pattern arrays

# Functions, Classes, and System Objects Supported for Code Generation

---

## Functions and Objects Supported for C/C++ Code Generation

You can generate efficient C/C++ code for a subset of MATLAB built-in functions and toolbox functions and System objects that you call from MATLAB code.

These functions and System objects are listed in the following tables. In these tables, a  icon before the name of a function or a System object indicates that there are specific usage notes and limitations related to C/C++ code generation for that function or System object. To view these usage notes and limitations, in the corresponding reference page, scroll down to the **Extended Capabilities** section at the bottom and expand the **C/C++ Code Generation** section.

- Functions and Objects Supported for C/C++ Code Generation (Category List)
- Functions and Objects Supported for C/C++ Code Generation (Alphabetical List)

# System Objects Supported for Code Generation

---

## Code Generation for System Objects

You can generate C and C++ code for a subset of System objects provided by the following toolboxes.

Toolbox Name	See
Communications Toolbox™	“System Objects in MATLAB Code Generation” (MATLAB Coder)
Computer Vision Toolbox	“System Objects in MATLAB Code Generation” (MATLAB Coder)
DSP System Toolbox	“System Objects in MATLAB Code Generation” (MATLAB Coder)
Image Acquisition Toolbox™	<ul style="list-style-type: none"> <li>• <code>imaq.VideoDevice</code></li> <li>• “Code Generation with VideoDevice System Object” (Image Acquisition Toolbox)</li> </ul>
Phased Array System Toolbox™	“Code Generation” (Phased Array System Toolbox)
System Identification Toolbox	“Generate Code for Online Parameter Estimation in MATLAB” (System Identification Toolbox)
WLAN Toolbox™	“System Objects in MATLAB Code Generation” (MATLAB Coder)

To use these System objects, you need to install the requisite toolbox. For a list of System objects supported for C and C++ code generation, see “Functions and Objects Supported for C/C++ Code Generation” on page 54-2.

System objects are MATLAB object-oriented implementations of algorithms. They extend MATLAB by enabling you to model dynamic systems represented by time-varying algorithms. System objects are well integrated into the MATLAB language, regardless of whether you are writing simple functions, working interactively in the command window, or creating large applications.

In contrast to MATLAB functions, System objects automatically manage state information, data indexing, and buffering, which is particularly useful for iterative computations or stream data processing. This enables efficient processing of long data sets. For general information about MATLAB objects, see “Classes”.

# Defining MATLAB Variables for C/C++ Code Generation

---

- “Supported Variable Types” on page 56-13
- “Edit and Represent Coder Type Objects and Properties” on page 56-14

## Variables Definition for Code Generation

In MATLAB, variables can change their properties dynamically at run time so you can use the same variable to hold a value of any class, size, or complexity. For example, the following code works in MATLAB:

```
function x = foo(c) %#codegen
if(c>0)
    x = 0;
else
    x = [1 2 3];
end
disp(x);
end
```

However, statically-typed languages like C must be able to determine variable properties at compile time. Therefore, for C/C++ code generation, you must explicitly define the class, size, and complexity of variables in MATLAB source code before using them. For example, rewrite the above source code with a definition for `x`:

```
function x = foo(c) %#codegen
x = zeros(1,3);
if(c>0)
    x = 0;
else
    x = [1 2 3];
end
disp(x);
end
```

## Best Practices for Defining Variables for C/C++ Code Generation

### In this section...

“Explicitly Define Variables Before Using Them” on page 56-3

“Use Caution When Reassigning Variable Properties” on page 56-4

“Define Variable Numeric Data Types” on page 56-4

“Define Matrices Before Assigning Indexed Variables” on page 56-5

“Index Arrays by Using Constant Value Vectors” on page 56-5

If you want to generate code from a MATLAB Function block, you must ensure the MATLAB code in the block complies with the C/C++ code generation requirements. Some coding practices that work in MATLAB code do not work when generating code. Follow these best practices to optimize your code and avoid simulation errors.

### Explicitly Define Variables Before Using Them

For C/C++ code generation, you must explicitly define variable values and properties before using them in operations or returning them as outputs. Doing this prevents errors that occur when the variable is not defined.

---

**Note** When you define variables, they are local by default and do not persist between function calls. To make variables persistent, use the `persistent` function.

---

### Define Variables on All Execution Paths

You must define a variable on all execution paths, such as execution paths dictated by `if` statements. Consider this MATLAB code that defines a variable before using it as an input to a function:

```
...
if c <= 0
    x = 11;
end
% Later in your code ...
if c > 0
% Use x in the function, foo
    foo(x);
end
...
```

The code assigns `x` to a value only if `c <= 0` and uses `x` only when `c > 0`. Depending on the value for `c`, this code can work in MATLAB without errors. However, the MATLAB code generates a compilation error when you generate C/C++ code from it because the code generator detects that `x` is undefined on the execution path when `c > 0`.

To make this code suitable for code generation, define `x` before using it:

```
x = 0;
...
if c <= 0
```

```

    x = 11;
end
% Later in your code ...
if c > 0
% Use x in the function, foo
    foo(x);
end
...

```

### Define Fields in a Structure

You must also define each structure field for all execution paths. Consider this MATLAB code:

```

...
if c > 0
    s.a = 11;
    disp(s);
else
    s.a = 12;
    s.b = 12;
end
% Use s in the function, foo
foo(s);
...

```

The first part of the `if` statement uses only the field `a`, and the `else` statement uses fields `a` and `b`. This code works in MATLAB, but generates a compilation error during C/C++ code generation. To prevent this error, do not add fields to a structure after you use the structure. For more information, see “Structure Definition for Code Generation” on page 59-2.

To make this code suitable for C/C++ code generation, define the fields of `s` before using them.

```

...
% Define fields in structure s
s = struct('a',0, 'b', 0);
if c > 0
    s.a = 11;
    disp(s);
else
    s.a = 12;
    s.b = 12;
end
% Use s in the function, foo
foo(s);
...

```

### Use Caution When Reassigning Variable Properties

You can reassign certain variables after the initial assignment with a value of different class, size, or complexity, as described in “Reassignment of Variable Properties” on page 56-9. However, if you reassign the variable type after the initial assignment, the code often returns a compilation error during code generation. In general, assign each variable a specific class, size, type, and complexity.

### Define Variable Numeric Data Types

`double` is the default numeric data type in MATLAB. To define variables of other data types, you must explicitly define the data type in the definition with the correct prefix or operator. Be mindful of

the data types you use, because using variables assigned to different data types in your code can cause type mismatch errors.

For example, this code defines the variable `x` as a double and `y` as an 8-bit integer:

```
x = 15;
y = uint8(x);
```

For more information on supported types in MATLAB, see “Numeric Types”.

## Define Matrices Before Assigning Indexed Variables

Growing a variable by writing an element beyond its current size results in a compile-time or run-time error. You must define the array before assigning values to its elements.

The only situation in which code generation supports growing arrays via indexing is when you use `end + 1`. See “Generate Code for Growing Arrays and Cell Arrays with `end + 1` Indexing” (MATLAB Coder).

For example, this assignment results in an error:

```
g(3,2) = 14.6;
```

Correct this code by defining the matrix with a specific size first.

```
g = zeros(5,5);
g(3,2) = 14.6;
```

For more information about indexing matrices, see “Incompatibility with MATLAB in Matrix Indexing Operations for Code Generation” on page 58-21.

You can grow the size of variables if you define the variable as variable size first. You can also specify output variables as variable size in the **Symbols** pane and Property Inspector. See “Define Variable-Size Data for Code Generation” on page 58-9 and “Declare Variable-Size MATLAB Function Block Variables” on page 49-76.

## Index Arrays by Using Constant Value Vectors

Although code generation can support variable size arrays, variable size arrays requires additional memory, which can slow performance. When possible, use constant value vectors as you index arrays.

If you need to index through an array, be careful when using the colon operator. In some cases the code generator does not correctly determine whether an array indexed with the colon operator is fixed size or variable size. As a result, you may define an array that does not change size, and should therefore be fixed-sized, but the code generator specifies the array as variable-sized.

For example, this code creates the array `out` by using the variable `i` indexed through the random row vector `A`:

```
...
% extract elements -1+2*i through 5+2*i for processing
A = rand(1,10);
out = A(-1+2*i:5+2*i);
```

In this example, `A` is always the same size. If `i` is a compile-time constant value, the code generator produces a fixed size object for `out`. If `i` is unknown at compile time, the code generator produces a variable size array for `out`.

By contrast, this example produces a fixed-sized array if `i` is known or unknown at compile time:

```
...
% extract elements i through 2+i for processing
A = rand(1,10);
out = A(i:2+i);
```

Occasionally, you can rewrite code to generate fixed size arrays. In this example, the first array is variable-sized, and second is fixed-sized, despite both producing the same array:

```
...
width = 25;
A = A(j-width:j+width); % A is variable-size, if j is unknown at compile time
fsA = A(j+(-width:width)); % This makes A fixed-size, even if j is unknown at compile time
...
```

## Eliminate Redundant Copies of Variables in Generated Code

### In this section...

“When Redundant Copies Occur” on page 56-7

“How to Eliminate Redundant Copies by Defining Uninitialized Variables” on page 56-7

“Defining Uninitialized Variables” on page 56-7

### When Redundant Copies Occur

During C/C++ code generation, the code generator checks for statements that attempt to access uninitialized memory. If it detects execution paths where a variable is used but is potentially not defined, it generates a compile-time error. To prevent these errors, define variables by assignment before using them in operations or returning them as function outputs.

Note, however, that variable assignments not only copy the properties of the assigned data to the new variable, but also initialize the new variable to the assigned value. This forced initialization sometimes results in redundant copies in C/C++ code. To eliminate redundant copies, define uninitialized variables by using the `coder.nullcopy` function, as described in “How to Eliminate Redundant Copies by Defining Uninitialized Variables” on page 56-7.

### How to Eliminate Redundant Copies by Defining Uninitialized Variables

- 1 Define the variable with `coder.nullcopy`.
- 2 Initialize the variable before reading it.

When the uninitialized variable is an array, you must initialize all of its elements before passing the array as an input to a function or operator — even if the function or operator does not read from the uninitialized portion of the array.

#### What happens if you access uninitialized data?

Uninitialized memory contains arbitrary values. Therefore, accessing uninitialized data may lead to segmentation violations or nondeterministic program behavior (different runs of the same program may yield inconsistent results).

### Defining Uninitialized Variables

In the following code, the assignment statement `X = zeros(1,N)` not only defines `X` to be a 1-by-5 vector of real doubles, but also initializes each element of `X` to zero.

```
function X = withoutNullcopy %#codegen
```

```
N = 5;
X = zeros(1,N);
for i = 1:N
    if mod(i,2) == 0
        X(i) = i;
    elseif mod(i,2) == 1
        X(i) = 0;
```

```
end  
end
```

This forced initialization creates an extra copy in the generated code. To eliminate this overhead, use `coder.nullcopy` in the definition of `X`:

```
function X = withNullcopy %#codegen  
  
N = 5;  
X = coder.nullcopy(zeros(1,N));  
for i = 1:N  
    if mod(i,2) == 0  
        X(i) = i;  
    else  
        X(i) = 0;  
    end  
end
```

## Reassignment of Variable Properties

For C/C++ code generation, there are certain variables that you can reassign after the initial assignment with a value of different class, size, or complexity:

### **Dynamically sized variables**

A variable can hold values that have the same class and complexity but different sizes. If the size of the initial assignment is not constant, the variable is dynamically sized in generated code. For more information, see “Variable-Size Data”.

### **Variables reused in the code for different purposes**

You can reassign the type (class, size, and complexity) of a variable after the initial assignment if each occurrence of the variable can have only one type. In this case, the variable is renamed in the generated code to create multiple independent variables. For more information, see “Reuse the Same Variable with Different Properties” on page 56-10.

## Reuse the Same Variable with Different Properties

### In this section...

“When You Can Reuse the Same Variable with Different Properties” on page 56-10

“When You Cannot Reuse Variables” on page 56-10

“Limitations of Variable Reuse” on page 56-11

For C/C++ code generation, there are certain variables that you can reassign after the initial assignment with a value of different class, size, or complexity. A variable can hold values that have the same class and complexity but different sizes. If the size of the initial assignment is not constant, the variable is dynamically sized in generated code. For more information, see “Variable-Size Data”.

You can reassign the type (class, size, and complexity) of a variable after the initial assignment if each occurrence of the variable can have only one type. In this case, the variable is renamed in the generated code to create multiple independent variables.

### When You Can Reuse the Same Variable with Different Properties

You can reuse (reassign) an input, output, or local variable with different class, size, or complexity if the code generator can unambiguously determine the properties of each occurrence of this variable during C/C++ code generation. If so, MATLAB creates separate uniquely named local variables in the generated code. You can view these renamed variables in the code generation report.

A common example of variable reuse is in `if-elseif-else` or `switch-case` statements. For example, the following function `example1` first uses the variable `t` in an `if` statement, where it holds a scalar double, then reuses `t` outside the `if` statement to hold a vector of doubles.

```
function y = example1(u) %#codegen
if all(all(u>0))
    % First, t is used to hold a scalar double value
    t = mean(mean(u)) / numel(u);
    u = u - t;
end
% t is reused to hold a vector of doubles
t = find(u > 0);
y = sum(u(t(2:end-1)));
```

### When You Cannot Reuse Variables

You cannot reuse (reassign) variables if it is not possible to determine the class, size, and complexity of an occurrence of a variable unambiguously during code generation. In this case, variables cannot be renamed and a compilation error occurs.

For example, the following `example2` function assigns a fixed-point value to `x` in the `if` statement and reuses `x` to store a matrix of doubles in the `else` clause. It then uses `x` after the `if-else` statement. This function generates a compilation error because after the `if-else` statement, variable `x` can have different properties depending on which `if-else` clause executes.

```
function y = example2(use_fixpoint, data) %#codegen
if use_fixpoint
    % x is fixed-point
    x = fi(data, 1, 12, 3);
```

```

else
    % x is a matrix of doubles
    x = data;
end
% When x is reused here, it is not possible to determine its
% class, size, and complexity
t = sum(sum(x));
y = t > 0;
end

```

### Example 56.1. Variable Reuse in an if Statement

To see how MATLAB renames a reused variable `t`:

- 1 Create a MATLAB file `example1.m` containing the following code.

```

function y = example1(u) %#codegen
if all(all(u>0))
    % First, t is used to hold a scalar double value
    t = mean(mean(u)) / numel(u);
    u = u - t;
end
% t is reused to hold a vector of doubles
t = find(u > 0);
y = sum(u(t(2:end-1)));
end

```

- 2 Generate a MEX function for `example1` and produce a code generation report.

```
codegen -o example1x -report example1.m -args {ones(5,5)}
```

- 3 Open the code generation report.

On the **Variables** tab, you see two uniquely named local variables `t>1` and `t>2`.

SUMMARY		ALL MESSAGES (0)		BUILD LOGS		COD
Name	Type	Size	Class			
y	Output	1 × 1	double			
u	Input	5 × 5	double			
t > 1	Local	1 × 1	double			
t > 2	Local	:25 × 1	double			

- 4 In the list of variables, click `t>1`. The report highlights the instances of the variable `t` that are inside of the `if` statement. These instances of `t` are scalar double.
- 5 Click `t>2`. The code generation report highlights the instances of `t` that are outside of the `if` statement. These instances of `t` are variable-size column vectors with an upper bound of 25.

## Limitations of Variable Reuse

The following variables cannot be renamed in generated code:

- Persistent variables.
- Global variables.

- Variables passed to C code using `coder.ref`, `coder.rref`, `coder.wref`.
- Variables whose size is set using `coder.varsize`.
- Variables whose names are controlled using `coder.cstructname`, when generating code by using MATLAB Coder.
- The index variable of a `for`-loop when it is used inside the loop body.
- The block outputs of a MATLAB Function block in a Simulink model.
- Chart-owned variables of a MATLAB function in a Stateflow chart.

## Supported Variable Types

You can use the following data types for C/C++ code generation from MATLAB:

Type	Description
char	Character array
complex	Complex data. Cast function takes real and imaginary components
double	Double-precision floating point
int8, int16, int32, int64	Signed integer
logical	Boolean true or false
single	Single-precision floating point
struct	Structure
uint8, uint16, uint32, uint64	Unsigned integer
Fixed-point	Fixed-point data types

## Edit and Represent Coder Type Objects and Properties

Passing an object to `coder.typeof` or passing a class name as a string scalar to `coder.newtype` creates an object that represents the type of object for code generation.

The coder type object displays a succinct description of the object properties while excluding internal state values. Nonconstant properties display their type and size, while constant properties display only their values.

To create a coder type object, pass a compatible object to `coder.typeof`. For example:

```
t = categorical({'r','g','b'});
tType = coder.typeof(t)
```

The representation of variable `t` is stored in coder type object `tType`.

```
tType =
    matlab.coder.type.CategoricalType
    1x3 categorical
    Categories : 3x1 homogeneous cell
    Ordinal : 1x1 logical
    Protected : 1x1 logical
```

### Object Properties

You can edit the properties of coder type objects. You can assign scalar values to the object properties. Values are implicitly converted to the corresponding coder type values when they are assigned to coder type object properties. The code generator implicitly converts constants assigned to coder type object properties to `coder.Constant` values. You can resize objects themselves

#### Resize Objects by Using `coder.resize`

You can resize most objects by using `coder.resize`. You can resize objects, its properties and create arrays within the properties.

For example, for a `timetable` coder object, you can resize the object:

```
t = timetable((1:5)',(11:15)', 'SampleRate',1);
tType = coder.typeof(t);
tType = coder.resize(tType, [10 2],[1 0])
```

This code resizes the `timetable` to a `:10x2` object.

```
tType =
    matlab.coder.type.RegularTimetableType
    :10x2 timetable
           Data : 1x2 homogeneous cell
           Description : 1x0 char
           UserData : 0x0 double
           DimensionNames : {'Time'} {'Variables'}
           VariableNames : {'Var1'} {'Var2'}
           VariableDescriptions : 1x2 homogeneous cell
           VariableUnits : 1x2 homogeneous cell
           VariableContinuity : 1x2 matlab.internal.coder.tabular.Continuity
```

```

StartTime : 1x1 matlab.coder.type.DurationType
SampleRate : 1x1 double
TimeStep : 1x1 matlab.coder.type.DurationType

```

The constant properties of `tType` display their values. The nonconstant properties display only their type and size.

---

**Note** Not all types representing MATLAB classes are compatible with `coder.resize`.

---

### Resize Objects by Editing Object Properties

You can resize the objects by editing the properties themselves. For a `duration` coder type object `x`, edit the `Size` property to change the size as needed.

```

x = coder.typeof(duration((1:3),0,0));
x.Size = [10 10]

```

This code changes the size of the coder type object.

```

x =
    matlab.coder.type.DurationType
    10x10 duration
    Format : 1x8 char

```

You can also make the coder type object variable-size by setting the `VarDims` flag:

```

x.VarDims(2) = true

```

The second dimension of the coder type object is upper-bounded at 10.

```

x =
    matlab.coder.type.DurationType
    10x:10 duration
    Format : 1x8 char

```

### Legacy Representation of Coder Type Objects

In R2021a, calling `coder.typeof` no longer returns a `coder.ClassType` object. If your workflow requires the legacy representation of coder type objects, use the `getCoderType` function on the variable that has the new representation of your class or object. For example, to get the legacy representation of a `datetime` variable, use the variable that has the new representation `tt` to call the `getCoderType` function:

```

t = datetime;
tt = coder.typeof(t);
ttLegacy = tt.getCoderType()

```

In the Coder Type Editor, the code generator includes the function `getCoderType` for coder type objects. Use this function to return the legacy representation of coder types. See, “Create and Edit Input Types by Using the Coder Type Editor” (MATLAB Coder)

Certain MATLAB data types provide customized type representations for MATLAB code generation. In other cases, the type is represented using `coder.ClassType`.

## Data Definition Considerations for Code Generation

To generate efficient standalone code, you must define the following types and classes of data differently from when you run your code in MATLAB.

Data	Type Considerations	More Information
Arrays	Maximum number of elements is restricted.	"Array Size Restrictions for Code Generation" on page 57-13
Numeric types	Assign numeric type variables a value before using them in operations or returning them as outputs.	"Best Practices for Defining Variables for C/C++ Code Generation" (MATLAB Coder)
Complex numbers	<ul style="list-style-type: none"> <li>Set complexity of variables at the time of assignment and before first use.</li> <li>Expressions containing a complex number or variable evaluate to a complex result, even if the imaginary part of the result is zero.</li> </ul>	"Code Generation for Complex Data" on page 57-8
Characters and strings	<ul style="list-style-type: none"> <li>Characters are restricted to 8 bits of precision.</li> <li>For code generation, string scalars do not support global variables, indexing with curly braces, missing values, or size changes by using the function <code>coder. varsize</code>.</li> </ul>	<ul style="list-style-type: none"> <li>"Encoding of Characters in Code Generation" on page 57-12</li> <li>"Code Generation for Strings" (MATLAB Coder)</li> </ul>
Variable-Size data	After initial fixed-size assignment to a variable, attempts to grow the variable might cause a compilation error.	<ul style="list-style-type: none"> <li>"Code Generation for Variable-Size Arrays" (MATLAB Coder)</li> <li>"Define Variable-Size Data for Code Generation" (MATLAB Coder)</li> </ul>
Structures	<ul style="list-style-type: none"> <li>Assign fields to structures in the same order on each control path.</li> <li>Assign corresponding fields in the structure array elements with same size, type, and complexity.</li> </ul>	<ul style="list-style-type: none"> <li>"Define Scalar Structures for Code Generation" (MATLAB Coder)</li> <li>"Define Arrays of Structures for Code Generation" (MATLAB Coder)</li> </ul>

Data	Type Considerations	More Information
Cell arrays	<ul style="list-style-type: none"> <li>Assign all cell array elements before passing the cell array to a function or returning it from a function.</li> <li>Variable-size cell array elements must all have the same size, type, and complexity.</li> </ul>	<ul style="list-style-type: none"> <li>“Code Generation for Cell Arrays” (MATLAB Coder)</li> <li>“Cell Array Limitations for Code Generation” (MATLAB Coder)</li> </ul>
Tables	<ul style="list-style-type: none"> <li>You must specify variable names by using the 'VariableNames' name-value argument when creating tables from input arrays.</li> <li>Limited data type support when you preallocate a table by using the table function and the 'Size' name-value argument.</li> <li>Table indices that specify variables must be compile time constant.</li> <li>You cannot change the size of a table by assignments.</li> <li>You cannot change the VariableNames, RowNames, DimensionNames, or UserData properties of a table after you create it.</li> </ul> <p>Limitations that apply to classes also apply to tables.</p>	<ul style="list-style-type: none"> <li>“Code Generation for Tables” (MATLAB Coder)</li> <li>“Table Limitations for Code Generation” (MATLAB Coder)</li> </ul>
Categorical arrays	<p>Categorical arrays do not support these inputs and operations:</p> <ul style="list-style-type: none"> <li>Arrays of MATLAB objects</li> <li>Sparse matrices</li> <li>Duplicate category names</li> <li>Growth by assignment</li> <li>Adding a category</li> <li>Deleting an element</li> </ul> <p>Limitations that apply to classes also apply to categorical arrays.</p>	<ul style="list-style-type: none"> <li>“Code Generation for Categorical Arrays” (MATLAB Coder)</li> <li>“Categorical Array Limitations for Code Generation” (MATLAB Coder)</li> </ul>

Data	Type Considerations	More Information
Datetime arrays	<p><code>datetime</code> arrays do not support these inputs and operations:</p> <ul style="list-style-type: none"> <li>• Text inputs</li> <li>• The 'Format' name-value argument</li> <li>• The 'TimeZone' name-value argument and the 'TimeZone' property</li> <li>• Setting time component properties</li> <li>• Growth by assignment</li> <li>• Deleting an element</li> </ul> <p>Limitations that apply to classes also apply to <code>datetime</code> arrays.</p>	<ul style="list-style-type: none"> <li>• “Code Generation for Datetime Arrays” (MATLAB Coder)</li> <li>• “Datetime Array Limitations for Code Generation” (MATLAB Coder)</li> </ul>
Duration arrays	<p>Duration arrays do not support these inputs and operations:</p> <ul style="list-style-type: none"> <li>• Text inputs</li> <li>• Growth by assignment</li> <li>• Deleting an element</li> <li>• Converting duration values to text by using <code>char</code>, <code>cellstr</code>, or <code>string</code> functions</li> </ul> <p>Limitations that apply to classes also apply to duration arrays.</p>	<ul style="list-style-type: none"> <li>• “Code Generation for Duration Arrays” (MATLAB Coder)</li> <li>• “Duration Array Limitations for Code Generation” (MATLAB Coder)</li> </ul>

Data	Type Considerations	More Information
Timetables	<ul style="list-style-type: none"> <li>• You must specify variable names by using the 'VariableNames' name-value argument when creating timetables from input arrays.</li> <li>• Limited data type support when you preallocate a table by using the timetable function and the 'Size' name-value argument.</li> <li>• Timetable indices that specify variables must be compile time constant.</li> <li>• You cannot change the size of a timetable by assignments.</li> <li>• You cannot change the VariableNames, DimensionNames, or UserData properties of a timetable after you create it.</li> <li>• If you create a regular timetable, and you attempt to set irregular row times, then an error is produced.</li> <li>• If you create an irregular timetable, then it remains irregular even if you set its sample rate or time step.</li> </ul> <p>Limitations that apply to classes also apply to timetables.</p>	<ul style="list-style-type: none"> <li>• “Code Generation for Timetables” (MATLAB Coder)</li> <li>• “Timetable Limitations for Code Generation” (MATLAB Coder)</li> </ul>
Enumerated data	Supports integer-based enumerated types only.	“Enumerations”

Data	Type Considerations	More Information
MATLAB Classes	<ul style="list-style-type: none"> <li>• Before generating code, it is a best practice to test class property validation by running a MEX function over the full range of input values.</li> <li>• If a property does not have an explicit initial value, the code generator assumes that it is undefined at the beginning of the constructor. The code generator does not assign an empty matrix as the default.</li> <li>• The <code>coder. varsize</code> function is not supported for class properties.</li> <li>• If the initial value of a property is an object, then the property must be constant. To make a property constant, declare the Constant attribute in the property block.</li> </ul>	<ul style="list-style-type: none"> <li>• “Generate C++ Classes for MATLAB Classes” (MATLAB Coder)</li> <li>• “MATLAB Classes Definition for Code Generation” (MATLAB Coder)</li> </ul>
Function handles	<ul style="list-style-type: none"> <li>• Assigning different function handles to the same variable can cause a compile-time error.</li> <li>• You cannot pass function handles to or from entry-point functions or extrinsic functions.</li> <li>• You cannot view function handles from the MATLAB Function Block debugger.</li> </ul>	“Function Handles”

Data	Type Considerations	More Information
Deep learning arrays	<p><code>dlarrays</code> do not support these inputs and operations:</p> <ul style="list-style-type: none"> <li>• The data format argument must be a compile-time constant</li> <li>• Define <code>dlarray</code> variables inside the entry-point function.</li> <li>• The input to a <code>dlarray</code> must be fixed-size.</li> <li>• Code generation does not support creating a <code>dlarray</code> type object by using the <code>coder.typeof</code> function with upper bound size and variable dimensions specified.</li> </ul>	<ul style="list-style-type: none"> <li>• “Code Generation for <code>dlarray</code>” (MATLAB Coder)</li> <li>• “<code>dlarray</code> Limitations for Code Generation” (MATLAB Coder)</li> </ul>

The information in the preceding table is not an exhaustive list of considerations for each data type. See the topics in the More Information column.

## Code Generation for Complex Data

### In this section...

“Restrictions When Defining Complex Variables” on page 57-8

“Code Generation for Complex Data with Zero-Valued Imaginary Parts” on page 57-8

“Results of Expressions That Have Complex Operands” on page 57-11

“Results of Complex Multiplication with Nonfinite Values” on page 57-11

### Restrictions When Defining Complex Variables

For code generation, you must set the complexity of variables at the time of assignment. Assign a complex constant to the variable or use the `complex` function. For example:

```
x = 5 + 6i; % x is a complex number by assignment.
y = complex(5,6); % y is the complex number 5 + 6i.
```

After assignment, you cannot change the complexity of a variable. Code generation for the following function fails because  $x(k) = 3 + 4i$  changes the complexity of  $x$ .

```
function x = test1( )
x = zeros(3,3); % x is real
for k = 1:numel(x)
    x(k) = 3 + 4i;
end
end
```

To resolve this issue, assign a complex constant to  $x$ .

```
function x = test1( )
x = zeros(3,3)+ 0i; %x is complex
for k = 1:numel(x)
    x(k) = 3 + 4i;
end
end
```

### Code Generation for Complex Data with Zero-Valued Imaginary Parts

For code generation, complex data that has all zero-valued imaginary parts remains complex. This data does not become real. This behavior has the following implications:

- In some cases, results from functions that sort complex data by absolute value can differ from the MATLAB results. See “Functions That Sort Complex Values by Absolute Value” on page 57-8.
- For functions that require that complex inputs are sorted by absolute value, complex inputs with zero-valued imaginary parts must be sorted by absolute value. These functions include `ismember`, `union`, `intersect`, `setdiff`, and `setxor`.

#### Functions That Sort Complex Values by Absolute Value

Functions that sort complex values by absolute value include `sort`, `issorted`, `sortrows`, `median`, `min`, and `max`. These functions sort complex numbers by absolute value even when the imaginary parts are zero. In general, sorting the absolute values produces a different result than sorting the real parts. Therefore, when inputs to these functions are complex with zero-valued imaginary parts in

generated code, but real in MATLAB, the generated code can produce different results than MATLAB. In the following examples, the input to `sort` is real in MATLAB, but complex with zero-valued imaginary parts in the generated code:

- **You Pass Real Inputs to a Function Generated for Complex Inputs**

- 1 Write this function:

```
function myout = mysort(A)
myout = sort(A);
end
```

- 2 Call `mysort` in MATLAB.

```
A = -2:2;
mysort(A)

ans =
```

```
    -2    -1     0     1     2
```

- 3 Generate a MEX function for complex inputs.

```
A = -2:2;
codegen mysort -args {complex(A)} -report
```

- 4 Call the MEX Function with real inputs.

```
mysort_mex(A)

ans =
```

```
     0     1    -1     2    -2
```

You generated the MEX function for complex inputs, therefore, it treats the real inputs as complex numbers with zero-valued imaginary parts. It sorts the numbers by the absolute values of the complex numbers. Because the imaginary parts are zero, the MEX function returns the results to the MATLAB workspace as real numbers. See “Inputs and Outputs for MEX Functions Generated for Complex Arguments” on page 57-10.

- **Input to `sort` Is Output from a Function That Returns Complex in Generated Code**

- 1 Write this function:

```
function y = myfun(A)
x = eig(A);
y = sort(x, 'descend');
```

The output from `eig` is the input to `sort`. In generated code, `eig` returns a complex result. Therefore, in the generated code, `x` is complex.

- 2 Call `myfun` in MATLAB.

```
A = [2 3 5;0 5 5;6 7 4];
myfun(A)
```

```
ans =
```

```
    12.5777
     2.0000
    -3.5777
```

The result of `eig` is real. Therefore, the inputs to `sort` are real.

- 3 Generate a MEX function for complex inputs.

```
codegen myfun -args {complex(A)}
```

- 4 Call the MEX function.

```
myfun_mex(A)
```

```
ans =
```

```
12.5777
-3.5777
2.0000
```

In the MEX function, `eig` returns a complex result. Therefore, the inputs to `sort` are complex. The MEX function sorts the inputs in descending order of the absolute values.

### Inputs and Outputs for MEX Functions Generated for Complex Arguments

For MEX functions created by the `codegen` command, the `fiaccl` command, or the MATLAB Coder app:

- Suppose that you generate the MEX function for complex inputs. If you call the MEX function with real inputs, the MEX function transforms the real inputs to complex values with zero-valued imaginary parts.
- If the MEX function returns complex values that have all zero-valued imaginary parts, the MEX function returns the values to the MATLAB workspace as real values. For example, consider this function:

```
function y = foo()
    y = 1 + 0i; % y is complex with imaginary part equal to zero
end
```

If you generate a MEX function for `foo` and view the code generation report, you see that `y` is complex.

```
codegen foo -report
```

Name	Type	Size	Class
y	Output	1 × 1	complex double

If you run the MEX function, you see that in the MATLAB workspace, the result of `foo_mex` is the real value 1.

```
z = foo_mex
```

```
ans =
```

```
1
```

## Results of Expressions That Have Complex Operands

In general, expressions that contain one or more complex operands produce a complex result in generated code, even if the value of the result is zero. Consider the following line of code:

```
z = x + y;
```

Suppose that at run time,  $x$  has the value  $2 + 3i$  and  $y$  has the value  $2 - 3i$ . In MATLAB, this code produces the real result  $z = 4$ . During code generation, the types for  $x$  and  $y$  are known, but their values are not known. Because either or both operands in this expression are complex,  $z$  is defined as a complex variable requiring storage for a real and an imaginary part.  $z$  equals the complex result  $4 + 0i$  in generated code, not  $4$ , as in MATLAB code.

Exceptions to this behavior are:

- When the imaginary parts of complex results are zero, MEX functions return the results to the MATLAB workspace as real values. See “Inputs and Outputs for MEX Functions Generated for Complex Arguments” on page 57-10.
- When the imaginary part of the argument is zero, complex arguments to extrinsic functions are real.

```
function y = foo()
    coder.extrinsic('sqrt')
    x = 1 + 0i; % x is complex
    y = sqrt(x); % x is real, y is real
end
```

- Functions that take complex arguments but produce real results return real values.

```
y = real(x); % y is the real part of the complex number x.
y = imag(x); % y is the real-valued imaginary part of x.
y = isreal(x); % y is false (0) for a complex number x.
```

- Functions that take real arguments but produce complex results return complex values.

```
z = complex(x,y); % z is a complex number for a real x and y.
```

## Results of Complex Multiplication with Nonfinite Values

When an operand of a complex multiplication contains a nonfinite value, the generated code might produce a different result than the result that MATLAB produces. The difference is due to the way that code generation defines complex multiplication. For code generation:

- Multiplication of a complex value by a complex value  $(a + bi)(c + di)$  is defined as  $(ac - bd) + (ad + bc)i$ . The complete calculation is performed, even when a real or an imaginary part is zero.
- Multiplication of a real value by a complex value  $c(a + bi)$  is defined as  $ca + cbi$ .

## Encoding of Characters in Code Generation

MATLAB represents characters in 16-bit Unicode. The code generator represents characters in an 8-bit codeset that the locale setting determines. Differences in character encoding between MATLAB and code generation have these consequences:

- Code generation of characters with numeric values greater than 255 produces an error.
- For some characters in the range 128–255, it might not be possible to represent the character in the codeset of the locale setting or to convert the character to an equivalent 16-bit Unicode character. Passing characters in this range between MATLAB and generated code can result in errors or different answers.
- For code generation, some toolbox functions accept only 7-bit ASCII characters.
- Casting a character that is not in the 7-bit ASCII codeset to a numeric type, such as double, can produce a different result in the generated code than in MATLAB. As a best practice, for code generation, avoid performing arithmetic with characters.

## Array Size Restrictions for Code Generation

For code generation, the maximum number of elements of an array is constrained by the code generator and the target hardware.

For fixed-size arrays and variable-size arrays that use static memory allocation, the maximum number of elements is the smaller of:

- `intmax('int32')`.
- The largest integer that fits in the C `int` data type on the target hardware.

For variable-size arrays that use dynamic memory allocation, the maximum number of elements is the smaller of:

- `intmax('int32')`.
- The largest power of 2 that fits in the C `int` data type on the target hardware.

These restrictions apply even on a 64-bit platform.

For a fixed-size array, if the number of elements exceeds the maximum, the code generator reports an error at compile time.

For a variable-size array, if the number of elements exceeds the maximum at run time, the error checking behavior depends on the code generation target:

- While running the code generated by using the `codegen` command, the `fiaccl` command, or the MATLAB Coder app, if run-time error checks are enabled, the generated code reports an error. By default, run-time error checks are enabled for MEX code and disabled for standalone C/C++ code.
- During simulation of a MATLAB Function block, the software reports an error. Generated standalone code for MATLAB Function blocks cannot report array size violations.

## Code Generation for Constants in Structures and Arrays

The code generator does not recognize constant structure fields or array elements in the following cases:

### Fields or elements are assigned inside control constructs

In the following code, the code generator recognizes that the structure fields `s.a` and `s.b` are constants.

```
function y = mystruct()
s.a = 3;
s.b = 5;
y = zeros(s.a,s.b);
```

If any structure field is assigned inside a control construct, the code generator does not recognize the constant fields. This limitation also applies to arrays with constant elements. Consider the following code:

```
function y = mystruct(x)
s.a = 3;
if x > 1
    s.b = 4;
else
    s.b = 5;
end
y = zeros(s.a,s.b);
```

The code generator does not recognize that `s.a` and `s.b` are constant. If variable-sizing is enabled, `y` is treated as a variable-size array. If variable-sizing is disabled, the code generator reports an error.

### Constants are assigned to array elements using non-scalar indexing

In the following code, the code generator recognizes that `a(1)` is constant.

```
function y = myarray()
a = zeros(1,3);
a(1) = 20;
y = coder.const(a(1));
```

In the following code, because `a(1)` is assigned using non-scalar indexing, the code generator does not recognize that `a(1)` is constant.

```
function y = myarray()
a = zeros(1,3);
a(1:2) = 20;
y = coder.const(a(1));
```

### A function returns a structure or array that has constant and nonconstant elements

For an output structure that has both constant and nonconstant fields, the code generator does not recognize the constant fields. This limitation also applies to arrays that have constant and nonconstant elements. Consider the following code:

```
function y = mystruct_out(x)
s = create_structure(x);
y = coder.const(s.a);
```

```
function s = create_structure(x)
s.a = 10;
s.b = x;
```

Because `create_structure` returns a structure `s` that has one constant field and one nonconstant field, the code generator does not recognize that `s.a` is constant. The `coder.const` call fails because `s.a` is not constant.

## Code Generation for Strings

Code generation supports 1-by-1 MATLAB string arrays. Code generation does not support string arrays that have more than one element.

A 1-by-1 string array, called a string scalar, contains one piece of text, represented as a 1-by-n character vector. An example of a string scalar is "Hello, world". For more information about strings, see "Text in String and Character Arrays".

### Limitations

For string scalars, code generation does not support:

- Global variables
- Indexing with curly braces {}
- Missing values
- Defining input types programmatically by using preconditioning with `assert` statements, when generating code by using the `codegen` command, the `fiaccl` command, or the MATLAB Coder app
- Their use with `coder. varsize`, when generating code by using the `codegen` command, the `fiaccl` command, or the MATLAB Coder app
- Their use as Simulink signals, parameters, or data store memory

For code generation, limitations that apply to classes apply to strings. See "MATLAB Classes Definition for Code Generation" on page 66-2.

### Differences Between Generated Code and MATLAB Code

- Converting a string that contains multiple unary operators to `double` can produce different results between MATLAB and the generated code. Consider this function:

```
function out = foo(op)
out = double(op + 1);
end
```

For an input value "--", the function converts the string "--1" to `double`. In MATLAB, the answer is NaN. In the generated code, the answer is 1.

- Double conversion for a string with misplaced commas (commas that are not used as thousands separators) can produce different results from MATLAB.

## Code Generation for Sparse Matrices

Sparse matrices provide efficient storage in memory for arrays with many zero elements. Sparse matrices can provide improved performance and reduced memory usage for generated code. Computation time on sparse matrices scales only with the number of operations on nonzero elements.

Functions for creating and manipulating sparse matrices are listed in “Sparse Matrices”. To check if a function is supported for code generation, see the function reference page. Code generation does not support sparse matrix inputs created by using `sparse` for all functions.

### Code Generation Guidelines

Initialize matrices by using sparse constructors to maximize your code efficiency. For example, to construct a 3-by-3 identity matrix, use `speye(3,3)` rather than `sparse(eye(3,3))`.

Indexed assignment into sparse matrices incurs an overhead compared to indexed assignment into full matrices. For example:

```
S = speye(10);
S(7,7) = 42;
```

As in MATLAB, sparse matrices are stored in compressed sparse column format. When you insert a new nonzero element into a sparse matrix, all subsequent nonzero elements must be shifted downward, column by column. These extra manipulations can slow performance. See “Accessing Sparse Matrices”.

### Code Generation Limitations

Code generation does not support sparse matrices for Simulink signals, parameters, or data store memory. Simulation state save and restore is not supported.

To generate code that uses sparse matrices, dynamic memory allocation must be enabled. To store the changing number of nonzero elements, and their values, sparse matrices use variable-size arrays in the generated code. To change dynamic memory allocation settings, see “Control Memory Allocation for Variable-Size Arrays in a MATLAB Function Block” on page 49-82. Because sparse matrices use variable-size arrays for dynamic memory allocation, limitations on “Variable-Size Data” also apply to sparse matrices.

You cannot assign sparse data to data that is not sparse. The generated code uses distinct data type representations for sparse and full matrices. To convert to and from sparse data, use the explicit `sparse` and `full` conversion functions.

You cannot define a sparse matrix with competing size specifications. The code generator fixes the size of the sparse matrix when it produces the corresponding data type definition in C/C++. As an example, the function `foo` causes an error in code generation:

```
function y = foo(n)
%#codegen
if n > 0
    y = sparse(3,2);
else
    y = sparse(4,3);
end
```

Logical indexing into sparse matrices is not supported for code generation. For example, this syntax causes an error:

```
S = magic(3);  
S(S > 7) = 42;
```

For sparse matrices, you cannot delete array elements by assigning empty arrays:

```
S(:,2) = [];
```

## Specify Array Layout in Functions and Classes

You can specialize individual MATLAB functions for row-major layout or column-major layout by inserting `coder.rowMajor` or `coder.columnMajor` calls into the function body. Using these function specializations, you can combine row-major data and column-major data in your generated code. You can also specialize classes for one specific array layout. Function and class specializations allow you to:

- Incrementally modify your code for row-major layout or column-major layout.
- Define array layout boundaries for applications that require different layouts in different components.
- Structure the inheritance of array layout between many different functions and classes.

For MATLAB Coder entry-point (top-level) functions, all inputs and outputs must use the same array layout. In the generated C/C++ code, the entry-point function interface accepts and returns data with the same array layout as the function array layout specification.

---

**Note** By default, code generation uses column-major array layout.

---

### Specify Array Layout in a Function

For an example of a specialized function, consider `addMatrixRM`:

```
function [S] = addMatrixRM(A,B)
%#codegen
S = zeros(size(A));
coder.rowMajor; % specify row-major code
for row = 1:size(A,1)
    for col = 1:size(A,2)
        S(row,col) = A(row,col) + B(row,col);
    end
end
```

For MATLAB Coder, you can generate code for `addMatrixRM` by using the `codegen` command.

```
codegen addMatrixRM -args {ones(20,10),ones(20,10)} -config:lib -launchreport
```

Because of the `coder.rowMajor` call, the code generator produces code that uses data stored in row-major layout.

Other functions called from a row-major function or column-major function inherit the same array layout. If a called function has its own distinct `coder.rowMajor` or `coder.columnMajor` call, the local call takes precedence.

You can mix column-major and row-major functions in the same code. The code generator inserts transpose or conversion operations when passing data between row-major and column-major functions. These conversion operations ensure that array elements are stored as required by functions with different array layout specifications. For example, the inputs to a column-major function, called from a row-major function, are converted to column-major layout before being passed to the column-major function.

## Query Array Layout of a Function

To query the array layout of a function at compile time, use `coder.isRowMajor` or `coder.isColumnMajor`. This query can be useful for specializing your generated code when it involves row-major and column-major functions. For example, consider this function:

```
function [S] = addMatrixRouted(A,B)
    if coder.isRowMajor
        %execute this code if row-major
        S = addMatrixRM(A,B);
    elseif coder.isColumnMajor
        %execute this code if column-major
        S = addMatrix_OptimizedForColumnMajor(A,B);
    end
```

This function behaves differently depending on whether it is row-major or column-major. When `addMatrixRouted` is row-major, it calls the `addMatrixRM` function, which has efficient memory access for row-major data. When the function is column-major, it calls a version of the `addMatrixRM` function optimized for column-major data.

For example, consider this function definition. The algorithm iterates through the columns in the outer loop and the rows in the inner loop, in contrast to the `addMatrixRM` function.

```
function [S] = addMatrix_OptimizedForColumnMajor(A,B)
    %#codegen
    S = zeros(size(A));
    for col = 1:size(A,2)
        for row = 1:size(A,1)
            S(row,col) = A(row,col) + B(row,col);
        end
    end
```

Code generation for this function yields:

```
...
/* column-major layout */
for (col = 0; col < 10; col++) {
    for (row = 0; row < 20; row++) {
        S[row + 20 * col] = A[row + 20 * col] + B[row + 20 * col];
    }
}
...
```

The generated code has a stride length of only one element. Due to the specializing queries, the generated code for `addMatrixRouted` provides efficient memory access for either choice of array layout.

## Specify Array Layout in a Class

You can specify array layout for a class so that object property variables are stored with a specific array layout. To specify the array layout, place a `coder.rowMajor` or `coder.columnMajor` call in the class constructor. If you assign an object with a specified array layout to the property of another object, the array layout of the assigned object takes precedence.

Consider the row-major class `rowMats` as an example. This class contains matrix properties and a method that consists of an element-wise addition algorithm. The algorithm in the method performs

more efficiently for data stored in row-major layout. By specifying `coder.rowMajor` in the class constructor, the generated code uses row-major layout for the property data.

```
classdef rowMats
    properties (Access = public)
        A;
        B;
        C;
    end
    methods
        function obj = rowMats(A,B)
            coder.rowMajor;
            if nargin == 0
                obj.A = 0;
                obj.B = 0;
                obj.C = 0;
            else
                obj.A = A;
                obj.B = B;
                obj.C = zeros(size(A));
            end
        end
        function obj = add(obj)
            for row = 1:size(obj.A,1)
                for col = 1:size(obj.A,2)
                    obj.C(row,col) = obj.A(row,col) + obj.B(row,col);
                end
            end
        end
    end
end
```

Use the class in a simple function `doMath`. The inputs and outputs of the entry-point function must all use the same array layout.

```
function [out] = doMath(in1,in2)
    %#codegen
    out = zeros(size(in1));
    myMats = rowMats(in1,in2);
    myMats = myMats.add;
    out = myMats.C;
end
```

For MATLAB Coder, you can generate code by entering:

```
A = rand(20,10);
B = rand(20,10);
cfg = coder.config('lib');
codegen -config cfg doMath -args {A,B} -launchreport
```

With default settings, the code generator assumes that the entry-point function inputs and outputs use column-major layout, because you do not specify row-major layout for the function `doMath`. Therefore, before calling the class constructor, the generated code converts `in1` and `in2` to row-major layout. Similarly, it converts the `doMath` function output back to column-major layout.

When designing a class for a specific array layout, consider:

- If you do not specify the array layout in a class constructor, objects inherit their array layout from the function that calls the class constructor, or from code generation configuration settings.
- You cannot specify the array layout in a nonstatic method by using `coder.rowMajor` or `coder.columnMajor`. Methods use the same array layout as the receiving object. Methods do not inherit the array layout of the function that calls them. For static methods, which are used similarly to ordinary functions, you can specify the array layout in the method.
- If you specify the array layout of a superclass, the subclass inherits this array layout specification. You cannot specify conflicting array layouts between superclasses and subclasses.

### **See Also**

`coder.rowMajor` | `coder.columnMajor` | `coder.isColumnMajor` | `coder.isRowMajor`

### **More About**

- “Interface with Row-Major Data in MATLAB Function Block” on page 49-123
- “Code Design for Row-Major Array Layout” on page 57-23
- “Code Generation of Matrices and Arrays” (Simulink Coder)

## Code Design for Row-Major Array Layout

Outside of code generation, MATLAB uses column-major layout by default. Array layout specifications do not affect self-contained MATLAB code. To test the efficiency of your generated code or your MATLAB Function block, create separate versions with row-major layout and column-major layout. Then, compare their performance.

You can design your MATLAB code to avoid potential inefficiencies related to array layout. Inefficiencies can be caused by:

- Conversions between row-major layout and column-major layout.
- One-dimensional or linear indexing of row-major data.
- Reshaping or rearrangement of row-major data.

Array layout conversions are necessary when you mix row-major and column-major specifications in the same code or model, or when you use linear indexing on data that is stored in row-major. When you simulate a model or generate code for a model that uses column-major, and that contains a MATLAB Function block that uses row-major, then the software converts input data to row-major and output data back to column-major as needed, and vice versa.

Inefficiencies can be caused by functions or algorithms that are less optimized for a given choice of array layout. If a function or algorithm is more efficient for a different layout, you can enforce that layout by embedding it in another function with a `coder.rowMajor` or `coder.columnMajor` call.

### Linear Indexing Uses Column-Major Array Layout

The code generator follows MATLAB column-major semantics for linear indexing. For more information on linear indexing in MATLAB, see “Array Indexing”.

To use linear indexing on row-major data, the code generator must first recalculate the data representation in column-major layout. This additional processing can slow performance. To improve code efficiency, avoid using linear indexing on row-major data, or use column-major layout for code that uses linear indexing.

For example, consider the function `sumShiftedProducts`, which accepts a matrix as an input and outputs a scalar value. The function uses linear indexing on the input matrix to sum up the product of each matrix element with an adjacent element. The output value of this operation depends on the order in which the input elements are stored.

```
function mySum = sumShiftedProducts(A)
%#codegen
mySum = 0;
% create linear vector of A elements
B = A(:);
% multiply B by B with elements shifted by one, and take sum
mySum = sum( B.*circshift(B,1) );
end
```

For MATLAB Coder, to generate code that uses row-major layout, enter:

```
codegen -config:mex sumShiftedProducts -args {ones(2,3)} -launchreport -rowmajor
```

For an example input, consider the matrix:

```
D = reshape(1:6,3,2)'
```

which yields:

```
D =  
    1    2    3  
    4    5    6
```

If you pass this matrix as input to the generated code, the elements of A are stored in the order:

```
    1    2    3    4    5    6
```

In contrast, because the vector B is obtained by linear indexing, it is stored in the order:

```
    1    4    2    5    3    6
```

The code generator must insert a reshaping operation to rearrange the data from row-major layout for A to column-major layout for B. This additional operation reduces the efficiency of the function for row-major layout. The inefficiency increases with the size of the array. Because linear indexing always uses column-major layout, the generated code for `sumShiftedProducts` produces the same output result whether generated with row-major layout or column-major layout.

In general, functions that compute indices or subscripts also use linear indexing, and produce results corresponding to data stored in column-major layout. These functions include:

- `ind2sub`
- `sub2ind`
- `colon`

## Generate Code for Growing Arrays and Cell Arrays with end + 1 Indexing

Code generation supports growing either an array or a cell array in your MATLAB code by using end + 1 indexing. To use this functionality, make sure that the code generation configuration property EnableVariableSizing or the corresponding setting **Enable variable-sizing** in the MATLAB Coder app is enabled.

### Grow Array with (end + 1) Indexing

To grow an array  $X$ , you can assign a value to  $X(\text{end} + 1)$ . If you make this assignment in your MATLAB code, the code generator treats the dimension you grow as variable-size.

For example, you can generate code for this code snippet:

```
...
a = [1 2 3 4 5 6];
a(end + 1) = 7;

b = [1 2];
for i = 3:10
    b(end + 1) = i;
end
...
```

When you use (end + 1) to grow an array, follow these restrictions:

- Use only (end + 1). Do not use (end + 2), (end + 3), and so on.
- Use (end + 1) with vectors only. For example, the following code is not allowed because  $X$  is a matrix, not a vector.

```
...
X = [1 2; 3 4];
X(end + 1) = 5;
...
```

- You can grow empty arrays of size  $1 \times 0$  by using (end + 1). Growing arrays of size  $0 \times 1$  is not supported. Growing an array of size  $0 \times 0$  is supported only if you create that array by using [].

### Growing Variable-Size Column Array That is Initialized as Scalar at Run Time

In MATLAB execution, if you grow a scalar array by using (end+1) indexing, the array grows along the second dimension and produces a row vector. For example, define the function grow:

```
function z = grow(n, m)
n(end+1) = m;
z = n;
end
```

Call grow with example inputs:

```
grow(2,3)
```

```
ans =
     2     3
```

By contrast, in code generation, suppose that:

- You specify the array to be of variable-size column type (for example, `:Inf x 1`) at compile time, *and*
- Initialize this array as a scalar at run time.

In such situations, the generated code attempts to grow the scalar along the first dimension and therefore, produces a run-time error. For example, generate MEX code for `grow`. Specify the input `n` to be a `:Inf x 1` double array. Specify the input `m` to be a double scalar.

```
codegen grow -args {coder.typeof(0, [Inf 1], [1 0]), 1}
```

Code generation successful.

Run the generated MEX with the same inputs as before.

```
grow_mex(2,3)
```

```
Attempted to grow a scalar along the first dimension using end+1 indexing. This
behavior differs from MATLAB execution which grows a scalar along the second
dimension.
```

```
Error in grow (line 2)
n(end+1) = m;
```

### How to Avoid This Error

To avoid this error and grow the array along the column dimension in both generated code and MATLAB execution, rewrite your MATLAB code in *either* of these ways:

- Grow the array using the concatenation operator instead of using `(end+1)`. For example, rewrite the `grow` function as:

```
function z = growCat(n, m)
n = [n;m];
z = n;
end
```

- In your function, create a temporary variable by transposing the variable that you want to grow. Then, grow this temporary variable by using `(end+1)` indexing. Finally, take a second transpose of this temporary variable. For example, rewrite the `grow` function as:

```
function z = growTransposed(n, m)
temp = n';
temp(end+1) = m;
z = temp';
end
```

### Grow Cell Array with `{end + 1}` Indexing

To grow a cell array `X`, you can use `X{end + 1}`. For example:

```
...
X = {1 2};
```

```
X{end + 1} = 'a';
...
```

When you use {end + 1} to grow a cell array, follow these restrictions:

- In a MATLAB Function block, do not use {end + 1} in a for-loop.
- Use only {end + 1}. Do not use {end + 2}, {end + 3}, and so on.
- Use {end + 1} with vectors only. For example, the following code is not allowed because X is a matrix, not a vector:

```
...
X = {1 2; 3 4};
X{end + 1} = 5;
```

- Use {end + 1} only with a variable. In the following code, {end + 1} does not cause {1 2 3} to grow. In this case, the code generator treats {end + 1} as an out-of-bounds index into X{2}.

```
...
X = {'a' { 1 2 3 }};
X{2}{end + 1} = 4;
```

- When {end + 1} grows a cell array in a loop, the cell array must be variable-size. Therefore, the cell array must be homogeneous on page 60-2.

This code is allowed because X is homogeneous.

```
...
X = {1 2};
for i=1:n
    X{end + 1} = 3;
end
...
```

This code is not allowed because X is heterogeneous.

```
...
X = {1 'a' 2 'b'};
for i=1:n
    X{end + 1} = 3;
end
...
```

- For a coding pattern that causes a difference in behavior between generated code and MATLAB, see “Growing Variable-Size Column Cell Array That is Initialized as Scalar at Run Time” on page 53-17.

# Code Generation for Variable-Size Data

---

## Code Generation for Variable-Size Arrays

For code generation, an array dimension is fixed-size or variable-size. If the code generator can determine the size of the dimension and that the size of the dimension does not change, then the dimension is fixed-size. When all dimensions of an array are fixed-size, the array is a fixed-size array. In the following example, *Z* is a fixed-size array.

```
function Z = myfcn()
Z = zeros(1,4);
end
```

The size of the first dimension is 1 and the size of the second dimension is 4.

If the code generator cannot determine the size of a dimension or the code generator determines that the size changes, then the dimension is variable-size. When at least one of its dimensions is variable-size, an array is a variable-size array.

A variable-size dimension is either bounded or unbounded. A bounded dimension has a fixed upper size. An unbounded dimension does not have a fixed upper size.

In the following example, the second dimension of *Z* is bounded, variable-size. It has an upper bound of 16.

```
function s = myfcn(n)
if (n > 0)
    Z = zeros(1,4);
else
    Z = zeros(1,16);
end
s = length(Z);
```

In the following example, if the value of *n* is unknown at compile time, then the second dimension of *Z* is unbounded.

```
function s = myfcn(n)
Z = rand(1,n);
s = sum(Z);
end
```

You can define variable-size arrays by:

- Using constructors, such as `zeros`, with a nonconstant dimension
- Assigning multiple, constant sizes to the same variable before using it
- Declaring all instances of a variable to be variable-size by using `coder.varsize`

For more information, see “Define Variable-Size Data for Code Generation” on page 58-9.

You can control whether variable-size arrays are allowed for code generation. See “Enabling and Disabling Support for Variable-Size Arrays” on page 58-3.

## Memory Allocation for Variable-Size Arrays

For fixed-size arrays and variable-size arrays whose size is less than a threshold, the code generator allocates memory statically on the stack. For unbounded, variable-size arrays and variable-size arrays

whose size is greater than or equal to a threshold, the code generator allocates memory dynamically on the heap.

For a MATLAB Function block, you cannot use dynamic memory allocation for:

- Input and output signals. Variable-size input and output signals must have an upper bound.
- Parameters or global variables. Parameters and global variables must be fixed-size.
- Fields of bus arrays. Bus arrays cannot have variable-size fields.

You can control whether dynamic memory allocation is allowed or when it is used for code generation. See “Control Memory Allocation for Variable-Size Arrays in a MATLAB Function Block” on page 49-82.

The code generator represents dynamically allocated data as a structure type called `emxArray`. The code generator generates utility functions that create and interact with `emxArrays`. If you use Embedded Coder, you can customize the generated identifiers for the `emxArray` types and utility functions. See “Identifier Format Control” (Embedded Coder).

## Enabling and Disabling Support for Variable-Size Arrays

By default, for MATLAB Function blocks, support for variable-size arrays is enabled. To disable this support:

- 1 In the MATLAB Function Block Editor, select **Edit Data**.
- 2 Clear the **Support variable-size arrays** check box.

## Variable-Size Arrays in a MATLAB Function Report

You can tell whether an array is fixed-size or variable-size by looking at the **Size** column of the **Variables** tab in a MATLAB Function Report.

Name	Type	Size	Class
y	Output	1 × 1	double
n	Input	1 × 1	double
x	Local	1 × :?	double

A colon (:) indicates that a dimension is variable-size. A question mark (?) indicates that the size is unbounded. For example, a size of 1-by-:? indicates that the size of the first dimension is fixed-size 1 and the size of the second dimension is unbounded, variable-size. Italic indicates that your code specifies that an array is variable-size, but the code generator determined that it does not change size.

ALL MESSAGES (0)		VARIABLES		
Name	Type	Size	Class	
y	Output	1 × 2	double	
n	Input	1 × 1	double	
Z	Local	1 × 4	double

- “Control Memory Allocation for Variable-Size Arrays in a MATLAB Function Block” on page 49-82
- “Specify Upper Bounds for Variable-Size Arrays” on page 58-7
- “Define Variable-Size Data for Code Generation” on page 58-9
- “Use Dynamic Memory Allocation for Variable-Size Arrays in a MATLAB Function Block” on page 49-84

## Control Dynamic Memory Allocation for Fixed-Size Arrays

The code generated by MATLAB Coder allocates memory to the program stack for fixed-size arrays, whose size is less than a threshold. For example, in the following code, the array Z is a fixed-size array with a first dimension of size 1 and a second dimension of size 4.

```
function Z = myfcn()
Z = zeros(1,4);
end
```

Dynamic memory allocation allocates memory on the heap for fixed-size arrays, instead of the program stack. Consider dynamically allocating fixed-size arrays when you have large arrays that could exhaust stack memory.

Dynamic memory allocation might result in slower execution of the generated code.

### Enable Dynamic Memory Allocation for Fixed-Size Arrays

By default, dynamic memory allocation for fixed-size arrays is disabled. To enable it:

- In a configuration object for code generation, set `EnableDynamicMemoryAllocation` and `DynamicMemoryAllocationForFixedSizeArrays` options to `true`.
- In the MATLAB Coder app, in the **Memory** settings, select **Enable dynamic memory allocation** and **Enable dynamic memory allocation for fixed-sized arrays**.

### Dynamic Memory Allocation Threshold for Fixed-Size Arrays

When `DynamicMemoryAllocationForFixedSizeArrays` is enabled, the code generator allocates memory dynamically on the heap for fixed-size arrays whose size (in bytes) is

greater than or equal to `DynamicMemoryAllocationThreshold`.

The default dynamic memory allocation threshold is 64 kilobytes. To configure the threshold:

- In a configuration object for code generation, set a value for the `DynamicMemoryAllocationThreshold`.
- In the MATLAB Coder app, in the **Memory** settings, set a value for **Dynamic memory allocation threshold**.

### Generating Code for Fixed-Size Arrays

Consider the following MATLAB function which calculates the product of two large fixed-size arrays a and b.

```
function y = tlargeSize(a,b)
y = a*b;
end
```

To generate C code, run these commands:

```
cfg = coder.config('lib');
cfg.VerificationMode="SIL";
cfg.DynamicMemoryAllocationForFixedSizeArrays = true;
```

```
t=coder.typeof(0,[1e4 1e4]);  
codegen tlargeSize -args {t,t} -config cfg - report
```

By enabling the `DynamicMemoryAllocationForFixedSizeArrays` option, arrays `a` and `b` are dynamically allocated on the heap preventing stack overflow.

### Generated Code

```
...  
void tlargeSize(const mxArray_real_T *a, const mxArray_real_T *b,  
               mxArray_real_T *y)  
{  
    const double *a_data;  
    const double *b_data;  
    double *y_data;  
    ...  
}
```

### Usage Notes and Limitations

When enabling `DynamicMemoryAllocationForFixedSizeArrays`:

- Input and output variables of the function changes to:
  - `coder::array` for C++ code generation. See, “Use Dynamically Allocated C++ Arrays in Generated Function Interfaces” (MATLAB Coder).
  - `mxArray` for C code generation. See, “Use C Arrays in the Generated Function Interfaces” (MATLAB Coder)
- Ensure C/C++ function signatures are updated when passing struct with fixed-size arrays to `coder.ceval` or Code Replacement Library (CRL).

---

**Note** Enabling `DynamicMemoryAllocationForFixedSizeArrays` is not supported for GPU code generation.

## Specify Upper Bounds for Variable-Size Arrays

Specify upper bounds for an array when:

- Dynamic memory allocation is disabled.

If dynamic memory allocation is disabled, you must specify upper bounds for all arrays.

- You do not want the code generator to use dynamic memory allocation for the array.

Specify upper bounds that result in an array size (in bytes) that is less than the dynamic memory allocation threshold.

## Specify Upper Bounds for MATLAB Function Block Inputs and Outputs

See “Declare Variable-Size MATLAB Function Block Variables” on page 49-76.

## Specify Upper Bounds for Local Variables

When using static allocation, the code generator uses a sophisticated analysis to calculate the upper bounds of local data. However, when the analysis fails to detect an upper bound or calculates an upper bound that is not precise enough for your application, you must specify upper bounds explicitly for local variables.

### Constrain the Value of Variables That Specify the Dimensions of Variable-Size Arrays

To constrain the value of variables that specify the dimensions of variable-size arrays, use the `assert` function with relational operators. For example:

```
function y = dim_need_bound(n) %#codegen
assert (n <= 5);
L = ones(n,n);
M = zeros(n,n);
M = [L; M];
y = M;
```

This `assert` statement constrains input `n` to a maximum size of 5. `L` is variable-size with upper bounds of 5 in each dimension. `M` is variable-size with an upper bound of 10 in the first dimension and 5 in the second dimension.

### Specify the Upper Bounds for All Instances of a Local Variable

To specify the upper bounds for all instances of a local variable in a function, use the `coder.varsize` function. For example:

```
function Y = example_bounds1(u) %#codegen
Y = [1 2 3 4 5];
coder.varsize('Y',[1 10]);
if (u > 0)
    Y = [Y Y+u];
else
    Y = [Y Y*u];
end
```

The second argument of `coder. varsize` specifies the upper bound for each instance of the variable specified in the first argument. In this example, the argument `[1 10]` indicates that for every instance of `Y`:

- The first dimension is fixed at size 1.
- The second dimension can grow to an upper bound of 10.

### **More About**

- “Code Generation for Variable-Size Arrays” on page 58-2
- “Define Variable-Size Data for Code Generation” on page 58-9

## Define Variable-Size Data for Code Generation

For code generation, before using variables in operations or returning them as outputs, you must assign them a specific class, size, and complexity. Generally, after the initial assignment, you cannot reassign variable properties. Therefore, after assigning a fixed size to a variable or structure field, attempts to grow the variable or structure field might cause a compilation error. In these cases, you must explicitly define the data as variable-size by using one of these methods.

Method	See
Assign the data from a variable-size matrix constructor such as: <ul style="list-style-type: none"> <li>ones</li> <li>zeros</li> <li>repmat</li> </ul>	“Use a Matrix Constructor with Nonconstant Dimensions” on page 58-9
Assign multiple, constant sizes to the same variable before using (reading) the variable.	“Assign Multiple Sizes to the Same Variable” on page 58-9
Grow an array by using $(\text{end} + 1)$ indexing.	“Growing an Array by Using $(\text{end} + 1)$ ” on page 58-10
Define all instances of a variable to be variable-size.	“Define Variable-Size Data Explicitly by Using <code>coder.varsize</code> ” on page 58-11

---

**Note** The MATLAB Function block does not support code generation if one of the variables uses an alias type and is variable size. This limitation does not apply to input or output variables. For more information on defining variable-size variables in MATLAB Function blocks, see “Create and Define MATLAB Function Block Variables” on page 49-31 and “Declare Variable-Size MATLAB Function Block Variables” on page 49-76.

---

### Use a Matrix Constructor with Nonconstant Dimensions

You can define a variable-size matrix by using a constructor with nonconstant dimensions. For example:

```
function s = var_by_assign(u) %#codegen
y = ones(3,u);
s = numel(y);
```

If you are not using dynamic memory allocation, you must also add an `assert` statement to provide upper bounds for the dimensions. For example:

```
function s = var_by_assign(u) %#codegen
assert (u < 20);
y = ones(3,u);
s = numel(y);
```

### Assign Multiple Sizes to the Same Variable

Before you use (read) a variable in your code, you can make it variable-size by assigning multiple, constant sizes to it. When the code generator uses static allocation on the stack, it infers the upper

bounds from the largest size specified for each dimension. When you assign the same size to a given dimension across all assignments, the code generator assumes that the dimension is fixed at that size. The assignments can specify different shapes and sizes.

When the code generator uses dynamic memory allocation, it does not check for upper bounds. It assumes that the variable-size data is unbounded.

### Inferring Upper Bounds from Multiple Definitions with Different Shapes

```
function s = var_by_multiassign(u) %#codegen
if (u > 0)
    y = ones(3,4,5);
else
    y = zeros(3,1);
end
s = numel(y);
```

When the code generator uses static allocation, it infers that `y` is a matrix with three dimensions:

- The first dimension is fixed at size 3
- The second dimension is variable-size with an upper bound of 4
- The third dimension is variable-size with an upper bound of 5

When the code generator uses dynamic allocation, it analyzes the dimensions of `y` differently:

- The first dimension is fixed at size 3.
- The second and third dimensions are unbounded.

### Growing an Array by Using `(end + 1)`

To grow an array `X`, you can assign a value to `X(end + 1)`. If you make this assignment in your MATLAB code, the code generator treats the dimension you grow as variable-size.

For example, you can generate code for this code snippet:

```
...
a = [1 2 3 4 5 6];
a(end + 1) = 7;

b = [1 2];
for i = 3:10
    b(end + 1) = i;
end
...

```

When you use `(end + 1)` to grow an array, follow these restrictions:

- Use only `(end + 1)`. Do not use `(end + 2)`, `(end + 3)`, and so on.
- Use `(end + 1)` with vectors only. For example, the following code is not allowed because `X` is a matrix, not a vector.

```
...
X = [1 2; 3 4];
X(end + 1) = 5;
...

```

- You can grow empty arrays of size  $1 \times 0$  by using `(end + 1)`. Growing arrays of size  $0 \times 1$  is not supported. Growing an array of size  $0 \times 0$  is supported only if you create that array by using `[]`.

## Define Variable-Size Data Explicitly by Using `coder.versize`

To explicitly define variable-size data, use the function `coder.versize`. Optionally, you can also specify which dimensions vary along with their upper bounds. For example:

- Define `B` as a variable-size 2-dimensional array, where each dimension has an upper bound of 64.

```
coder.versize('B', [64 64]);
```

- Define `B` as a variable-size array:

```
coder.versize('B');
```

When you supply only the first argument, `coder.versize` assumes that all dimensions of `B` can vary and that the upper bound is `size(B)`.

If a MATLAB Function block output signal is variable-size, in the Property Inspector, you must specify that the signal is variable-size. You must also provide the upper bounds. You do not have to use `coder.versize` with the corresponding output variable inside the MATLAB Function block. However, if you specify upper bounds with `coder.versize`, they must match the upper bounds in the Property Inspector.

### Specify Which Dimensions Vary

You can use the function `coder.versize` to specify which dimensions vary. For example, the following statement defines `B` as an array whose first dimension is fixed at 2, but whose second dimension can grow to a size of 16:

```
coder.versize('B',[2, 16],[0 1])
```

.

The third argument specifies which dimensions vary. This argument must be a logical vector or a double vector containing only zeros and ones. Dimensions that correspond to zeros or `false` have fixed size. Dimensions that correspond to ones or `true` vary in size. `coder.versize` usually treats dimensions of size 1 as fixed. See “Define Variable-Size Matrices with Singleton Dimensions” on page 58-12.

### Allow a Variable to Grow After Defining Fixed Dimensions

Function `var_by_if` defines matrix `Y` with fixed 2-by-2 dimensions before the first use (where the statement `Y = Y + u` reads from `Y`). However, `coder.versize` defines `Y` as a variable-size matrix, allowing it to change size based on decision logic in the `else` clause:

```
function Y = var_by_if(u) %#codegen
if (u > 0)
    Y = zeros(2,2);
    coder.versize('Y');
    if (u < 10)
        Y = Y + u;
    end
else
    Y = zeros(5,5);
end
```

Without `coder. varsize`, the code generator infers `Y` to be a fixed-size, 2-by-2 matrix. It generates a size mismatch error.

### Define Variable-Size Matrices with Singleton Dimensions

A singleton dimension is a dimension for which `size(A, dim) = 1`. Singleton dimensions are fixed in size when:

- You specify a dimension with an upper bound of 1 in `coder. varsize` expressions.

For example, in this function, `Y` behaves like a vector with one variable-size dimension:

```
function Y = dim_singleton(u) %#codegen
Y = [1 2];
coder. varsize('Y', [1 10]);
if (u > 0)
    Y = [Y 3];
else
    Y = [Y u];
end
```

- You initialize variable-size data with singleton dimensions by using matrix constructor expressions or matrix functions.

For example, in this function, `X` and `Y` behave like vectors where only their second dimensions are variable-size.

```
function [X,Y] = dim_singleton_vects(u) %#codegen
Y = ones(1,3);
X = [1 4];
coder. varsize('Y', 'X');
if (u > 0)
    Y = [Y u];
else
    X = [X u];
end
```

You can override this behavior by using `coder. varsize` to specify explicitly that singleton dimensions vary. For example:

```
function Y = dim_singleton_vary(u) %#codegen
Y = [1 2];
coder. varsize('Y', [1 10], [1 1]);
if (u > 0)
    Y = [Y Y+u];
else
    Y = [Y Y*u];
end
```

In this example, the third argument of `coder. varsize` is a vector of ones, indicating that each dimension of `Y` varies in size.

### Define Variable-Size Structure Fields

To define structure fields as variable-size arrays, use a colon (`:`) as the index expression. The colon (`:`) indicates that all elements of the array are variable-size. For example:

```
function y=struct_example() %#codegen
```

```

d = struct('values', zeros(1,0), 'color', 0);
data = repmat(d, [3 3]);
coder.varsize('data(:).values');

for i = 1:numel(data)
    data(i).color = rand-0.5;
    data(i).values = 1:i;
end

y = 0;
for i = 1:numel(data)
    if data(i).color > 0
        y = y + sum(data(i).values);
    end
end

```

The expression `coder.varsize('data(:).values')` defines the field values inside each element of matrix `data` to be variable-size.

Here are other examples:

- `coder.varsize('data.A(:).B')`

In this example, `data` is a scalar variable that contains matrix `A`. Each element of matrix `A` contains a variable-size field `B`.

- `coder.varsize('data(:).A(:).B')`

This expression defines field `B` inside each element of matrix `A` inside each element of matrix `data` to be variable-size.

## Diagnose and Fix Variable-Size Data Errors

### Diagnosing and Fixing Size Mismatch Errors

#### Issue: Assigning Variable-Size Matrices to Fixed-Size Matrices

You cannot assign variable-size matrices to fixed-size matrices in generated code. Consider this example:

```
function Y = example_mismatch1(n) %#codegen
assert(n < 10);
B = ones(n,n);
A = magic(3);
A(1) = mean(A(:));
if (n == 3)
    A = B;
end
Y = A;
```

Compiling this function produces this error:

```
??? Dimension 1 is fixed on the left-hand side
but varies on the right ...
```

There are several ways to fix this error:

- Allow matrix A to grow by adding the `coder.varsize` construct:

```
function Y = example_mismatch1_fix1(n) %#codegen
coder.varsize('A');
assert(n < 10);
B = ones(n,n);
A = magic(3);
A(1) = mean(A(:));
if (n == 3)
    A = B;
end
Y = A;
```

- Explicitly restrict the size of matrix B to 3-by-3 by modifying the `assert` statement:

```
function Y = example_mismatch1_fix2(n) %#codegen
coder.varsize('A');
assert(n == 3)
B = ones(n,n);
A = magic(3);
A(1) = mean(A(:));
if (n == 3)
    A = B;
end
Y = A;
```

- Use explicit indexing to make B the same size as A:

```
function Y = example_mismatch1_fix3(n) %#codegen
assert(n < 10);
B = ones(n,n);
A = magic(3);
```

```
A(1) = mean(A(:));
if (n == 3)
    A = B(1:3, 1:3);
end
Y = A;
```

### Issue: Empty Matrix Reshaped to Match Variable-Size Specification

If you assign an empty matrix `[]` to variable-size data, MATLAB might silently reshape the data in generated code to match a `coder. varsize` specification. For example:

```
function Y = test(u) %#codegen
Y = [];
coder. varsize('Y', [1 10]);
if u < 0
    Y = [Y u];
end
```

In this example, `coder. varsize` defines `Y` as a column vector of up to 10 elements, so its first dimension is fixed at size 1. The statement `Y = []` designates the first dimension of `Y` as 0, creating a mismatch. The right hand side of the assignment is an empty matrix and the left hand side is a variable-size vector. In this case, MATLAB reshapes the empty matrix `Y = []` in generated code to `Y = zeros(1,0)` so it matches the `coder. varsize` specification.

### Issue: Assigning Implicitly Expanded Outputs to Fixed-Size Variable

If you assign the implicitly expanded output of a binary operation or function to a variable of different size, the code generator might produce an error. For example:

```
function out = test(n) %#codegen
x = ones(n,1);
if mod(n,2) == 1
    y = ones(n,n);
    x = y + x;
end
out = out + x(2);
end
```

In this example, `x` is an unbounded vector. Due to implicit expansion, the plus operation on `x` and `y` results in an unbounded matrix (Inf-by-Inf). Assigning an unbounded matrix to `x`, which is an unbounded vector, results in an error.

If you want to use the implicitly expanded output, assign the output to a new variable with the same size as the output.

If you want `x` to retain its size and not apply implicit expansion in the generated code, use `coder. sameSizeBinaryOp` to apply the operation. You can also call `coder. noImplicitExpansionInFunction` in your function body to disable implicit expansion in the code generated for that function.

Implicit expansion automatically expands the operands to apply binary operations on arrays of compatible sizes. See “Generate Code With Implicit Expansion Enabled” (MATLAB Coder), “Optimize Implicit Expansion in Generated Code” (MATLAB Coder), and “Compatible Array Sizes for Basic Operations”.

## Diagnosing and Fixing Errors in Detecting Upper Bounds

### Issue: Using Nonconstant Dimensions in a Matrix Constructor

You can define variable-size data by assigning a variable to a matrix with nonconstant dimensions. For example:

```
function y = dims_vary(u) %#codegen
if (u > 0)
    y = ones(3,u);
else
    y = zeros(3,1);
end
```

However, compiling this function generates an error because you did not specify an upper bound for `u`.

To fix the problem, add an `assert` statement before the first use of `u`:

```
function y = dims_vary_fix(u) %#codegen
assert (u < 20);
if (u > 0)
    y = ones(3,u);
else
    y = zeros(3,1);
end
```

## Incompatibilities with MATLAB in Variable-Size Support for Code Generation

“Incompatibility with MATLAB in Matrix Indexing Operations for Code Generation” on page 58-21

“Incompatibility with MATLAB in Concatenating Variable-Size Matrices” on page 58-22

“Differences When Curly-Brace Indexing of Variable-Size Cell Array Inside Concatenation Returns No Elements” on page 58-22

### Incompatibility with MATLAB for Scalar Expansion

Scalar expansion is a method of converting scalar data to match the dimensions of vector or matrix data. If one operand is a scalar and the other is not, scalar expansion applies the scalar to every element of the other operand.

During code generation, scalar expansion rules apply except when operating on two variable-size expressions. In this case, both operands must be the same size. The generated code does not perform scalar expansion even if one of the variable-size expressions turns out to be scalar at run time. Therefore, when run-time error checks are enabled, a run-time error can occur.

Consider this function:

```
function y = scalar_exp_test_err1(u) %#codegen
y = ones(3);
switch u
    case 0
        z = 0;
    case 1
        z = 1;
    otherwise
        z = zeros(3);
end
y(:) = z;
```

When you generate code for this function, the code generator determines that `z` is variable size with an upper bound of 3.

Summary	All Messages (0)	Build Logs	Code Insights (1)	Variables
<b>Name</b>		<b>Type</b>	<b>Size</b>	<b>Class</b>
y		Output	3 × 3	double
u		Input	1 × 1	double
z		Local	:3 × :3	double

If you run the MEX function with `u` equal to 0 or 1, the generated code does not perform scalar expansion, even though `z` is scalar at run time. Therefore, when run-time error checks are enabled, a run-time error can occur.

```
scalar_exp_test_err1_mex(0)
Subscripted assignment dimension mismatch: [9] ~= [1].

Error in scalar_exp_test_err1 (line 11)
y(:) = z;
```

To avoid this issue, use indexing to force `z` to be a scalar value.

```
function y = scalar_exp_test_err1(u) %#codegen
y = ones(3);
switch u
    case 0
        z = 0;
    case 1
        z = 1;
    otherwise
        z = zeros(3);
end
y(:) = z(1);
```

## Incompatibility with MATLAB in Determining Size of Variable-Size N-D Arrays

For variable-size N-D arrays, the `size` function can return a different result in generated code than in MATLAB. In generated code, `size(A)` returns a fixed-length output because it does not drop trailing singleton dimensions of variable-size N-D arrays. By contrast, `size(A)` in MATLAB returns a variable-length output because it drops trailing singleton dimensions.

For example, if the shape of array `A` is `?x:?x:?` and `size(A,3)==1`, `size(A)` returns:

- Three-element vector in generated code
- Two-element vector in MATLAB code

### Workarounds

If your application requires generated code to return the same size of variable-size N-D arrays as MATLAB code, consider one of these workarounds:

- Use the two-argument form of `size`.  
For example, `size(A,n)` returns the same answer in generated code and MATLAB code.
- Rewrite `size(A)`:

```
B = size(A);
X = B(1:ndims(A));
```

This version returns `X` with a variable-length output. However, you cannot pass a variable-size `X` to matrix constructors such as `zeros` that require a fixed-size argument.

## Incompatibility with MATLAB in Determining Size of Empty Arrays

The size of an empty array in generated code might be different from its size in MATLAB source code. The size might be  $1 \times 0$  or  $0 \times 1$  in generated code, but  $0 \times 0$  in MATLAB. Therefore, you should not write code that relies on the specific size of empty matrices.

For example, consider the following code:

```
function y = foo(n) %#codegen
x = [];
i = 0;
while (i < 10)
    x = [5 x];
    i = i + 1;
end
if n > 0
    x = [];
end
y = size(x);
end
```

Concatenation requires its operands to match on the size of the dimension that is not being concatenated. In the preceding concatenation, the scalar value has size  $1 \times 1$  and  $x$  has size  $0 \times 0$ . To support this use case, the code generator determines the size for  $x$  as  $[1 \times ?]$ . Because there is another assignment  $x = []$  after the concatenation, the size of  $x$  in the generated code is  $1 \times 0$  instead of  $0 \times 0$ .

This behavior persists while determining the size of empty character vectors which are denoted as `''`. For example, consider the following code:

```
function out = string_size
out = size('');
end
```

Here, the value of `out` might be  $1 \times 0$  or  $0 \times 1$  in generated code, but  $0 \times 0$  in MATLAB.

For incompatibilities with MATLAB in determining the size of an empty array that results from deleting elements of an array, see “Size of Empty Array That Results from Deleting Elements of an Array” on page 53-17.

## Workaround

If your application checks whether a matrix is empty, use one of these workarounds:

- Rewrite your code to use the `isempty` function instead of the `size` function.
- Instead of using `x=[]` to create empty arrays, create empty arrays of a specific size using `zeros`. For example:

```
function y = test_empty(n) %#codegen
x = zeros(1,0);
i=0;
while (i < 10)
    x = [5 x];
    i = i + 1;
end
if n > 0
    x = zeros(1,0);
end
```

```
y=size(x);
end
```

## Incompatibility with MATLAB in Determining Class of Empty Arrays

The class of an empty array in generated code can be different from its class in MATLAB source code. Therefore, do not write code that relies on the class of empty matrices.

For example, consider the following code:

```
function y = fun(n)
x = [];
if n > 1
    x = ['a' x];
end
y=class(x);
end
```

`fun(0)` returns `double` in MATLAB, but `char` in the generated code. When the statement `n > 1` is false, MATLAB does not execute `x = ['a' x]`. The class of `x` is `double`, the class of the empty array. However, the code generator considers all execution paths. It determines that based on the statement `x = ['a' x]`, the class of `x` is `char`.

### Workaround

Instead of using `x=[]` to create an empty array, create an empty array of a specific class. For example, use `blanks(0)` to create an empty array of characters.

```
function y = fun(n)
x = blanks(0);
if n > 1
    x = ['a' x];
end
y=class(x);
end
```

## Incompatibility with MATLAB in Matrix-Matrix Indexing

In matrix-matrix indexing, you use one matrix to index into another matrix. In MATLAB, the general rule for matrix-matrix indexing is that the size and orientation of the result match the size and orientation of the index matrix. For example, if `A` and `B` are matrices, `size(A(B))` equals `size(B)`. When `A` and `B` are vectors, MATLAB applies a special rule. The special vector-vector indexing rule is that the orientation of the result is the orientation of the data matrix. For example, if `A` is 1-by-5 and `B` is 3-by-1, then `A(B)` is 1-by-3.

The code generator applies the same matrix-matrix indexing rules as MATLAB. If `A` and `B` are variable-size matrices, to apply the matrix-matrix indexing rules, the code generator assumes that `size(A(B))` equals `size(B)`. If, at run time, `A` and `B` become vectors and have different orientations, then the assumption is incorrect. Therefore, when run-time error checks are enabled, an error can occur.

To avoid this issue, force your data to be a vector by using the colon operator for indexing. For example, suppose that your code intentionally toggles between vectors and regular matrices at run time. You can do an explicit check for vector-vector indexing.

```

...
if isvector(A) && isvector(B)
    C = A(:);
    D = C(B(:));
else
    D = A(B);
end
...

```

The indexing in the first branch specifies that `C` and `B(:)` are compile-time vectors. Therefore, the code generator applies the indexing rule for indexing one vector with another vector. The orientation of the result is the orientation of the data vector, `C`.

## Incompatibility with MATLAB in Vector-Vector Indexing

In MATLAB, the special rule for vector-vector indexing is that the orientation of the result is the orientation of the data vector. For example, if `A` is 1-by-5 and `B` is 3-by-1, then `A(B)` is 1-by-3. If, however, the data vector `A` is a scalar, then the orientation of `A(B)` is the orientation of the index vector `B`.

The code generator applies the same vector-vector indexing rules as MATLAB. If `A` and `B` are variable-size vectors, to apply the indexing rules, the code generator assumes that the orientation of `B` matches the orientation of `A`. At run time, if `A` is scalar and the orientation of `A` and `B` do not match, then the assumption is incorrect. Therefore, when run-time error checks are enabled, a run-time error can occur.

To avoid this issue, make the orientations of the vectors match. Alternatively, index single elements by specifying the row and column. For example, `A(row, column)`.

## Incompatibility with MATLAB in Matrix Indexing Operations for Code Generation

The following limitation applies to matrix indexing operations for code generation:

- Initialization of the following style:

```

for i = 1:10
    M(i) = 5;
end

```

In this case, the size of `M` changes as the loop is executed. Code generation does not support increasing the size of an array over time.

For code generation, preallocate `M`.

```

M = zeros(1,10);
for i = 1:10
    M(i) = 5;
end

```

The following limitation applies to matrix indexing operations for code generation when dynamic memory allocation is disabled:

- $M(i:j)$  where  $i$  and  $j$  change in a loop

During code generation, memory is not dynamically allocated for the size of the expressions that change as the program executes. To implement this behavior, use `for`-loops as shown:

```

...
M = ones(10,10);
for i=1:10
    for j = i:10
        M(i,j) = 2*M(i,j);
    end
end
...

```

---

**Note** The matrix  $M$  must be defined before entering the loop.

---

## Incompatibility with MATLAB in Concatenating Variable-Size Matrices

For code generation, when you concatenate variable-size arrays, the dimensions that are not being concatenated must match exactly.

## Differences When Curly-Brace Indexing of Variable-Size Cell Array Inside Concatenation Returns No Elements

Suppose that:

- $c$  is a variable-size cell array.
- You access the contents of  $c$  by using curly braces. For example,  $c\{2:4\}$ .
- You include the results in concatenation. For example,  $[a \ c\{2:4\} \ b]$ .
- $c\{I\}$  returns no elements. Either  $c$  is empty or the indexing inside the curly braces produces an empty result.

For these conditions, MATLAB omits  $c\{I\}$  from the concatenation. For example,  $[a \ c\{I\} \ b]$  becomes  $[a \ b]$ . The code generator treats  $c\{I\}$  as the empty array  $[c\{I\}]$ . The concatenation becomes  $[\dots [c\{i\}] \dots]$ . This concatenation then omits the array  $[c\{I\}]$ . So that the properties of  $[c\{I\}]$  are compatible with the concatenation  $[\dots [c\{i\}] \dots]$ , the code generator assigns the class, size, and complexity of  $[c\{I\}]$  according to these rules:

- The class and complexity are the same as the base type of the cell array.
- The size of the second dimension is always 0.
- For the rest of the dimensions, the size of  $N_i$  depends on whether the corresponding dimension in the base type is fixed or variable size.
  - If the corresponding dimension in the base type is variable size, the dimension has size 0 in the result.
  - If the corresponding dimension in the base type is fixed size, the dimension has that size in the result.

Suppose that  $c$  has a base type with class `int8` and size `10x7x8x?`. In the generated code, the class of  $[c\{I\}]$  is `int8`. The size of  $[c\{I\}]$  is `0x0x8x0`. The second dimension is 0. The first and

last dimensions are 0 because those dimensions are variable size in the base type. The third dimension is 8 because the size of the third dimension of the base type is a fixed size 8.

Inside concatenation, if curly-brace indexing of a variable-size cell array returns no elements, the generated code can have the following differences from MATLAB:

- The class of `[...c{i}...]` in the generated code can differ from the class in MATLAB.

When `c{I}` returns no elements, MATLAB removes `c{I}` from the concatenation. Therefore, `c{I}` does not affect the class of the result. MATLAB determines the class of the result based on the classes of the remaining arrays, according to a precedence of classes. See “Valid Combinations of Unlike Classes”. In the generated code, the class of `[c{I}]` affects the class of the result of the overall concatenation `[...[c{I}]...]` because the code generator treats `c{I}` as `[c{I}]`. The previously described rules determine the class of `[c{I}]`.

- In the generated code, the size of `[c{I}]` can differ from the size in MATLAB.

In MATLAB, the concatenation `[c{I}]` is a 0x0 double. In the generated code, the previously described rules determine the size of `[c{I}]`.

## Variable-Sizing Restrictions for Code Generation of Toolbox Functions

### In this section...

“Common Restrictions” on page 58-24

“Toolbox Functions with Restrictions for Variable-Size Data” on page 58-24

### Common Restrictions

The following common restrictions apply to multiple toolbox functions, but only for code generation. To determine which of these restrictions apply to specific library functions, see the table in “Toolbox Functions with Restrictions for Variable-Size Data” on page 58-24.

#### Variable-length vector restriction

Inputs to the library function must be variable-length vectors or fixed-size vectors. A variable-length vector is a variable-size array that has the shape  $1 \times n$  or  $n \times 1$  (one dimension is variable sized and the other is fixed at size 1). Other shapes are not permitted, even if they are vectors at run time.

#### Automatic dimension restriction

This restriction applies to functions that take the working dimension (the dimension along which to operate) as input. In MATLAB and in code generation, if you do not supply the working dimension, the function selects it. In MATLAB, the function selects the first dimension whose size does not equal 1. For code generation, the function selects the first dimension that has a variable size or that has a fixed size that does not equal 1. If the working dimension has a variable size and it becomes 1 at run time, then the working dimension is different from the working dimension in MATLAB. Therefore, when run-time error checks are enabled, an error can occur.

For example, suppose that  $X$  is a variable-size matrix with dimensions  $1 \times 3 \times 5$ . In the generated code, `sum(X)` behaves like `sum(X,2)`. In MATLAB, `sum(X)` behaves like `sum(X,2)` unless `size(X,2)` is 1. In MATLAB, when `size(X,2)` is 1, `sum(X)` behaves like `sum(X,3)`.

To avoid this issue, specify the intended working dimension explicitly as a constant value. For example, `sum(X,2)`.

#### Array-to-vector restriction

The function issues an error when a variable-size array that is not a variable-length vector assumes the shape of a vector at run time. To avoid the issue, specify the input explicitly as a variable-length vector instead of a variable-size array.

#### Array-to-scalar restriction

The function issues an error if a variable-size array assumes a scalar value at run time. To avoid this issue, specify scalars as fixed size.

### Toolbox Functions with Restrictions for Variable-Size Data

The following table lists functions that have code generation restrictions for variable-size data. For additional restrictions for these functions, and restrictions for all functions and objects supported for

code generation, see “Functions and Objects Supported for C/C++ Code Generation” (MATLAB Coder).

Function	Restrictions for Variable-Size Data
all	<ul style="list-style-type: none"> <li>See “Automatic dimension restriction” on page 58-24.</li> <li>An error occurs if you pass the first argument a variable-size matrix that is 0-by-0 at run time.</li> </ul>

## Generate Code With Implicit Expansion Enabled

Implicit expansion refers to the automatic size change of compatible operands to apply element-wise operations. Two dimensions have compatible sizes if, for every dimension, the dimension sizes of the arrays are either the same or one of them is singleton. See “Compatible Array Sizes for Basic Operations”.

Implicit expansion in the generated code is enabled by default. Code generated with implicit expansion enabled might differ from code generated with implicit expansion disabled in these ways:

- Output size
- Additional code generation
- Performance variation

For variable-size dynamic arrays, the generated code exhibits these changes to accomplish implicit expansion at run-time.

For fixed-size and constant arrays, because the values and sizes of the operands are known at compile time, the code generated to calculate the implicitly expanded output does not require additional code generation or cause performance variations.

To control implicit expansion in the generated code, see “Optimize Implicit Expansion in Generated Code” (MATLAB Coder).

### Output Size

Implicit expansion automatically expands the operands to apply element-wise operations. For example, consider these input types of compatible size:

```
a_type = coder.typeof(1,[2 1]);
b_type = coder.typeof(1,[2 inf]);
```

A binary operation on these two operands with implicit expansion enabled automatically expands the second dimension of `a_type` to result in an output size of 2-by-Inf. With implicit expansion disabled, the second dimension of `a_type` is not automatically expanded, and the output size is 2-by-1.

For existing workflows created with implicit expansion disabled in the generated code, generating code for the same MATLAB code with implicit expansion enabled might generate size mismatch errors or change the size of outputs from binary operations and functions. To troubleshoot size mismatch errors, see “Diagnose and Fix Variable-Size Data Errors” (MATLAB Coder).

### Additional Code Generation

Implicit expansion enables the operands to be automatically expanded if the operand sizes are compatible. To perform this size change, the generated code introduces code that allows the operands to be expanded.

For example, consider the following code snippet. The function `vector_sum` finds the sum of two arrays.

```
function out = vector_sum(a,b)
out = a + b;
end
```

Consider the variable-size dynamic array defined here:

```
c_type = coder.typeof(1,[1 Inf]);
```

Generate code for `vector_sum` by using this command:

```
codegen vector_sum -args {c_type, c_type} -config:lib -report
```

The generated code for this function with implicit expansion:

```
static void plus(emxArray_real_T *out,
... const emxArray_real_T *b, const emxArray_real_T *a)
{
    int i;
    ....
    if (a->size[1] == 1) {
        out->size[1] = b->size[1];
    } else {
        out->size[1] = a->size[1];
    }
    ....
    if (a->size[1] == 1) {
        loop_ub = b->size[1];
    }
    else {
        loop_ub = a->size[1];
    }
    for (i = 0; i < loop_ub; i++) {
        out->data[i] = b->data[i * stride_0_1] + a->data[i * stride_1_1];
    }
}
void vector_sum(const emxArray_real_T *a, const emxArray_real_T *b, emxArray_real_T *out)
{
    int i;
    int loop_ub;
    if (b->size[1] == a->size[1]) {
        i = out->size[0] * out->size[1];
        out->size[0] = 1;
        out->size[1] = b->size[1];
        emxEnsureCapacity_real_T(out, i);
        loop_ub = b->size[1];
        for (i = 0; i < loop_ub; i++) {
            out->data[i] = b->data[i] + a->data[i];
        }
    } else {
        plus(out, b, a);
    }
}
```

The generated code for this function without implicit expansion:

```
void vector_sum(const emxArray_real_T *a,
... const emxArray_real_T *b, emxArray_real_T *out){
    int i;
    int loop_ub;
    i = out->size[0] * out->size[1];
    out->size[0] = 1;
    out->size[1] = b->size[1];
```

```

    emxEnsureCapacity_real_T(out, i);
    loop_ub = b->size[1];
    for (i = 0; i < loop_ub; i++) {
        out->data[i] = b->data[i] + a->data[i];
    }
}

```

With implicit expansion enabled, the code generator creates a supporting function, in this case `plus`, to carry out the size change and to calculate the output.

In most cases, the supporting function carrying out implicit expansion is named after the binary operation it is assisting. In the previous example, if the expression `out = a + b` is changed to `out = a - b`, the name of the supporting function changes to `minus`.

Some supporting functions might also be named as `expand_op`, where `op` refers to the binary operation. In the previous example, if the expression `out = a + b` is replaced with `out = max(a, b)`, the name of the supporting function in the generated code changes to `expand_max`.

If multiple operations in an expression require implicit expansion, the generated code includes a supporting function that is named `binary_expand_op`. The supporting functions change the size of the operand and apply the binary operations.

If you want to apply specific binary operations and functions without implicit expansion, use `coder.sameSizeBinaryOp`. The code generated to apply this function does not include additional code to expand the operands. The output of this function does not expand the operands in MATLAB. This function does not support scalar expansion. Operands must be of the same size.

If you want to disable implicit expansion inside a function for all binary operations within that function in the generated code, call `coder.noImplicitExpansionInFunction` in the required function. Implicit expansion in MATLAB code is still enabled.

## Performance Variation

Code generated with implicit expansion enabled might perform differently than when implicit expansion is disabled. Depending on the input to the generated code that uses implicit expansion, the code might take longer to evaluate the output.

If the generated code does not match the performance requirements of your workflow due to implicit expansion, generate code for your project by turning off implicit expansion for specific binary operations, specific function bodies, or for your whole project. See “Optimize Implicit Expansion in Generated Code” (MATLAB Coder).

---

**Note** Before disabling implicit expansion, ensure that the external code does not use implicit expansion. Disabling implicit expansion for an entire project might cause errors when generating code if your project includes MATLAB code from external sources.

## Optimize Implicit Expansion in Generated Code

Implicit expansion in the generated code is enabled by default. The code generator introduces modifications in the generated code to perform implicit expansion. The changes in the generated code might result in additional code to expand the operands. The expansion of the operands might affect the performance of the generated code. See “Generate Code With Implicit Expansion Enabled” (MATLAB Coder).

Implicit expansion might change the size of the outputs from the supported operators and functions causing size and type mismatch errors in your workflow.

For fine-grained control of where implicit expansion is enabled in the generated code, use the following functions in your MATLAB code:

- `coder.noImplicitExpansionInFunction`
- `coder.sameSizeBinaryOp`

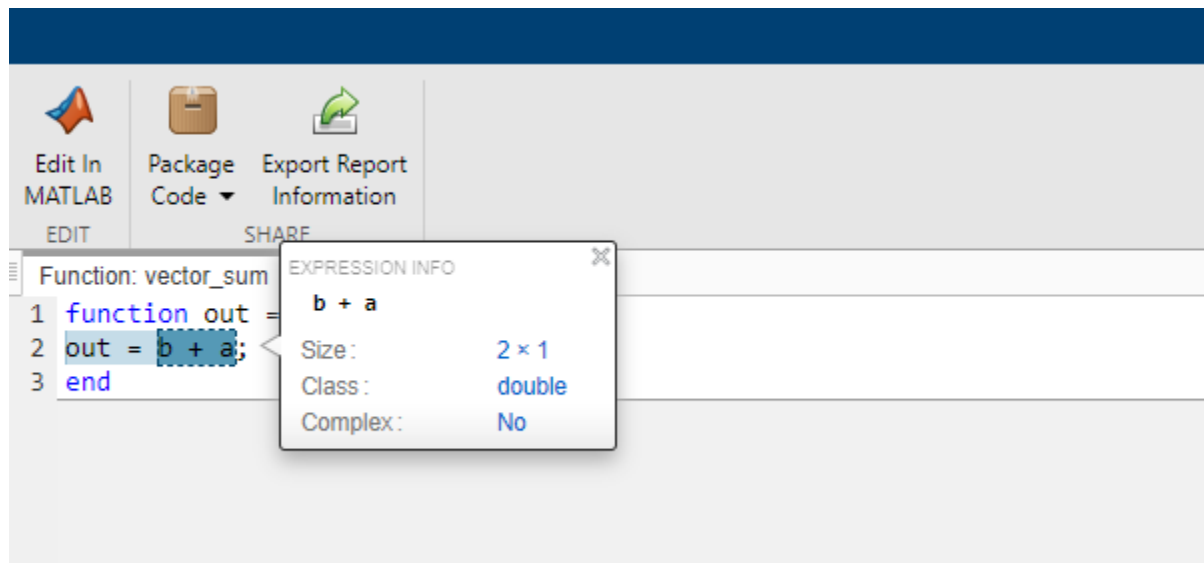

For example, consider this code snippet. The function `vector_sum` finds the sum of two arrays of compatible sizes.

```
function out = vector_sum(a,b)
out = b + a;
end
```

The types of operands `a` and `b` are defined as:

```
a_type = coder.typeof(1,[2 1])      %size: 2x1
b_type = coder.typeof(1,[2 Inf])    %size: 2x:inf
```

Without implicit expansion, the size of the `out` variable is calculated as `2x1`.

With implicit expansion, the size of the variable `out` is calculated as `2x:?`.

These code snippets outline the changes in the generated code for the function `vector_sum`, while implicit expansion is disabled and enabled. To generate the code, the types of operands `a` and `b` are defined as:

```
a_type = coder.typeof(1,[1 Inf])    %size: 1x:inf
b_type = coder.typeof(1,[1 Inf])    %size: 1x:inf
```

Generated Code With Implicit Expansion Disabled	Generated Code With Implicit Expansion Enabled
<pre>void vector_sum(const emxArray_real_T *a, const emxArray_real_T *out) {     int i;     int loop_ub;     i = out-&gt;size[0] * out-&gt;size[1];     out-&gt;size[0] = 1;     out-&gt;size[1] = b-&gt;size[1];     emxEnsureCapacity_real_T(out, i);     loop_ub = b-&gt;size[1];     for (i = 0; i &lt; loop_ub; i++) {         out-&gt;data[i] = b-&gt;data[i] + a-&gt;data[i];     } }</pre>	<pre>static void plus(const emxArray_real_T *out, const emxArray_real_T *a) {     int i;     ....     if (a-&gt;size[1] == 1) {         out-&gt;size[1] = b-&gt;size[1];     } else {         out-&gt;size[1] = a-&gt;size[1];     }     ....     if (a-&gt;size[1] == 1) {         loop_ub = b-&gt;size[1];     } else {         loop_ub = a-&gt;size[1];     }     for (i = 0; i &lt; loop_ub; i++) {         out-&gt;data[i] = b-&gt;data[i * stride_0_1] + a-&gt;data[i];     } }  void vector_sum(const emxArray_real_T *a, const emxArray_real_T *out) {     int i;     int loop_ub;     if (b-&gt;size[1] == a-&gt;size[1]) {         i = out-&gt;size[0] * out-&gt;size[1];         out-&gt;size[0] = 1;         out-&gt;size[1] = b-&gt;size[1];         emxEnsureCapacity_real_T(out, i);         loop_ub = b-&gt;size[1];         for (i = 0; i &lt; loop_ub; i++) {             out-&gt;data[i] = b-&gt;data[i] + a-&gt;data[i];         }     } else {         plus(out, b, a);     } }</pre>

## Disable Implicit Expansion in Specified Function by Using `coder.noImplicitExpansionInFunction`

If you require implicit expansion in your project but not in specific functions, disable implicit expansion for the generated code of that function by calling `coder.noImplicitExpansionInFunction` within the function.

For example, the code generated for `vector_sum` does not apply implicit expansion.

MATLAB Code	Generated Code with <code>coder.sameSizeBinaryOp</code>
<pre>function out = vector_sum(a,b) coder.noImplicitExpansionInFunction(); out = a + b; end  a = coder.typeof(1,[1 Inf]) %size: 1x:inf b = coder.typeof(1,[1 Inf]) %size: 1x:inf codegen vector_sum -launchreport ... -args {a,b} -config:lib</pre>	<pre>void vector_sum(const emxArray_real_T *a, const emxArray_real_T *b, emxArray_real_T *out) {     int i;     int loop_ub;     i = out-&gt;size[0] * out-&gt;size[1];     out-&gt;size[0] = 1;     out-&gt;size[1] = a-&gt;size[1];     emxEnsureCapacity_real_T(out, i);     loop_ub = a-&gt;size[1];     for (i = 0; i &lt; loop_ub; i++) {         out-&gt;data[i] = a-&gt;data[i] + b-&gt;data[i];     } }</pre>

**Note** `coder.noImplicitExpansionInFunction` does not disable implicit expansion in your MATLAB code. It disables implicit expansion only in the generated code.

## Disable Implicit Expansion for Specific Binary Operation by Using `coder.sameSizeBinaryOp`

Use the function `coder.sameSizeBinaryOp` to perform an error check to ensure that the operands are the same size and prevent the code generator from generating implicitly expanded code for that function.

For example, this code snippet applies the plus operation by using `coder.sameSizeBinaryOp` without implicit expansion.

MATLAB Code	Generated Code
<pre>function out = vector_sum(a,b) out = coder.sameSizeBinaryOp(@plus, a, b); end  a = coder.typeof(1,[1 Inf]) %size: 1x:inf b = coder.typeof(1,[1 Inf]) %size: 1x:inf codegen vector_sum -launchreport ... -args {a,b} -config:lib</pre>	<pre>void vector_sum(const emxArray_real_T *a, const emxArray_real_T *b, emxArray_real_T *out) {     int i;     int loop_ub;     i = out-&gt;size[0] * out-&gt;size[1];     out-&gt;size[0] = 1;     out-&gt;size[1] = a-&gt;size[1];     emxEnsureCapacity_real_T(out, i);     loop_ub = a-&gt;size[1];     for (i = 0; i &lt; loop_ub; i++) {         out-&gt;data[i] = a-&gt;data[i] + b-&gt;data[i];     } }</pre>

`coder.sameSizeBinaryOp` does not support scalar expansion. Operands given to `coder.sameSizeBinaryOp` must be of the same size.

## Disable Implicit Expansion in your Project

If you do not require implicit expansion in your generated code or do not want the modifications to affect your generated code, turn it off by setting the `EnableImplicitExpansion` flag in your `coder.config` object to `false`. This flag is set to `true` by default.

```
cfg = coder.config;  
cfg.EnableImplicitExpansion = false;
```

Disable implicit expansion in your Simulink model by setting the model-wide parameter **Enable Implicit Expansion in MATLAB functions** to `false`. Alternatively, use this command:

```
set_param(gcs, 'EnableImplicitExpansion', false);
```

---

**Note** Before turning off implicit expansion, ensure that the external code does not use implicit expansion. Disabling implicit expansion for an entire project might cause errors when generating code if your project includes MATLAB code from external sources.

## Representation of Arrays in Generated Code

The code generator produces C/C++ array definitions that depend on the array element type and whether the array uses static or dynamic memory allocation. Use the generated array implementations to interface your arrays with the generated code.

Memory allocation for arrays require different implementations:

- For a fixed-size array or a variable-size array whose size is bounded within a predefined memory threshold, the generated C/C++ definition consists of a fixed-size array of elements and a size vector that stores the total number of array elements. In some cases, the fixed-size element array and the size vector are stored within a structure. The memory for this array comes from the program stack and is statically allocated.
- For an array whose size is unbounded at compile time, or whose bounds exceed the predefined threshold, the generated C definition consists of a data structure called an `emxArray`. The generated C++ definition consists of a `coder::array` class template.

The predefined threshold size (in bytes) is specified in your configuration objects. The default value of the parameter is 65536. See `DynamicMemoryAllocationThreshold` in `coder.MexCodeConfig`, `coder.CodeConfig`, or `coder.EmbeddedCodeConfig`.

For dynamically allocated arrays, the run-time allocated size is set based on the current array size. During program execution, as run-time allocated size is exceeded, the generated code reallocates additional memory space from the heap and adds it to the dynamic array storage.

This table lists a few typical cases for array representation in the generated code.

Algorithm Description and Array Size	MATLAB Function	Generated C/C++ Code
<p>Create a fixed-size 1-by-500 row vector. The array is the output of the MATLAB function</p> <p>The generated code allocates memory to a fixed-size vector on the program stack.</p>	<pre>function B = create_vec0 B = zeros(1,500); end</pre>	<pre>create_vec0(double B[500]) {     memset(&amp;B[0], 0, 500U * sizeof(double)); }</pre> <p>The array is the input to the function in the generated code.</p>
<p>Create a fixed-size 1-by-20 row vector. Declare the array as variable-size with bounds at 500 elements. Assign this variable-size array to the input array.</p> <p>This array is bound within the size threshold and is the input to the function in the generated code.</p>	<pre>function create_vec1(B) A = zeros(1,20); coder.ysize('A',[1 500],[0 1]); B = A; end</pre>	<pre>create_vec1(double B_data[], int B_size[]) {     int i;     B_size[0] = 1;     B_size[1] = 20;     for (i = 0; i &lt; 20; i++) {         B_data[i] = 1.0;     } }</pre> <p><b>Note</b> The generated code includes the inputs in the function parameters.</p>

Algorithm Description and Array Size	MATLAB Function	Generated C/C++ Code
<p>Create a local fixed-size 1-by-20000 row vector. Declare the array as variable-size with bounds at 30,000 elements.</p> <p>The variable-size array exceeds the predefined dynamic memory allocation threshold. This array is stored on heap memory.</p> <p>The generated code includes the output array in the function parameter.</p>	<pre>function B = create_vec2() %C A = ones(1,20000); coder.varsize("A",[1 30000], B = [1 A]; end</pre>	<pre>C: void create_vec2(emxArray_real_T *B) {     double *B_data;     int i;     i = B-&gt;size[0] * B-&gt;size[1];     B-&gt;size[0] = 1;     B-&gt;size[1] = 20001;     emxEnsureCapacity_real_T(B, i);     B_data = B-&gt;data;     B_data[0] = 1.0;     for (i = 0; i &lt; 20000; i++) {         B_data[i + 1] = 1.0;     } }  C++: void create_vec2(coder::array&lt;double, 2 {     B.set_size(1, 20001);     B[0] = 1.0;     for (int i{0}; i &lt; 20000; i++) {         B[i + 1] = 1.0;     } }</pre>

Algorithm Description and Array Size	MATLAB Function	Generated C/C++ Code
<p>Create an array that has the size determined by an unbounded integer input.</p> <p>The generated array size is unknown and unbounded at compile time.</p>	<pre>function y = create_vec3(n) y = ones(1,n,'int8');</pre>	<pre>%codegen void create_vec3(double n, mxArray_int {     int i;     int loop_ub_tmp;     signed char *y_data;     i = y-&gt;size[0] * y-&gt;size[1];     y-&gt;size[0] = 1;     loop_ub_tmp = (int)n;     y-&gt;size[1] = (int)n;     emxEnsureCapacity_int8_T(y, i);     y_data = y-&gt;data;     for (i = 0; i &lt; loop_ub_tmp; i++) {         y_data[i] = 1;     } }  C++:  void create_vec3(double n, coder::array {     int loop_ub_tmp;     loop_ub_tmp = static_cast&lt;int&gt;(n);     y.set_size(1, loop_ub_tmp);     for (int i{0}; i &lt; loop_ub_tmp; i++)         y[i] = 1; } }</pre>

To learn about the `emxArray` data structure, see “Use C Arrays in the Generated Function Interfaces” (MATLAB Coder).

To learn about the `coder::array` class template, see “Use Dynamically Allocated C++ Arrays in Generated Function Interfaces” (MATLAB Coder).

## Customize Interface Generation

By default, the generated C++ code uses the `coder::array` template to implement dynamically allocated arrays. You can choose to generate C++ code that uses the C style `emxArray` data structure to implement dynamically allocated arrays. To generate C style `emxArray` data structures, do either of the following:

- In a code configuration object (`coder.MexCodeConfig`, `coder.CodeConfig`, or `coder.EmbeddedCodeConfig`), set the `DynamicMemoryAllocationInterface` parameter to 'C'.
- Alternatively, In the MATLAB Coder app, on the **Memory** tab, set **Dynamic memory allocation interface** to Use C style `EmxArray`.

To create dynamically allocated arrays for variable-size arrays in the generated code, do either of the following:

- Set the `EnabledDynamicMemoryAllocation` flag to `true`.
- Alternatively, in the MATLAB Coder App, on the **Memory** tab, select the **Enable dynamic memory allocation** option.

By default, arrays that are bounded within a threshold size do not use dynamic allocation in the generated code. Alternatively, you can disable dynamic memory allocation and change the dynamic memory allocation threshold. See “Control Memory Allocation for Variable-Size Arrays” (MATLAB Coder).

## Control Memory Allocation for Fixed-Size Arrays

Dynamic memory allocation for fixed-size arrays allocates memory for the array on the heap instead of allocating memory on the program stack. Consider using dynamic memory allocation when:

- The fixed-size arrays are large and you do not want to allocate memory on the stack.
- Your target hardware memory is limited and you do not want to allocate memory for the arrays on the program stack.

For larger arrays, you can significantly reduce storage requirements. Dynamic memory allocation might result in slower execution of the generated code.

### Enable Dynamic Memory Allocation for All Fixed-Size Arrays

By default, dynamic memory allocation for fixed-size arrays is disabled. To enable it:

- In a configuration object for code generation, set the `DynamicMemoryAllocationForFixedSizeArrays` parameter to `'Always'`.
- Alternatively, in the app, under **Memory** settings, set **Dynamic memory allocation fixed-sized arrays** to `'Always'`.

The code generator dynamically allocates memory on the heap for all fixed-size arrays whose size is greater than 64 bytes.

### Enable Dynamic Memory Allocation for Arrays Bigger Than a Threshold

Instead of allocating all fixed-size arrays dynamically on the heap, you can specify the threshold size above which memory is dynamically allocated. To instruct the code generator to use dynamic memory allocation for fixed-size arrays whose size is greater than or equal to the threshold:

- In the configuration object, set the `DynamicMemoryAllocationForFixedSizeArrays` to `'Threshold'`.
- In the MATLAB Coder app, in the **Memory settings**, set **Dynamic memory allocation for fixed-sized arrays** to `For arrays with max size at or above threshold`.

## Resolve Error: Size Mismatches

### Issue

The code generator produces size mismatch errors when array sizes are incompatible or implicit expansion is unavailable.

Most binary operators and functions in MATLAB and generated code support numeric arrays that have compatible sizes. Two inputs have compatible sizes if, for every dimension, the sizes of the inputs are either the same or one of them is 1. In the simplest cases, two array sizes are compatible if they are exactly the same or if one is a scalar. For example:

```
magic(4) + ones(4,1);
% where magic(4) =          ones(4,1) =
%   16     2     3     13          1
%   5     11    10     8          1
%   9     7     6     12          1
%   4     14    15     1          1

ans =

    17     3     4    14
     6    12    11     9
    10     8     7    13
     5    15    16     2
```

The second array implicitly expands to match the dimensions of the first matrix. For more information, see “Compatible Array Sizes for Basic Operations”.

Implicit expansion might be unavailable while performing binary operations on arrays of compatible size if any the following conditions are true :

- Your function scope includes the `coder.noImplicitExpansionInFunction` function.
- You use the `coder.sameSizeBinaryOp` function to carry out the binary operation.
- You turn off implicit expansion for your project.

Size mismatches or unavailability of implicit expansion generates the following error:

```
%Size mismatch between two arrays
Size mismatch (size [10][1] ~= size [1][10])
```

When the above conditions are true for structure fields and cell elements, the code generator produces the following errors respectively:

```
%Size mismatch in structure fields
Size mismatch (size [10][1] ~= size [1][10]) in field StructField

%Size mismatch in cell elements
Size mismatch (size [10][1] ~= size [1][10]) in element cellElement.
```

### Possible Solutions

Verify that, in binary operations where you enable implicit expansion, the operations are in the scope of functions. Check for these conditions:

- Array size compatibility.
- Binary operations in the scope of functions that call `coder.noImplicitExpansionInFunction`.
- `coder.sameSizeBinaryOp` does not implicitly expand its operands or support scalar expansion.
- If you have turned off implicit expansion for the whole project, all operations that require implicit expansion generate an error.

### **Perform Binary Operations on Arrays of Compatible Sizes**

If you must carry out a binary operation on arrays of differing sizes, make sure that sizes are compatible and implicit expansion is enabled in the function scope. See “Compatible Array Sizes for Basic Operations”.

### **Call Binary Operation Without `coder.noImplicitExpansionInFunction`**

If you must include `coder.noImplicitExpansionInFunction` in your function, call the required binary operation in another function where implicit expansion is enabled.

### **Call Binary Operation Without `coder.sameSizeBinaryOp`**

If you do not want implicit expansion for a specific operation, provide input arguments that are of same size to `coder.sameSizeBinaryOp`. `coder.sameSizeBinaryOp` does not allow scalar expansion and generates an error if the input arguments are not of the same size.

### **Enable Implicit Expansion for Project**

If enabling implicit expansion does not affect your project, consider enabling it by setting the `EnableImplicitExpansion` property in your code configuration object to `true`.

If you need implicit expansion for specific operations, consider using `coder.sameSizeBinaryOp` or `coder.noImplicitExpansionInFunction` to prevent the other operations from implicitly expanding. See “Optimize Implicit Expansion in Generated Code” (MATLAB Coder).

- “Assign Values to Structures and Fields” on page 59-10
- “Pass Large Structures as Input Parameters” on page 59-11

## Structure Definition for Code Generation

To generate efficient standalone code for structures, you must define and use structures differently than you normally would when running your code in the MATLAB environment:

<b>What's Different</b>	<b>More Information</b>
Use a restricted set of operations.	"Structure Operations Allowed for Code Generation" on page 59-3
Observe restrictions on properties and values of scalar structures.	"Define Scalar Structures for Code Generation" on page 59-4
Make structures uniform in arrays.	"Define Arrays of Structures for Code Generation" on page 59-6
Reference structure fields individually during indexing.	"Index Substructures and Fields" on page 49-67
Avoid type mismatch when assigning values to structures and fields.	"Assign Values to Structures and Fields" on page 49-71

## Structure Operations Allowed for Code Generation

To generate efficient standalone code for MATLAB structures, you are restricted to the following operations:

- Index structure fields using dot notation
- Define primary function inputs as structures
- Pass structures to local functions

## Define Scalar Structures for Code Generation

### In this section...

“Restrictions When Defining Scalar Structures by Assignment” on page 59-4

“Adding Fields in Consistent Order on Each Control Flow Path” on page 59-4

“Restriction on Adding New Fields After First Use” on page 59-4

### Restrictions When Defining Scalar Structures by Assignment

When you define a scalar structure by assigning a variable to a preexisting structure, you do not need to define the variable before the assignment. However, if you already defined that variable, it must have the same class, size, and complexity as the structure you assign to it. In the following example, `p` is defined as a structure that has the same properties as the predefined structure `S`:

```
...
S = struct('a', 0, 'b', 1, 'c', 2);
p = S;
...
```

### Adding Fields in Consistent Order on Each Control Flow Path

When you create a structure, you must add fields in the same order on each control flow path. For example, the following code generates a compiler error because it adds the fields of structure `x` in a different order in each `if` statement clause:

```
function y = fcn(u) %#codegen
if u > 0
    x.a = 10;
    x.b = 20;
else
    x.b = 30; % Generates an error (on variable x)
    x.a = 40;
end
y = x.a + x.b;
```

In this example, the assignment to `x.a` comes before `x.b` in the first `if` statement clause, but the assignments appear in reverse order in the `else` clause. Here is the corrected code:

```
function y = fcn(u) %#codegen
if u > 0
    x.a = 10;
    x.b = 20;
else
    x.a = 40;
    x.b = 30;
end
y = x.a + x.b;
```

### Restriction on Adding New Fields After First Use

You cannot add fields to a structure after you perform the following operations on the structure:

- Reading from the structure
- Indexing into the structure array
- Passing the structure to a function

For example, consider this code:

```
...  
x.c = 10; % Defines structure and creates field c  
y = x; % Reads from structure  
x.d = 20; % Generates an error  
...
```

In this example, the attempt to add a new field `d` after reading from structure `x` generates an error.

This restriction extends across the structure hierarchy. For example, you cannot add a field to a structure after operating on one of its fields or nested structures, as in this example:

```
function y = fcn(u) %#codegen  
  
x.c = 10;  
y = x.c;  
x.d = 20; % Generates an error
```

In this example, the attempt to add a new field `d` to structure `x` after reading from the structure's field `c` generates an error.

## Define Arrays of Structures for Code Generation

### In this section...

“Ensuring Consistency of Fields” on page 59-6

“Using repmat to Define an Array of Structures with Consistent Field Properties” on page 59-6

“Defining an Array of Structures by Using struct” on page 59-6

“Defining an Array of Structures Using Concatenation” on page 59-7

### Ensuring Consistency of Fields

For code generation, when you create an array of MATLAB structures, corresponding fields in the array elements must have the same size, type, and complexity.

Once you have created the array of structures, you can make the structure fields variable-size by using `coder. varsize`. See “Declare Variable-Size Structure Fields” (MATLAB Coder).

### Using repmat to Define an Array of Structures with Consistent Field Properties

You can create an array of structures from a scalar structure by using the MATLAB `repmat` function, which replicates and tiles an existing scalar structure:

- 1 Create a scalar structure, as described in “Define Scalar Structures for Code Generation” on page 59-4.
- 2 Call `repmat`, passing the scalar structure and the dimensions of the array.
- 3 Assign values to each structure using standard array indexing and structure dot notation.

For example, the following code creates `X`, a 1-by-3 array of scalar structures. Each element of the array is defined by the structure `s`, which has two fields, `a` and `b`:

```
...  
s.a = 0;  
s.b = 0;  
X = repmat(s,1,3);  
X(1).a = 1;  
X(2).a = 2;  
X(3).a = 3;  
X(1).b = 4;  
X(2).b = 5;  
X(3).b = 6;  
...
```

### Defining an Array of Structures by Using struct

To create an array of structures using the `struct` function, specify the field value arguments as cell arrays. Each cell array element is the value of the field in the corresponding structure array element. For code generation, corresponding fields in the structures must have the same type. Therefore, the elements in a cell array of field values must have the same type.

For example, the following code creates a 1-by-3 structure array. For each structure in the array of structures, `a` has type `double` and `b` has type `char`.

```
s = struct('a', {1 2 3}, 'b', {'a' 'b' 'c'});
```

## Defining an Array of Structures Using Concatenation

To create a small array of structures, you can use the concatenation operator, square brackets ( `[ ]` ), to join one or more structures into an array. See “Creating, Concatenating, and Expanding Matrices”. For code generation, the structures that you concatenate must have the same size, class, and complexity.

For example, the following code uses concatenation and a local function to create the elements of a 1-by-3 structure array:

```
...  
W = [ sab(1,2) sab(2,3) sab(4,5) ];  
  
function s = sab(a,b)  
    s.a = a;  
    s.b = b;  
...
```

## Index Substructures and Fields

Use these guidelines when indexing substructures and fields for code generation:

### Reference substructure field values individually using dot notation

For example, the following MATLAB code uses dot notation to index fields and substructures:

```

...
substruct1.a1 = 15.2;
substruct1.a2 = int8([1 2;3 4]);

mystruct = struct('ele1',20.5,'ele2',single(100),
                 'ele3',substruct1);

substruct2 = mystruct;
substruct2.ele3.a2 = 2*(substruct1.a2);
...

```

The generated code indexes elements of the structures in this example by resolving symbols as follows:

Dot Notation	Symbol Resolution
substruct1.a1	Field a1 of local structure substruct1
substruct2.ele3.a1	Value of field a1 of field ele3, a substructure of local structure substruct2
substruct2.ele3.a2(1,1)	Value in row 1, column 1 of field a2 of field ele3, a substructure of local structure substruct2

### Reference field values individually in structure arrays

To reference the value of a field in a structure array, you must index into the array to the structure of interest and then reference that structure's field individually using dot notation, as in this example:

```

...
y = X(1).a % Extracts the value of field a
           % of the first structure in array X
...

```

To reference all the values of a particular field for each structure in an array, use this notation in a for loop, as in this example:

```

...
s.a = 0;
s.b = 0;
X = repmat(s,1,5);
for i = 1:5
    X(i).a = i;
    X(i).b = i+1;
end
...

```

This example uses the `repmat` function to define an array of structures, each with two fields `a` and `b` as defined by `s`. See “Define Arrays of Structures for Code Generation” on page 59-6 for more information.

**Do not reference fields dynamically**

You cannot reference fields in a structure by using dynamic names, which express the field as a variable expression that MATLAB evaluates at run time (see “Generate Field Names from Variables”).

## Assign Values to Structures and Fields

When assigning values to a structure, substructure, or field for code generation, use these guidelines:

### Field properties must be consistent across structure-to-structure assignments

If:	Then:
Assigning one structure to another structure.	Define each structure with the same number, type, and size of fields.
Assigning one structure to a substructure of a different structure and vice versa.	Define the structure with the same number, type, and size of fields as the substructure.
Assigning an element of one structure to an element of another structure.	The elements must have the same type and size.

### For structures with constant fields, do not assign field values inside control flow constructs

In the following code, the code generator recognizes that the structure fields `s.a` and `s.b` are constants.

```
function y = mystruct()
s.a = 3;
s.b = 5;
y = zeros(s.a,s.b);
```

If a field of a structure is assigned inside a control flow construct, the code generator does not recognize that `s.a` and `s.b` are constant. Consider the following code:

```
function y = mystruct(x)
s.a = 3;
if x > 1
    s.b = 4;
else
    s.b = 5;
end
y = zeros(s.a,s.b);
```

If variable-sizing is enabled, `y` is treated as a variable-size array. If variable-sizing is disabled, `y`, the code generator reports an error.

### Do not assign mxArray to structures

You cannot assign `mxArrays` to structure elements; convert `mxArrays` to known types before code generation (see “Working with `mxArrays`” on page 69-9).

### Do not assign handle classes or sparse arrays to global structure variables

Global structure variables cannot contain handle objects or sparse arrays.

## Pass Large Structures as Input Parameters

If you generate a MEX function for a MATLAB function that takes a large structure as an input parameter, for example, a structure containing fields that are matrices, the MEX function might fail to load. This load failure occurs because, when you generate a MEX function from a MATLAB function that has input parameters, the code generator allocates memory for these input parameters on the stack. To avoid this issue, pass the structure by reference to the MATLAB function. For example, if the original function signature is:

```
y = foo(a, S)
```

where S is the structure input, rewrite the function to:

```
[y, S] = foo(a, S)
```

# Code Generation for Cell Arrays

- “Code Generation for Cell Arrays” on page 60-2
- “Control Whether a Cell Array Is Variable-Size” on page 60-4
- “Cell Array Limitations for Code Generation” on page 60-6

## Code Generation for Cell Arrays

When you generate code from MATLAB code that contains cell arrays, the code generator classifies the cell arrays as homogeneous or heterogeneous. This classification determines how a cell array is represented in the generated code. It also determines how you can use the cell array in MATLAB code from which you generate code.

When you use cell arrays in MATLAB code that is intended for code generation, you must adhere to certain restrictions. See “Cell Array Limitations for Code Generation” on page 60-6.

### Homogeneous vs. Heterogeneous Cell Arrays

A homogeneous cell array has these characteristics:

- The cell array is represented as an array in the generated code.
- All elements have the same properties. The type associated with the cell array specifies the properties of all elements rather than the properties of individual elements.
- The cell array can be variable-size.
- You can index into the cell array with an index whose value is determined at run time.

A heterogeneous cell array has these characteristics:

- The cell array is represented as a structure in the generated code. Each element is represented as a field of the structure.
- The elements can have different properties. The type associated with the cell array specifies the properties of each element individually.
- The cell array cannot be variable-size.
- You must index into the cell array with a constant index or with `for`-loops that have constant bounds.

The code generator uses heuristics to determine the classification of a cell array as homogeneous or heterogeneous. It considers the properties (class, size, complexity) of the elements and other factors, such as how you use the cell array in your program. Depending on how you use a cell array, the code generator can classify a cell array as homogeneous in one case and heterogeneous in another case. For example, consider the cell array `{1 [2 3]}`. The code generator can classify this cell array as a heterogeneous 1-by-2 cell array. The first element is double scalar. The second element is a 1-by-2 array of doubles. However, if you index into this cell array with an index whose value is determined at run time, the code generator classifies it as a homogeneous cell array. The elements are variable-size arrays of doubles with an upper bound of 2.

### Controlling Whether a Cell Array Is Homogeneous or Heterogeneous

For cell arrays with certain characteristics, you cannot control the classification as homogeneous or heterogeneous:

- If the elements have different classes, the cell array must be heterogeneous.
- If the cell array is variable-size, it must be homogeneous.
- If you index into the cell array with an index whose value is determined at run time, the cell array must be homogeneous.

For other cell arrays, you can control the classification as homogeneous or heterogeneous.

- If the cell array elements have the same class, you can force a cell array to be homogeneous by using `coder. varsize`. See “Control Whether a Cell Array Is Variable-Size” on page 60-4.

## Cell Arrays in Reports

To see whether a cell array is homogeneous or heterogeneous, view the variable in the MATLAB Function report.

For a homogeneous cell array, the report has one entry that specifies the properties of all elements. The notation `{:}` indicates that all elements of the cell array have the same properties.

ALL MESSAGES (0)		VARIABLES	
Name	Type	Size	Class
z	Output	1 × 1	double
▲ c	Local	1 × 3	cell
{:}		1 × 1	double

For a heterogeneous cell array, the report has an entry for each element. For example, for a heterogeneous cell array `c` with two elements, the entry for `c{1}` shows the properties for the first element. The entry for `c{2}` shows the properties for the second element.

ALL MESSAGES (0)		VARIABLES	
Name	Type	Size	Class
z	Output	1 × 1	double
▲ c	Local	1 × 2	cell
{1}		1 × 1	double
{2}		1 × 1	char

## Control Whether a Cell Array Is Variable-Size

The code generator classifies a variable-size cell array as homogeneous. The cell array elements must have the same class. In the generated code, the cell array is represented as an array.

To make a cell array variable-size:

- Create the cell array by using the `cell` function. For example:

```
function z = mycell(n, j)
%#codegen
assert (n < 100);
x = cell(1,n);
for i = 1:n
    x{i} = i;
end
z = x{j};
end
```

For code generation, when you create a variable-size cell array by using `cell`, you must adhere to certain restrictions. See “Definition of Variable-Size Cell Array by Using `cell`” on page 60-7.

- Grow the cell array. For example:

```
function z = mycell(n)
%#codegen
c = {1 2 3};
if n > 3
    c = {1 2 3 4};
end
z = c{n};
end
```

- Force the cell array to be variable-size by using `coder. varsize`. Consider this code:

```
function y = mycellfun()
%#codegen
c = {1 2 3};
coder. varsize('c', [1 10]);
y = c{1};
end
```

Without `coder. varsize`, `c` is fixed-size with dimensions 1-by-3. With `coder. varsize`, `c` is variable-size with an upper bound of 10.

Sometimes, using `coder. varsize` changes the classification of a cell array from heterogeneous to homogeneous. Consider this code:

```
function y = mycell()
%#codegen
c = {1 [2 3]};
y = c{2};
end
```

The code generator classifies `c` as heterogeneous because the elements have different sizes. `c` is fixed-size with dimensions 1-by-2. If you use `coder. varsize` with `c`, it becomes homogeneous. For example:

```
function y = mycell()
    %#codegen
    c = {1 [2 3]};
    coder.varsize('c', [1 10], [0 1]);
    y = c{2};
end
```

c becomes a variable-size homogeneous cell array with dimensions 1-by-:10.

To force c to be homogeneous, but not variable-size, specify that none of the dimensions vary. For example:

```
function y = mycell()
    %#codegen
    c = {1 [2 3]};
    coder.varsize('c', [1 2], [0 0]);
    y = c{2};
end
```

## Cell Array Limitations for Code Generation

When you use cell arrays in MATLAB code that is intended for code generation, you must adhere to these restrictions:

- “Cell Array Element Assignment” on page 60-6
- “Variable-Size Cell Arrays” on page 60-7
- “Definition of Variable-Size Cell Array by Using `cell`” on page 60-7
- “Cell Array Indexing” on page 60-10
- “Growing a Cell Array by Using `{end + 1}`” on page 60-11
- “Cell Array Contents” on page 60-12
- “Passing Cell Arrays to External C/C++ Functions” on page 60-12
- “Use in MATLAB Function Block” on page 60-12

### Cell Array Element Assignment

You must assign a cell array element on all execution paths before you use it. For example:

```
function z = foo(n)
%#codegen
c = cell(1,3);
if n < 1
    c{2} = 1;

else
    c{2} = n;
end
z = c{2};
end
```

The code generator considers passing a cell array to a function or returning it from a function as a use of all elements of the cell array. Therefore, before you pass a cell array to a function or return it from a function, you must assign all of its elements. For example, the following code is not allowed because it does not assign a value to `c{2}` and `c` is a function output.

```
function c = foo()
%#codegen
c = cell(1,3);
c{1} = 1;
c{3} = 3;
end
```

The assignment of values to elements must be consistent on all execution paths. The following code is not allowed because `y{2}` is double on one execution path and char on the other execution path.

```
function y = foo(n)
y = cell(1,3)
if n > 1;
    y{1} = 1
    y{2} = 2;
    y{3} = 3;
else
    y{1} = 10;
```

```

    y{2} = 'a';
    y{3} = 30;
end

```

## Variable-Size Cell Arrays

- `coder.versize` is not supported for heterogeneous cell arrays.
- If you use the `cell` function to define a fixed-size cell array, you cannot use `coder.versize` to specify that the cell array has a variable size. For example, this code causes a code generation error because `x = cell(1,3)` makes `x` a fixed-size,1-by-3 cell array.

```

...
x = cell(1,3);
coder.versize('x',[1 5])
...

```

You can use `coder.versize` with a cell array that you define by using curly braces. For example:

```

...
x = {1 2 3};
coder.versize('x',[1 5])
...

```

- To create a variable-size cell array by using the `cell` function, use this code pattern:

```

function mycell(n)
%#codegen
x = cell(1,n);
for i = 1:n
    x{i} = i;
end
end

```

See “Definition of Variable-Size Cell Array by Using `cell`” on page 60-7.

To specify upper bounds for the cell array, use `coder.versize`.

```

function mycell(n)
%#codegen
x = cell(1,n);
for i = 1:n
    x{i} = i;
coder.versize('x',[1,20]);
end
end

```

## Definition of Variable-Size Cell Array by Using `cell`

For code generation, before you use a cell array element, you must assign a value to it. When you use `cell` to create a variable-size cell array, for example, `cell(1,n)`, MATLAB assigns an empty matrix to each element. However, for code generation, the elements are unassigned. For code generation, after you use `cell` to create a variable-size cell array, you must assign all elements of the cell array before any use of the cell array. For example:

```

function z = mycell(n, j)
%#codegen

```

```

assert(n < 100);
x = cell(1,n);
for i = 1:n
    x{i} = i;
end
z = x{j};
end

```

The code generator analyzes your code to determine whether all elements are assigned before the first use of the cell array. If the code generator detects that some elements are not assigned, code generation fails with an error message. For example, modify the upper bound of the for-loop to j.

```

function z = mycell(n, j)
%#codegen
assert(n < 100);
x = cell(1,n);
for i = 1:j %<- Modified here
    x{i} = i;
end
z = x{j};
end

```

With this modification and with inputs j less than n, the function does not assign values to all of the cell array elements. Code generation produces the error:

```

Unable to determine that every element of 'x{:}' is assigned
before this line.

```

Sometimes, even though your code assigns all elements of the cell array, the code generator reports this message because the analysis does not detect that all elements are assigned. See “Unable to Determine That Every Element of Cell Array Is Assigned” on page 71-8.

To avoid this error, follow these guidelines:

- When you use cell to define a variable-size cell array, write code that follows this pattern:

```

function z = mycell(n, j)
%#codegen
assert(n < 100);
x = cell(1,n);
for i = 1:n
    x{i} = i;
end
z = x{j};
end

```

Here is the pattern for a multidimensional cell array:

```

function z = mycell(m,n,p)
%#codegen
assert(m < 100);
assert(n < 100);
assert(p < 100);
x = cell(m,n,p);
for i = 1:m
    for j = 1:n
        for k = 1:p
            x{i,j,k} = i+j+k;
        end
    end
end

```

```

        end
    end
end
z = x{m,n,p};
end

```

- Increment or decrement the loop counter by 1.
- Define the cell array within one loop or one set of nested loops. For example, this code is not allowed:

```

function z = mycell(n, j)
assert(n < 50);
assert(j < 50);
x = cell(1,n);
for i = 1:5
    x{i} = 5;
end
for i = 6:n
    x{i} = 5;
end
z = x{j};
end

```

- Use the same variables for the cell dimensions and loop initial and end values. For example, code generation fails for the following code because the cell creation uses `n` and the loop end value uses `m`:

```

function z = mycell(n, j)
assert(n < 50);
assert(j < 50);
x = cell(1,n);
m = n;
for i = 1:m
    x{i} = 2;
end
z = x{j};
end

```

Rewrite the code to use `n` for the cell creation and the loop end value:

```

function z = mycell(n, j)
assert(n < 50);
assert(j < 50);
x = cell(1,n);
for i = 1:n
    x{i} = 2;
end
z = x{j};
end

```

- Create the cell array with this pattern:

```
x = cell(1,n)
```

Assign the cell array to a field of a structure or a property of an object by initializing a temporary variable with the required cell. For example:

```
t = cell(1,n)
for i = 1:n
```

```
    t{i} = i+1;
end
myObj.prop = t;
```

Do not assign a cell array to a field of a structure or a property of an object directly. For example, this code is not allowed:

```
myObj.prop = cell(1,n);
for i = 1:n
    myObj.prop{i} = i+1;
end
```

Do not use the `cell` function inside the cell array constructor `{}`. For example, this code is not allowed:

```
x = {cell(1,n)};
```

- The cell array creation and the loop that assigns values to the cell array elements must be together in a unique execution path. For example, the following code is not allowed.

```
function z = mycell(n)
assert(n < 100);
if n > 3
    c = cell(1,n);
else
    c = cell(n,1);
end
for i = 1:n
    c{i} = i;
end
z = c{n};
end
```

To fix this code, move the assignment loop inside the code block that creates the cell array.

```
function z = cellerr(n)
assert(n < 100);
if n > 3
    c = cell( 1,n);
    for i = 1:n
        c{i} = i;
    end
else
    c = cell(n,1);
    for i = 1:n
        c{i} = i;
    end
end
z = c{n};
end
```

## Cell Array Indexing

- You cannot index cell arrays by using smooth parentheses `()`. Consider indexing cell arrays by using curly braces `{}` to access the contents of the cell.
- You must index into heterogeneous cell arrays by using constant indices or by using `for`-loops with constant bounds.

For example, the following code is not allowed.

```
x = {1, 'mytext'};
disp(x{randi});
```

You can index into a heterogeneous cell array in a `for`-loop with constant bounds because the code generator unrolls the loop. Unrolling creates a separate copy of the loop body for each loop iteration, which makes the index in each loop iteration constant. However, if the `for`-loop has a large body or it has many iterations, the unrolling can increase compile time and generate inefficient code.

If `A` and `B` are constant, the following code shows indexing into a heterogeneous cell array in a `for`-loop with constant bounds.

```
x = {1, 'mytext'};
for i = A:B
    disp(x{i});
end
```

## Growing a Cell Array by Using `{end + 1}`

To grow a cell array `X`, you can use `X{end + 1}`. For example:

```
...
X = {1 2};
X{end + 1} = 'a';
...
```

When you use `{end + 1}` to grow a cell array, follow these restrictions:

- In a MATLAB Function block, do not use `{end + 1}` in a `for`-loop.
- Use only `{end + 1}`. Do not use `{end + 2}`, `{end + 3}`, and so on.
- Use `{end + 1}` with vectors only. For example, the following code is not allowed because `X` is a matrix, not a vector:

```
...
X = {1 2; 3 4};
X{end + 1} = 5;
```

- Use `{end + 1}` only with a variable. In the following code, `{end + 1}` does not cause `{1 2 3}` to grow. In this case, the code generator treats `{end + 1}` as an out-of-bounds index into `X{2}`.

```
...
X = {'a' { 1 2 3 }};
X{2}{end + 1} = 4;
```

- When `{end + 1}` grows a cell array in a loop, the cell array must be variable-size. Therefore, the cell array must be homogeneous on page 60-2.

This code is allowed because `X` is homogeneous.

```
...
X = {1 2};
for i=1:n
```

```
    X{end + 1} = 3;  
end  
...
```

This code is not allowed because `X` is heterogeneous.

```
...  
X = {1 'a' 2 'b'};  
for i=1:n  
    X{end + 1} = 3;  
end  
...
```

## Cell Array Contents

Cell arrays cannot contain `mxarrays`. In a cell array, you cannot store a value that an extrinsic function returns.

## Passing Cell Arrays to External C/C++ Functions

You cannot pass a cell array to `coder.ceval`. If a variable is an input argument to `coder.ceval`, define the variable as an array or structure instead of as a cell array.

## Use in MATLAB Function Block

You cannot use cell arrays for Simulink signals, parameters, or data store memory.

# Code Generation for Categorical Arrays

---

## Code Generation for Categorical Arrays

### In this section...

“Define Categorical Arrays for Code Generation” on page 61-2

“Allowed Operations on Categorical Arrays” on page 61-2

“MATLAB Toolbox Functions That Support Categorical Arrays” on page 61-3

Categorical arrays store data with values from a finite set of discrete categories. You can specify an order for the categories, but it is not required. A categorical array provides efficient storage and manipulation of nonnumeric data, while also maintaining meaningful names for the values.

When you use categorical arrays with code generation, adhere to these restrictions:

### Define Categorical Arrays for Code Generation

For code generation, use the `categorical` function to create categorical arrays. For example, suppose the input argument to your MATLAB function is a numeric array of arbitrary size whose elements have values of either 1, 2, or 3. You can convert these values to the categories `small`, `medium`, and `large` and turn the input array into a categorical array, as shown in this code.

```
function c = foo(x) %#codegen
    c = categorical(x,1:3,{'small','medium','large'});
end
```

### Allowed Operations on Categorical Arrays

For code generation, you are restricted to the operations on categorical arrays listed in this table.

Operation	Example	Notes
assignment operator: =	<pre>c = categorical(1:3,1:3,{'small','medium','large'}); c(1) = 'large';</pre>	Code generation does not support using the assignment operator = to: <ul style="list-style-type: none"> <li>Delete an element.</li> <li>Expand the size of a categorical array.</li> <li>Add a new category, even when the array is not protected.</li> </ul>
relational operators: < > <= >= == ~=	<pre>c = categorical(1:3,'Ordinal',true); tf = c(1) &lt; c(2);</pre>	Code generation supports all relational operators.
cast to numeric type	<pre>c = categorical(1:3); double(c(1));</pre>	Code generation supports casting categorical arrays to arrays of double- or single-precision floating-point numbers, or to integers.

Operation	Example	Notes
conversion to text	<pre>c = categorical(1:3,1:3,{'small','medium','large'}); c1 = cellstr(c(1)); % One element c2 = cellstr(c); % Entire array</pre>	<p>Code generation does not support using the <code>char</code> or <code>string</code> functions to convert categorical values to text.</p> <p>To convert one or more elements of a categorical array to text, use the <code>cellstr</code> function.</p>
indexing operation	<pre>c = categorical(1:3,1:3,{'small','medium','large'}); idx = [1 2]; c(idx); idx = logical([1 1 0]); c(idx);</pre>	Code generation supports indexing by position, linear indexing, and logical indexing.
concatenation	<pre>c1 = categorical(1:3,1:3,{'small','medium','large'}); c2 = categorical(4:6,[2 1 4],{'medium','small','extra-large'}); c = [c1 c2];</pre>	Code generation supports concatenation of categorical arrays along any dimension.

## MATLAB Toolbox Functions That Support Categorical Arrays

For code generation, you can use categorical arrays with these MATLAB toolbox functions:

- `addcats`
- `cat`
- `categorical`
- `categories`
- `cellstr`
- `countcats`
- `ctranspose`
- `double`
- `eq`
- `ge`
- `gt`
- `histcounts`
- `horzcat`
- `int8`
- `int16`
- `int32`
- `int64`
- `intersect`
- `iscategory`
- `iscolumn`
- `isempty`
- `isequal`

- `isequaln`
- `ismatrix`
- `ismember`
- `isordinal`
- `isprotected`
- `isrow`
- `isscalar`
- `issorted`
- `issortedrows`
- `isundefined`
- `isvector`
- `le`
- `length`
- `lt`
- `max`
- `mergecats`
- `min`
- `ndims`
- `ne`
- `numel`
- `permute`
- `removecats`
- `renamecats`
- `reordercats`
- `reshape`
- `setcats`
- `setdiff`
- `setxor`
- `single`
- `size`
- `sort`
- `sortrows`
- `transpose`
- `uint8`
- `uint16`
- `uint32`
- `uint64`
- `union`
- `unique`

- `vertcat`

## **See Also**

## **More About**

- “Categorical Array Limitations for Code Generation” on page 61-8

## Define Categorical Array Inputs

### Define Categorical Array Inputs at the Command Line

Use one of these procedures:

- “Provide an Example Categorical Array Input” on page 61-6
- “Provide a Categorical Array Type” on page 61-6
- “Provide a Constant Categorical Array Input” on page 61-6

Alternatively, if you have a test file that calls your entry-point function with example inputs, you can determine the input types by using `coder.getArgTypes`.

#### Provide an Example Categorical Array Input

##### Provide a Categorical Array Type

To provide a type for a categorical array to :

- 1 Define a categorical array. For example:

```
C = categorical({'r','g','b'});
```

- 2 Create a type from C.

```
t = coder.typeof(C);
```

##### Provide a Constant Categorical Array Input

To specify that a categorical array input is constant, use `coder.Constant` with the `-args` option:

## Representation of Categorical Arrays

A coder type object for a categorical array describes the object and its properties. Use `coder.typeof` or pass `categorical` as a string scalar to `coder.newtype`.

The coder type object displays a succinct description of the object properties while excluding internal state values. Nonconstant properties display their type and size, while constant properties display only their values. For example:

```
t = categorical({'r','g','b'});  
tType = coder.typeof(t)
```

The representation of variable `t` is stored in coder type object `tType`.

```
tType =
```

```
matlab.coder.type.CategoricalType  
  1x3 categorical  
  Categories : 3x1 homogeneous cell  
  Ordinal : 1x1 logical  
  Protected : 1x1 logical
```

If your workflow requires the legacy representation of coder type objects, use the `getCoderType` function on the variable that has the new representation of your class or object. See “Legacy Representation of Coder Type Objects” (MATLAB Coder).

### Resize Object Properties by Using `coder.resize`

You can resize most objects by using `coder.resize`. You can resize objects, its properties and create arrays within the properties.

For a categorical coder object, you can resize the object properties:

```
t = categorical({'r','g','b'});
tType = coder.typeof(t);
tType.Categories = coder.resize(tType.Categories, [3 1],[1 0])
```

This code resizes the `Categories` property to be upper-bounded at 3 for the first dimension.

```
tType =
  matlab.coder.type.CategoricalType
  1x3 categorical
  Categories : :3x1 homogeneous cell
  Ordinal : 1x1 logical
  Protected : 1x1 logical
```

You can also resize the object by using `coder.resize`. See “Edit and Represent Coder Type Objects and Properties” (MATLAB Coder).

### More About

- “Code Generation for Categorical Arrays” on page 61-2
- “Categorical Array Limitations for Code Generation” on page 61-8

## Categorical Array Limitations for Code Generation

When you create categorical arrays in MATLAB code that you intend for code generation, you must specify the categories and elements of each categorical array by using the `categorical` function. See “Categorical Arrays”.

For categorical arrays, code generation does not support the following inputs and operations:

- Arrays of MATLAB objects.
- Sparse matrices.
- Duplicate category names when you specify them using the `categoryNames` input argument of the `categorical` function.
- Growth by assignment. For example, assigning a value beyond the end of an array produces an error.

```
function c = foo() %#codegen
    c = categorical(1:3,1:3,{'small','medium','large'});
    c(4) = 'medium';
end
```

- Adding a category. For example, specifying a new category by using the `=` operator produces an error, even when the categorical array is unprotected.

```
function c = foo() %#codegen
    c = categorical(1:3,1:3,{'small','medium','large'});
    c(1) = 'extra-large';
end
```

- Deleting an element. For example, assigning an empty array to an element produces an error.

```
function c = foo() %#codegen
    c = categorical(1:3,1:3,{'small','medium','large'});
    c(1) = [];
end
```

- Converting categorical values to text by using the `char` or `string` functions. To convert elements of a categorical array to text, use the `cellstr` function.

Limitations that apply to classes also apply to categorical arrays. For more information, see “MATLAB Classes Definition for Code Generation” (MATLAB Coder).

- “Code Generation for Datetime Arrays” on page 62-2
- “Define Datetime Array Inputs” on page 62-5
- “Datetime Array Limitations for Code Generation” on page 62-7

## Code Generation for Datetime Arrays

### In this section...

“Define Datetime Arrays for Code Generation” on page 62-2  
 “Allowed Operations on Datetime Arrays” on page 62-2  
 “MATLAB Toolbox Functions That Support Datetime Arrays” on page 62-2

The values in a `datetime` array represent points in time using the proleptic ISO calendar.

When you use `datetime` arrays with code generation, adhere to these restrictions.

### Define Datetime Arrays for Code Generation

For code generation, use the `datetime` function to create `datetime` arrays. For example, suppose the input arguments to your MATLAB function are numeric arrays whose values indicate the year, month, day, hour, minute, and second components for a point in time. You can create a `datetime` array from these input arrays.

```
function d = foo(y,mo,d,h,mi,s) %#codegen
    d = datetime(y,mo,d,h,mi,s);
end
```

### Allowed Operations on Datetime Arrays

For code generation, you are restricted to the operations on `datetime` arrays listed in this table.

Operation	Example	Notes
Assignment operator: =	<code>d = datetime(2019,1:12,1,12,0,0);</code> <code>d(1) = datetime(2019,1,31);</code>	Code generation does not support using the assignment operator = to: <ul style="list-style-type: none"> <li>Delete an element.</li> <li>Expand the size of a <code>datetime</code> array.</li> </ul>
Relational operators: < > <= >= == ~=	<code>d = datetime(2019,1:12,1,12,0,0);</code> <code>tf = d(1) &lt; d(2);</code>	Code generation supports relational operators.
Indexing operation	<code>d = datetime(2019,1:12,1,12,0,0);</code> <code>idx = [1 2];</code> <code>d(idx);</code> <code>idx = logical([1 1 0]);</code> <code>d(idx);</code>	Code generation supports indexing by position, linear indexing, and logical indexing.
Concatenation	<code>d1 = datetime(2019,1:6,1,12,0,0);</code> <code>d2 = datetime(2019,7:12,1,12,0,0);</code> <code>d = [d1 d2];</code>	Code generation supports concatenation of <code>datetime</code> arrays.

### MATLAB Toolbox Functions That Support Datetime Arrays

For code generation, you can use `datetime` arrays with these MATLAB toolbox functions:

- `cat`

- colon
- ctranspose
- datetime
- datevec
- diff
- eq
- ge
- gt
- hms
- horzcat
- hour
- interp1
- intersect
- iscolumn
- isempty
- isequal
- isequaln
- isfinite
- isinf
- ismatrix
- ismember
- isnat
- isreal
- isrow
- isscalar
- issorted
- issortedrows
- isvector
- le
- length
- linspace
- lt
- max
- mean
- min
- minus
- minute
- NaT
- ndims

- `ne`
- `numel`
- `permute`
- `plus`
- `posixtime`
- `repmat`
- `reshape`
- `setdiff`
- `setxor`
- `size`
- `sort`
- `sortrows`
- `topkrows`
- `transpose`
- `union`
- `unique`
- `vertcat`
- `ymd`

## **See Also**

### **More About**

- “Datetime Array Limitations for Code Generation” on page 62-7

## Define Datetime Array Inputs

### Define Datetime Array Inputs at the Command Line

Use one of these procedures:

- “Provide an Example Datetime Array Input” on page 62-5
- “Provide a Datetime Array Type” on page 62-5
- “Provide a Constant Datetime Array Input” on page 62-5

Alternatively, if you have a test file that calls your entry-point function with example inputs, you can determine the input types by using `coder.getArgTypes`.

#### Provide an Example Datetime Array Input

##### Provide a Datetime Array Type

To provide a type for a datetime array to :

- 1 Define a `datetime` array. For example:

```
D = datetime(2019,1:12,1,12,0,0);
```

- 2 Create a type from D.

```
t = coder.typeof(D);
```

##### Provide a Constant Datetime Array Input

To specify that a datetime array input is constant, use `coder.Constant` with the `-args` option:

### Representation of Datetime Arrays

A coder type object for a datetime array describes the object and its properties. Use `coder.typeof` or pass `datetime` as a string scalar to `coder.newtype`.

The coder type object displays a succinct description of the object properties while excluding internal state values. Nonconstant properties display their type and size, while constant properties display only their values. For example:

```
t = datetime(2019,1:12,1,12,0,0);
tType = coder.typeof(t)
```

The representation of variable `t` is stored in coder type object `tType`.

```
tType =
```

```
matlab.coder.type.DatetimeType
  1x12 datetime
  Format : 1x0 char
  TimeZone : 1x0 char
```

If your workflow requires the legacy representation of coder type objects, use the `getCoderType` function on the variable that has the new representation of your class or object. See “Legacy Representation of Coder Type Objects” (MATLAB Coder).

### Resize Object Properties by Using `coder.resize`

You can resize most objects by using `coder.resize`. You can resize objects, its properties and create arrays within the properties.

For a `datetime` coder object, you can resize the object properties:

```
t = datetime(2019,1:12,1,12,0,0);
tType = coder.typeof(t)
tType.Format = coder.resize(tType.Format, [1 12])
```

This code resizes the `Format` property to be a `1x12 char` property.

```
tType =
  matlab.coder.type.DatetimeType
    1x12 datetime
      Format : 1x12 char
      TimeZone : 1x0 char
```

You can also resize the object by using `coder.resize`. See “Edit and Represent Coder Type Objects and Properties” (MATLAB Coder).

### More About

- “Code Generation for Datetime Arrays” on page 62-2
- “Datetime Array Limitations for Code Generation” on page 62-7

## Datetime Array Limitations for Code Generation

When you create `datetime` arrays in MATLAB code that you intend for code generation, you must specify the values by using the `datetime` function. See “Dates and Time”.

For `datetime` arrays, code generation does not support the following inputs and operations:

- Text inputs. For example, specifying a character vector as the input argument produces an error.

```
function d = foo() %#codegen
    d = datetime('2019-12-01');
end
```

- The 'Format' name-value pair argument. You cannot specify the display format by using the `datetime` function, or by setting the `Format` property of a `datetime` array. To use a specific display format, create a `datetime` array in MATLAB, then pass it as an input argument to a function that is intended for code generation.
- The 'TimeZone' name-value pair argument and the `TimeZone` property. When you use `datetime` arrays in code that is intended for code generation, they must be unzoned.
- Setting time component properties. For example, setting the `Hour` property in the following code produces an error:

```
d = datetime;
d.Hour = 2;
```

- Growth by assignment. For example, assigning a value beyond the end of an array produces an error.

```
function d = foo() %#codegen
    d = datetime(2019,1:12,1,12,0,0);
    d(13) = datetime(2020,1,1,12,0,0);
end
```

- Deleting an element. For example, assigning an empty array to an element produces an error.

```
function d = foo() %#codegen
    d = datetime(2019,1:12,1,12,0,0);
    d(1) = [];
end
```

- Converting `datetime` values to text by using the `char`, `cellstr`, or `string` functions.

Limitations that apply to classes also apply to `datetime` arrays. For more information, see “MATLAB Classes Definition for Code Generation” (MATLAB Coder).

# Code Generation for Duration Arrays

---

- “Code Generation for Duration Arrays” on page 63-2
- “Define Duration Array Inputs” on page 63-6
- “Duration Array Limitations for Code Generation” on page 63-8

## Code Generation for Duration Arrays

### In this section...

“Define Duration Arrays for Code Generation” on page 63-2

“Allowed Operations on Duration Arrays” on page 63-2

“MATLAB Toolbox Functions That Support Duration Arrays” on page 63-3

The values in a duration array represent elapsed times in units of fixed length, such as hours, minutes, and seconds. You can create elapsed times in terms of fixed-length (24-hour) days and fixed-length (365.2425-day) years.

You can add, subtract, sort, compare, concatenate, and plot duration arrays.

When you use duration arrays with code generation, adhere to these restrictions.

### Define Duration Arrays for Code Generation

For code generation, use the `duration` function to create duration arrays. For example, suppose the input arguments to your MATLAB function are three numeric arrays of arbitrary size whose elements specify lengths of time as hours, minutes, and seconds. You can create a duration array from these three input arrays.

```
function d = foo(h,m,s) %#codegen
    d = duration(h,m,s);
end
```

You can use the `years`, `days`, `hours`, `minutes`, `seconds`, and `milliseconds` functions to create duration arrays in units of years, days, hours, minutes, or seconds. For example, you can create an array of hours from an input numeric array.

```
function d = foo(h) %#codegen
    d = hours(h);
end
```

### Allowed Operations on Duration Arrays

For code generation, you are restricted to the operations on duration arrays listed in this table.

Operation	Example	Notes
assignment operator: =	<pre>d = duration(1:3,0,0); d(1) = hours(5);  d = duration(1:3,0,0); d(1) = hours(5);</pre>	<p>Code generation does not support using the assignment operator = to:</p> <ul style="list-style-type: none"> <li>Delete an element.</li> <li>Expand the size of a duration array.</li> </ul>
relational operators: < > <= >= == ~=	<pre>d = duration(1:3,0,0); tf = d(1) &lt; d(2);  d = duration(1:3,0,0); tf = d(1) &lt; d(2);</pre>	<p>Code generation supports relational operators.</p>

Operation	Example	Notes
indexing operation	<pre>d = duration(1:3,0,0); idx = [1 2]; d(idx); idx = logical([1 1 0]); d(idx);  d = duration(1:3,0,0); idx = [1 2]; d(idx); idx = logical([1 1 0]); d(idx);</pre>	Code generation supports indexing by position, linear indexing, and logical indexing.
concatenation	<pre>d1 = duration(1:3,0,0); d2 = duration(4,30,0); d = [d1 d2];  d1 = duration(1:3,0,0); d2 = duration(4,30,0); d = [d1 d2];</pre>	Code generation supports concatenation of duration arrays.

## MATLAB Toolbox Functions That Support Duration Arrays

For code generation, you can use duration arrays with these MATLAB toolbox functions:

- abs
- cat
- ceil
- colon
- cummax
- cummin
- cumsum
- ctranspose
- datevec
- days
- diff
- duration
- eps
- eq
- floor
- ge
- gt
- hms
- horzcat
- hours
- interp1
- intersect
- iscolumn

- isempty
- isequal
- isequaln
- isfinite
- isinf
- ismatrix
- ismember
- isnan
- isreal
- isrow
- isscalar
- issorted
- issortedrows
- isvector
- ldivide
- le
- length
- linspace
- lt
- max
- mean
- median
- milliseconds
- min
- minus
- minutes
- mldivide
- mode
- mrdivide
- mod
- mtimes
- ndims
- ne
- nnz
- numel
- permute
- plus
- repmat
- rdivide

- rem
- reshape
- seconds
- setdiff
- setxor

- size
- sort
- sortrows
- std
- sum
- times
- transpose
- uminus
- union
- unique
- uplus
- vertcat
- years

## **See Also**

## **More About**

- “Duration Array Limitations for Code Generation” on page 63-8

## Define Duration Array Inputs

### Define Duration Array Inputs at the Command Line

Use one of these procedures:

- “Provide an Example Duration Array Input” on page 63-6
- “Provide a Duration Array Type” on page 63-6
- “Provide a Constant Duration Array Input” on page 63-6

Alternatively, if you have a test file that calls your entry-point function with example inputs, you can determine the input types by using `coder.getArgTypes`.

#### Provide an Example Duration Array Input

##### Provide a Duration Array Type

To provide a type for a duration array to :

- 1 Define a duration array. For example:

```
D = duration(1:3,0,0);
```

- 2 Create a type from D.

```
t = coder.typeof(D);
```

##### Provide a Constant Duration Array Input

To specify that a duration array input is constant, use `coder.Constant` with the `-args` option:

## Representation of Duration Arrays

A coder type object for a duration array describes the object and its properties. Use `coder.typeof` or pass `duration` as a string scalar to `coder.newtype`.

The coder type object displays a succinct description of the object properties while excluding internal state values. Nonconstant properties display their type and size, while constant properties display only their values. For example:

```
tType = coder.newtype('duration')
```

A representation of an empty duration variable is stored in coder type object `tType`.

```
tType =  
  
    matlab.coder.type.DurationType  
    1x1 duration  
    Format : 1x8 char
```

If your workflow requires the legacy representation of coder type objects, use the `getCoderType` function on the variable that has the new representation of your class or object. See “Legacy Representation of Coder Type Objects” (MATLAB Coder).

## Resize duration Properties by Editing Object Properties

You can resize most objects by editing the object properties. You can resize duration objects, its properties and create arrays within the properties.

For a duration coder object, you can resize the object properties:

```
t = duration((1:3),0,0);
tType = coder.typeof(t)
tType.Format = 'DD/MM/YYYY'
```

This code resizes the Format property to be a 1x10 char property.

```
tType =
  matlab.coder.type.DurationType
    1x3 duration
    Format : 1x10 char
```

You can also resize the object by using `coder.resize`. See “Edit and Represent Coder Type Objects and Properties” (MATLAB Coder).

## Duration Array Limitations for Code Generation

When you create duration arrays in MATLAB code that you intend for code generation, you must specify the durations by using the `duration`, `years`, `days`, `hours`, `minutes`, `seconds`, or `milliseconds` functions. See “Dates and Time”.

For duration arrays, code generation does not support the following inputs and operations:

- Text inputs. For example, specifying a character vector as the input argument produces an error.

```
function d = foo() %#codegen
    d = duration('01:30:00');
end
```

- Growth by assignment. For example, assigning a value beyond the end of an array produces an error.

```
function d = foo() %#codegen
    d = duration(1:3,0,0);
    d(4) = hours(4);
end
```

- Deleting an element. For example, assigning an empty array to an element produces an error.

```
function d = foo() %#codegen
    d = duration(1:3,0,0);
    d(1) = [];
end
```

- Converting duration values to text by using the `char`, `cellstr`, or `string` functions.

Limitations that apply to classes also apply to duration arrays. For more information, see “MATLAB Classes Definition for Code Generation” (MATLAB Coder).

# Code Generation for Tables

---

- “Code Generation for Tables” on page 64-2
- “Define Table Inputs” on page 64-5
- “Table Limitations for Code Generation” on page 64-7

## Code Generation for Tables

### In this section...

“Define Tables for Code Generation” on page 64-2

“Allowed Operations on Tables” on page 64-2

“MATLAB Toolbox Functions That Support Tables” on page 64-3

The `table` data type is a data type suitable for column-oriented or tabular data that is often stored as columns in a text file or in a spreadsheet. Tables consist of rows and column-oriented variables. Each variable in a table can have a different data type and a different size with one restriction: each variable must have the same number of rows. For more information, see “Tables”.

When you use tables with code generation, adhere to these restrictions.

### Define Tables for Code Generation

For code generation, use the `table` function. For example, suppose the input arguments to your MATLAB function are three arrays that have the same number of rows and a cell array that has variable names. You can create a table that contains these arrays as table variables.

```
function T = foo(A,B,C,vnames) %#codegen
    T = table(A,B,C,'VariableNames',vnames);
end
```

You can use the `array2table`, `cell2table`, and `struct2table` functions to convert arrays, cell arrays, and structures to tables. For example, you can convert an input cell array to a table.

```
function T = foo(C,vnames) %#codegen
    T = cell2table(C,'VariableNames',vnames);
end
```

For code generation, you must supply table variable names when you create a table. Table variable names do not have to be valid MATLAB identifiers. The names must be composed of ASCII characters, but can include any ASCII characters (such as commas, dashes, and space characters).

### Allowed Operations on Tables

For code generation, you are restricted to the operations on tables listed below.

Operation	Example	Notes
assignment operator: =	<code>T = table(A,B,C,'VariableNames',vnames)</code> <code>T(:,1) = D;</code>	Code generation does not support using the assignment operator = to: <ul style="list-style-type: none"> <li>Delete a variable or a row.</li> <li>Add a variable or a row.</li> </ul>

Operation	Example	Notes
indexing operation	<pre>T = table(A,B,C, 'VariableNames', vnames); T(1:5,1:3);</pre>	<p>Code generation supports indexing by position, variable or row name, and logical indexing.</p> <p>Code generation supports:</p> <ul style="list-style-type: none"> <li>• Table indexing with smooth parentheses, ().</li> <li>• Content indexing with curly braces, {}.</li> <li>• Dot notation to access a table variable.</li> </ul>
concatenation	<pre>T1 = table(A,B,C, 'VariableNames', vnames); T2 = table(D,E,F, 'VariableNames', vnames); T = [T1 ; T2];</pre>	<p>Code generation supports table concatenation.</p> <ul style="list-style-type: none"> <li>• For vertical concatenation, tables must have variables that have the same names in the same order.</li> <li>• For horizontal concatenation, tables must have the same number of rows. If the tables have row names, then they must have the same row names in the same order.</li> </ul>

## MATLAB Toolbox Functions That Support Tables

For code generation, you can use tables with these MATLAB toolbox functions:

- `addvars`
- `array2table`
- `cat`
- `cell2table`
- `convertvars`
- `height`
- `horzcat`
- `innerjoin`
- `intersect`
- `isempty`
- `ismember`
- `issortedrows`
- `join`
- `mergevars`

- `movevars`
- `ndims`
- `numel`
- `outerjoin`
- `removevars`
- `renamevars`
- `rows2vars`
- `setdiff`
- `setxor`
- `size`
- `sortrows`
- `splitvars`
- `stack`
- `struct2table`
- `table`
- `table2array`
- `table2cell`
- `table2struct`
- `union`
- `unique`
- `unstack`
- `varfun`
- `vertcat`
- `width`

### **More About**

- “Table Limitations for Code Generation” on page 64-7

## Define Table Inputs

### Define Table Inputs at the Command Line

Use one of these procedures:

- “Provide an Example Table Input” on page 64-5
- “Provide a Table Type” on page 64-5
- “Provide a Constant Table Input” on page 64-5

Alternatively, if you have a test file that calls your entry-point function with example inputs, you can determine the input types by using `coder.getArgTypes`.

### Provide an Example Table Input

#### Provide a Table Type

To provide a type for a table to :

- 1 Define a table. For example:

```
T = table(A,B,C, 'VariableNames', vnames);
```

- 2 Create a type from T.

```
t = coder.typeof(T);
```

#### Provide a Constant Table Input

To specify that a table input is constant, use `coder.Constant` with the `-args` option:

## Representation of Tables

A coder type object for a table describes the object and its properties. Use `coder.typeof` or pass `table` as a string scalar to `coder.newtype`.

The coder type object displays a succinct description of the object properties while excluding internal state values. Nonconstant properties display their type and size, while constant properties display only their values. For example:

```
A = [1 2 3]';
B = [4 5 6]';
C = [7 8 9]';
t = table(A,B,C);
tType = coder.typeof(t)
```

The representation of variable `t` is stored in coder type object `tType`.

```
tType =
```

```
matlab.coder.type.TableType
  3x3 table
           Data : 1x3 homogeneous cell
  Description : 1x0 char
           UserData : 0x0 double
```

```

    DimensionNames : {'Row'}    {'Variables'}
    VariableNames  : {'A'}     {'B'}     {'C'}
    VariableDescriptions : 1x3 homogeneous cell
    VariableUnits  : 1x3 homogeneous cell
    VariableContinuity : 1x3 matlab.internal.coder.tabular.Continuity
    RowNames       : 0x0 homogeneous cell

```

If your workflow requires the legacy representation of coder type objects, use the `getCoderType` function on the variable that has the new representation of your class or object. See “Legacy Representation of Coder Type Objects” (MATLAB Coder).

### Resize Object Properties by Using `coder.resize`

You can resize most objects by using `coder.resize`. You can resize objects, its properties and create arrays within the properties.

For a table coder object, you can resize the object properties:

```

A = [1 2 3]';
B = [4 5 6]';
C = [7 8 9]';
t = table(A,B,C);
tType = coder.typeof(t)
tType.Description = coder.resize(tType.Description,[1 12],[0 1])

```

This code resizes the `Description` property to be a `1x:12 char` property which has an upper bound of 12.

```

tType =
    matlab.coder.type.TableType
    3x3 table
        Data : 1x3 homogeneous cell
        Description : 1x:12 char
        UserData : 0x0 double
        DimensionNames : {'Row'}    {'Variables'}
        VariableNames  : {'A'}     {'B'}     {'C'}
    VariableDescriptions : 1x3 homogeneous cell
        VariableUnits  : 1x3 homogeneous cell
    VariableContinuity : 1x3 matlab.internal.coder.tabular.Continuity
        RowNames       : 0x0 homogeneous cell

```

You can also resize the object by using `coder.resize`. See “Edit and Represent Coder Type Objects and Properties” (MATLAB Coder).

- “Table Limitations for Code Generation” on page 64-7

## Table Limitations for Code Generation

If you create tables, modify them, or use table functions in MATLAB code that you intend for code generation, then code generation has limitations described in the next sections. Limitations that apply to classes also apply to tables. For more information on class limitations, see “MATLAB Classes Definition for Code Generation” (MATLAB Coder).

### Creating Tables Limitations

If your MATLAB code creates tables, then code generation has these limitations.

Inputs for Table Creation	Limitations
Any inputs	<ul style="list-style-type: none"> <li>Table variable names do not have to be valid MATLAB identifiers. The names must be composed of ASCII characters, which can include commas, dashes, and space characters.</li> </ul>
Table created from input arrays	<ul style="list-style-type: none"> <li>You must specify variables names by using the 'VariableNames' name-value argument when creating tables from input arrays by using the <code>table</code>, <code>array2table</code>, or <code>cell2table</code> functions.</li> </ul>
Table created with preallocated variables	<ul style="list-style-type: none"> <li>You do not have to specify the 'VariableNames' argument when you preallocate a table by using the <code>table</code> function and the 'Size' name-value argument.</li> <li>You can specify only the following data types by using the 'VariableTypes' name-value argument: <ul style="list-style-type: none"> <li>'double'</li> <li>'single'</li> <li>'doublenan' or 'doubleNaN'</li> <li>'singlenan' or 'singleNaN'</li> <li>'int8', 'int16', 'int32', or 'int64'</li> <li>'uint8', 'uint16', 'uint32', or 'uint64'</li> <li>'logical'</li> <li>'duration'</li> <li>'cellstr'</li> <li>'char'</li> </ul> </li> </ul>

### Modifying Tables Limitations

If your MATLAB code modifies data in a table or its properties, then code generation has these limitations.

Table Operation or Property	Limitations
VariableNames, RowNames, DimensionNames, or UserData properties	<ul style="list-style-type: none"> <li>You cannot change the VariableNames, RowNames, DimensionNames, or UserData properties of a table after you create it.</li> </ul> <p>You can specify the 'VariableNames', 'RowNames', and 'DimensionNames' input arguments when you create a table. These input arguments specify the properties.</p>
Table indices that specify variables as input arguments to generated code	<ul style="list-style-type: none"> <li>To pass table indices that specify variables as input arguments into generated code, first make the indices constant by using the <code>coder.Constant</code> function. If table indices are not constant, then indexing into variables produces an error.</li> </ul>
Custom metadata	<ul style="list-style-type: none"> <li>You cannot add custom metadata to a table. The <code>addprop</code> and <code>rmprop</code> functions are not supported.</li> </ul>
Assignments that change size of table	<ul style="list-style-type: none"> <li>You cannot change the size of a table by assignments. For example, adding a new row produces an error.</li> </ul> <pre data-bbox="906 989 1581 1129">function T = foo() %#codegen     T = table((1:3)',(1:3)', 'VariableNames', ...         {'Var1', 'Var2'});     T{4,2} = 5; end</pre> <p>Deleting a row or a variable also produces an error.</p>
Vertical concatenation	<ul style="list-style-type: none"> <li>When you vertically concatenate tables, they must have the same variable names in the same order. In MATLAB, the variable names must be the same but can be in different orders in the tables.</li> </ul>
Horizontal concatenation	<ul style="list-style-type: none"> <li>When you horizontally concatenate tables and the tables have row names, they must have the same row names in the same order. In MATLAB, the row names must be the same but can be in different orders in the tables.</li> </ul>
Table variables that are N-D cell arrays	<ul style="list-style-type: none"> <li>If two tables have variables that are N-D cell arrays, then the tables cannot be vertically concatenated.</li> <li>You cannot use curly braces to extract data from multiple table variables that are N-D cell arrays because this operation is horizontal concatenation.</li> </ul>

## Using Table Functions Limitations

If your MATLAB code uses the functions listed in the table, then code generation has these limitations.

Function	Limitations
<code>convertvars</code>	<ul style="list-style-type: none"> <li>Function handles are not supported.</li> <li>The second and third input arguments (<code>vars</code> and <code>dataType</code>) must be constant.</li> <li>You cannot specify <code>dataType</code> as <code>'cell'</code>, <code>'cellstr'</code>, or <code>'char'</code>.</li> </ul>
<code>innerjoin</code>	<ul style="list-style-type: none"> <li>In general, the input tables cannot have any nonkey variables with the same names. However, you can join subsets of the input tables if you specify the <code>'LeftVariables'</code> and <code>'RightVariables'</code> name-value arguments. Specify these arguments so that no variable name appears in both <code>'LeftVariables'</code> and <code>'RightVariables'</code>.</li> <li>The values of these name-value arguments must be constant: <ul style="list-style-type: none"> <li><code>'Keys'</code></li> <li><code>'LeftKeys'</code></li> <li><code>'RightKeys'</code></li> <li><code>'LeftVariables'</code></li> <li><code>'RightVariables'</code></li> </ul> </li> <li>Nested tables are not supported.</li> </ul>
<code>intersect</code> <code>setdiff</code> <code>setxor</code> <code>union</code>	<ul style="list-style-type: none"> <li>These functions support unsorted tables in all cases. You do not have to specify the <code>'stable'</code> option.</li> </ul>
<code>issortedrows</code>	<ul style="list-style-type: none"> <li>The input argument <code>vars</code> must be constant.</li> <li>If any table variables have multiple columns, then those variables must have fixed widths.</li> </ul>

Function	Limitations
join	<ul style="list-style-type: none"><li>• In general, input tables cannot have nonkey variables with the same names. However, you can join subsets of the input tables if you specify the name-value arguments:<ul style="list-style-type: none"><li>• 'KeepOneCopy', where you list variables to take from the left input table only.</li><li>• 'LeftVariables' and 'RightVariables', where you list variables to take from either the left input table or the right input table, but not both.</li></ul></li><li>• The values of these name-value arguments must be constant:<ul style="list-style-type: none"><li>• 'Keys'</li><li>• 'LeftKeys'</li><li>• 'RightKeys'</li><li>• 'LeftVariables'</li><li>• 'RightVariables'</li><li>• 'KeepOneCopy'</li></ul></li><li>• Nested tables are not supported.</li></ul>
movevars	<ul style="list-style-type: none"><li>• The input argument <code>vars</code> cannot contain duplicate variable names.</li></ul>

Function	Limitations
outerjoin	<ul style="list-style-type: none"> <li>• Input tables cannot have key variables with the same names unless the value of 'MergeKeys' is true (logical 1).</li> <li>• In general, the input tables cannot have any nonkey variables with the same names. However, you can join subsets of the input tables if you specify the 'LeftVariables' and 'RightVariables' name-value arguments. Specify these arguments so that no variable name appears in both 'LeftVariables' and 'RightVariables'.</li> <li>• The values of these name-value arguments must be constant: <ul style="list-style-type: none"> <li>• 'Keys'</li> <li>• 'LeftKeys'</li> <li>• 'RightKeys'</li> <li>• 'MergeKeys'</li> <li>• 'LeftVariables'</li> <li>• 'RightVariables'</li> <li>• 'Type'</li> </ul> </li> <li>• Nested tables are not supported.</li> </ul>
rows2vars	<ul style="list-style-type: none"> <li>• The input table cannot be variable-size.</li> <li>• The 'VariableNamesSource' name-value argument is not supported.</li> <li>• The value of the 'DataVariables' name-value argument must be constant.</li> <li>• The value of the 'VariableNamingRule' name-value argument must be constant.</li> <li>• If you assign row names to the input table, then the vector of row names must be constant.</li> </ul>
sortrows	<ul style="list-style-type: none"> <li>• The input argument vars must be constant.</li> <li>• If tblA has a variable that is a cell array of character vectors with multiple columns, then you cannot sort the table using the values in that variable.</li> </ul>
splitvars	<ul style="list-style-type: none"> <li>• The value of the 'NewVariableNames' name-value argument must be constant.</li> <li>• The variables that are split cannot have a variable number of columns.</li> </ul>

Function	Limitations
stack	<ul style="list-style-type: none"> <li>• The second input argument, <code>vars</code>, must be constant.</li> <li>• The values of the <code>'ConstantVariables'</code>, <code>'NewDataVariableName'</code>, and <code>'IndexVariableName'</code> name-value arguments must be constant.</li> </ul>
unstack	<ul style="list-style-type: none"> <li>• The <code>'NewDataVariableNames'</code> name-value argument must be specified. Its value must be constant.</li> <li>• The <code>vars</code> and <code>ivars</code> input arguments (data variables and indicator variables) must be constant.</li> <li>• If you specify grouping variables and constant variables, then they must be constant.</li> <li>• If you specify an aggregation function, then it must be constant.</li> <li>• If a variable of the input table is a cell array of character vectors, then <code>unstack</code> fills empty cells in the corresponding output variable with 1-by-0 character arrays in the generated code. In MATLAB, <code>unstack</code> fills such gaps with 0-by-0 character arrays.</li> <li>• The <code>unstack</code> function does not support code generation when the input table has a variable that is a heterogeneous cell array that cannot be converted to a homogeneous cell array. <ul style="list-style-type: none"> <li>• If the input has a variable that is a homogeneous cell array, or that can be converted to one, then the <code>'AggregationFunction'</code> name-value argument must be specified. The default value of <code>'AggregationFunction'</code> is <code>'unique'</code>. But the <code>unique</code> function does not support cell arrays.</li> </ul> </li> </ul>

Function	Limitations
varfun	<ul style="list-style-type: none"> <li>• The function handle input, <code>func</code>, must be constant.</li> <li>• While function handles can be inputs to <code>varfun</code> itself, they cannot be inputs to your entry point functions. Specify <code>func</code> within the code meant for code generation. For more information, see “Function Handle Limitations for Code Generation” (MATLAB Coder).</li> <li>• The values for all name-value arguments must be constant.</li> <li>• The <code>'ErrorHandler'</code> name-value argument is not supported for code generation.</li> <li>• Variable-size input arguments are not supported.</li> <li>• Grouping variables cannot have duplicate values in generated code.</li> <li>• You cannot specify the value of <code>'OutputFormat'</code> as <code>'cell'</code> if you specify the <code>'GroupingVariables'</code> name-value argument and the function returns a different data type for each variable specified by <code>'InputVariables'</code>.</li> <li>• If you specify groups and the number of groups is not known at compile time, and that number is zero, then empty double variables in the output might have sizes of 1-by-0 in generated code. In MATLAB, such variables have sizes of 0-by-0.</li> </ul>

## Code Generation for Timetables

### In this section...

“Define Timetables for Code Generation” on page 65-2

“Allowed Operations on Timetables” on page 65-2

“MATLAB Toolbox Functions That Support Timetables” on page 65-3

The `timetable` data type is a data type suitable for tabular data with time-stamped rows. Like tables, timetables consist of rows and column-oriented variables. Each variable in a timetable can have a different data type and a different size with one restriction: each variable must have the same number of rows.

The *row times* of a timetable are time values that label the rows. You can index into a timetable by row time and variable. To index into a timetable, use smooth parentheses ( ) to return a subtable or curly braces { } to extract the contents. You can refer to variables and to the vector of row times by their names. For more information, see “Timetables”.

When you use timetables with code generation, adhere to these restrictions.

### Define Timetables for Code Generation

For code generation, use the `timetable` function. For example, suppose the input arguments to your MATLAB function are three arrays that have the same number of rows (A, B, and C), a `datetime` or `duration` vector containing row times (D), and a cell array that has variable names (vnames). You can create a timetable that contains these arrays as timetable variables.

```
function TT = foo(A,B,C,D,vnames) %#codegen
    TT = table(A,B,C,'RowTimes',D,'VariableNames',vnames);
end
```

To convert arrays and tables to timetables, use the `array2timetable` and `table2timetable` functions. For example, you can convert an input M-by-N matrix to a timetable, where each column of the matrix becomes a variable in the timetable. Assign row times by using a `duration` vector.

```
function TT = foo(A,D,vnames) %#codegen
    TT = array2timetable(A,'RowTimes',D,'VariableNames',vnames);
end
```

For code generation, you must supply timetable variable names when you create a timetable. Timetable variable names do not have to be valid MATLAB identifiers. The names must be composed of ASCII characters, but can include any ASCII characters (such as commas, dashes, and space characters).

The row times can have either the `datetime` or `duration` data type.

### Allowed Operations on Timetables

For code generation, you are restricted to the operations on timetables listed in this table.

Operation	Example	Notes
Assignment operator: =	<pre>TT = timetable(A,B,C,'RowTimes',D,... 'VariableNames',vnames); TT{: ,1} = X;</pre>	<p>Code generation does not support using the assignment operator = to:</p> <ul style="list-style-type: none"> <li>• Delete a variable or a row.</li> <li>• Add a variable or a row.</li> </ul>
Indexing operation	<pre>D = seconds(1:10); TT = timetable(A,B,C,'RowTimes',D,... 'VariableNames',vnames); TT(seconds(3:7),1:3);</pre>	<p>Code generation supports indexing by position, variable or row time, and logical indexing. Also, you can index using objects created by using the <code>timerange</code> or <code>withtol</code> functions.</p> <p>Code generation supports:</p> <ul style="list-style-type: none"> <li>• Timetable indexing with smooth parentheses, <code>()</code>.</li> <li>• Content indexing with curly braces, <code>{}</code>.</li> <li>• Dot notation to access a timetable variable.</li> </ul>
Concatenation	<pre>TT1 = timetable(A,B,C,'RowTimes',D1,... 'VariableNames',vnames); TT2 = timetable(D,E,F,'RowTimes',D2,... 'VariableNames',vnames); TT = [TT1 ; TT2];</pre>	<p>Code generation supports timetable concatenation.</p> <ul style="list-style-type: none"> <li>• For vertical concatenation, timetables must have variables that have the same names in the same order.</li> <li>• For horizontal concatenation, timetables must have the same number of rows. They also must have the same row times in the same order.</li> </ul>

## MATLAB Toolbox Functions That Support Timetables

For code generation, you can use timetables with these MATLAB toolbox functions:

- `addvars`
- `array2timetable`
- `cat`
- `convertvars`
- `height`
- `horzcat`
- `innerjoin`

- intersect
- isempty
- ismember
- isregular
- issorted
- issortedrows
- join
- mergevars
- movevars
- ndims
- numel
- outerjoin
- removevars
- renamevars
- rows2vars
- retime
- setdiff
- setxor
- size
- sortrows
- splitvars
- stack
- synchronize
- table2timetable
- timerange
- timetable
- timetable2table
- union
- unique
- unstack
- varfun
- vertcat
- width
- withtol

## **See Also**

### **More About**

- “Timetable Limitations for Code Generation” on page 65-8

## Define Timetable Inputs

### Define Timetable Inputs at the Command Line

Use one of these procedures:

- “Provide an Example Timetable Input” on page 65-5
- “Provide a Timetable Type” on page 65-5
- “Provide a Constant Timetable Input” on page 65-5

Alternatively, if you have a test file that calls your entry-point function with example inputs, you can determine the input types by using `coder.getArgTypes`.

### Provide an Example Timetable Input

#### Provide a Timetable Type

To provide a type for a timetable to :

- 1 Define a timetable. For example:

```
TT = timetable(A,B,C, 'RowTimes',D, 'VariableNames',vnames);
```

- 2 Create a type from T.

```
t = coder.typeof(TT);
```

### Provide a Constant Timetable Input

To specify that a timetable input is constant, use `coder.Constant` with the `-args` option:

## Representation of Timetables

A coder type object for a timetable describes the object and its properties. Use `coder.typeof` or pass `timetable` as a string scalar to `coder.newtype`.

The coder type object displays a succinct description of the object properties while excluding internal state values. Nonconstant properties display their type and size, while constant properties display only their values. For example:

```
t = timetable((1:5)',(11:15)', 'SampleRate',1);
tType = coder.typeof(t)
```

The representation of variable `t` is stored in coder type object `tType`.

```
tType =
```

```
matlab.coder.type.RegularTimetableType
 5x2 timetable
      Data : 1x2 homogeneous cell
      Description : 1x0 char
      UserData : 0x0 double
      DimensionNames : {'Time'} {'Variables'}
      VariableNames : {'Var1'} {'Var2'}
      VariableDescriptions : 1x2 homogeneous cell
```

```

VariableUnits : 1x2 homogeneous cell
VariableContinuity : 1x2 matlab.internal.coder.tabular.Continuity
StartTime : 1x1 matlab.coder.type.DurationType
SampleRate : 1x1 double
TimeStep : 1x1 matlab.coder.type.DurationType

```

Define a regular timetable by specifying the `SampleRate` or `TimeStep`. You can also define an irregular timetable by specifying the `RowTimes`. For example:

```

t1 = timetable((1:3)', 'RowTimes', seconds(1:3));
t1Type = coder.typeof(t)

```

The representation of irregular table `t1` is stored in coder type object `t1Type`.

```

t1Type =
matlab.coder.type.TimetableType
  3x1 timetable
      Data : 1x1 homogeneous cell
      Description : 1x0 char
      UserData : 0x0 double
      DimensionNames : {'Time'} {'Variables'}
      VariableNames : {'Var1'}
VariableDescriptions : 1x1 homogeneous cell
VariableUnits : 1x1 homogeneous cell
VariableContinuity : 1x1 matlab.internal.coder.tabular.Continuity
RowTimes : 3x1 matlab.coder.type.DurationType

```

If your workflow requires the legacy representation of coder type objects, use the `getCoderType` function on the variable that has the new representation of your class or object. See “Legacy Representation of Coder Type Objects” (MATLAB Coder).

### Resize Object Properties by Using `coder.resize`

You can resize most objects by using `coder.resize`. You can resize objects, its properties and create arrays within the properties.

For a timetable coder object, you can resize the object properties:

```

t = timetable((1:5)', (11:15)', 'SampleRate', 1);
tType = coder.typeof(t);
tType.UserData = coder.resize(tType.UserData, [10 1], [1 0])

```

This code resizes the `UserData` property to be a `:10x1` double property. The first dimension is upper-bound at 10.

```

tType =
matlab.coder.type.RegularTimetableType
  5x2 timetable
      Data : 1x2 homogeneous cell
      Description : 1x0 char
      UserData : :10x1 double
      DimensionNames : {'Time'} {'Variables'}
      VariableNames : {'Var1'} {'Var2'}
VariableDescriptions : 1x2 homogeneous cell
VariableUnits : 1x2 homogeneous cell
VariableContinuity : 1x2 matlab.internal.coder.tabular.Continuity

```

```
StartTime : 1x1 matlab.coder.type.DurationType
SampleRate : 1x1 double
TimeStep : 1x1 matlab.coder.type.DurationType
```

You can also resize the object by using `coder.resize`. See “Edit and Represent Coder Type Objects and Properties” (MATLAB Coder).

- “Timetable Limitations for Code Generation” on page 65-8

## Timetable Limitations for Code Generation

If you create timetables, modify them, or use timetable functions in MATLAB code that you intend for code generation, then code generation has limitations described in the next sections. Limitations that apply to classes also apply to timetables. For more information on class limitations, see “MATLAB Classes Definition for Code Generation” (MATLAB Coder).

### Creating Timetables Limitations

If your MATLAB code creates timetables, then code generation has these limitations.

Inputs for Timetable Creation	Limitations
Any inputs	<ul style="list-style-type: none"> <li>• The name of the first dimension of a timetable is 'Time' unless you specify it by using the 'DimensionNames' name-value argument.  The name of the first dimension is also the name of the vector of row times, which you can refer to by using dot notation.</li> <li>• To create a regular timetable when the 'SampleRate', 'StartTime', or 'TimeStep' name-value arguments are passed in by an entry point function, first use the <code>coder.Constant</code> function to make the values constant. If you do not make them constant, then the row times are considered to be irregular.</li> <li>• If you create a regular timetable, and you attempt to set irregular row times, then an error is produced.</li> <li>• If you create an irregular timetable, then it remains irregular even if you set its sample rate or time step.</li> <li>• Timetable variable names do not have to be valid MATLAB identifiers. The names must be composed of ASCII characters, which can include commas, dashes, and space characters.</li> </ul>
Timetable created from input arrays	<ul style="list-style-type: none"> <li>• You must specify variables names by using the 'VariableNames' name-value argument when creating timetables from input arrays by using the <code>timetable</code> or <code>array2timetable</code> functions.</li> </ul>

Inputs for Timetable Creation	Limitations
<p>Timetable created with preallocated variables</p>	<ul style="list-style-type: none"> <li>• You do not have to specify the 'VariableNames' argument when you preallocate a timetable by using the timetable function and the 'Size' name-value argument.</li> <li>• You can specify only the following data types by using the 'VariableTypes' name-value argument: <ul style="list-style-type: none"> <li>• 'double'</li> <li>• 'single'</li> <li>• 'doublenan' or 'doubleNaN'</li> <li>• 'singlenan' or 'singleNaN'</li> <li>• 'int8', 'int16', 'int32', or 'int64'</li> <li>• 'uint8', 'uint16', 'uint32', or 'uint64'</li> <li>• 'logical'</li> <li>• 'datetime'</li> <li>• 'duration'</li> <li>• 'cellstr'</li> <li>• 'char'</li> </ul> </li> </ul>

## Modifying Timetables Limitations

If your MATLAB code modifies data in a timetable, its row times, or its properties, then code generation has these limitations.

Timetable Operation or Property	Limitations
<p>VariableNames, DimensionNames, or UserData properties</p>	<ul style="list-style-type: none"> <li>• After you create a timetable, you cannot change the VariableNames, DimensionNames, or UserData properties.</li> </ul> <p>When you create a timetable, you can specify the 'VariableNames', 'DimensionNames', and 'RowTimes' input arguments to set the properties having those names.</p>

Timetable Operation or Property	Limitations
Timetable indices as input arguments to generated code	<ul style="list-style-type: none"> <li>To pass timetable indices that specify variables into generated code as input arguments, first use the <code>coder.Constant</code> function to make the indices into the second dimension of the timetable constant. If indices into the second dimension are not constant, then indexing into variables produces an error.</li> <li>If a timetable has row times that are <code>duration</code> values, and you index into it by using either <code>duration</code> values or an object produced by the <code>timerange</code> or <code>withtol</code> functions, then the output is nonconstant with a variable number of rows.</li> <li>If a regular timetable has row times that are <code>duration</code> values, and you index into it by using either <code>duration</code> values or an object produced by the <code>timerange</code> or <code>withtol</code> functions, then the output is considered to be irregular.</li> </ul>
Custom metadata	<ul style="list-style-type: none"> <li>You cannot add custom metadata to a timetable. The <code>addprop</code> and <code>rmprop</code> functions are not supported.</li> </ul>
Assignments that change size of timetable	<ul style="list-style-type: none"> <li>You cannot change the size of a timetable by assignments. For example, this call to add a new row produces an error. <pre data-bbox="906 1192 1437 1360">function TT = foo() %#codegen     TT = timetable((1:3)',(1:3)',...         'RowTimes',seconds([0,5,10]),...         'VariableNames',{'Var1','Var2'});     TT{4,:} = [5,5]; end</pre> <p>Deleting a row or a variable by assignment also produces an error.</p> </li> <li>You cannot add a new row by using a new row time in an assignment. For example, this call to add a new row by using a new row time instead of a numeric index does not produce an error, but also does not add the new row. <pre data-bbox="906 1654 1437 1814">function TT = foo() %#codegen     TT = timetable((1:3)',(1:3)',...         'RowTimes',seconds([0,5,10]),...         'VariableNames',{'Var1','Var2'});     TT{seconds(15),:} = [5,5]; end</pre> </li> </ul>

Timetable Operation or Property	Limitations
Vertical concatenation	<ul style="list-style-type: none"> <li>When you vertically concatenate timetables, they must have the same variable names in the same order. In MATLAB, the variable names must be the same but can be in different orders in the timetables.</li> </ul>
Horizontal concatenation	<ul style="list-style-type: none"> <li>When you horizontally concatenate timetables, they must have the same row times in the same order. In MATLAB, the row times must be the same but can be in different orders in the timetables.</li> </ul>
Timetable variables that are N-D cell arrays	<ul style="list-style-type: none"> <li>If two timetables have variables that are N-D cell arrays, then you cannot vertically concatenate the timetables.</li> <li>You cannot use curly braces to extract data from multiple timetable variables that are N-D cell arrays because this operation is horizontal concatenation.</li> </ul>

## Using Timetable Functions Limitations

If your MATLAB code uses the functions listed in the table, then code generation has these limitations.

Function	Limitations
convertvars	<ul style="list-style-type: none"> <li>Function handles are not supported.</li> <li>The second and third input arguments (<code>vars</code> and <code>dataType</code>) must be constant.</li> <li>You cannot specify <code>dataType</code> as <code>'cell'</code>, <code>'cellstr'</code>, or <code>'char'</code>.</li> </ul>

Function	Limitations
innerjoin	<ul style="list-style-type: none"> <li>• In general, the input timetables cannot have any nonkey variables with the same names. However, you can join subsets of the input timetables if you specify the 'LeftVariables' and 'RightVariables' name-value arguments. Specify these arguments so that no variable name appears in both 'LeftVariables' and 'RightVariables'.</li> <li>• The values of these name-value arguments must be constant: <ul style="list-style-type: none"> <li>• 'Keys'</li> <li>• 'LeftKeys'</li> <li>• 'RightKeys'</li> <li>• 'LeftVariables'</li> <li>• 'RightVariables'</li> </ul> </li> <li>• Nested timetables are not supported.</li> </ul>
intersect setdiff setxor union	<ul style="list-style-type: none"> <li>• These functions support unsorted timetables in all cases. You do not have to specify the 'stable' option.</li> </ul>
isregular	<ul style="list-style-type: none"> <li>• Use <code>coder.Constant</code> to make the input argument <code>timeComponent</code> constant.</li> <li>• The input argument <code>timeComponent</code> cannot be a calendar unit. If you specify it, then its value must be 'time'.</li> </ul>
issortedrows	<ul style="list-style-type: none"> <li>• The input argument <code>vars</code> must be constant.</li> <li>• If any timetable variables have multiple columns, then those variables must have fixed widths.</li> </ul>

Function	Limitations
join	<ul style="list-style-type: none"><li>• In general, input timetables cannot have nonkey variables with the same names. However, you can join subsets of the input timetables if you specify the name-value arguments:<ul style="list-style-type: none"><li>• 'KeepOneCopy', where you list variables to take from the left input timetable only.</li><li>• 'LeftVariables' and 'RightVariables', where you list variables to take from either the left input timetable or the right input timetable, but not both.</li></ul></li><li>• The values of these name-value arguments must be constant:<ul style="list-style-type: none"><li>• 'Keys'</li><li>• 'LeftKeys'</li><li>• 'RightKeys'</li><li>• 'LeftVariables'</li><li>• 'RightVariables'</li><li>• 'KeepOneCopy'</li></ul></li><li>• Nested timetables are not supported.</li></ul>
movevars	<ul style="list-style-type: none"><li>• The input argument <code>vars</code> cannot contain duplicate variable names.</li></ul>

Function	Limitations
outerjoin	<ul style="list-style-type: none"> <li>• Input timetables cannot have key variables with the same names unless the value of 'MergeKeys' is true (logical 1).</li> <li>• In general, the input timetables cannot have any nonkey variables with the same names. However, you can join subsets of the input timetables if you specify the 'LeftVariables' and 'RightVariables' name-value arguments. Specify these arguments so that no variable name appears in both 'LeftVariables' and 'RightVariables'.</li> <li>• The values of these name-value arguments must be constant: <ul style="list-style-type: none"> <li>• 'Keys'</li> <li>• 'LeftKeys'</li> <li>• 'RightKeys'</li> <li>• 'MergeKeys'</li> <li>• 'LeftVariables'</li> <li>• 'RightVariables'</li> <li>• 'Type'</li> </ul> </li> <li>• Nested timetables are not supported.</li> </ul>
retime synchronize	<ul style="list-style-type: none"> <li>• The row times of the output timetable are considered to be irregular, even when synchronized to row times that have a regular time step.</li> <li>• The 'makima' interpolation method is not supported.</li> <li>• If the VariableContinuity properties of the input timetables are not constant, then this function ignores them.</li> <li>• The 'weekly', 'monthly', and 'quarterly' time steps are not supported. <ul style="list-style-type: none"> <li>• If the input timetables have row times that are datetime values, then the 'daily' and 'yearly' time steps also are not supported.</li> </ul> </li> </ul>
sortrows	<ul style="list-style-type: none"> <li>• The input argument vars must be constant.</li> <li>• If tblA has a variable that is a cell array of character vectors with multiple columns, then you cannot sort the timetable using the values in that variable.</li> </ul>

Function	Limitations
splitvars	<ul style="list-style-type: none"><li>• The value of the 'NewVariableNames' name-value argument must be constant.</li><li>• The variables that are split cannot have a variable number of columns.</li></ul>
stack	<ul style="list-style-type: none"><li>• The second input argument, vars, must be constant.</li><li>• The values of the 'ConstantVariables', 'NewDataVariableName', and 'IndexVariableName' name-value arguments must be constant.</li></ul>
timerange	<ul style="list-style-type: none"><li>• The input argument unitOfTime is not supported.</li></ul>

Function	Limitations
unstack	<ul style="list-style-type: none"> <li>• The 'NewDataVariableNames' name-value argument must be specified. Its value must be constant.</li> <li>• The vars and ivars input arguments (data variables and indicator variables) must be constant.</li> <li>• If you specify grouping variables and constant variables, then they must be constant.</li> <li>• If you specify an aggregation function, then it must be constant.</li> <li>• If the input is a timetable with regular row times and you specify grouping variables that do not include the row times, then the output timetable might have irregular row times. Even though the intervals between output row times might look the same, the output timetable considers the vector of row times to be irregular.</li> <li>• If a variable of the input timetable is a cell array of character vectors, then unstack fills empty cells in the corresponding output variable with 1-by-0 character arrays in the generated code. In MATLAB, unstack fills such gaps with 0-by-0 character arrays.</li> <li>• The unstack function does not support code generation when the input timetable has a variable that is a heterogeneous cell array that cannot be converted to a homogeneous cell array. <ul style="list-style-type: none"> <li>• If the input has a variable that is a homogeneous cell array, or that can be converted to one, then the 'AggregationFunction' name-value argument must be specified. The default value of 'AggregationFunction' is 'unique'. But the unique function does not support cell arrays.</li> </ul> </li> </ul>

Function	Limitations
varfun	<ul style="list-style-type: none"> <li>• The function handle input, <code>func</code>, must be constant.</li> <li>• While function handles can be inputs to <code>varfun</code> itself, they cannot be inputs to your entry point functions. Specify <code>func</code> within the code meant for code generation. For more information, see “Function Handle Limitations for Code Generation” (MATLAB Coder).</li> <li>• The values for all name-value arguments must be constant.</li> <li>• The <code>'ErrorHandler'</code> name-value argument is not supported for code generation.</li> <li>• Variable-size input arguments are not supported.</li> <li>• If you specify <code>'GroupingVariables'</code>, then the output is always an irregular timetable.</li> <li>• Grouping variables cannot have duplicate values in generated code.</li> <li>• You cannot specify the value of <code>'OutputFormat'</code> as <code>'cell'</code> if you specify the <code>'GroupingVariables'</code> name-value arguments and the function returns a different data type for each variable specified by <code>'InputVariables'</code>.</li> <li>• If you specify groups and the number of groups is not known at compile-time, and that number turns out to be zero, then empty double variables in the output might have sizes of 1-by-0 in generated code. In MATLAB, such variables have sizes of 0-by-0.</li> </ul>

## MATLAB Classes Definition for Code Generation

To generate efficient standalone code for MATLAB classes, you must use classes differently than when running your code in the MATLAB environment.

### Language Limitations

Although code generation support is provided for common features of classes such as properties and methods, there are a number of advanced features which are not supported, such as:

- Events
- Listeners
- Arrays of objects
- Recursive data structures
  - Linked lists
  - Trees
  - Graphs
- Nested functions in constructors
- Overloadable operators `subsref`, `subsassign`, and `subsindex`

In MATLAB, classes can define their own versions of the `subsref`, `subsassign`, and `subsindex` methods. Code generation does not support classes that have their own definitions of these methods.

- The empty method

In MATLAB, classes have a built-in static method, `empty`, which creates an empty array of the class. Code generation does not support this method.

- The following MATLAB handle class methods:
  - `addlistener`
  - `eq`
  - `findobj`
  - `findprop`
- The `AbortSet` property attribute

### Code Generation Features Not Compatible with Classes

- You can generate code for entry-point MATLAB functions that use classes, but you cannot generate code directly for a MATLAB class.

For example, if `ClassNameA` is a class definition, you cannot generate code by executing:

```
codegen ClassNameA
```

- A handle class object cannot be an entry-point function input or output.
- A value class object can be an entry-point function input or output. However, if a value class object contains a handle class object, then the value class object cannot be an entry-point function input or output. A handle class object cannot be an entry-point function input or output.

- Code generation does not support global variables that are handle classes.
- Code generation does not support multiple outputs from constructors.
- You cannot use classes for Simulink signals, parameters, or data store memory.
- Code generation does not support assigning an object of a value class into a nontunable property. For example, `obj.prop=v`; is invalid when `prop` is a nontunable property and `v` is an object based on a value class.
- You cannot use `coder.extrinsic` to declare a class or method as extrinsic.
- You cannot pass a MATLAB class to `coder.ceval`. You can pass class properties to `coder.ceval`.
- If a property has a get method, a set method, or validators, or is a System object property with certain attributes, then you cannot pass the property by reference to an external function. See “Passing By Reference Not Supported for Some Properties” on page 66-20.
- If you use classes in code in the MATLAB Function block, you cannot use the debugger to view class information.
- If an object has duplicate property names and the code generator tries to constant-fold the object, code generation can fail. The code generator constant-folds an object when it is used with `coder.const`, or when it is an input to or output from a constant-folded extrinsic function.

Duplicate property names occur in an object of a subclass in these situations:

- The subclass has a property with the same name as a property of the superclass.
- The subclass derives from multiple superclasses that use the same name for a property.

Duplicate property names must be consistently constant or non-constant across multiple inheritance related classes. For example, code generation produces an error if an object with a constant property `aProp` inherits `aProp` from a superclass where `aProp` is defined as non-constant.

For information about when MATLAB allows duplicate property names, see “Subclassing Multiple Classes”.

## Defining Class Properties for Code Generation

For code generation, you must define class properties differently than you do when running your code in the MATLAB environment:

- A property validation error ends a simulation with an error message. To test property validation, it is a best practice to run a simulation over the full range of input values. C/C++ code generated by Simulink Coder does not detect or report property validation errors.
- After defining a property, do not assign it an incompatible type. Do not use a property before attempting to grow it.

When you define class properties for code generation, consider the same factors that you take into account when defining variables. In the MATLAB language, variables can change their class, size, or complexity dynamically at run time so you can use the same variable to hold a value of varying class, size, or complexity. C and C++ use static typing. Before using variables, to determine their type, the code generator requires a complete assignment to each variable. Similarly, before using properties, you must explicitly define their class, size, and complexity.

- Initial values:

- If the property does not have an explicit initial value, the code generator assumes that it is undefined at the beginning of the constructor. The code generator does not assign an empty matrix as the default.
- If the property does not have an initial value and the code generator cannot determine that the property is assigned prior to first use, the software generates a compilation error.
- For System objects, if a nontunable property is a structure, you must completely assign the structure. You cannot do partial assignment using subscripting.

For example, for a nontunable property, you can use the following assignment:

```
mySystemObject.nonTunableProperty=struct('fieldA','a','fieldB','b');
```

You cannot use the following partial assignments:

```
mySystemObject.nonTunableProperty.fieldA = 'a';
mySystemObject.nonTunableProperty.fieldB = 'b';
```

- `coder. varsize` is not supported for class properties.
- If the initial value of a property is an object, then the property must be constant. To make a property constant, declare the `Constant` attribute in the property block. For example:

```
classdef MyClass
    properties (Constant)
        p1 = MyClass2;
    end
end
```

Code generation does not support a constant property that is assigned to an object that contains a System object.

- MATLAB computes class initial values at class loading time before code generation. If you use persistent variables in MATLAB class property initialization, the value of the persistent variable computed when the class loads belongs to MATLAB; it is not the value used at code generation time. If you use `coder.target` in MATLAB class property initialization, `coder.target('MATLAB')` returns `true (1)`.
- Variable-size properties:
  - Code generation supports upper-bounded and unbounded variable-size properties for both value and handle classes.
  - To generate unbounded variable-size class properties, enable dynamic memory allocation.
  - To make a variable-size class property, make two sequential assignments of a class property, one to a scalar and the next to an array.

```
classdef varSizeProp1 < handle
    properties
        prop
        varProp
    end
end

function extFunc(n)
    obj = varSizeProp1;
    % Assign a scalar value to the property.
    obj.prop = 1;
    obj.varProp = 1;
    % Assign an array to the same property to make it variable-sized.
    obj.prop = 1:98;
    obj.varProp = 1:n;
end
```

In the preceding code, the first assignment to `prop` and `varProp` is scalar, and their second assignment is to an array with the same base type. The size of `prop` has an upper bound of 98, making it an upper-bounded, variable-size property.

If `n` is unknown at compile time, `obj.varProp` is an unbounded variable-size property. If it is known, it is an upper-bounded, variable-size class property.

- If the class property is initialized with a variable-size array, the property is variable-size.

```
classdef varSizeProp2
    properties
        prop
    end
    methods
        function obj = varSizeProp2(inVar)
            % Assign incoming value to local variable
            locVar = inVar;

            % Declare the local variable to be a variable-sized column
            % vector with no size limit
            coder.varsize('locVar',[inf 1],[1 0]);

            % Assign value
            obj.prop = locVar;
        end
    end
end
```

In the preceding code, `inVar` is passed to the class constructor and stored in `locVar`. `locVar` is modified to be variable-size by `coder.varsize` and assigned to the class property `obj.prop`, which makes the property variable-size.

- If the input to the function call `varSizeProp2` is variable-size, `coder.varsize` is not required.

```
function z = constructCall(n)
    z = varSizeProp2(1:n);
end
```

- If the value of `n` is unknown at compile-time and has no specified bounds, `z.prop` is an unbounded variable-size class property.
- If the value of `n` is unknown at compile-time and has specified bounds, `z.prop` is an upper-bounded variable-size class property.
- If a property is constant and its value is an object, you cannot change the value of a property of that object. For example, suppose that:
  - `obj` is an object of `myClass1`.
  - `myClass1` has a constant property `p1` that is an object of `myClass2`.
  - `myClass2` has a property `p2`.

Code generation does not support the following code:

```
obj.p1.p2 = 1;
```

## Inheritance from Built-In MATLAB Classes Not Supported

You cannot generate code for classes that inherit from built-in MATLAB classes. For example, you cannot generate code for the following class:

```
classdef myclass < double
```

An exception to this rule is the MATLAB enumeration class. You can generate code for enumeration classes that inherit from built-in MATLAB classes. See “Code Generation for Enumerations” (MATLAB Coder).

- “Classes That Support Code Generation” on page 66-7

## Classes That Support Code Generation

You can generate code for MATLAB value and handle classes and user-defined System objects. Your class can have multiple methods and properties and can inherit from multiple classes.

<b>To generate code for:</b>	<b>Example:</b>
Value classes	"Generate Code for MATLAB Value Classes" on page 66-8
Handle classes including user-defined System objects	"Generate Code for MATLAB Handle Classes and System Objects" on page 66-12

For more information, see:

- "Role of Classes in MATLAB"
- "MATLAB Classes Definition for Code Generation" on page 66-2

## Generate Code for MATLAB Value Classes

This example shows how to generate code for a MATLAB value class and then view the generated code in the code generation report.

- 1 In a writable folder, create a MATLAB value class, Shape. Save the code as Shape.m.

```

classdef Shape
% SHAPE Create a shape at coordinates
% centerX and centerY
    properties
        centerX;
        centerY;
    end
    properties (Dependent = true)
        area;
    end
    methods
        function out = get.area(obj)
            out = obj.getarea();
        end
        function obj = Shape(centerX,centerY)
            obj.centerX = centerX;
            obj.centerY = centerY;
        end
    end
end
methods(Abstract = true)
    getarea(obj);
end
methods(Static)
    function d = distanceBetweenShapes(shape1,shape2)
        xDist = abs(shape1.centerX - shape2.centerX);
        yDist = abs(shape1.centerY - shape2.centerY);
        d = sqrt(xDist^2 + yDist^2);
    end
end
end
end

```

- 2 In the same folder, create a class, Square, that is a subclass of Shape. Save the code as Square.m.

```

classdef Square < Shape
% Create a Square at coordinates center X and center Y
% with sides of length of side
    properties
        side;
    end
    methods
        function obj = Square(side,centerX,centerY)
            obj@Shape(centerX,centerY);
            obj.side = side;
        end
        function Area = getarea(obj)
            Area = obj.side^2;
        end
    end
end
end
end

```

- 3 In the same folder, create a class, Rhombus, that is a subclass of Shape. Save the code as Rhombus.m.

```

classdef Rhombus < Shape
    properties
        diag1;
        diag2;
    end
    methods
        function obj = Rhombus(diag1,diag2,centerX,centerY)
            obj@Shape(centerX,centerY);
            obj.diag1 = diag1;
            obj.diag2 = diag2;
        end
        function Area = getarea(obj)
            Area = 0.5*obj.diag1*obj.diag2;
        end
    end
end
end

```

- 4 Write a function that uses this class.

```

function [TotalArea, Distance] = use_shape
    %#codegen
    s = Square(2,1,2);
    r = Rhombus(3,4,7,10);
    TotalArea = s.area + r.area;
    Distance = Shape.distanceBetweenShapes(s,r);

```

- 5 Generate a static library for use\_shape and generate a code generation report.

```

codegen -config:lib -report use_shape

```

codegen generates a C static library with the default name, use\_shape, and supporting files in the default folder, codegen/lib/use\_shape.

- 6 Click the **View report** link.

- 7 To see the Rhombus class definition, on the **MATLAB Source** pane, under Rhombus.m, click Rhombus. The Rhombus class constructor is highlighted.

- 8 Click the **Variables** tab. You see that the variable obj is an object of the Rhombus class. To see its properties, expand obj.

The screenshot shows the MATLAB Coder Report Viewer interface. The 'MATLAB Source' pane is active, and the 'Call Tree' view is selected. The Call Tree shows a hierarchy: use\_shape.m calls Rhombus.m, which calls Shape.m. The code pane displays the Rhombus class definition, including properties (diag1, diag2), methods (Rhombus constructor, obj@Shape, Area), and a function Area = getarea(obj). The bottom pane shows a table with columns: Name, Type, Size, and Class.

Name	Type	Size	Class
obj	Output	1 × 1	Rhombus
centerX		1 × 1	double
centerY		1 × 1	double
diag1		1 × 1	double
diag2		1 × 1	double
centerX	Input	1 × 1	double
centerY	Input	1 × 1	double
diag1	Input	1 × 1	double
diag2	Input	1 × 1	double

- 9 In the **MATLAB Source** pane, click **Call Tree**.

The **Call Tree** view shows that `use_shape` calls the `Rhombus` constructor and that the `Rhombus` constructor calls the `Shape` constructor.

The close-up shows the 'MATLAB SOURCE' pane with 'Function List' and 'Call Tree' tabs. The 'Call Tree' tab is active, showing a tree structure: use\_shape calls Square/Square, Rhombus/Rhombus, and Shape/get.area. Rhombus/Rhombus calls Shape/Shape, which then calls Shape/get.area. Shape/get.area calls Shape/distanceBetweenShapes.

- 10 In the code pane, in the `Rhombus` class constructor, move your pointer to this line:

```
obj@Shape(centerX,centerY)
```

The `Rhombus` class constructor calls the `Shape` method of the base `Shape` class. To view the `Shape` class definition, in `obj@Shape`, double-click `Shape`.

```
Shape.m
1 classdef Shape
2 % SHAPE Create a shape at coordinates
3 % centerX and centerY
4     properties
5         centerX;
6         centerY;
7     end
8     properties (Dependent = true)
9         area;
10    end
11    methods
12        function out = get.area(obj)
13            out = obj.getarea();
14        end
15        function obj = Shape(centerX,centerY)
16            obj.centerX = centerX;
17            obj.centerY = centerY;
18        end
19    end
20    methods(Abstract = true)
21        getarea(obj);
22    end
23    methods(Static)
24        function d = distanceBetweenShapes(shape1,shape2)
25            xDist = abs(shape1.centerX - shape2.centerX);
26            yDist = abs(shape1.centerY - shape2.centerY);
27            d = sqrt(xDist^2 + yDist^2);
28        end
29    end
30 end
31
32
```

## Generate Code for MATLAB Handle Classes and System Objects

This example shows how to generate code for a user-defined System object and then view the generated code in the code generation report.

- 1 In a writable folder, create a System object, `AddOne`, which subclasses from `matlab.System`. Save the code as `AddOne.m`.

```
classdef AddOne < matlab.System
% ADDONE Compute an output value that increments the input by one

    methods (Access=protected)
        % stepImpl method is called by the step method
        function y = stepImpl(~,x)
            y = x+1;
        end
    end
end
```

- 2 Write a function that uses this System object.

```
function y = testAddOne(x)
%#codegen
    p = AddOne();
    y = p.step(x);
end
```

- 3 Generate a MEX function for this code.

```
codegen -report testAddOne -args {0}
```

The `-report` option instructs `codegen` to generate a code generation report, even if no errors or warnings occur. The `-args` option specifies that the `testAddOne` function takes one scalar double input.

- 4 Click the **View report** link.
- 5 In the **MATLAB Source** pane, click `testAddOne`. To see information about the variables in `testAddOne`, click the **Variables** tab.

The screenshot shows the MATLAB IDE interface. The top toolbar includes navigation and editing tools. The left pane shows the MATLAB SOURCE tree with 'testAddOne.m' selected. The main editor displays the code for 'testAddOne.m':

```

1 function y = test
2 %#codegen
3 p = AddOne();
4 y = p.step(x);
5 end

```

A tooltip for the variable 'p' is visible, showing its properties: Size: 1 x 1, Class: AddOne. Below the code editor, a SUMMARY table is displayed:

Name	Type	Size	Class
y	Output	1 x 1	double
x	Input	1 x 1	double
p	Local	1 x 1	AddOne

6 To view the class definition for addOne, in the **MATLAB Source** pane, click AddOne.

The screenshot shows the MATLAB IDE interface with the 'AddOne.m' file selected in the MATLAB SOURCE pane. The main editor displays the class definition code for 'AddOne.m':

```

1 classdef AddOne < matlab.System
2 % ADDONE Compute an output value that increments the input by one
3
4 methods (Access=protected)
5 % stepImpl method is called by the step method
6 function y = stepImpl(~,x)
7     y = x+1;
8 end
9 end
10 end

```

- “Code Generation for Handle Class Destructors” on page 66-15

## Code Generation for Handle Class Destructors

You can generate code for MATLAB code that uses `delete` methods (destructors) for handle classes. To perform clean-up operations, such as closing a previously opened file before an object is destroyed, use a `delete` method. The generated code calls the `delete` method at the end of an object's lifetime, even if execution is interrupted by a run-time error. When System objects are destroyed, `delete` calls the `release` method, which in turn calls the user-defined `releaseImpl`. For more information on when to define a `delete` method in a MATLAB code, see "Handle Class Destructor".

### Guidelines and Restrictions

When you write the MATLAB code, adhere to these guidelines and restrictions:

- Code generation does not support recursive calls of the `delete` method. Do not create an object of a certain class inside the `delete` method for the same class. This usage might cause a recursive call of `delete` and result in an error message.
- The generated code always calls the `delete` method, when an object goes out of scope. Code generation does not support explicit calls of the `delete` method.
- Initialize all properties of `MyClass` that the `delete` method of `MyClass` uses either in the constructor or as the default property value. If `delete` tries to access a property that has not been initialized in one of these two ways, the code generator produces an error message.
- Suppose a property `prop1` of `MyClass1` is itself an object (an instance of another class `MyClass2`). Initialize all properties of `MyClass2` that the `delete` method of `MyClass1` uses. Perform this initialization either in the constructor of `MyClass2` or as the default property value. If `delete` tries to access a property of `MyClass2` that has not been initialized in one of these two ways, the code generator produces an error message. For example, define the two classes `MyClass1` and `MyClass2`:

```
classdef MyClass1 < handle
    properties
        prop1
    end
    methods
        function h = MyClass1(index)
            h.prop1 = index;
        end
        function delete(h)
            fprintf('h.prop1.prop2 is: %1.0f\n',h.prop1.prop2);
        end
    end
end

classdef MyClass2 < handle
    properties
        prop2
    end
end
```

Suppose you try to generate code for this function:

```
function MyFunction
obj2 = MyClass2;
```

```
obj1 = MyClass1(obj2); % Assign obj1.prop1 to the input (obj2)
end
```

The code generator produces an error message because you have not initialized the property `obj2.prop2` that the `delete` method displays.

## Behavioral Differences of Objects in Generated Code and in MATLAB

The behavior of objects in the generated code can be different from their behavior in MATLAB in these situations:

- The order of destruction of several independent objects might be different in MATLAB than in the generated code.
- The lifetime of objects in the generated code can be different from their lifetime in MATLAB. MATLAB calls the `delete` method when an object can no longer be reached from any live variable. The generated code calls the `delete` method when an object goes out of scope. In some situations, this difference causes `delete` to be called later on in the generated code than in MATLAB. For example, define the class:

```
classdef MyClass < handle
    methods
        function delete(h)
            global g
            % Destructor displays current value of global variable g
            fprintf('The global variable is: %1.0f\n',g);
        end
    end
end
```

Run the function:

```
function MyFunction
    global g
    g = 1;
    obj = MyClass;
    obj = MyClass;
    % MATLAB destroys the first object here
    g = 2;
    % MATLAB destroys the second object here
    % Generated code destroys both objects here
end
```

The first object can no longer be reached from any live variable after the second instance of `obj = MyClass` in `MyFunction`. MATLAB calls the `delete` method for the first object after the second instance of `obj = MyClass` in `MyFunction` and for the second object at the end of the function. The output is:

```
The global variable is: 1
The global variable is: 2
```

In the generated code, both `delete` method calls happen at the end of the function when the two objects go out of scope. Running `MyFunction_mex` results in a different output:

```
The global variable is: 2
The global variable is: 2
```

- In MATLAB, persistent objects are automatically destroyed when they cannot be reached from any live variable. In the generated code, you have to call the `terminate` function explicitly to destroy the persistent objects.
- The generated code does not destroy partially constructed objects. If a handle object is not fully constructed at run time, the generated code produces an error message but does not call the `delete` method for that object. For a System object, if there is a run-time error in `setupImpl`, the generated code does not call `releaseImpl` for that object.

MATLAB does call the `delete` method to destroy a partially constructed object.

## Class Does Not Have Property

If a MATLAB class has a method, `mymethod`, that returns a handle class with a property, `myprop`, you cannot generate code for the following type of assignment:

```
obj.mymethod().myprop=...
```

For example, consider the following classes:

```
classdef MyClass < handle
    properties
        myprop
    end
    methods
        function this = MyClass
            this.myprop = MyClass2;
        end
        function y = mymethod(this)
            y = this.myprop;
        end
    end
end

classdef MyClass2 < handle
    properties
        aa
    end
end
```

You cannot generate code for function `foo`.

```
function foo

h = MyClass;

h.mymethod().aa = 12;
```

In this function, `h.mymethod()` returns a handle object of type `MyClass2`. In MATLAB, the assignment `h.mymethod().aa = 12;` changes the property of that object. Code generation does not support this assignment.

### Solution

Rewrite the code to return the object and then assign a value to a property of the object.

```
function foo

h = MyClass;

b=h.mymethod();
b.aa=12;
```

- “MATLAB Classes Definition for Code Generation” on page 66-2

## Passing By Reference Not Supported for Some Properties

The code generator does not support passing a property by reference to an external function for these types of properties:

- A property with a get method or a set method.
- A property that uses validation functions.
- A System object property with an attribute, such as `Logical` or `PositiveInteger`, that constrains or modifies the property value.

Instead of passing a property by reference, save the property value in a temporary variable. Then, pass the temporary variable by reference to the external function. After the external function call, assign the temporary variable to the property. For example:

```
tmp = myObj.prop;  
coder.ceval('myFcn', coder.ref(tmp));  
myObj.prop = tmp;
```

The assignment after the `coder.ceval` call validates or modifies the property value according to the property access methods, validation functions, or attributes.

## Handle Object Limitations for Code Generation

The code generator statically determines the lifetime of a handle object. When you use handle objects, this static analysis has certain restrictions.

With static analysis the generated code can reuse memory rather than rely on a dynamic memory management scheme, such as reference counting or garbage collection. The code generator can avoid dynamic memory allocation and run-time automatic memory management. These generated code characteristics are important for some safety-critical and real-time applications.

For limitations, see:

- “A Variable Outside a Loop Cannot Refer to a Handle Object Allocated Inside a Loop” on page 66-21
- “A Handle Object That a Persistent Variable Refers To Must Be a Singleton Object” on page 66-22

The code generator analyzes whether all variables are defined prior to use. Undefined variables or data types cause an error during code generation. In certain circumstances, the code generator cannot determine if references to handle objects are defined. See “References to Handle Objects Can Appear Undefined” on page 66-23.

### A Variable Outside a Loop Cannot Refer to a Handle Object Allocated Inside a Loop

Consider the handle class `mycls` and the function `usehandle1`.

```
classdef mycls < handle
    properties
        prop
    end

    methods
        function obj = mycls(x)
            obj.prop = x;
        end
    end
end

function y = usehandle1
    p = mycls(0); % Instance of mycls with prop value 10 created

    for i = 1:10
        p = mycls(i); % Handle object allocated inside loop
    end

    y = p.prop; % Handle object referenced outside loop
end
```

If you try to generate code for the `usehandle1` function, the code generator produces an error. The error occurs because:

- A handle object is allocated inside the `for` loop. The variable `p.prop` refers to this handle object.

- Outside the loop, the variable `x` refers to the property `prop` handle object.

## A Handle Object That a Persistent Variable Refers To Must Be a Singleton Object

If a persistent variable refers to a handle object, the code generator allows only one instance of the object during the program's lifetime. The object must be a singleton object. To create a singleton handle object, enclose statements that create the object in the `if isempty()` guard for the persistent variable.

For example, consider the class `mycls` and the function `usehandle2`. The code generator reports an error for `usehandle2` because `p.prop` refers to the `mycls` object that the statement `inner = mycls` creates. This statement creates a `mycls` object for each invocation of `usehandle2`.

```
classdef mycls < handle
    properties
        prop
    end
end

function usehandle2(x)
    assert(isa(x, 'double'));
    persistent p;
    inner = mycls;
    inner.prop = x;
    if isempty(p)
        p = mycls;
        p.prop = inner;
    end
end
```

If you move the statements `inner = mycls` and `inner.prop = x` inside the `if isempty()` guard, code generation succeeds. The statement `inner = mycls` executes only once during the program's lifetime.

```
function usehandle2(x)
    assert(isa(x, 'double'));
    persistent p;
    if isempty(p)
        inner = mycls;
        inner.prop = x;
        p = mycls;
        p.prop = inner;
    end
end
```

Consider the function `usehandle3`. The code generator reports an error for `usehandle3` because the persistent variable `p` refers to the `mycls` object that the statement `myobj = mycls` creates. This statement creates a `mycls` object for each invocation of `usehandle3`.

```
function usehandle3(x)
    assert(isa(x, 'double'));
    myobj = mycls;
    myobj.prop = x;
    doinit(myobj);
    disp(myobj.prop);
    function doinit(obj)
        persistent p;
    end
end
```

```

if isempty(p)
    p = obj;
end

```

If you make `myobj` persistent and enclose the statement `myobj = mycls` inside an `if isempty()` guard, code generation succeeds. The statement `myobj = mycls` executes only once during the program's lifetime.

```

function usehandle3(x)
assert(isa(x, 'double'));
persistent myobj;
if isempty(myobj)
    myobj = mycls;
end

```

```

doinit(myobj);

```

```

function doinit(obj)
persistent p;
if isempty(p)
    p = obj;
end

```

## References to Handle Objects Can Appear Undefined

Consider the function `refHandle` that copies a handle object property to another object. The function uses a simple handle class and value class. In MATLAB, the function runs without error.

```

function [out1, out2, out3] = refHandle()
    x = myHandleClass;
    y = x;
    v = myValueClass();
    v.prop = x;
    x.prop = 42;
    out1 = x.prop;
    out2 = y.prop;
    out3 = v.prop.prop;
end

```

```

classdef myHandleClass < handle
    properties
        prop
    end
end

```

```

classdef myValueClass
    properties
        prop
    end
end

```

During code generation, an error occurs:

```
Property 'v.prop.prop' is undefined on some execution paths.
```

Three variables reference the same memory location: `x`, `y`, and `v.prop`. The code generator determines that `x.prop` and `y.prop` share the same value. The code generator cannot determine

that the handle object property `v.prop.prop` shares its definition with `x.prop` and `y.prop`. To avoid the error, define `v.prop.prop` directly.

## System Objects in MATLAB Code Generation

### In this section...

“Usage Rules and Limitations for System Objects for Generating Code” on page 66-25

“System Objects in codegen” on page 66-27

“System Objects in the MATLAB Function Block” on page 66-27

“System Objects in the MATLAB System Block” on page 66-27

“System Objects and MATLAB Compiler Software” on page 66-27

You can generate C/C++ code in MATLAB from your system that contains System objects by using MATLAB Coder. You can generate efficient and compact code for deployment in desktop and embedded systems and accelerate fixed-point algorithms.

### Usage Rules and Limitations for System Objects for Generating Code

The following usage rules and limitations apply to using System objects in code generated from MATLAB.

#### Object Construction and Initialization

- If objects are stored in persistent variables, initialize System objects once by embedding the object handles in an `if` statement with a call to `isempty()`.
- Set arguments to System object constructors as compile-time constants.
- Initialize all System objects properties that `releaseImpl` uses before the end of `setupImpl`.
- You cannot initialize System objects properties with other MATLAB class objects as default values in code generation. You must initialize these properties in the constructor.

#### Inputs and Outputs

- System objects accept a maximum of 1024 inputs. A maximum of eight dimensions per input is supported.
- The data type of the inputs should not change.
- The complexity of the inputs should not change.
- If you want the size of inputs to change, verify that support for variable-size is enabled. Code generation support for variable-size data also requires that variable-size support is enabled. By default in MATLAB, support for variable-size data is enabled.
- System objects predefined in the software do not support variable-size if their data exceeds the `DynamicMemoryAllocationThreshold` value.
- Do not set System objects to become outputs from the MATLAB Function block.
- Do not use the Save and Restore Simulation Operating Point option for any System object in a MATLAB Function block.
- Do not pass a System object as an example input argument to a function being compiled with `codegen`.
- Do not pass a System object to functions declared as extrinsic (functions called in interpreted mode) using the `coder.extrinsic` function. System objects returned from extrinsic functions and scope System objects that automatically become extrinsic can be used as inputs to another extrinsic function. But, these functions do not generate code.

## Properties

- In MATLAB System blocks, you cannot use variable-size for discrete state properties of System objects. Private properties can be variable-size.
- Objects cannot be used as default values for properties.
- You can only assign values to nontunable properties once, including the assignment in the constructor.
- Nontunable property values must be constant.
- For fixed-point inputs, if a tunable property has dependent data type properties, you can set tunable properties only at construction time or after the object is locked.
- For `getNumInputsImpl` and `getNumOutputsImpl` methods, if you set the return argument from an object property, that object property must have the `Nontunable` attribute.

## Global Variables

- Global variables are allowed in a System object, unless you are using that System object in Simulink via the MATLAB System block. See “Generate Code for Global Data” (MATLAB Coder).

## Methods

- Code generation support is available only for these System object methods:
  - `get`
  - `getNumInputs`
  - `getNumOutputs`
  - `isDone` (for sources only)
  - `isLocked`
  - `release`
  - `reset`
  - `set` (for tunable properties)
  - `step`
- For System objects that you define, code generation support is available only for these methods:
  - `getDiscreteStateImpl`
  - `getNumInputsImpl`
  - `getNumOutputsImpl`
  - `infoImpl`
  - `isDoneImpl`
  - `isInputDirectFeedthroughImpl`
  - `outputImpl`
  - `processTunedPropertiesImpl`
  - `releaseImpl` — Code is not generated automatically for this method. To release an object, you must explicitly call the `release` method in your code.
  - `resetImpl`
  - `setupImpl`

- `stepImpl`
- `updateImpl`
- `validateInputsImpl`
- `validatePropertiesImpl`

## System Objects in codegen

You can include System objects in MATLAB code in the same way you include any other elements. You can then compile a MEX file from your MATLAB code by using the `codegen` command, which is available if you have a MATLAB Coder license. This compilation process, which involves a number of optimizations, is useful for accelerating simulations. See “Get Started with MATLAB Coder” (MATLAB Coder) and “MATLAB Classes” (MATLAB Coder) for more information.

---

**Note** Most, but not all, System objects support code generation. Refer to the particular object’s reference page for information.

---

## System Objects in the MATLAB Function Block

Using the MATLAB Function block, you can include any System object and any MATLAB language function in a Simulink model. This model can then generate embeddable code. System objects provide higher-level algorithms for code generation than do most associated blocks. For more information, see “Implement MATLAB Functions in Simulink with MATLAB Function Blocks” on page 49-3.

## System Objects in the MATLAB System Block

Using the MATLAB System block, you can include in a Simulink model individual System objects that you create with a class definition file. The model can then generate embeddable code. For more information, see “MATLAB System Block” on page 50-3.

## System Objects and MATLAB Compiler Software

MATLAB Compiler software supports System objects for use inside MATLAB functions. The compiler product does not support System objects for use in MATLAB scripts.

### More About

- “Generate Code That Uses Row-Major Array Layout” (MATLAB Coder)

## Work Around Language Limitation: Code Generation Does Not Support Object Arrays

### Issue

In certain situations, your MATLAB algorithm uses an array of objects that are instances of the same class. But code generation does not support object arrays. When attempting to generate code for such MATLAB code, you get this or a similar error message:

Code generation does not support object arrays.

### Possible Solutions

#### Use Cell Array of Objects

Code generation supports cell arrays of objects. In your MATLAB code, represent the collection of objects by using a cell array instead of an array.

For example, suppose that your MATLAB algorithm uses the class `Square`:

```
classdef Square
    properties(Access = private)
        side
    end

    methods(Access = public)
        function obj = Square(side)
            obj.side = side;
        end

        function area = calculateArea(obj)
            area = obj.side^2;
        end
    end
end
```

The function `addAreas` constructs and uses a 1-by-3 array of `Square` objects:

```
function y = addAreas(n)
    obj = Square(0);
    collection = [obj obj obj]; % collection is an array

    for i = 1:numel(collection)
        collection(i) = Square(n + i);
    end

    y = 0;
    for i = 1:numel(collection)
        y = y + collection(i).calculateArea;
    end
end
```

Attempt to generate a MEX function for `addAreas`. Code generation fails because the local variable `collection` is an object array.

```
codegen addAreas -args 0 -report
```

??? Code generation does not support object arrays.

```
Error in ==> addAreas Line: 3 Column: 14
Code generation failed: View Error Report
```

Redefine `collection` to be a cell array instead. Modify the code to use cell array indexing to index into `collection`. Name the modified function `addAreas_new`.

```
function y = addAreas_new(n)
obj = Square(0);
collection = {obj obj obj}; % collection is a cell array

for i = 1:numel(collection)
    collection{i} = Square(n + i);
end

y = 0;
for i = 1:numel(collection)
    y = y + collection{i}.calculateArea;
end
end
```

Attempt to generate a MEX function for `addAreas_new`. Code generation succeeds and produces `addAreas_new_mex`.

```
codegen addAreas_new -args 0 -report
```

```
Code generation successful: View report
```

Verify that `addAreas_new` and `addAreas_new_mex` have the same runtime behavior.

```
disp([addAreas_new(0) addAreas_new_mex(0)])
```

```
14    14
```

### For Assignment with Nonscalar Indexing, Use Curly Braces and deal

Suppose that your original MATLAB code performs assignment to the array of objects by using nonscalar indexing. For example, you might add this line after the first `for` loop in the `addAreas` function:

```
collection(1:2) = [Square(10) Square(20)];
```

In the modified function `addAreas_new`, index into the corresponding cell array by using curly braces `{}` and perform assignment by using the `deal` function. Replace the above line by:

```
[collection{1:2}] = deal(Square(10),Square(20));
```

# Code Generation for Function Handles

---

## Function Handle Limitations for Code Generation

When you use function handles in MATLAB code intended for code generation, adhere to the following restrictions:

### Do not use the same bound variable to reference different function handles

In some cases, using the same bound variable to reference different function handles causes a compile-time error. For example, this code does not compile:

```
function y = foo(p)
x = @plus;
if p
    x = @minus;
end
y = x(1, 2);
```

### Do not pass function handles to or from `coder.ceval`

You cannot pass function handles as inputs to or outputs from `coder.ceval`. For example, suppose that `f` and `str.f` are function handles:

```
f = @sin;
str.x = pi;
str.f = f;
```

The following statements result in compilation errors:

```
coder.ceval('foo', @sin);
coder.ceval('foo', f);
coder.ceval('foo', str);
```

### Do not associate a function handle with an extrinsic function

You cannot create a function handle that references an extrinsic MATLAB function.

### Do not pass function handles to or from extrinsic functions

You cannot pass function handles to or from `feval` and other extrinsic MATLAB functions.

### Do not pass function handles to or from entry-point functions

You cannot pass function handles as inputs to or outputs from entry-point functions. For example, consider this function:

```
function x = plotFcn(fhandle, data)

assert(isa(fhandle,'function_handle') && isa(data,'double'));

plot(data, fhandle(data));
x = fhandle(data);
```

In this example, the function `plotFcn` receives a function handle and its data as inputs. `plotFcn` attempts to call the function referenced by the `fhandle` with the input `data` and plot the results. However, this code generates a compilation error. The error indicates that the function `isa` does not recognize `'function_handle'` as a class name when called inside a MATLAB function to specify properties of inputs.

**Do not try to view function handles from the debugger**

You cannot display or watch function handles from the debugger. The function handles appear as empty matrices.

**Do not use function handles for Simulink signals, parameters, or data store memory**

You can use function handles in a MATLAB Function block. You cannot use function handles for Simulink signals, parameters, or data store memory.

- “Use the `coder.extrinsic` Construct” on page 69-7

# Defining Functions for Code Generation

---

- “Code Generation for Variable Length Argument Lists” on page 68-2
- “Generate Code for arguments Block That Validates Input and Output Arguments” on page 68-3
- “Code Generation for Anonymous Functions” on page 68-6
- “Code Generation for Nested Functions” on page 68-7

## Code Generation for Variable Length Argument Lists

When you use `varargin` and `varargout` for code generation, there are these restrictions:

- You cannot use `varargin` or `varargout` in the function definition for a top-level function in a MATLAB Function block or in a Stateflow chart that uses MATLAB as the action language.
- You cannot write to `varargin`. If you want to write to input arguments, copy the values into a local variable.
- To index into `varargin` and `varargout`, use curly braces `{}`, not parentheses `()`.
- The code generator must be able to determine the value of the index into `varargin` or `varargout`.

### See Also

### More About

- “Nonconstant Index into `varargin` or `varargout` in a for-Loop” on page 71-12

## Generate Code for arguments Block That Validates Input and Output Arguments

You can generate code for `arguments` blocks that perform input and output argument validation in your MATLAB function. Using argument validation, you can constrain the class, size, and other aspects of function input and output values without writing code in the body of the function to perform these tests. See “Function Argument Validation”.

```
function myFunction(inputArg)
    arguments
        inputArg (dim1,dim2,...) ClassName {fcn1,fcn2,...} = defaultValue
    end
    % Function code
end
```

### Supported Features

Code generation supports most features of `arguments` blocks, including size and class validation, validation functions, and default values. Code generation also supports the `namedargs2cell` function.

Code generation does not support these features of `arguments` blocks:

- Size validation, class validation, and validation functions for repeating arguments
- Multiple repeating input arguments
- Name-value input arguments at entry-point functions
- Name-value input arguments from class properties using the `structName.?ClassName` syntax
- Size validation for `table`, `timetable`, or `dlarray` objects.

### Names Must Be Compile-Time Constants

Suppose that `foo` is a function that uses name-value argument validation. When you call `foo` from another function `bar`, the code generator must be able to determine the names that you provide to `foo` at compile time.

For example, code generation succeeds for the entry-point function `myNamedArg_valid`. This function contains two calls to the function `local`. For both these calls, the argument name `'x'` is known during code generation.

```
function [out1,out2] = myNamedArg_valid(in1,in2)
    out1 = local(x=in1);
    out2 = local('x',in2);
end
```

```
function out = local(args)
arguments
    args.x
end

out = args.x;
end

codegen myNamedArg_valid -args {0,0}
```

Code generation successful.

By contrast, code generation fails for the entry-point function `myNamedArg_invalid` because the argument name for the function `local` is supplied at run time.

```
function out = myNamedArg_invalid(value, inputName)
out = local(inputName, value);
end

function out = local(args)
arguments
    args.x
end

out = args.x;
end

codegen myNamedArg_invalid -args {0,coder.typeof('a')}
```

Error calling 'myNamedArg\_invalid/local'. This call-site passes more inputs to this function than caused by: This argument is not constant, and therefore does not match against a name-value argument 'myNamedArg\_invalid/local' during code generation. Code generation might fail or produce results if a name passed at a call site is not known during code generation.

Error in ==> myNamedArg\_invalid Line: 2 Column: 17  
Code generation failed: View Error Report

In certain situations, the code generator assigns the name that you passed to an optional positional or repeating input argument. In such situations, code generation succeeds with a warning and the generated code might produce results that are different from MATLAB execution. See “Passing Input Argument Name at Run Time” (MATLAB Coder).

## Using the Structure That Holds Name-Value Arguments

Suppose that your MATLAB function for which you intend to generate code uses a structure named `NameValueArgs` to define two name-value arguments, `Name1` and `Name2`:

```
function result = myFunction(NameValueArgs)
    arguments
        NameValueArgs.Name1
        NameValueArgs.Name2
    end
    ...
end
```

In the body of your function, directly use the structure fields `NameValueArgs.Name1` and `NameValueArgs.Name2` to read or write data.

Do not use the whole structure variable `NameValueArgs` itself (without the dot syntax), except in these situations:

- Use the `isfield` function to check if the caller has supplied a value for a certain name-value argument. For example, to provide a default value for `NameValueArgs.Name2` outside of the arguments block, you can use this code snippet:

```
if ~isfield(NameValueArgs, 'Name2')
    NameValueArgs.Name2 = defaultValue;
end
```

- Use the `namedargs2cell` function to forward the name-value arguments to another function. For example:

```
argsCell = namedargs2cell(NameValueArgs);
foo(argsCell{:});
```

Any use of the whole structure variable `NameValueArgs` (including the above two special cases) is not supported inside loops, anonymous functions, or nested functions.

## Differences Between Generated Code and MATLAB Code

Certain unusual code patterns might cause the code generated for argument validation to behave differently from MATLAB. To learn about some of these differences, see these links:

- “Empty Repeating Input Argument” (MATLAB Coder)
- “Passing Input Argument Name at Run Time” (MATLAB Coder)
- “Output Argument Validation of Conditionally-Assigned Outputs” (MATLAB Coder)

## Code Generation for Anonymous Functions

You can use anonymous functions in MATLAB code intended for code generation. For example, you can generate code for the following MATLAB code that defines an anonymous function that finds the square of a number.

```
sqr = @(x) x.^2;  
a = sqr(5);
```

Anonymous functions are useful for creating a function handle to pass to a MATLAB function that evaluates an expression over a range of values. For example, this MATLAB code uses an anonymous function to create the input to the `fzero` function:

```
b = 2;  
c = 3.5;  
x = fzero(@(x) x^3 + b*x + c,0);
```

### Anonymous Function Limitations for Code Generation

Anonymous functions have the code generation limitations of value classes and cell arrays.

You can use anonymous functions in a MATLAB Function block. You cannot use anonymous functions for Simulink signals, parameters, or data store memory.

- “Parameterizing Functions”

## Code Generation for Nested Functions

You can generate code for MATLAB functions that contain nested functions. For example, you can generate code for the function `parent_fun`, which contains the nested function `child_fun`.

```
function parent_fun
x = 5;
child_fun

    function child_fun
        x = x + 1;
    end

end
```

### Nested Function Limitations for Code Generation

When you generate code for nested functions, you must adhere to the code generation restrictions for value classes, cell arrays, and handle classes. You must also adhere to these restrictions:

- If the parent function declares a persistent variable, it must assign the persistent variable before it calls a nested function that uses the persistent variable.
- A nested recursive function cannot refer to a variable that the parent function uses.
- If a nested function refers to a structure variable, you must define the structure by using `struct`.
- If a nested function uses a variable defined by the parent function, you cannot use `coder.varsize` with the variable in either the parent or the nested function.

## Resolution of Function Calls for Code Generation

From a MATLAB function, you can call local functions, supported toolbox functions, and other MATLAB functions. MATLAB resolves function names for code generation as follows:

### Key Points About Resolving Function Calls

The diagram illustrates key points about how MATLAB resolves function calls for code generation:

- Searches two paths, the code generation path and the MATLAB path  
See “Compile Path Search Order” on page 69-2.
- Attempts to compile functions unless the code generator determines that it should not compile them or you explicitly declare them to be extrinsic.

If a MATLAB function is not supported for code generation, you can declare it to be extrinsic by using the construct `coder.extrinsic`, as described in “Use the `coder.extrinsic` Construct” on page 69-7. During simulation, the code generator produces code for the call to an extrinsic function, but does not generate the internal code for the function. Therefore, simulation can run only on platforms where MATLAB software is installed. During standalone code generation, the code generator attempts to determine whether the extrinsic function affects the output of the function in which it is called — for example by returning `mxArrays` to an output variable. If the output does not change, code generation proceeds, but the extrinsic function is excluded from the generated code. Otherwise, compilation errors occur.

The code generator detects calls to many common visualization functions, such as `plot`, `disp`, and `figure`. The software treats these functions like extrinsic functions but you do not have to declare them extrinsic using the `coder.extrinsic` function.

- Resolves file type based on precedence rules described in “Resolution of File Types on Code Generation Path” on page 69-4

### Compile Path Search Order

During code generation, function calls are resolved on two paths:

#### 1 Code generation path

MATLAB searches this path first during code generation. The code generation path contains the toolbox functions supported for code generation.

#### 2 MATLAB path

If the function is not on the code generation path, MATLAB searches this path.

MATLAB applies the same dispatcher rules when searching each path (see “Function Precedence Order”).

### When to Use the Code Generation Path

Use the code generation path to override a MATLAB function with a customized version. A file on the code generation path shadows a file of the same name on the MATLAB path.

For more information on how to add additional folders to the code generation path, see “Paths and File Infrastructure Setup” (MATLAB Coder).

## **Resolution of File Types on Code Generation Path**

MATLAB uses the following precedence rules for code generation:

## Compilation Directive %#codegen

Add the %#codegen directive (or pragma) to your function after the function signature to indicate that you intend to generate code for the MATLAB algorithm. Adding this directive instructs the MATLAB Code Analyzer to help you diagnose and fix violations that would result in errors during code generation.

```
function y = my_fcn(x) %#codegen
```

```
.....
```

---

**Note** The %#codegen directive is not necessary for MATLAB Function blocks. Code inside a MATLAB Function block is always intended for code generation. The %#codegen directive, or the absence of it, does not change the error checking behavior.

---

## Use MATLAB Engine to Execute a Function Call in Generated Code

When processing a call to a function `foo` in your MATLAB code, the code generator finds the definition of `foo` and generates code for its body. In some cases, you might want to bypass code generation and instead use the MATLAB engine to execute the call. Use `coder.extrinsic('foo')` to declare that calls to `foo` do not generate code and instead use the MATLAB engine for execution. In this context, `foo` is referred to as an extrinsic function. This functionality is available only when the MATLAB engine is available during execution. Examples of such situations include execution of MEX functions, Simulink simulations, or function calls at the time of code generation (also known as compile time).

If you generate standalone code for a function that calls `foo` and includes `coder.extrinsic('foo')`, the code generator attempts to determine whether `foo` affects the output. If `foo` does not affect the output, the code generator proceeds with code generation, but excludes `foo` from the generated code. Otherwise, the code generator produces a compilation error.

Including the `coder.extrinsic('foo')` directive inside a certain MATLAB function declares all calls to `foo` inside that MATLAB function as extrinsic. Alternatively, you might want to narrow the scope of extrinsic declaration to just one call to `foo`. See “Call MATLAB Functions Using `feval`” (MATLAB Coder).

### When To Declare a Function as Extrinsic

These are some common situations in which you might consider declaring a MATLAB function as extrinsic:

- The function performs display or logging actions. Such functions are useful primarily during simulation and are not used in embedded systems.
- In your MEX execution or Simulink simulation, you want to use a MATLAB function that is not supported for code generation. This workflow does not apply to non-simulation targets.
- You instruct the code generator to constant fold a function call by using `coder.const`. In such situations, the function is called only during code generation when the MATLAB engine is available for executing the call.

## Use the `coder.extrinsic` Construct

To declare a function `foo` as extrinsic, include this statement in your MATLAB code.

```
coder.extrinsic('foo')
```

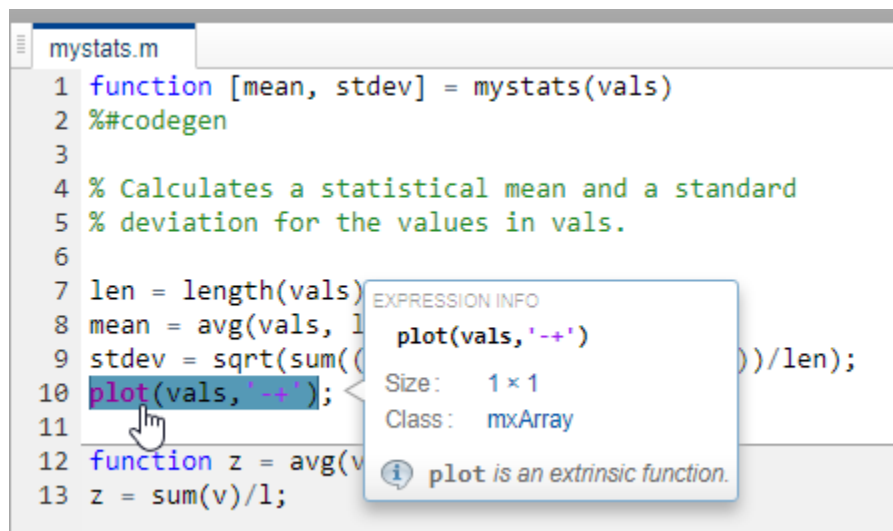

When declaring functions as extrinsic for code generation, adhere to these rules:

- Declare the function as extrinsic before you call it.
- Do not use the extrinsic declaration in conditional statements.
- Assign the return value of an extrinsic function to a known type. See “Working with mxArrays” (MATLAB Coder).

For additional information and examples, see `coder.extrinsic`.

The code generator automatically treats many common MATLAB visualization functions, such as `plot`, `disp`, and `figure`, as extrinsic. You do not have to explicitly declare them as extrinsic functions by using `coder.extrinsic`. For example, you might want to call `plot` to visualize your results in the MATLAB environment. If you generate a MEX function from a function that calls `plot`, and then run the generated MEX function, the code generator dispatches calls to the `plot` function to the MATLAB engine. If you generate a library or executable, the generated code does not contain calls to the `plot` function.

If you generate MEX or standalone C/C++ code by using MATLAB Coder, the code generation report highlights calls from your MATLAB code to extrinsic functions. By inspecting the report, you can determine which functions are supported only in the MATLAB environment.

```
mystats.m
1 function [mean, stdev] = mystats(vals)
2 %#codegen
3
4 % Calculates a statistical mean and a standard
5 % deviation for the values in vals.
6
7 len = length(vals);
8 mean = avg(vals, 1);
9 stdev = sqrt(sum((vals - mean).^2)/len);
10 plot(vals, '--');
11
12 function z = avg(v, l);
13 z = sum(v)/l;
```

EXPRESSION INFO

`plot(vals, '--')`

Size: 1 × 1

Class: mxArray

*plot is an extrinsic function.*

### Scope of Extrinsic Function Declarations

The `coder.extrinsic` construct has function scope. For example, consider the following code:

```
function y = foo %#codegen
coder.extrinsic('rat','min');
[N D] = rat(pi);
y = 0;
y = min(N, D);
```

In this example, `rat` and `min` are treated as extrinsic every time they are called in the main function `foo`. There are two ways to narrow the scope of an extrinsic declaration inside the main function:

- Declare the MATLAB function extrinsic in a local function, as in this example:

```
function y = foo %#codegen
coder.extrinsic('rat');
[N D] = rat(pi);
y = 0;
y = mymin(N, D);

function y = mymin(a,b)
coder.extrinsic('min');
y = min(a,b);
```

Here, the function `rat` is extrinsic every time it is called inside the main function `foo`, but the function `min` is extrinsic only when called inside the local function `mymin`.

- Instead of using the `coder.extrinsic` construct, call the MATLAB function using `feval`. This approach is described in the next section.

### Extrinsic Declaration for Nonstatic Methods

Suppose that you define a class `myClass` that has a nonstatic method `foo`, and then create an instance `obj` of this class. If you want to declare the method `obj.foo` as extrinsic in your MATLAB code that you intend for code generation, follow these rules:

- Write the call to `foo` as a function call. Do not write the call by using the dot notation.
- Declare `foo` to be extrinsic by using the syntax `coder.extrinsic('foo')`.

For example, define `myClass` as:

```
classdef myClass
    properties
        prop = 1
    end
    methods
        function y = foo(obj,x)
            y = obj.prop + x;
        end
    end
end
```

Here is an example MATLAB function that declares `foo` as extrinsic.

```
function y = myFunction(x) %#codegen
coder.extrinsic('foo');
```

```
obj = myClass;
y = foo(obj,x);
end
```

Nonstatic methods are also known as ordinary methods. See “Method Syntax”.

### Additional Uses

Use the `coder.extrinsic` construct to:

- Call MATLAB functions that do not produce output during simulation without generating unnecessary code.
- Make your code self-documenting and easier to debug. You can scan the source code for `coder.extrinsic` statements to isolate calls to MATLAB functions, which can potentially create and propagate `mxArrays`. See “Working with `mxArrays`” (MATLAB Coder).

## Call MATLAB Functions Using `feval`

To narrow the scope of extrinsic declaration to just one function call, use the function `feval`. `feval` is automatically interpreted as an extrinsic function during code generation. So, you can use `feval` to call functions that you want to execute in the MATLAB environment, rather than compile to generated code.

Consider this example:

```
function y = foo
coder.extrinsic('rat');
[N D] = rat(pi);
y = 0;
y = feval('min',N,D);
```

Because `feval` is extrinsic, the statement `feval('min',N,D)` is evaluated by MATLAB, not compiled, which has the same result as declaring the function `min` extrinsic for just this one call. By contrast, the function `rat` is extrinsic throughout the function `foo`.

The code generator does not support the use of `feval` to call local functions or functions that are located in a private folder.

## Working with `mxArrays`

The run-time output of an extrinsic function is an `mxArray`, also known as a MATLAB array. The only valid operations for `mxArrays` are:

- Storing an `mxArray` in a variable.
- Passing an `mxArray` to an extrinsic function.
- Returning an `mxArray` from a function back to MATLAB.
- Converting an `mxArray` to a known type at run time. Assign the `mxArray` to a variable whose type is already defined by a prior assignment. See the following example.

To use an `mxArray` returned by an extrinsic function in other operations (for example, returning it from a MATLAB Function block to Simulink execution), you must first convert it to a known type.

If the input arguments of a function are `mxArrays`, the code generator automatically treats the function as extrinsic.

### Convert `mxArrays` to Known Types

To convert an `mxArray` to a known type, assign the `mxArray` to a variable whose type is defined. At run time, the `mxArray` is converted to the type of the variable that it is assigned to. If the data in the `mxArray` is not consistent with the type of the variable, you get a run-time error.

For example, consider this code:

```
function y = foo %#codegen
coder.extrinsic('rat');
[N D] = rat(pi);
y = min(N,D);
```

Here, the top-level function `foo` calls the extrinsic MATLAB function `rat`, which returns two `mxArrays` representing the numerator `N` and denominator `D` of the rational fraction approximation of `pi`. You can pass these `mxArrays` to another MATLAB function, in this case, `min`. Because the inputs passed to `min` are `mxArrays`, the code generator automatically treats `min` as an extrinsic function. As a result, `min` returns an `mxArray`.

While generating a MEX function by using MATLAB Coder, you can directly assign this `mxArray` returned by `min` to the output `y` because the MEX function returns its output to MATLAB.

```
codegen foo
```

```
Code generation successful.
```

But if you put `foo` in a MATLAB Function block in a Simulink model and then update or run the model, you get this error:

```
Function output 'y' cannot be an mxArray in this context.
Consider preinitializing the output variable with a known type.
```

This error occurs because returning an `mxArray` back to Simulink is not supported. To fix this issue, define `y` to be the type and size of the value that you expect `min` to return, in this case, a scalar double:

```
function y = foo %#codegen
coder.extrinsic('rat');
[N D] = rat(pi);
y = 0; % Define y as a scalar of type double
y = min(N,D);
```

In this example, the output of the extrinsic function `min` affects the output `y` of the entry-point function `foo` for which you are generating code. If you attempt to generate standalone code (for example, a static library) for `foo`, the code generator is unable to ignore the extrinsic function call and produces a code generation error.

```
codegen -config:lib foo
```

```
??? The extrinsic function 'min' is not available for
standalone code generation. It must be eliminated for
stand-alone code to be generated. It could not be
eliminated because its outputs appear to influence the
calling function. Fix this error by not using 'min'
```

or by ensuring that its outputs are unused.

```
Error in ==> foo Line: 4 Column: 5  
Code generation failed: View Error Report
```

```
Error using codegen
```

## Restrictions on Using Extrinsic Functions

The full MATLAB run-time environment is not supported during code generation. Therefore, the following restrictions apply when calling MATLAB functions extrinsically:

- MATLAB functions that inspect the caller, or read or write to the caller workspace, do not work during code generation. Such functions include:
  - `dbstack`
  - `evalin`
  - `assignin`
  - `save`
- Functions in generated code can produce unpredictable results if your extrinsic function performs these actions at run time:
  - Changes folders
  - Changes the MATLAB path
  - Deletes or adds MATLAB files
  - Changes warning states
  - Changes MATLAB preferences
  - Changes Simulink parameters
- The code generator does not support the use of `coder.extrinsic` to call functions that are located in a private folder.
- The code generator does not support the use of `coder.extrinsic` to call local functions.
- You can call extrinsic functions with up to 64 inputs and 64 outputs.

## Code Generation for Recursive Functions

To generate code for recursive MATLAB functions, the code generator uses compile-time recursion on page 69-12 or run-time recursion on page 69-12. You can influence whether the code generator uses compile-time or run-time recursion by modifying your MATLAB code. See “Force Code Generator to Use Run-Time Recursion” on page 69-14.

You can disallow recursion on page 69-13 or disable run-time recursion on page 69-13 by modifying configuration parameters.

When you use recursive functions in MATLAB code that is intended for code generation, you must adhere to certain restrictions. See “Recursive Function Limitations for Code Generation” on page 69-13.

### Compile-Time Recursion

With compile-time recursion, the code generator creates multiple versions of a recursive function in the generated code. The inputs to each version have values or sizes that are customized for that version. These versions are known as function specializations. You can tell that the code generator used compile-time recursion by looking at the MATLAB Function report or the generated C code. Here is an example of compile-time recursion in the report.

### Run-Time Recursion

With run-time recursion, the code generator produces a recursive function in the generated code. You can tell that the code generator used run-time recursion by looking at the MATLAB Function report or the generated C code. Here is an example of run-time recursion in the report.

## Disallow Recursion

In the model configuration parameters, set **Compile-time recursion limit for MATLAB functions** to 0.

## Disable Run-Time Recursion

Some coding standards, such as MISRA™, do not allow recursion. To increase the likelihood of generating code that is compliant with MISRA C™, disable run-time recursion.

In the model configuration parameters, clear the **Enable run-time recursion for MATLAB functions** check box.

If your code requires run-time recursion and run-time recursion is disabled, you must rewrite your code so that it uses compile-time recursion or does not use recursion.

## Recursive Function Limitations for Code Generation

When you use recursion in MATLAB code that is intended for code generation, follow these restrictions:

- The top-level function in a MATLAB Function block cannot be a recursive function, but it can call a recursive function.
- Assign all outputs of a run-time recursive function before the first recursive call in the function.
- Assign all elements of cell array outputs of a run-time recursive function.
- Inputs and outputs of run-time recursive functions cannot be classes.
- The **Maximum stack size** parameter is ignored for run-time recursion.

## See Also

### Related Examples

- “Output Variable Must Be Assigned Before Run-Time Recursive Call” on page 71-5
- “Compile-Time Recursion Limit Reached” on page 71-2
- “Compile-time recursion limit for MATLAB functions”
- “MATLAB Function Reports” on page 49-40

## Force Code Generator to Use Run-Time Recursion

When your MATLAB code includes recursive function calls, the code generator uses compile-time or run-time recursion. With compile-time recursion on page 69-12, the code generator creates multiple versions of the recursive function in the generated code. These versions are known as function specializations. With run-time recursion on page 69-12, the code generator produces a recursive function. If compile-time recursion results in too many function specializations or if you prefer run-time recursion, you can try to force the code generator to use run-time recursion. Try one of these approaches:

- “Treat the Input to the Recursive Function as a Nonconstant” on page 69-14
- “Make the Input to the Recursive Function Variable-Size” on page 69-15
- “Assign Output Variable Before the Recursive Call” on page 69-16

### Treat the Input to the Recursive Function as a Nonconstant

Consider this function:

```
function y = call_recfcn(n)
A = ones(1,n);
x = 5;
y = recfcn(A,x);
end

function y = recfcn(A,x)
if size(A,2) == 1 || x == 1
    y = A(1);
else
    y = A(1)+recfcn(A(2:end),x-1);
end
end
```

`call_recfcn` calls `recfcn` with the value 5 for the second argument. `recfcn` calls itself recursively until `x` is 1. For each `recfcn` call, the input argument `x` has a different value. The code generator produces five specializations of `recfcn`, one for each call. You can see the specializations in the MATLAB Function report.

To force run-time recursion, in `call_recfcn`, in the call to `recfcn`, instruct the code generator to treat the value of the input argument `x` as a nonconstant value by using `coder.ignoreConst`.

```

function y = call_recfcn(n)
A = ones(1,n);
x = coder.ignoreConst(5);
y = recfcn(A,x);
end

function y = recfcn(A,x)
if size(A,2) == 1 || x == 1
    y = A(1);
else
    y = A(1)+recfcn(A(2:end),x-1);
end
end

```

In the MATLAB Function report, you see only one specialization.

## Make the Input to the Recursive Function Variable-Size

Consider this code:

```

function z = call_mysum(A)
%#codegen
z = mysum(A);
end

function y = mysum(A)
coder.inline('never');
if size(A,2) == 1
    y = A(1);
else
    y = A(1)+mysum(A(2:end));
end
end

```

If the input to mysum is fixed-size, the code generator uses compile-time recursion. To force the code generator to use run-time conversion, make the input to mysum variable-size by using `coder.varsize`.

```

function z = call_mysum(A)
%#codegen
B = A;
coder.varsize('B');
z = mysum(B);
end

function y = mysum(A)
coder.inline('never');
if size(A,2) == 1

```

```
        y = A(1);
else
    y = A(1)+ mysum(A(2:end));
end
end
```

## Assign Output Variable Before the Recursive Call

The code generator uses compile-time recursion for this code:

```
function y = callrecursive(n)
x = 10;
y = myrecursive(x,n);
end

function y = myrecursive(x,n)
coder.inline('never')
if x > 1
    y = n + myrecursive(x-1,n-1);

else
    y = n;
end
end
```

To force the code generator to use run-time recursion, modify `myrecursive` so that the output `y` is assigned before the recursive call. Place the assignment `y = n` in the `if` block and the recursive call in the `else` block.

```
function y = callrecursive(n)
x = 10;
y = myrecursive(x,n);
end

function y = myrecursive(x,n)
coder.inline('never')
if x == 1
    y = n;
else
    y = n + myrecursive(x-1,n-1);
end
end
```

## Avoid Duplicate Functions in Generated Code

### Issue

You generate code and it contains multiple, duplicate copies of the same functions, with only slight differences, such as modifications to the function signature. For example, your generated code might contain functions called `foo` and `b_foo`. Duplicate functions can make the generated code more difficult to analyze and manage.

### Cause

Duplicate functions in the generated code are the result of function specializations. The code generator specializes functions when it detects that they differ at different call sites by:

- Number of input or output variables.
- Type of input or output variables.
- Size of input or output variables.
- Values of input variables.

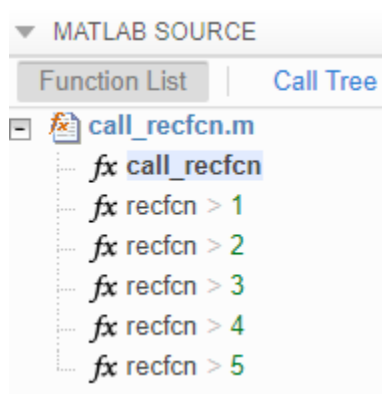

In some cases, these specializations are necessary for the generated C/C++ code because C/C++ functions do not have the same flexibility as MATLAB functions. In other cases, the code generator specializes functions to optimize the generated code or because of a lack of information.

### Solution

In certain cases, you can alter your MATLAB code to avoid the generation of duplicate functions.

#### Identify Duplicate Functions by Using Code Generation Report

You can determine whether the code generator created duplicate functions by inspecting the code generation report or in Simulink, the MATLAB Function report. The report shows a list of the duplicate functions underneath the entry-point function. For example:

#### Duplicate Functions Generated for Multiple Input Sizes

If your MATLAB code calls a function multiple times and passes inputs of different sizes, the code generator can create specializations of the function for each size. To avoid this issue, use

`coder.ignoreSize` on the function input. For example, this code uses `coder.ignoreSize` to avoid creating multiple copies of the function `indexOf`:

```
function [out1, out2] = test1(in)
    a = 1:10;
    b = 2:40;
    % Without coder.ignoreSize duplicate functions are generated
    out1 = indexOf(coder.ignoreSize(a), in);
    out2 = indexOf(coder.ignoreSize(b), in);
end

function index = indexOf(array, value)
    coder.inline('never');
    for i = 1:numel(array)
        if array(i) == value
            index = i;
            return
        end
    end
    index = -1;
    return
end
```

To generate code, enter:

```
codegen test1 -config:lib -report -args {1}
```

### Duplicate Functions Generated for Different Input Values

If your MATLAB code calls a function and passes multiple different constant inputs, the code generator can create specializations of the function for each different constant. In this case, use `coder.ignoreConst` to indicate to the code generator not to treat the value as an immutable constant. For example:

```
function [out3, out4] = test2(in)
    c = ['a', 'b', 'c'];
    if in > 0
        c(2)='d';
    end
    out3 = indexOf(c, coder.ignoreConst('a'));
    out4 = indexOf(c, coder.ignoreConst('b'));
end

function index = indexOf(array, value)
    coder.inline('never');
    for i = 1:numel(array)
        if array(i) == value
            index = i;
            return
        end
    end
    index = -1;
    return
end
```

To generate code, enter:

```
codegen test2 -config:lib -report -args {1}
```

### Duplicate Functions Generated for Different Number of Outputs

If your MATLAB code calls a function and accepts a different number of outputs at different call sites, the code generator can produce specializations for each call. For example:

```
[a b] = foo();  
c = foo();
```

To make each call return the same number of outputs and avoid duplicate functions, use the ~ symbol:

```
[a b] = foo();  
[c, ~] = foo();
```

## Avoid Data Copies of Function Inputs in Generated Code

You can reduce the number of copies in your generated code by writing functions that use the same variable as both an input and an output. For example:

```
function A = foo( A, B ) %#codegen
A = A * B;
end
```

This coding practice uses a reference parameter optimization. When a variable acts as both input and output, the generated code passes the variable by reference instead of redundantly copying the input to a temporary variable. In the preceding example, input A is passed by reference in the generated code because it also acts as an output for function foo:

```
...
/* Function Definitions */
void foo(double *A, double B)
{
    *A *= B;
}
...
```

The reference parameter optimization reduces memory usage and execution time, especially when the variable passed by reference is a large data structure. To achieve these benefits at the call site, call the function with the same variable as both input and output.

By contrast, suppose that you rewrite function foo without the optimization:

```
function y = foo2( A, B ) %#codegen
y = A * B;
end
```

The generated code passes the inputs by value and returns the value of the output:

```
...
/* Function Definitions */
double foo2(double A, double B)
{
    return A * B;
}
...
```

In some cases, the output of the function cannot be a modified version of its inputs. If you do not use the inputs later in the function, you can modify your code to operate on the inputs instead of on a copy of the inputs. One method is to create additional return values for the function. For example, consider the code:

```
function y1=foo(u1) %#codegen
    x1=u1+1;
    y1=bar(x1);
end

function y2=bar(u2)
    % Since foo does not use x1 later in the function,
    % it would be optimal to do this operation in place
    x2=u2.*2;
    % The change in dimensions in the following code
```

```

    % means that it cannot be done in place
    y2=[x2,x2];
end

```

You can modify the code to eliminate redundant copies.

```

function y1=foo(u1) %#codegen
    u1=u1+1;
    [y1, u1]=bar(u1);
end

function [y2, u2]=bar(u2)
    u2=u2.*2;
    % The change in dimensions in the following code
    % still means that it cannot be done in place
    y2=[u2,u2];
end

```

The reference parameter optimization does not apply to constant inputs. If the same variable is an input and an output, and the input is constant, the code generator treats the output as a separate variable. For example, consider the function `foo`:

```

function A = foo( A, B ) %#codegen
A = A * B;
end

```

Generate code in which A has a constant value 2.

```
codegen -config:lib foo -args {coder.Constant(2) 3} -report
```

The generated code defines the constant A and returns the value of the output.

```

...
#define A                                (2.0)
...
double foo(double B)
{
    return A * B;
}
...

```

## Inline Code

Inlining is a technique that replaces a function call with the contents (body) of that function. Inlining eliminates the overhead of a function call, but can produce larger C/C++ code. Inlining can create opportunities for further optimization of the generated C/C++ code. The code generator uses internal heuristics to determine whether to inline functions in the generated code. You can use the `coder.inline` directive to fine-tune these heuristics for individual functions. For more information, see `coder.inline`.

## Unroll for-Loops and parfor-Loops

When the code generator unrolls a `for`-loop or `parfor`-loop, instead of producing a loop in the generated code, it produces a copy of the loop body for each iteration. For small, tight loops, unrolling can improve performance. However, for large loops, unrolling can significantly increase code generation time and generate inefficient code.

### Force for-Loop Unrolling by Using `coder.unroll`

The code generator uses heuristics to determine when to unroll a `for`-loop. To force loop unrolling, use `coder.unroll`. This affects only the `for` loop that is immediately after `coder.unroll`. For example:

```
function z = call_myloop()
    %#codegen
    z = myloop(5);
end

function b = myloop(n)
    b = zeros(1,n);
    coder.unroll();
    for i = 1:n
        b(i)=i+n;
    end
end
```

Here is the generated code for the `for`-loop:

```
z[0] = 6.0;
z[1] = 7.0;
z[2] = 8.0;
z[3] = 9.0;
z[4] = 10.0;
```

To control when a `for`-loop is unrolled, use the `coder.unroll` flag argument. For example, unroll the loop only when the number of iterations is less than 10.

```
function z = call_myloop()
    %#codegen
    z = myloop(5);
end

function b = myloop(n)
    unroll_flag = n < 10;
    b = zeros(1,n);
    coder.unroll(unroll_flag);
    for i = 1:n
        b(i)=i+n;
    end
end
```

To unroll a `for`-loop, the code generator must be able to determine the bounds of the `for`-loop. For example, code generation fails for the following code because the value of `n` is not known at code generation time.

```
function b = myloop(n)
    b = zeros(1,n);
```

```
coder.unroll();  
for i = 1:n  
    b(i)=i+n;  
end  
end
```

## Generate Reusable Code

With MATLAB, you can generate reusable code in the following ways:

- Write reusable functions using standard MATLAB function file names which you can call from different locations, for example, in a Simulink model or MATLAB function library.
- Compile external functions on the MATLAB path and integrate them into generated C code for embedded targets.

See “Resolution of Function Calls for Code Generation” (MATLAB Coder).

Common applications include:

- Overriding generated library function with a custom implementation.
- Implementing a reusable library on top of standard library functions that can be used with Simulink.
- Swapping between different implementations of the same function.

## LAPACK Calls for Linear Algebra in a MATLAB Function Block

To improve the simulation speed of MATLAB Function block algorithms that call certain linear algebra functions, Simulink can call LAPACK functions. LAPACK is a software library for numerical linear algebra. If the input arrays for the linear algebra functions meet certain criteria, the simulation calls LAPACK functions in the LAPACK library that is included with MATLAB. MATLAB uses LAPACK in some linear algebra functions such as `eig` and `svd`.

If you use Simulink Coder to generate code for these algorithms, you can specify that the code generator produce LAPACK function calls. The code generator uses the LAPACKE C interface to LAPACK. If you specify that you want to generate LAPACK calls, and the input arrays for the linear algebra functions meet the criteria, the code generator produces LAPACK calls. The build process links to the LAPACK library that you specify. See “Speed Up Linear Algebra in Code Generated from a MATLAB Function Block” (Simulink Coder).

## BLAS Calls for Matrix Operations in a MATLAB Function Block

To improve the simulation speed of MATLAB Function block algorithms that call certain low-level vector and matrix functions (such as matrix multiplication), Simulink can call BLAS functions. BLAS is a software library for low-level vector and matrix computations that has several highly optimized machine-specific implementations. If the input arrays for the matrix functions meet certain criteria, the simulation calls BLAS functions in the BLAS library that is included with MATLAB.

If you use Simulink Coder to generate code for these algorithms, you can specify that the code generator produce BLAS function calls. The code generator uses the CBLAS C interface to BLAS. If you specify that you want to generate BLAS calls, and the input arrays for the matrix functions meet the criteria, the code generator produces BLAS calls. The build process links to the BLAS library that you specify. See “Speed Up Matrix Operations in Code Generated from a MATLAB Function Block” (Simulink Coder).

## **FFTW calls for fast Fourier transform functions in a MATLAB Function Block**

To execute MATLAB Function block algorithms that call MATLAB fast Fourier transform (FFT) functions (`fft`, `fft2`, `fftn`, `ifft`, `ifft2`, or `ifftn`), Simulink uses the library that MATLAB uses for FFT algorithms.

If you use Simulink Coder to generate code for these algorithms, by default, the code generator produces code for the FFT algorithms instead of producing FFT library calls. To increase the speed of fast Fourier transforms in generated code, you can specify that the code generator produce calls to a specific installed FFTW library. See “Speed Up Fast Fourier Transforms in Code Generated from a MATLAB Function Block” (Simulink Coder).

## Compile-Time Recursion Limit Reached

### Issue

You see a message such as:

```
Compile-time recursion limit reached. Size or type of
input #1 of function 'foo' may change at every call.
```

```
Compile-time recursion limit reached. Value of input #1
of function 'foo' may change at every call.
```

### Cause

With compile-time recursion, the code generator produces multiple versions of the recursive function instead of producing a recursive function in the generated code. These versions are known as function specializations. The code generator is unable to use compile-time recursion for a recursive function in your MATLAB code because the number of function specializations exceeds the limit.

### Solutions

To address the issue, try one of these solutions:

- “Force Run-Time Recursion” on page 71-2
- “Increase the Compile-Time Recursion Limit” on page 71-4

### Force Run-Time Recursion

- For this message:

```
Compile-time recursion limit reached. Value of input #1
of function 'foo' may change at every call.
```

Use this solution:

“Force Run-Time Recursion by Treating the Input Value as Nonconstant” on page 71-2.

- For this message:

```
Compile-time recursion limit reached. Size or type of
input #1 of function 'foo' may change at every call.
```

In the MATLAB Function report, look at the function specializations. If you can see that the size of an argument is changing for each function specialization, then try this solution:

“Force Run-Time Recursion by Making the Input Variable-Size” on page 71-3.

### Force Run-Time Recursion by Treating the Input Value as Nonconstant

Consider this function:

```
function y = call_recfcn(n)
A = ones(1,n);
```

```

x = 100;
y = recfcn(A,x);
end

function y = recfcn(A,x)
if size(A,2) == 1 || x == 1
    y = A(1);
else
    y = A(1)+recfcn(A(2:end),x-1);
end
end

```

The second input to `recfcn` has the constant value 100. The code generator determines that the number of recursive calls is finite and tries to produce 100 copies of `recfcn`. This number of specializations exceeds the compile-time recursion limit. To force run-time recursion, instruct the code generator to treat the second input as a nonconstant value by using `coder.ignoreConst`.

```

function y = call_recfcn(n)
A = ones(1,n);
x = coder.ignoreConst(100);
y = recfcn(A,x);
end

function y = recfcn(A,x)
if size(A,2) == 1 || x == 1
    y = A(1);
else
    y = A(1)+recfcn(A(2:end),x-1);
end
end

```

If the code generator cannot determine that the number of recursive calls is finite, it produces a run-time recursive function.

### Force Run-Time Recursion by Making the Input Variable-Size

Consider this function:

```

function z = call_mysum(A)
%#codegen
z = mysum(A);
end

function y = mysum(A)
coder.inline('never');
if size(A,2) == 1
    y = A(1);
else
    y = A(1)+mysum(A(2:end));
end
end

```

If the input to `mysum` is fixed-size, the code generator uses compile-time recursion. If `A` is large enough, the number of function specializations exceeds the compile-time limit. To cause the code generator to use run-time conversion, make the input to `mysum` variable-size by using `coder.varsize`.

```
function z = call_mysum(A)
%#codegen
B = A;
coder.varsize('B');
z = mysum(B);
end

function y = mysum(A)
coder.inline('never');
if size(A,2) == 1
    y = A(1);
else
    y = A(1)+ mysum(A(2:end));
end
end
```

## Increase the Compile-Time Recursion Limit

The default compile-time recursion limit of 50 is large enough for most recursive functions that require compile-time recursion. Usually, increasing the limit does not fix the issue. However, if you can determine the number of recursive calls and you want compile-time recursion, increase the limit. For example, consider this function:

```
function z = call_mysum()
%#codegen
B = 1:125;
z = mysum(B);
end

function y = mysum(A)
coder.inline('never');
if size(A,2) == 1
    y = A(1);
else
    y = A(1)+ mysum(A(2:end));
end
end
```

You can determine that the code generator produces 125 copies of the `mysum` function. In this case, if you want compile-time recursion, increase the compile-time recursion limit to 125.

To increase the limit, increase the value of the **Compile-time recursion limit for MATLAB functions** configuration parameter.

# Output Variable Must Be Assigned Before Run-Time Recursive Call

## Issue

You see one of these messages:

```
All outputs must be assigned before any run-time
recursive call. Output 'y' is not assigned here.
```

```
Simulink does not have enough information to determine output
sizes for this block
```

.

## Cause

Run-time recursion produces a recursive function in the generated code. The code generator is unable to use run-time recursion for a recursive function in your MATLAB code because an output is not assigned before the first recursive call.

## Solution

Rewrite the code so that it assigns the output before the recursive call.

### Direct Recursion Example

In the following code, the statement `y = A(1)` assigns a value to the output `y`. This statement occurs after the recursive call `y = A(1)+ mysum(A(2:end))`.

```
function z = call_mysum(A)
B = A;
coder.varsize('B');
z = mysum(B);
end

function y = mysum(A)
coder.inline('never');
if size(A,2) > 1
    y = A(1)+ mysum(A(2:end));

else
    y = A(1);
end
end
```

Rewrite the code so that assignment `y = A(1)` occurs in the `if` block and the recursive call occurs in the `else` block.

```
function z = call_mysum(A)
B = A;
coder.varsize('B');
z = mysum(B);
```

```

end

function y = mysum(A)
coder.inline('never');

if size(A,2) == 1
    y = A(1);
else
    y = A(1)+ mysum(A(2:end));
end
end

```

Alternatively, before the if block, add an assignment, for example,  $y = 0$ .

```

function z = call_mysum(A)
B = A;
coder.varsize('B');
z = mysum(B);
end

function y = mysum(A)
coder.inline('never');
y = 0;
if size(A,2) > 1
    y = A(1)+ mysum(A(2:end));

else
    y = A(1);
end
end

```

### Indirect Recursion Example

In the following code, `rec1` calls `rec2` before the assignment  $y = 0$ .

```

function z = callrec(n)
z = rec1(n);
end

function y = rec1(x)
%#codegen

if x >= 0
    y = rec2(x-1)+1;
else
    y = 0;
end
end

function y = rec2(x)
y = rec1(x-1)+2;
end

```

Rewrite this code so that in `rec1`, the assignment  $y = 0$  occurs in the if block and the recursive call occurs in the else block.

```

function z = callrec(n)
z = rec1(n);

```

```
end

function y = rec1(x)
    %#codegen

    if x < 0
        y = 0;
    else
        y = rec2(x-1)+1;
    end
end

function y = rec2(x)
    y = rec1(x-1)+2;
end
```

- “Code Generation for Recursive Functions” on page 69-12

## Unable to Determine That Every Element of Cell Array Is Assigned

### Issue

You see one of these messages:

```
Unable to determine that every element of 'y' is
assigned before this line.
```

```
Unable to determine that every element of 'y' is
assigned before exiting the function.
```

```
Unable to determine that every element of 'y' is
assigned before exiting the recursively called function.
```

### Cause

For code generation, before you use a cell array element, you must assign a value to it. When you use `cell` to create a variable-size cell array, for example, `cell(1,n)`, MATLAB assigns an empty matrix to each element. However, for code generation, the elements are unassigned. For code generation, after you use `cell` to create a variable-size cell array, you must assign all elements of the cell array before any use of the cell array.

The code generator analyzes your code to determine whether all elements are assigned before the first use of the cell array. The code generator detects that all elements are assigned when the code follows this pattern:

```
function z = CellVarSize1D(n, j)
%#codegen
assert(n < 100);
x = cell(1,n);
for i = 1:n
    x{i} = i;
end
z = x{j};
end
```

Here is the pattern for a multidimensional cell array:

```
function z = CellAssign3D(m,n,p)
%#codegen
assert(m < 100);
assert(n < 100);
assert(p < 100);
x = cell(m,n,p);
for i = 1:m
    for j = 1:n
        for k = 1:p
            x{i,j,k} = i+j+k;
        end
    end
end
end
```

```
z = x{m,n,p};
end
```

If the code generator detects that some elements are not assigned, code generation fails. Sometimes, even though your code assigns all elements of the cell array, code generation fails because the analysis does not detect that all elements are assigned.

Here are examples where the code generator is unable to detect that elements are assigned:

- Elements are assigned in different loops

```
...
x = cell(1,n)
for i = 1:5
    x{i} = 5;
end
for i = 6:n
    x{i} = 7;
end
...
```

- The variable that defines the loop end value is not the same as the variable that defines the cell dimension.

```
...
x = cell(1,n);
m = n;
for i = 1:m
    x{i} = 2;
end
...
```

For more information, see “Definition of Variable-Size Cell Array by Using cell” on page 60-7.

## Solution

Try one of these solutions:

- “Use recognized pattern for assigning elements” on page 71-9
- “Use repmat” on page 71-9
- “Use coder.nullcopy” on page 71-10

### Use recognized pattern for assigning elements

If possible, rewrite your code to follow this pattern:

```
...
x = cell(1,n);
for i = 1:n
    x{i} = i;
end
z = x{j};
...
```

### Use repmat

Sometimes, you can use repmat to define the variable-size cell array.

Consider this code that defines a variable-size cell array. It assigns the value 1 to odd elements and the value 2 to even elements.

```
function z = repDefine(n, j)
%#codegen
assert(n < 100);
c =cell(1,n);
for i = 1:2:n-1
    c{i} = 1;
end
for i = 2:2:n
    c{i} = 2;
end
z = c{j};
```

Code generation does not allow this code because:

- More than one loop assigns the elements.
- The loop counter does not increment by 1.

Rewrite the code to first use `cell` to create a 1-by-2 cell array whose first element is 1 and whose second element is 2. Then, use `repmat` to create a variable-size cell array whose element values alternate between 1 and 2.

```
function z = repVarSize(n, j)
%#codegen
assert(n < 100);
c = cell(1,2);
c{1} = 1;
c{2} = 2;
c1= repmat(c,1,n);
z = c1{j};
end
```

You can pass an initially empty, variable-size cell array into or out of a function by using `repmat`. Use the following pattern:

```
function x = emptyVarSizeCellArray
x = repmat({'abc'},0,0);
coder.ysize('x');
end
```

This code indicates that `x` is an empty, variable-size cell array of 1x3 characters that can be passed into or out of functions.

### Use `coder.nullcopy`

As a last resort, you can use `coder.nullcopy` to indicate that the code generator can allocate the memory for your cell array without initializing the memory. For example:

```
function z = nulcpyCell(n, j)
%#codegen
assert(n < 100);
c =cell(1,n);
c1 = coder.nullcopy(c);
for i = 1:n
    c1{i} = 1;
end
```

```
end
for i = 5:n
    c1{i} = 2;
end
z = c1{j};
end
```

Use `coder.nullcopy` with caution. If you access uninitialized memory, results are unpredictable.

## More About

- “Cell Array Limitations for Code Generation” on page 60-6

## Nonconstant Index into varargin or varargout in a for-Loop

### Issue

Your MATLAB code contains a for-loop that indexes into varargin or varargout. When you generate code, you see this error message:

```
Non-constant expression or empty matrix. This expression
must be constant because its value determines the size
or class of some expression.
```

### Cause

At code generation time, the code generator must be able to determine the value of an index into varargin or varargout. When varargin or varargout are indexed in a for-loop, the code generator determines the index value for each loop iteration by unrolling the loop. Loop unrolling makes a copy of the loop body for each loop iteration. In each iteration, the code generator determines the value of the index from the loop counter.

The code generator is unable to determine the value of an index into varargin or varargout when:

- The number of copies of the loop body exceeds the limit for loop unrolling.
- Heuristics fail to identify that loop unrolling is warranted for a particular for-loop. For example, consider the following function:

```
function [x,y,z] = fcn(a,b,c)
    %#codegen

    [x,y,z] = subfcn(a,b,c);

    function varargout = subfcn(varargin)
        j = 0;
        for i = 1:nargin
            j = j+1;
            varargout{j} = varargin{j};
        end
```

The heuristics do not detect the relationship between the index *j* and the loop counter *i*. Therefore, the code generator does not unroll the for-loop.

### Solution

Use one of these solutions:

- “Force Loop Unrolling” on page 71-12
- “Rewrite the Code” on page 71-13

#### Force Loop Unrolling

Force loop unrolling by using `coder.unroll`. For example:

```
function [x,y,z] = fcn(a,b,c)
    %#codegen
```

```
[x,y,z] = subfcn(a,b,c);  
  
function varargout = subfcn(varargin)  
j = 0;  
  
coder.unroll();  
for i = 1:nargin  
    j = j + 1;  
    varargout{j} = varargin{j};  
end
```

### Rewrite the Code

Rewrite the code so that the code generator can detect the relationship between the index and the loop counter. For example:

```
function [x,y,z] = fcn(a,b,c)  
%#codegen  
[x,y,z] = subfcn(a,b,c);  
  
function varargout = subfcn(varargin)  
for i = 1:nargin  
    varargout{i} = varargin{i};  
end
```

## Unknown Output Type for coder.ceval

### Issue

You see this error message:

```
Output of 'coder.ceval' has unknown type. The enclosing
expression cannot be evaluated.
Specify the output type by assigning the output of
'coder.ceval' to a variable with a known type.
```

### Cause

This error message occurs when the code generator cannot determine the output type of a `coder.ceval` call.

### Solution

Initialize a temporary variable with the expected output type. Assign the output of `coder.ceval` to this variable.

### Example

Assume that you have a C function called `cFunctionThatReturnsDouble`. You want to generate C library code for a function `foo`. The code generator returns the error message because it cannot determine the return type of `coder.ceval`.

```
function foo
%#codegen
callFunction(coder.ceval('cFunctionThatReturnsDouble'));
end

function callFunction(~)
end
```

To fix the error, define the type of the C function output by using a temporary variable.

```
function foo
%#codegen
temp = 0;
temp = coder.ceval('cFunctionThatReturnsDouble');
callFunction(temp);
end

function callFunction(~)
end
```

You can also use `coder.opaque` to initialize the temporary variable.

### Example Using Classes

Assume that you have a class with a custom `set` method. This class uses the `set` method to ensure that the object property value falls within a certain range.

```

classdef classWithSetter
    properties
        expectedResult = []
    end
    properties(Constant)
        scalingFactor = 0.001
    end
    methods
        function obj = set.expectedResult(obj,erIn)
            if erIn >= 0 && erIn <= 100
                erIn = erIn.*obj.scalingFactor;
                obj.expectedResult = erIn;
            else
                obj.expectedResult = NaN;
            end
        end
    end
end
end
end

```

When generating C library code for the function `foo`, the code generator produces the error message. The input type into the `set` method cannot be determined.

```

function foo
    %#codegen
    obj = classWithSetter;
    obj.expectedResult = coder.ceval('cFunctionThatReturnsDouble');
end

```

To fix the error, initialize a temporary variable with a known type. For this example, use a type of scalar double.

```

function foo
    %#codegen
    obj = classWithSetter;
    temp = 0;
    temp = coder.ceval('cFunctionThatReturnsDouble');
    obj.expectedResult = temp;
end

```

## About Data Types in Simulink

The term *data type* refers to the way in which a computer represents numbers or text in memory. A data type determines the amount of storage allocated to a number or letter, the method used to encode the number's value as a pattern of binary digits, and the operations available for manipulating the type. Most computers provide a choice of data types for representing numbers, each with specific advantages in the areas of precision, dynamic range, performance, and memory usage. To optimize performance, you can specify the data types of variables used in the MATLAB technical computing environment. Simulink builds on this capability by allowing you to specify the data types of Simulink signals and block parameters.

The ability to specify the data types of a model's signals and block parameters is particularly useful in real-time control applications. For example, it allows a Simulink model to specify the optimal data types to use to represent signals and block parameters in code generated from a model by automatic code-generation tools, such as the Simulink Coder product. By choosing the most appropriate data types for your model's signals and parameters, you can dramatically increase performance and decrease the size of the code generated from the model.

Simulink performs extensive checking before and during a simulation to ensure that your model is *typesafe*, that is, that code generated from the model will not overflow or underflow and thus produce incorrect results. Simulink models that use the default data type (`double`) are inherently typesafe. Thus, if you never plan to generate code from your model or use a nondefault data type in your models, you can skip the remainder of this section.

On the other hand, if you plan to generate code from your models and use nondefault data types, read the remainder of this section carefully, especially the section on data type rules (see “Data Typing Guidelines” on page 72-2). In that way, you can avoid introducing data type errors that prevent your model from running to completion or simulating at all.

### Data Typing Guidelines

Observing the following rules can help you to create models that are typesafe and, therefore, execute without error:

- Signal data types generally do not affect parameter data types, and vice versa.

A significant exception to this rule is the Constant block, whose output data type is determined by the data type of its parameter.

- If the output of a block is a function of an input and a parameter, and the input and parameter differ in type, Simulink converts the parameter to the input type before computing the output.
- In general, a block outputs the data type that appears at its inputs.

Significant exceptions include Constant blocks and Data Type Conversion blocks, whose output data types are determined by block parameters.

- Virtual blocks accept signals of any type on their inputs.

Examples of virtual blocks include Mux and Demux blocks and unconditionally executed subsystems.

- The elements of a signal array connected to a port of a nonvirtual block must be of the same data type.

- The signals connected to the input data ports of a nonvirtual block cannot differ in type.
- Control ports (for example, Enable and Trigger ports) accept any data type.
- Solver blocks accept only double signals.
- Connecting a non-double signal to a block disables zero-crossing detection for that block.

## Data Type Propagation

Whenever you start a simulation, enable display of port data types, or refresh the port data type display, Simulink performs a processing step called data type propagation. This step involves determining the types of signals whose type is not otherwise specified and checking the types of signals and input ports to ensure that they do not conflict. If type conflicts arise, an error dialog is displayed that specifies the signal and port whose data types conflict. The signal path that creates the type conflict is also highlighted.

---

**Note** You can insert typecasting (data type conversion) blocks in your model to resolve type conflicts. For more information, see [Data Type Conversion](#).

- “Simulink Strings” on page 72-43

## Data Types Supported by Simulink

Simulink supports all built-in numeric MATLAB data types. The term *built-in data type* refers to data types defined by MATLAB itself as opposed to data types defined by MATLAB users. Unless otherwise specified, the term data type in the Simulink documentation refers to built-in data types.

The following table lists the built-in MATLAB data types supported by Simulink.

Name	Description
<code>double</code>	Double-precision floating point
<code>single</code>	Single-precision floating point
<code>int8</code>	Signed 8-bit integer
<code>uint8</code>	Unsigned 8-bit integer
<code>int16</code>	Signed 16-bit integer
<code>uint16</code>	Unsigned 16-bit integer
<code>int32</code>	Signed 32-bit integer
<code>uint32</code>	Unsigned 32-bit integer
<code>int64</code>	Signed 64-bit integer
<code>uint64</code>	Unsigned 64-bit integer
<code>half</code>	Half-precision floating point (requires Fixed-Point Designer license)
<code>string</code>	Text

Some model elements do not support all data types. For more information on the data types supported by a specific block for parameter and input and output values, see the Data Type Support section of the reference page for that block.

Besides these built-in types, Simulink defines a `boolean` (`true` or `false`) type. The values `1` and `0` represent `true` and `false` respectively. For this data type, Simulink represents real, nonzero numeric values (including `Inf`) as `true` (`1`).

### Block Support for Data and Signal Types

All Simulink blocks accept signals of type `double` by default. Some blocks prefer `boolean` input and others support multiple data types on their inputs. For more information on the data types supported by a specific block for parameter and input and output values, see the reference page for that block. If the documentation for a block does not specify a data type, the block inputs or outputs only data of type `double`.

Several blocks support bus objects (`Simulink.Bus`) as data types. See “Data Types for Buses” on page 72-42.

Many Simulink blocks also support fixed-point data types. For more information about fixed-point data, see “Specify Fixed-Point Data Types” on page 72-28. For more information on the data types supported by a specific block for parameter and input and output values, in the Simulink documentation see the Data Type Support section of the reference page for that block. If the documentation for a block does not specify a data type, the block inputs or outputs only data of type `double`.

To specify an image of the `Simulink.ImageType` data type and generate code for the model, use the Computer Vision Toolbox. Specify this data type for signals and other data in the model. The `Simulink.ImageType` data type is an encapsulated object that defines an image that has fixed meta-attributes specific to this data type.

To view a table that summarizes the data types supported by the blocks in the Simulink block libraries, execute the following command at the MATLAB command line:

```
showblockdatatypetable
```

## Control Data Types of Signals

To control the data type of a signal in a Simulink model, you specify a data type for the corresponding block output.

You can also introduce a new signal of a specific data type into a model in any of the following ways:

- Load signal data of the desired type from the MATLAB workspace into your model via a root-level Inport block or a From Workspace block.
- Create a Constant block in your model and set its parameter to the desired type.
- Use a Data Type Conversion block to convert a signal to the desired data type.

Simulink blocks determine the data type of their outputs by default. Many blocks allow you to override the default type and explicitly specify an output data type, using a block parameter that is typically named **Output data type**. For example, the **Output data type** parameter appears on the **Signal Attributes** pane of the Constant block dialog box.

See the following topics for more information:

For Information About...	See...
Valid data type values that you can specify	"Entering Valid Data Type Values" on page 72-6
An assistant that helps you specify valid data type values	"Specify Data Types Using Data Type Assistant" on page 72-30
Specifying valid data type values for multiple blocks simultaneously	"Use the Model Data Editor for Batch Editing" on page 72-8

### Entering Valid Data Type Values

In general, you can specify the output data type as any of the following:

- A rule that inherits a data type (see "Data Type Inheritance Rules" on page 72-7)
- The name of a built-in data type (see "Built-In Data Types" on page 72-8)

- An expression that evaluates to a data type (see “Data Type Expressions” on page 72-8)

Valid data type values vary among blocks. You can use the drop-down menu associated with a block data type parameter to view the data types that a particular block supports. For example, the **Data type** drop-down menu on the Data Store Memory block dialog box lists the data types that it supports, as shown here.

For more information about the data types that a specific block supports, see the documentation for the block in the Simulink documentation.

### Data Type Inheritance Rules

Blocks can inherit data types from a variety of sources, including signals to which they are connected and particular block parameters. You can specify the value of a data type parameter as a rule that determines how the output signal inherits its data type. To view the inheritance rules that a block supports, use the data type drop-down menu on the block dialog box. The following table lists typical rules that you can select.

Inheritance Rule	Description
Inherit: Inherit via back propagation	Simulink automatically determines the output data type of the block during data type propagation (see “Data Type Propagation” on page 72-3). In this case, the block uses the data type of a downstream block or signal object.
Inherit: Same as input	The block uses the data type of its sole input signal for its output signal.
Inherit: Same as first input	The block uses the data type of its first input signal for its output signal.
Inherit: Same as second input	The block uses the data type of its second input signal for its output signal.

Inheritance Rule	Description
Inherit: Inherit via internal rule	The block uses an internal rule to determine its output data type. The internal rule chooses a data type that optimizes numerical accuracy, performance, and generated code size, while taking into account the properties of the embedded target hardware. It is not always possible for the software to optimize efficiency and numerical accuracy at the same time.

When you apply inherited data types to a signal, Simulink determines the specific data type of the signal only after you update the block diagram.

- To display this specific data type on the block diagram, see “Port Data Types” on page 80-55.
- To inspect this specific data type for multiple signals in a searchable, sortable table, use the Model Data Editor (on the **Modeling** tab, click **Model Data Editor**). The right side of the **Data Type** column shows the specific data type for each signal. For more information, see **Model Data Editor**.

### Built-In Data Types

You can specify the value of a data type parameter as the name of a built-in data type, for example, `single` or `boolean`. To view the built-in data types that a block supports, use the data type drop-down menu on the block dialog box. See “Data Types Supported by Simulink” on page 72-4 for a list of all built-in data types that are supported.

### Data Type Expressions

You can specify the value of a data type parameter as an expression that evaluates to a numeric data type object. Simply enter the expression in the data type field on the block dialog box. In general, enter one of these expressions:

- **fixdt Command**

Specify the value of a data type parameter as a command that invokes the `fixdt` function. This function allows you to create a `Simulink.NumericType` object that describes a fixed-point or floating-point data type.

- **Data Type Object Name**

Specify the value of a data type parameter as the name of an object that represents a data type. `Simulink.NumericType`, `Simulink.AliasType`, `Simulink.ValueType`, and `Simulink.BusElement` objects simplify the task of making model-wide changes to output data types. `Simulink.AliasType` objects allow you to use custom aliases for data types. `Simulink.ValueType` and `Simulink.BusElement` objects allow you to specify the data type and other parameters, such as the unit, minimum value, and maximum value.

### Use the Model Data Editor for Batch Editing

Using the **Model Data Editor**, you can assign the same data type to multiple signals simultaneously. You can use this technique to design the interface of your model by configuring data types and other attributes of multiple Inport and Outport blocks at once (see “Configure Data Interfaces” on page 23-21). You can also finely control the data types of arbitrary signals in your block algorithm.

For example, the `slexAircraftExample` model in the “Aircraft Longitudinal Flight Control” example contains numerous Gain blocks. Suppose you want to specify the output data type of the three Gain blocks at the root level of the model as `single`. You can achieve this task as follows:

- 1 In the Model Data Editor (on the **Modeling** tab, click **Model Data Editor**), inspect the **Signals** tab.
- 2 Next to the **Filter contents** box, toggle the **Filter using selection** button.
- 3 At the top level of the model, select the signal lines that represent the outputs of the three Gain blocks (labeled `Zw`, `Mw`, and `Mq`). The Model Data Editor shows three rows that correspond to the three signals.
- 4 In the Model Data Editor, select all three signals (rows). For example, you can press **Ctrl+A** or hold **Shift** while clicking the top and bottom rows in the **Source** column.
- 5 For any of the three signals, click the cell in the **Data Type** column. From the drop-down list, select `single`. The Model Data Editor applies this selection to all of the selected rows.

To convert a model to a strict single precision design, see “Validate a Floating-Point Embedded Model” on page 72-12.

## Share a Data Type Between Separate Algorithms, Data Paths, Models, and Bus Elements

In some cases, you cannot rely on data type inheritance (see “Data Type Inheritance Rules” on page 72-7) to establish equivalence between the data types of different data items (such as signal lines in parallel data paths or bus elements in a `Simulink.Bus` object). Instead, you can create a `Simulink.NumericType` or `Simulink.AliasType` object in a workspace or data dictionary.

Create a `Simulink.NumericType` object if you do not want to rename the shared data type by creating an alias. Set the `IsAlias` property to `false` (the default).

This example shows how to use a `Simulink.NumericType` object to share an output data type between two lookup table blocks in the same model.

- 1 Open the “Model a Fault-Tolerant Fuel Control System” example model `sldemo_fuelsys`.

```
openExample('simulink_automotive/ModelingAFaultTolerantFuelControlSystemExample')
sldemo_fuelsys
```

The model creates `Simulink.NumericType` objects in the base workspace. One of the objects is named `s16En15`.

- 2 At the command prompt, inspect the properties of `s16En15`.

```
s16En15
s16En15 =
    NumericType with properties:
        DataTypeMode: 'Single'
        IsAlias: 0
        DataScope: 'Auto'
        HeaderFile: ''
        Description: ''
```

This object represents the built-in Simulink data type `single`.

- 3 In the model, navigate into the `fuel_rate_control/airflow_calc` subsystem.
- 4 On the **Modeling** tab, click **Model Data Editor**. In the Model Data Editor, inspect the **Signals** tab.
- 5 In the model, click the output signal of the Pumping Constant block. The Model Data Editor **Data Type** column shows that the signal data type is set to `s16En15`.
- 6 Click the output signal of the Ramp Rate Ki block. The output data type of this block is also set to `s16En15`.
- 7 Update the block diagram and, if necessary, expand the width of the **Data Type** column. The right side of the column shows that the two lookup table blocks use the data type `single`.
- 8 At the command prompt, configure `s16En15` to represent the data type `double`.

```
s16En15.DataTypeMode = 'Double';
```

- 9 Update the block diagram.

The output signals of the two lookup table blocks now use the data type `double`. Due to data type inheritance, other signals, such as `e0` and `e1`, acquire the same data type.

Alternatively, to establish data type equivalence between algorithms or data paths in the same model, you can use blocks such as Data Type Propagation and Data Type Conversion Inherited. When you use these blocks, you do not need to create and permanently store a data type object. However, you cannot use the blocks to share a data type between signals in different models unless the models are in the same model reference hierarchy.

## Reuse Custom C Data Types for Signal Data

In a model, you can create signals that conform to custom C data types, such as structures, that your existing C code defines. Use these signals to:

- Replace existing C code with a Simulink model.
- Integrate C code for simulation in Simulink (for example, by using the Legacy Code Tool).
- Prepare to generate code (Simulink Coder) that you can integrate with existing code.

Use these techniques to match your custom data types:

- For a structure type, create a `Simulink.Bus` object. Use the object as the data type for bus signals. See “Data Types for Buses” on page 72-42.
- For an enumeration, create an enumeration class and use it as the data type for signals. See “Use Enumerated Data in Simulink Models” on page 73-5.
- To match a `typedef` statement that represents an alias of a primitive, numeric data type, use a `Simulink.AliasType` object as the data type for signals. See `Simulink.AliasType`.

To create these classes and objects, you can use the function `Simulink.importExternalCTypes`.

If a MATLAB Function block or Stateflow chart in your model uses an imported enumeration or structure type, configure the model configuration parameters to include (`#include`) the type definition from your external header file. See “Control Imported Bus and Enumeration Type Definitions” on page 49-116 (for a MATLAB Function block) and “Access Custom Code Variables and Functions in Stateflow Charts” (Stateflow) and “Integrate Custom Structures in Stateflow Charts” (Stateflow) (for a chart).

## Determine Data Type of Signal That Uses Inherited Setting

When a signal uses an inherited data type setting such as `Inherit: Inherit via internal rule` (the default setting for most blocks), to determine the meaningful data type that the signal uses for simulation, update the block diagram and then use one or both of these techniques:

- In the Simulink Editor, on the **Debug** tab, select **Information Overlays** and navigate to the ports section. Select the port data type you want to display. The data types appear on the block diagram next to each signal. For more information, see “Port Data Types” on page 80-55.
- Inspect the right side of the **Data Type** column in the Model Data Editor (on the **Modeling** tab, click **Model Data Editor**). For more information, see **Model Data Editor**.

Using these techniques to inspect data types helps you to:

- Design the data type strategy for a model on a high level.
- Debug numerical issues due to quantization and overflows.
- Make a model more easily understood when sharing it.

For more information, see “Port Data Types” on page 80-55.

## Data Types Remain double Despite Changing Settings

If many of the data items (signals, parameters, and states) in your model continue to use the data type `double` after you configure block parameters such as **Output data type**, confirm that the model is not configured to override data types. See “Control Data Type Override” on page 72-26.

- “Specify Data Types Using Data Type Assistant” on page 72-30
- “About Data Types in Simulink” on page 72-2
- “Data Types Supported by Simulink” on page 72-4
- “Data Types for Buses” on page 72-42

## Validate a Floating-Point Embedded Model

You can use data type override mode to temporarily switch the data types in your model. This capability allows you to maintain one model but simulate your model using multiple data types, and validate the numerical behavior for each type. For example, if you implement an algorithm using double-precision data types and want to check whether the algorithm is also suitable for single-precision use, you can apply a data type override to floating-point data types to replace all doubles with singles without permanently affecting any other data types in your model.

To apply data type override, you must specify the data type that you want to apply and the data type that you want to replace.

You can set data type override using the following method. This example changes all floating-point data types to single.

For example:

```
set_param(gcs, 'DataTypeOverride', 'Single', ...  
    'DataTypeOverrideAppliesTo', 'Floating-point');
```

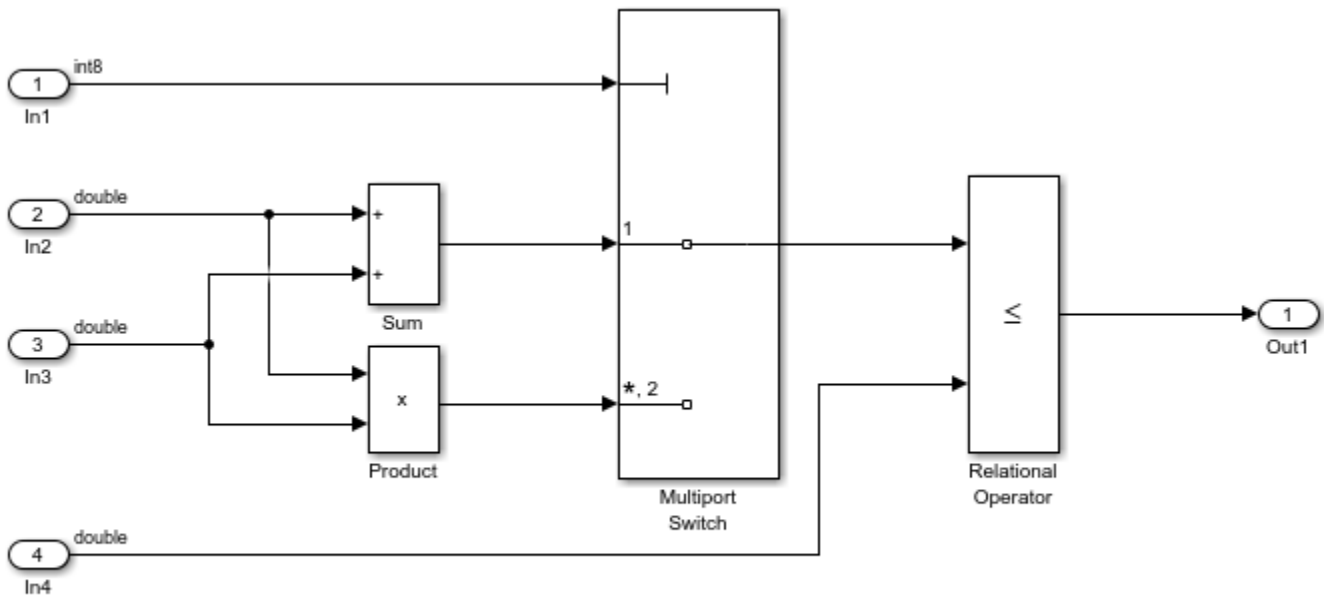

For more information on data type override settings, see “Control Data Type Override” on page 72-26.

### Explore the Model

This example uses the `ex_single_validation` model to show how you can use data type override. It proves that an algorithm, which implements double-precision data types, is also suitable for single-precision embedded use.

Open the model

```
open_system('ex_single_validation')
```

Copyright 1994-2020 The MathWorks, Inc.

- The inputs In2 and In3 are double-precision inputs to the Sum and Product blocks.
- The outputs of the Sum and Product blocks are data inputs to the Multiport Switch block.
- The input In1 is the control input to the Multiport Switch block. The value of this control input determines which of its other inputs, the sum of In2 and In3 or the product of In2 and In3, passes to the output port. Because In1 is a control input, its data type is int8.
- The Relational Operator block compares the output of the Multiport Switch block to In4, and outputs a Boolean signal.

## Validate a Single-Precision Model

### Override Floating-Point Data Types with Singles

- 1 At the command line, override the floating-point data types in the model with singles

```
set_param(gcs, 'DataTypeOverride', 'Single', ...
'DataTypeOverrideAppliesTo', 'Floating-point');
```

- 2 In the model, on the **Modeling** tab, click **Update Model**.

The data type override replaces all the floating-point (double) data types in the model with single data types, but does not affect the integer or Boolean data types.

### Run Model Advisor Check

- 1 From the model, on the **Modeling** tab, click **Model Advisor**.
- 2 In the System Selector dialog box, click **OK**.

The Model Advisor opens.

- 3 In the Model Advisor, expand the **By Task** node and, under **Modeling Single-Precision Systems**, select the **Identify questionable operations for strict single-precision design** check.
- 4 In the right pane, click **Run This Check**.

The check passes indicating that this algorithm is suitable for single-precision use. To ensure that no double-precision data types remain in the generated code, use the Single-Precision Converter before generating code for single-precision embedded use. For more information, see “Getting Started with Single Precision Converter” (Fixed-Point Designer).

### Blocks That Support Single Precision

To identify Simulink blocks that support single precision, at the command prompt, enter `showblockdatatypetable`. In a model, to find blocks that do not support single precision, use the Model Advisor check “Identify questionable operations for strict single-precision design”.

## Fixed-Point Numbers

### In this section...

“Binary Point Interpretation” on page 72-16

“Signed Fixed-Point Numbers” on page 72-17

In digital hardware, numbers are stored in binary words. A binary word is a fixed-length sequence of binary digits (1's and 0's). The way in which hardware components or software functions interpret this sequence of 1's and 0's is described by a data type. There are several distinct differences between fixed-point data types and the built-in integer types in MATLAB. The most notable difference, is that the built-in integer data types can only represent whole numbers, while the fixed-point data types also contain information on the position of the binary point, or the scaling of the number.

Binary numbers are represented as either fixed-point or floating-point data types. A fixed-point data type is characterized by the word size in bits, the binary point, and whether it is signed or unsigned. The position of the binary point is the means by which fixed-point values are scaled and interpreted. With Fixed-Point Designer, fixed-point data types can be integers, fractionals, or generalized fixed-point numbers. The main difference between these data types is their default binary point. For example, a binary representation of a generalized fixed-point number (either signed or unsigned) is shown below:

where

- $b_i$  is the  $i^{\text{th}}$  binary digit.
- $wl$  is the word length in bits.
- $b_{wl-1}$  is the location of the most significant, or highest, bit (MSB).
- $b_0$  is the location of the least significant, or lowest, bit (LSB).
- The binary point is shown four places to the left of the LSB. In this example, therefore, the number is said to have four fractional bits, or a fraction length of four.

### Binary Point Interpretation

The binary point is the means by which fixed-point numbers are scaled. It is usually the software that determines the binary point. When performing basic math functions such as addition or subtraction, the hardware uses the same logic circuits regardless of the value of the scale factor. In essence, the logic circuits have no knowledge of a scale factor. They are performing signed or unsigned fixed-point binary algebra as if the binary point is to the right of  $b_0$ .

Fixed-Point Designer supports the general binary point scaling  $V=Q*2^E$ .  $V$  is the real-world value,  $Q$  is the stored integer value, and  $E$  is equal to  $-\text{FractionLength}$ . In other words,  $\text{RealWorldValue} = \text{StoredInteger} * 2^{-\text{FractionLength}}$ .

$\text{FractionLength}$  defines the scaling of the stored integer value. The word length limits the values that the stored integer can take, but it does not limit the values  $\text{FractionLength}$  can take. The

software does not restrict the value of exponent  $E$  based on the word length of the stored integer  $Q$ . Because  $E$  is equal to  $-\text{FractionLength}$ , restricting the binary point to being contiguous with the fraction is unnecessary; the fraction length can be negative or greater than the word length.

For example, a word consisting of three unsigned bits is usually represented in scientific notation in one of the following ways.

$$\begin{aligned}bbb. &= bbb. \times 2^0 \\bb.b &= bbb. \times 2^{-1} \\b.bb &= bbb. \times 2^{-2} \\\.bbb &= bbb. \times 2^{-3}\end{aligned}$$

If the exponent were greater than 0 or less than -3, then the representation would involve lots of zeros.

$$\begin{aligned}bbb00000. &= bbb. \times 2^5 \\bbb00. &= bbb. \times 2^2 \\\.00bbb &= bbb. \times 2^{-5} \\\.00000bbb &= bbb. \times 2^{-8}\end{aligned}$$

These extra zeros never change to ones, however, so they don't show up in the hardware. Furthermore, unlike floating-point exponents, a fixed-point exponent never shows up in the hardware, so fixed-point exponents are not limited by a finite number of bits.

Consider a signed value with a word length of 8, a fraction length of 10, and a stored integer value of 5 (binary value 00000101). The real-world value is calculated using the formula  $\text{RealWorldValue} = \text{StoredInteger} * 2^{-\text{FractionLength}}$ . In this case,  $\text{RealWorldValue} = 5 * 2^{-10} = 0.0048828125$ . Because the fraction length is 2 bits longer than the word length, the binary value of the stored integer is  $x.xx00000101$ , where  $x$  is a placeholder for implicit zeros.  $0.0000000101$  (binary) is equivalent to  $0.0048828125$  (decimal). For an example using a `fi` object, see "Fraction Length Greater Than Word Length" (Fixed-Point Designer).

## Signed Fixed-Point Numbers

Computer hardware typically represents the negation of a binary fixed-point number in three different ways: sign/magnitude, one's complement, and two's complement. Two's complement is the preferred representation of signed fixed-point numbers and is the only representation used by Fixed-Point Designer.

Negation using two's complement consists of a bit inversion (translation into one's complement) followed by the addition of a one. For example, the two's complement of 000101 is 111011.

Whether a fixed-point value is signed or unsigned is usually not encoded explicitly within the binary word; that is, there is no sign bit. Instead, the sign information is implicitly defined within the computer architecture.

## Benefits of Using Fixed-Point Hardware

Digital hardware is becoming the primary means by which control systems and signal processing filters are implemented. Digital hardware can be classified as either off-the-shelf hardware (for example, microcontrollers, microprocessors, general-purpose processors, and digital signal processors) or custom hardware. Within these two types of hardware, there are many architecture designs. These designs range from systems with a single instruction, single data stream processing unit to systems with multiple instruction, multiple data stream processing units.

Within digital hardware, numbers are represented as either fixed-point or floating-point data types. For both of these data types, word sizes are fixed at a set number of bits. However, the dynamic range of fixed-point values is much less than floating-point values with equivalent word sizes. Therefore, in order to avoid overflow or unreasonable quantization errors, fixed-point values must be scaled. Since floating-point processors can greatly simplify the real-time implementation of a control law or digital filter, and floating-point numbers can effectively approximate real-world numbers, then why use a microcontroller or processor with fixed-point hardware support?

- **Size and Power Consumption** — The logic circuits of fixed-point hardware are much less complicated than those of floating-point hardware. This means that the fixed-point chip size is smaller with less power consumption when compared with floating-point hardware. For example, consider a portable telephone where one of the product design goals is to make it as portable (small and light) as possible. If one of today's high-end floating-point, general-purpose processors is used, a large heat sink and battery would also be needed, resulting in a costly, large, and heavy portable phone.
- **Memory Usage and Speed** — In general fixed-point calculations require less memory and less processor time to perform.
- **Cost** — Fixed-point hardware is more cost effective where price/cost is an important consideration. When digital hardware is used in a product, especially mass-produced products, fixed-point hardware costs much less than floating-point hardware and can result in significant savings.

After making the decision to use fixed-point hardware, the next step is to choose a method for implementing the dynamic system (for example, control system or digital filter). Floating-point software emulation libraries are generally ruled out because of timing or memory size constraints. Therefore, you are left with fixed-point math where binary integer values are scaled.

## Scaling, Precision, and Range

### In this section...

“Scaling” on page 72-20

“Precision” on page 72-20

“Range” on page 72-21

The dynamic range of fixed-point values is less than floating-point values with equivalent word sizes. To avoid overflow and minimize quantization errors, fixed-point numbers must be scaled.

### Scaling

With Fixed-Point Designer, you can select a fixed-point data type whose scaling is defined by its binary point, or you can select an arbitrary linear scaling that suits your needs.

#### Slope and Bias Scaling

You can represent a fixed-point number by a general slope and bias encoding scheme. The real world value of a slope bias scaled number can be represented by:

$$\text{real-world value} = (\text{slope} \times \text{integer}) + \text{bias}$$

$$\text{slope} = \text{slope adjustment factor} \times 2^{\text{fixed exponent}}$$

The slope and bias together represent the scaling of the fixed-point number. In a number with zero bias, only the slope affects the scaling. A fixed-point number that is only scaled by binary point position is equivalent to a number in slope bias representation that has a bias equal to zero and a slope adjustment factor equal to one. This is referred to as binary point-only scaling or power-of-two scaling.

#### Binary-Point-Only Scaling

Binary-point-only or power-of-two scaling involves moving the binary point within the fixed-point word. The advantage of this scaling mode is to minimize the number of processor arithmetic operations. The real world value of a binary-point only scaled number can be represented by:

$$\text{real world value} = 2^{-\text{fraction length}} \times \text{integer}$$

### Precision

The precision of a fixed-point number is the difference between successive values representable by its data type and scaling, which is equal to the value of its least significant bit. The value of the least significant bit, and therefore the precision of the number, is determined by the number of fractional bits. A fixed-point value can be represented to within half of the precision of its data type and scaling.

For example, a fixed-point representation with four bits to the right of the binary point has a precision of  $2^{-4}$  or 0.0625, which is the value of its least significant bit. Any number within the range of this data type and scaling can be represented to within  $(2^{-4})/2$  or 0.03125, which is half the precision.

#### Rounding Methods

When you represent numbers with finite precision, not every number in the available range can be represented exactly. If a number cannot be represented exactly by the specified data type and

scaling, a rounding method is used to cast the value to a representable number. Although precision is always lost in the rounding operation, the cost of the operation and the amount of bias that is introduced depends on the rounding method itself. For more information on the rounding methods available with Fixed-Point Designer, see “Rounding Methods” (Fixed-Point Designer)

## Range

Range is the span of numbers that a fixed-point data type and scaling can represent. The range of representable numbers for an unsigned two’s complement fixed-point number of word length  $w$ , scaling  $S$ , and bias  $B$  is illustrated below:

The following figure illustrates the range of representable numbers for a two’s complement signed fixed-point number:

For both signed and unsigned fixed-point numbers of any data type, the number of different bit patterns is  $2^{wl}$ .

For example, in two’s complement, negative numbers must be represented as well as zero, so the maximum value is  $2^{wl-1}-1$ . Because there is only one representation for zero, there are an unequal number of positive and negative numbers. This means there is a representation for  $-2^{wl-1}$ , but not for  $2^{wl-1}$ .

## Fixed-Point Data in MATLAB and Simulink

In this section...
“Fixed-Point Data in Simulink” on page 72-22
“Fixed-Point Data in MATLAB” on page 72-23
“Scaled Doubles” on page 72-24

### Fixed-Point Data in Simulink

You can use the `fixdt` function in Simulink to specify a fixed-point data type. The `fixdt` function creates a `Simulink.NumericType` object.

#### Fixed-Point Data Type and Scaling Notation

Simulink data type names must be valid MATLAB identifiers with less than 128 characters. The data type name provides information about container type, number encoding, and scaling.

The following table provides a key for various symbols that appear in Simulink products to indicate the data type and scaling of a fixed-point value.

Symbol	Description	Example
<b>Container Type</b>		
<code>ufix</code>	Unsigned fixed-point data type	<code>ufix8</code> is an 8-bit unsigned fixed-point data type
<code>sfix</code>	Signed fixed-point data type	<code>sfix128</code> is a 128-bit signed fixed-point data type
<code>fltu</code>	Scaled double override of an unsigned fixed-point data type ( <code>ufix</code> )	<code>fltu32</code> is a scaled doubles override of <code>ufix32</code>
<code>flts</code>	Scaled double override of a signed fixed-point data type ( <code>sfix</code> )	<code>flts64</code> is a scaled doubles override of <code>sfix64</code>
<b>Number Encoding</b>		
<code>e</code>	$10^{\wedge}$	<code>125e8</code> equals $125 * (10^{\wedge}(8))$
<code>n</code>	Negative	<code>n31</code> equals -31
<code>p</code>	Decimal point	<code>1p5</code> equals 1.5 <code>p2</code> equals 0.2
<b>Scaling Encoding</b>		
<code>S</code>	Slope	<code>ufix16_S5_B7</code> is a 16-bit unsigned fixed-point data type with Slope of 5 and Bias of 7
<code>B</code>	Bias	<code>ufix16_S5_B7</code> is a 16-bit unsigned fixed-point data type with Slope of 5 and Bias of 7

Symbol	Description	Example
E	Fixed exponent ( $2^{\wedge}$ ) A negative fixed exponent describes the fraction length	<code>sfix32_En31</code> is a 32-bit signed fixed-point data type with a fraction length of 31
F	Slope adjustment factor	<code>ufix16_F1p5_En50</code> is a 16-bit unsigned fixed-point data type with a <code>SlopeAdjustmentFactor</code> of 1.5 and a <code>FixedExponent</code> of -50
C,c,D, or d	Compressed encoding for Bias  <b>Note</b> If you pass this character vector to the <code>slDataTypeAndScale</code> function, it returns a valid <code>fixdt</code> data type.	No example available. For backwards compatibility only.  To identify and replace calls to <code>slDataTypeAndScale</code> , use the "Check for calls to <code>slDataTypeAndScale</code> " Model Advisor check.
T or t	Compressed encoding for Slope  <b>Note</b> If you pass this character vector to the <code>slDataTypeAndScale</code> , it returns a valid <code>fixdt</code> data type.	No example available. For backwards compatibility only.  To identify and replace calls to <code>slDataTypeAndScale</code> , use the "Check for calls to <code>slDataTypeAndScale</code> " Model Advisor check.

## Fixed-Point Data in MATLAB

To assign a fixed-point data type to a number or variable in MATLAB, use the `fi` constructor. The resulting fixed-point value is called a `fi` object. For example, the following creates `fi` objects `a` and `b` with attributes shown in the display, all of which we can specify when the variables are constructed. Note that when the `FractionLength` property is not specified, it is set automatically to "best precision" for the given word length, keeping the most-significant bits of the value. When the `WordLength` property is not specified it defaults to 16 bits.

```
a = fi(pi)
```

```
a =
```

```
3.1416015625
```

```
DataTypeMode: Fixed-point: binary point scaling
Signedness: Signed
WordLength: 16
FractionLength: 13
```

```
b = fi(0.1)
```

```
b =
```

```
0.0999984741210938
```

```
DataTypeMode: Fixed-point: binary point scaling
```

```
Signedness: Signed  
WordLength: 16  
FractionLength: 18
```

### **Read Fixed-Point Data from the Workspace**

Use the From Workspace block to read fixed-point data from the MATLAB workspace into a Simulink model. To do this, the data must be in structure format with a `fi` object in the `values` field. In array format, the From Workspace block only accepts real, double-precision data.

### **Write Fixed-Point Data to the Workspace**

You can write fixed-point output from a model to the MATLAB workspace via the To Workspace block in either array or structure format. Fixed-point data written by a To Workspace block to the workspace in structure format can be read back into a Simulink model in structure format by a From Workspace block.

## **Scaled Doubles**

Scaled doubles are a hybrid between floating-point and fixed-point numbers. Fixed-Point Designer stores them as doubles with the scaling, sign, and word length information retained. For example, the storage container for a fixed-point data type `sfixed16_En14` is `int16`. The storage container of the equivalent scaled doubles data type, `floats16_En14` is floating-point double. Fixed-Point Designer applies the scaling information to the stored floating-point double to obtain the real-world value. Storing the value in a double almost always eliminates overflow and precision issues.

`fi` | `fimath` | `fixdt` | `Simulink.NumericType`

## Share Fixed-Point Models

You can edit a model containing fixed-point blocks without having Fixed-Point Designer. However, you must have Fixed-Point Designer to:

- Update a Simulink diagram (**Ctrl+D**) containing fixed-point data types
- Run a model containing fixed-point data types
- Generate code from a model containing fixed-point data types
- Log the minimum and maximum values produced by a simulation
- Automatically scale the output of a model

If you do not have Fixed-Point Designer, you can work with a model containing Simulink blocks with fixed-point settings as follows:

- 1 `set_param(gcs, 'DataTypeOverride', 'Double', ...  
'DataTypeOverrideAppliesTo', 'AllNumericTypes', ...  
'MinMaxOverflowLogging', 'ForceOff')`
- 2 If you use `fi` objects or embedded numeric data types in your model, set the `fipref` `DataTypeOverride` property to `TrueDoubles` or `TrueSingles` (to be consistent with the model-wide data type override setting) and the `DataTypeOverrideAppliesTo` property to `All numeric types`.

For example, at the MATLAB command line, enter:

```
p = fipref('DataTypeOverride', 'TrueDoubles', ...  
         'DataTypeOverrideAppliesTo', 'AllNumericTypes');
```

---

**Note** If you use `fi` objects or embedded numeric data types in your model or workspace, you might introduce fixed-point data types into your model. You can set `fipref` to prevent the checkout of a Fixed-Point Designer license.

---

## Control Fixed-Point Instrumentation and Data Type Override

### In this section...

“Control Instrumentation Settings” on page 72-26

“Control Data Type Override” on page 72-26

“Instrumentation Settings and Data Type Override for a Model Reference Hierarchy” on page 72-26

The conversion of a model from floating point to fixed point requires configuring fixed-point instrumentation and data type overrides. However, leaving these settings on after the conversion can lead to unexpected results. If you do not have Fixed-Point Designer, you can work with a model containing Simulink blocks with fixed-point settings by turning off fixed-point instrumentation and setting data type override to scaled doubles.

### Control Instrumentation Settings

The fixed-point instrumentation mode controls which objects log minimum, maximum, and overflow data during simulation. Instrumentation is required to collect simulation ranges using the Fixed-Point Tool. These ranges are used to propose data types for the model. When you are not actively converting your model to fixed point, disable the fixed-point instrumentation to restore the maximum simulation speed to your model.

To enable instrumentation outside of the Fixed-Point Tool, at the command line set the `MinMaxOverflowLogging` parameter to `MinMaxAndOverflow` or `OverflowOnly`.

```
set_param('MyModel', 'MinMaxOverflowLogging', 'MinMaxAndOverflow')
```

Instrumentation requires a Fixed-Point Designer license. To disable instrumentation on a model, set the parameter to `ForceOff` or `UseLocalSettings`.

```
set_param('MyModel', 'MinMaxOverflowLogging', 'UseLocalSettings')
```

### Control Data Type Override

Use data type override to simulate your model using double, single, or scaled double data types. If you do not have Fixed-Point Designer software, you can still configure data type override settings to simulate a model that specifies fixed-point data types. Using this setting, the software temporarily overrides data types with floating-point data types during simulation.

```
set_param('MyModel', 'DataTypeOverride', 'Double')
```

To observe the true behavior of your model, set the data type override parameter to `UseLocalSettings` or `Off`.

```
set_param('MyModel', 'DataTypeOverride', 'Off')
```

### Instrumentation Settings and Data Type Override for a Model Reference Hierarchy

When you simulate a model that contains referenced models, the data type override and fixed-point instrumentation settings for the top-level model do not control the settings for the referenced models.

You must specify these settings separately for the referenced model. If the settings are inconsistent, for example, if you set the top-level model data type override setting to double and the referenced model to use local settings and the referenced model uses fixed-point data types, data type propagation issues might occur.

When you change the fixed-point instrumentation and data type override settings for any instance of a referenced model, the settings change on all instances of the model and on the referenced model itself.

## **See Also**

### **More About**

- “Share Fixed-Point Models” on page 72-25

## Specify Fixed-Point Data Types

Simulink allows you to create models that use fixed-point numbers to represent signals and parameter values. Use of fixed-point data can reduce the memory requirements and increase the speed of code generated from a model.

To execute a model that uses fixed-point numbers, you must have the Fixed-Point Designer product installed on your system. Specifically, you must have the product to:

- Update a Simulink diagram (**Ctrl+D**) containing fixed-point data types
- Run a model containing fixed-point data types
- Generate code from a model containing fixed-point data types
- Log the minimum and maximum values produced by a simulation
- Automatically scale the output of a model using the autoscaling tool

If the Fixed-Point Designer product is not installed on your system, you can execute a fixed-point model as a floating-point model by enabling automatic conversion of fixed-point data to floating-point data during simulation. See “Overriding Fixed-Point Specifications” on page 72-28 for details.

If you do not have the Fixed-Point Designer product installed and do not enable automatic conversion of fixed-point to floating-point data, an error occurs if you try to execute a fixed-point model.

---

**Note** You do not need the Fixed-Point Designer product to edit a model containing fixed-point blocks, or to use the Data Type Assistant to specify fixed-point data types, as described in “Specifying a Fixed-Point Data Type” on page 72-32.

Fixed-point data types that resolve to a base integer type do not require a Fixed-Point Designer license. For example, a block or signal that specifies a data type of `fixdt(1,8,0)`, which is equivalent to the `int8` built-in type will not check out a Fixed-Point Designer license.

---

## Overriding Fixed-Point Specifications

Most of the functionality in the Fixed-Point Tool is for use with Fixed-Point Designer. However, even if you do not have Fixed-Point Designer, you can configure data type override settings to simulate a model that specifies fixed-point data types. In this mode, Simulink temporarily overrides fixed-point data types with floating-point data types when simulating the model.

---

**Note** If you use `fi` (Fixed-Point Designer) objects or embedded numeric data types in your model or workspace, you might introduce fixed-point data types into your model. You can set `fipref` (Fixed-Point Designer) to prevent the checkout of a Fixed-Point Designer license.

---

To simulate a model without using Fixed-Point Designer, enter the following at the command line.

```
set_param(gcs, 'DataTypeOverride', 'Double', ...  
'DataTypeOverrideAppliesTo', 'AllNumericTypes')
```

If you use `fi` objects or embedded numeric data types in your model, set the `fipref` `DataTypeOverride` property to `TrueDoubles` or `TrueSingles` (to be consistent with the model-

wide data type override setting) and the `DataTypeOverrideAppliesTo` property to All numeric types.

For example, at the MATLAB command line, enter:

```
p = fipref('DataTypeOverride', 'TrueDoubles', ...  
         'DataTypeOverrideAppliesTo', 'AllNumericTypes');
```

For these blocks, data type override is not supported.

- Stateflow Chart blocks that use MATLAB as the action language
- State Transition Table blocks that use MATLAB as the action language
- Truth Table blocks that use MATLAB as the action language
- Test Sequence block
- MATLAB Function block
- MATLAB Discrete-Event System block
- Requirements Table block

- “Data Types Supported by Simulink” on page 72-4

## Specify Data Types Using Data Type Assistant

The **Data Type Assistant** is an interactive graphical tool that simplifies the task of specifying data types for blocks and data objects. The assistant appears on block and object dialog boxes, adjacent to parameters that provide data type control, such as the **Output data type** parameter. For example, it appears on the **Signal Attributes** tab of the Block Parameters dialog box for the Constant block.

You can selectively show or hide the **Data Type Assistant** by clicking the applicable button:

- Click the **Show data type assistant** button  to display the assistant.
- Click the **Hide data type assistant** button  to hide a visible assistant.

Use the **Data Type Assistant** to specify a data type as follows:

- 1 From the **Mode** list, select the category of data type that you want to specify. In general, these options are included.

Mode	Description
Inherit	Inheritance rules for data types
Built in	Built-in data types
Fixed point	Fixed-point data types
Enumerated	Enumerated data types
Bus object	Bus object data types
Image	Simulink image data types (Computer Vision Toolbox)
Value type	Application-specific value types, such as wind velocity
Expression	Expressions that evaluate to data types

The assistant changes dynamically to display different options that correspond to the selected mode. For example, setting **Mode** to **Expression** in the Block Parameters dialog box for a Constant block updates the values in the boxes next to **Output data type** and **Mode**.

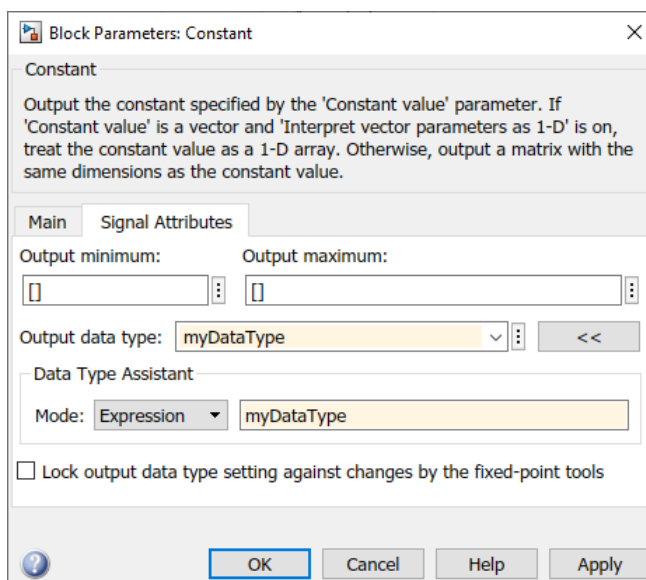

- 2 To the right of the **Mode** list, select or enter a data type.

For example, suppose you designate the variable `myDataType` as an alias for a single data type. You create an instance of the `Simulink.AliasType` class and set its `BaseType` property by entering these commands.

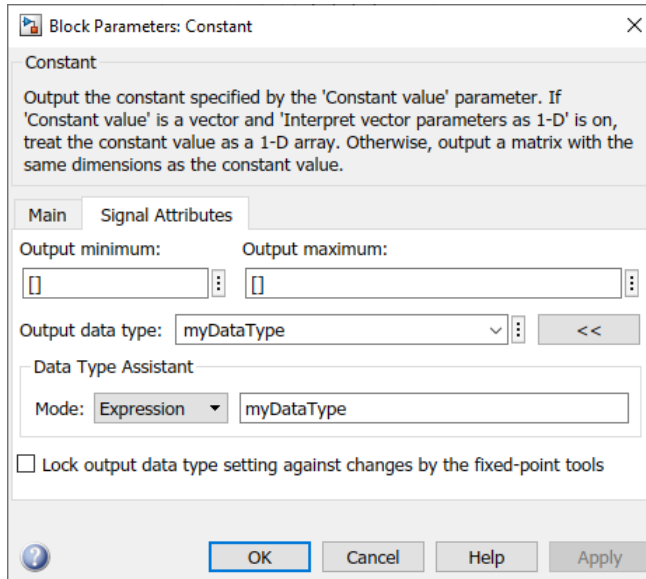

```
myDataType = Simulink.AliasType
myDataType.BaseType = 'single'
```

You can use this data type object to specify the output data type of a Constant block. Enter the data type alias name, `myDataType`, as the value of the expression in the assistant.

- 3 Click **OK** or **Apply** to apply your changes.

The assistant uses the data type that you specified to populate the associated data type parameter in the block or object dialog box. For example, the **Output data type** parameter of the Constant block specifies the same expression that you entered using the assistant.

For more information about the data types that you can specify using the **Data Type Assistant**, see “Entering Valid Data Type Values” on page 72-6. For details about specifying fixed-point data types, see “Specify Fixed-Point Data Types with the Data Type Assistant” (Fixed-Point Designer).

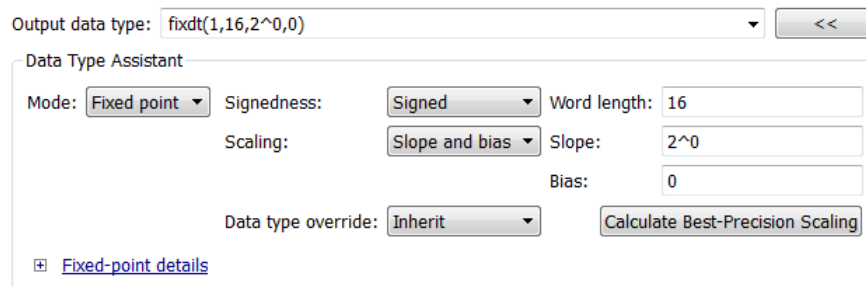

## Specifying a Fixed-Point Data Type

When the Data Type Assistant **Mode** is **Fixed point**, the Data Type Assistant displays fields for specifying information about your fixed-point data type. For example, the next figure shows the Block Parameters dialog box for a Gain block, with the **Signal Attributes** tab selected and a fixed-point data type specified.

If the **Scaling** is Slope and bias rather than Binary point, the Data Type Assistant displays a **Slope** field and a **Bias** field rather than a **Fraction length** field:

You can use the Data Type Assistant to set these fixed-point properties:

### Signedness

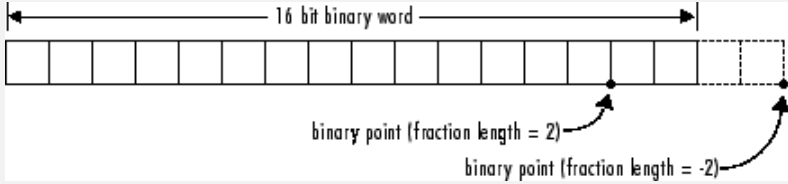

Specify whether you want the fixed-point data to be **Signed** or **Unsigned**. Signed data can represent positive and negative values, but unsigned data represents positive values only. The default setting is **Signed**.

### Word length

Specify the bit size of the word that will hold the quantized integer. Large word sizes represent large values with greater precision than small word sizes. Word length can be any integer between 0 and 128. The default bit size is 16.

## Scaling

Specify the method for scaling your fixed-point data to avoid overflow conditions and minimize quantization errors. The default method is Binary point scaling. You can select one of two scaling modes:

Scaling Mode	Description
Binary point	<p>If you select this mode, the Data Type Assistant displays the <b>Fraction Length</b> field, which specifies the binary point location.</p> <p>Binary points can be positive or negative integers. A positive integer moves the binary point left of the rightmost bit by that amount. For example, an entry of 2 sets the binary point in front of the second bit from the right. A negative integer moves the binary point further right of the rightmost bit by that amount, as in this example:</p>  <p>The default binary point is 0.</p>
Slope and bias	<p>If you select this mode, the Data Type Assistant displays fields for entering the <b>Slope</b> and <b>Bias</b>.</p> <p>Slope can be any positive real number, and the default slope is 1.0. Bias can be any real number, and the default bias is 0.0. You can enter slope and bias as expressions that contain parameters you define in the MATLAB workspace.</p>

**Note** Use binary-point scaling whenever possible to simplify the implementation of fixed-point data in generated code. Operations with fixed-point data using binary-point scaling are performed with simple bit shifts and eliminate expensive code implementations, which are required for separate slope and bias values.

For more information about fixed-point scaling, see “Scaling” (Fixed-Point Designer).

### Data type override

When the **Mode** is **Built in** or **Fixed point**, you can use the **Data type override** option to specify whether you want this data type to inherit or ignore the data type override setting specified for its context, that is, for the block, Simulink.Signal object or Stateflow chart in Simulink that is using the signal. The default behavior is **Inherit**.

Data Type Override Mode	Description
Inherit (default)	Inherits the data type override setting from its context, that is, from the block, Simulink.Signal object or Stateflow chart in Simulink that is using the signal.

Data Type Override Mode	Description
Off	Ignores the data type override setting of its context and uses the fixed-point data type specified for the signal.

The ability to turn off data type override for an individual data type provides greater control over the data types in your model when you apply data type override. For example, you can use this option to ensure that data types meet the requirements of downstream blocks regardless of the data type override setting.

### Calculate Best-Precision Scaling

Click this button to calculate best-precision values for both **Binary point** and **Slope and bias** scaling, based on the specified minimum and maximum values. Simulink displays the scaling values in the **Fraction Length** field or the **Slope** and **Bias** fields. For more information, see “Constant Scaling for Best Precision” (Fixed-Point Designer).

### Showing Fixed-Point Details

When you specify a fixed-point data type, you can use the **Fixed-point details** subpane to see information about the fixed-point data type that is currently displayed in the Data Type Assistant. To see the subpane, click the expander next to **Fixed-point details** in the Data Type Assistant. The **Fixed-point details** subpane appears at the bottom of the Data Type Assistant:

Output minimum:  Output maximum:

Output data type:  <<

Data Type Assistant

Mode:  Signedness:  Word length:

Scaling:  Slope:

Bias:

Data type override:

[Fixed-point details](#)

Representable maximum: 32767

Output maximum:

Constant value: 90

Output minimum:

Representable minimum: -32768

Precision: 1

The rows labeled **Output minimum** and **Output maximum** show the same values that appear in the corresponding **Output minimum** and **Output maximum** fields above the Data Type Assistant. The names of these fields may differ from those shown. For example, a fixed-point block parameter would show **Parameter minimum** and **Parameter maximum**, and the corresponding **Fixed-point details** rows would be labeled accordingly. See “Specify Signal Ranges” on page 80-36 and “Specify Minimum and Maximum Values for Block Parameters” on page 40-52 for more information.

The rows labeled `Representable minimum`, `Representable maximum`, and `Precision` always appear. These rows show the minimum value, maximum value, and precision that can be represented by the fixed-point data type currently displayed in the Data Type Assistant.

The values displayed by the **Fixed-point details** subpane *do not* automatically update if you click **Calculate Best-Precision Scaling**, or change the range limits, the values that define the fixed-point data type, or anything elsewhere in the model. To update the values shown in the **Fixed-point details** subpane, click **Refresh Details**. The Data Type Assistant then updates or recalculates all values and displays the results.

Clicking **Refresh Details** does not change anything in the model, it only changes the display. Click **OK** or **Apply** to put the displayed values into effect. If the value of a field cannot be known without first compiling the model, the **Fixed-point details** subpane shows the value as `Unknown`.

If any errors occur when you click **Refresh Details**, the **Fixed-point details** subpane shows an error flag on the left of the applicable row, and a description of the error on the right. For example, the next figure shows two errors:

The screenshot shows the Data Type Assistant interface. At the top, there are fields for "Output minimum:" (containing "MySymbol") and "Output maximum:" (containing "50000"). Below these is a dropdown for "Output data type:" set to "fixdt(1,16,0)". The main area is titled "Data Type Assistant" and contains several settings: "Mode:" set to "Fixed point", "Signedness:" set to "Signed", "Word length:" set to "16", "Scaling:" set to "Binary point", and "Fraction length:" set to "0". There is a "Data type override:" dropdown set to "Inherit" and a "Calculate Best-Precision Scaling" button. Below these settings is a table with the following rows:

Fixed-point details		
Representable maximum:	32767	
⚠ Output maximum:	50000	Outside representable range by 17233 (17233 x precision)
⚠ Output minimum:	MySymbol	Cannot evaluate
Representable minimum:	-32768	
Precision:	1	

At the bottom right of the table area is a "Refresh Details" button.

The row labeled `Output minimum` shows the error `Cannot evaluate` because evaluating the expression `MySymbol`, specified in the **Output minimum** field, did not return an appropriate numeric value. When an expression does not evaluate successfully, the **Fixed-point details** subpane displays the unevaluated expression (truncating to 10 characters if necessary to save space) in place of the unavailable value.

To correct the error in this case, you would need to define `MySymbol` in an accessible workspace to provide an appropriate numeric value. After you clicked **Refresh Details**, the value of `MySymbol` would appear in place of its unevaluated text, and the error indicator and error description would disappear.

To correct the error shown for `Output maximum`, you would need to decrease **Output maximum**, increase **Word length**, or decrease **Fraction length** (or some combination of these changes) sufficiently to allow the fixed-point data type to represent the maximum value that it could have.

Other values relevant to a particular block can also appear in the **Fixed-point details** subpane. For example, on a Discrete-Time Integrator block **Signal Attributes** tab, the subpane can look like this:

<input type="checkbox"/> <a href="#">Fixed-point details</a>	
Representable maximum:	32767
Output maximum:	<input type="text" value="[]"/>
Upper saturation limit:	inf
Initial condition:	1 .. 4
Lower saturation limit:	-inf
Output minimum:	<input type="text" value="[]"/>
Representable minimum:	-32768
Precision:	1

The values displayed for **Upper saturation limit** and **Lower saturation limit** are greyed out. This appearance indicates that the corresponding parameters are not currently used by the block. The greyed-out values can be ignored.

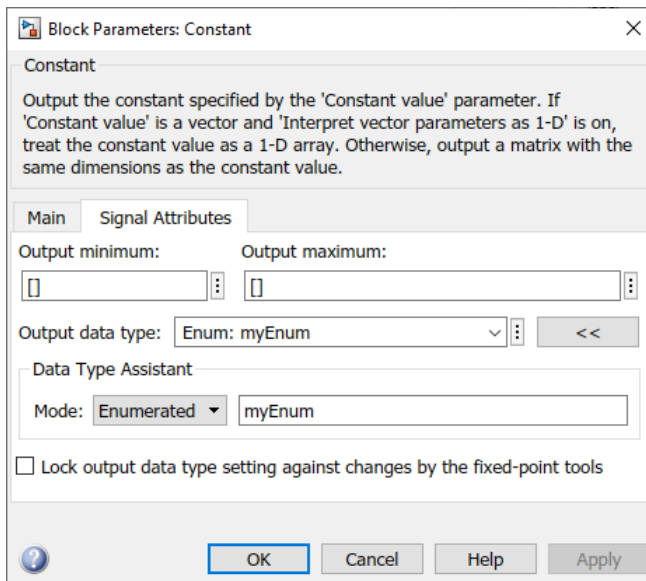

To conserve space, **Initial condition** displays the smallest value and the largest value in the vector or matrix, using ellipsis to represent the other values. The underlying definition of the vector or matrix is unaffected.

### Lock output data type setting against changes by the fixed-point tools

Select this check box to prevent replacement of the current data type with a type that the Fixed-Point Tool or Fixed-Point Advisor chooses. For instructions on autoscaling fixed-point data, see “Scaling” (Fixed-Point Designer).

## Specify an Enumerated Data Type

You can use the **Data Type Assistant** to specify an enumerated object as a data type for a block. In the **Data Type Assistant**, set **Mode** to Enumerated and specify an enumerated object.

For details about enumerated data types, see “Data Types”.

## Specify a Bus Object Data Type

You can use the **Data Type Assistant** to specify a `Simulink.Bus` object as a data type for a block or data object.

- For information on blocks that support Bus object data types, see “Data Types for Buses” on page 72-42. You can use the Block Parameters dialog box to access the Data Type Assistant.
- For `Simulink.Signal` and `Simulink.Parameter` objects, use the **Model Explorer** to access the Data Type Assistant.
- For `Simulink.BusElement` objects, use the **Type Editor** to access the Data Type Assistant.

In the **Data Type Assistant**, set **Mode** to `Bus` object and specify a Bus object.

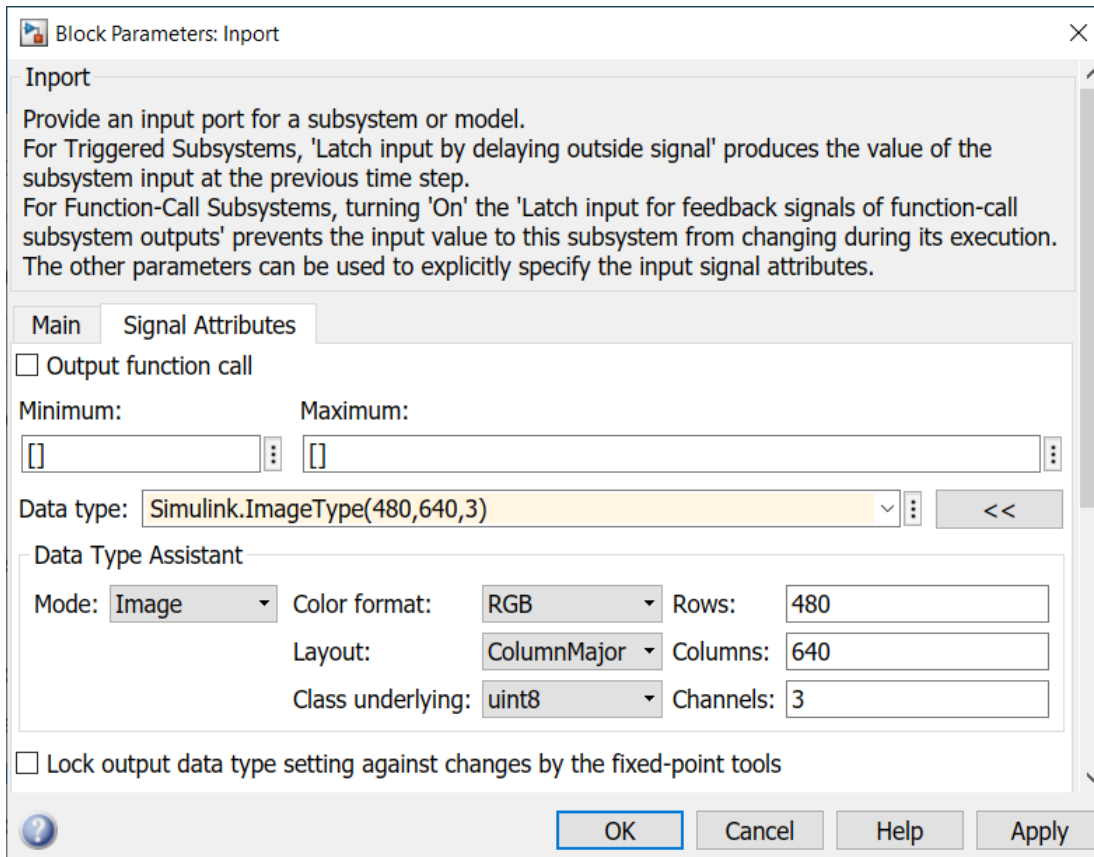

For more information on specifying a Bus object data type, see “Specify Bus Properties with `Simulink.Bus` Object Data Types” on page 81-58.

## Specify an Image Data Type

If you have Computer Vision Toolbox, you can use the **Data Type Assistant** to specify a `Simulink.ImageType` object as a data type for a block or data object.

In the **Data Type Assistant**, set **Mode** to `Image` and specify a `Simulink.ImageType` object.

You can use the Data Type Assistant to set these image properties:

### Color format

Specify the color format of the underlying image data as one of these formats:

- RGB
- BGR
- BGRA
- Grayscale

The color format determines what each color channel of a pixel in the image represents. The default setting is RGB.

### Layout

Specify the memory arrangement of the matrix data in the image as `ColumnMajor` or `RowMajor`. The default setting is `ColumnMajor`.

### Class underlying

Specify the data type of the underlying image data as one of these types:

- `uint8`

- `uint16`
- `uint32`
- `int8`
- `int16`
- `int32`
- `single`
- `double`

The default setting is `uint8`.

### Rows

Specify the number of rows in the image data as a positive integer. The default setting is **480**.

### Columns

Specify the number of columns in the image data as a positive integer. The default setting is **640**.

### Channels

Specify the number of color channels or samples for each pixel in the array as one of these numbers:

- 1
- 3
- 4

The number of channels must correspond to the number of color channels in the color format of the image data. These values are the values of `Channels` for the supported color formats.

Color Format	Channels
Grayscale	1
RGB	3
BGR	3
BGRA	4

The default setting is 3.

## Specify a Value Type

You can use the **Data Type Assistant** to specify a `Simulink.ValueType` object as a data type for a block or `Simulink.BusElement` object.

- For information on blocks that support `ValueType` object data types, see `Simulink.ValueType`. You can use the Block Parameters dialog box to access the Data Type Assistant.
- For `Simulink.BusElement` objects, use the **Type Editor** to access the Data Type Assistant.

In the **Data Type Assistant**, set **Mode** to `Value` type and specify a `ValueType` object.

For more information on specifying value types, see “Specify Application-Specific Signal Properties” on page 80-50.

## Data Types for Buses

A `Simulink.Bus` object specifies the architectural properties of a bus, as distinct from the values of the signals or messages it contains. For example, a `Bus` object can specify the number of elements in a bus, the order of those elements, whether and how elements are nested, and the data types of constituent elements; but not the values.

You can specify a `Bus` object as a data type for the following blocks:

- Bus Creator
- Constant
- Data Store Memory
- In Bus Element
- Inport
- Out Bus Element
- Outport
- Signal Specification

You can specify a `Bus` object as a data type for the following objects:

- `Simulink.BusElement`
- `Simulink.Parameter`
- `Simulink.Signal`

See “Specify a Bus Object Data Type” on page 72-38 for information about how to specify a `Bus` object as a data type for blocks and objects.

## Simulink Strings

Use strings in multiple applications when you want to pass and manipulate text. For example, when modeling a fuel control system, instead of using enumerated data to model the fuel levels, you can use strings like "LOW" or "EMPTY". Simulink strings are compatible with MATLAB strings.

Simulink strings are a built-in signal data type. They appear in the Simulink Editor as "strN" (for example, string with maximum length of  $N$  characters) or "string" for strings without maximum length (dynamic strings). String lengths can range from 1 to 32,766 characters.

Simulink string signals are inherently discrete. If your string signal has a continuous sample time, the model generates an error at compilation time.

Simulink treats string variables and expressions, such as "a" + "b", the same way it treats numeric variables. The value of a string variable can be both a character vector and a MATLAB string. String variables can exist in base, model, and mask workspaces.

String literals are specified with double quotes ("Hello") or single quotes ('Hello'). To be consistent with MATLAB strings, use double quotes. Strings appear on ports and in the Display block with double quotes.

Simulink strings support 256 characters of the ISO/IEC 8859-1 character set. These characters are the first 256 code points of Unicode. Simulink does not support the first character char(0) ("NULL") and returns an error if the string contains this character.

When a character cannot be displayed, the block stores the actual information and outputs an escape character with the associated octal value for the character. For example, the decimal value control character for BREAK PERMITTED HERE is 130. The block displays this control character as the escaped octal \02. The ASCII to String block returns as escaped octals characters in the Unicode set range 0000 to 001F and 007F-009F.

This topic describes how to use strings in Simulink, including:

- A list of available string blocks and blocks particular to string conversions
- Passing string constants into other string blocks
- Null characters in strings
- Strings with no maximum length
- Interactions with Stateflow
- Generated code
- Limitations

This topic also includes simple examples illustrating how to use string blocks. Examples in this topic enable the display of block names. To control the display of block names, on the **Format** tab, select **Auto > Hide Automatic Block Names**. For example, you can use string blocks to display and extract coordinate data and find patterns in strings.

To work with strings in your model, use this table:

Action	Block
Convert a uint8 vector to a string signal.	ASCII to String

Action	Block
Compose an output string signal based on the <b>Format</b> parameter and input signals.	Compose String
Scan an input string and convert it to signals per the format specified by <b>Format</b> parameter.	Scan String
Compare two input strings.	String Compare
Concatenate input strings to form one output string.	String Concatenate
Output the string specified by the <b>String</b> parameter.	String Constant
Return the index of the first occurrence of the pattern string <b>sub</b> in the text string <b>str</b> .	String Find
Output the number of characters in the input string.	String Length
Convert a string signal to a uint8 vector.	String to ASCII
Convert string signal to double signal.	String to Double
Convert string signal to single signal.	String to Single
Convert an input string to an enumerated signal.	String to Enum
Extract a substring from a string signal.	Substring
Convert the input signal to a string signal.	To String

These Simulink blocks support strings.

Block	Notes
Bus Assignment	Nonvirtual and virtual.
Bus Creator	Nonvirtual and virtual.
Bus Selector	Nonvirtual and virtual.
Data Store Memory	—
Data Store Read	—
Data Store Write	—
Data Type Duplicate	—
Display	Display strings with double quotes.
From	—

Variant Model	—
Variant Subsystem	—
Width	—

## String Constants

To specify string constants, use the String Constant block. Do not use the Constant block, which does not accept strings. In the String Constant block, enter the string with double quotes, such as "Hello!" in the **String** parameter. It is the same as adding a numeric constant in the **Constant value** parameter of the Constant block.

## Simulink Strings and Null Characters

Simulink strings automatically deal with string termination. Do not use a null terminator at the end of a string. If Simulink detects a null character anywhere in a string, it generates an error. Simulink handles strings during simulation and code generation as follows:

- During simulation, the model simulates. You do not need to do anything else.
- During C code generation, the software adds a null terminator to the end of the string. For example, if the string buffer size is 10 and the real string value is "AB", the third character in the generated code is a null terminator.

## String Data Type

As necessary, string blocks create and use string data types, for example, when a block outputs a string type. You can create strings without specifying a maximum length of characters. We refer to strings without a maximum length of characters as dynamic strings.

To create string data types for blocks that support strings, you can:

- Use the **Output data type** or **Data type** parameter on the **Signal Attributes** tab of a Simulink block.
  - To create a string data type with no maximum length of characters, specify `string`. This action creates a dynamic string.
  - To create a string data type with maximum length of characters, such as 100, enter `stringtype(100)`. You can also use the `stringtype` function on the MATLAB command line to create a string data type.
- Use the `set_param` function with the `OutDataTypeStr` parameter, for example:

```
set_param(gcf, 'OutDataTypeStr', 'stringtype(100)')
```

This function creates a string data type object with a maximum length of 100 characters. String type lengths can range from 1 to 32,766 characters, inclusive.

For example, using the String Constant block to create a string with the **Output data type** parameter set to `stringtype(31)` creates a string data type of `str31`. 31 is the maximum number of characters the string can have.

## Strings in Bus Objects

To configure an element of a `Simulink.Bus` object to accept strings using the Type Editor, for the **Data Type** parameter of the `Simulink.BusElement` object, enter a string type. For example, to specify a string data type whose maximum length of characters is 10, enter `stringtype(10)`. The **Mode** parameter updates accordingly. To specify a dynamic signal with a variable length, enter `string`. You can create mixed use numeric and string objects for bus elements. For more information on creating Bus and BusElement objects with the Type Editor, see **Type Editor**.

## Strings and Generated Code

Consider these notes for strings and generated C and C++ code.

### Differences Between Simulation and Generated C Code for the Dynamic String Data Type

Simulation of blocks that use a dynamic string data type differ from generated C code in these ways:

- Signals with `string` data type have dynamic sizes during simulation. In other words, the size of a string can vary between 0 and 32766. However, in generated C code, the coder stores strings as fixed-size `char_T` arrays. Therefore, the size of a string is limited by a fixed buffer size in generated C code. The software truncates extra characters and inserts a null terminator at the end (for example, at the output of a String Concatenate block).
- The coder generates string invariants (parameters or signals) as C-style double-quoted strings.

- The default buffer size for a signal with string data type is 256 bytes (contains at most 255 8-bit ASCII characters). To change this buffer size, use the Buffer size of dynamically-sized string (bytes) (Simulink Coder) configuration parameter.
- To override a model-wide setting for an individual string signal, use `stringtype(N)` as the signal data type. Signals with this data type are allocated a buffer of  $N+1$  bytes in generated C code ( $N$  characters plus one null terminator).
- There is no difference between simulation and generated C++ code when strings are stored as `std::string` objects that have the same dynamic behavior as simulation.

### C++ Code Generation String Library

For C++ code generation, `std::string` library is available for an ERT-based target with an Embedded Coder license. For more information, see “Generate Code for String Blocks by Using the Standard C++ String Library” (Embedded Coder).

## String Data Type Conversions

You cannot use the Data Type Conversion block to convert string data types to other data types and conversely. Instead, use these string conversion blocks.

To Convert	Block
String signal to uint8 vector signal while preserving ASCII characters	String to ASCII
Uint8 vector signal to string signal	ASCII to String
String signal to numerical signal double data type	String to Double
String signal to numerical signal single data type	String to Single
String signal to enumerated signal data type	String to Enum
Input signal to string signal	To String

### Convert String to ASCII and Back to String

- 1 Add these blocks to a model:
  - String Constant
  - String to ASCII
  - ASCII to String
  - Two Display blocks
- 2 Connect the blocks as shown.

- 3 In the String Constant block, enter a string, such as "Hello!".
- 4 In the String to ASCII block, change the maximum string size to 10.
- 5 Simulate the model and observe the contents of the Display blocks.
  - Display1 shows Hello! converted to its ASCII equivalent. For example, 72 is the ASCII equivalent of H and 33 is the ASCII equivalent of !.
  - Display1 has filled the remaining space to the maximum string length of 10 with zeros (null characters).
  - Display shows Hello! after the ASCII to String block reconverts the ASCII code to a string.

### Convert String to Enumerated Data Type

- 1 Add these blocks to a model:
  - String Constant
  - String to Enum
  - Display
- 2 Connect the blocks as shown.

- 3 In the String Constant block, enter a string, such as "Hello!"
- 4 Create a Simulink enumeration class named BasicStrings and store it in the current folder with the file name BasicStrings.m, for example:

```

classdef BasicStrings < Simulink.IntEnumType
    enumeration
  
```

```

Hello(0)
Red(1)
Blue(2)
end
end

```

- 5 In the String to Enum block, enter the enumeration class as Enum: `BasicStrings`.
- 6 Simulate the model and observe the contents of the Display block.

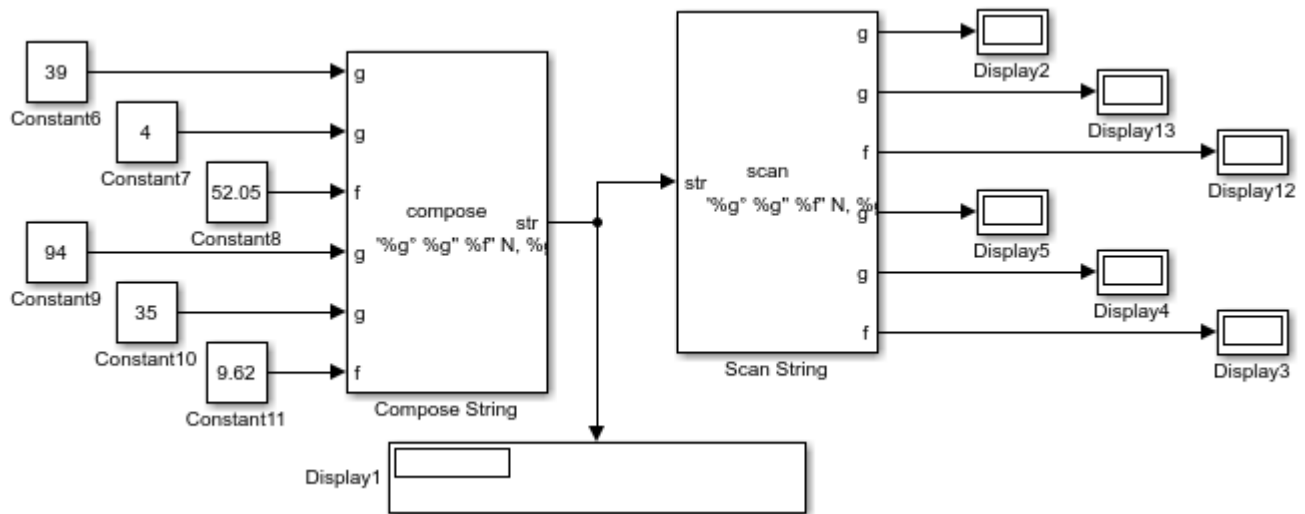

## Display and Extract Coordinate Data

This example shows how you can format and output a set of data as geographic coordinates using the Compose String and Scan String blocks. Based on the C `scanf` and `printf` functions, the Compose String and Scan String blocks are similar in concept to the `sprintf` and `sscanf` functions, with the primary exception being that those functions work with arrays, which the blocks do not. For more information on string block formatted characters, see Compose String and Scan String.

The Compose String block constructs a string from multiple string and numerical inputs combined. Use the **Format** parameter to format the output of each input, one format operator for each input. Each format operator starts with a percent sign, `%`, followed by the conversion character, for example, `%f` generates fixed point output. To supplement the string output, you can also add extra characters to the format specification to appear in the output.

- 1 Add these blocks to a model:
  - Six Constant
  - One Compose String
  - One Scan String
  - Seven Display
- 2 Change the Constant block constant values to those shown and connect the blocks.

3 In the **Format** parameter for the Compose String blocks, enter these format specifications:

```
'%g° %g' ' %f" N, %f" W'
```

- The %g and %f formatting operators convert numeric inputs to floating point values. %g is a more compact version of %f.
- The degree symbol (°), N, W, and ' are supplemental strings to display in the output string.

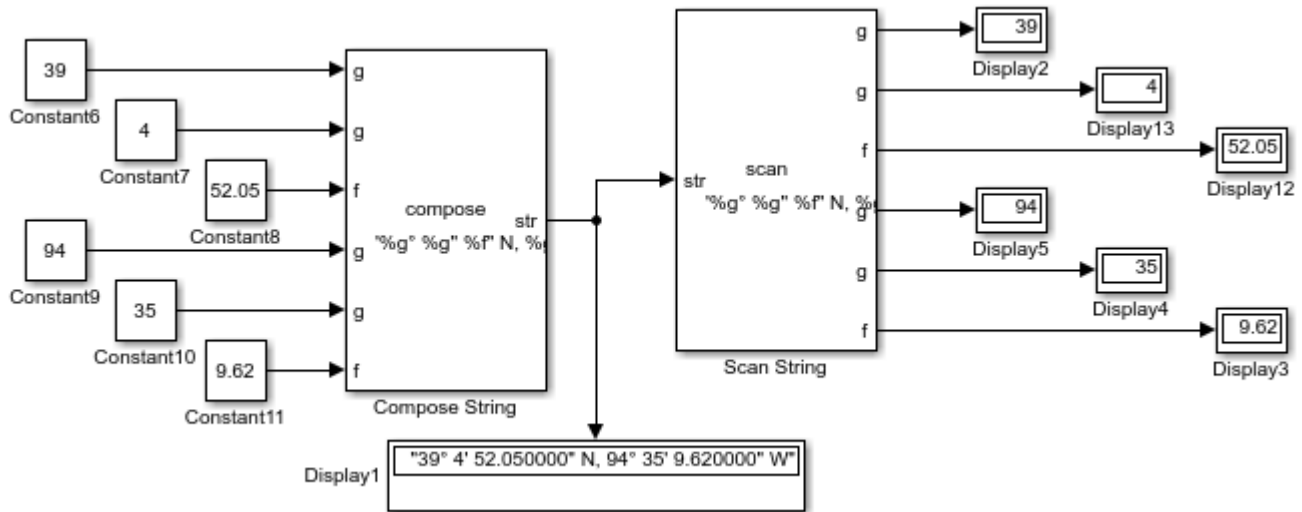

The Compose String block combines the output in the input order, formats each input according to its format operator, adds the extra strings, and outputs the string, formatted as directed and surrounded by double quotes (").

4 In the **Format** parameter for the Scan String block, enter these format specifications:

```
'%g° %g' ' %f" N, %f" W'
```

- The %g and %f formatting operators convert numeric inputs to floating point values. %g is a more compact version of %f.
- The degree symbol (°), N, W, and ' are supplemental strings to display in the output string.

The Scan String block reads its input, converts it according to the format specified by a conversion specification, and returns the results as scalars. The block formats each output according to its conversion specification. It ignores specified text immediately before or after a conversion specifier.

## Find Patterns in Strings

To find a pattern in a string, use the String Find block.

- 1 Add these blocks to a model:
  - Two String Constant
  - String Find
  - One Display
- 2 Connect the blocks as shown.

- 3 In the first String Constant block, enter a string, such as "Hello!Goodbye!".

Connecting this block to the **str** input port of the String Find block causes the String Find block to look for the pattern in this string.

- 4 In the second String Constant block, enter a string (or pattern) to look for in the first String Constant string, such as "Goodbye!".

Connecting this block to the **sub** input port of the block means that the String Find looks for this pattern from the **str** input.

- 5 Simulate the model and observe the contents of the Display block. For this example, the block displays 7, which is the location of the letter G.

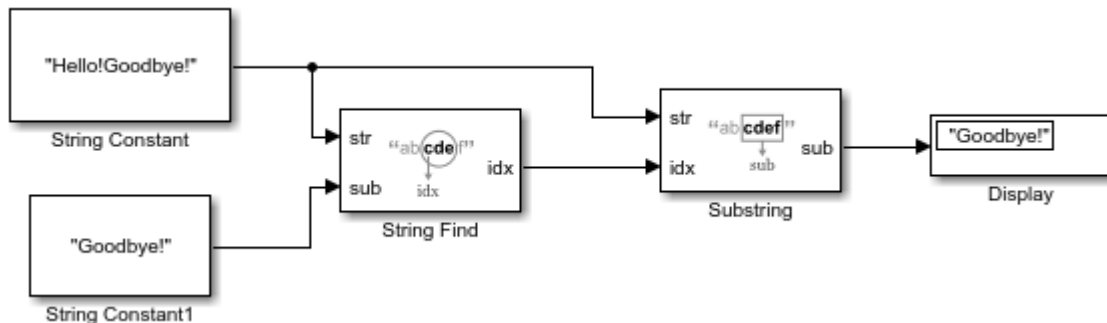

## Extract a String

To extract a string from a source string, use the Substring block. This example uses the model described in "Find Patterns in Strings" on page 72-51.

- 1 Add a Substring block to the model.
- 2 In the Substring block, select the **Output string from 'idx' to end** parameter. Setting this parameter extracts the string from the location input at the idx port to the end of the string.
- 3 Connect the new block as shown.

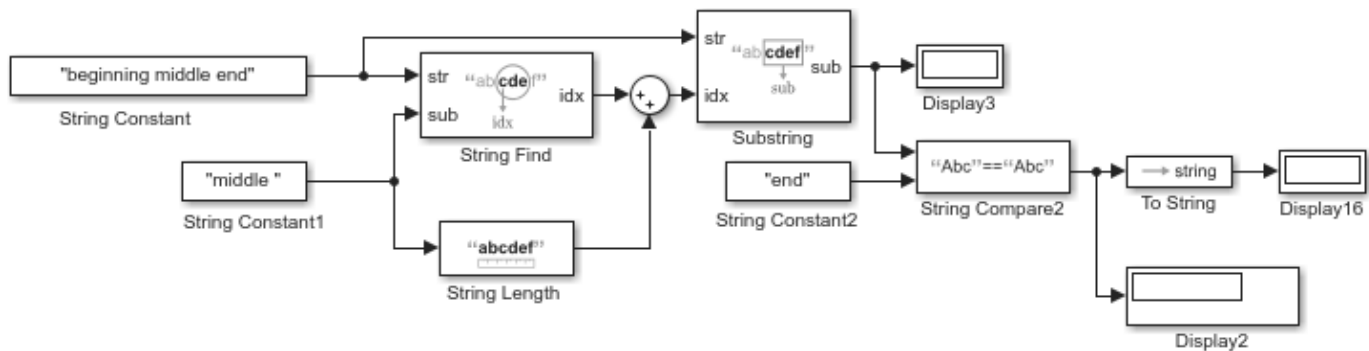

- 4 Simulate the model and observe the contents of the Display block. For this example, the block displays "Goodbye!", which is the substring extracted starting **idx** to the end of the string.

## Get Text Following a Keyword

This example shows basic string manipulation using the Simulink string blocks.

For a model that looks like the following, simulate it.

Observe that the model:

- Creates two strings, "beginning middle end" and "middle", using String Constant blocks.
- Looks for the first occurrence of "middle" (**idx**) and adds the location of the first letter (11) to the length of "middle" (7). It uses the String Find and String Length blocks.
- Extracts from "beginning middle end" the substring that starts from the end of "middle" ( $\text{idx} + \text{string length} = 18$ ), which is the string "end". It uses the Substring block.
- Compares the calculated value of "end" with the actual string "end", which returns the Boolean value "1". It uses the String Constant and String Compare blocks.
- Converts the Boolean value "1" to its string equivalent, "true". It uses the To String block.

To see the locations of the characters throughout the model, add one Display block each to the output of the String Find and String Length blocks and simulate it.

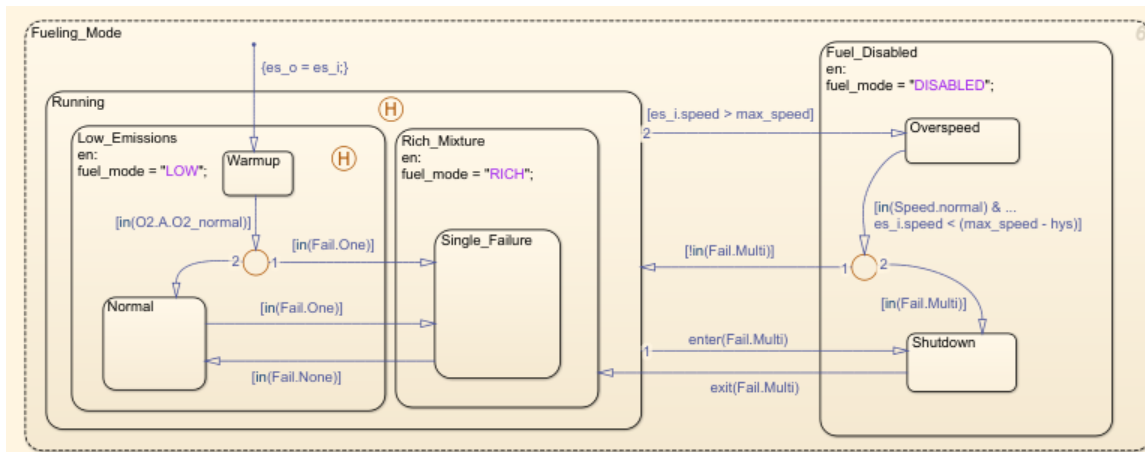

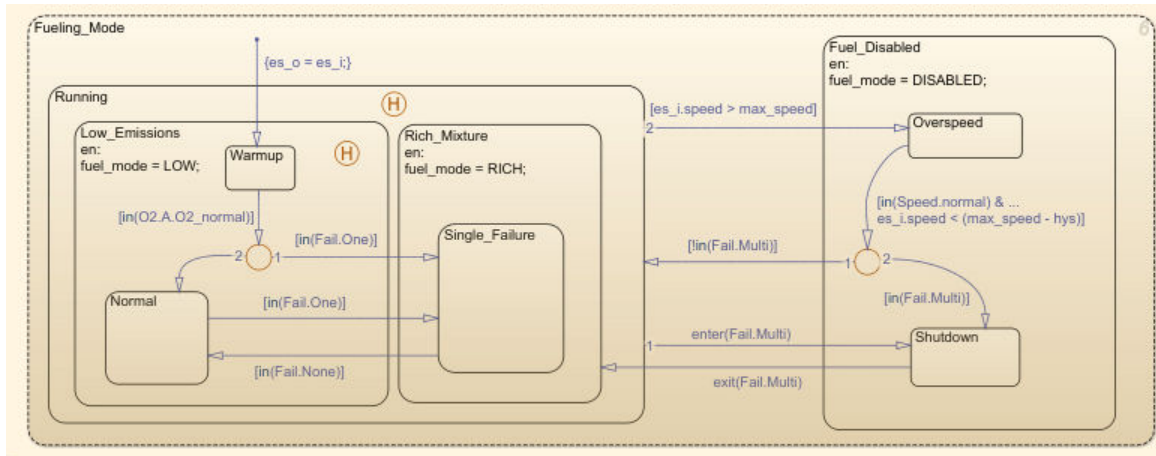

## Change Existing Models to Use Strings

In addition to using strings in new models, you can update existing models to use strings. Using strings can simplify the model and make it easier to understand.

For example, in older models, you may have used enumerated data types to represent or pass text in your model. The “Model a Fault-Tolerant Fuel Control System” example model `sldemo_fuelsys` enumerates constants in multiple areas to work with textual data.

In `sldemo_fuelsys/fuel_rate_control/control_logic`, the Stateflow chart uses enumerated data to indicate fuel levels.

In `sldemo_fuelsys/fuel_rate_control/airflow_calc`, to detect if the fuel is low, the model uses Enumerated Constant and Relational Operator blocks.

Instead, you can use the String Constant and String Compare blocks by setting:

- The String Constant **String** parameter to `LOW`.
- Using the String Compare block to detect if `LOW` is coming from another part of the model.

Instead of removing all instances of enumerated constants, you can use strings in conjunction with enumerated constants. Doing so allows you to incrementally migrate your model to use strings. In `sldemo_fuelsys/fuel_rate_control/fuel_calc/feedforward_fuel_rate`, the Multiport Switch block accepts four enumerated data inputs.

If the **fuel\_mode** port is outputting a string, you can convert that string to an enumerated data type to work with the output from the Constant blocks in this model.

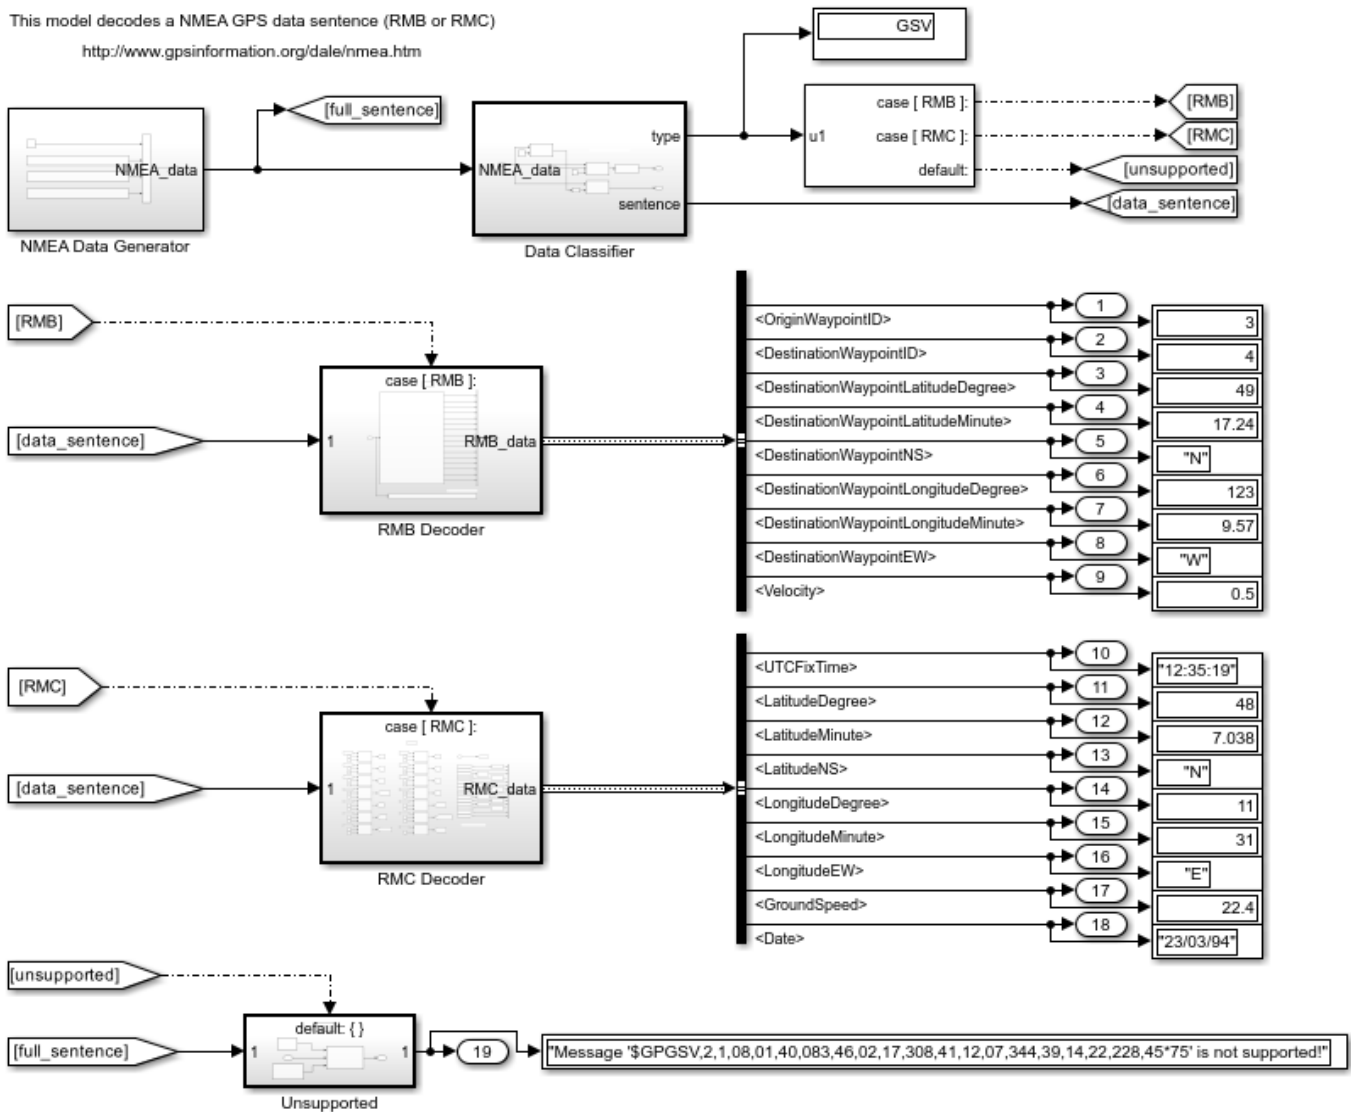

## Parse NMEA GPS Text Message

This example shows how to parse text messages in NMEA GPS format using Simulink® string blocks.

### Overview

This model shows how to use string data type and blocks provided by Simulink® to read input text messages and extract numeric and text data.

This model decodes a NMEA GPS data sentence (RMB or RMC)  
<http://www.gpsinformation.org/dale/nmea.htm>

Copyright 2018 The MathWorks, Inc.

### Read message header and convert to enumeration

Simulink® provides the String To Enum block to convert a string to the corresponding enumeration value. In this model, header string "RMB" is converted to NMEASentence.RMB.

### Parse text message using Scan String block

One way to parse a text message is to use the Scan String block. It works like sscanf function in C and MATLAB®.

Definition of NMEA GPRMB data sentence can be found at:  
<http://www.gpsinformation.org/dale/nmea.htm#RMB>

case [ RMB ];  
 Action Port

Scan String block is as powerful as sscanf function in C or MATLAB  
 It provides a flexible approach to parse input string message

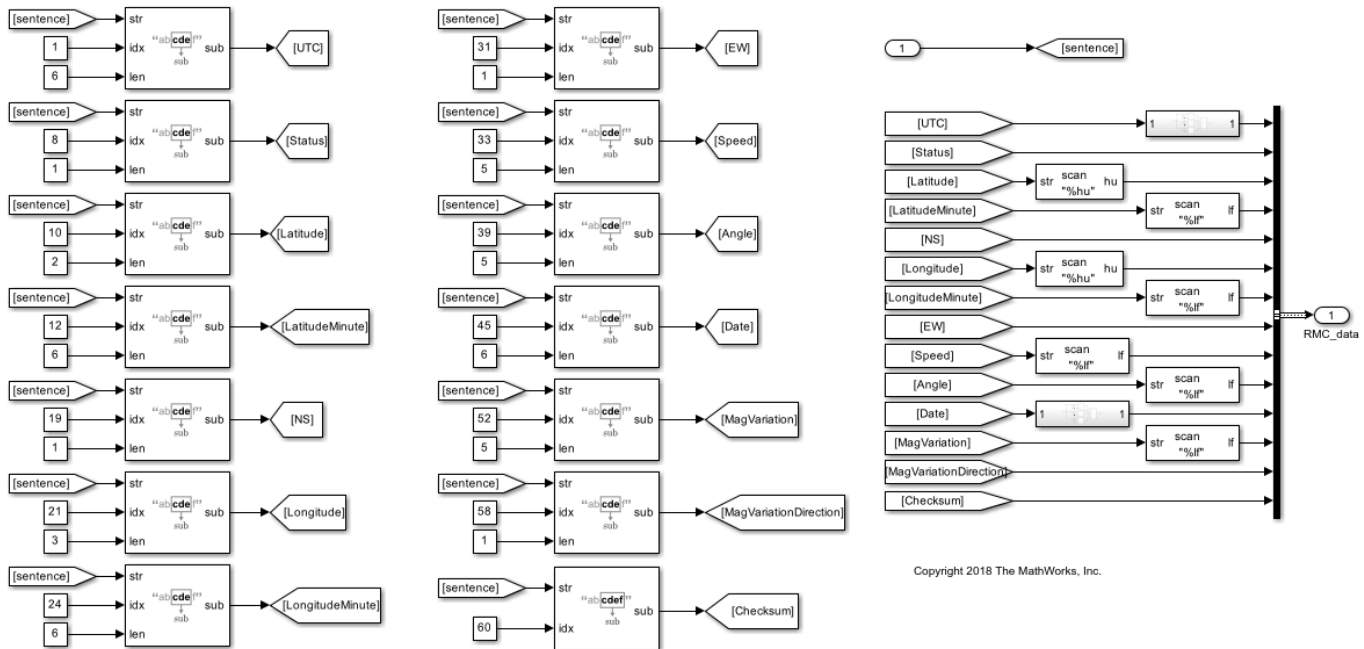

**Parse text message with fixed field width**

When a text message has fixed width for each data field, Simulink® provides blocks to split the string by index. After the strings have been split, each field can be handled separately.

Definition of NMEA GPRMC sentence can be found at:  
<http://www.gpsinformation.org/dale/nmea.htm#RMC>

case [ RMC ]  
 Action Port

String messages that have fields with fixed width can be split by the width and each fields can be handled separately.

Copyright 2018 The MathWorks, Inc.

## Simulink String Limitations

These capabilities are currently not supported:

Category	Limitation Description	Workaround
String array	String arrays are not supported.	Use strings only as scalars.
Unicode characters	Simulink strings do not support the entire Unicode set.	Simulink strings support 256 characters of the ISO/IEC 8859-1 character set (Basic Latin and Latin-1 supplement). These characters are the first 256 code points of Unicode.
MATLAB S-Function	Custom blocks created with this block do not support strings.	—
Constant, Initial Condition	These blocks do not work with strings.	Use String Constant block.
Control input of the Switch, Multiport Switch, Switch Case, and If blocks	The control input of the Switch block does not accept strings.	Use the data inputs of these blocks.
Simulink.Signal, Simulink.Parameter	The Simulink.Signal and Simulink.Parameter objects do not support strings.	—

Category	Limitation Description	Workaround
Data Type Conversion block	Do not use the Data Type Conversion block to convert to or from strings.	Use the string conversion blocks
To File block	Load strings using the To File block.	—
Scope and Spectrum Analyzer blocks, Logic Analyzer app	The Scope and Spectrum Analyzer blocks and the Logic Analyzer app do not display strings.	Use the Display, the Simulation Data Inspector, or the Sequence Viewer in Stateflow.

You can create data objects to specify values, value ranges, data types, tunability, and other characteristics of signals, states, and block parameters. You use the object names in Simulink dialog boxes to specify signal, state, and parameter characteristics. The objects exist in a workspace such as the base workspace, a model workspace, or a Simulink data dictionary. Data objects allow you to make model-wide changes to signal, state, and parameter characteristics by changing only the values of workspace objects.

You create data objects as instances of data classes. Memory structures called data class packages contain the data class definitions. The built-in package `Simulink` defines two data classes, `Simulink.Signal` and `Simulink.Parameter`, that you can use to create data objects. To store lookup table data for sharing between lookup table blocks (such as n-D Lookup Table), you can use the `Simulink.LookupTable` and `Simulink.Breakpoint` classes.

To decide whether to use data objects to configure signals, including Inport and Outport blocks, see “Store Design Attributes of Signals and States” on page 80-5.

You can customize data object properties and methods by defining subclasses of the built-in data classes. For more information about creating a data class package, see “Define Data Classes” on page 72-89.

### Data Class Naming Conventions

Simulink uses dot notation to name data classes:

*package.class*

- *package* is the name of the package that contains the class definition.
- *class* is the name of the class.

This notation allows you to create and reference identically named classes that belong to different packages. In this notation, the name of the package qualifies the name of the class.

Class and package names are case sensitive. For example, you cannot use `MYPACKAGE.MYCLASS` and `mypackage.myclass` interchangeably to refer to the same class.

## Use Data Objects in Simulink Models

To specify simulation and code generation options for signals, block parameters, and states by modifying variables in a workspace or data dictionary, use data objects. Associate the objects with signals, parameters, and states in a model diagram.

### Use Parameter Objects

You can use parameter objects, instead of numeric MATLAB variables, to specify values for block parameters. For example, to create and use a `Simulink.Parameter` object named `myParam` to specify the **Gain** parameter of a Gain block:

- 1 In the model, on the **Modeling** tab, under **Design**, click **Property Inspector**.
- 2 In the model, click the target Gain block. The Property Inspector shows the properties and parameters of the block.
- 3 Set the value of the **Gain** parameter to `myParam`.
- 4 Next to the parameter value, click the action button  and select **Create**.
- 5 In the **Create New Data** dialog box, set **Value** to `Simulink.Parameter(15.23)` and click **Create**.

The `Simulink.Parameter` object, `myParam`, appears in the base workspace. The property dialog box shows that the object stores the parameter value `15.23` in the **Value** property.

- 6 Use the property dialog box to specify other characteristics for the block parameter by adjusting the object properties. For example, to specify the minimum and maximum values the parameter can take, use the **Minimum** and **Maximum** properties.

During simulation, the **Gain** parameter now uses the value `15.23`.

To share lookup table data by using `Simulink.LookupTable` and `Simulink.Breakpoint` objects, see “Package Shared Breakpoint and Table Data for Lookup Tables” on page 40-29.

### Use Signal Objects

You can associate a signal line or block state, such as the state of a Unit Delay block, with a signal object.

#### For Signals

To use a signal object to control the characteristics of a signal in a model, create the object in a workspace by using the same name as the signal.

- 1 In the model, on the **Modeling** tab, click **Model Data Editor**.
- 2 In the Model Data Editor, select the **Signals** tab.
- 3 In the model, select the target signal. The Model Data Editor highlights the row that corresponds to the signal.

- 4 In the Model Data Editor, in the **Name** column, give the signal a name such as mySig.
- 5 Click the button  next to the signal name. Select **Create and Resolve**.
- 6 In the Create New Data dialog box, set **Value** to Simulink.Signal. Use the **Location** drop-down list to select a workspace to store the object (the default value is Base Workspace). Click **Create**.

The Simulink.Signal object mySig appears in the target workspace. Simulink selects the signal property **Signal name must resolve to Simulink signal object**, which forces the signal in the model to use the properties that the signal object stores. To learn how to control the way that signal names resolve to signal objects, see “Symbol Resolution” on page 72-126.

The property dialog box of the new object opens.

- 7 Use the property dialog box to specify the signal characteristics. Click **OK**.

To configure the signal programmatically:

```
% Create the signal object.
mySig = Simulink.Signal;
mySig.DataType = 'boolean';

% Get a handle to the block port that creates the
% target signal.
portHandles = get_param('myModel/myBlock','portHandles');
outputHandle = portHandles.Output;

% Specify the programmatic port parameter 'Name'.
set_param(outputHandle,'Name','mySig')

% Set the port parameter 'MustResolveToSignalObject'.
set_param(outputHandle,'MustResolveToSignalObject','on')
```

To configure a root-level Outport block programmatically, you must use a slightly different technique:

```
% Create the signal object.
mySig = Simulink.Signal;
mySig.DataType = 'boolean';

% Specify the programmatic block parameter 'SignalName'.
set_param('myModel/myOutport','SignalName','mySig')

% Set the block parameter 'MustResolveToSignalObject'.
set_param('myModel/myOutport','MustResolveToSignalObject','on')
```

#### For States

You can use a signal object to control the characteristics of a block state, such as that of the Discrete-Time Integrator block.

- 1 In the model, on the **Modeling** tab, click **Model Data Editor**.
- 2 In the Model Data Editor, select the **States** tab.
- 3 In the model, select the block that harbors the target state. The Model Data Editor highlights the row that corresponds to the state.
- 4 In the Model Data Editor, in the **Name** column, give the state a name such as myState.

- 5 Click the button  next to the state name. Select **Create and Resolve**.
- 6 In the Create New Data dialog box, set **Value** to `Simulink.Signal`. Use the **Location** drop-down list to select a workspace to store the object (the default value is `Base Workspace`). Click **Create**.

The `Simulink.Signal` object `myState` appears in the target workspace. Simulink selects the block parameter **State name must resolve to Simulink signal object**, which forces the state in the model to use the properties that the signal object stores. To learn how to control the way that state names resolve to signal objects, see “Symbol Resolution” on page 72-126.

The property dialog box of the new object opens.

- 7 Use the property dialog box to specify the state characteristics. Click **OK**.

To configure the state programmatically:

```
% Create the signal object.
myState = Simulink.Signal;
myState.DataType = 'int16';

% Set the state name in the block.
set_param('myModel/myBlock', 'StateName', 'myState')

% Set the port parameter 'StateMustResolveToSignalObject'.
set_param('myModel/myBlock', 'StateMustResolveToSignalObject', 'on')
```

## Data Object Properties

To control parameter and signal characteristics using data objects, you specify values for the data object properties. For example, parameter and signal data objects have a `DataType` property that determines the data type of the target block parameter or signal. Data class definitions determine the names, value types, default values, and valid value ranges of data object properties.

You can use either the Model Explorer or MATLAB commands to change a data object's properties.

For a list of signal object properties, see `Simulink.Signal`. For a list of parameter object properties, see `Simulink.Parameter`.

### Use the Model Explorer to Change an Object's Properties

To use the Model Explorer to change an object's properties, select the workspace that contains the object in the Model Explorer's **Model Hierarchy** pane. Then select the object in the Model Explorer's **Contents** pane.

The Model Explorer displays the object's property dialog box in its **Dialog** pane (if the pane is visible).

You can configure the Model Explorer to display some or all of the properties of an object in the **Contents** pane (see **Model Explorer**). To edit a property, click its value in the **Contents** or **Dialog** pane. The value is replaced by a control that allows you to change the value.

### Use MATLAB Commands to Change an Object's Properties

You can also use MATLAB commands to get and set data object properties. Use the following dot notation in MATLAB commands and programs to get and set a data object's properties:

```
value = obj.property;
obj.property = value;
```

where *obj* is a variable that references either the object if it is an instance of a value class or a handle to the object if the object is an instance of a handle class (see “Handle Versus Value Classes” on page 72-73), PROPERTY is the property's name, and VALUE is the property's value. For example, the following MATLAB code creates a data type alias object (i.e., an instance of Simulink.AliasType) and sets its base type to uint8:

```
gain = Simulink.AliasType;
gain.BaseType = 'uint8';
```

You can use dot notation recursively to get and set the properties of objects that are values of other object's properties, e.g.,

```
gain.CoderInfo.StorageClass = 'ExportedGlobal';
```

## Create Data Objects from Built-In Data Class Package Simulink

The built-in package Simulink defines two data object classes Simulink.Parameter and Simulink.Signal. You can create these data objects using the user interface or programmatically.

### Create Data Objects

- 1 In the Model Explorer **Model Hierarchy** pane, select a workspace to contain the data objects. For example, click Base Workspace.
- 2 On the toolbar, click the arrow next to **Add Parameter**  or **Add Signal** . From the drop-down list, select **Simulink Parameter** or **Simulink Signal**.

A parameter or signal object appears in the base workspace. The default name for new parameter objects is Param. The default name for new signal objects is Sig.

- 3 To create more objects, click **Add Parameter** or **Add Signal**.

To create `Simulink.LookupTable` and `Simulink.Breakpoint` objects, on the Model Explorer toolbar, use the  button.

### Programmatically Create Data Objects

```
% Create a Simulink.Parameter object named myParam whose value is 15.23.
myParam = Simulink.Parameter(15.23);
```

```
% Create a Simulink.Signal object named mySig.
mySig = Simulink.Signal;
```

### Convert Numeric Variable into Parameter Object

You can convert a numeric variable into a `Simulink.Parameter` object as follows.

```
/* Define numeric variable in base workspace
myVar = 5;
/* Create data object and assign variable value
myObject = Simulink.Parameter(myVar);
```

## Create Data Objects from Another Data Class Package

You can create your own package to define custom data object classes that subclass `Simulink.Parameter` and `Simulink.Signal`. You can use this technique to add your own properties and methods to data objects. If you have an Embedded Coder license, you can define storage classes and memory sections in the package. For more information about creating a data class package, see “Define Data Classes” on page 72-89.

### Create Data Objects from Another Package

Suppose that you define a data class package called `myPackage`. Before you can create data objects from the package, you must include the folder containing the package folder on your MATLAB path.

- 1 In the Model Explorer **Model Hierarchy** pane, select a workspace to contain the data objects. For example, click `Base Workspace`.
- 2 Click the arrow next to **Add Parameter**  or **Add Signal**  and select **Customize class lists**.
- 3 In the dialog box, select the check box next to the class that you want. For example, select the check boxes next to `myPackage.Parameter` and `myPackage.Signal`. Click **OK**.
- 4 Click the arrow next to **Add Parameter** or **Add Signal**. Select the class for the data object that you want to create. For example, select **myPackage.Parameter** or **myPackage.Signal**.

A parameter or signal object appears in the base workspace. The default name for new parameter objects is `Param`. The default name for new signal objects is `Sig`.

- 5 To create more data objects from the package `myPackage`, click **Add Parameter** or **Add Signal** again.

### Programmatically Create Data Objects from Another Package

Suppose that you define a data class package called `myPackage`. Before you can create data objects from the package, you must include the folder containing the package folder on your MATLAB path.

```
% Create a myPackage.Parameter object named
% myParam whose value is 15.23.
```

```
myParam = myPackage.Parameter(15.23);

% Create a myPackage.Signal object named mySig.
mySig = myPackage.Signal;
```

## Create Data Objects Directly from Dialog Boxes

When you open a Signal Properties dialog box, a block dialog box, or the Property Inspector (on the **Modeling** tab, under **Design**, click **Property Inspector**), you can efficiently create a signal or parameter data object in a workspace or data dictionary.

### Create Parameter Object from Block Dialog Box

- 1 In a numeric block parameter in the dialog box, specify the name that you want for the data object. For example, specify the name `myParam`.
- 2 Click the button  next to the value of the block parameter. Select **Create**.
- 3 In the **Create New Data** dialog box, specify **Value** as `Simulink.Parameter`.

Alternatively, you can specify the name of a data class that you created, such as `myPackage.Parameter`. You can also use the drop-down list to select from a list of available data object classes.

- 4 Specify **Location** as `Base Workspace` and click **Create**.

You can use the **Location** option to select a workspace to contain the new data object. If a model is linked to a data dictionary, you can choose to create a data object in the dictionary.

- 5 In the dialog box that opens, configure the data object properties. Specify a numeric value for the parameter in the **Value** box. Click **OK**.

The parameter object `myParam` appears in the base workspace.

- 6 In the block parameter dialog box, click **OK**.

### Create Signal Object from Signal Properties Dialog Box

- 1 In the **Signal name** box, specify a signal name such as `mySig`. Click **Apply**.
- 2 Click the button  next to the value of **Signal name**. Select **Create and Resolve**.
- 3 In the **Create New Data** dialog box, specify **Value** as `Simulink.Signal`.

Alternatively, you can specify the name of a data class that you created, such as `myPackage.Signal`. Also, from the drop-down list, you can select a data object class that exists on the MATLAB path.

- 4 Specify **Location** as `Base Workspace` and click **Create**.

You can use the **Location** option to select a workspace to contain the new data object. If a model is linked to a data dictionary, you can choose to create a data object in the dictionary.

- 5 In the dialog box that opens, configure the data object properties and click **OK**.

The signal object `mySig` appears in the base workspace. In the Signal Properties dialog box, the **Signal name must resolve to Simulink signal object** property is selected.

## Create Data Objects for a Model Using Data Object Wizard

To create data objects that represent signals, parameters, and states in a model, you can use the Data Object Wizard. The wizard finds data in the model that do not have corresponding data objects.

Based on specifications in the model, the wizard creates the objects and assigns these characteristics:

- Signal, parameter, or state name.
  - Numeric value for parameter objects.
  - Data type. For signal objects, includes alias types such as `Sumlink.AliasType` and `Simulink.NumericType`.
- 1 In the Simulink Editor, on the **Modeling** tab, under **Design**, click **Data Object Wizard**.

- 2 In the **Model name** box, enter the name of the model that you want to search.

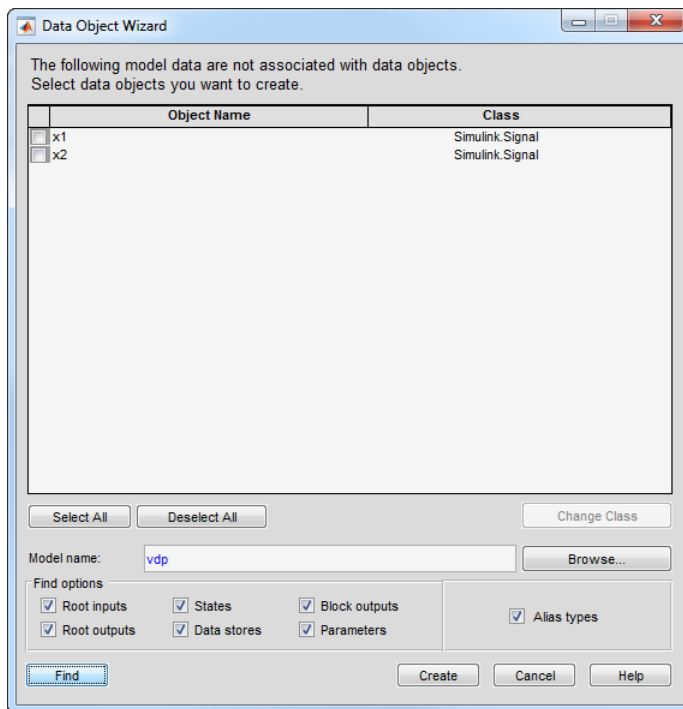

By default, the box contains the name of the model from which you opened the wizard.

- 3 Under **Find options**, select the check boxes next to the data object types that you want to create. The table describes the options.

Option	Description
<b>Root inputs</b>	Named signals from root-level Inport blocks.
<b>Root outputs</b>	Named signals from root-level Outport blocks.
<b>States</b>	States associated with these discrete blocks: Discrete Filter Discrete State-Space Discrete-Time Integrator Discrete Transfer Fcn Discrete Zero-Pole Memory Discrete PID Controller Discrete PID Controller (2DOF) Unit Delay
<b>Data stores</b>	Data stores. For more information about data stores, see “Local and Global Data Stores” on page 78-2.
<b>Block outputs</b>	Named signals whose sources are non-root-level blocks.
<b>Parameters</b>	<ul style="list-style-type: none"> <li>Numeric parameters, for example the parameters in these blocks: Constant Gain Relay</li> <li>Stateflow data with <b>Scope</b> set to Parameter.</li> </ul>
<b>Alias types</b>	Data type replacement names that you specify in <b>Configuration Parameters &gt; Code Generation &gt; Data Type Replacement</b> . If you have an Embedded Coder license, the Data Object Wizard creates Simulink.AliasType objects for these data type replacement names. For more information about data type replacement, see “Model Configuration Parameters: Code Generation Data Type Replacement” (Embedded Coder)

- 4 Click **Find**.

The data object table displays the proposed objects.

- 5 (Optional) To create objects from a data class other than the default classes, select the check box next to the objects whose class you want to change. To select all of the objects, click **Select All**. Click **Change Class**. In the dialog box that opens, select classes by using the drop-down lists next to **Parameter** and **Signal**.

If the classes that you want do not appear in the drop-down list, select **Customize class lists**. In the dialog box that opens, select the check box next to the classes that you want, and click **OK**.

To change the default parameter and signal classes that the wizard uses to propose objects:

- On the Model Explorer **Model Hierarchy** pane, select a workspace. For example, select **Base Workspace**.
- On the toolbar, click the arrow next to **Add Parameter**  or **Add Signal** .
- From the drop-down list, select the class that you want the wizard to use. For example, select **myPackage Parameter** or **myPackage Signal**.

A parameter or signal object appears in the selected workspace. The default name for new parameter objects is **Param**. The default name for new signal objects is **Sig**.

The next time that you use the Data Object Wizard, the wizard proposes objects using the parameter or signal class that you selected in Model Explorer.

- 6 Select the check box next to the proposed objects that you want to create. To select all of the proposed objects, click **Select All**.
- 7 Click **Create**.

The data objects appear in the base workspace. If the target model is linked to a data dictionary, the objects appear in the dictionary.

The wizard changes settings in your model depending on the configuration parameter **Configuration Parameters > Diagnostics > Data Validity > Signal resolution**.

- If you set the parameter to `Explicit only`, the wizard forces the corresponding signals and states in your model to resolve to the new signal objects. The wizard selects the option **Signal name must resolve to Simulink signal object** in each Signal Properties dialog box and **State name must resolve to Simulink signal object** in each block dialog box.
- If you set the parameter to `Explicit and implicit` or `Explicit and warn implicit`, the wizard does not change the setting of **Signal name must resolve to Simulink signal object** or **State name must resolve to Simulink signal object** for any signals or states.

Consider turning off implicit signal object resolution for your model by using the function `disableimplicitsignalresolution`. For more information, see “Explicit and Implicit Symbol Resolution” on page 72-128.

### Data Object Wizard Troubleshooting

- The Data Object Wizard compiles models for code generation in order to propose creation of signal objects. Because of this, the wizard cannot be used for models that are not valid for code generation.
- The Data Object Wizard does not propose creation of data objects for these entities in a model:
  - Multiple separate signals that have the same name.
  - A signal with the same name as a variable used in a block parameter.
  - A signal that lacks a single contiguous source block.
  - A signal whose source block is commented out or commented through.
  - Data items that are rendered inactive by Variant Source and Variant Sink blocks. The wizard proposes objects only for data items that are associated with active blocks.
  - Signals and states when you set the model configuration parameter **Signal resolution** to `None`.

### Create Data Objects from External Data Source Programmatically

This example shows how to create data objects based on an external data source (such as a Microsoft Excel file) by using a script.

- 1 Create a new MATLAB script file.
- 2 Place information in the file that describes the data in the external file that you want to convert to data objects. For example, the following information creates two Simulink data objects with the indicated properties. The first is for a parameter and the second is for a signal:

```
% Parameters
ParCon = Simulink.Parameter;
ParCon.CoderInfo.StorageClass = 'Custom'
ParCon.CoderInfo.CustomStorageClass = 'Const';
ParCon.Value = 3;
% Signals
SigGlb = Simulink.Signal;
SigGlb.DataType = 'int8';
```

- 3 Run the script file. The data objects appear in the MATLAB workspace.

If you want to import the target data from the external source, you can write MATLAB functions and scripts that read the information, convert the information to data objects, and load the objects into the base workspace.

You can use these functions to interact with files that are external to MATLAB:

- `xmlread`
- `xmlwrite`
- `xlsread`
- `xlswrite`
- `csvread`
- `csvwrite`
- `dlmread`
- `dlmwrite`

## Data Object Methods

Data classes define functions, called methods, for creating and manipulating the objects that they define. A class may define any of the following kinds of methods.

### Dynamic Methods

A dynamic method is a method whose identity depends on its name and the class of an object specified implicitly or explicitly as its first argument. You can use either function or dot notation to specify this object, which must be an instance of the class that defines the method or an instance of a subclass of the class that defines the method. For example, suppose class A defines a method called `setName` that assigns a name to an instance of A. Further, suppose the MATLAB workspace contains an instance of A assigned to the variable `obj`. Then, you can use either of the following statements to assign the name 'foo' to `obj`:

```
obj.setName('foo');  
setName(obj, 'foo');
```

A class may define a set of methods having the same name as a method defined by one of its super classes. In this case, the method defined by the subclass overrides the behavior of the method defined by the parent class. Simulink determines which method to invoke at runtime from the class of the object that you specify as its first or implicit argument. Hence, the term dynamic method.

---

**Note** Most Simulink data object methods are dynamic methods. Unless the documentation for a method specifies otherwise, you can assume that a method is a dynamic method.

---

### Static Methods

A static method is a method whose identity depends only on its name and hence cannot change at runtime. To invoke a static method, use its fully qualified name, which includes the name of the class that defines it followed by the name of the method itself. For example, `Simulink.ModelAdvisor` class defines a static method named `getModelAdvisor`. The fully qualified name of this static method is `Simulink.ModelAdvisor.getModelAdvisor`. The following example illustrates invocation of a static method.

```
ma = Simulink.ModelAdvisor.getModelAdvisor('vdp');
```

## Constructors

Every data class defines a method for creating instances of that class. The name of the method is the same as the name of the class. For example, the name of the `Simulink.Parameter` class's constructor is `Simulink.Parameter`. The constructors defined by Simulink data classes take no arguments.

The value returned by a constructor depends on whether its class is a handle class or a value class. The constructor for a handle class returns a handle to the instance that it creates if the class of the instance is a handle class; otherwise, it returns the instance itself (see “Handle Versus Value Classes” on page 72-73).

## Handle Versus Value Classes

Simulink classes, including data object classes, fall into two categories: value classes and handle classes.

### About Value Classes

The constructor for a *value* class (see “Constructors” on page 72-73) returns an instance of the class and the instance is permanently associated with the MATLAB variable to which it is initially assigned. Reassigning or passing the variable to a function causes MATLAB to create and assign or pass a copy of the original object.

For example, `Simulink.NumericType` is a value class. Executing the following statements

```
x = Simulink.NumericType;  
y = x;
```

creates two instances of class `Simulink.NumericType` in the workspace, one assigned to the variable `x` and the other to `y`.

### About Handle Classes

The constructor for a *handle* class returns a handle object. The handle can be assigned to multiple variables or passed to functions without causing a copy of the original object to be created. For example, `Simulink.Parameter` class is a handle class. Executing

```
x = Simulink.Parameter;  
y = x;
```

creates only one instance of `Simulink.Parameter` class in the MATLAB workspace. Variables `x` and `y` both refer to the instance via its handle.

A program can modify an instance of a handle class by modifying any variable that references it, e.g., continuing the previous example,

```
x.Description = 'input gain';  
y.Description
```

```
ans =  
input gain
```

Most Simulink data object classes are value classes. Exceptions include `Simulink.Signal` and `Simulink.Parameter` class.

To determine whether the value of a variable is an object (value class) or a handle to an object, see “Determine If an Object Is a Handle”.

### Copy Handle Objects

Use the copy method of a handle object to create copies of instances of that object. For example, `ConfigSet` is a handle object that represents model configuration sets. The following code creates a copy of the current model's active configuration set and attaches it to the model as an alternate configuration geared to model development.

```
activeConfig = getActiveConfigSet(gcs);
develConfig = copy(activeConfig);
develConfig.Name = 'develConfig';
attachConfigSet(gcs, develConfig);
```

### Compare Data Objects

Simulink data objects provide a method, named `isequal`, that determines whether object property values are equal. This method compares the property values of one object with those belonging to another object and returns true (1) if all of the values are the same or false (0) otherwise. For example, the following code instantiates two signal objects (A and B) and specifies values for particular properties.

```
A = Simulink.Signal;
B = Simulink.Signal;
A.DataType = 'int8';
B.DataType = 'int8';
A.InitialValue = '1.5';
B.InitialValue = '1.5';
```

Afterward, use the `isequal` method to verify that the object properties of A and B are equal.

```
result = isequal(A,B)

result =

    1
```

### Resolve Conflicts in Configuration of Signal Objects for Code Generation

If a signal is defined in the Signal Properties dialog box and a signal object of the same name is defined by using the command line or in the Model Explorer, the potential exists for ambiguity when the Simulink engine attempts to resolve the symbol representing the signal name. One way to resolve the ambiguity is to specify that a signal resolve to a `Simulink.Signal` data object. Select the **Signal name must resolve to Simulink signal object** option in the Signal Properties dialog box.

To configure the signal data, use the Code Mappings editor or code mappings API to add the signal to the model code mappings and set the storage class and storage class properties. For Simulink Coder, see “Configure Signal Data for C Code Generation” (Simulink Coder). For Embedded Coder, see “Configure Signal Data for C Code Generation” (Embedded Coder).

## Create Persistent Data Objects

To preserve data objects so that they persist when you close MATLAB, you can:

- Store the objects in a data dictionary or model workspace. To decide where to permanently store model data, see “Determine Where to Store Variables and Objects for Simulink Models” on page 72-94.
- Use the `save` command to save data objects in a MAT-file and the `load` command to restore them to the MATLAB base workspace in the same or a later session. Configure the model to load the objects from the MAT-file or a script file when the model loads.

To load data objects from a file when you load a model, write a script that creates the objects and configures their properties. Alternatively, save the objects in a MAT-file. Then use either the script or a `load` command as the `PreLoadFcn` callback routine for the model that uses the objects. Suppose that you save the data objects in a file named `data_objects.mat`, and the model to which they apply is open and active. At the command prompt, entering:

```
set_param(gcs, 'PreLoadFcn', 'load data_objects');
```

sets `load data_objects` as the model's preload function. Whenever you open the model, the data objects appear in the base workspace.

Definitions of the classes of saved objects must exist on the MATLAB path for them to be restored. If the class of a saved object acquires new properties after the object is saved, Simulink adds the new properties to the restored version of the object. If the class loses properties after the object is saved, only the properties that remain are restored.

## Simulink.DualScaledParameter Property Dialog Box

Create a `Simulink.DualScaledParameter` object so that you can store two scaled values of the same physical parameter value, for example, for the **Gain** parameter of a Gain block. For examples and programmatic information, see `Simulink.DualScaledParameter`.

### Main Attributes Tab

The screenshot shows the 'Main Attributes' tab of the 'Simulink.DualScaledParameter: param' dialog box. The dialog has three tabs: 'Calibration Attributes', 'Main Attributes', and 'Code Generation'. The 'Main Attributes' tab is active. The fields are as follows:

- Value:** A text box containing `[]`.
- Data type:** A dropdown menu set to 'auto' with a '>>' button to its right.
- Dimensions:** A text box containing `[0 0]`.
- Complexity:** A dropdown menu set to 'real'.
- Minimum:** A text box containing `[]`.
- Maximum:** A text box containing `[]`.
- Unit:** An empty text box.
- Description:** A large empty text area.

At the bottom of the dialog are four buttons: 'OK', 'Cancel', 'Help', and 'Apply'. The 'OK' button is highlighted with a blue border.

This tab shows the properties inherited from the `Simulink.Parameter` class. For more information, see `Simulink.Parameter`.

## Calibration Attributes Tab

Simulink.DualScaledParameter: param

Calibration Attributes Main Attributes Code Generation

Calibration value: []

Calibration minimum: [] Calibration maximum: []

CalToMain compute numerator: []

CalToMain compute denominator: []

Calibration name: ""

Calibration units: ""

Parameter validation

Is configuration valid: true

Diagnostic message: ""

OK Cancel Help Apply

### Calibration value

Calibration value of the parameter. The value that you prefer to use. The default value is [] (unspecified). Specify a finite, real, double value.

Before specifying **Calibration value**, you must specify **CalToMain compute numerator** and **CalToMain compute denominator** to define the computation method. The parameter uses the computation method and the calibration value to calculate the main value that Simulink uses.

### Calibration minimum

Minimum value for the calibration parameter. The default value is [] (unspecified). Specify a finite, real, double scalar value.

Before specifying **Calibration minimum**, you must specify **CalToMain compute numerator** and **CalToMain compute denominator** to define the computation method. The parameter uses

the computation method and the calibration minimum value to calculate the minimum or maximum value that Simulink uses. A first order rational function is strictly monotonic, either increasing or decreasing. If it is increasing, setting the calibration minimum sets the main minimum value. If it is decreasing, setting the calibration minimum sets the main maximum.

If the parameter value is less than the minimum value or if the minimum value is outside the range of the parameter data type, Simulink generates a warning. In these cases, when updating the diagram or starting a simulation, Simulink generates an error.

### Calibration maximum

Maximum value for the calibration parameter. The default value is [] (unspecified). Specify a finite, real, double scalar value.

Before specifying **Calibration maximum**, you must specify **CalToMain compute numerator** and **CalToMain compute denominator** to define the computation method. The parameter uses the computation method and the calibration maximum value to calculate the corresponding maximum or minimum value that Simulink uses. A first order rational function is strictly monotonic, either increasing or decreasing. If it is increasing, setting the calibration maximum sets the main maximum value. If it is decreasing, setting the calibration maximum sets the main minimum.

If the parameter value is less than the minimum value or if the minimum value is outside the range of the parameter data type, Simulink generates a warning. In these cases, when updating the diagram or starting a simulation, Simulink generates an error.

### CalToMain compute numerator

Specify the numerator coefficients a and b of the first-order linear equation:

$$y = \frac{ax + b}{cx + d}$$

The default value is [] (unspecified). Specify finite, real, double scalar values for a and b. For example, [1 1] or, for reciprocal scaling, 1.

Once you have applied **CalToMain compute numerator**, you cannot change it.

### CalToMain compute denominator

Specify the denominator coefficients c and d of the first-order linear equation:

$$y = \frac{ax + b}{cx + d}$$

The default value is [] (unspecified). Specify finite, real, double scalar values for c and d. For example, [1 1].

Once you have applied **CalToMain compute denominator**, you cannot change it.

### Calibration name

Specify the name of the calibration parameter. The default value is ''. Specify a character vector value, for example, 'T1'.

### Calibration units

Specify the measurement units for this calibration value. This field is intended for use in documenting this parameter. The default value is ''. Specify a character vector value, for example, 'Fahrenheit'.

**Is configuration valid**

Simulink indicates whether the configuration is valid. The default value is `true`. If Simulink detects an issue with the configuration, it sets this field to `false` and provides information in the **Diagnostic message** field. You cannot set this field.

**Diagnostic message**

If you specify invalid parameter settings, Simulink displays a message in this field. Use the diagnostic information to help you fix an invalid configuration issue. You cannot set this field.

## Simulink.NumericType Property Dialog Box

Use a `Simulink.AliasType` object to set and share data types for signal, state, and parameter data in a model. For examples and programmatic information, see `Simulink.NumericType`.

### Data type mode

Data type of this numeric type. The options are listed in this table.

Option	Description
Double	Same as the MATLAB double type.
Single	Same as the MATLAB single type.
Boolean	Same as the MATLAB boolean type.
Fixed-point: unspecified scaling	A fixed-point data type with unspecified scaling.
Fixed-point: binary point scaling	A fixed-point data type with binary-point scaling.
Fixed-point: slope and bias scaling	A fixed-point data type with slope and bias scaling.

Selecting a data type mode causes Simulink software to enable controls on the dialog box that apply to the mode and to disable other controls that do not apply. Selecting a fixed-point data type mode can, depending on the other dialog box options that you select, cause the model to run only on systems that have a Fixed-Point Designer option installed.

### Data type override

Data type override setting for this numeric type. The options are listed in this table.

Option	Description
Inherit (default)	Data type override setting for the context in which this numeric type is used (block, signal, Stateflow chart in Simulink) applies to this numeric type.
Off	Data type override setting does not affect this numeric type.

### Is alias

If you select this option for a workspace object of this type, Simulink software uses the name of the object as the data type for all objects that specify the object as its data type. Otherwise, Simulink software uses the data type mode of the data type as its name, or, if the data type mode is a fixed-point mode, Simulink software generates a name that encodes the type properties, using the encoding specified by Fixed-Point Designer.

### Data scope

Specifies whether the data type definition is imported from, or exported to, a header file during code generation. The possible values are listed in this table.

Value	Action
Auto (default)	If no value is specified for <b>Header file</b> , export the type definition to <i>model_types.h</i> . <i>model</i> is the model name. If a value is specified for <b>Header file</b> , import the data type definition from the specified header file.
Exported	Export the data type definition to a header file, which can be specified in the <b>Header file</b> field. If no value is specified for <b>Header file</b> , the header file name defaults to <i>type.h</i> . <i>type</i> is the data type name.
Imported	Import the data type definition from a header file, which can be specified in the <b>Header file</b> field. If no value is specified for <b>Header file</b> , the header file name defaults to <i>type.h</i> . <i>type</i> is the data type name.

### Header file

Name of a C header file from which a data type definition is imported, or to which a data type definition is exported, based on the value of **Data scope**. If this field is specified, the specified name is used during code generation for importing or exporting. If this field is empty, the value defaults to *type.h* if **Data scope** equals Imported or Exported, or defaults to *model\_types.h* if **Data scope** equals Auto.

By default, the generated `#include` directive uses the preprocessor delimiter `"` instead of `<` and `>`. To generate the directive `#include <myTypes.h>`, specify **Header file** as `<myTypes.h>`.

### Description

Description of this data type. This field is intended for use in documenting this data type. Simulink software ignores it.

### Signedness

Specifies whether the data type is signed or unsigned, or inherits its signedness. Set the option to Signed, Unsigned, or Auto. This option is enabled only for fixed-point data type modes as shown.

**Word length**

Word length in bits of the fixed-point data type. This option is enabled only for fixed-point data type modes.

**Fraction length**

Number of bits to the right of the binary point. This option is enabled only if the data type mode is Fixed-point: binary point scaling.

### Slope

Slope for slope and bias scaling. This option is enabled only if the data type mode is Fixed-point: slope and bias scaling.

**Bias**

Bias for slope and bias scaling. This option is enabled only if the data type mode is Fixed-point: slope and bias scaling. See the preceding figure.

## Use Simulink.Signal Objects to Specify and Control Signal Attributes

A `Simulink.Signal` object enables you to assign or validate the attributes of a signal or discrete state, such as its data type, numeric type, dimensions, and so on.

### Using Signal Objects to Assign or Validate Signal Attributes

You can use signal objects to assign or validate signal attributes. The same techniques work with discrete states also. To use a signal object to assign or validate signal attribute values:

- 1 Create a `Simulink.Signal` object that has the same name as the signal to which you want to assign attributes or whose attributes you want to validate.
  - a Open the Model Explorer.
  - b In the Model Hierarchy pane, select either the Base workspace or Model workspace node, depending on the context you want for the signal object. If you create the signal object in a model workspace, you must set the **Storage class** parameter to `Auto`.
  - c Select **Add > Simulink Signal**.
- 2 Set the properties of the object that correspond to the attributes left unspecified by the signal source, or that correspond to the attributes you want to validate.
- 3 Enable explicit or implicit signal resolution:
  - **Explicit resolution:** In the Signal Properties dialog box for the signal, enable **Signal name must resolve to Simulink signal object**. This is the preferred technique. See “Explicit and Implicit Symbol Resolution” on page 72-128 for more information.  
  
When you use this technique, set **Configuration Parameters > Diagnostics > Data Validity > Signal resolution** to a value other than `None`. To use only explicit resolution (a best practice), set the parameter to `Explicit only`.
  - **Implicit resolution:** Set the **Configuration Parameters > Diagnostics > Data Validity > Signal resolution** option for the model to `Explicit and implicit` or `Explicit and warn implicit`. Explicit resolution is the preferred technique.
- 4 Assign the signal object to a workspace variable.
- 5 Associate the signal object with the source signal.
  - Give the signal the same name as the workspace variable that references the signal object.
  - You can use a variety of techniques to associate a signal object with a signal. For examples, see “Use Signal Objects to Initialize Signals and Discrete States” on page 80-43, “Using Signal Objects to Tune Initial Values” on page 80-45, and “Organize Parameter Data into a Structure by Using Struct Storage Class” (Embedded Coder).

### Validation

The result when a signal does not match a signal object can depend on several factors. Simulink software can validate a signal property when you update the diagram, while you run a simulation, or both. When and how validation occurs can depend on internal rules that are subject to change, and sometimes on configuration parameter settings.

Not all signal validation compares signal source attributes with signal object properties. For example, if you specify **Minimum** and **Maximum** signal values using a signal object, the signal source must specify the same values as the signal object (or inherit the values from the object) but such validation relates only to agreement between the source and the object, not to enforcement of the minimum and maximum values during simulation.

If the value of **Configuration Parameters > Diagnostics > Data Validity > Simulation range checking** is none (the default), Simulink does not enforce any minimum and maximum signal values during simulation, even though a signal object provided or validated them. To enforce minimum and maximum signal values during simulation, set **Simulation range checking** to warning or error. See “Specify Signal Ranges” on page 80-36 and “Model Configuration Parameters: Data Validity Diagnostics” for more information.

## Multiple Signal Objects

You can associate a given *signal object* with more than one signal if the storage class of the signal object is `Auto` or `Reusable`. If the storage class is `Auto` and you clear optimizations such as **Signal storage reuse** so that the generated code allocates memory for all of the associated signals, the signals each appear as a uniquely named field of the global structure that contains signal and state data. If the storage class of the object is other than `Auto` or `Reusable`, you can associate the signal object with no more than one signal.

You can associate a given *signal* with no more than one signal object. The signal can refer to the signal object more than once, but every reference must resolve to exactly the same signal object. Referencing two different signal objects that have exactly the same properties causes a compile-time error.

A compile-time error occurs if a model associates more than one signal object with any signal. To prevent the error, decide which object you want the signal to use, then delete or reconfigure all references to any other signal objects, so that all remaining references resolve to the chosen signal object. See “Highlight Signal Sources and Destinations” on page 80-28 for a description of techniques that you can use to trace the full extent of a signal.

## Signal Specification Block: An Alternative to Simulink.Signal

You can use a Signal Specification block rather than a `Simulink.Signal` object to assign properties left unspecified by a signal source. Each technique has advantages and disadvantages:

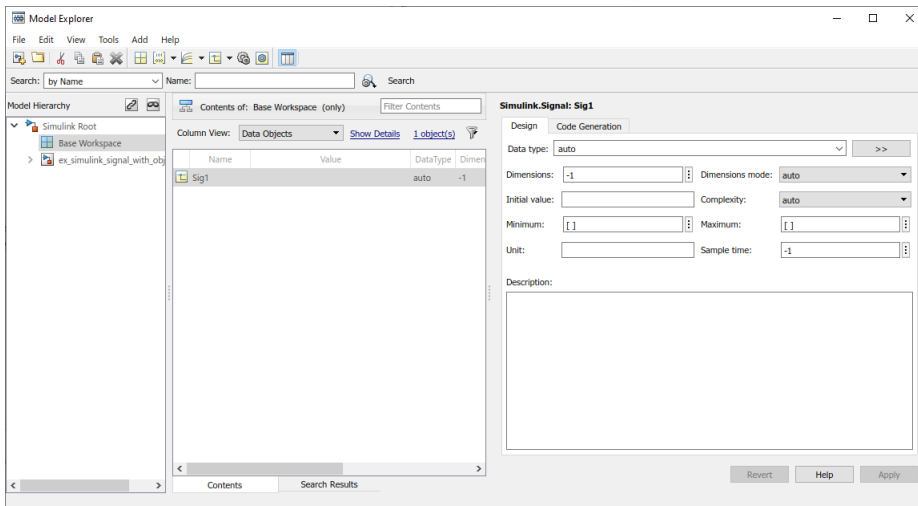

- Using a signal object simplifies the model and allows you to change signal property values without editing the model, but does not show signal property values directly in the block diagram.
- Using a Signal Specification block displays signal property values directly in the block diagram, but complicates the model and requires editing it to change signal property values.

The following two models illustrate the respective advantages of the two ways of assigning attributes to a signal.

In the first example, the signal object named `Sig1` specifies the sample time and data type of the signal emitted by input port `In1`.

To determine the properties of the `Sig1` signal, you can view the signal object in the Model Explorer. In this model, the sample time is `-1` and the data type is `auto`.

Using a signal object to specify the sample time and data type properties of signal `Sig1` allows you to change the sample time or data type without having to edit the model. For example, you could use the Model Explorer, the MATLAB command line, or a MATLAB program to change these properties.

The second example uses a Signal Specification block specifies the sample time and data type of the signal emitted by input port `In2`. The Signal Specification block displays the data type and signal sample time properties right in the diagram, which in this case are `uint8` and `4`, respectively.

## Bus Support

### Using Bus Objects as the Data Type

`Simulink.Signal` supports nonvirtual buses as the output data type.

If you set the **Data type** of the signal object to be a bus object, then you cannot associate the signal object with a non-bus signal.

### Using Structures for the Initial Value

If you use a bus object as the data type, set **Initial value** to `0` or a MATLAB structure that matches the bus object.

The structure you specify must contain a value for every element of the bus represented by the bus object.

You can use the `Simulink.Bus.createMATLABStruct` to create a full structure that corresponds to a bus.

You can use `Simulink.Bus.createObject` to create a bus object from a MATLAB structure.

## Define Data Classes

This example shows how to subclass Simulink data classes.

Use MATLAB class syntax to create a data class in a package. Optionally, assign properties to the data class and define storage classes.

### In this section...

“Use an example to define data classes” on page 72-89

“Manually define data class” on page 72-89

“Optional: Add properties to data class” on page 72-90

“Optional: Add initialization code to data class” on page 72-91

“Optional: Define storage classes” on page 72-91

“Optional: Define custom attributes for storage classes” on page 72-91

### Use an example to define data classes

- 1 View the +SimulinkDemos data class package in the folder *matlabroot/toolbox/simulink/simdemos/dataclasses* (open).

This package contains predefined data classes.

- 2 Copy the folder to the location where you want to define your data classes.
- 3 Rename the folder +mypkg and add its parent folder to the MATLAB path.
- 4 Modify the data class definitions.

### Manually define data class

- 1 Create a package folder +mypkg and add its parent folder to the MATLAB path.
- 2 Create class folders @Parameter and @Signal inside +mypkg.

**Note** Simulink requires data classes to be defined inside +Package/@Class folders.

- 3 In the @Parameter folder, create a MATLAB file Parameter.m and open it for editing.
- 4 Define a data class that is a subclass of Simulink.Parameter using MATLAB class syntax.

```
classdef Parameter < Simulink.Parameter
end % classdef
```

To use a custom class name other than Parameter or Signal, name the class folders using the custom name. For example, to define a class mypkg.myParameter:

- Define the data class as a subclass of Simulink.Parameter or Simulink.Signal.

```
classdef myParameter < Simulink.Parameter
end % classdef
```

- In the class definition, name the constructor method as `myParameter` or `mySignal`.
- Name the class folder, which contains the class definition, as `@myParameter` or `@mySignal`.

## Optional: Add properties to data class

The `properties` and `end` keywords enclose a property definition block.

```
classdef Parameter < Simulink.Parameter
    properties % Unconstrained property type
        Prop1 = [];
    end

    properties(PropertyType = 'logical scalar')
        Prop2 = false;
    end

    properties(PropertyType = 'char')
        Prop3 = '';
    end

    properties(PropertyType = 'char',...
        AllowedValues = {'red'; 'green'; 'blue'})
        Prop4 = 'red';
    end
end % classdef
```

If you add properties to a subclass of `Simulink.Parameter`, `Simulink.Signal`, or `Simulink.CustomStorageClassAttributes`, you can specify the following property types.

Property Type	Syntax
Double number	<code>properties(PropertyType = 'double scalar')</code>
int32 number	<code>properties(PropertyType = 'int32 scalar')</code>
Logical number	<code>properties(PropertyType = 'logical scalar')</code>
Character vector (char)	<code>properties(PropertyType = 'char')</code>
Character vector with limited set of allowed values	<code>properties(PropertyType = 'char', AllowedValues = {'a', 'b', 'c'})</code>

If you add a property that requires special copy behavior, you define that behavior by overriding the `copyElement` method. For example, in the `+SimulinkDemos` data class package, the class definition file `Parameter.m` defines the property `GenericProperty` with an unconstrained property type. The `copyElement` method specifies the copy behavior for `GenericProperty`. When you add, remove, or change a property that requires special copy behavior, you must also be sure to update the `copyElement` method.

If you use MATLAB property validation (see “Validate Property Values”) instead of `PropertyType`, the properties are displayed as an edit field in the property dialog box of the class. If you use `PropertyType` and `AllowedValues`, then the property dialog box displays:

- A check box for logical scalar properties.

- A dropdown menu for character vectors and AllowedValues.

## Optional: Add initialization code to data class

You can add a constructor within your data class to perform initialization activities when the class is instantiated. The added constructor cannot require an input argument.

In this example, the constructor initializes the value of object `obj` based on an optional input argument.

```
classdef Parameter < Simulink.Parameter
    methods
        function obj = Parameter(optionalValue)
            if (nargin == 1)
                obj.Value = optionalValue;
            end
        end
    end % methods
end % classdef
```

## Optional: Define storage classes

Use the `setupCoderInfo` method to configure the `CoderInfo` object of your class. Then, create a call to the `useLocalCustomStorageClasses` method and open the Custom Storage Class Designer.

- 1 In the constructor within your data class, call the `useLocalCustomStorageClasses` method.

```
classdef Parameter < Simulink.Parameter
    methods
        function setupCoderInfo(obj)
            useLocalCustomStorageClasses(obj, 'mypkg');

            obj.CoderInfo.StorageClass = 'Custom';
        end
    end % methods
end % classdef
```

- 2 Open the Custom Storage Class Designer for your package.

```
cscdesigner('mypkg')
```

- 3 Define storage classes.

## Optional: Define custom attributes for storage classes

- 1 Create a MATLAB file `myCustomAttribs.m` and open it for editing. Save this file in the `+mypkg/@myCustomAttribsfolder`, where `+mypkg` is the folder containing the `@Parameter` and `@Signal` folders.
- 2 Define a subclass of `Simulink.CustomStorageClassAttributes` using MATLAB class syntax. For example, consider a storage class that defines data using the original identifier but also provides an alternate name for the data in generated code.

```
classdef myCustomAttribs < Simulink.CustomStorageClassAttributes
    properties(PropertyType = 'char')
        AlternateName = '';
    end
end
```

```

    end
end % classdef

```

- 3 Override the default implementation of the `isAddressable` method to determine whether the storage class is writable.

```

classdef myCustomAttribs < Simulink.CustomStorageClassAttributes
    properties(PropertyType = 'logical scalar')
        IsAlternateNameInstanceSpecific = true;
    end

    methods
        function retVal = isAddressable(hObj, hCSCDefn, hData)
            retVal = false;
        end
    end % methods
end % classdef

```

- 4 Override the default implementation of the `getInstanceSpecificProps` method.

For example, see these override functions:

```

function props = getInstanceSpecificProps(hObj)
% GETINSTANCESPECIFICPROPERTIES Return instance-specific properties
% (custom attributes that can be modified on each data object).

    if hObj.IsStructNameInstanceSpecific
        props = findprop(hObj, 'StructName');
    else
        props = [];
    end
end

function props = getInstanceSpecificProps(hObj)
% GETINSTANCESPECIFICPROPERTIES Return instance-specific properties
% (custom attributes that can be modified on each data object).
    props = [];

    if hObj.IsOwnerInstanceSpecific
        ptmp = findprop(hObj, 'Owner');
        props = [props; ptmp];
    end

    if hObj.IsDefinitionFileInstanceSpecific
        ptmp = findprop(hObj, 'DefinitionFile');
        props = [props; ptmp];
    end

    if hObj.IsPersistenceLevelInstanceSpecific
        ptmp = findprop(hObj, 'PersistenceLevel');
        props = [props; ptmp];
    end
end

```

---

**Note** This is an optional step. By default, all custom attributes are instance-specific and are modifiable for each data object. However, you can limit which properties are allowed to be instance-specific.

---

- 5 Override the default implementation of the `getIdentifiersForInstance` method to define identifiers for objects of the data class.

---

**Note** In its default implementation, this method queries the name or identifier of the data object and uses that identifier in generated code. By overriding this method, you can control the identifier of your data objects in generated code.

---

```

classdef myCustomAttribs < Simulink.CustomStorageClassAttributes
    properties(PropertyType = 'char')
        GetFunction = '';
        SetFunction = '';
    end

    methods
        function retVal = getIdentifiersForInstance(hCSCAttrib,...
            hCSCDefn, hData, identifier)
            retVal = struct('GetFunction',...
                hData.CoderInfo.CustomAttributes.GetFunction, ...
                'SetFunction', hData.CoderInfo.CustomAttributes.SetFunction);
        end%
    end % methods
end % classdef

```

- 6 If you are using grouped storage classes, override the default implementation of the `getIdentifiersForGroup` method to specify the identifier for the group in generated code.

For an example, see `CSCTypeAttributes_FlatStructure.m` in the folder *matlabroot* \toolbox\simulink\simulink\dataclasses\+Simulink \@CSCTypeAttributes\_FlatStructure (open).

## Determine Where to Store Variables and Objects for Simulink Models

Model data are objects and variables that you create in workspaces such as the base workspace or a data dictionary. Model data include:

- Numeric values for block parameters, such as `Simulink.Parameter` objects and MATLAB variables
- Signals, such as `Simulink.Signal` objects
- Value types defined by `Simulink.ValueType` objects
- Data types
- Model configuration sets
- Simulation input and output data

You can store, partition, and share model data in a location that is appropriate for your design. The storage locations that you choose can depend on:

- Your modeling goals.
- The model architecture (referenced models, subsystems, and other partitioning strategies) and component structure.
- The types of data that you use.

### Types of Data

- Simulation data is the set of input data that you use to drive a simulation and the set of output data that a simulation generates. For example, you can use variables to store input data that a simulation acquires through Inport blocks. A simulation can export output data through, for example, Outport blocks, To Workspace blocks, and logged signals.

You can store simulation data for your current MATLAB session in the base workspace. To permanently store this simulation data, save it in a MAT-file or script file. For more information about loading, generating, and storing simulation data, see “Comparison of Signal Loading Techniques” on page 75-21 and “Save Simulation Data” on page 77-2.

- Design data is the set of variables that you use to specify block parameters and signal characteristics in a model. For example, design data includes numeric MATLAB variables, value type objects, parameter and signal data objects, data type objects, and bus objects.

You can store design data in the base workspace, model workspaces, or the Design Data section of a data dictionary. To permanently store local design data with a model, use model workspaces. To share design data between models, use data dictionaries or the base workspace. Data dictionaries permanently store the data, and you can control the data scope to establish ownership, partition the data to ease readability and maintenance, and track changes. If you use the base workspace, to permanently store the data, you must save it in a MAT-file or script file.

- Configuration sets are sets of model configuration parameters. By default, configuration sets reside in the model file, so you do not need to store the sets separately from the model. However, you cannot share these sets with other models.

To share configuration sets between models, you must create `Simulink.ConfigSet` objects. Each object represents a standalone configuration set. You can store these objects in the base

workspace or in the Configurations section of a data dictionary. If you use data dictionaries, you can define the scope of each configuration set, compare different configuration sets, and track changes. A data dictionary inherently partitions configuration sets from other kinds of data.

## Store Data for Your Design

The table shows the techniques you can use to store, partition, and manage design data and configuration sets.

Modeling Scenario	Scenario Description	Storage Locations and Techniques
Rapid prototyping and model experimentation	<p>You want to create temporary data, such as variables to specify numeric block parameters, while you learn to use Simulink.</p> <p>You want to experiment with modeling techniques. You do not need to permanently store the data that you create.</p>	Store data in the base workspace so you can quickly create and change the data.
Standalone model	You have a single model that does not depend on other systems for data. The model stands alone because it is not a piece of a larger system.	<p>Store data in the model workspace to improve model portability. Use a data dictionary to store data that you cannot store in the model workspace.</p> <p>Alternatively, store all of the model data in a data dictionary. If you use a dictionary, you can partition the data by using referenced dictionaries.</p>
Standalone hierarchy of referenced models	You have a hierarchy of referenced models that does not depend on other systems for data. The hierarchy stands alone because it is not a piece of a larger system.	<p>Store local model data in each model workspace.</p> <p>Store data that the models share, such as bus objects and configuration sets, in a data dictionary. Link all of the models in the hierarchy to the dictionary.</p> <p>For examples, see “Migrate Model Reference Hierarchy to Use Dictionary” on page 79-7 and “Using a Data Dictionary to Manage the Data for a Fuel Control System”.</p>

Modeling Scenario	Scenario Description	Storage Locations and Techniques
System of components	One or more teams maintain the components of a system of models. A component is a single model or a hierarchy of referenced models that represents a piece of a larger system.	<p>Store local model data in model workspaces.</p> <p>Store data that the models in a component share, such as bus objects and configuration sets, in a data dictionary. Link all of the models in the component to the dictionary.</p> <p>Use additional referenced dictionaries to store data that the components share.</p> <p>For an example, see “Partition Data for Model Reference Hierarchy Using Data Dictionaries” on page 79-30.</p>

## Storage Locations

Choose any of these locations to store data:

- The MATLAB base workspace. Use the base workspace to store variables while you experiment with temporary models.
- A model workspace. Use a model workspace to permanently store data that is local to a model.
- A data dictionary. Use data dictionaries to permanently store global data, share data between models, and track changes made to data.

The chart shows the capabilities and advantages of each storage location.

Capability	Base Workspace	Model Workspace	Data Dictionary
Data-model linkage	implicit	implicit	✓
Unified interface for defining data	✓	✓	✓
Model-data dependency	✓	✓	✓
Data entry comparison	✓	✓	✓
Data entry persistence		✓	✓
Options to remedy a missing variable	✓	✓	Additional options
Shared data	✓		✓
Data grouping			✓
Change tracking for data entries			✓
Change tracking for configuration sets			✓
Data entry merging and reconciliation			✓
Storage and partitioning of auxiliary data			✓
Requirements linking			✓

For information about the way that models interact with workspaces and workspace variables, see “Symbol Resolution” on page 72-126.

### Temporary Data: Base Workspace

Use the base workspace to temporarily store data:

- While you learn to use Simulink
- When you need to quickly create variables while experimenting with modeling techniques
- When you do not need to store the data permanently

To create variables in the base workspace, you can use the MATLAB command prompt or the Model Explorer. All open models can use the data that you create in the base workspace.

If you use variables to specify numeric block parameters in the model, you can programmatically change the parameter values during simulation by using commands at the command prompt. To programmatically change the values of parameters that you store in the model workspace or data dictionaries, you must use the function interfaces for those storage locations.

To permanently store base workspace data before you end a MATLAB session, you can save the data in a MAT-file or a script file. During a later session, you can load the data from the file. However, if you make changes to the data in the base workspace, you must save the data to the file again. Consider instead using a model workspace or data dictionary to permanently store data.

### Local Data: Model Workspace

Use a model workspace to store data that you use only in the associated model. This data can include:

- Constant parameters, for example, numeric variables that you use to specify block parameter values.
- Data objects, such as `Simulink.Signal` and `Simulink.Parameter` objects, that you use to control signal and parameter characteristics. However, signal objects in a model workspace can use only the `Auto` storage class. If you store an `AUTOSAR.Parameter` object in a model workspace, the code generator ignores the storage class that you specify for the object.
- `Simulink.NumericType` objects that you use to specify data types. However, you cannot use the object as a data type alias. You must set the `IsAlias` property to `false`.
- Model arguments.

You can improve model portability and establish data ownership by storing the data in the model workspace. In this case, the model file permanently stores the data.

In a model reference hierarchy, each model workspace acts as a unique namespace. Therefore, you can use the same variable name in multiple model workspaces. You can then assign a unique variable value for each model.

You can use the Model Explorer to manipulate model workspace data. Alternatively, you can use the command prompt or scripts in conjunction with the model workspace programmatic interface.

For more information about using model workspaces to store local data, see “Model Workspaces” on page 72-113.

## Global and Shared Data: Data Dictionary

A data dictionary is a standalone file that permanently stores data. Use data dictionaries instead of the base workspace to partition data, track changes, control access, and share data. If you link a model to a data dictionary, you can still use variables in the base workspace by configuring access from either the model or the dictionary.

As you can with model workspaces, you can use data dictionaries to directly associate data with a model. You can use this association to scope the data and to establish ownership.

When you use dictionaries, you can partition the data by storing it in additional referenced dictionaries. However, each entry in a dictionary must use a unique name. You must manage each dictionary as a separate file.

Use a data dictionary to store data that multiple models or system components share. This data can include:

- Numeric variables that multiple models use to specify block parameter values.
- `Simulink.AliasType` and `Simulink.NumericType` objects that you use to specify data types in multiple models at once.
- Data objects, including signal objects (such as `Simulink.Signal`) that use a storage class other than `Auto`. If you have a Simulink Coder license, these objects can represent signals and tunable parameters that appear as global variables in the generated code.
- `Simulink.ValueType` and `Simulink.Bus` objects that you use to define interfaces of model components, such as referenced models.
- `Simulink.ConfigSet` objects that you use to maintain configuration parameter uniformity across multiple models.
- Enumerated type definitions, which you store using `Simulink.data.dictionary.EnumTypeDefinition` objects.

You can use the Model Explorer to manipulate dictionary data. Alternatively, you can use the command prompt or scripts in conjunction with the data dictionary programmatic interface.

For basic information about data dictionaries, see “What Is a Data Dictionary?” on page 79-2.

## Considerations for Code Generation

If you intend to generate C code from a model (Simulink Coder), take these considerations into account.

- If you apply a storage class other than `Auto` to a signal object (such as `Simulink.Signal`) to control the appearance of a signal or block state in the generated code, you cannot store the object in a model workspace. Store the object in the base workspace or a data dictionary. For more information about storage classes for signals and states, see “C Code Generation Configuration for Model Interface Elements” (Simulink Coder).
- If you apply a storage class other than `Auto` to a parameter object (such as `Simulink.Parameter`), you can store the object in the base workspace, a model workspace, or a data dictionary. However, if you store the object in a model workspace, the code generator assumes that the containing model owns the parameter. For more information, see “Code Generation Impact of Storage Location for Parameter Objects” (Simulink Coder).

- “Symbol Resolution” on page 72-126

## Create, Edit, and Manage Workspace Variables

To share information such as parameter values and signal data types between separate blocks and models, you use workspace variables. For example, you can create a numeric MATLAB variable in the base workspace and use the variable to set the value of the **Gain** parameter in multiple Gain blocks simultaneously (see “Share and Reuse Block Parameter Values by Creating Variables” on page 40-9). You can create a `Simulink.Bus` object to explicitly define the structure of a bus signal.

You can store workspace variables in the base workspace, model workspaces, or data dictionaries. To decide where to store variables, see “Determine Where to Store Variables and Objects for Simulink Models” on page 72-94.

### Tools for Managing Variables

Use one or more of these techniques to create, modify, store, evaluate, and migrate workspace variables:

- To share block parameter values and create `Simulink.Parameter` and `Simulink.Signal` objects (for example, in preparation for code generation), you can use the Model Data Editor. You can interact with all of the block parameters, signal lines, and block states in a model at once. You can also inspect tunable block parameters in a list that you can search, sort, and filter.

- To create a variable, in the data table, begin editing the cell that corresponds to a block parameter value (in the **Value** column) or a signal or state name (in the **Name** column). Enter the name of the variable you want to create and click the action button  in the right side of the cell.

If a block parameter value is already set to a simple numeric expression, you can create a variable for that expression. Click  in the right side of the cell that corresponds to the value, then select **Create variable**. In the Create New Data dialog box, set the name and location for the new variable, then click **Create**. The cell now displays the new variable.

- To modify variables by using the columns in the data table, click the **Show/refresh additional information** button. Then, the data table contains rows that correspond to the variables and objects that the model uses.
- To interact with one variable at a time (for example, to inspect all of the variable properties at once), open the Property Inspector (on the **Modeling** tab, under **Design**, click **Property Inspector**) and select the relevant row in the data table. The Property Inspector shows the properties of the selected variable.

For more information, see **Model Data Editor**.

- To interact with a small number of parameters, signals, or states at a time, use individual block parameter dialog boxes or the Property Inspector to create variables for sharing block parameter values and create and configure parameter and signal objects for code generation.

In the dialog box or the Property Inspector, click the action button  next to the value of a block parameter, signal name, or state name.

- To create and edit any type or class of variable or object, move variables between workspaces, and inspect all of the variables in a workspace at once, use the Model Explorer. You can also rename variables and precisely analyze the way that an entire model or an individual block uses variables.

See **Model Explorer** and “Edit and Manage Workspace Variables by Using Model Explorer” on page 72-104.

- To check the value of a parameter that you set as a variable or variable expression during simulation, open the Block Parameters dialog box or the Property Inspector. The text box where you enter the parameter value displays the variable or expression on the left and the value on the right. The displayed value is the value of the variable or expression in the simulation at the time step when you open the Block Parameters dialog box or the Property Inspector. For more information, see “View Values of Parameters Set as Variables” on page 30-70.

## Edit Variable Value or Property from Block Parameter

This example shows how to change the value of a **Gain** parameter (Gain block) whose value is set by a numeric variable. Modify the variable, not the block parameter.

- 1 Open the model f14. The model loads variables into the base workspace.
- 2 In the model, open the Property Inspector. On the **Modeling** tab, under **Design**, click **Property Inspector**.
- 3 In the model, select the Gain block that uses the variable Mw.
- 4 In the Property Inspector, click the button  next to the value of the **Gain** parameter. Select **Open**.
- 5 In the **Data properties** dialog box, type a new value for the variable in the **Value** box and click **OK**.

## Modify Structure and Array Variables Interactively

To inspect and modify a variable whose value is a structure or array, you can launch the Variable Editor by clicking the nearby button . Choose one of these techniques:

- In the Model Explorer, select the variable in the **Contents** pane. In the Dialog pane (the right pane), the button appears.
- In the Model Data Editor (on the **Modeling** tab, click **Model Data Editor**), on the **Parameters** tab, click the **Show/refresh additional information** button. In the data table, find the row that corresponds to the variable and, in the **Value** column, begin editing the value of the variable. The button appears in the right side of the cell.
- In a block dialog box or the Property Inspector, the button appears next to the value of a block parameter that uses the variable. Click the button and use the menu options to open the property dialog box for the variable. Then, in the property dialog box, click the button again to launch the Variable Editor. You can use this technique only for parameter objects such as `Simulink.Parameter`.

## Ramifications of Modifying or Deleting a Variable

When you modify or delete a variable, the change can impact multiple blocks and models that use the variable. To assess the impact by determining where the variable is used, use the Model Explorer (see “Analyze Variable Usage in a Model” on page 72-102). However, you can analyze variable usage only for models that are open at the time of the analysis. Before you perform the analysis, open any models that you suspect use the variable.

Models and blocks use variables through name resolution (see “Symbol Resolution” on page 72-126). When you change the name of a variable without making corresponding changes to dependent blocks and models, the blocks and models generate errors. Instead, to rename a variable in the context of one or more models, see “Rename a Variable Throughout a Model” on page 72-102.

When a block or model cannot access a variable that it needs, it generates an error in the Diagnostic Viewer. In some cases, you can use buttons in the Diagnostic Viewer to fix the error (for example, by restoring a deleted variable). To increase the likelihood that you can use the Diagnostic Viewer to recover from the absence of a variable, use these techniques:

- Store variables in a data dictionary instead of the base workspace. With a data dictionary, you gain additional options for recovery. For information about data dictionaries, see “What Is a Data Dictionary?” on page 79-2.
- For every model, keep the corresponding Simulink cache file available. For example, when you share the model with someone else, share the cache file, too. When you fetch the latest model design files from a source control system, fetch the cache file from the continuous integration system or latest build folder. The cache file preserves information that Simulink Coder can use to help you recover from the absence of a variable. For more information about Simulink cache files, see “Share Simulink Cache Files for Faster Simulation” on page 8-54.

## Analyze Variable Usage in a Model

To analyze the ways in which a model uses variables, use the Model Explorer. You can:

- Determine where a variable is used in a model.
- Determine whether a model uses a variable.
- Determine which variables in a workspace are not used by a model.

For more information, see “Edit and Manage Workspace Variables by Using Model Explorer” on page 72-104.

## Rename a Variable Throughout a Model

This example shows how to rename a variable in the Model Data Editor.

- 1 Open the model f14. The model loads variables into the base workspace.
- 2 In the model, on the **Modeling** tab, click **Model Data Editor**. In the Model Data Editor, inspect the **Parameters** tab.
- 3 In the model, click the Gain block labeled Mw.

In the Model Data Editor, the **Value** column shows that the block uses the variable Mw. Suppose you want to rename this variable.

- 4 In the Model Data Editor, click the **Show/refresh additional information** button.

Now, the data table contains rows that correspond to workspace variables that the model uses.

- 5 Activate the **Change scope** button.

Now, the data table shows information about data items in subsystems.

- 6 In the **Filter contents** box, enter Mw.

The data table shows rows that correspond to the variable and to blocks that use the variable.

- 7 In the row that represents Mw, right-click and select **Rename All**.
- 8 In the **Select a system** dialog box, click the name of the model f14 to select it as the context for renaming the variable Mw.
- 9 Clear the **Search in referenced models** check box, since f14 does not reference any models, and click **OK**.

With **Search in referenced models** selected, you can rename the target variable everywhere it is used in a model reference hierarchy. However, renaming the target variable in an entire hierarchy can take more time.

The **Update diagram to include recent changes** check box is cleared by default to save time by avoiding unnecessary model diagram updates. Select the check box to incorporate recent changes you made to the model by forcing a diagram update.

- 10 In the **Rename All** dialog box, type the new name for the variable in the **New name** box and click **OK**.
- 11 Click **Show/refresh additional information** again. Because the renaming operation changed the name of the variable and the values of some block parameters, for more accurate information in the Model Data Editor, you must click **Show/refresh additional information**.

## Interact with Variables Programmatically

At the command prompt, you can create and modify variables in the base workspace by entering commands such as `myVar = 15;`. To programmatically create, modify, and store variables in a different workspace, such as a model workspace, use the programmatic interface for the target workspace. The table shows the interfaces and techniques that you can use to programmatically manage variables.

Target Workspace	Technique or Interface
Base workspace	Enter commands at the command prompt.
Model workspace	See <code>Simulink.ModelWorkspace</code> .
Data dictionary	See “Store Data in Dictionary Programmatically” on page 79-40.

To programmatically list the variables that a model uses or does not use, see `Simulink.findVars`.

To programmatically access variables for the purpose of sweeping block parameter values, consider using `Simulink.SimulationInput` objects instead of modifying the variables through the programmatic workspace interfaces. See “Optimize, Estimate, and Sweep Block Parameter Values” on page 40-38.

“Rename Variables” on page 72-108

“Compare Duplicate Workspace Variables” on page 72-109

“Export Workspace Variables” on page 72-110

“Importing Workspace Variables” on page 72-112

To learn all of the techniques you can use to create, edit, and manage workspace variables, see “Create, Edit, and Manage Workspace Variables” on page 72-100.

### Finding Variables That Are Used by a Model or Block

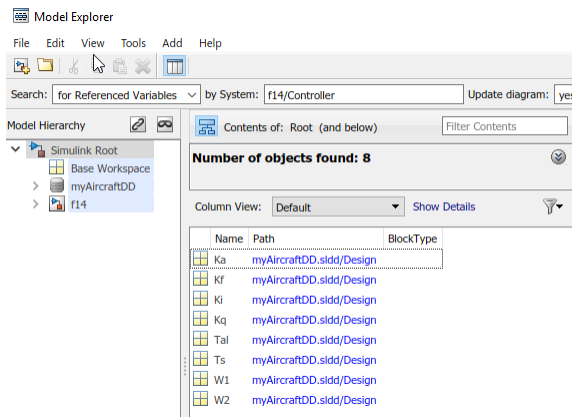

In the Model Explorer, you can get a list of variables that a model or block uses. The following approach is one way to get that list of variables:

- 1 In the **Contents** pane, right-click the block for which you want to find the variables that it uses.
- 2 Select the **Find Referenced Variables** menu item.

Model Explorer returns results similar to these:

For performance, Model Explorer uses cached information from the last compiled version of the model. If you want to recompile the model, either do so manually or, in the Model Explorer, set the **Update diagram** field to yes and repeat the search.

You can also use the following approaches to find variables that a model or block uses:

- In the Model Explorer, in the **Model Hierarchy** pane, right-click a block or model node and select the **Find Referenced Variables** menu item.
- In the Model Explorer, in the search bar, use the for Referenced Variables search type option.
- In the Simulink Editor, right-click a block, subsystem, or in the canvas and select the **Find Referenced Variables** menu item. Clicking the canvas returns results for the whole model.

The `Simulink.findVars` function provides additional options for returning information about workspace variables that is not available from the Model Explorer or Simulink Editor.

For information about limitations when finding referenced variables, see the `Simulink.findVars` documentation.

### Using the Set of Returned Variables

For a variable in the set of returned variables, you can find the blocks that use that variable (for details, see “Finding Blocks That Use a Specific Variable” on page 72-105). Also, you can export variables from the returned set of variables. For details, see “Export Workspace Variables” on page 72-110.

## Finding Blocks That Use a Specific Variable

This example shows how to use Model Explorer to get a list of blocks that use a specific workspace variable.

- 1 Open the model f14.
- 2 Open Model Explorer.
- 3 In the **Model Hierarchy** pane, select the Base Workspace node.
- 4 In the **Contents** pane, right-click the variable Mq and select **Find Where Used**.
- 5 In the **Select a system** dialog box, select f14.

- 6 Clear the **Search in referenced models** check box, since f14 does not reference any models, and click **OK**.

With **Search in referenced models** selected, you can find the target variable everywhere it is used in a model reference hierarchy. However, finding the target variable in an entire hierarchy can take more time.

The **Update diagram to include recent changes** check box is cleared by default to save time by avoiding unnecessary model diagram updates. Select the check box to incorporate recent changes you made to the model by forcing a diagram update.

- 7 Click **OK** in response to the message to update the model diagram.

Because you just opened the model, you must update the model diagram at least once before finding a variable. You could have selected **Update diagram to include recent changes** in the **Select a system** dialog box to force an initial diagram update, though you typically use that option when you make changes to the model while performing multiple searches with **Find Where Used**.

- 8 Model Explorer displays the search results:

The property columns whose values include Mq represent the block parameters that use the Mq variable. If those property columns are not already in the view, then the Model Explorer adds them to the end of the search results display.

You can also find blocks that use a specific variable by using one of these approaches:

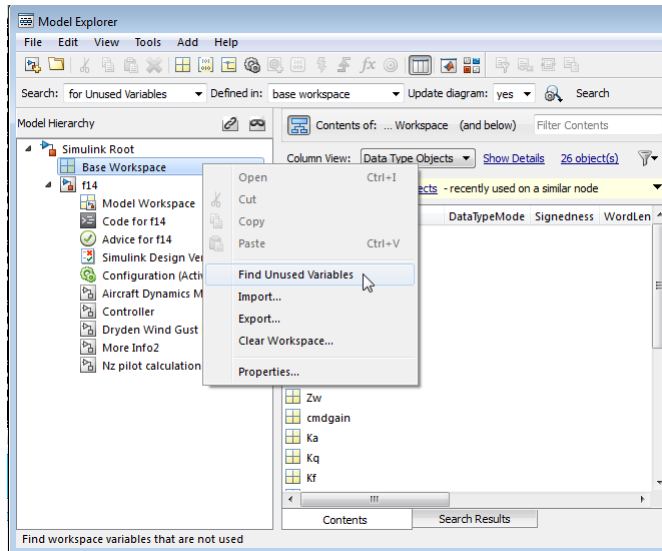

- In the search bar, select the for Variable Usage search type option.
- In the **Search Results** pane, right-click a variable and select the **Find Where Used** menu item.
- In the Model Data Editor, right-click a workspace variable and select the **Find Where Used** menu item.

## Finding Unused Workspace Variables

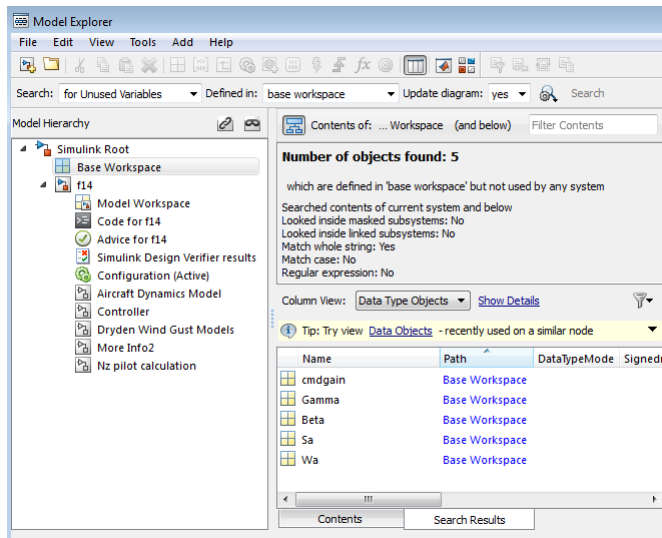

You can use the Model Explorer to get a list of variables that are defined in a workspace but not used by a model or block. One way to get that list of variables is to right-click a workspace name in the **Model Hierarchy** pane and select the **Find Unused Variables** menu item. For example:

- 1 Open the f14 model.
- 2 Open the Model Explorer.
- 3 In the search toolbar, set the **Update diagram** field to yes.

- 4 In the **Model Hierarchy** pane, right-click the Base Workspace node and select the **Find Unused Variables** menu item.

- 5 The Model Explorer displays output similar to this:

The `Simulink.findVars` function provides additional options for returning information about unused workspace variables that is not available from the Model Explorer or Simulink Editor.

## Editing Workspace Variables

In the Model Explorer, you can use the Variable Editor to edit variables from the MATLAB base workspace or model workspace. The Variable Editor is available for editing large arrays and structures.

To open the Variable Editor:

- 1 In the **Contents** pane, select the variable.
- 2 In the Dialog pane (the right pane), click the button  near the value of the variable.
- 3 In the menu, select **Open Variable Editor**.

Alternatively, to open the Variable Editor from the **Contents** pane instead of the Dialog pane, begin editing the value of the variable by clicking the appropriate cell. The button appears in the cell.

### Representation of Arrays with Three or More Dimensions

When the value of a variable or `Simulink.Parameter` object is an array with three or more dimensions, the **Value** column displays the array as an expression that contains a call to the `reshape` function.

To edit the values in the array, modify the first argument of the `reshape` call, which contains all of the array values in a serialized vector. When you add or remove elements along a dimension, you must also correct the argument that represents the length of the modified dimension.

### Rename Variables

This example shows how to use Model Explorer to rename a variable everywhere it is used by blocks in Simulink models.

- 1 Open the “Modeling an Anti-Lock Braking System” example model `sldemo_absbrake`. The model loads data to the MATLAB base workspace.
- 2 Open Model Explorer.
- 3 In the **Model Hierarchy** pane, select the base workspace.
- 4 In the **Contents** pane, right-click the base workspace variable `m` and select **Rename All**.
- 5 In the **Select a system** dialog box, click the name of the model `sldemo_absbrake` to select it as the context for renaming the variable `m`.
- 6 Clear the **Search in referenced models** check box and click **OK**. The model `sldemo_absbrake` references the model `sldemo_wheelspeed_absbrake`, but only `sldemo_absbrake` uses the variable `m`.

With **Search in referenced models** selected, you can rename the target variable everywhere it is used in a model reference hierarchy. However, renaming the target variable in an entire hierarchy can take more time.

The **Update diagram to include recent changes** check box is cleared by default to save time by avoiding unnecessary model diagram updates. Select the check box to incorporate recent changes you made to the model by forcing a diagram update.

- 7 Click **OK** in response to the message to update the model diagram.

Since you just opened the model, you must update the model diagram at least once before renaming a variable. You could have selected **Update diagram to include recent changes** in the **Select a system** dialog box to force an initial diagram update, though you typically use that option when you make changes to the model while performing multiple variable renaming operations.

- 8 In the **Rename All** dialog box, type a new name for the variable in the **New name** box and click **OK**.

You can use the hyperlinks in the **Corresponding blocks** section of the **Rename All** dialog box to view the target blocks.

---

**Note** You can rename only variables that the function `Simulink.findVars` supports.

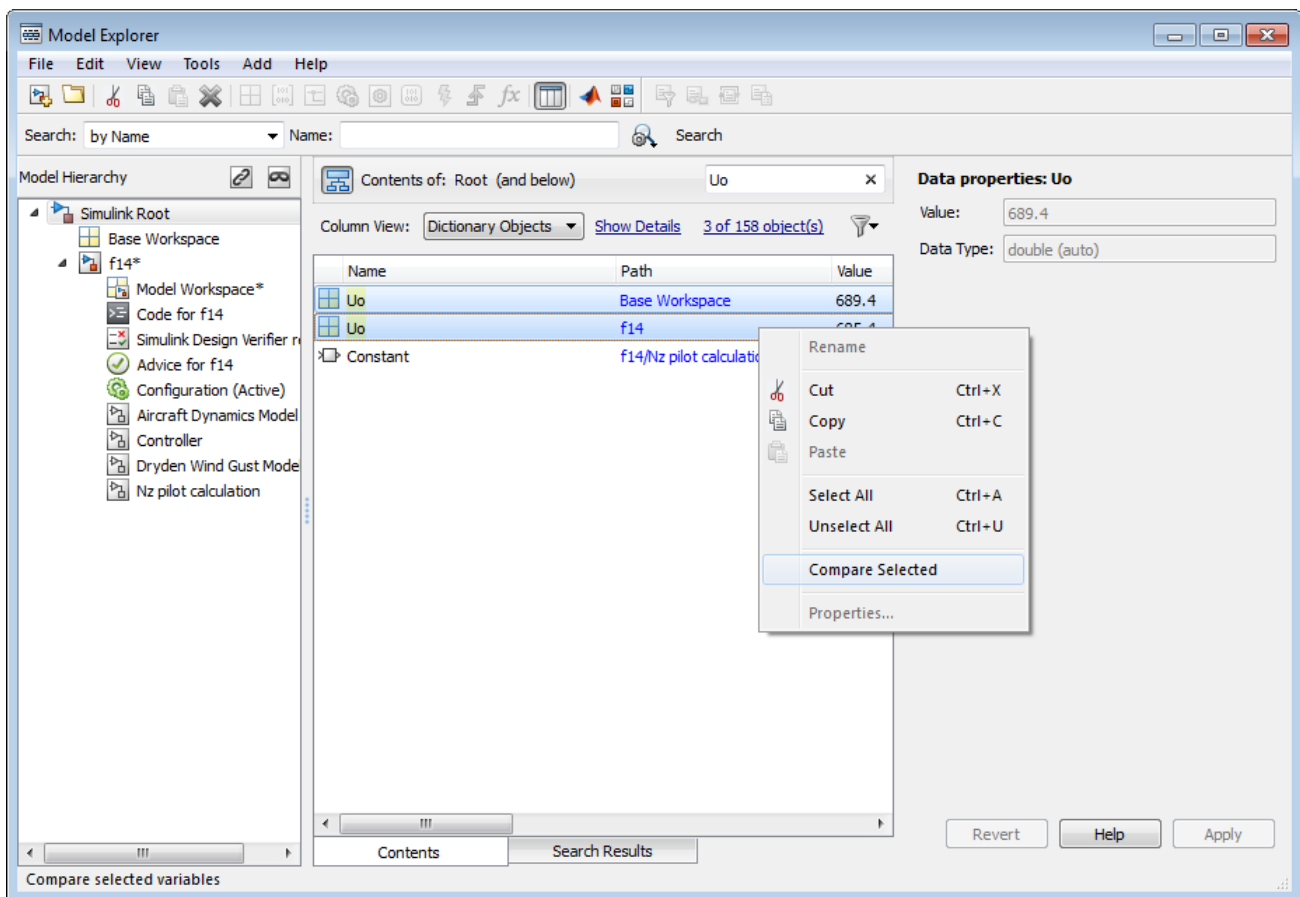

---

For help with renaming files, use a project. See “Automatic Updates When Renaming, Deleting, or Removing Files” on page 17-10.

## Compare Duplicate Workspace Variables

You can compare duplicate variables that are stored in the same workspace or in different workspaces. For example, you can compare a variable stored in the base workspace with its duplicate, which is stored in the model workspace.

- 1 Open a model and the Model Explorer.
- 2 In the search toolbar, search for the variable that is duplicated. Select the rows with the duplicate entries. Then, right-click and select **Compare Selected**.

- 3 Review the differences in the **Comparison Viewer**.

## Export Workspace Variables

You can export (save) a set of variables listed in the Model Explorer, exporting either individual variables or all the variables in the base or model workspace.

One possible workflow is to export the set of variables returned with the **Find Referenced Variables** option or the `Simulink.findVars` function. For details, see “Finding Variables That Are Used by a Model or Block” on page 72-104.

---

**Note** All the variables that you export must be from the same workspace.

---

To export all the variables in a workspace in the Model Explorer to a MATLAB code file or MAT-file:

- 1 Select the variables that you want to export.
  - a To select all the variables in a workspace, right-click the workspace node (for example, Base Workspace) and select the **Export** menu item. For example:

- b To select individual variables, in the **Contents** pane, select the variables that you want to export. Right-click one of the highlighted variables and select the **Export Selected** menu item.

If the **Contents** pane has data grouped by a property, selecting the top line in a group does not select all the variables in that group. For details about grouped data, see **Model Explorer**.

- 2 Specify whether to save the variables in a MATLAB code file or a MAT-file.

The MATLAB code file format is easier to read, is editable, and supports version control. The MAT-file format is binary, which has performance advantages.

If you specify a MATLAB code file format, the Model Explorer may create an associated MAT-file, reflecting the name of the MATLAB code file, but with an extension of `.mat` instead of `.m`.

- 3 Specify a name and location for the file.
- 4 If the file already exists, Model Explorer displays a dialog box asking you to choose one of these options:
- **Overwrite entire file**
    - Replaces all variables in the target file with the selected variables, which are stored in alphabetical order.
  - **Update variables that exist in file and append new variables to file**
    - Updates existing variables in place and appends new variables.
  - **Only update variables that exist in file**
    - Updates existing variables, but does not add any new variables, which eliminates potentially extraneous variables.

To permanently store workspace variables for a model, instead of using the base workspace, create a data dictionary. See “What Is a Data Dictionary?” on page 79-2.

## Importing Workspace Variables

You can import (load) a set of variables from a file into the base workspace or into a model workspace using the Model Explorer. When you import variables into a workspace, the Model Explorer overwrites existing variables and adds any new variables.

To import variables into a workspace:

- 1** In the **Model Hierarchy** pane, right-click the workspace into which you want to import variables.
- 2** Select the **Import** menu item.
- 3** In the Import from File dialog box, select a MATLAB code file or MAT-file for the variables that you want to import.

---

**Note** If you import a MATLAB code file, then Simulink also imports the associated MAT-file.

---

## Model Workspaces

### In this section...

“Model Workspace Differences from MATLAB Workspace” on page 72-113

“Troubleshooting Memory Issues” on page 72-113

“Manipulate Model Workspace Programmatically” on page 72-114

### Model Workspace Differences from MATLAB Workspace

Each model is provided with its own workspace for storing variable values.

The model workspace is similar to the base MATLAB workspace except that:

- Variables in a model workspace are visible only in the scope of the model.

If both the MATLAB workspace and a model workspace define a variable of the same name, and the variable does not appear in any intervening masked subsystem or model workspaces, the Simulink software uses the value of the variable in the model workspace. A model's workspace effectively provides it with its own name space, allowing you to create variables for the model without risk of conflict with other models.

- When the model is loaded, the workspace is initialized from a data source.

The data source can be a Model file, a MAT-file, a MATLAB file, or MATLAB code stored in the model file. For more information, see “Data source” on page 72-116.

- You can interactively reload and save MAT-file, MATLAB file, and MATLAB code data sources.
- To store a signal object in a model workspace, set the storage class of the object to `Auto`. Signal objects include `Simulink.Signal` and subclasses that you create.

If you specify a storage class other than `Auto`, you must store signal objects in the base workspace or a data dictionary to ensure the objects are unique within the global Simulink context and accessible to all models.

- When you store MATLAB variables and parameter objects (such as `Simulink.Parameter`) in a model workspace, some tunability limitations apply. See “Tunability Considerations and Limitations for Other Modeling Goals” on page 40-36. In addition, if you store an `AUTOSAR.Parameter` object in a model workspace, the code generator ignores the storage class that you specify for the object.

---

**Note** When resolving references to variables used in a referenced model, the variables of the referenced model are resolved as if the parent model did not exist. For example, suppose a referenced model references a variable that is defined in both the parent model's workspace and in the MATLAB workspace but not in the referenced model's workspace. In this case, the MATLAB workspace is used.

---

### Troubleshooting Memory Issues

When you use a workspace variable as a block parameter, Simulink creates a copy of the variable during the compilation phase of the simulation and stores the variable in memory. This can cause

your system to run out of memory during simulation, or in the process of generating code. Your system might run out of memory if you have:

- Large models with many parameters
- Models with parameters that have a large number of elements

This issue does not affect the amount of memory that is used to represent parameters in generated code.

## **Manipulate Model Workspace Programmatically**

An object of the `Simulink.ModelWorkspace` class describes a model workspace. Simulink creates an instance of this class for each model that you open during a Simulink session. The methods associated with this class can be used to accomplish a variety of tasks related to the model workspace, including:

- Listing the variables in the model workspace
- Assigning values to variables
- Evaluating expressions
- Clearing the model workspace
- Reloading the model workspace from the data source
- Saving the model workspace to a specified MAT-file or MATLAB file
- Saving the workspace to the MAT-file or MATLAB file that the workspace designates as its data source

### **See Also**

`Simulink.ModelWorkspace`

## Specify Source for Data in Model Workspace

When you use a model workspace to contain the variables that a model uses, you can choose to store the variables in one of these sources:

- The model file, which can store static variable definitions.
- A separate MAT-file or MATLAB file. You can reload the variables from the external file into the model workspace at any time.
- Your own custom MATLAB code that creates variables. You can save the code as part of the model file, and reload the code at any time.

To specify a data source for a model workspace, in the Model Explorer, use the Model Workspace dialog box. To display the dialog box for a model workspace:

- 1 Open the Model Explorer. On the **Modeling** tab, click **Model Data Editor**.
- 2 In the **Model Hierarchy** pane, right-click the model workspace.

- 3 Select the **Properties** menu item, which opens the Model Workspace dialog box.

To use MATLAB commands to change data in a model workspace, see “Use MATLAB Commands to Change Workspace Data” on page 72-119.

## Data source

The **Data source** field in the Model Workspace dialog box includes the following data source options for a workspace:

- Model File

Specifies that the data source is the model itself.

- MAT-File

Specifies that the data source is a MAT file. Selecting this option causes additional controls to appear (see “MAT-File and MATLAB File Source Controls” on page 72-116).

- MATLAB File

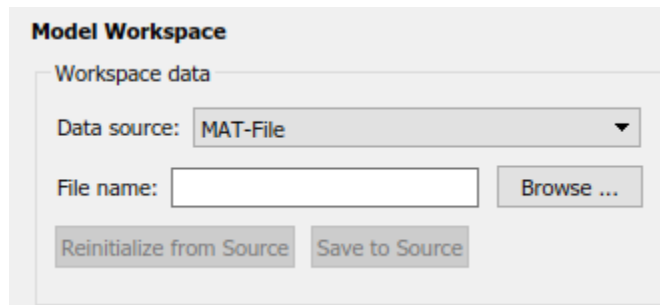

Specifies that the data source is a MATLAB file. Selecting this option causes additional controls to appear (see “MAT-File and MATLAB File Source Controls” on page 72-116).

- MATLAB Code

Specifies that the data source is MATLAB code stored in the model file. Selecting this option causes additional controls to appear (see “MATLAB Code Source Controls” on page 72-117).

## MAT-File and MATLAB File Source Controls

Selecting MAT-File or MATLAB File as the **Data source** for a workspace causes the Model Workspace dialog box to display additional controls.

### File name

Specifies the file name or path name of the MAT-file or MATLAB file that is the data source for the selected workspace. If you specify a file name, the name must reside on the MATLAB path.

### Reinitialize From Source

Clears the workspace and reloads the data from the MAT-file or MATLAB file specified by the **File name** field.

### Save To Source

Saves the workspace in the MAT-file or MATLAB file specified by the **File name** field.

## MATLAB Code Source Controls

Selecting MATLAB Code as the **Data source** for a workspace causes the Model Workspace dialog box to display additional controls.

### MATLAB Code

Specifies MATLAB code that initializes the selected workspace. To change the initialization code, edit this field, then select the **Reinitialize from source** button on the dialog box to clear the workspace and execute the modified code.

### Reinitialize from Source

Clears the workspace and executes the contents of the **MATLAB Code** field.

### Create Model Mask

Mask the model, which enables you to control how users of the model interact with model arguments. For more information, see “Introduction to System Mask” on page 42-42.

- “Change Model Workspace Data” on page 72-118

## Change Model Workspace Data

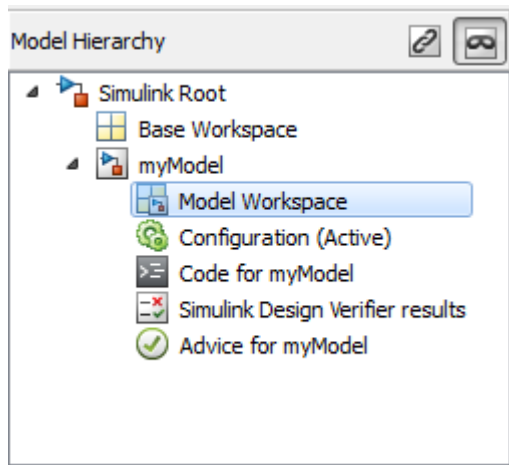

When you use a model workspace to contain the variables that a model uses, you choose a source to store the variables, such as the model file or an external MAT-file. To modify the variables at the source, you use a different procedure depending on the type of source that you selected.

### Change Workspace Data Whose Source Is the Model File

If the data source of a model workspace is the model file, you can use Model Explorer or MATLAB commands to modify the stored variables (see “Use MATLAB Commands to Change Workspace Data” on page 72-119).

For example, to create a variable in a model workspace:

- 1 Open the Model Explorer. On the **Modeling** tab, click **Model Explorer** or press **Ctrl+H**.
- 2 In the Model Explorer **Model Hierarchy** pane, expand the node for your model, and select the model workspace.

- 3 Select **Add > MATLAB Variable**.

You can similarly use the **Add** menu or toolbar to add a `Simulink.Parameter` object to a model workspace.

To change the value of a model workspace variable:

- 1 Open the Model Explorer. On the **Modeling** tab, click **Model Explorer**.
- 2 In the Model Explorer **Model Hierarchy** pane, select the model workspace.
- 3 In the **Contents** pane, select the variable.
- 4 In the **Contents** pane or in **Dialog** pane, edit the value displayed.

To delete a model workspace variable:

- 1 Open the Model Explorer. On the **Modeling** tab, click **Model Explorer**.
- 2 In the Model Explorer **Model Hierarchy** pane, select the model workspace.

- 3 In **Contents** pane, select the variable.
- 4 Select **Edit > Delete**.

## Change Workspace Data Whose Source Is a MAT-File or MATLAB File

You can use Model Explorer or MATLAB commands to modify workspace data whose source is a MAT-file or MATLAB file.

To make the changes permanent, in the Model Workspace dialog box, use the **Save To Source** button to save the changes to the MAT-file or MATLAB file.

- 1 Open the Model Explorer. On the **Modeling** tab, click **Model Explorer**.
- 2 In the Model Explorer **Model Hierarchy** pane, right-click the workspace.
- 3 Select the **Properties** menu item.
- 4 In the Model Workspace dialog box, use the **Save To Source** button to save the changes to the MAT-file or MATLAB file.

To discard changes to the workspace, in the Model Workspace dialog box, use the **Reinitialize From Source** button.

## Changing Workspace Data Whose Source Is MATLAB Code

The safest way to change data whose source is MATLAB code is to edit and reload the source. Edit the MATLAB code and then in the Model Workspace dialog box, use **Reinitialize From Source** button to clear the workspace and re-execute the code.

To save and reload alternative versions of the workspace that result from editing the MATLAB code source or the workspace variables themselves, see “Export Workspace Variables” on page 72-110 and “Importing Workspace Variables” on page 72-112.

## Use MATLAB Commands to Change Workspace Data

To use MATLAB commands to change data in a model workspace, first get the workspace for the currently selected model:

```
hws = get_param(bdroot, 'modelworkspace');
```

This command returns a handle to a `Simulink.ModelWorkspace` object whose properties specify the source of the data used to initialize the model workspace. Edit the properties to change the data source.

Use the workspace methods to:

- List, set, and clear variables
- Evaluate expressions in the workspace
- Save and reload the workspace

For example, the following MATLAB code creates variables specifying model parameters in the model workspace, saves the parameters, modifies one of them, and then reloads the workspace to restore it to its previous state.

```
hws = get_param(bdroot, 'modelworkspace');  
hws.DataSource = 'MAT-File';  
hws.FileName = 'params';  
hws.assignin('pitch', -10);  
hws.assignin('roll', 30);  
hws.assignin('yaw', -2);  
hws.saveToSource;  
hws.assignin('roll', 35);  
hws.reload;
```

To programmatically access variables for the purpose of sweeping block parameter values, consider using `Simulink.SimulationInput` objects instead of modifying the variables through the programmatic interface of the model workspace. See “Optimize, Estimate, and Sweep Block Parameter Values” on page 40-38.

## Create Model Mask

Mask the model, which enables you to control how users of the model interact with model arguments. For more information, see “Introduction to System Mask” on page 42-42.

## Create External File Adapter for Loading Variables into Simulink.SimulationInput Object

You can create and register a custom file adapter that the `loadVariablesFromExternalSource` function uses to load variables from a custom external source file into a `Simulink.SimulationInput` object. This simulation object allows you to temporarily make changes to a model and run simulations with those changes. To create an adapter for your custom file format:

- 1 Write a class definition for your custom file adapter derived from the `Simulink.data.adapters.BaseMatlabFileAdapter` base class.
- 2 Test that the adapter can load data from a supported external file source.
- 3 Register the adapter and make it available on the MATLAB path.

### Write Class Definition for Custom File Adapter

In this example, write a custom file adapter for an XML file with a format similar to the following.

```
<customerData>
  <x>10</x>
  <y>15</y>
</customerData>
```

To write a custom file adapter, you must first create a new class that derives from the base file adapter class `Simulink.data.adapters.BaseMatlabFileAdapter`.

```
classdef xml_adapter < Simulink.data.adapters.BaseMatlabFileAdapter
```

#### Required File Adapter Code Definitions

In your new file adapter class, you must provide code definitions for these methods:

- `getAdapterName`
- `getSupportedExtensions`
- `getData`

The `getAdapterName` method provides the display name for the adapter. This display name is used by the `Simulink.data.adapters.catalog` function to list available registered adapters. The display name is also used in the user interface and in error messages.

```
function name = getAdapterName(adapterObj)
    name = 'XML Adapter';
end
```

The `getSupportedExtensions` method defines the file extensions that the file adapter supports. When you call the `loadVariablesFromExternalSource` function, Simulink uses this method to determine if there is a registered adapter that supports the format of the external source file. Use the `Simulink.data.adapters.catalog` function to display registered adapters and their supported extensions.

```
function fileExtensions = getSupportedExtensions(adapterObj)
    fileExtensions = {'.XML'};
end
```

The `getData` method populates the data from an external source file into a workspace for that data source. The method receives a `Simulink.data.DataSourceWorkspace` object and an empty diagnostic structure.

The method reads data from the external source and populates it into the workspace object in the form of MATLAB variables and objects. The workspace acts as a cache for Simulink, and symbol resolution includes symbols in the workspace. Using the workspace object functions, you can interact with a data source workspace just as you do with a base workspace. You can get, set, clear, list, and query variables in the workspace and run MATLAB scripts.

The empty diagnostic structure allows you to specify error information that the `getData` method can return. The diagnostic structure has these fields.

Field	Description
AdapterDiagnostic	Type of error, specified as an enumeration value from the enumeration class <code>Simulink.data.adapters.AdapterError</code> . These are the possible enumeration values. <ul style="list-style-type: none"> <li>• NoDiagnostic (default)</li> <li>• GenericFailure</li> <li>• HardError</li> <li>• Inaccessible</li> <li>• AmbiguousSource</li> <li>• NoPermission</li> <li>• UnrecognizedFormat</li> <li>• Unsupported</li> </ul>
DiagnosticMessage	Message to return as the error text, specified as a string. When <code>AdapterDiagnostic</code> is set to <code>NoDiagnostic</code> , the value is an empty string.

Here is an example of a `getData` implementation for your XML file. Because each call to the `getData` method on the same source file uses the same data source workspace object as the last call to the method, begin the `getData` code definition by clearing the variables from the workspace.

```
function diagnostic = getData(adapterObj, sourceWorkspace, previousChecksum, diagnostic)
    % Each time getData is called on the same source, sourceWorkspace is the same as
    % the last time it was called. Clear it to make sure no old variables exist.
    clearAllVariables(sourceWorkspace);
    dom = xmlread(adapterObj.source);
    tree = dom.getFirstChild;
    if tree.hasChildNodes
        item = tree.getFirstChild;
        while ~isempty(item)
            name = item.getNodeName.toCharArray';
            if isvarname(name)
                value = item.getTextContent;
                setVariable(sourceWorkspace, name, str2num(value));
            end
            item = item.getNextSibling;
        end
    end
end
```

```

    end
end

```

### Optional File Adapter Code Definitions

In addition to the code definitions you must provide for your file adapter, you might also choose to override the code definitions for these methods:

- `open` — Called when the file adapter is first loaded. By default, this method saves the source file name and section name as properties of the file adapter.
- `close` — Called when the file adapter is finished.
- `isSourceValid` — By default, this method validates that the source file exists and that the file adapter supports the file extension.
- `supportsReading` — By default, this method validates that the source file has read attributes. You can override this method to allow multiple adapters to read the same file types but with different headers. For example:

```

function retVal = supportsReading(adapterObj, source)
    retVal = false;
    % call base class method to ensure permissions are correct
    if supportsReading@Simulink.data.adapters.BaseMatlabFileAdapter(adapterObj, source)
        dom = xmlread(source);
        tree = dom.getFirstChild;
        if strcmpi(tree.getNodeName, "customerData")
            retVal = true;
        end
    end
end

```

- `getSectionNames` — By default, this method returns the adapter display name returned by the `getAdapterName` method. You can override the method to define a logical division of the data contained in the external file. For example, consider a car manufacturer with a spreadsheet containing data for different tires. A file adapter used to load data from the spreadsheet can divide the data into sections based on the tire manufacturer. This section definition allows the car manufacturer to load the data into a set of `Simulink.SimulationInput` objects (one for each type of tire) that can be used by the `parsim` function to run parallel simulations.
- `getCurrentChecksum` — By default, this method returns the returns the timestamp for the last modified date of the file. The cache uses this method to determine if the adapter needs to get updates from the external file.

### Test Custom File Adapter

Before registering your file adapter, you can test that it can load variables from a supported external source file by using a `Simulink.data.adapters.AdapterDataTester` object. Create the test object using an instance of your custom file adapter class, an external source file, and a section name.

```
adapterTester = Simulink.data.adapters.AdapterDataTester(adapterObj, 'test.xml', 'XML Adapter');
```

The `readFromSource` function of the `Simulink.data.adapters.AdapterDataTester` object calls the `getData` method for your adapter and returns the variables read from the external source file into the `WorkspaceVariables` property of the tester object.

```
readFromSource(adapterTester);
variables = adapterTester.WorkspaceVariables
```

The `WorkspaceVariables` property is a `containers.Map` object that uses the variables as the key set.

```
variables =  
  Map with properties:  
    Count: 2  
    KeyType: char  
    ValueType: double
```

```
variables.keys
```

```
ans =  
  1x2 cell array  
    {"x"} {"y"}
```

```
variables[x]
```

```
ans =  
  10
```

```
variables[y]
```

```
ans =  
  15
```

To test the adapter again with different data in the file, first use the `clear` function to clear the workspace variables.

```
clear(adapterTester);
```

Then, update the XML file with this data.

```
<customerData>  
  <a>3</a>  
  <b>4</b>  
</customerData>
```

```
readFromSource(adapterTester);  
variables = adapterTester.WorkspaceVariables
```

```
variables =  
  Map with properties:  
    Count: 2  
    KeyType: char  
    ValueType: double
```

```
variables.keys
```

```
ans =  
  1x2 cell array  
    {"a"} {"b"}
```

```
variables[a]
```

```
ans =  
  3
```

```
variables[b]
```

```
ans =  
  4
```

## Register Custom File Adapter

Now that you have written and tested your file adapter, you must register the adapter before it can be used. Consider adding the registration to a startup script, since an adapter must be registered at the start of each MATLAB session. These functions allow you to manage your file adapter registrations.

- `Simulink.data.adapters.registerAdapter` — Registers your file adapter.
- `Simulink.data.adapters.unregisterAdapter` — Unregisters your file adapter.
- `Simulink.data.adapters.catalog` — Displays a list of registered file adapters. For each adapter, the display provides the class name, display name, supported extensions, and full path of the adapter class.

## Use Custom File Adapter to Load Variables for Simulation

Once you have registered the file adapter, it is available for use by the `loadVariablesFromExternalSource` function to load data from files supported by the adapter.

## Symbol Resolution

### In this section...

“Symbols” on page 72-126  
 “Symbol Resolution Process” on page 72-126  
 “Numeric Values with Symbols” on page 72-127  
 “Other Values with Symbols” on page 72-128  
 “Limit Signal Resolution” on page 72-128  
 “Explicit and Implicit Symbol Resolution” on page 72-128

### Symbols

When you create a Simulink model, you can use symbols to provide values and definitions for many types of entities in the model. Model entities that you can define with symbols include block parameters, configuration set parameters, data types, signals, signal properties, and bus architecture.

A symbol that provides a value or definition must be a legal MATLAB identifier. Such an identifier starts with an alphabetic character, followed by alphanumeric or underscore characters up to the length given by the function `namelengthmax`. You can use the function `isvarname` to determine whether a symbol is a legal MATLAB identifier.

A symbol provides a value or definition in a Simulink model by corresponding to some item that:

- Exists in an accessible workspace
- Has a name that matches the symbol
- Provides the required information

### Symbol Resolution Process

The process of finding an item that corresponds to a symbol is called *symbol resolution* or *resolving the symbol*. The matching item can provide the needed information directly, or it can itself be a symbol. A symbol must resolve to some other item that provides the information.

When the Simulink software compiles a model, it tries to resolve every symbol in the model, except symbols in MATLAB code that runs in a callback or as part of mask initialization. Depending on the particular case, the item to which a symbol resolves can be a variable, object, or function.

Simulink attempts to resolve a symbol by searching through the accessible workspaces in hierarchical order for a MATLAB variable or Simulink object whose name is the same as the symbol.

The search path is identical for every symbol. The search begins with the block that uses the symbol, or is the source of a signal that is named by the symbol, and proceeds upward. Except when simulation occurs via the `sim` command, the search order is:

- 1 Any mask workspaces, in order from the block upwards (see “Masking Fundamentals” on page 42-3).
- 2 The model workspace of the model that contains the block (see “Model Workspaces” on page 72-113).

- 3 The MATLAB base workspace (see “Create and Edit Variables”) or, if the model is linked to a data dictionary, the dictionary (see “What Is a Data Dictionary?” on page 79-2). If the data dictionary has the **Enable dictionary access to base workspace** property selected, the search treats the dictionary and the base workspace as a single namespace.

---

**Note** If the model references a configuration set that is stored in the base workspace, the search begins in the base workspace. Unlike a configuration set that is attached to the model, a configuration set that is in the base workspace does not have access to the model workspace.

The **Input** and **Initial state** parameters do not load data from a data dictionary. When a model uses a data dictionary and you disable model access to the base workspace, the **Input** and **Initial state** parameters still access data in the base workspace.

---

If Simulink finds a matching item in the course of this search, the search terminates successfully at that point, and the symbol resolves to the matching item. The result is the same as if the value of that item had appeared literally instead of the symbol that resolved to the item. An object defined at a lower level shadows any object defined at a higher level.

If no matching item exists on the search path, Simulink attempts to evaluate the symbol as a function. If the function is defined and returns an appropriate value, the symbol resolves to whatever the function returned. Otherwise, the symbol remains unresolved, and an error occurs. Evaluation as a function occurs as the final step whenever a hierarchical search terminates without having found a matching workspace variable.

If the model that contains the symbol is a referenced model, and the search reaches the model workspace but does not succeed there, the search jumps directly to the base workspace or data dictionary *without* trying to resolve the symbol in the workspace of any parent model. Thus a given symbol resolves to the same item, irrespective of whether the model that contains the symbol is a referenced model. For information about model referencing, see “Model References”.

## Numeric Values with Symbols

You can specify any block parameter that requires a numeric value by providing a literal value, a symbol, or an expression, which can contain symbols and literal values. Each symbol is resolved separately, as if none of the others existed. Different symbols in an expression can thus resolve to items on different workspaces, and to different types of item.

When a single symbol appears and resolves successfully, its value provides the value of the parameter. When an expression appears, and all symbols resolve successfully, the value of the expression provides the value of the parameter. If any symbol cannot be resolved, or resolves to a value of inappropriate type, an error occurs.

For example, suppose that the **Gain** parameter of a Gain block is given as  $\cos(a*(b+2))$ . The symbol `cos` will resolve to the MATLAB cosine function, and `a` and `b` must resolve to numeric values, which can be obtained from the same or different types of items in the same or different workspaces. If the symbols resolve to numeric values, the value returned by the cosine function becomes the value of the **Gain** parameter.

## Other Values with Symbols

Most symbols and expressions that use them provide numeric values, but the same techniques that provide numeric values can provide any type of value that is appropriate for its context.

Another common use of symbols is to name objects that provide definitions of some kind. For example, a signal name can resolve to a signal object (`Simulink.Signal`) that defines the properties of the signal, and a Bus Creator block **Data type** parameter can name a bus object (`Simulink.Bus`) that defines the properties of the bus. You can use symbols for many purposes, including:

- Define data types
- Specify input data sources
- Specify logged data destinations

For hierarchical symbol resolution, all of these different uses of symbols, whether singly or in expressions, are the same. Each symbol is resolved, if possible, independently of any others, and the result becomes available where the symbol appeared. The only difference between one symbol and another is the specific item to which the symbol resolves and the use made of that item. The only requirement is that every symbol must resolve to something that can legally appear at the location of the symbol.

## Limit Signal Resolution

Hierarchical symbol resolution traverses the complete search path by default. You can truncate the search path by using the **Permit Hierarchical Resolution** option of any subsystem. This option controls what happens if the search reaches that subsystem without resolving to a workspace variable. The **Permit Hierarchical Resolution** values are:

- All

Continue searching up the workspace hierarchy trying to resolve the symbol. This is the default value.

- None

Do not continue searching up the hierarchy.

- `ExplicitOnly`

Continue searching up the hierarchy only if the symbol specifies a block parameter value, data store memory (where no block exists), or a signal or state that explicitly requires resolution. Do not continue searching for an implicit resolution. See “Explicit and Implicit Symbol Resolution” on page 72-128 for more information.

If the search does not find a match in the workspace, and terminates because the value is `ExplicitOnly` or `None`, Simulink evaluates the symbol as a function. The search succeeds or fails depending on the result of the evaluation, as previously described.

## Explicit and Implicit Symbol Resolution

Models and some types of model entities have associated parameters that can affect symbol resolution. For example, suppose that a model includes a signal named `Amplitude`, and that a

Simulink.Signal object named Amplitude exists in an accessible workspace. If the Amplitude signal's **Signal name must resolve to Simulink signal object** option is selected, the signal resolves to the object. For more information, see **Signal Properties**.

If the option is not selected, the signal may or may not resolve to the object, depending on the value of **Configuration Parameters > Diagnostics > Data Validity > Signal resolution**. This parameter can suppress resolution to the object even though the object exists, or it can specify that resolution occurs on the basis of the name match alone. For more information, see “Model Configuration Parameters: Data Validity Diagnostics” > “Signal resolution”.

Resolution that occurs because an option such as **Signal name must resolve to Simulink signal object** requires it is called *explicit symbol resolution*. Resolution that occurs on the basis of name match alone, without an explicit specification, is called *implicit symbol resolution*.

---

**Tip** Implicit symbol resolution can be useful for fast prototyping. However, when you are done prototyping, consider using explicit symbol resolution, because implicit resolution slows performance, complicates model validation, and can have nondeterministic effects.

---

- “Model Workspaces” on page 72-113

## Upgrade Level-1 Data Classes

Simulink no longer supports level-1 data classes. You must upgrade data classes that you created using the level-1 data class infrastructure, which was removed in a previous release.

Run the following utility function while specifying the destination folder for the upgraded classes.

---

**Note** Property types defined in level-1 data classes that are not subclasses of `Simulink.Parameter`, `Simulink.Signal`, or `Simulink.CustomStorageClassAttributes` are not preserved during an upgrade. Only subclasses of these three classes will preserve attributes `PropertyType` and `AllowedValues`.

---

- 1 This command upgrades all your level-1 data class packages. You cannot upgrade selected data packages.

```
Simulink.data.upgradeClasses('C:\MyDataClasses')
```

Here, `C:\MyDataClasses` is the destination folder for your level-2 data classes.

---

**Note** Do not place your upgraded level-2 classes and their equivalent level-1 classes in the same folder.

---

`Simulink.data.upgradeClasses` uses the `packagedefn.mat` file in your level-1 class packages for the upgrade and creates level-2 classes in the specified destination folder. Then, `Simulink.data.upgradeClasses` adds the folder to top of the MATLAB path and saves the path.

---

**Note** If `Simulink.data.upgradeClasses` cannot save the MATLAB path because of restricted access, a warning appears. In this case, manually add the folder to the top of the MATLAB path and save the path using `savepath`.

---

- 2 You can change the location of the level-2 package folders after they have been generated. However, you will need to update your MATLAB path so that MATLAB can find these package folders.
- 3 Resave MAT-files and models that contain level-1 data objects.
- 4 Retain your level-1 classes on the MATLAB path until you have resaved all of your models and MAT-files that contain level-1 data objects. Any models or MAT-files that contain level-1 data objects will continue to load successfully while your level-1 data classes are on the MATLAB path.

---

**Note** You cannot use both level-1 and level-2 data classes at the same time. Level-2 classes need to be above the level-1 classes on the MATLAB path so that they are found by MATLAB.

---

- “Data Objects” on page 72-61

## Associating User Data with Blocks

You can use the `set_param` command to associate your own data with a block. For example, the following command associates the value of the variable `mydata` with the currently selected block.

```
set_param(gcf, 'UserData', mydata)
```

The value of `mydata` can be any MATLAB data type, including arrays, structures, objects, and Simulink data objects.

Use `get_param` to retrieve the user data associated with a block.

```
get_param(gcf, 'UserData')
```

The following command saves the user data associated with a block in the model file of the model containing the block.

```
set_param(gcf, 'UserDataPersistent', 'on');
```

---

**Note** If persistent `UserData` for a block contains any Simulink data objects, the directories containing the definitions for the classes of those objects must be on the MATLAB path when you open the model containing the block.

---

## Support Limitations for Simulink Software Features

Simulink Design Verifier does not support the following Simulink software features. Avoid using these unsupported features.

Not Supported	Description
Variable-step solvers	<p>The software supports only fixed-step solvers.</p> <p>For more information, see “Fixed Step Solvers in Simulink” on page 27-24.</p>
Callback functions	<p>The software does not execute model callback functions during the analysis. The results that the analysis generates, such as the harness model, may behave inconsistently with the expected behavior.</p> <ul style="list-style-type: none"> <li>• If a model or any referenced model calls a callback function that changes any block parameters, model parameters, or workspace variables, the analysis does not reflect those changes.</li> <li>• Changing the storage class of base workspace variables on model callback functions or mask initializations is not supported.</li> <li>• Callback functions called prior to analysis, such as the <code>PreLoadFcn</code> or <code>PostLoadFcn</code> model callbacks, are fully supported.</li> </ul>
Model callback functions	<p>The software supports model callback functions only if the <code>InitFcn</code> callback of the model is empty.</p>
Algebraic loops	<p>The software does not support models that contain algebraic loops.</p> <p>For more information, see “Algebraic Loop Concepts” on page 3-39.</p>
Masked subsystem initialization functions	<p>The software does not support models whose masked subsystem initialization:</p> <ul style="list-style-type: none"> <li>• Modifies any attribute of any workspace parameter.</li> <li>• Deletes or creates blocks.</li> </ul>

Not Supported	Description
Variable-size signals	<p>The software supports test generation for models with bounded variable-size signals. For more information on how to generate test cases when input signals are of variable-size, see “Achieve Coverage in Models with Variable-Size Inputs” (Simulink Design Verifier).</p> <p>In addition, the following are the limitations for analysis:</p> <ol style="list-style-type: none"> <li>1 Relational boundary coverage objectives</li> <li>2 Enhanced MCDC coverage objectives</li> <li>3 Models with variable-size signals at root level input port</li> <li>4 Models with variable-size signals with maximum size 1</li> </ol> <hr/> <p><b>Note</b></p> <ul style="list-style-type: none"> <li>• Coverage objectives of single port logical and min-max blocks with variable size signals are not considered.</li> <li>• The analysis is performed under the assumptions that at any step, all the variable-size inputs of a block will have same size.</li> </ul>
Multiword fixed-point data types	The software does not support multiword fixed-point data types larger than 128 bits.
Nonzero start times	<p>Although Simulink allows you to specify a nonzero simulation start time, the analysis generates signal data that begins only at zero. If your model specifies a nonzero start time:</p> <ul style="list-style-type: none"> <li>• If you do not select the <b>Reference input model in generated harness</b> parameter (the default), the harness model is a subsystem. The analysis sets the start time of the harness model to 1 and continues the analysis.</li> <li>• If you select the <b>Reference input model in generated harness</b> parameter, a Model block references the harness model. The software cannot change the start time of the harness model, so the analysis stops and you see a recommendation to set the <b>Start time</b> parameter to 0.</li> <li>• Simulink Design Verifier assumes zero start time for analysis and generates signal data that begins at zero. Zero start time might impact the reporting of the objective status. For example, in the test generation analysis, the software might report some objectives as <b>Undecided with Testcases</b>. For more information, see “Simulation Basics” on page 27-2.</li> </ul>

Not Supported	Description
Nonfinite data	<p>The software does not support nonfinite data (for example, NaN and Inf) and related operations.</p> <p>In the Relational Operator block, the software assigns the output as follows:</p> <ul style="list-style-type: none"> <li>• If the <b>Relational operator</b> parameter is <code>isFinite</code>, the output is always 1.</li> <li>• If the <b>Relational operator</b> parameter is <code>isNan</code> or <code>isInf</code>, the output is always 0.</li> </ul> <p>In the MATLAB Function block, the software assigns the return value as follows:</p> <ul style="list-style-type: none"> <li>• For the <code>isFinite</code> function, the output is always 1.</li> <li>• For the <code>isNan</code> and <code>isInf</code> functions, the output is always 0.</li> </ul>
Concurrent execution	The software does not support models that are configured for concurrent execution.
Signals with nonzero sample time offset	The software does not support models with signals that have nonzero sample time offsets.
Models with no output ports	The software only supports models that have one or more output ports. If a model contains test condition or test objective blocks and no output ports are present in the model, then nominal test cases will be generated.
Large floating-point constants outside the range $[-\text{realmax}/2, \text{realmax}/2]$	The use of large floating-point constants can cause out of memory errors or substantial loss of precision. Avoid using such constants if possible.
Symbolic Dimensions	The software does not support symbolic dimensions for test generation, property proving, or design error detection.
Simulink Strings	Models that contain blocks with string data types as block parameters are not supported. For more information, see “Simulink Strings” on page 72-43.
Parameter Tuning	The software does not support parameter tuning for the parameters that are defined in the Model Workspace.
Row-major Algorithms	The software does not support models that contain MATLAB System blocks that use <code>coder.rowMajor</code> directive. For more information see, “Use algorithms optimized for row-major array layout”.

## Supported and Unsupported Simulink Blocks

The Simulink Design Verifier provides various levels of support for Simulink blocks:

- Fully supported
- Partially supported
- Not supported

If your model contains unsupported blocks, you can enable automatic stubbing. Automatic stubbing considers the interface of the unsupported blocks, but not their behavior. If any of the unsupported blocks affect the simulation outcome, however, the analysis may achieve only partial results. For details about automatic stubbing, see “Handle Incompatibilities with Automatic Stubbing” (Simulink Design Verifier).

To achieve 100% coverage, avoid using unsupported blocks in models that you analyze. Similarly, for partially supported blocks, specify only the block parameters that the software recognizes.

The following tables summarize the Simulink Design Verifier analysis support for Simulink blocks. Each table lists the blocks in a Simulink library and describes support information for that particular block.

### Additional Math and Discrete Library

The software supports all blocks in the Additional Math and Discrete library.

### Commonly Used Blocks Library

The Commonly Used Blocks library includes blocks from other libraries. Those blocks are listed under their respective libraries.

### Continuous Library

Block	Support Notes
Derivative	Not supported
Integrator	Not supported
Integrator Limited	Not supported
PID Controller	Not supported
PID Controller (2DOF)	Not supported
Second-Order Integrator	Not supported
Second-Order Integrator Limited	Not supported
State-Space	Not supported
Transfer Fcn	Not supported
Transport Delay	Not supported
Variable Time Delay	Not supported
Variable Transport Delay	Not supported
Zero-Pole	Not supported

### Discontinuities Library

The software supports all blocks in the Discontinuities library.

### Discrete Library

Block	Support Notes
Delay	Supported
Difference	Supported
Discrete Derivative	Supported
Discrete Filter	Supported
Discrete FIR Filter	Supported
Discrete PID Controller	Supported
Discrete PID Controller (2DOF)	Supported
Discrete State-Space	Not supported
Discrete Transfer Fcn	Supported
Discrete Zero-Pole	Not supported
Discrete-Time Integrator	Supported
Memory	Supported
Tapped Delay	Supported
Transfer Fcn First Order	Supported
Transfer Fcn Lead or Lag	Supported
Transfer Fcn Real Zero	Supported
Unit Delay	Supported
Zero-Order Hold	Supported

### Logic and Bit Operations Library

The software supports all blocks in the Logic and Bit Operations library.

### Lookup Tables Library

Block	Support Notes
Cosine	Supported
Direct Lookup Table (n-D)	Supported
Interpolation Using Prelookup	Partially supported when: <ul style="list-style-type: none"> <li>• The <b>Interpolation method</b> parameter is <b>Linear</b> and the <b>Number of table dimensions</b> parameter is greater than 4.</li> </ul> or <ul style="list-style-type: none"> <li>• The <b>Interpolation method</b> parameter is <b>Linear</b> and the <b>Number of sub-table selection dimensions</b> parameter is not 0.</li> </ul>

Block	Support Notes
1-D Lookup Table	Partially supported when the <b>Interpolation method</b> or the <b>Extrapolation method</b> parameter is Cubic Spline.
2-D Lookup Table	Not supported when the <b>Interpolation method</b> or the <b>Extrapolation method</b> parameter is Akima Spline.
n-D Lookup Table	Partially supported when: <ul style="list-style-type: none"> <li>The <b>Interpolation method</b> or the <b>Extrapolation method</b> parameter is Cubic Spline.</li> </ul> or <ul style="list-style-type: none"> <li>The <b>Interpolation method</b> parameter is Linear and the <b>Number of table dimensions</b> parameter is greater than 5.</li> </ul> Not supported when the <b>Interpolation method</b> or the <b>Extrapolation method</b> parameter is Akima Spline.
Lookup Table Dynamic	Supported
Prelookup	Supported
Sine	Supported

### Math Operations Library

Block	Support Notes
Abs	Supported
Add	Supported
Algebraic Constraint	Supported
Assignment	Supported
Bias	Supported
Complex to Magnitude-Angle	Supported
Complex to Real-Imag	Supported
Divide	Supported
Dot Product	Supported
Find Nonzero Elements	Not supported
Gain	Supported
Magnitude-Angle to Complex	Supported
Math Function	Supported. Support for pow function is limited to integer exponents only.
Matrix Concatenate	Supported
MinMax	Supported
MinMax Running Resettable	Supported
Permute Dimensions	Supported
Polynomial	Supported

Block	Support Notes
Product	Supported
Product of Elements	Supported
Real-Imag to Complex	Supported
Reciprocal Sqrt	Partially supported
Reshape	Supported
Rounding Function	Supported
Sign	Supported
Signed Sqrt	Partially supported
Sine Wave Function	Partially supported
Slider Gain	Supported
Sqrt	Partially supported
Squeeze	Supported
Subtract	Supported
Sum	Supported
Sum of Elements	Supported
Trigonometric Function	Supported if <b>Function</b> is sin, cos, or sincos, and <b>Approximation method</b> is CORDIC. Partially supported otherwise.
Unary Minus	Supported
Vector Concatenate	Supported
Weighted Sample Time Math	Supported

### Model Verification Library

The software supports all blocks in the Model Verification library.

### Model-Wide Utilities Library

Block	Support Notes
Block Support Table	Supported
DocBlock	Supported
Model Info	Supported
Timed-Based Linearization	Not supported
Trigger-Based Linearization	Not supported

### Ports & Subsystems Library

Block	Support Notes
Atomic Subsystem	Supported
Code Reuse Subsystem	Supported

Block	Support Notes
Configurable Subsystem	Supported
Enable	Supported
Enabled Subsystem	<p>Design range checks do not consider specified minimum and maximum values for blocks connected to the output port of the subsystem. For more information on design range checks, see “Check for Specified Minimum and Maximum Value Violations” (Simulink Design Verifier).</p> <p>Simulink Design Verifier treats Enabled Subsystems as short-circuited during test generation.</p>
Enabled and Triggered Subsystem	<p>Not supported when the trigger control signal specifies a fixed-point data type.</p> <p>Design range checks do not consider specified minimum and maximum values for blocks connected to the output port of the subsystem. For more information on design range checks, see “Check for Specified Minimum and Maximum Value Violations” (Simulink Design Verifier).</p> <p>Simulink Design Verifier treats Enabled and Triggered Subsystems as short-circuited during test generation.</p>
For Each	<p>Supported with the following limitations:</p> <ul style="list-style-type: none"> <li>• When For Each Subsystem contains one or more Simulink Design Verifier Test Condition, Test Objective, Proof Assumption, or Proof Objective blocks, not supported.</li> <li>• When the mask parameters of the For Each Subsystem are partitioned, not supported.</li> </ul>
For Each Subsystem	<p>Supported with the following limitations:</p> <ul style="list-style-type: none"> <li>• When For Each Subsystem contains one or more Simulink Design Verifier Test Condition, Test Objective, Proof Assumption, or Proof Objective blocks, not supported.</li> <li>• When the mask parameters of the For Each Subsystem are partitioned, not supported.</li> </ul>
For Iterator Subsystem	Supported
Function-Call Feedback Latch	Supported
Function-Call Generator	Supported
Function-Call Split	Supported
Function-Call Subsystem	<p>Design range checks do not consider specified minimum and maximum values for blocks connected to the output port of the subsystem. For more information on design range checks, see “Check for Specified Minimum and Maximum Value Violations” (Simulink Design Verifier).</p>
If	Parameter configurations are not supported. The analysis ignores parameter configurations that you specify for an If block.

Block	Support Notes
If Action Subsystem	Supported
In Bus Element	Supported
Inport	Supported
Model	Supported except for the limitations described in “Support Limitations for Model Blocks” (Simulink Design Verifier).
Out Bus Element	Supported
Outport	Supported
Resettable Subsystem	Supported
Subsystem	Supported
Variant Transitions in Stateflow	Supported. Only the active variant is analyzed.
Switch Case	Supported
Switch Case Action Subsystem	Supported
Trigger	Supported
Triggered Subsystem	Not supported when the trigger control signal specifies a fixed-point data type.  Design range checks do not consider specified minimum and maximum values for blocks connected to the output port of the subsystem. For more information on design range checks, see “Check for Specified Minimum and Maximum Value Violations” (Simulink Design Verifier).  Simulink Design Verifier treats Enabled Subsystems as short-circuited during test generation.
Variant Subsystem	Not supported when the <b>Generate preprocessor conditionals</b> parameter is enabled.  Only the active variant is analyzed.
While Iterator Subsystem	Supported

### Signal Attributes Library

The software supports all blocks in the Signal Attributes library.

### Signal Routing Library

Block	Support Notes
Bus Assignment	Supported
Bus Creator	Supported
Bus Selector	Supported
Data Store Memory	Supported
Data Store Read	Supported

Block	Support Notes
Data Store Write	Supported
Demux	Supported
Environment Controller	Supported
From	Supported
Goto	Supported
Goto Tag Visibility	Supported
Index Vector	Supported
Manual Switch	The Manual Switch block is compatible with the software, but the analysis ignores this block in a model. The analysis does not flag the coverage objectives for this block as satisfiable or unsatisfiable.  Model coverage data is collected for the Manual Switch block.
Merge	Supported
Multiport Switch	Supported
Mux	Supported
Selector	Supported
Switch	Supported
Vector Concatenate	Supported

### Sinks Library

Block	Support Notes
Display	Supported
Floating Scope	Supported
Outport (Out1)	Supported
Out Bus Element	Supported
Scope	Supported
Stop Simulation	Not supported
Terminator	Supported
To File	Supported
To Workspace	Supported

### Sources Library

Block	Support Notes
Band-Limited White Noise	Not supported
Chirp Signal	Partially supported
Clock	Supported

Block	Support Notes
Constant	Supported unless <b>Constant value</b> is <code>inf</code> or <code>nan</code> (in which case, it is not supported).
Counter Free-Running	Supported
Counter Limited	Supported
Digital Clock	Supported
Enumerated Constant	Supported
From File	Partially supported. When MAT-file data is stored in MATLAB <code>timeseries</code> format, not supported.
From Workspace	Partially supported
Ground	Supported
Inport (In1)	Supported
In Bus Element	Supported if <code>Simulink.Bus</code> type is defined for the In Bus Element.
Pulse Generator	Supported
Ramp	Supported
Random Number	Not supported
Repeating Sequence	Partially supported
Repeating Sequence Interpolated	Partially supported
Repeating Sequence Stair	Supported
Signal Editor	Not supported
Signal Generator	Partially supported if wave form is <code>sine</code> . Supported if wave form is <code>square</code> . Not supported if wave form is <code>random</code> .
Sine Wave	Partially supported
Step	Supported
Uniform Random Number	Not supported

### User-Defined Functions Library

Block	Support Notes
C Function	Partially supported. The C Function block is stubbed out during the Simulink Design Verifier analysis.
C Caller	Supported.
Initialize Function	<ul style="list-style-type: none"> <li>Not Supported for Initialize function containing Parameter Writer blocks.</li> <li>Not supported as a target for subsystem analysis.</li> </ul>
Interpreted MATLAB Function	Partially supported
Level-2 MATLAB S-Function	For limitations, see "Support Limitations and Considerations for S-Functions and C/C++ Code" (Simulink Design Verifier).
MATLAB Function	For limitations, see "Support Limitations for MATLAB for Code Generation" (Simulink Design Verifier).

Block	Support Notes
MATLAB System	<ul style="list-style-type: none"> <li>• Decision, Condition and MCDC Coverage objectives are supported in Test Generation. Enhanced MCDC, Relational Boundary and Custom Test objectives are not supported.</li> <li>• Custom Proof objectives are not supported in Property Proving.</li> <li>• For further limitations, see “Support Limitations for MATLAB for Code Generation” (Simulink Design Verifier).</li> </ul> <p>Logical expressions within assignment statements are not analyzed for coverage objectives.</p>
Reset Function	Not supported
S-Function Builder	For limitations, see “Support Limitations and Considerations for S-Functions and C/C++ Code” (Simulink Design Verifier).
Simulink Function	<ul style="list-style-type: none"> <li>• For export-function models, see “Analyze Export-Function Models” (Simulink Design Verifier).</li> <li>• Global Simulink functions within a non export-function model reference are not supported.</li> </ul>
Terminate Function	<p>Partially supported.</p> <ul style="list-style-type: none"> <li>• The behaviour of Terminate function is ignored and is replaced by an empty function during the analysis.</li> <li>• Not supported as a target for subsystem analysis.</li> </ul>
Observer Reference	Supported with limitations. See “Isolate Verification Logic with Observers” (Simulink Design Verifier).
Simscape Library	Not supported

## Support Limitations for Stateflow Software Features

Simulink Design Verifier does not support the following Stateflow software features. Avoid using these unsupported features in models that you analyze.

### In this section...

“ml Namespace Operator, ml Function, ml Expressions” on page 72-145

“C or C++ Operators” on page 72-145

“C Math Functions” on page 72-145

“Atomic Subcharts That Call Exported Graphical Functions Outside a Subchart” on page 72-146

“Atomic Subchart Input and Output Mapping” on page 72-146

“Recursion and Cyclic Behavior” on page 72-146

“Custom C/C++ Code” on page 72-147

“Textual Functions with Literal String Arguments” on page 72-148

### ml Namespace Operator, ml Function, ml Expressions

The software does not support calls to MATLAB functions or access to MATLAB workspace variables, which the Stateflow software allows. See “Access MATLAB Functions and Workspace Data in C Charts” (Stateflow).

### C or C++ Operators

The software does not support the `sizeof` operator, which the Stateflow software allows.

### C Math Functions

The software supports calls to the following C math functions:

- `abs`
- `ceil`
- `fabs`
- `floor`
- `fmod`
- `labs`
- `ldexp`
- `pow` (only for integer exponents)

The software does not support calls to other C math functions, which the Stateflow software allows. If automatic stubbing is enabled, which it is by default, the software eliminates these unsupported functions during the analysis.

For information about C math functions in Stateflow, see “Call C Library Functions in C Charts” (Stateflow).

---

**Note** For details about automatic stubbing, see “Handle Incompatibilities with Automatic Stubbing” (Simulink Design Verifier).

---

## Atomic Subcharts That Call Exported Graphical Functions Outside a Subchart

The software does not support atomic subcharts that call exported graphical functions, which the Stateflow software allows.

---

**Note** For information about exported functions, see “Export Stateflow Functions for Reuse” (Stateflow).

---

## Atomic Subchart Input and Output Mapping

If an input or output in an atomic subchart maps to chart-level data of a different scope, the software does not support the chart that contains that atomic subchart.

For an atomic subchart input, this incompatibility applies when the input maps to chart-level data of output, local, or parameter scope. For an atomic subchart output, this incompatibility applies when the output maps to chart-level data of local scope.

## Recursion and Cyclic Behavior

The software does not support recursive functions, which occur when a function calls itself directly or indirectly through another function call. Stateflow software allows you to implement recursion using graphical functions.

In addition, the software does not support recursion that the Stateflow software allows you to implement using a combination of event broadcasts and function calls.

---

**Note** For information about avoiding recursion in Stateflow charts, see “Avoid Unwanted Recursion in a Chart” (Stateflow).

---

Stateflow software also allows you to create *cyclic behavior*, where a sequence of steps is repeated indefinitely. If your model has a chart with cyclic behavior, the software cannot analyze it.

---

**Note** For information about cyclic behavior in Stateflow charts, see “Detect Cyclic Behavior” (Stateflow).

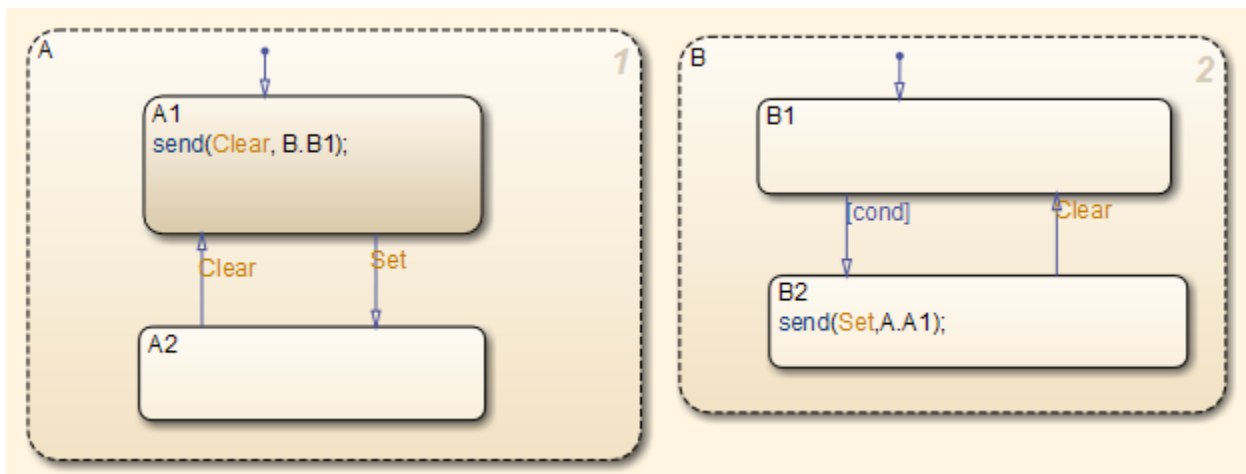

---

However, you can modify a chart with cyclic behavior so that it is compatible, as in the following example.

The following chart creates cyclic behavior. State A calls state A1, which broadcasts a `Clear` event to state B, which calls state B2, which broadcasts a `Set` event back to state A, causing the cyclic behavior.

If you change the send function calls to use directed event broadcasts so that the Set and Clear events are broadcast directly to the states B1 and A1, respectively, the cyclic behavior disappears and the software can analyze the model.

**Note** For information about the benefits of directed event broadcasts, see “Broadcast Local Events to Synchronize Parallel States” (Stateflow).

## Custom C/C++ Code

If your model consists of custom C/C++ code, Simulink Design Verifier supports analysis based on these settings:

- If you enable import custom code and custom code analysis options, the software supports custom C/C++ code for analysis. For more information, see “Import custom code” and “Enable custom code analysis”.
- If you enable import custom code option and the custom code analysis option is set to `Off`, the model is compatible for analysis, but calls to the custom code are stubbed during analysis.
- If the import custom code option is set to `Off`, the custom code is not supported and the model is incompatible for analysis.

## **Textual Functions with Literal String Arguments**

The software does not support literal string arguments to textual functions in a Stateflow chart.

## Custom State Attributes in Discrete FIR Filter block

This example shows how to customize the state attributes of the Discrete FIR Filter block using the **Model Data Editor**. The Model Data Editor enables you to inspect and edit data items in a list that you can sort, group, and filter.

Consider a simple model that contains the Discrete FIR Filter block.

Using the Code Mappings editor or code mappings API, you can configure the state of the Discrete FIR Filter to appear in the generated code as a separate global variable. This is done by declaring the storage class of the state as `ExportedGlobal`. For details on how the generated code stores internal states, see “How Generated Code Stores Internal Signal, State, and Parameter Data” (Simulink Coder). For more details on storage classes and how to apply them to the states, see “C Code Generation Configuration for Model Interface Elements” (Simulink Coder).

## Open Model Data Editor

Open the Model Data Editor. On the **Modeling** tab, click **Model Data Editor**.

Under the **States** tab, enter the **Name** as myState. In the coder app, set the **Storage Class** to **ExportedGlobal**. You can alternatively select the **Resolve** check box, which requires the state name to resolve to a Simulink signal object.

The screenshot shows the Simulink Model Data Editor for a model named 'custom\_state\_attributes'. The main workspace displays a block diagram of a discrete FIR filter. The filter consists of an input port with a gain of 1, followed by a discrete transfer function block with the numerator  $0.5 + 0.5z^{-1}$  and denominator 1, and finally an output port with a gain of 1.

The Model Data Editor window is open at the bottom, showing the 'States' tab. The table below lists the state configuration for the 'Discrete FIR Filter' block.

Source	Name	Resolve	Storage Class	Header File	Definition File	Get Function	Set Function	Struct
Discrete FIR Filter	myState	<input type="checkbox"/>	ExportedGlobal	—	—	—	—	—

The status bar at the bottom indicates 'Ready', '300%' zoom, and 'FixedStepDiscrete'.

## Build the Model and Inspect the Generated Code

This example configures the model to generate code only. Open the Configuration Parameters by clicking the configuration button  in the Simulink editor. In the **Code Generation** pane, select **Generate code only**. Click **Apply**.

In the **Report** pane, select **Create code generation report** and **Open report automatically**. Click **Apply**. These settings create a report and automatically open the report in a web browser.

To initiate the build, click the build model button  in the Simulink editor or press **Ctrl+B**. The build process writes the code generation report files to the `html` subfolder of the build folder. Next, the build process automatically opens a MATLAB web browser window and displays the code generation report. Using this report, you can view and analyze the generated code. For more information on the generated report, see “Reports for Code Generation” (Simulink Coder).

The screenshot shows the 'Code Generation Report' window for the model 'custom\_state\_attributes'. The window is divided into several sections:

- Contents:** A list of report sections including Summary (highlighted), Subsystem Report, and Code Interface Report.
- Generated Code:** A list of files generated for the model, categorized into Model files, Data files, Utility files (9), Interface files (1), and Other files (1).
- Model Information:** A table showing details about the model's generation, including Author (rdukkipa), Last Modified By (rdukkipa), Model Version (1.5), and Tasking Mode (SingleTasking).
- Code Information:** A table showing details about the code generation process, including System Target File (grt.tlc), Hardware Device Type (Intel->x86-64 (Windows64)), Simulink Coder Version (8.14 (R2018a) 21-Dec-2017), Timestamp of Generated (Fri Jan 12 10:02:53 2018), Source Code, Location of Generated Source (H:\Documents\MATLAB\custom\_state\_attributes\custom\_state\_attributes\_grt\_rtw\Code), Type of Build (Model), and Objectives Specified (Unspecified).

At the bottom right of the window, there are 'OK' and 'Help' buttons.

In the `custom_state_attributes.h` file, you can see that the filter state is declared as an external variable since the storage class is `ExportedGlobal`.

If you change the storage class and rebuild the model, you can see the generated code reflect the change. With the ability to customize the state attributes, you can streamline and customize how the state appears in the generated code.

# Enumerations and Modeling

---

- “Simulink Enumerations” on page 73-2
- “Use Enumerated Data in Simulink Models” on page 73-5

## Simulink Enumerations

*Enumerated data* is data that is restricted to a finite set of values. An *enumerated data type* is a MATLAB class that defines a set of *enumerated values*. Each enumerated value consists of an *enumerated name* and an *underlying integer* which the software uses internally and in generated code.

Before you begin to use enumerations in a modeling context, you should understand information provided in “Enumerations”.

To define an enumeration for use in Simulink models, choose one of these techniques:

- Use the function `Simulink.defineIntEnumType`. The enumeration exists for the duration of your MATLAB session.
- Create a permanent enumeration class by subclassing one of these built-in classes:
  - Many of the built-in integer data types such as `int8` and `uint16`
  - `Simulink.IntEnumType`
- Use the function `Simulink.importExternalCTypes` to create a Simulink representation of an enumerated data type (enum) that your external C code defines.

Use this technique to help you:

- Replace existing C code with a Simulink model.
- Integrate existing C code for simulation in Simulink (for example, by using the Legacy Code Tool).
- Generate C code (Simulink Coder) that you can compile with existing C code into a single application.

For more information, see “Define Simulink Enumerations” on page 73-5.

The following examples show how to use enumerations in Simulink and Stateflow.

Example	Shows How To Use...
“Data Typing in Simulink”	Data types in Simulink, including enumerated data types
“Model Media Player by Using Enumerated Data” (Stateflow)	Enumerated data types in a Simulink model that contains a Stateflow chart

For information on using enumerations in Stateflow, see “Enumerated Data” (Stateflow).

## Simulink Constructs that Support Enumerations

### Overview

In general, all Simulink tools and constructs support enumerated types for which the support makes sense given the purpose of enumerated types: to represent program states and to control program logic. The Simulink Editor, Simulink Debugger, Port Value Displays, referenced models, subsystems, masks, buses, data logging, and most other Simulink capabilities support enumerated types without imposing any special requirements.

Enumerated types are not intended for mathematical computation, so no block that computes a numeric output (as distinct from passing a numeric input through to the output) supports enumerated types. Thus an enumerated type is not considered to be a numeric type, even though an enumerated value has an underlying integer. See “Enumerated Values in Computation” on page 73-16 for more information.

Most capabilities that do not support enumerated types obviously could not support them. Therefore, the Simulink documentation usually mentions enumerated type nonsupport only where necessary to prevent a misconception or describe an exception. See “Simulink Enumeration Limitations” on page 73-3 for information about certain constructs that could support enumerated types but do not.

### **Block Support**

Many Simulink blocks support enumerated types. The Data Type Support section of each block reference page describes all data types that the block supports.

In particular, all members of the following categories of Simulink blocks support enumerated types:

- Bus-capable blocks (see “Bus-Capable Blocks” on page 81-45)
- Pass-through blocks:
  - With state, like the Data Store Memory and Unit Delay blocks.
  - Without state, like the Mux block.

### **Class Support**

The following Simulink classes support enumerated types:

- `Simulink.ValueType`
- `Simulink.Signal`
- `Simulink.Parameter`
- `Simulink.AliasType`
- `Simulink.BusElement`

### **Logging Enumerated Data**

Top-level model output ports, To Workspace blocks, and Scope blocks can all export enumerated values. Signal and State logging work with enumerated data in the same way as with any other data. All logging formats are supported. See “Save Run-Time Data from Simulation” for more information.

### **Importing Enumerated Data**

Top-level model input ports and From Workspace blocks can output enumerated signals during simulation. Data must be provided in a `Structure`, `Structure with Time`, or `timeseries` object. No interpolation occurs for enumerated values between the specified simulation times. See “Load Signal Data for Simulation” for more information.

## **Simulink Enumeration Limitations**

- “Enumerations and Scopes” on page 73-4
- “Enumerated Types for Switch Blocks” on page 73-4

- “Nonsupport of Enumerations” on page 73-4

### Enumerations and Scopes

When a Scope block displays an enumerated signal, the vertical axis displays the names of the enumerated values only if the scope was open during simulation. If you open the Scope block for the first time before any simulation has occurred, or between simulations, the block displays only numeric values. When simulation begins, enumerated names replace the numeric values, and thereafter appear whenever the Scope block is opened.

When a Floating Scope block displays multiple signals, the names of enumerated values appear on the Y axis only if all signals are of the same enumerated type. If the Floating Scope block displays more than one type of enumerated signal, or any numeric signal, no names appear, and any enumerated values are represented by their underlying integers.

### Enumerated Types for Switch Blocks

The control input of a Switch block can be of any data type supported by Simulink. However, the `u2 ~ = 0` mode is not supported for enumerations. If the control input has an enumeration, choose one of the following methods to specify the criteria for passing the first input:

- Select `u2 >= Threshold` or `u2 > Threshold` and specify a threshold value of the same enumerated type as the control input.
- Use a Relational Operator block to do the comparison and then feed the Boolean result of this comparison into the control port of the Switch block.

### Nonsupport of Enumerations

The following limitations exist when using enumerated data types with Simulink:

- Packages cannot contain enumeration class definitions.
- The If Action block does not support enumerations.
- Generated code does not support logging enumerated data.
- Custom Stateflow targets do not support enumerated types.

### See Also

- “Use Enumerated Data in Generated Code” (Simulink Coder)
- “Manipulate Enumerations in Data Dictionary” on page 79-16

## Use Enumerated Data in Simulink Models

### In this section...

“Define Simulink Enumerations” on page 73-5  
 “Simulate with Enumerations” on page 73-10  
 “Specify Enumerations as Data Types” on page 73-12  
 “Get Information About Enumerated Data Types” on page 73-12  
 “Enumeration Value Display” on page 73-13  
 “Instantiate Enumerations” on page 73-14  
 “Enumerated Values in Computation” on page 73-16

*Enumerated data* is data that is restricted to a finite set of values. An *enumerated data type* is a MATLAB class that defines a set of *enumerated values*. Each enumerated value consists of an *enumerated name* and an *underlying integer* which the software uses internally and in generated code.

For basic conceptual information about enumerations in Simulink, see “Simulink Enumerations” on page 73-2.

For information about generating code with enumerations, see “Use Enumerated Data in Generated Code” (Simulink Coder).

### Define Simulink Enumerations

To define an enumerated data type that you can use in Simulink models, use one of these methods:

- Define an enumeration class using a `classdef` block in a MATLAB file.
- Use the function `Simulink.defineIntEnumType`. You do not need a script file to define the type. For more information, see the function reference page.
- Use the function `Simulink.importExternalCTypes` to create a Simulink representation of an enumerated data type (enum) that your external C code defines.

#### Workflow to Define a Simulink Enumeration Class

- 1 Create a class definition on page 73-5.
- 2 Optionally, customize the enumeration on page 73-6.
- 3 Optionally, save the enumeration in a MATLAB file on page 73-8.
- 4 Optionally, permanently store the enumeration definition in a Simulink data dictionary. See “Permanently Store Enumerated Type Definition” on page 73-10.

#### Create Simulink Enumeration Class

To create a Simulink enumeration class, in the class definition:

- Define the class as a subclass of `Simulink.IntEnumType`. You can also base an enumerated type on one of these built-in integer data types: `int8`, `uint8`, `int16`, `uint16`, and `int32`.
- Add an enumeration block that specifies enumeration values with underlying integer values.

Consider the following example:

```
classdef BasicColors < Simulink.IntEnumType
    enumeration
        Red(0)
        Yellow(1)
        Blue(2)
    end
end
```

The first line defines an integer-based enumeration that is derived from built-in class `Simulink.IntEnumType`. The enumeration is integer-based because `IntEnumType` is derived from `int32`.

The `enumeration` section specifies three enumerated values.

Enumerated Value	Enumerated Name	Underlying Integer
Red(0)	Red	0
Yellow(1)	Yellow	1
Blue(2)	Blue	2

When defining an enumeration class for use in the Simulink environment, consider the following:

- The name of the enumeration class must be unique among data type names and base workspace variable names, and is case-sensitive.
- Underlying integer values in the `enumeration` section need not be unique within the class and across types.
- Often, the underlying integers of a set of enumerated values are consecutive and monotonically increasing, but they need not be either consecutive or ordered.
- For simulation, an underlying integer can be any `int32` value. Use the MATLAB functions `intmin` and `intmax` to get the limits.
- For code generation, every underlying integer value must be representable as an integer on the target hardware, which may impose different limits. See “Configure a System Target File” (Simulink Coder) for more information.

For more information on superclasses, see “Convert to Superclass Value”. For information on how enumeration classes are handled when there is more than one name for an underlying value, see “How to Alias Enumeration Names”.

## Customize Simulink Enumeration

### About Simulink Enumeration Customizations

You can customize a Simulink enumeration by implementing specific static methods in the class definition. If you define these methods using the appropriate syntax, you can change the behavior of the class during simulation and in generated code.

The table shows the methods you can implement to customize an enumeration.

Static Method	Purpose	Default Value Without Implementing Method	Custom Return Value	Usage Context
<code>getDefaultValue</code>	Specifies the default enumeration member for the class.	First member specified in the enumeration definition	A character vector containing the name of an enumeration member in the class (see “Instantiate Enumerations” on page 73-14)	Simulation and code generation
<code>getDescription</code>	Specifies a description of the enumeration class.	' '	A character vector containing the description of the type	Code generation
<code>getHeaderFile</code>	Specifies the name of a header file. The method <code>getDataScope</code> determines the significance of the file.	' '	A character vector containing the name of the header file that defines the enumerated type	Code generation
<code>getDataScope</code>	Specifies whether generated code exports or imports the definition of the enumerated data type. Use the method <code>getHeaderFile</code> to specify the generated or included header file that defines the type.	'Auto'	One of: 'Auto', 'Exported', or 'Imported'	Code generation
<code>addClassNameToEnumNames</code>	Specifies whether to prefix the class name in generated code.	false	true or false	Code generation

For more examples of these methods as they apply to code generation, see “Customize Enumerated Data Type” (Simulink Coder).

### Specify a Default Enumerated Value

Simulink and related generated code use an enumeration's default value for ground-value initialization of enumerated data when you provide no other initial value. For example, an enumerated signal inside a conditionally executed subsystem that has not yet executed has the enumeration's default value. Generated code uses an enumeration's default value if a safe cast fails, as described in “Type Casting for Enumerations” (Simulink Coder).

Unless you specify otherwise, the default value for an enumeration is the first value in the enumeration class definition. To specify a different default value, add your own `getDefaultValue` method to the `methods` section. The following code shows a shell for the `getDefaultValue` method:

```
function retVal = getDefaultValue()
% GETDEFAULTVALUE Specifies the default enumeration member.
% Return a valid member of this enumeration class to specify the default.
% If you do not define this method, Simulink uses the first member.
retVal = ThisClass.EnumName;
end
```

To customize this method, provide a value for *ThisClass.EnumName* that specifies the desired default.

- *ThisClass* must be the name of the class within which the method exists.
- *EnumName* must be the name of an enumerated value defined in that class.

For example:

```
classdef BasicColors < Simulink.IntEnumType
    enumeration
        Red(0)
        Yellow(1)
        Blue(2)
    end
    methods (Static)
        function retVal = getDefaultValue()
            retVal = BasicColors.Blue;
        end
    end
end
```

This example defines the default as `BasicColors.Blue`. If this method does not appear, the default value would be `BasicColors.Red`, because that is the first value listed in the enumerated class definition.

The seemingly redundant specification of *ThisClass* inside the definition of that same class is necessary because `getDefaultValue` returns an instance of the default enumerated value, not just the name of the value. The method, therefore, needs a complete specification of what to instantiate. See “Instantiate Enumerations” on page 73-14 for more information.

### Save Enumeration in a MATLAB File

You can define an enumeration within a MATLAB file.

- The name of the definition file must match the name of the enumeration exactly, including case. For example, the definition of enumeration `BasicColors` must reside in a file named `BasicColors.m`. Otherwise, MATLAB will not find the definition.
- You must define each class definition in a separate file.
- Save each definition file on the MATLAB search path. MATLAB searches the path to find a definition when necessary.

To add a file or folder to the MATLAB search path, type `addpath pathname` at the MATLAB command prompt. For more information, see “What Is the MATLAB Search Path?”, `addpath`, and `savepath`.

- You do not need to execute an enumeration class definition to use the enumeration. The only requirement, as indicated in the preceding bullet, is that the definition file be on the MATLAB search path.

### Change and Reload Enumeration Classes

You can change the definition of an enumeration by editing and saving the file that contains the definition. You do not need to inform MATLAB that a class definition has changed. MATLAB automatically reads the modified definition when you save the file. However, the class definition changes do not take full effect if any class instances (enumerated values) exist that reflect the previous class definition. Such instances might exist in the base workspace or might be cached.

The following table explains options for removing instances of an enumeration from the base workspace and cache.

If In Base Workspace...	If In Cache...
Do one of the following: <ul style="list-style-type: none"> <li>• Locate and delete specific obsolete instances.</li> <li>• Delete everything from the workspace by using the <code>clear</code> command.</li> </ul>	<ul style="list-style-type: none"> <li>• Delete obsolete instances by closing all models that you updated or simulated while the previous class definition was in effect.</li> <li>• Clear functions and close models that are caching instances of the class.</li> </ul>

Similarly, if you defined an enumeration class by using `Simulink.defineIntEnumType`, you can redefine that class, using the same function, even if instances exist. However, you cannot change `StorageType` for the class while instances exist.

For more information about applying enumeration changes, see “Automatic Updates for Modified Classes”.

### Import Enumerations Defined Externally to MATLAB

If you have enumerations defined externally to MATLAB that you want to import for use within the Simulink environment, you can do so programmatically with calls to one of these functions:

- `Simulink.defineIntEnumType` — Defines an enumeration that you can use in MATLAB as if it is defined by a class definition file. In addition to specifying the enumeration class name and values, each function call can specify:
  - Character vector that describes the enumeration class.
  - Which of the enumeration values is the default.

For code generation, you can specify:

- Header file in which the enumeration is defined for generated code.
- Whether the code generator applies the class name as a prefix to enumeration members — for example, `BasicColors_Red` or `Red`.

As an example, consider the following class definition:

```
classdef BasicColors < Simulink.IntEnumType
    enumeration
        Red(0)
        Yellow(1)
        Blue(2)
    end
    methods (Static = true)
        function retVal = getDescription()
            retVal = 'Basic colors...';
        end
        function retVal = getDefaultValue()
            retVal = BasicColors.Blue;
        end
        function retVal = getHeaderFile()
            retVal = 'mybasiccolors.h';
        end
        function retVal = addClassNameToEnumNames()
```

```

        retVal = true;
    end
end
end

```

The following function call defines the same class for use in MATLAB:

```

Simulink.defineIntEnumType('BasicColors', ...
    {'Red', 'Yellow', 'Blue'}, [0;1;2],...
    'Description', 'Basic colors', ...
    'DefaultValue', 'Blue', ...
    'HeaderFile', 'mybasiccolors.h', ...
    'DataScope', 'Imported', ...
    'AddClassNameToEnumNames', true);

```

- `Simulink.importExternalCTypes` — Creates Simulink representations of enumerated data types (enum) that your existing C code defines.

If a MATLAB Function block in your model uses the enumerated type, configure the model configuration parameters to include (`#include`) the type definition from your external header file. See “Control Imported Bus and Enumeration Type Definitions” on page 49-116.

### Permanently Store Enumerated Type Definition

Whether you define an enumeration by using a class file or by using the function `Simulink.defineIntEnumType`, you can permanently store the enumeration definition in a Simulink data dictionary. Models that are linked to the dictionary can use the enumeration. For more information, see “Enumerations in Data Dictionary” on page 79-14.

## Simulate with Enumerations

Consider the following enumeration class definition — `BasicColors` with enumerated values Red, Yellow, and Blue, with Blue as the default value:

```

classdef BasicColors < Simulink.IntEnumType
    enumeration
        Red(0)
        Yellow(1)
        Blue(2)
    end
    methods (Static)
        function retVal = getDefaultValue()
            retVal = BasicColors.Blue;
        end
    end
end
end

```

Once this class definition is known to MATLAB, you can use the enumeration in Simulink and Stateflow models. Information specific to enumerations in Stateflow appears in “Enumerated Data” (Stateflow). The following Simulink model uses the enumeration defined above:

The output of the model looks like this:

The Data Type Conversion block `OrigToInt` specifies an **Output data type** of `int32` and **Integer rounding mode**: `Floor`, so the block converts the Sine Wave block output, which appears in the top graph of the Scope display, to a cycle of integers: 1, 2, 1, 0, 1, 2, 1. The Data Type Conversion block `IntToColor` uses these values to select colors from the enumerated type `BasicColors` by referencing their underlying integers.

The result is a cycle of colors: Yellow, Blue, Yellow, Red, Yellow, Blue, Yellow, as shown in the middle graph. The Enumerated Constant block `EnumConst` outputs `Yellow`, which appears in the second graph as a straight line. The Relational Operator block compares the constant `Yellow` to each value in the cycle of colors. It outputs 1 (true) when `Yellow` is less than the current color, and 0 (false) otherwise, as shown in the third graph.

The sort order used by the comparison is the numeric order of the underlying integers of the compared values, *not* the lexical order in which the enumerated values appear in the enumerated class definition. In this example the two orders are the same, but they need not be. See “Specify Enumerations as Data Types” on page 73-12 and “Enumerated Values in Computation” on page 73-16 for more information.

## Specify Enumerations as Data Types

Once you define an enumeration, you can use it much like any other data type. Because an enumeration is a class rather than an instance, you must use the prefix `?` or `Enum:` when specifying the enumeration as a data type. You must use the prefix `?` in the MATLAB Command Window. However, you can use either prefix in a Simulink model. `Enum:` has the same effect as the `?` prefix, but `Enum:` is preferred because it is more self-explanatory in the context of a graphical user interface.

Depending on the context, type `Enum:` followed by the name of an enumeration, or select `Enum:` `<class name>` from a menu (for example, for the **Output data type** block parameter) , and replace `<class name>`.

To use the Data Type Assistant, set the **Mode** to **Enumerated**, then enter the name of the enumeration. For example, in the previous model, the Data Type Conversion block `IntToColor`, which outputs a signal of type `BasicColors`, has the following output signal specification:

You cannot set a minimum or maximum value for a signal defined as an enumeration, because the concepts of minimum and maximum are not relevant to the purpose of enumerations. If you change the minimum or maximum for a signal of an enumeration from the default value of `[]`, an error occurs when you update the model. See “Enumerated Values in Computation” on page 73-16 for more information.

## Get Information About Enumerated Data Types

The functions `enumeration` and `Simulink.data.getEnumTypeInfo` return information about enumerated data types.

### Get Information About Enumeration Members

Use the function `enumeration` to:

- Return an array that contains all enumeration values for an enumeration class in the MATLAB Command Window
- Get the enumeration values programmatically
- Provide the values to a Simulink block parameter that accepts an array or vector of enumerated values, such as the **Case conditions** parameter of the Switch Case block

## Get Information About Enumerated Class

Use the function `Simulink.data.getEnumTypeInfo` to return information about an enumeration class, such as:

- The default enumeration member
- The name of the header file that defines the type in generated code
- The data type used in generated code to store the integer values underlying the enumeration members

## Enumeration Value Display

Wherever possible, Simulink displays enumeration values by name, not by the underlying integer value. However, the underlying integers can affect value display in Scope and Floating Scope blocks.

Block...	Affect on Value Display..
Scope	When displaying an enumerated signal, the names of the enumerated values appear as labels on the Y axis. The names appear in the order given by their underlying integers, with the lowest value at the bottom.
Floating Scope	When displaying signals that are of the same enumeration, names appear on the Y axis as they would for a Scope block. If the Floating Scope block displays mixed data types, no names appear, and any enumerated values are represented by their underlying integers.

## Enumerated Values with Non-Unique Integers

More than one value in an enumeration can have the same underlying integer value, as described in “Specify Enumerations as Data Types” on page 73-12. When this occurs, the value on an axis of Scope block output or in Display block output always is the first value listed in the enumerated class definition that has the shared underlying integer. For example:

Although the Enumerated Constant block outputs True, both On and True have the same underlying integer, and On is defined first in the class definition enumeration section. Therefore, the Display block shows On. Similarly, a Scope axis would show only On, never True, no matter which of the two values is input to the Scope block.

## Instantiate Enumerations

Before you can use an enumeration, you must instantiate it. You can instantiate an enumeration in MATLAB, in a Simulink model, or in a Stateflow chart. The syntax is the same in all contexts.

### Instantiating Enumerations in MATLAB

To instantiate an enumeration in MATLAB, enter `ClassName.EnumName` in the MATLAB Command Window. The instance is created in the base workspace. For example, if `BasicColors` is defined as in “Create Simulink Enumeration Class” on page 73-5, you can type:

```
bcy = BasicColors.Yellow
```

```
bcy =
```

```
Yellow
```

Tab completion works for enumerations. For example, if you enter:

```
bcy = BasicColors.<tab>
```

MATLAB displays the elements and methods of `BasicColors` in alphabetical order:

```

addClassNameToEnumNames
Blue
getDefaultValue
getDescription
getHeaderFile
getStorageType
Red
Yellow

```

Double-click an element or method to insert it at the position where you pressed <tab>. See “Code Suggestions and Completions” for more information.

### Casting Enumerations in MATLAB

In MATLAB, you can cast directly from an integer to an enumerated value:

```
bcb = BasicColors(2)
```

```
bcb =
```

```
    Blue
```

You can also cast from an enumerated value to its underlying integer:

```
>> bci = int32(bcb)
```

```
bci =
```

```
     2
```

In either case, MATLAB returns the result of the cast in a 1x1 array of the relevant data type.

Although casting is possible, use of enumeration values is not robust in cases where enumeration values and the integer equivalents defined for an enumeration class might change.

### Instantiating Enumerations in Simulink (or Stateflow)

To instantiate an enumeration in a Simulink model, you can enter *ClassName.EnumName* as a value in a dialog box. For example, consider the following model:

The Enumerated Constant block EnumConst, which outputs the enumerated value Yellow, defines that value as follows:

You can enter any valid MATLAB expression that evaluates to an enumerated value, including arrays and workspace variables. For example, you could enter `BasicColors(1)`, or if you had previously executed `bcy = BasicColors.Yellow` in the MATLAB Command Window, you could enter `bcy`. As another example, you could enter an array, such as `[BasicColors.Red, BasicColors.Yellow, BasicColors.Blue]`.

You can use a Constant block to output enumerated values. However, that block displays parameters that do not apply to enumerated types, such as **Output Minimum** and **Output Maximum**.

If you create a `Simulink.Parameter` object as an enumeration, you must specify the **Value** parameter as an enumeration member and the **Data type** with the `Enum:` or `?` prefix, as explained in “Specify Enumerations as Data Types” on page 73-12.

You *cannot* specify the integer value of an enumeration member for the **Value** parameter. See “Enumerated Values in Computation” on page 73-16 for more information. Thus, the following fails even though the integer value for `BasicColors.Yellow` is 1.

The same syntax and considerations apply in Stateflow. See “Enumerated Data” (Stateflow) for more information.

## Enumerated Values in Computation

By design, Simulink prevents enumerated values from being used as numeric values in mathematical computation, even though an enumerated class is a subclass of the MATLAB `int32` class. Thus, an enumerated type does not function as a numeric type despite the existence of its underlying integers. For example, you cannot input an enumerated signal directly to a Gain block.

You can use a Data Type Conversion block to convert in either direction between an integer type and an enumerated type, or between two enumerated types. That is, you can use a Data Type Conversion block to convert an enumerated signal to an integer signal (consisting of the underlying integers of

the enumerated signal values) and input the resulting integer signal to a Gain block. See “Casting Enumerated Signals” on page 73-17 for more information.

Enumerated types in Simulink are intended to represent program states and control program logic in blocks like the Relational Operator block and the Switch block. When a Simulink block compares enumerated values, the values compared must be of the same enumerated type. The block compares enumerated values based on their underlying integers, not their order in the enumerated class definition.

When a block like the Switch block or Multiport Switch block selects among multiple data signals, and any data signal is of an enumerated type, all the data signals must be of that same enumerated type. When a block inputs both control and data signals, as Switch and Multiport Switch do, the control signal type need not match the data signal type.

### Casting Enumerated Signals

You can use a Data Type Conversion block to cast an enumerated signal to a signal of any numeric type, provided that the underlying integers of all enumerated values input to the block are within the range of the numeric type. Otherwise, an error occurs during simulation.

Similarly, you can use a Data Type Conversion block to cast a signal of any integer type to an enumerated signal, provided that every value input to the Data Type Conversion block is the underlying integer of some value in the enumerated type. Otherwise, an error occurs during simulation.

You cannot use a Data Type Conversion block to cast a numeric signal of any non-integer data type to an enumerated type. For example, the model used in “Simulate with Enumerations” on page 73-10 needed two Data Conversion blocks to convert a sine wave to enumerated values.

The first block casts double to int32, and the second block casts int32 to BasicColors. You cannot cast a complex signal to an enumerated type regardless of the data types of its real and imaginary parts.

### Casting Enumerated Block Parameters

You cannot cast a block parameter of any numeric data type to an enumerated data type. For example, suppose that an Enumerated Constant block specifies a **Value** of 2 and an **Output data type** of Enum: BasicColors:

An error occurs because the specifications implicitly cast a `double` value to an enumerated type. The error occurs even though the numeric value corresponds arithmetically to one of the enumerated values in the enumerated type.

You cannot cast a block parameter of an enumeration to any other data type. For example, suppose that a Constant block specifies a **Constant value** of `BasicColors.Blue` and an **Output data type** of `int32`.

An error occurs because the specifications implicitly cast an enumerated value to a numeric type. The error occurs even though the enumerated value's underlying integer is a valid `int32`.

## Create and Edit Signal Data

### In this section...

“Differences Between the Root Inport Mapper Signal Editor and Other Signal Editors” on page 74-3

“Table Editing Data Support” on page 74-3

“Add and Edit Multidimensional Signals” on page 74-3

“Draw a Ramp Using Snap to Grid for Accuracy” on page 74-6

“Save and Send Changes to the Root Inport Mapper Tool” on page 74-8

Use the Signal Editor to create and edit input signals that you can organize for multiple simulations. You can then save the signal data to a MAT-file for simulation or to map to root-level ports. By default, Signal Editor creates signal data in `timeseries` format. You can access the Signal Editor in the following ways:

- `signalEditor` function — Signal Editor starts from the command line.
- From the Root Inport Mapper on page 76-7 — To create a MAT-file for your new signal data, select **Signals > New MAT-File**. To link in an existing signal data file from an existing scenario and edit the signals in that file, use the **Signals > Edit MAT-File**.
- From the Signal Editor block

Signal Editor works only with MAT-files.

You can manipulate signals in these ways:

- Create and edit multiple signals in multiple data sets. By default, Signal Editor creates `timeseries` format data.
- Use signal notations to create more complicated signals using MATLAB expressions. You can use the **Author and Insert** dialog box or manually enter simple MATLAB expressions in the tabular area.
- Use existing scenarios to get existing data sets for which you can edit and create signals.
- Create and edit multidimensional signals.
- Edit signals imported as registered custom file types. For more information, see “Import Custom File Type” on page 74-30.

While editing signal data:

- Use tabular editing or MATLAB to modify signal data.
- Use mouse or multi-touch editing to graphically modify signal data.
- Modify signal properties such as name, interpolation, and unit properties.
- Drag and drop signals to change signal hierarchies for buses and data sets.
- Use signal notations and variables to replace signal data.

Alternatively, you can import data from external sources and edit them in Signal Editor. For more information, see “Link in Signal Data from Signal Builder Block and Simulink Design Verifier Environment” on page 74-9.

To graphically create and edit signal data, see “Create Freehand Signal Data Using Mouse or Multi-Touch Gestures” on page 74-27.

## Differences Between the Root Inport Mapper Signal Editor and Other Signal Editors

Generally, the Signal Editor user interface is the same regardless of how you access it. Here are the differences in the Root Inport Mapper Signal Editor:

- FILE section **Save and Sync** and **SAVE** commands save and synchronize to the Root Inport Mapper.
- **Insert** section **Scenario** command always has the option, **Scenario from Model**.

If you start the function with a model name, the `signalEditor` function Signal Editor user interface shows the option **Scenario from Model** in the **Insert** section.

## Table Editing Data Support

The Signal Editor user interface supports all signal data types that Simulink supports and that are editable.

## Add and Edit Multidimensional Signals

To add multidimensional signals, use either of these options:

- Change the **Dimensions** property in the Default Properties for Insertion dialog box, and then use **Insert > Blank Signal** to insert a new blank signal. For a multidimensional blank signal, enter a dimension greater than 1.
- Enter multidimensional signal data in the Author and Insert dialog box **Data** parameter, such as `[(1:10)' (1:10)']`.

When you click the **Plot/Edit** check box for the signal, the tabular area displays the signal with columns for each dimension. You can edit the data individually in the tabular area, or click the replace button  to replace the signal with a MATLAB expression. Use the Author and Replace Signal Data dialog box as though you are inserting a new expression with the Author and Insert dialog box. For more information, see “Create Signals with MATLAB Expressions and Variables” on page 74-21.

---

**Tip** When replacing a signal, the signal dimension and complexity of the new signal must be the same as the signal being replaced.

---

For example, to create signal data with two columns and time from 1 to 10:

- 1 In the Signal Editor, select **Insert > Author Signal**.
- 2 Enter signal data with two columns and time from 1 to 10:
  - **Time** — `[1:10]`
  - **Data** — `[(1:10)' (1:10)']`

**Author and Insert** ✕

To specify times and data values for the signals, type MATLAB expressions or existing workspace variables.

Time: [1:10]

Data: [(1:10)' (1:10)]

Data type: double ▾

Number of samples: 10  
Data type: double  
Dimensions: 2

Show Examples >>

Help Insert Signal Cancel

- 3 Click **Insert Signal**.

The hierarchy updates with the new signal data.

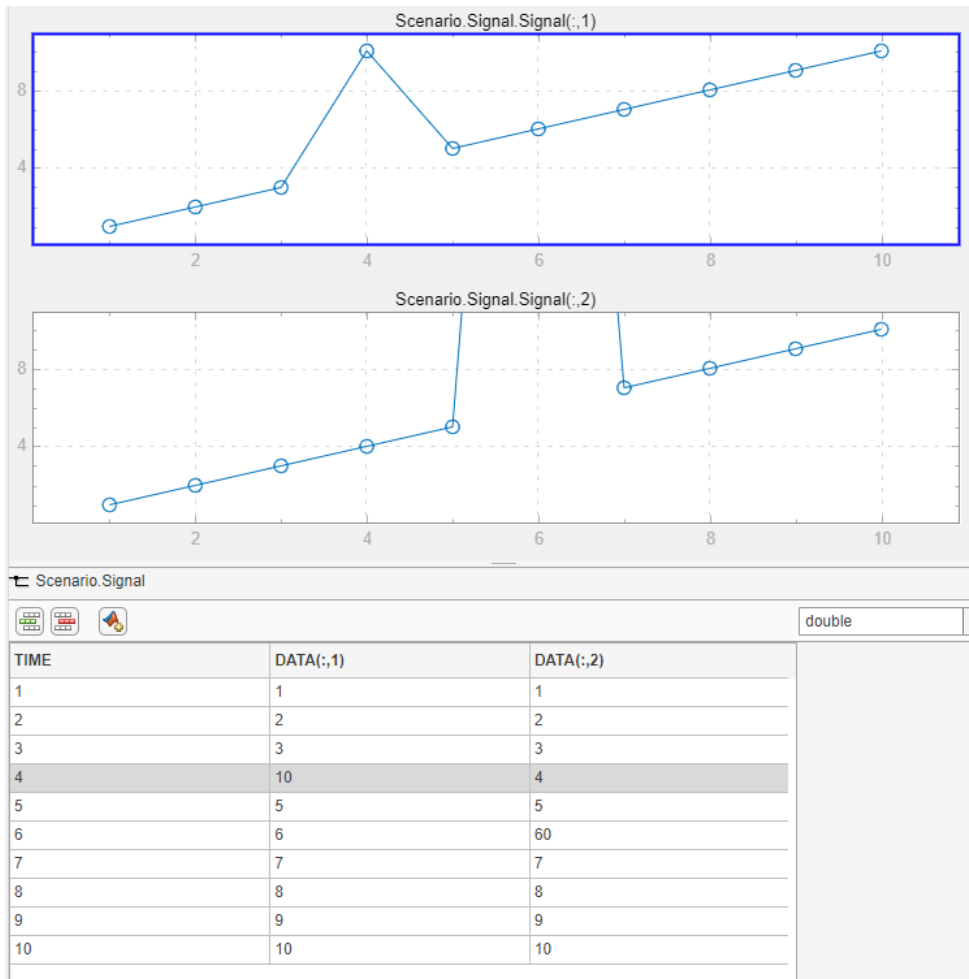

- 4 Expand the new signal and click the **Plot/Edit** check boxes for the new signal data. Observe the associated plots and the tabular data for the signal.

**Tip** If the data does not plot as expected, use the **Fit to window** button in the **Zoom & Pan** section. For multidimensional signals, also make sure that you have the right plot selected for the column data you are editing.

- 5 You can edit the data directly in the table.

Or you can replace data completely with a new expression by clicking the **Replace** button and entering a new time range and data in the Author and Replace Signal Data dialog box.

## Draw a Ramp Using Snap to Grid for Accuracy

This example describes how to create a ramp signal by selecting some points in the canvas.

- 1 In the Signal Editor tab, select **Signal > Draw Signal**.
- 2 To line up the signal data values along horizontal and vertical lines, select **Snap X to Grid** and **Snap Y to Grid**.

Move and zoom also honor snap to grid settings.

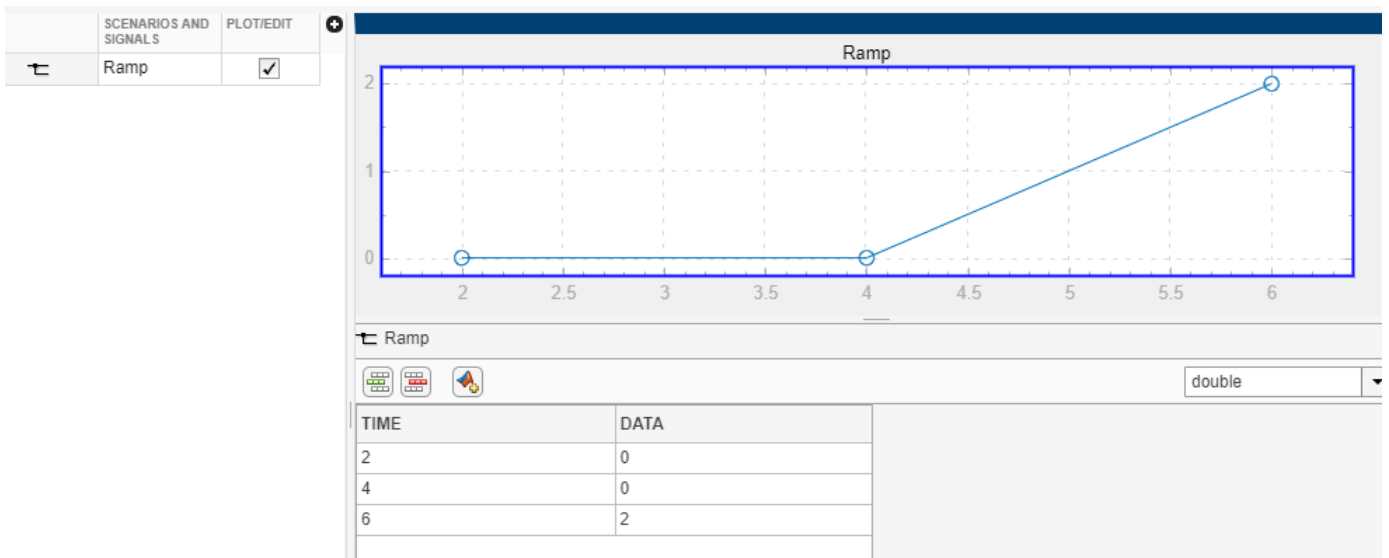

- 3 In the canvas, add three points:
  - Two points horizontal to each other
  - One point set to the right at an angle to the other signals
- 4 In the Signal Properties section, in **Name**, change the signal name to Ramp and press **Enter**.

5 To add the signal to the Signal Editor, in the **Insert** section, click .

6 To return to the main Signal Editor window and check that the signal has been added, click .

7 To observe the drawn signal data In Signal Editor, click the **Plot/Edit** check box for the Ramp signal name in the hierarchy.

## Save and Send Changes to the Root Inport Mapper Tool

When you are done adding and modifying signals and scenarios, use the **Save and Sync** button to save the changes to a MAT-file. The Signal Editor also sends the data to the Root Inport Mapper Tool:

- If the Root Inport Mapper tool has the scenario loaded, the Root Inport Mapper tool updates with the new data.
- If the Root Inport Mapper tool has the scenarios mapped and your changes affect the mapping, the Root Inport Mapper tool unmaps the scenario.

## Use Scenarios and Insert Signals in Signal Editor

### Use Scenarios to Group and Organize Inputs

Signal Editor uses scenarios to group and organize sets of inputs to be saved to a MAT-file for a single simulation. To create signal data using existing data sets from existing scenarios, or create an empty scenario into which to add signals, use the Signal Editor **Scenario** menu.

Action	Option
To create a scenario from the root inports of a model	Select <b>Scenario &gt; Scenario from Model</b> . (Available only when accessing Signal Editor from the Root Inport Mapper.)  You can also use the <code>signaleditor</code> function with a model argument.  <b>Note</b> When using this option, the resulting scenario contains signals with the data types and dimensions of the inport ports.
To create an empty scenario and create signals from scratch	Select <b>Scenario &gt; Blank Scenario</b> .
To import scenarios from MATLAB workspace	Select <b>Scenario &gt; From Workspace</b> .

After you have your scenario:

- To begin inserting signals, use the other options in the **Insert** section. For more information, see “Create Signals and Signal Data” on page 74-17.
- To change the signal order in the hierarchy or change the name of a signal, see “Change Signal Names and Hierarchy Orders”.

### Link in Signal Data from Signal Builder Block and Simulink Design Verifier Environment

You can use **Signals > Edit MAT-File** to link in MAT-file data from these sources for editing.

- Signal Builder blocks.
- Simulink Design Verifier.

### Link in Data from Signal Builder

You can link in and edit data exported from the Signal Builder block in a MAT-file or MATLAB. Use one of these methods to export the data:

- Signal Builder block **File > Export Data > To MAT-file** option, then link in the MAT-file.
- `signalbuilder` get function with data sets, then perform either of these steps:
  - Import the data sets in the workspace and save to a MAT-file
  - Save the data sets in the workspace to a MAT-file and import the MAT-file

For more information on exporting from a Signal Builder block, see “Exporting Signal Group Data” on page 80-88.

### Link in Test Vectors from Simulink Design Verifier Environment

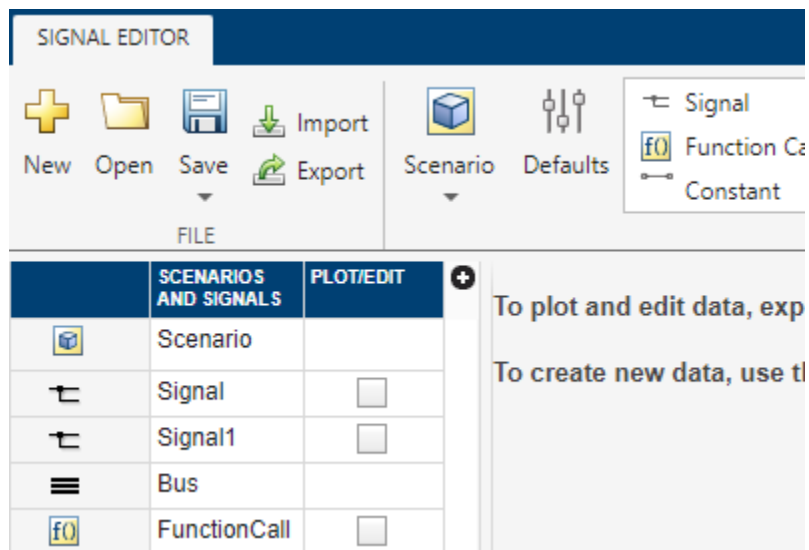

You can link in and edit Simulink Design Verifier test vectors. This workflow requires a Simulink Design Verifier license.

Before linking in, use the Simulink Design Verifier `sldvsimdata` function to convert a Simulink Design Verifier test structure to a set of `Simulink.SimulationData.Dataset` objects. This file contains a test vector structure `sldvData`. Save the output to a MAT-file and then import that file into Signal Editor.

## Insert Signals

To insert signals into scenarios, select the scenario, then click a signal type from the **Insert** section.

The new signals appear in the **Scenarios and Signals** section.

You can also insert multiple signals of the same type. For more information, see “Create Signals with the Same Properties”.

To change the signal order in the hierarchy or change the name of a signal, see “Change Signal Names and Hierarchy Orders”.

To edit the properties of a signal:

- For tabular editing, see “Work with Basic Signal Data with a Tabular Editor” on page 74-17.
- To replace the signal data or edit the signal notation using MATLAB expressions, see “Replace Signal Data with MATLAB Expressions” on page 74-24.

## Add Signals to Scenarios

This example describes how to create a scenario to be linked to from the Root Inport Mapper tool. You can then start the Signal Editor to manipulate and add signals to this scenario.

- 1 In the MATLAB Command Window, create some data by typing:

```
ts = timeseries([0;20],[0;10]);
```

- 2 In Simulink Editor, create a model that contains three Inport blocks, three Gain blocks, a Mux block, and a Scope block. Connect these blocks as shown:

- 3 Set the gain for the Gain blocks to 5, 10, and 15, respectively.
- 4 Click one of the Inport blocks, then click the **Connect Inputs** button.

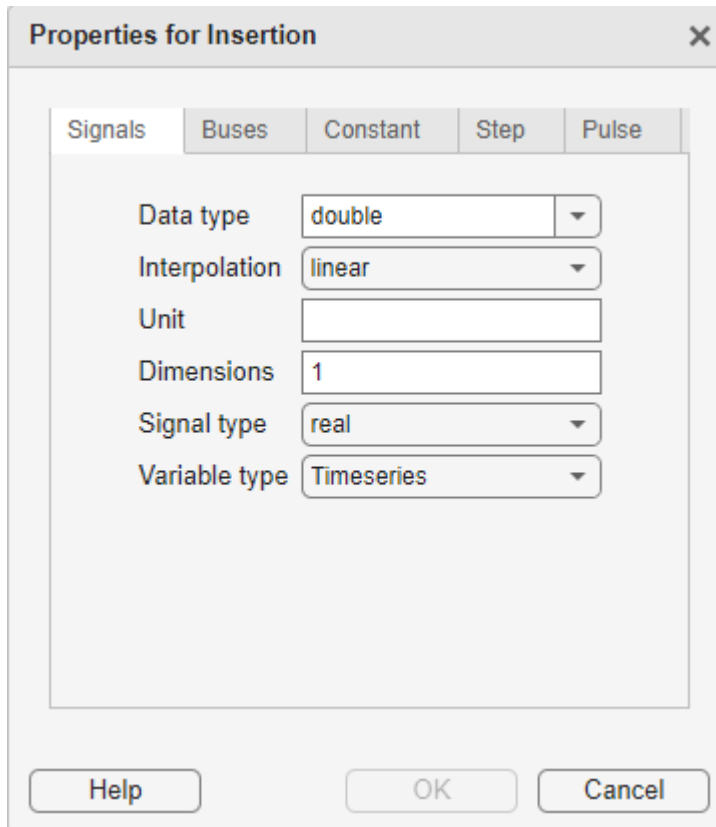

The Root Inport Mapper tool displays.

- 5 In Root Inport Mapper **Link** section, select **From Workspace**.
- 6 In the From Workspace window, enter a name to store the MAT-file, then click **OK**.
- 7 In the **Scenario** section of the Signal Editor, click **Signals > Edit MAT-File**.
- 8 In the Edit Signal File window, select the new MAT-file and click **OK**.

The Signal Editor displays.

- 9 Add a signal, *Signal*, to the scenario. Right-click the scenario and select **Insert > Blank Signal**.

This action adds *Signal* with these default properties.

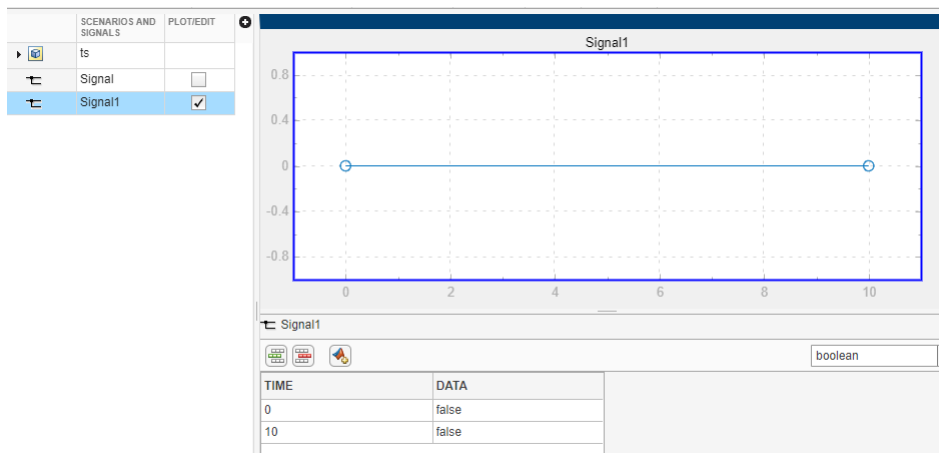

Alternatively, insert signals by clicking a signal type from the **Insert** section or using the **Signal** split button to author a signal using signal notations.

- 10 Change the default properties of signals you want to add. In the **Insert** section, select **Defaults**. In the Default Properties for Insertion dialog box, change the data type to **boolean**, then right-click the scenario and select **Insert** > **Blank Signal**.

This action adds *Signal1* with the data type **boolean**.

- 11 To check that the data type is **boolean**, click the plot check box for *Signal1*.

## More About

- “Create and Edit Signal Data” on page 74-2
- “Work with Basic Signal Data” on page 74-17
- “Create Signals with MATLAB Expressions and Variables” on page 74-21
- “Create Freehand Signal Data Using Mouse or Multi-Touch Gestures” on page 74-27

## Create Signal Data Using Standard Waveforms

In the **Signal Editor** tab, create signal data from the standard waveform options. These are the standard waveforms with default properties.

- **Constant** — Straight line waveform with a default value of 1.

- **Step** — Step waveform with default initial value of 0 and final value of 5.

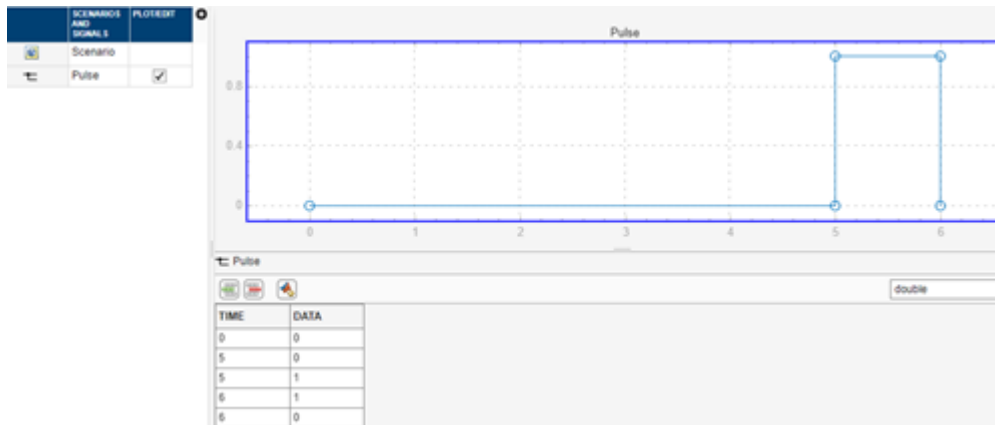

- **Pulse** — Pulse waveform with default initial value of 0, pulse at trigger 5, and pulse duration of 1.

To change the data from these waveforms, you can manually modify them in the plot. If you want to create multiple waveform plots with the same set of initial data, you can change the default signal properties for the waveform.

- 1 Start Signal Editor.
- 2 In the toolstrip, click **Scenario**.
- 3 To add a pulse waveform to the scenario, select the scenario and from the **Insert** section, click **Pulse**.
- 4 In the signal hierarchy, click the **Pulse** check box.

5

To change the default of the pulse waveform and its data, in the toolstrip, click **Defaults** (  ).

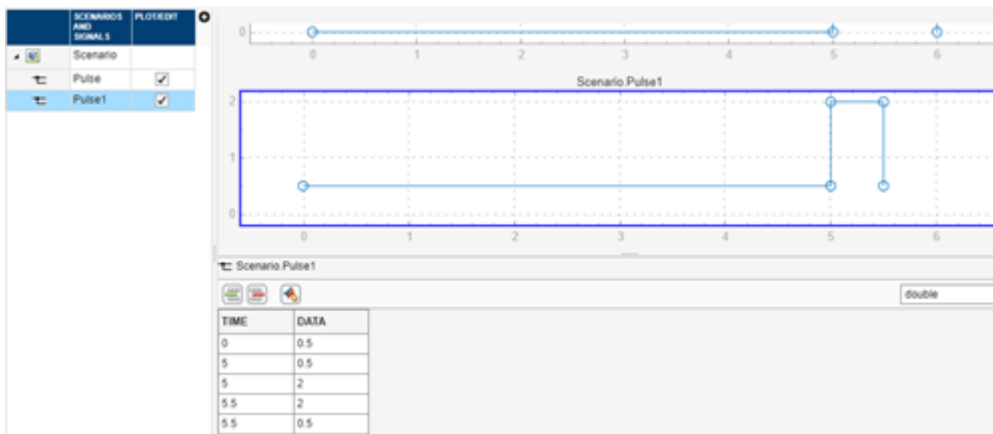

6 In the **Pulse** tab of the **Defaults** dialog box, change the values as desired. For example:

The screenshot shows the "Properties for Insertion" dialog box with the "Pulse" tab selected. The dialog box has five input fields for pulse parameters:

Property	Value
Initial value	.5
Value at trigger	2
Pulse duration	.5
Start time	0
Trigger time	5

At the bottom of the dialog box are three buttons: "Help", "OK", and "Cancel".

7 To add a second pulse waveform to the scenario, select the scenario and from the **Insert** section, click **Pulse**.

## More About

- “Create and Edit Signal Data” on page 74-2
- “Use Scenarios and Insert Signals in Signal Editor” on page 74-9
- “Work with Basic Signal Data” on page 74-17
- “Create Signals with MATLAB Expressions and Variables” on page 74-21
- “Create Freehand Signal Data Using Mouse or Multi-Touch Gestures” on page 74-27

## Work with Basic Signal Data

### Create Signals and Signal Data

In the **Signal Editor** tab, create signal data either from existing model data (scenarios) or start with an empty scenario. By default, Signal Editor creates data in `timeseries` format. To a scenario, add signals and data by:

- Adding basic signals or waveforms to Signal Editor (“Insert Signals” on page 74-10)
- Adding signal data directly into a table (“Work with Basic Signal Data with a Tabular Editor” on page 74-17).
- Authoring signal data using signal notations and variables (“Create Signals with MATLAB Expressions and Variables” on page 74-21).
- Drawing signal points and lines (“Create Freehand Signal Data Using Mouse or Multi-Touch Gestures” on page 74-27)

After inserting the signal, view, plot, and edit the data by clicking the **Plot/Edit** check box. The plot opens in the **Edit** tab.

If the data does not plot as expected, use the **Fit to window** button in the **Zoom & Pan** section. For multidimensional signals, also make sure that you have the right plot selected for the column data you are editing.

Explore the plots using the **Measure** and **Zoom & Pan** sections on the toolbar.

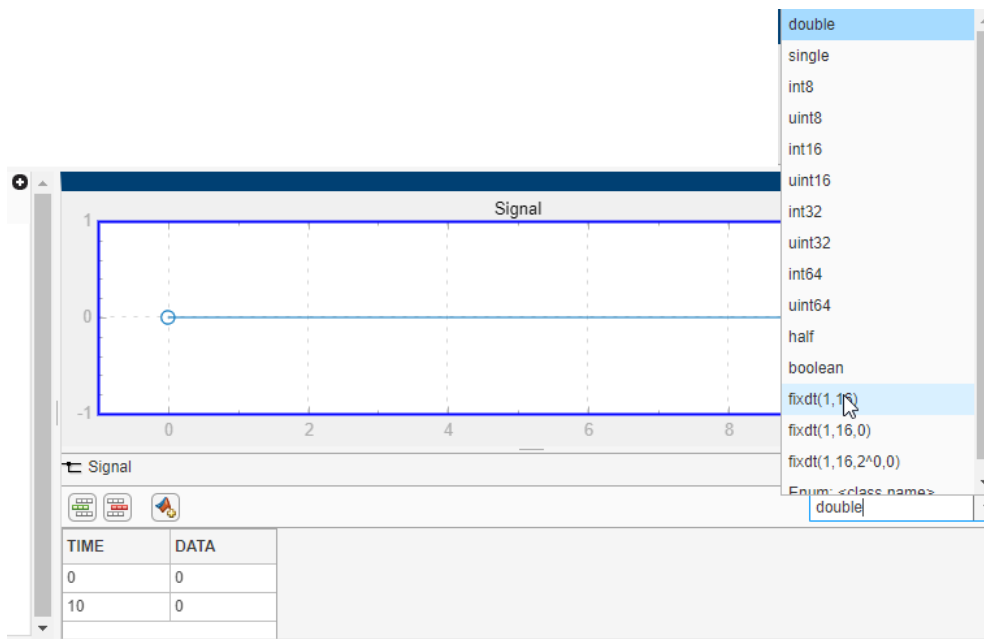

- In the **Measure** section, use the **Data Cursors** button to display one or two cursors for the plot. These cursors display the T and Y values of a data point in the plot. To view a data point, click a point on the plot line.
- In the **Zoom & Pan** section, select how you want to zoom and pan the signal plots. Zooming is only for the selected axis.

### Work with Basic Signal Data with a Tabular Editor

To add and edit basic signal data, select a signal and click the associated **Plot/Edit** check box. The **Edit** tab opens with a plot of the signal. Each data point in the signal is demarcated with a circle (marker), which you can toggle off and on through the context menu **Show > Toggle Markers** option. Under the signal plot is a tabular editor.

- To insert or delete a data row for a signal, use  or , respectively.
- To change the data type for signal data, select the type from the drop-down.

- To change the time or data for each signal, edit the associated column of the data row, then click anywhere in the canvas to update the plot of the signal. You may need to click **Fit to View** in the toolstrip to adjust the plot axes.

**Note** If the data is fixed-point data, hovering over the data in the table displays a summary of the data

- Ideal Value — Requested value.
  - Fixed-Point Value — Value resulting from casting the ideal value as a fixed-point value.
  - Absolute Error — Absolute error of value.
  - Relative Error — Difference between cast value and the original value.
  - Additional error information, such as whether the error is an overflow or underflow.
- 
- To change the size of the plot or tabular area, move the separator up and down.

- To evaluate MATLAB expressions in table cells, type them in a table cell:
  - The expression must be a valid MATLAB syntax.
  - The result of the syntax must be a scalar value.
  - The result of the syntax must be a valid value based on the signal properties such as data type and complexity.

Expressions can access variables in the base workspace. If an expression does not satisfy these guidelines, Simulink reverts the cell entry to the original value. When you start the Signal Editor interface launched from a Signal Editor block, expressions can contain variables from the model workspace or data dictionary. When you start the Signal Editor interface separately from the block, you must provide the model parameter to access variables from the model workspace or data dictionary.

- To create multidimensional signals, use one of these methods. For more information, see “Add and Edit Multidimensional Signals” on page 74-3.

- In the Default Properties for Insertion dialog box, enter a dimension greater than 1 in the **Dimensions** parameter.
- In the Author and Insert dialog box, enter a MATLAB expression that creates multidimensional signals in the **Data** parameter
- You can now navigate through the Signal Editor user interface tabular area using **Tab** and **Shift+Tab**.
  - 1 In the Signal Editor tabular area, enter the cell edit mode of the tabular area by either
    - a Double-clicking a table cell
    - b Pressing the **Enter** key

When cell edit mode is enabled, the resulting cell is white and outlined in blue:

TIME	DATA(:,1)	DATA(:,2)	
1	1	1	
2	2	2	
3	3	3	
4	4	4	
5	5	5	

- 2 To navigate forward through the table, press **Tab**.
- 3 To navigate backward through the table, press **Shift+Tab**.

Instead of using the tabular editor to define signal data, you can use MATLAB expressions.

- “Create Signals with MATLAB Expressions and Variables” on page 74-21
- “Create Freehand Signal Data Using Mouse or Multi-Touch Gestures” on page 74-27

## Create Signals with MATLAB Expressions and Variables

To add signals using MATLAB expressions and variables, select the Signal Editor **Signal > Author Signal** option.

Author and Insert

To specify times and data values for the signals, type MATLAB expressions or existing workspace variables.

Time:

Data:

Number of samples:  
Data type:  
Dimensions:

Show Examples >>

Help Insert Signal Cancel

For a description of these parameters, see “Author Signal”.

When you click **Insert Signal**, the interface evaluates the signal, updates the signal information in the dialog box, and adds the signal to the **Scenarios and Signals** section. In addition, the number of samples, signal data type, and signal dimension also appear.

To see example **Time** and **Data** entries, click the **Show Examples** button. To experiment with the signals from these example signal notations, click the **Apply Example** button for the associated example. You can also modify the examples before inserting.

For example, to create a sine wave, click the **Apply Example** button next to that example and click the **Insert Signal** button. Observe that dialog box displays the number of samples, signal data type, and signal dimensions.

**Author and Insert** ✕

To specify times and data values for the signals, type MATLAB expressions or existing workspace variables.

Time:

Data:

Data type:  ▼

Number of samples: 101  
Data type: double  
Dimensions: 1

[Hide Examples <<](#)

**Examples**

To create a vector, enter values:

Time:

Data:

To create a 2-D column vector, enter a range of values for each column:

Time:

Data:

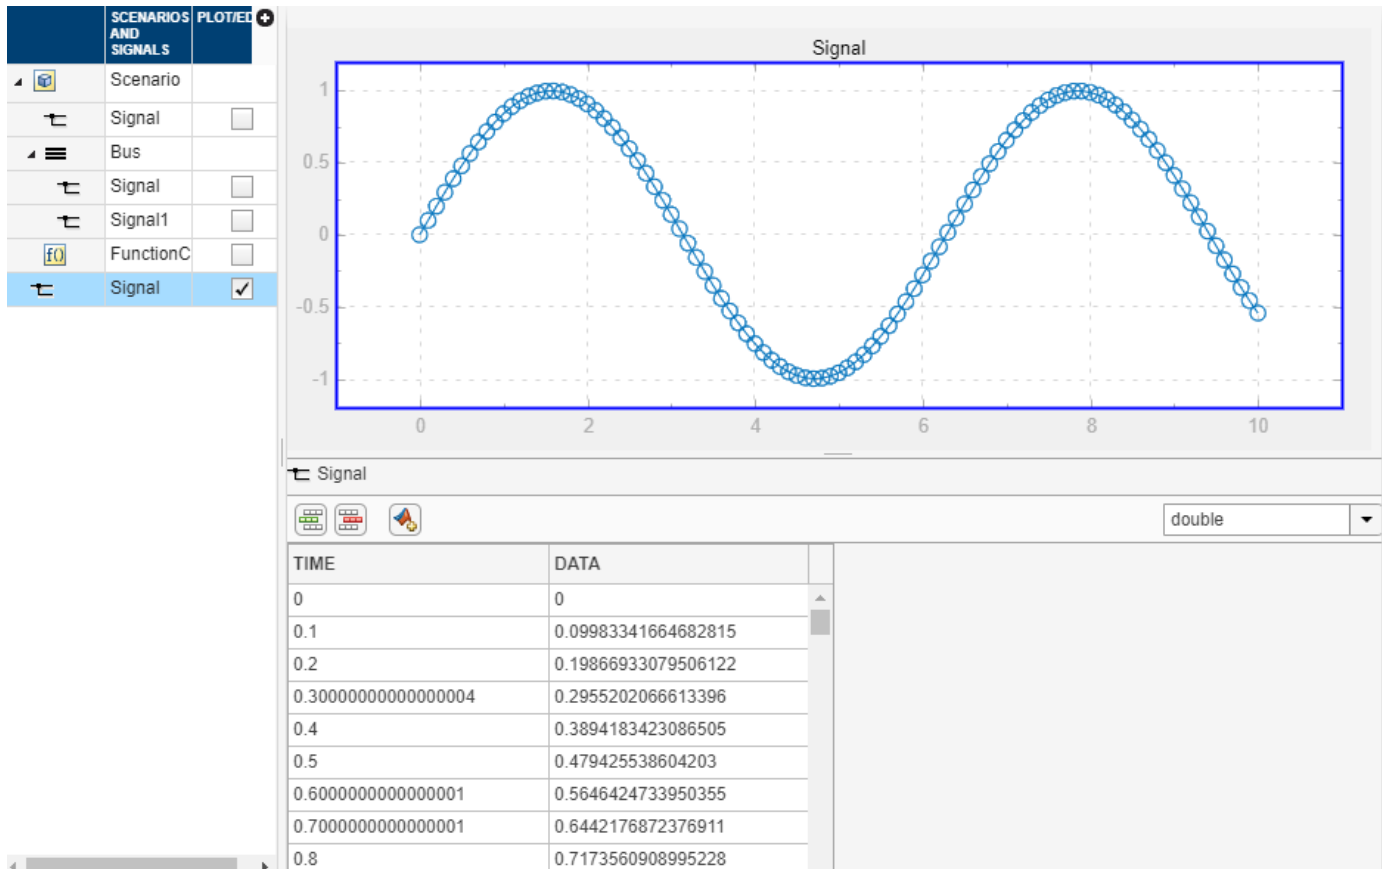

Create a sine wave:

Time:

Data:

To reference MATLAB workspace variables, enter the variable names in the 'Time' and 'Data' fields.

To view the signal, cancel the Author and Insert dialog box, navigate to the **Scenarios and Signals** section, and click the **Plot/Edit** button for the new signal. If a signal has real and imaginary parts, both parts display in one plot. The tabular editor also reflects the signal data.

Explore the plots using the plot context menus **Align** and **Zoom & Pan**.

If the data does not plot as expected, use the **Fit to view** button in the **Zoom & Pan** section. For multidimensional signals, also make sure that you have the right plot selected for the column data you are editing.

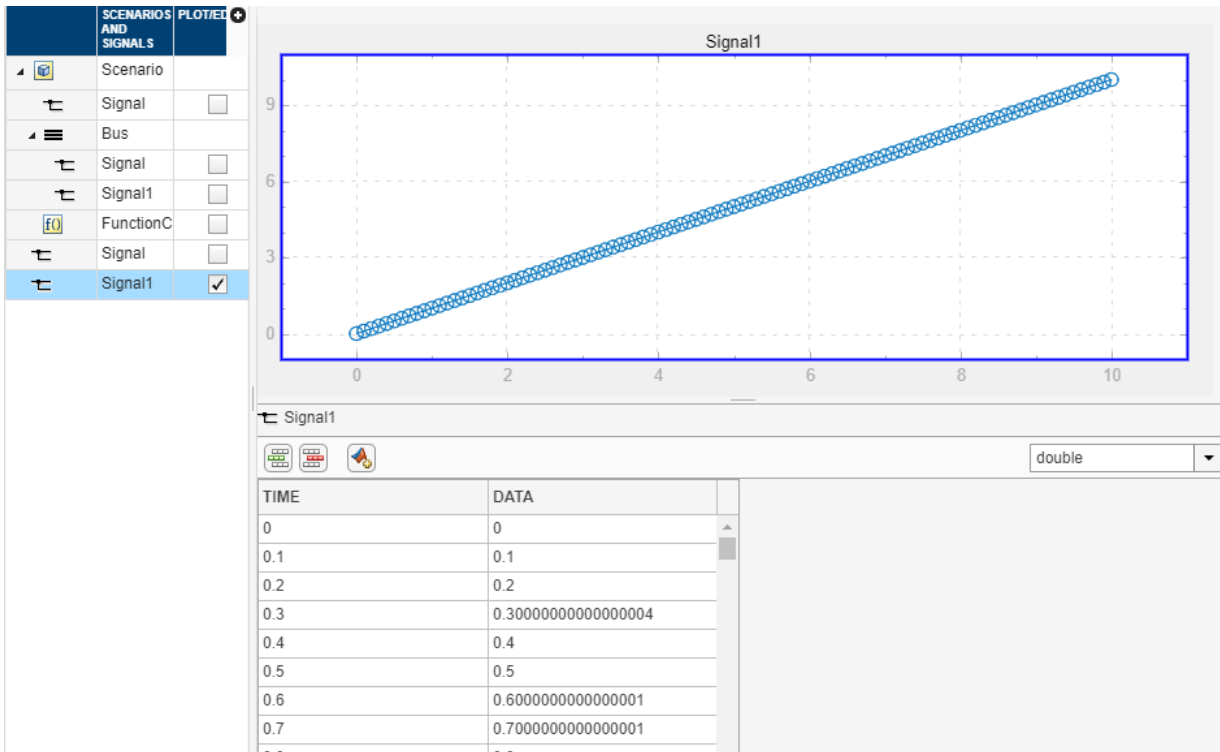

- In the **Measure** section, use the **Data Cursors** button to display one or two cursors for the plot. These cursors display the T and Y values of a data point in the plot. To view a data point, click a point on the plot line.
- In the **Zoom & Pan** section, select how you want to zoom and pan the signal plots. Zooming is only for the selected axis.

Type of Zoom or Pan	Button to Click
Zoom in along the T and Y axes.	
Zoom in along the time axis. After selecting the icon, on the graph, drag the mouse to select an area to enlarge.	
Zoom in along the data value axis. After selecting the icon, on the graph, drag the mouse to select an area to enlarge.	
Zoom out from the graph.	

Type of Zoom or Pan	Button to Click
Fit the plot to the graph. After selecting the icon, click the graph to enlarge the plot to fill the graph.	
Pan the graph up, down, left, or right. Select the icon. On the graph, hold the left mouse button and move the mouse to the area of the graph that you want to view.	

**Tip** To produce signals with linearly spaced values for time, use the `linspace` function, for example:

- **Time** — `linspace(0,10,101)`
- **Data** — `[0:0.1:10]`

To edit signal data without using MATLAB expressions, see “Work with Basic Signal Data” on page 74-17.

## Replace Signal Data with MATLAB Expressions

You can replace signal data using MATLAB expressions at any time, regardless of how you created the original signal data. To replace signal data, select that signal in the **Scenarios and Signals**

section, and then click the replace button (). Use the Author and Replace Signal Data dialog box as if you were inserting a new expression with the Author and Insert dialog box. For more information, see “Create Signals with MATLAB Expressions and Variables” on page 74-21.

---

**Note** You cannot change data types to or from a fixed-point data type.

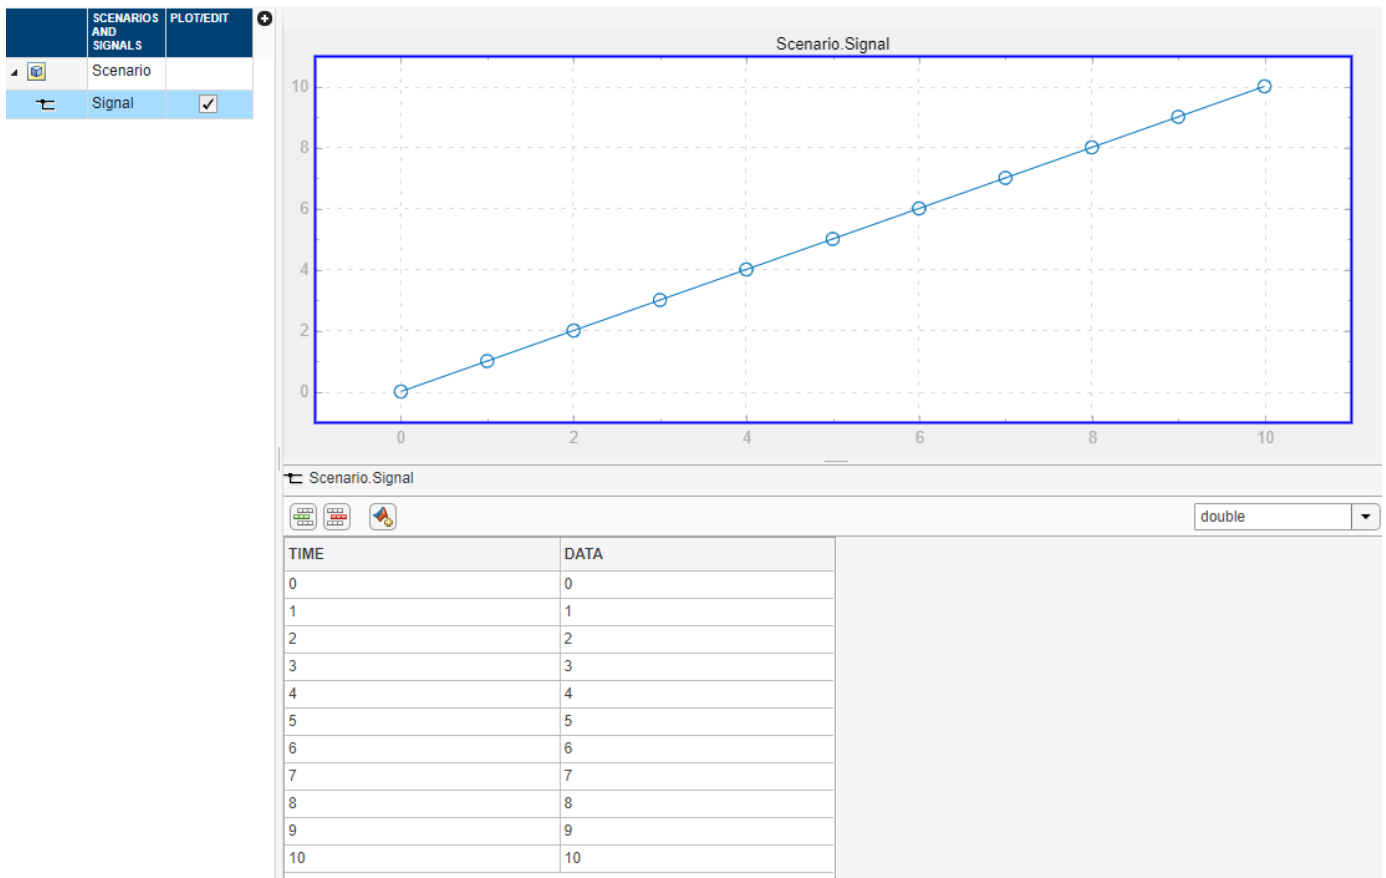

---

**Tip** When replacing a signal, the signal dimension and complexity of the new signal must be the same as the signal being replaced.

---

**Tip** To produce signals with linearly spaced values for time, use the `linspace` function. For example, using:

- **Time** — `linspace(0,10,11)`
- **Data** — `[0:10]`

## More About

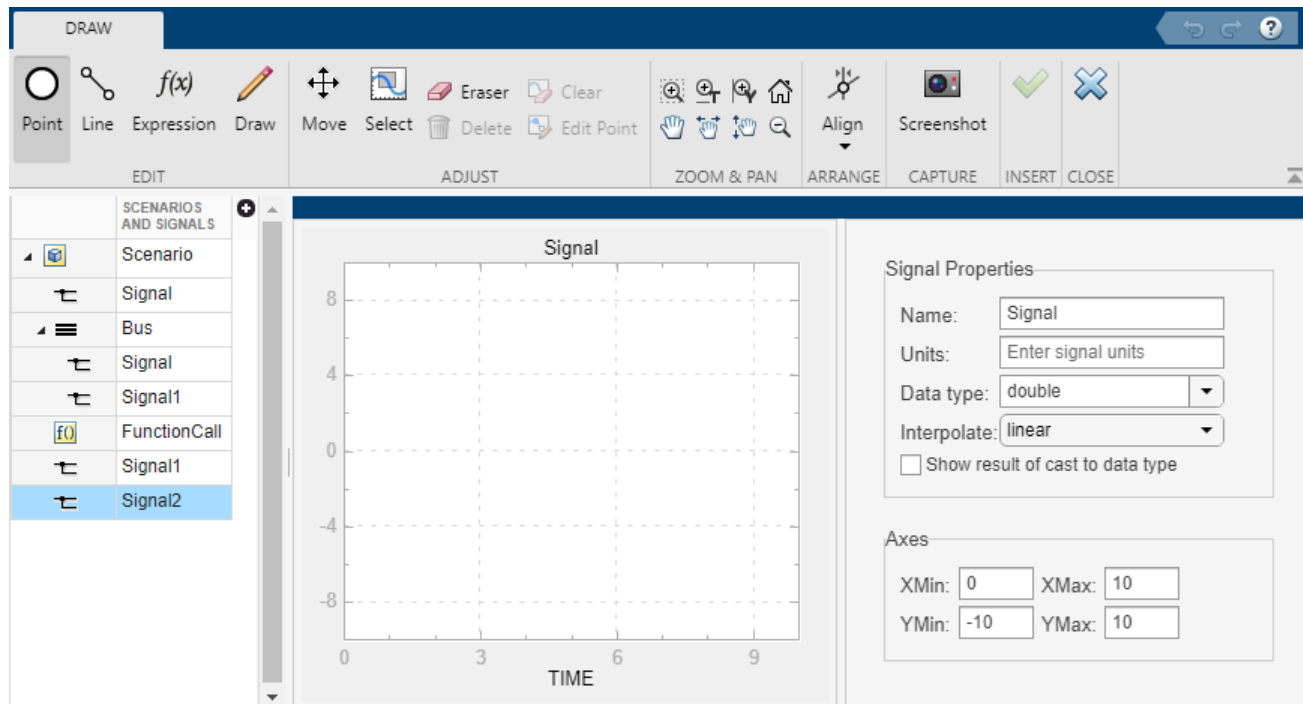

- “Create and Edit Signal Data” on page 74-2
- “Use Scenarios and Insert Signals in Signal Editor” on page 74-9
- “Work with Basic Signal Data” on page 74-17

- “Create Freehand Signal Data Using Mouse or Multi-Touch Gestures” on page 74-27

## Create Freehand Signal Data Using Mouse or Multi-Touch Gestures

Freehand signal data is data that you add graphically. Signal Editor allows you to add freehand signal data using a mouse or touchscreen (if available and supported). While using a touchscreen, use common multi-touch gestures such as tap, pan, pinch, and double-tap (select all). By default, freehand signal data is in timeseries format.

To add freehand signal data, in the **Signal Editor** tab, select **Insert > Draw Signal** option. A **Draw** tab opens.

You can draw your own signal lines or points, use MATLAB expression to enter data, move signal lines or points across the canvas, take an image of the lines of the canvas, and add the data to the Signal Editor.

To create signal data, in the **Edit** section:

- Insert a single data point by clicking **Point** and then clicking in the graph area. If you add additional points, the tool connects the points.
- Insert a signal line by clicking **Line** and then clicking in the graph area. To extend the line, click on the endpoints of the line and draw the extension.

---

**Tip** When you insert signals or signal lines, the canvas adds a shaded area bound by the leftmost and rightmost endpoints. While in **Insert Line** mode, you cannot add more points within this shaded area. You add additional line points outside the shaded area.

---

- Draw a signal freehand by clicking **Draw**.

- Draw a signal using MATLAB expressions by clicking **Expression** ( $f(x)$ , Ctrl+E). Enter time and data values that create signal points that are scalars or vectors whose number of points match the time points.

To select or move signal data, in the **Signal** section:

- Select a point or line by clicking **Select** and then selecting the point or area to be selected.
- Move a point or line by clicking **Move**.

To edit or remove the signal data, in the **Edit** section:

- Change the data of a point by clicking **Edit Point**. In the Edit Point dialog box, enter the new **Time** and **Data** values. These values must be scalar.

To work with the canvas, use the tools in the **Align**, **Show**, and **Zoom** sections.

- Snap the canvas graph to various grids using the tools in the **Align** section. Snapping to grid helps you better control data accuracy while drawing signals. For example, consider snapping to the x-grid to uniformly sample signal values or snapping to the y-grid to control the amplitude of a ramp signal.
- Toggle the display of data points, grid lines, and data markers in the canvas, explore the commands in the **Align** and **Show** sections. To zoom in and out of the canvas, see **Zoom & Pan**. These actions are touchscreen supported with the pan and pinch gestures. For more information, see “Create Signals and Signal Data” on page 74-17.

To work with signal properties, use the parameters in the **Signal Properties** section. For example, to see the changed values of your signal as you change data types in the **Data type** parameter, select the **Show result of cast to data type**. The original line is blue, the changed values are represented by the black line. This graphic illustrates a signal line with negative double values recast as uint8.

To capture an image of the signal data, in the **Capture** section, click **Screenshot** (). In the Save a screenshot dialog box, specify a name and graphic type for the file.

When you are done drawing the signal, in the **Insert** section:

- 1** To add the signal to the Signal Editor, click **Insert signal** (.
- 2** To return to the main Signal Editor window and check that the signal has been added, click **Close draw tab** (). Signal Editor discards any noninserted signal data.
- 3** To observe the drawn signal data In Signal Editor, click the signal name in the hierarchy.

For an example of how to add a freehand ramp signal, see “Draw a Ramp Using Snap to Grid for Accuracy” on page 74-6.

- “Work with Basic Signal Data” on page 74-17
- “Create Signals with MATLAB Expressions and Variables” on page 74-21
- How to Create Freehand Input Signals in the Signal Editor in Simulink

## Import Custom File Type

To edit signals that are in your own custom data format or a non-MAT-file, click **Import** on the **Signal Editor** tab. Custom file types:

- Are external to MATLAB or Simulink, such as Microsoft Excel or JSON format files.
- Contain signal data whose format does not conform to those listed in “Forms of Input Data” on page 75-48.

Simulink provides these file types.

- `Simulink.io.SignalBuilderSpreadsheet` — Signal Builder file type
- `Simulink.io.BaseWorkspace` — Base workspace file type
- `Simulink.io.MatFile` — MAT-file file type
- `Simulink.io.ModelWorkspace` — Model workspace file type
- Example file types
  - `Simulink.io.MySignalMatFile`
  - `Simulink.io.CreateSignals`

Simulink Test provides the `sltest.io.SimulinkTestSpreadsheet` file type.

To import custom file types that you develop in-house, you can create and register your own custom file type reader. For information, see “Create Custom File Type for Import to Signal Editor” on page 74-32. Afterwards, use this workflow to import custom file types into Signal Editor.

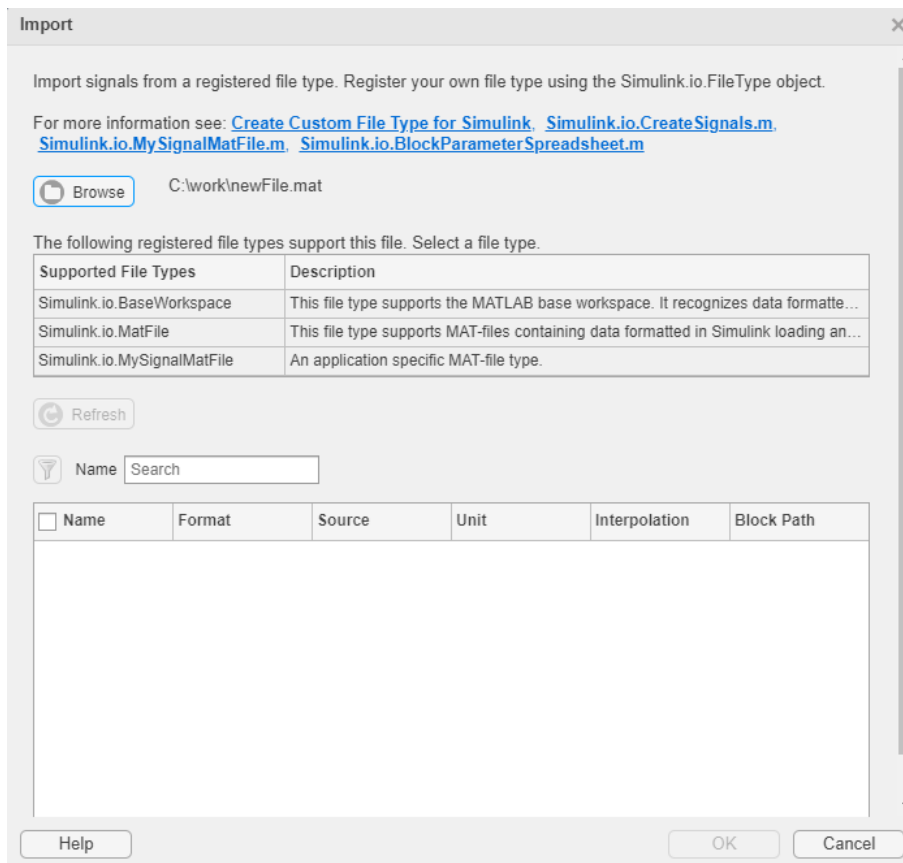

---

**Note** Before starting, check that nobody is editing the custom file type class file. Editing the custom file type class file while trying to import it as a reader causes unexpected behavior.

---

- 1 Check that your custom file types have been registered in Simulink. In the **Signal Editor** tab, click **Import**. The **Import** dialog box displays.
- 2 Click **Browse**.
- 3 From the list of custom MAT-files, select the one that contains your signals, such as `custompath/newFile.mat`.

All registered file types appear in the Supported File Types table.

- 4 Select the signals you want to see in Signal Editor and click **OK**. To search for a signal name, enter it in **Name**.
- 5 In the **Signal Editor** tab, observe that the signals are now in the hierarchy. You can edit these signals as you would any signal.

## More About

- “Create Custom File Type for Import to Signal Editor” on page 74-32
- “Export Signals to Custom Registered File Types” on page 74-36

## Create Custom File Type for Import to Signal Editor

By default, Simulink supports signals in the forms listed in “Forms of Input Data” on page 75-48. To import file types containing signals that are not of the supported format, create and register your own custom file type reader. Simulink supports custom file type readers written with `Simulink.io.FileType`.

Simulink provides these file types.

- `Simulink.io.SignalBuilderSpreadsheet` — Signal Builder file type
- `Simulink.io.BaseWorkspace` — Base workspace file type
- `Simulink.io.MatFile` — MAT-file file type
- `Simulink.io.ModelWorkspace` — Model workspace file type
- `Simulink.io.SLDVMatFile` — MAT-file containing Simulink Design Verifier `sldvData` structure
- Example file types
  - `Simulink.io.MySignalMatFile`
  - `Simulink.io.CreateSignals`
- Simulink Test provides the `sltest.io.SimulinkTestSpreadsheet` file type.

Creating a file reader requires you to be familiar with object-oriented programming. It is intended for an advanced audience.

- 1 To contain your package folders, create a folder and add that folder path to the MATLAB path.
- 2 To that folder, add the custom file that contains your signals, such as `mySignals.mat`.

In that folder, create a `+Simulink` folder, and inside that folder, create a `+io` folder.

- 3 Create a class that inherits from the `Simulink.io.FileType`.

```
classdef MyFileType < Simulink.io.FileType
```

- 4 Save this class to *yourfolder*/`+Simulink/+io`.

- 5 To register and interact with Signal Editor, implement these static methods:

- `Simulink.io.FileType.isFileSupported`
- `Simulink.io.FileType.getFileTypeDescription`

- 6 Implement these public methods:

- `validateFileNameImpl`
- `whosImpl`

At run time, call `whosImpl` via `whos` when you run the `Simulink.io.FileType` object. `whos` has the same syntax as `whosImpl`.

- 7 Check if your class is registered. In the **Signal Editor** tab, click **Import**, then in the **Import** dialog box window, click **Browse**.

The custom file that contains your signals, such as `custompath/mySignals.mat`, appears in the file browser.

- 8 Select the custom file that contains your custom signals.

9 Return to the class file and implement these additional public methods:

- `loadAVariableImpl`
- `loadImpl`

At run-time, call `loadImpl` via `load` when you run the `Simulink.io.FileType` object. `load` has the same syntax as `loadImpl`.

10 To import the custom signals, use the `import` method.

`dataOnFile = import(reader)`, where `reader` is the file type object for the reader, specified as a `Simulink.io.FileType` object. The output, `dataOnFile`, is a structure with the fields `structure.Data`, which is a cell array of signals, and `structure.Name`, which is a cell array of the corresponding signal names. For example, `dataOnFile.Data` is the cell array of signals and `dataOnFile.Name` contains the corresponding signal names.

11 Return to the Signal Editor, click **Import** and try to import again.

After you successfully import your custom signals, you can manipulate them in Signal Editor. When done, and if you have implemented the `exportImpl` method, you can export the results by calling the `export` method for your reader at run time. Alternatively, you can use the export dialog from “Export Signals to Custom Registered File Types” on page 74-36.

For example implementations, see:

- `open('Simulink.io.CreateSignals')` — Implementation of how to create signals
- `open('Simulink.io.MySignalMatFile')` — Implementation of how to register custom file types to import into Simulink.

## Define New FileType Object for Use in Simulink

A `FileType` object is a component you can use to create readers for signals that exist in formats not currently supported in Simulink. Write the reader in MATLAB and in the Signal Editor tab, click **Import** to register the reader and import the custom format file.

---

**Note** Before importing, check that all editors for the custom file type class file are closed. Editing the custom file type class file while trying to import it as a reader causes unexpected behavior.

---

## Define FileType Object

- 1 Create a `FileType` object for use in Simulink. This example creates a reader for signals with a custom format.
- 2 Create a class definition text file to define your `FileType` object.
- 3 On the first line of the class definition file, specify the name of your `FileType` and subclass from `Simulink.io.FileType`. The `Simulink.io.FileType` base class enables you to use all the basic `FileType` object methods.
- 4 For your class:
  - a Add the appropriate basic `FileType` object methods to register and interact with Signal Editor.
  - b Validate the signal formats.

- c** Determine the contents of the signal file.
- d** Load variables from the signal file.
- e** Import the signals.

See the reference pages for each method and the full class definition file below for the implementation of each of these methods. To see the full class definition for a custom signal reader, run: `open('Simulink.io.MySignalMatFile')`.

## More About

- “Import Custom File Type” on page 74-30
- “Create sldvData Custom File Type Reader to Import to Signal Editor” on page 74-35
- “Export Signals to Custom Registered File Types” on page 74-36
- “Forms of Input Data” on page 75-48

## Create sldvData Custom File Type Reader to Import to Signal Editor

Import Simulink Design Verifier sldvData structures into Simulink for editing.

- 1 Create an sldvData MAT-file reader using the `Simulink.io.SLDVMatFile` class and register that class. For more information, see “Create Custom File Type for Import to Signal Editor” on page 74-32.
- 2 Create a model and add a Signal Editor block.
- 3 Leave the Signal Editor **File name** parameter as `untitled.mat`.
- 4 From within the Signal Editor block dialog, click **To create and edit scenarios, launch Signal Editor user interface**.
- 5 In the **Signal Editor** tab, click **Import**.

The Signal Editor Import dialog displays.

- 6 In the Signal Editor Import dialog, click **Browse**.

The custom MAT-file that contains your sldvData signals, appears in the file browser.

- 7 From the table of registered file types, select `Simulink.io.SLDVMatFile` as the reader class for the sldvData MAT-file.

The table of datasets lists the test cases from the sldvData MAT-file.

- 8 Select the check boxes that correspond to the test cases you want to import to the Signal Editor for editing.
- 9 Click **OK**.

The Signal Editor loads the sldvData datasets.

- 10 When you finish editing the datasets, click **Save**, then enter a new MAT-file name to contain the edited sldvData datasets.

The file to which the edited sldvData datasets are saved is associated with the underlying Signal Editor block.

## Export Signals to Custom Registered File Types

To export signals from Signal Editor to your own custom file types, on the **Signal Editor** tab, click **Export**. Custom file types:

- Are external to MATLAB or Simulink, such as Microsoft Excel or JSON format files.
- Contain signal data whose format does not conform to those listed in “Forms of Input Data” on page 75-48.
- When exporting a `Simulink.io.SignalBuilderSpreadsheet` file type, it must contain a dataset represented with `Simulink.SimulationData.Dataset` objects that contain `timeseries` data with vector data.

Simulink provides these file types.

---

**Note** You cannot export from an `Simulink.io.SLDVMatFile` reader.

---

- `Simulink.io.SignalBuilderSpreadsheet` — Signal Builder file type
  - Example file types
    - `Simulink.io.MySignalMatFile`
    - `Simulink.io.CreateSignals`
- 1 In Signal Editor, create signals to export to your custom file type.
    - a Click **Scenario > Blank Scenario**.
    - b Click **Signal > Author Signal**.
    - c Click **Show Examples**. Select **Apply Example** for the 2-D column vector.
  - 2 Check that your custom file types have been registered in Simulink. In the **Signal Editor** tab, click **Export**. The **Export** dialog box displays.
  - 3 Click **Browse**.
  - 4 From the list of custom MAT-files, select the one that contains your signals, such as `custompath/newFile.mat`.

All registered file types appear in the Supported File Types table.

The signals in your custom file type appear in the file browser.

- 5 Select the signals you want to export from Signal Editor, then click **OK**.

## Provide Signal Data for Simulation

### In this section...

“Identify Model Signal Data Requirements” on page 75-2  
“Signal Data Storage for Loading” on page 75-2  
“Load Input Signal Data” on page 75-5  
“Log Output Signal Data” on page 75-6

A Simulink model performs algorithms on input signal data and produces output signals. The model defines what input data to use at the start of simulation and what output to capture at the end of simulation. As you create and simulate your model, you:

- 1 “Identify Model Signal Data Requirements” on page 75-2
- 2 “Load Input Signal Data” on page 75-5
- 3 “Log Output Signal Data” on page 75-6

As you create, debug, and test a model, you can use different sets of input signal data for simulation. You can use logged simulation data as input to another simulation.

### Identify Model Signal Data Requirements

To use system-generated signal data, use source blocks such as a Sine Wave block. Source blocks do not require the use of a variable or external data source. If you cannot configure source blocks to meet your modeling requirements, then supply the signal data.

As you determine your signal data requirements, identify the:

- Blocks (including subsystems and Model blocks) that you need to provide data for — Design interfaces for blocks and for model components, including data types of signals.
- Range characteristics of signals, such as sample time, dimensions, and data type.
- Storage location for data for each input signal — Determine where to store signal data: in workspace variables, a MAT-file, or an external data file such as an Microsoft Excel spreadsheet.

Create a list of equation variables and constant coefficients, and then determine the coefficient values from published sources or by performing experiments on the system.

For information about storage locations for signal data, see “Signal Data Storage for Loading” on page 75-2.

### Signal Data Storage for Loading

- “MATLAB Workspace for Signal Data” on page 75-3
- “Source and Signal Editor Blocks for Signal Data” on page 75-4
- “MAT-Files for Signal Data” on page 75-4
- “Spreadsheets for Signal Data” on page 75-4

Store signal data for loading into a model in these locations:

- MATLAB (base) workspace, or function workspace
- Model workspace
- Function workspace
- Masking workspace
- Blocks
- MAT-files
- Spreadsheets

The MATLAB (base) workspace is the most common workspace to use for loading signal data.

### **MATLAB Workspace for Signal Data**

Consider using the MATLAB (base) workspace when you want to:

- Use a small amount of signal data for iterative simulations.
- Use signal data logged during one simulation as input for another simulation.
- Have multiple models use the same signal data.

### **Create Signal Data in the MATLAB Workspace**

- At the MATLAB command line or editor, create the signal data.
- Use the `xlsread` function to read data from an Excel spreadsheet into the MATLAB workspace.
- Use the `readmatrix` function to read data from a CSV spreadsheet into the MATLAB workspace.
- Use a model callback to load signal data.
- Use one of these Simulink logging techniques:
  - Signal logging
  - To Workspace block
  - Scope block
  - The **Configuration Parameters > Data Import/Export** pane, the **Output, States, or Final states** parameters.
  - Data store
  - The `sim` command configured to log simulation data

### **Load Signal Data from the MATLAB Workspace**

To load signal data from a workspace, use one of these techniques:

- Add a From Workspace block.
- Use a root-level input port.
  - Specify workspace variables in the **Configuration Parameters > Data Import/Export > Input** parameter.
  - Use the Root Inport Mapper tool to specify the data for the **Input** parameter.

### Source and Signal Editor Blocks for Signal Data

Source blocks, such as the Sine Wave block, generate signals that you can use as inputs to other blocks. Source blocks do not store signal data. Source blocks can be useful for initial prototyping of a model when the generated signal data serves your modeling requirements.

To define scenarios to use as inputs to a model, you can use the Signal Editor block. The Signal Editor block stores the scenario definitions.

Consider using a source block to:

- Avoid having to create the data manually.
- Reduce memory consumption — source blocks do not store signal data.
- Graphically represent in the model the kind of signal data.

Consider using a Signal Editor block to:

- Create and import scenarios for use in testing.

You can use scenarios with Simulink and with these products:

- Simulink Test
- Simulink Coverage
- Simulink Design Verifier
- Switch between scenarios quickly.

### MAT-Files for Signal Data

Consider storing signal data in a MAT-file to:

- Load a large amount of signal data efficiently.
- Reuse the same signal data in different models.
- Reduce memory requirements for the model.
- Use different sets of signal data with the same model, with minimal model updates.

#### Store Signal Data in a MAT-File

To create a MAT-file to store signal data to import, you can use:

- A To File block
- The Signal Editor user interface
- MATLAB to create signal data that you store in a MAT-file

#### Load Signal Data from a MAT-File

To load signal data from a MAT-file into a model, you can use a From File block.

### Spreadsheets for Signal Data

Consider using an Excel or CSV spreadsheet to:

- Use an existing spreadsheet that already has the necessary signal data or that you can update easily to contain the signal data.

- Load a large amount of signal data efficiently.
- Reduce memory requirements for the model.
- Use different sets of signal data with the same model, with minimal model updates.
- Share the signal data with other people who do not have Simulink installed.

### Store Signal Data in a Spreadsheet

Use one of these approaches:

- Create the signal data directly in the spreadsheet.
- Export MATLAB signal data to an Excel or CSV spreadsheet using the `xlswrite` or `csvwrite` function.

### Load Signal Data from a Spreadsheet

Use the From Spreadsheet.

The From Spreadsheet block loads Microsoft Excel on all platforms. This block loads CSV spreadsheets only on Microsoft Windows platforms.

The From Spreadsheet block incrementally loads the data directly from the spreadsheet, to reduce memory consumption.

## Load Input Signal Data

You can use various sources for input signal data for simulating a model. You can:

- Use existing data from a file, such as a spreadsheet.
- Write a MATLAB script to define variables for the signal data. For example, you can create Dataset format data that you can use with all the signal loading techniques.
- Use data logged from a previous simulation.

You can use several different approaches to load data into a model, including:

- Root-level input ports — Import signal data from a workspace, using the **Input** configuration parameter to import it to a root-level input port of a Inport, Enable, or Trigger block. You can specify the input data directly in the **Input** parameter. To import multiple signals to root-level input ports, consider using the Root Inport Mapping tool on page 76-2. That tool updates the **Input** parameter based on the signal data that you import and map to root-level input ports.
- Source blocks — Add a source block, such Sine Wave block, to generate signals to input to another block.
- From File block — Read data from a MAT-file, outputting the data as a signal.
- From Spreadsheet block — Read data from Microsoft Excel spreadsheets or CSV spreadsheets, outputting the data as one or more signals.

To determine the approach to meet the input signal data requirements of your model, see “Comparison of Signal Loading Techniques” on page 75-21.

## Log Output Signal Data

You can save signal values to the MATLAB workspace or to a MAT-file during simulation for later retrieval and postprocessing. Saving simulation data is also known as logging or exporting simulation data.

To determine which approach to use for logging signal data, see “Save Simulation Data” on page 77-2.

Saving simulation data in `Dataset` format simplifies postprocessing by providing a common format for the results of various logging techniques. Using `Dataset` format stores the data as MATLAB `timeseriesobjects`, which you can process with MATLAB. Simulink provides tools for converting data logged in other formats to `Dataset` format.

For more information about logging output signal data, see “Save Run-Time Data from Simulation”.

## Load Big Data for Simulations

### In this section...

“Stream Individual Signals Using SimulationDatastore Objects” on page 75-7

“Stream Entire Dataset Using DatasetRef Object” on page 75-8

“Load Individual Signals from a DatasetRef Object” on page 75-9

Simulating models with many time steps and signals can use and create data that is too large to fit into working memory on your computer. When your simulation input data does not fit into memory, you can choose one of several strategies to use that data as simulation input with root-level Inport blocks. These strategies work for loading data stored in `Dataset` format in a Version 7.3 MAT-file, including data logged from another simulation.

- 1 When individual input signals are too large to fit into memory, you can use a `matlab.io.datastore.SimulationDatastore` object to access the signal data. The data from the `SimulationDatastore` object loads into the simulation incrementally in chunks that fit into memory.
- 2 When your simulation inputs are specified by a `Simulink.SimulationData.Dataset` object in a file that is too large to load into memory, you can stream the entire contents of the `Dataset` object into your model using a `Simulink.SimulationData.DatasetRef` object.
- 3 When the signals fit into memory and are stored in a file that is too large to load into memory, you can load individual signals from the file into memory using a `Simulink.SimulationData.DatasetRef` object.

---

**Note** When you want to use data logged in one simulation as input for another, you can also stream data into the model using a `matlab.io.datastore.sd datastore` object. The `sd datastore` object references data in the Simulation Data Inspector repository on disk, so you do not have to save the logged data to a file. Consider using a `sd datastore` object as simulation input for iterative workflows.

---

All big data loading strategies are for the special case when your data does not fit into memory and can require extra steps. These examples use data that fits fully into memory to illustrate the steps required for big data loading. When your simulation inputs fit into memory, consider using other loading techniques.

### Stream Individual Signals Using SimulationDatastore Objects

When individual signals in your input data are too large to fit into memory, you can create `matlab.io.datastore.SimulationDatastore` objects for those signals and stream them into your model. To create a `SimulationDatastore` object for a signal you want to stream into your model, first create a `Simulink.SimulationData.DatasetRef` object to reference the `Dataset` object that contains your signal of interest. For example, create a `DatasetRef` for logged data from a simulation of the `slexAircraftExample` model.

```
logout_DSR = Simulink.SimulationData.DatasetRef('aircraftData.mat', 'logout');
```

You can create a `SimulationDatastore` object for your desired signal by indexing into the `DatasetRef` object with curly braces or using the `getAsDatastore` method for the `DatasetRef`

object. In both cases, the `SimulationDatastore` object exists in the `Values` property of the returned `Simulink.SimulationData.Signal` object.

When you know the index of the signal within the `Dataset` object, you can index into the `DatasetRef` object with curly braces to create a `SimulationDatastore` for your signal.

```
alphaRad_ds = lognout_DSR{4}

alphaRad_ds =
  Simulink.SimulationData.Signal
  Package: Simulink.SimulationData

  Properties:
      Name: 'alpha, rad'
  PropagatedName: ''
      BlockPath: [1x1 Simulink.SimulationData.BlockPath]
      PortType: 'outport'
      PortIndex: 4
      Values: [1x1 matlab.io.datastore.SimulationDatastore]
```

Methods, Superclasses

To create a `SimulationDatastore` object for a signal using the signal index, name, or block path, use the `getAsDatastore` method. For example, create a `SimulationDatastore` object for the `Stick` signal.

```
stick_ds = lognout_DSR.getAsDatastore('Stick')

stick_ds =
  Simulink.SimulationData.Signal
  Package: Simulink.SimulationData

  Properties:
      Name: 'Stick'
  PropagatedName: ''
      BlockPath: [1x1 Simulink.SimulationData.BlockPath]
      PortType: 'outport'
      PortIndex: 1
      Values: [1x1 matlab.io.datastore.SimulationDatastore]
```

Methods, Superclasses

Because the `Values` properties of the `stick_ds` and `alphaRad_ds` `Simulink.SimulationData.Signal` objects are `SimulationDatastores`, the signal data streams into your model. You can include a `SimulationDatastore` backed `Signal` object as an element in a `Dataset` object or as an item in the `Input` parameter comma-separated list.

## Stream Entire Dataset Using DatasetRef Object

When your simulation inputs are saved in a `Dataset` object in a file that is too large to load into memory, you can create a `Simulink.SimulationData.DatasetRef` object to stream your simulation inputs into your model. When you specify a `DatasetRef` object as the value for the **Input** parameter on the **Data Import/Export** pane of the model Configuration Parameters, all the signals in

the `Dataset` object used to create the `DatasetRef` stream into your model during simulation. Use another big data loading technique to load or stream individual signals from a `Dataset` object.

When the file that contains the `Dataset` object with your simulation inputs also contains other data, you can use the `Simulink.SimulationData.DatasetRef.getDatasetVariableNames` function to view a list of the `Dataset` objects contained in the file. Previewing the names of variables in the file that contain `Dataset` objects is particularly useful when the file contents do not fit into memory.

```
dsNames = Simulink.SimulationData.DatasetRef.getDatasetVariableNames('aircraftData.mat')

dsNames = 1x3 cell
    {'logout'}    {'xout'}    {'yout'}
```

Create a `DatasetRef` object that references the data in the `Dataset` object `logout`.

```
logout_DSR = Simulink.SimulationData.DatasetRef('aircraftData.mat', 'logout');
```

You can load `logout_DSR` using the **Input** parameter the same way you would load a `Simulink.SimulationData.Dataset` object. Each signal in the `Dataset` object used to create the `DatasetRef` streams into the model in chunks that fit into memory.

## Load Individual Signals from a DatasetRef Object

When your simulation input signals individually fit into memory and are stored in a `Dataset` object in a file that does not fit into memory, use a `Simulink.SimulationData.DatasetRef` object to load each signal of interest into memory. Then, you can load the signals as simulation inputs for your model.

First, create the `DatasetRef` object to reference the `Dataset` object in the file that contains the signals you want to load. For example, create a `DatasetRef` object for data logged to file from a simulation of the `slexAircraftExample` model.

```
logout_DSR = Simulink.SimulationData.DatasetRef('aircraftData.mat', 'logout');
```

You can use the `get` or `getElement` methods to load individual signals into memory with the `DatasetRef` object. Both methods load the specified element into memory, using the same syntax. You can specify the signal you want to load into memory using its index within the `Dataset` object or its name. If you don't know the name of the signal you want to load, use the `getElementNames` method to see the names of the elements in the `Dataset` object referenced by the `DatasetRef` object.

```
elNames = logout_DSR.getElementNames
```

```
elNames = 15x1 cell
    {0x0 char }
    {0x0 char }
    {0x0 char }
    {'alpha, rad'}
    {'q, rad/sec'}
    {0x0 char }
    {'qGust' }
    {'wGust' }
    {0x0 char }
```

```
{0x0 char }  
{0x0 char }  
{'Stick' }  
{0x0 char }  
{0x0 char }  
{0x0 char }
```

Load the `qGust` signal into memory using its name.

```
qGust = logout_DSR.getElement('qGust')
```

```
qGust =  
  Simulink.SimulationData.Signal  
  Package: Simulink.SimulationData  
  
Properties:  
  Name: 'qGust'  
  PropagatedName: ''  
  BlockPath: [1x1 Simulink.SimulationData.BlockPath]  
  PortType: 'outport'  
  PortIndex: 2  
  Values: [1x1 timeseries]
```

Methods, Superclasses

You can add the `qGust` signal to a `Dataset` object of simulation input signals to load to the root-level Inport blocks in your model, or you can specify `qGust` as an item in the `Input` parameter comma-separated list.

## Related Examples

- “Work with Big Data for Simulations” on page 77-30
- “Log Data to Persistent Storage” on page 77-32
- “Analyze Big Data from a Simulation” on page 77-36

## Stream Data from a MAT-File as Input for a Parallel Simulation

This example shows how to use `Simulink.SimulationData.DatasetRef` objects and the `parsim` function to stream input data from a version 7.3 MAT-file for parallel simulations. Consider following the steps outlined in this example when the inputs for your simulation are too large to load into memory. For example, you can use data logged to persistent storage from one set of parallel simulations as input for another.

This example uses `parsim` to run multiple simulations of a model, with each simulation using unique input data. The model is based on the “Multiple Simulations Workflow Tips” `sldemo_suspn_3dof` model, modified to use Inport blocks as the source for inputs instead of the Signal Editor block. The model simulates the response of a suspension system to different road conditions. The MAT-file used in this example contains multiple `Simulink.SimulationData.Dataset` objects representing various road conditions. The example uses `DatasetRef` objects to stream the contents of an entire referenced `Dataset` object as simulation input.

You can also stream data for individual signals into parallel simulations run with `parsim` using `matlab.io.datastore.SimulationDatastore` objects. For details on creating `SimulationDatastore` objects, see “Stream Individual Signals Using SimulationDatastore Objects” on page 75-7.

### Load Model and Access Input Data

Load the `ex_sldemo_suspn_3dof_parsim_stream` model. The model receives input data through two Inport blocks, and each `Dataset` object used as simulation input contains two elements: one for each Inport.

```
mdl = 'ex_sldemo_suspn_3dof_parsim_stream';
open_system(mdl)
```

You can use the `Simulink.SimulationData.DatasetRef.getDatasetVariableNames` function to evaluate the contents of the MAT-file containing the input data without loading the data into memory. The function returns a cell array that contains elements for the name of each `Simulink.SimulationData.Dataset` variable the file contains. Use the function to access the variable names and determine the number of test cases in the file.

```
varNames = Simulink.SimulationData.DatasetRef.getDatasetVariableNames('suspn_3dof_test_cases.mat');
numTestCases = numel(varNames);
```

You can stream the test case data into the model using `Simulink.SimulationData.DatasetRef` objects. The `DatasetRef` object references a variable in the file used to create it and loads the variable data incrementally. Create a `DatasetRef` object for each `Simulink.SimulationData.Dataset` object in the test cases file.

```
for idx1 = 1:numTestCases
    inputData(idx1) = Simulink.SimulationData.DatasetRef('suspn_3dof_test_cases.mat', ...
        varNames{idx1});
end
```

### Configure and Run Parallel Simulations

To use the set of test case inputs as input for a set of parallel simulations, create an array of `Simulink.SimulationInput` objects that you can pass to the `parsim` function. Use the

`setExternalInput` function to specify a `Simulink.SimulationData.DatasetRef` object corresponding to a test case as data to stream as simulation input.

```
in(1:numTestCases) = Simulink.SimulationInput mdl);

for idx2 = 1:numTestCases
    in(idx2) = setExternalInput(in(idx2),inputData(idx2));
end
```

Use the `parsim` function to run a simulation for each test case. When you have the Parallel Computing Toolbox™, the `parsim` function runs simulations in parallel. Without the Parallel Computing Toolbox, the `parsim` function runs the simulations in serial.

The `parsim` function creates a worker pool based on the Parallel Computing Toolbox configuration. By default, `parsim` uses a local pool. If you use remote workers, you can use the `AttachedFiles` name-value pair to send the MAT-file containing the test case input data to each worker. When you specify the `AttachedFiles` name-value pair, `parsim` sends a copy of the file to each worker, which can take some time for large files. For streaming input data from a large file, local workers may be faster because the workers have access to the file without creating and sending copies. When you use remote workers, consider storing the MAT-file in a location that all remote workers can access and creating `DatasetRef` objects that reference that copy of the file.

```
out = parsim(in);

### View Simulation Results

You can access the simulation results programmatically when the simulations finish. Create a plot showing the vertical displacement for the vehicle for all the road profile test cases.

```

if isempty(out(1).ErrorMessage)
    legend_labels = cell(1,numTestCases);
    for i = 1:numTestCases
        if isempty(out(i).ErrorMessage)
            simOut = out(i);
            ts = simOut.logout.get('vertical_disp').Values;
            ts.plot;
            legend_labels{i} = ['Run ' num2str(i)];
        end
        hold all
    end
    title('Response of a 3-DoF Suspension Model')
    xlabel('Time (s)');
    ylabel('Vehicle vertical displacement (m)');
    legend(legend_labels,'Location','NorthEastOutside');
end

```

You can also view `parsim` simulation results using the Simulation Manager. To view results in the Simulation Manager, use the `ShowSimulationManager` name-value pair for `parsim`. With the

Simulation Manager, you can monitor the progress of the runs, view simulation data, and show the `parsim` results in the Simulation Data Inspector.

### **Close Parallel Workers**

When you have finished running parallel simulations, you can close the worker pool.

```
delete(gcf('nocreate'));
```

## Overview of Signal Loading Techniques

### In this section...

“Source Blocks” on page 75-15  
 “Root-Level Input Ports” on page 75-16  
 “From File Block” on page 75-17  
 “From Spreadsheet Block” on page 75-18  
 “From Workspace Block” on page 75-19  
 “Signal Editor Block” on page 75-19

Simulink provides several techniques for importing signal data into a model. Each of the signal data loading techniques uses blocks to represent signal data sources visually.

For additional details about which technique to use to meet specific modeling requirements, see “Comparison of Techniques” on page 75-22.

### Source Blocks

You can add a source block, such as a Sine Wave block, to generate signals to input to another block. To specify how to generate the signal, use the Block Parameters dialog box. For example, in the Sine Wave Block Parameters dialog box, you can specify the `sim` function to use and time-based or sample-based data.

The output data types of source blocks vary. For example, a Sine Wave block outputs a vector of real doubles.

For an example of using a source block, see “Open Models” on page 1-18.

### Recommended Uses

- Do initial prototyping in a model, when the generated signal data serves your modeling requirements

- Avoid creating the data manually.
- Reduce memory consumption. Source blocks do not store signal data.
- Make the kind of signal data visually clear in the model.

### Limitations

Source blocks generate signals based on a predefined algorithm. To use actual data from an external source or to test a model without having to modify the model, use a different signal loading technique.

## Root-Level Input Ports

You can import signal data from a workspace and apply it to a root-level input port using one of these blocks:

- Enable
- Inport
- Trigger block that has an edge-based (rising, falling, or either) trigger type

The root-level input ports load external inputs from the MATLAB (base), model, or mask workspace. These blocks import data from the workspace based on the value of the **Configuration Parameters** > **Data Import/Export** > **Input** parameter or a `sim` command argument. For an example, see “Load Data to Model Variable-Step Input from Model Hierarchy” on page 75-36.

To import many signals to root-level input ports, consider using the Root Inport Mapper tool. This tool updates the **Input** configuration parameter based on the signal data that you import and map to root-level input ports. For an example, see “Map Data Using Root Inport Mapper Tool” on page 76-2.

### Recommended Uses

Use root input ports to:

- Import many signals to many blocks
- Test your model as a referenced model in a wider context with signals from the workspace, without modifying your model

For importing signal data to meet most modeling requirements and to maintain model flexibility, root-level inport mapping is a convenient technique. Root-level inport mapping:

- Displays signal data for you to inspect without loading all the signal data into MATLAB memory
- Provides memory-efficient signal viewing

## Requirements

To ensure that the Simulink variable solver executes at the times that you specify in the imported data, set the **Configuration Parameters** > **Data Import/Export** > **Additional parameters** > **Output options** parameter to Produce additional output.

## Limitations

- You cannot use input ports to import buses in external modes. To import bus data in rapid accelerator mode, use Dataset format.
- The Root Inport Mapper tool supported map modes depend on the data type of a signal. For details, see “Choose a Base Workspace and MAT-File Format” on page 76-9.

## From File Block

A From File block reads data from a MAT-file and outputs the data as a signal.

For more information, see “Load Data Using the From File Block” on page 75-73.

## Recommended Uses

Consider using a From File block for loading:

- Large amounts of data. For a Version 7.3 MAT-file, the From File block loads data incrementally from the MAT-file during simulation.

---

**Tip** To convert a Version 7.0 file to Version 7.3 (for example, `my_data_file.mat` that contains the variable `var`), at the MATLAB command line, enter:

```
load('my_data_file.mat')
save('my_data_file.mat', 'var', '-v7.3')
```

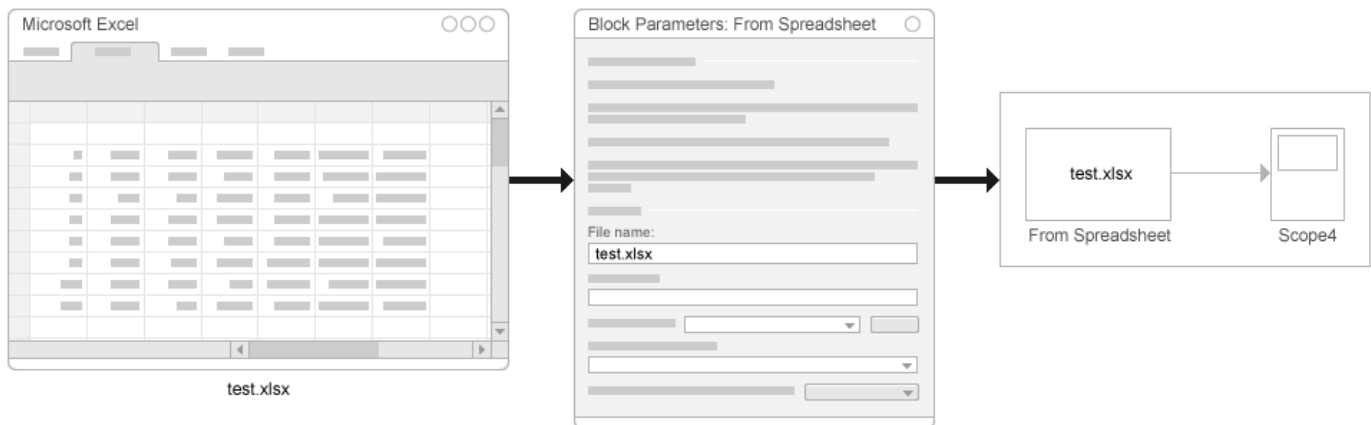

- 
- Data that was exported to a To File block. The From File block reads data written by a To File block without any you modifying the data or making other special provisions.
  - Data stored in a MAT-file that is separate from the model file.

## Limitations

- For *Version 7.0* or earlier MAT-file, the From File block reads only array-format data.
- Version 7.3 and Version 7.0 or earlier MAT-files handle multiple variables differently.
- The From File block supports loading input data for a nonvirtual bus stored as a structure of `timeseries` objects.
- For array data, the From File block reads only double signal data.
- Code generation that involves building ERT or GRT targets, or using SIL or PIL simulation modes, has some special considerations. See “Code Generation”.

## From Spreadsheet Block

The From Spreadsheet block reads data from Microsoft Excel spreadsheets (all platforms) or CSV spreadsheets (Microsoft Windows platform with Microsoft Office only) and outputs the data as one or more signals.

## Recommended Uses

Use the From Spreadsheet block for loading:

- Large Microsoft Excel or CSV spreadsheets. The From Spreadsheet block incrementally reads data from the spreadsheet during simulation, rather than loading the data into Simulink memory.
- Spreadsheets that you expect to modify. The From Spreadsheet block handles changes to worksheet values automatically, because it loads data directly from the spreadsheet.

## Limitations

- You cannot import bus data.
- The From Spreadsheet file has requirements for the spreadsheet data. Organize Excel spreadsheet data using the format described in “Supported Microsoft Excel File Formats”.
- Linux and Mac platforms do not support using a From Spreadsheet block to import data from a CSV spreadsheet.

## From Workspace Block

The From Workspace block reads signal data from a workspace and outputs the data as a signal. In the Block Parameters dialog box, in the **Data** parameter, enter a MATLAB expression that specifies the workspace data.

For an example of how to use a From Workspace block, see “Load Data Using the From Workspace Block” on page 75-78.

### Recommended Uses

Use the From Workspace block for loading:

- A small set of signal data to perform local, temporary testing
- Data from the MATLAB (base), model, mask, or function workspace
- Variable-size signals
- Data that you saved using a To Workspace block in MATLAB `timeseries` format, without manual changes to the data
- Data saved in a previous simulation by a To Workspace block in either `Timeseries` or `Structure with Time` format for use in a later simulation

### Limitations

The data expressions that you specify must evaluate to one of these types of data:

- A `timeseries` or `timetable` object
- A structure of `timeseries` or `timetable` objects
- A structure, with or without time
- A two-dimensional matrix

## Signal Editor Block

Using a Signal Editor block, you can create interchangeable scenarios to use in a model.

For examples of how to use a Signal Editor block, see:

- “Load Input Data for Basic Test Cases” on page 75-43
- “Parallel Simulations Using Parsim: Parameter Sweep in Normal Mode”

### **Recommended Uses**

Use the Signal Editor block to create and load scenarios to use in testing.

These products integrate the Signal Editor block into their workflows:

- Simulink Test
- Simulink Coverage
- Simulink Design Verifier

### **Limitations**

- Function-calls
- Array of buses
- Buses while using rapid accelerator mode
- `timetable` objects
- Ground signals

The Signal Editor block supports dynamic strings. It does not support strings with maximum length. In addition, strings in the Signal Editor block cannot output:

- Non-scalar MATLAB strings.
- String data that contains missing values.
- String data that contains non-ASCII characters.

## Comparison of Signal Loading Techniques

### In this section...

“Techniques” on page 75-21

“Impact of Loading Techniques on Block Diagrams” on page 75-21

“Comparison of Techniques” on page 75-22

### Techniques

Simulink provides several techniques for importing signal data into a model. Each signal data loading technique uses a block to represent signal data sources visually. You can use a:

- Source on page 75-15 block, such as the Sine Wave block, to generate signal data as input to another block
- Root-level input port on page 75-16 (Inport, Enable, or Trigger block). Loading signal data to root-level input ports, either manually or by using the Root Inport Mapper tool. “Root-level input ports” refers to both approaches and “Root Inport Mapper tool” refers specifically to using that tool.
- From File on page 75-17 block
- From Spreadsheet on page 75-18 block
- From Workspace on page 75-19 block
- Signal Editor block

### Impact of Loading Techniques on Block Diagrams

To test reusable systems, it is helpful to separate signal data loading from the block diagram. Loading root-level input ports provides a good framework for testing complex systems on an ongoing basis. Using the Root Inport Mapper tool allows you to visualize the signal data that is loaded.

To perform temporary testing on standalone models, adding data loading blocks can be simpler and make the source of the signal data visible from within the block diagram.

To avoid adding data loading blocks to a model, load the signal data to root-level input ports. You can change the data to use by changing the **Configuration Parameters > Data Import/Export > Input** parameter. You do not need to add or change blocks, or reset block parameters. You can use the Root Inport Mapper tool to update the **Input** parameter so that it reflects the mapping of signal data to the appropriate ports.

### Test Harness Models

You can use a test harness model with different test cases to load:

- Different signal data to a port
- Signal data to different ports

The Signal Editor block is useful in test harness models to simplify loading data to multiple input ports.

Alternatively, you can use the Root Inport Mapper tool to create scenarios that you can use instead of creating separate test harness models. Creating separate test harness models can be simpler than

setting up root inport mapping. However, you then need to manage the separate test harness models. For an example of using root inport mapping instead of a test harness, see “Create Harness-Free Models with MAT File Input Data”.

## Comparison of Techniques

Each technique addresses many of these modeling considerations:

- “Purpose of Importing Signal Data” on page 75-22
- Model Development Phase on page 75-23
- “Signal Data” on page 75-23
- “Data Format or Type” on page 75-23
- “Bus Support” on page 75-24
- “Time Points” on page 75-25
- “Location for Data Storage” on page 75-25
- “Signal Data Inspection” on page 75-25
- “Handling of Loaded Data” on page 75-25
- “Simulation Mode” on page 75-26

### Purpose of Importing Signal Data

The model development phase you are in and your goals for loading signal data can influence the signal loading technique that you choose.

Modeling Goal	Supported Techniques
Perform local, temporary testing by importing a small set of signal data	All Root-level input ports for reusable systems.
Test a model that you want to use as a referenced model	Root-level input ports.
Verify a model by using multiple test cases	Root Inport Mapper tool, using exported signal data. Signal Editor block.
Represent a continuous plant	All Root-level input ports work well for this goal.
Test a discrete algorithm	All Root-level input ports work well for this goal.

## Model Development Phase

Modeling Requirement	Suggested Signal Loading Technique
Initial prototyping	When signals generated by source blocks meet your requirements, use Source blocks on page 75-15.  From File, From Spreadsheet, and From Workspace blocks.
System testing, sharing, and code generation	Root-level input port on page 75-16.  You can use the Root Inport Mapper tool to create and map signal data to load  Signal Editor block

For many models, loading signal data to a root Inport block is an effective approach. The Root Inport Mapping tool on page 76-2 provides a convenient way to load data for several signals to root inports.

## Signal Data

The amount, source, and kind of the signal data can influence the signal loading technique that you choose.

Signal Data	Supported Techniques
Large data set	From File and From Spreadsheet blocks work well for large data sets, because they incrementally load the data.  You can log simulation data to persistent storage and then incrementally load data from a file to root-level Inport blocks.
Data exported by using a To File block	From File block.
Data exported by using a To Workspace block	From Workspace block.
Excel or CSV spreadsheet	From Spreadsheet block, which can import Microsoft Excel (all platforms) or CSV (Microsoft Windows platform with Microsoft Office only) spreadsheet data directly into Simulink.
Variable-size signals	From Workspace block.

## Data Format or Type

Each of the signal loading techniques supports a wide range of data formats for signal data (such as array or Dataset). A few signal loading techniques have some limitations for specific formats.

**Note** Some of the Root Inport Mapper tool map modes do not support all the data types that you can use with the tool. For details, see “Choose a Base Workspace and MAT-File Format” on page 76-9.

Data Format or Type	Supported Techniques
Array	All.
Structure with time	Root-level Inport block From Workspace block Signal Editor block
Structure without time	Root-level Inport block From Workspace block Signal Editor block
timeseries	All.
timetable	Root-level Inport block From Workspace block Signal Editor block
Simulink.SimulationData.Dataset	Root-level Inport blocks Signal Editor block
Enumeration	All.
Fixed-point	From Workspace block supports loading <code>fi</code> objects created using Fixed-Point Designer. From File block has a word length limit of 32 or fewer bits.
Function-call	Root-level input ports (select the <b>Output function call</b> parameter).

### Bus Support

You can use any of the signal loading techniques to load input data for a bus. However, for some kinds of bus data, you need to use a specific technique.

Type of Bus or Bus Element	Supported Techniques
Nonvirtual buses	All techniques support loading input data for a nonvirtual bus. The Signal Editor block does not support loading bus data in rapid accelerator mode.
Partial bus specification	Root-level Inport block From Workspace block From File block Signal Editor block

Type of Bus or Bus Element	Supported Techniques
Array of buses	Root-level Inport block From Workspace block

### Time Points

The kind of time points in signal data impacts the signal loading technique that you choose.

Time Points for Signal Data	Supported Techniques
Single time point	All.
Continuous	All.
Discrete	All.
Repeated sequence without time	Structure data by using root-level input ports and From Workspace block.

### Location for Data Storage

Whether you want to store the signal data with the model or separate from the model impacts the signal loading technique that you choose.

Location	Supported Techniques
In the base or model workspace	From Workspace block.  Root-level input ports or a Trigger, Enable, or Function-Call Subsystem block.
In a MAT-file separate from the model file	From File and Signal Editor blocks.  You can log big simulation data to persistent storage and then incrementally load data from a file to root-level Inport blocks.
In an Excel or CSV spreadsheet	From Spreadsheet block.  <b>Note</b> Loading CSV data is supported only for Microsoft Windows platforms.

### Signal Data Inspection

The Root Inport Mapper tool, From File block, and Signal Editor block each provide an interface for plotting and inspecting the signal data to load.

### Handling of Loaded Data

How Simulink processes the signal data as it loads it into a model impacts the signal loading technique that you choose.

Data Loading Handling	Supported Techniques
Incremental data loading	From File and From Spreadsheet blocks.  Root-level Inport blocks, when you load data from a <code>Simulink.SimulationData.DatasetRef</code> object or <code>matlab.io.datastore.SimulationDatastore</code> object
Interpolation	All.
Extrapolation	From File, From Spreadsheet, and Signal Editor blocks. For information about From Workspace extrapolation, see “Form output after final data value by”.
Zero-crossing detection	All except root-level input ports.
Fast restart	All techniques.

### Simulation Mode

All signal loading techniques support all simulation modes except for SIL or PIL. Some techniques have limitations for specific simulation modes.

Simulation Modes	Supported Techniques
Normal and accelerator	All
Rapid accelerator	All
ERT/GRT	All  From Workspace and From File blocks are not tunable.
SIL or PIL	From Workspace block
External mode	From Workspace block  Root-level input ports output ground values in external mode.

## Control How Models Load Input Data

When you load external input data, the time values you specify in external input data do not determine how the model loads the data during simulation. The solver determines which time steps to take in simulation. The sample time for the block that loads the data determines when the block executes and provides a new signal value. The solver can consider the dynamics of the input data only after the loading block loads each value into the model.

You can use model parameters, block parameters, and different input data formats to ensure that your model loads your input data as you expect.

### Configure Input Data Interpolation

When you load external input data, the time steps the solver chooses typically do not match the time steps you specify for external inputs. When the simulation takes a time step that does not match a time value provided in the external input data, the software uses the time and data values in the external input data to interpolate the signal value.

You can configure how a loading block interpolates the data it loads using block parameters. The table summarizes how to configure available interpolation options for each loading block.

Loading Block	Interpolation Options
Inport	Linear interpolation — Select <b>Interpolate data</b> .
From Workspace	Zero-order hold — Clear <b>Interpolate data</b> .
Signal Editor	Configure the interpolation for each input signal by selecting the signal from the <b>Active Signal</b> list.  Linear interpolation — Select <b>Interpolate data</b> .  Zero-order hold — Clear <b>Interpolate data</b> .
In Bus Element	Always linearly interpolates input data.
From Spreadsheet	Linear interpolation — Set <b>Data interpolation within time range</b> to Linear interpolation.
From File	Zero-order-hold — Set <b>Data interpolation within time range</b> to Zero order hold.
Playback	Configure the interpolation for the input data using the <b>Interp Method</b> property for the signal or message.  Linear interpolation — Set <b>Interp Method</b> to linear.  Zero-order hold — Set <b>Interp Method</b> to zoh.  No interpolation — Set <b>Interp Method</b> to event-based (none).

## Capture Dynamics of Input Data

The solver considers the dynamics of external input data, such as discontinuities and transient variations, only after a loading block loads the data into the simulation. For blocks with continuous sample time, the solver also determines when the block executes. When the external input data changes faster than the system dynamics, the solver can miss dynamics in the input data that can affect the simulation. If the simulation takes too large of a step for your input data, you can take one of these actions to ensure the signal produced in the model reflects your input data:

Action	Details and Considerations
Specify a sample time for the loading block	<p>The sample time for a block specifies when the block executes in simulation. You can specify the sample time for a block as something other than inherited (-1) or continuous (0) to control when the loading block samples a value from the input data.</p> <p>This strategy might introduce a new sample time into your model or cause extraneous time steps when the input signal changes gradually.</p>
Specify required time steps for variable-step simulations using the <b>Output times</b> model configuration parameter	<p>The <b>Output times</b> parameter for a model specifies times of interest for variable-step simulations. When you specify a value for the <b>Output times</b> parameter, the solver takes a major time step for each time value.</p> <p>You can specify the value for the <b>Output times</b> parameter using all or part of the time vector for your input data.</p> <p>This parameter does not affect time steps for simulations that use a fixed-step solver.</p>
Configure a root-level input port to use input events	<p>When you configure a root-level input port to use input events, the external input data drives the execution of the block. The <code>simulink.event.InputWrite</code> event triggers a schedule event each time the input port reads a new input value.</p> <p>Only Inport blocks and In Bus Element blocks support input events. When you use input events, you must specify a partition of your model to execute each time the input event occurs.</p>

## Load Data as Continuous Signal

A *continuous signal* has a value at any time point. When the loading block has constant (0) sample time, the block executes and provides an output value for the continuous signal for every time step in the simulation. To load input data as a continuous signal, use a data format that includes time values and use linear interpolation.

## Open and Examine Model

Open the model `LoadInputData`. The model uses an Inport block to load external input data from the base workspace.

```
mdl = "LoadInputData";
open_system(mdl);
```

The **Input** parameter for the model is configured to load data from the variable `simIn`.

```
get_param(mdl, "LoadExternalInput")
```

```
ans =
'on'
```

```
get_param(mdl, "ExternalInput")
```

```
ans =
'simIn'
```

## Create and Format Input Data

Create data for a sine wave in the base workspace. You can load data from the workspace using several formats, most of which fundamentally consist of signal values paired with time values. For this example, use the `timetable` format.

First, create a column vector of time values.

```
sampleTime = 0.1;
numSteps = 101;
time = sampleTime*(0:numSteps-1);
time = time';
```

To create a `timetable`, the time data must be a `duration` vector. Use the `seconds` function to create a `duration` vector with units of seconds.

```
secs = seconds(time);
```

Use the `sin` function to create the signal values for each value in the time vector.

```
data = sin(2*pi/3*time);
```

Create the `timetable` object.

```
simIn = timetable(secs,data);
```

## Configure Inport Block to Produce Continuous Signal

Configure the Inport block to have continuous sample time and to linearly interpolate the input data during simulation.

- 1 Select the Inport block.

- 2 Open the Property Inspector by clicking the **Property Inspector** tab on the right of the model or by pressing **Ctrl+Shift+I**.
- 3 Expand the **Execution** section.
- 4 Set the **Sample time** to 0 to use continuous sample time.
- 5 Select **Interpolate data**.

Alternatively, use the `set_param` function to set the block parameters.

```
set_param(strcat mdl, "/Inport"), "SampleTime", "0", ...
        "Interpolate", "on")
```

### Simulate Model

Simulate the model by clicking **Run** or by using the `sim` function.

```
contOut = sim(mdl);
```

The Dashboard Scope block shows the output signal as a smooth, continuous sine wave.

### Load Data as Discrete Signal

The values for a *discrete signal* change only at specific times, typically represented as an evenly spaced vector of sample times. Between each sample of the signal, the signal value remains the same. To load input data as a discrete signal, choose an input data format, use zero-order-hold interpolation, and specify a sample time for the loading block.

#### Open and Examine Model

Open the model `LoadInputData`. The model uses an Inport block to load external input data from the base workspace.

```
mdl = "LoadInputData";
open_system(mdl)
```

The **Input** parameter is configured to load data from the variable `simIn`.

```
get_param mdl, "LoadExternalInput")
```

```
ans =  
'on'
```

```
get_param mdl, "ExternalInput")
```

```
ans =  
'simIn'
```

### Create and Format Input Data

Create input data for a sine wave in the base workspace. To start, create an evenly spaced time vector to pass to the `sin` function to generate the data values.

When you create data to load as a discrete signal, use the expression in this example. Other techniques for creating an evenly spaced time vector, such as the `linspace` function or using the colon operator with a specified increment (`a:b:c`), can introduce floating-precision rounding errors that can lead to unexpected simulation results.

```
sampleTime = 0.1;  
numSteps = 101;  
time = sampleTime*(0:numSteps-1);  
time = time';
```

Create the signal values by using the `sin` function to create a value for each element in the time vector.

```
data = sin(2*pi/3*time);
```

Format the workspace data to load into the simulation. When you load input data for a discrete signal, you can avoid the effect of floating-precision rounding errors in data you provide by using the structure without time format.

When you use the structure without time format, you do not specify time data along with the signal values. Instead, the simulation associates time values with the signal values using the sample time you specify for the block. During simulation, the block loads the input values sequentially at the specified rate.

The structure format has two fields:

- `time`: A common time vector for all signals in the structure
- `signals`: An array of structures that contain the data and dimensions information for each signal

Create the structure `simIn` to load the sine wave data into the model using the structure without time format.

```
simIn.signals.values = data;  
simIn.signals.dimension = 1;  
simIn.time = [];
```

### Configure Block to Produce Discrete Signal

Configure the block to use a sample time of `0.1` and use zero-order-hold interpolation.

- 1 Select the Inport block.
- 2 Open the Property Inspector by clicking the **Property Inspector** tab on the right of the model or by pressing **Ctrl+Shift+I**.
- 3 Expand the **Execution** section.
- 4 Set the **Sample time** to 0.1.
- 5 Clear **Interpolate data**.

Alternatively, use the `set_param` function to configure the block.

```
set_param(strcat mdl, "/Inport"), "SampleTime", "0.1", ...
        "Interpolate", "off")
```

### Simulate Model

Simulate the model.

```
out = sim mdl;
```

The Dashboard Scope block displays the sine wave signal. The zero-order hold creates a stair step effect between each sample value.

### Use Format with Time Data

When you create the evenly spaced time vector yourself, using the expression in this example, you can also load input data using formats that include time values without floating-precision rounding issues. For example, create a `timetable` using the time and signal values for the sine wave.

```
secs = seconds(time);
simIn = timetable(secs,data);
```

Simulate the model again.

```
out2 = sim mdl;
```

The results on the Dashboard Scope look the same as the previous simulation.

The values in the time vector are the same for the simulation that used the structure without time format and the simulation that used the timetable format with a time vector created using the expression in this example.

```
isequal(out.yout{1}.Values.Time,out2.yout{1}.Values.Time)
```

```
ans = logical
      1
```

## Load Data Logged In Another Simulation

### In this section...

“Load Logged Data” on page 75-34

“Configure Logging to Meet Loading Requirements” on page 75-35

A common source of signal data to load into a model is data that you log from a simulation. You can use the signal data captured from a simulation as roundtrip input to:

- Simulate the same model again from a known starting point.
- Test simulation results.
- Simulate another model starting with the captured signal values from a model. For example, you can log signal data when you simulate a model. Then load the signal data from that simulation as inputs to a second model that you want to reference from the first model.

You can capture the signal data from a simulation in a workspace or in a file. Use one of these techniques to capture signal data from a simulation:

- Signal logging
- To Workspace block
- To File block
- Scope block
- In the **Configuration Parameters > Data Import/Export** pane, the **Output, States, or Final states** parameters
- Data store
- The `sim` command configured to log simulation data

For an example of using simulation data for roundtrip signal data loading, see “Load Data to Model Variable-Step Input from Model Hierarchy” on page 75-36.

### Load Logged Data

Here is a workflow for using signal logging data for standalone simulation of a referenced model. You can use a similar approach for other data logged in `Dataset` format.

- 1 Use the default signal logging output variable, `logsout`, or specify a variable using the **Configuration Parameters > Data Import/Export > Signal logging** edit box.
- 2 Simulate the parent model.

The signal logging output is a `Simulink.SimulationData.Dataset` object.

- 3 Use the `Simulink.SimulationData.Dataset.getElement` method to access the logged data. The logging data for individual signals is stored in `Simulink.SimulationData.Signal` objects.
- 4 For the referenced model that you want to simulate standalone, use the `Simulink.SimulationData.Signal.getElement` method to specify signal elements for the **Configuration Parameters > Data Import/Export > Input** parameter.

For example:

##### 5 Simulate the referenced model.

For an example of loading signal logging data for a model that uses model referencing, see “Logging Intervals”. After you open the model, double-click the blue block labeled **Interface Specification** and see the sections called:

- Logging Model Reference Signals
- Loading Data

Also, the “Load Data to Model Variable-Step Input from Model Hierarchy” on page 75-36 example illustrates loading signal logging data.

To import signal logging data for array of buses signals, see “Import Array of Buses Data” on page 75-62.

## Configure Logging to Meet Loading Requirements

Different logging techniques support different data formats. Most logging techniques support the Dataset format, which provides a consistent data format for logged signal data. You can use the `Simulink.SimulationData.Dataset` constructor to convert other data formats to Dataset format.

To log only the data that you require, use the **Configuration Parameters > Data Import/Export > Logging intervals** parameter to specify start and stop time intervals.

## Load Data to Model Variable-Step Input from Model Hierarchy

A model hierarchy can include discrete and continuous components that operate with different dynamics. You might simulate a model hierarchy that contains both discrete and continuous components using a variable-step solver.

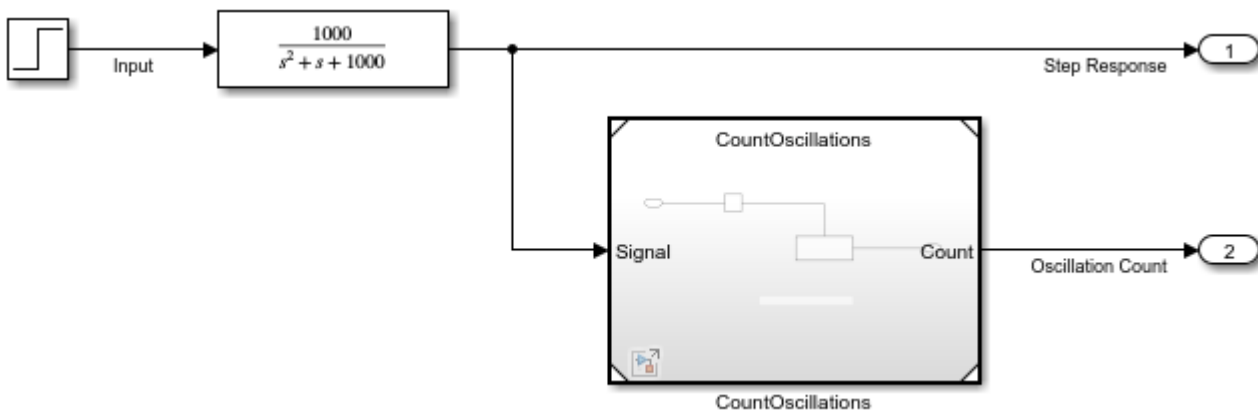

As you develop each component, you can simulate the referenced model that implements the component as a top model. Instead of the input data coming from the model hierarchy, the Inport block loads external input data you specify using the **Input** model configuration parameter.

This example shows how you can use the **Output times** model configuration parameter to ensure such a simulation captures dynamics of continuous input signals logged from a variable-step simulation. For more information, see “Control How Models Load Input Data” on page 75-27.

### Open Top Model

Open the model `ContinuousPlant`. The model contains a Transfer Fcn block that models a continuous plant. A Step block provides the input for the continuous plant. The plant output signal is connected to an output port and a referenced model that processes the signal using a discrete algorithm. The algorithm counts the number of oscillations that reach a value of 1.5 or higher. The top model uses a variable-step solver to capture the continuous dynamics of the plant.

```
mdl = "ContinuousPlant";
open_system(mdl)
```

### Simulate Top Model

Suppose you want to test and refine the model `CountOscillations` in isolation. You can use data logged from a simulation of the top model as input data when you simulate the referenced model as a top model.

Simulate the top model. On the Simulink® Toolstrip, on the **Simulation** tab, click **Run**. Alternatively, use the `sim` function.

```
out = sim(mdl);
```

Get the logged data for the two outputs `Step Response` and `Oscillation Count`.

```

yout = out.yout;
stepResp = getElement(yout,"Step Response");
oscCount = getElement(yout,"Oscillation Count");

```

Plot the plant step response. The plot shows that the step response is underdamped and the algorithm counts 7 oscillations that go above a value of 1.5.

```

figure(1)
subplot(2,1,1)
plot(stepResp.Values)
subplot(2,1,2)
plot(oscCount.Values)

```

### Simulate Referenced Model as Top Model

Open the model CountOscillations as a top model.

```

mdl2 = "CountOscillations";
open_system(mdl2)

```

Configure the model to load the data in the variable `stepResp` as simulation input.

- 1 In the Simulink Toolstrip, on the **Modeling** tab, click **Model Settings**.
- 2 Select the **Data Import/Export** pane.
- 3 Select **Input**.
- 4 In the **Input** field, enter `stepResp`.
- 5 Click **OK**.

Alternatively, you can configure the simulation to load the external input data programmatically, using a `Simulink.SimulationInput` object.

Create a `Simulink.SimulationInput` object for the referenced model. Then, use the `setExternalInput` function to specify the external input for the simulation as the variable `stepResp`.

```
simIn = Simulink.SimulationInput mdl2;
simIn = setExternalInput(simIn, "stepResp");
```

To see how the model loads the input data, mark the input signal for logging. Select the signal `Step Response`. Then, in the **Simulation** tab, click **Log Signals**.

Alternatively, you can mark the signal for logging using the `Simulink.sdi.markSignalsForStreaming` function.

```
blkPth = strcat(mdl2, "/Signal");
Simulink.sdi.markSignalForStreaming(blkPth, 1, "on")
```

Simulate the model.

```
out2 = sim(simIn);
```

Get the data for the logged input signal and the oscillation count.

```
logcout = out2.logcout;
stepRespInput = getElement(logcout, "Step Response");

yout2 = out2.yout;
oscCount2 = getElement(yout2, "Oscillation Count");
```

Plot the input signal and the oscillation count. The response appears no longer underdamped, and the algorithm counts zero oscillations due to the way the simulation loaded the step response data.

```
figure(2)
subplot(2,1,1)
```

```

plot(stepRespInput.Values)
subplot(2,1,2)
plot(oscCount2.Values)

```

When you simulate the referenced model as a top model, the solver is aware of the step response dynamics only after the Inport block loads the input data into the model. Because the signal had continuous sample time in a variable-step simulation, the samples are not evenly spaced. To load the data in a way that accurately reflects the step response, the Inport block needs to load more input values from the step response data.

### Specify Additional Output Times for Simulation

You can use the **Output times** model configuration parameter to force the variable-step solver to take time steps at specified values in addition to those the solver determines. You can use the time values in the logged data from the first simulation to specify the value of the **Output times** parameter.

For this example, because the oscillations in the step response continue throughout the simulation, specify the value of the **Output times** parameter as the entire time vector for the input data. Get the vector of time values.

```
outTimes = stepResp.Values.Time;
```

Specify the **Output times** parameter value as the variable `outTimes`.

- 1 In the Simulink Toolstrip, on the **Modeling** tab, click **Model Settings**.

- 2 Select the **Data Import/Export** tab.
- 3 Expand **Additional parameters**.
- 4 Set **Output options** to Produce additional output.
- 5 In the **Output times** field, type outTimes.
- 6 Click **OK**.

Alternatively, you can configure the parameter values for the simulation using the SimulationInput object.

```
simIn = setModelParameter(simIn,...  
    "OutputOption", "AdditionalOutputTimes", ...  
    "OutputTimes", "outTimes");
```

Simulate the model again.

```
out3 = sim(simIn);
```

Get the data for the logged input signal and the oscillation count.

```
logcout2 = out3.logcout;  
stepRespInput2 = getElement(logcout2, "Step Response");
```

```
yout3 = out3.yout;  
oscCount3 = getElement(yout3, "Oscillation Count");
```

Plot the logged input signal and the oscillation count. Now, the plots look the same as those from the first simulation of the entire model hierarchy.

```
figure(3)  
subplot(2,1,1)  
plot(stepRespInput2.Values)  
subplot(2,1,2)  
plot(oscCount3.Values)
```

Depending on the requirements for your system, you can specify the value for the **Output times** parameter using the time vector for the entire input signal or using one or more relevant portions of the input signal time data.

To extract portions of a `timeseries` object, you can create a `tsdata.event` object that describes a point of interest within the timeseries and then use a function such as `gettsbeforeevent` or `gettsafterevent` to extract the desired portion of the `timeseries` object. Then, you can use the time vector for one or more of these timeseries objects to specify the value for the **Output times** parameter.

## Load Input Data for Basic Test Cases

You can develop tests for models to verify that key behaviors match expectations and requirements as you continue development. You can create a basic test case by creating an input signal to load into the model. The input signal defines input values for the system at specific times of interest. By logging simulation results, you can verify that signals of interest have the expected values at each point of interest.

### Create Input Data

For a basic test case, you typically want to analyze as few points of interest as possible to verify your system behavior. To ensure that the simulation takes a time step at each point of interest, include discontinuities in the input data and use a block that supports zero-crossing detection to load the data. The From File, From Workspace, and Signal Editor blocks all support zero-crossing detection for input data when you simulate using a variable-step solver.

To create the input signal, create a vector of time values and a vector of signal values that define the time and input value for each point of interest. Include a duplicate time and signal value at each discontinuity in the data. The loading blocks detect zero crossings in the input signal by checking for duplicate time values in the input data.

For this example, use these vectors of time and signal data to define the points of interest for the basic test case. The input data includes duplicate times to capture the discontinuities at times 1, 5, and 8.

```
time = [0 1 1 5 5 8 8 10]';  
vals = [0 0 2 2 2 3 3 3]';
```

These time and signal values define an input signal where:

- The input value is 0 between times 0 and 1.
- At time 1, the input value jumps from 0 to 2.
- Between times 1 and 5, the value remains 2.
- Between times 5 and 8, the signal value increases linearly to a final value of 3.
- The value remains 3 until time 10.

To visualize the signal, plot the data.

```
plot(time,vals)
```

To load the input data for the test case, you must use an input data format supported by the loading block you choose.

For this example, create a `timetable` to load using the From Workspace block. To create a `timetable`, the time data must be a `duration` vector. Use the `seconds` function to create a `duration` vector with units of seconds.

```
time = seconds(time);  
simin = timetable(time,vals);
```

### Open Example Model

Open the model `FromWorkspaceTestCase`. The model contains a From Workspace block that loads the data in the variable `simin`. The input data is conditioned using a Gain block, and the conditioned signal output from the Gain block is connected to an Outport block.

```
mdl = "FromWorkspaceTestCase";  
open_system(mdl)
```

## Configure Zero-Crossing Detection for Model and Block

To ensure the simulation takes a major time step at each point of interest, the model and block must be configured to detect zero crossings in the input data. The model `FromWorkspaceTestCase` uses the default model and block parameter values and is already configured appropriately.

To check or configure zero-crossing detection for a model:

- 1 On the **Modeling** tab, under **Setup**, click **Model Settings**.
- 2 On the **Solver** tab, expand **Solver details**.
- 3 Set **Zero-crossing control** to `Use local settings` or `Enable all`. When you choose `Use local settings`, you configure zero-crossing detection for each block. When you select `Enable all`, zero-crossing detection is enabled for all blocks that support zero-crossing detection, regardless of the block parameter value for each block.
- 4 Click **OK**.

Alternatively, use the `get_param` function or the `set_param` function to check or set the parameter value.

```
get_param mdl, "ZeroCrossControl"
```

```
ans =  
'UseLocalSettings'
```

To check or configure zero-crossing detection for the From Workspace block:

- 1 Select the block in the model.
- 2 Open the Property Inspector by clicking the **Property Inspector** tab on the right of the Simulink® Editor or by pressing **Ctrl+Shift+I**.
- 3 Select **Enable zero-crossing detection**.

Alternatively, use the `get_param` function or the `set_param` function to check or set the parameter value.

```
get_param(strcat(mdl, "/From Workspace"), "ZeroCross")
```

```
ans =  
'on'
```

## Run Test Case and Analyze Results

Simulate the model.

```
out = sim(mdl);
```

You can verify the model behavior at each point of interest by plotting the signal data or by analyzing logged output data.

The model in this example uses a Dashboard Scope to display the input signal and the conditioned output signal. By inspecting the signal values in the plot, you can see that the model correctly multiplies each input value by 2 at each point of interest.

## Load Data to Root-Level Input Ports

### In this section...

“Specify Input Data” on page 75-47  
 “Forms of Input Data” on page 75-48  
 “Time Values for the Input Parameter” on page 75-49  
 “Data Loading” on page 75-49  
 “Loading Dataset Data to Root-Level Inputs” on page 75-49  
 “Loading MATLAB Timeseries Data to Root-Level Inputs” on page 75-50  
 “Loading MATLAB Timetable Data to Root-Level Inputs” on page 75-51  
 “Loading Data Structures to Root-Level Inputs” on page 75-51  
 “Loading Data Arrays to Root-Level Inputs” on page 75-54  
 “Loading MATLAB Time Expressions to Root Inports” on page 75-56

You can load data from a workspace to a root-level inport modeled using one of these blocks:

- Inport block
- Enable block
- Trigger block that has an edge-based (rising, falling, or either) trigger type

These blocks import data from the workspace based on the value of the **Configuration Parameters > Data Import/Export > Input** parameter.

**Tip** To import many signals to root-level input ports, consider using the Root Inport Mapper tool. For more information, see “Map Root Inport Signal Data” on page 76-7.

You can also import data from a workspace using a From Workspace block. For details, see the From Workspace documentation and “Load Input Data for Basic Test Cases” on page 75-43.

### Specify Input Data

You can specify input data manually, using the **Input** configuration parameter. To load many signals to root-level input ports, consider using the Root Inport Mapping tool, which automatically specifies in the **Input** parameter the data you map using the tool. For details, see “Map Data Using Root Inport Mapper Tool” on page 76-2.

- 1 Select the **Configuration Parameters > Data Import/Export > Input** parameter.

**Note** The use of the **Input** configuration parameter is independent of the setting for the **Format** configuration parameter for saving logged data.

- 2 Enter an external input specification in the adjacent edit box and click **Apply**. For a list of the forms of data you can specify, see “Forms of Input Data” on page 75-48.

In the **Input** box, specify the signal input using one of these approaches:

- Create data at run-time for each simulation time step using the input  $u = UT(\tau)$  for either a MATLAB function (expressed as a string) or MATLAB expression.
- Specify the data directly, using one of the input data forms described in “Forms of Input Data” on page 75-48.

### Comma-Separated List

If you specify **Dataset** data, specify only one **Dataset** object for the **Input** parameter. Do not include it in a comma-separated list.

Each variable or expression must evaluate to an appropriate object that corresponds to a specific root-level input port in the model. Each variable or expression in the list must evaluate to the appropriate object that corresponds to one of the root-level input ports of the model. The first item corresponds to the first root-level input port, the second to the second root-level input port, and so on. The dimensions for each data sample must match the dimensions of the data specified in the input block parameter.

For an Enable or Trigger block, the signal driving the enable or trigger port must be the last item in the comma-separated list. If you have both an enable and a trigger port, then specify:

- The enable port as the next-to-last item in the list
- The trigger port as the last item

Use an empty matrix to specify ground values for a port. For example, to load data for input ports `in1` and `in3`, and to use ground values for port `in2`, enter the following in the **Input** parameter:

```
in1, [], in3
```

### Forms of Input Data

You can provide input data with the following formats:

- `Simulink.SimulationData.Dataset` — Collection of logged data in MATLAB timeseries format. For more information, see “Loading Dataset Data to Root-Level Inputs” on page 75-49.
- MATLAB timeseries — For more information, see:
  - “Loading MATLAB Timeseries Data to Root-Level Inputs” on page 75-50
  - “Load Bus Data to Root-Level Input Ports” on page 75-58
- `Simulink.SimulationData.DatasetRef` — For more information, see “Load Big Data for Simulations” on page 75-7
- MATLAB timetable — For more information, see “Loading MATLAB Timetable Data to Root-Level Inputs” on page 75-51.
- Array — See “Loading Data Arrays to Root-Level Inputs” on page 75-54.
- `Simulink.SimulationData.Signal` — For more information, see “Load Data Logged In Another Simulation” on page 75-34.
- `matlab.io.datastore.SimulationDatastore` — For more information, see “Work with Big Data for Simulations” on page 77-30.
- `matlab.io.datastore.sd datastore`
- Structure — To simplify the specification of external input data, you can load data for a subset of root-level input port blocks. This approach avoids having to create data structures for the ports for

which you want to use ground values. For information about ground values, see “Initialize Signals and Discrete States” on page 80-42. For more information about loading structure data, see “Loading Data Structures to Root-Level Inputs” on page 75-51.

- Structure array containing data for all input ports.
- Empty matrix — Use an empty matrix for ports for which you want to use ground values, without having to create data values.
- Time expression — For more information, see “Loading MATLAB Time Expressions to Root Inports” on page 75-56.

---

**Note** When you specify timetable data to load, the timetable must contain data for only one signal.

---

For information about importing bus data, see “Load Bus Data to Root-Level Input Ports” on page 75-58.

## Time Values for the Input Parameter

Time values that you specify in the **Input** parameter do not control the times the solver uses. Solvers have their own logic for propagating time and might require input data at an arbitrary time value. The **Interpolate** parameter setting for the root-level input block (for example, the root-level Inport block) specifies how to handle output at time steps for which no corresponding workspace data exists.

The time values specified in the **Input** parameter cannot be sparse or include NAN or Inf values.

## Data Loading

If you select the **Interpolate data** option for the corresponding Inport, Enable, or Trigger block, Simulink linearly interpolates or extrapolates input values as necessary.

Simulink resolves symbols used in the external input specification as described in “Symbol Resolution” on page 72-126. The `sim` command provides some data import capabilities that are available only for programmatic simulation.

If you use a `Simulink.SimulationData.Dataset` object that includes a `matlab.io.datastore.SimulationDatastore` object as an element, then the data stored in persistent storage is streamed in from a file. For more information, see “Load Big Data for Simulations” on page 75-7.

## Loading Dataset Data to Root-Level Inputs

You can use a Dataset object as a value for the **Configuration Parameters > Data Import/Export > Input** parameter. Specify only one Dataset object and do not include it in a comma-separated list. The number of elements in the Dataset must match the number of root-level input ports.

### Dataset Elements

A Dataset object can include elements with different data types.

For individual non-bus signal data, you can specify these types of data for Dataset elements:

- `timeseries`
- `timetable`
- `matlab.io.datastore.SimulationDatastore`
- double vectors or structure of double data
- a `Simulink.SimulationData.Signal`, `Simulink.SimulationData.State`, or `Simulink.SimulationData.DataStoreMemory` object
- An array that meets one of these requirements:
  - An array with time in the first column and the remaining columns each corresponding to an input port. See “Loading Data Arrays to Root-Level Inputs” on page 75-54.
  - An  $n \times 1$  array for a root inport that drives a function-call subsystem.
- Structure — See “Loading Data Structures to Root-Level Inputs” on page 75-51.

For bus signals, use a structure with a data element for each leaf signal, using one of these formats:

- A MATLAB `timeseries` object
- A MATLAB `timetable` object
- A `matlab.io.datastore.SimulationDatastore` object
- An empty matrix
- Another structure, with data elements for each signal that are consistent with these requirements for a structure for bus data

---

**Note** When you specify `timetable` data to load, the `timetable` can contain data for only one signal.

---

### Create a Dataset Object for Inport Blocks

To generate a `Simulink.SimulationData.Dataset` object from the root-level Inport blocks in a model, you can use the `createInputDataset` function. Signals in the generated dataset have the properties of the Inport blocks and the corresponding ground values at model start and stop times. You can create `timeseries` and `timetable` objects for the time and values for signals for loading. The other signals use ground values. Each `timetable` object must contain data for only one signal.

You can load into a root-level input port data specified by a MATLAB `timeseries` object that resides in a workspace.

---

**Note** This documentation about importing MATLAB `timeseries` data includes examples of root Inport blocks. Unless specifically noted otherwise, the examples are applicable to root-level Enable, Trigger, and From Workspace blocks.

---

## Loading MATLAB Timeseries Data to Root-Level Inputs

### Time Dimension

When you create a MATLAB `timeseries` object to import data to Simulink, the time dimension (number of time samples) depends on the dimension and the type of signal data.

Signal Data Dimension or Type	Time Dimension Alignment	Example of timeseries Constructor
Scalar or a 1D vector	First	Constructor for a scalar signal. Time is aligned with the first dimension.  <pre>t = (0:10)'; ts = timeseries(sin(t), t);</pre>
2D (including row and column vectors) or greater	Last	Constructor for a matrix signal. Time is aligned with the last dimension.  <pre>t = 0; ts = timeseries([1 2; 3 4], t);</pre>
2D row vector, and there is only one time step	Last	'InterpretSingleRowDataAs3D', true  For example:  <pre>t = 0; ts = timeseries([1 2], t, 'InterpretSin</pre>

### Enum Data

If you specify an enum in timetable data, clear the **Interpolate data** parameter for the corresponding Inport block.

## Loading MATLAB Timetable Data to Root-Level Inputs

In general, you can load MATLAB timetable data the same way you load MATLAB timeseries data. Each timetable must contain data for only one signal.

## Loading Data Structures to Root-Level Inputs

### Data Structures

You can load to a root-level input port data from the workspace in the form of a structure, whose name you specify in the **Configuration Parameters > Data Import/Export > Input** parameter. For information about defining MATLAB structures, see “Structure Arrays”.

You can specify structures for the model as a whole or on a per-port basis. For information about specifying per-port structures for the **Input** parameter, see “Structures for All Ports or for Each Port” on page 75-52.

The structure always includes a signals substructure, which contains a values field and a dimensions field. Depending on the modeling task that you want to perform, the structure can also include a time field. The form of a structure that you use depends on the type of signals for which you are importing data:

- Discrete signals (the signal is defined at evenly spaced values of time) — Use a structure that has an empty time vector. Specify a **signals** field, which contains an array of substructures, each of which corresponds to a model input port.
- Continuous signals (the signal is defined for all values of time) — The approach that you use depends on whether the data represents a smooth curve (continuous) or a curve that has

discontinuities (jumps) over its range (discrete). Specify a `signals` field, which contains an array of substructures, each of which corresponds to a model input port. You can specify a `time` field, which contains a time vector. See “Specify Time Data” on page 75-52.

For examples of importing data for discrete and continuous signals, see “Control How Models Load Input Data” on page 75-27.

### Structures for All Ports or for Each Port

You can specify one structure to provide input to all root-level input ports in a model, or you can specify a separate structure for each port.

The per-port structure format consists of a separate structure-with-time or structure-without-time for each port. The input data structure for each has only one `signals` field. To specify this option, enter the names of the structures in the **Input** text field as a comma-separated list, `in1, in2, ..., inN`. The value `in1` is the data for first input port in the model, `in2` for the second input port, and so on.

To specify one structure for all ports:

- The `values` field must contain an array of inputs for the corresponding input port. If you specify a time vector, each input must correspond to a time value specified in the `time` field.

If the inputs for a port are scalar or vector values, the `values` field must be an M-by-N array. If you specify a time vector, M must be the number of time points specified by the `time` field and N is the length of each vector value.

If the inputs for a port are matrices (2-D arrays), the `values` field must be an M-by-N-by-T array. M and N are the dimensions of each matrix input and T is the number of time points. For example, suppose that you want to input 51 time samples of a 4-by-5 matrix signal into one of the input ports in your model. Then, the corresponding `dimensions` field of the workspace structure must equal [4 5] and the `values` array must have the dimensions 4-by-5-by-51.

- The `dimensions` field specifies the dimensions of the input. If each input is a scalar or vector (1-D array) value, the `dimensions` field must be a scalar value specifying the length of the vector (1 for a scalar). If each input is a matrix (2-D array), the `dimensions` field must be a two-element vector whose:
  - First element specifies the number of rows in the matrix
  - Second element specifies the number of columns

---

**Note** Set the **Port dimensions** parameter of the Inport or the Trigger block to be the same value as the `dimensions` field of the corresponding input structure. If the values differ, you get an error message when you try to simulate the model.

---

### Specify Time Data

You can specify a time vector of doubles as part of the data structure to import. For example, specify a time vector when importing signal data to represent a continuous plant or to create a test case. To test a discrete algorithm, use a structure with an empty time vector. This table provides additional recommendations for specifying time values, based on the kind of signal data you want to load.

Signal Data	Time Data Recommendation
Inport or Trigger block with a discrete sample time	Do not specify a time vector. Simulink loads one signal value at each time step.
Evenly spaced discrete signals	<p>Use an expression in this form:</p> <pre>timeVector = startTime + sampleTime*(0:numSteps-1)';</pre> <p>Use the colon operator to count in increments of 1 from zero to the desired number of time steps minus one, for the first point, 0. Then, scale the resulting vector by the desired sample time so the increments between elements in the vector is now equal to the sample time. The vector is transposed because most data formats supported for loading require a column time vector. To create a time vector with a start time other than zero, add the desired start time to the vector.</p> <p>For example, use this code to create an evenly-spaced time vector that starts at 1, includes 101 time points, and has a sample time of 0.2.</p> <pre>T1 = 1 + 0.2*(0:100)'</pre> <hr/> <p><b>Note</b> Do not use an expression in this form:</p> <pre>timeVector = [startTime:timeStep:endTime]'</pre> <p>For example, do not use:</p> <pre>T2 = [0:0.2:10]'</pre> <p>The time vector T2 is not equal to the time vector T1 because of double-precision rounding. The double-precision rounding in a time vector like T2 can lead to differences between the input time vector and the time steps calculated by the solver, leading to unexpected simulation results.</p>
Unevenly spaced values	<p>Use any valid MATLAB array expression; for example, [1:5 5:10] or (1 6 10 15).</p> <p>The From Workspace, From File, and Signal Editor blocks support zero-crossing detection. If the root-level input port is connected to one of those blocks, you can specify a zero-crossing time by using a duplicate time entry.</p>

### Examples of Specifying Signal and Time Data

In the first example, consider the following model that has a single input port:

- 1 Create an input structure for loading 11 time samples of a two-element signal vector of type `int8` into the model:

```
N = 10
Ts = 0.1
a.time = Ts*[0:N]';
c1 = int8([0:1:10]');
c2 = int8([0:10:100]');
a.signals(1).values = [c1 c2];
a.signals(1).dimensions = 2;
```

- 2 In the **Configuration Parameters** > **Data Import/Export** > **Input** parameter edit box, specify the variable `a`.
- 3 In the Inport block dialog box, in the **Signal Attributes** tab, set **Port dimensions** to 2 and **Data type** to `int8`.

As another example, consider a model that has two inputs.

Suppose that you want to input a sine wave into the first port and a cosine wave into the second port. Define a structure, `a`, as follows, in the MATLAB workspace:

```
a.time = 0.1*[0:1]';
a.signals(1).values = sin(a.time);
a.signals(1).dimensions = 1;
a.signals(2).values = cos(a.time);
a.signals(2).dimensions = 1;
```

Enter the structure name (`a`) in the **Configuration Parameters** > **Data Import/Export** > **Input** parameter edit box.

---

**Note** In this model you do not need to specify the dimension and data type, because the default values are 1 and `double`.

---

## Loading Data Arrays to Root-Level Inputs

You can load to a root-level input port data from the workspace in the form of a data array, which you specify in the **Configuration Parameters** > **Data Import/Export** > **Input** parameter.

This import format consists of a real (noncomplex) matrix of data type `double`. The first column of the matrix must be a vector of times in ascending order. The remaining columns specify input values.

- Each column represents the input for a different Inport or Trigger block signal (in sequential order).
- Each row is the input value for the corresponding time point.

For a Trigger block, the signal that drives the trigger port must be the last data item.

The total number of columns of the input matrix must equal  $n + 1$ , where  $n$  is the total number of signals entering the model input ports.

### Specify the Input Expression

The default input expression for a model is `[t, u]` and the default input format is `Array`. If you define `t` and `u` in the MATLAB workspace, simply select the **Configuration Parameters > Data Import/Export > Input** parameter to input data from the model workspace.

Suppose that you have a model with two Inport blocks:

- The In1 block accepts two signals (the block has the **Port dimensions** parameter set to 2).
- The In2 block accepts one signal (the block uses the default value for the **Port dimensions** parameter).

You define `t` and `u` in the MATLAB workspace:

```
numSteps = 9;
timeStep = 0.1;
t = (timeStep*(0:numSteps))';
u = [sin(t), cos(t), 4*cos(t)];
```

When the simulation runs, the signal data `sin(t)` and `cos(t)` are assigned to In1 and the signal data `4*cos(t)` is assigned to In2. Signal data is input for 100 time points.

---

**Note** The array input format allows you to load only real (noncomplex) scalar or vector data of type `double`. Use the structure format to input complex data, matrix (2-D) data, and data types other than `double`.

---

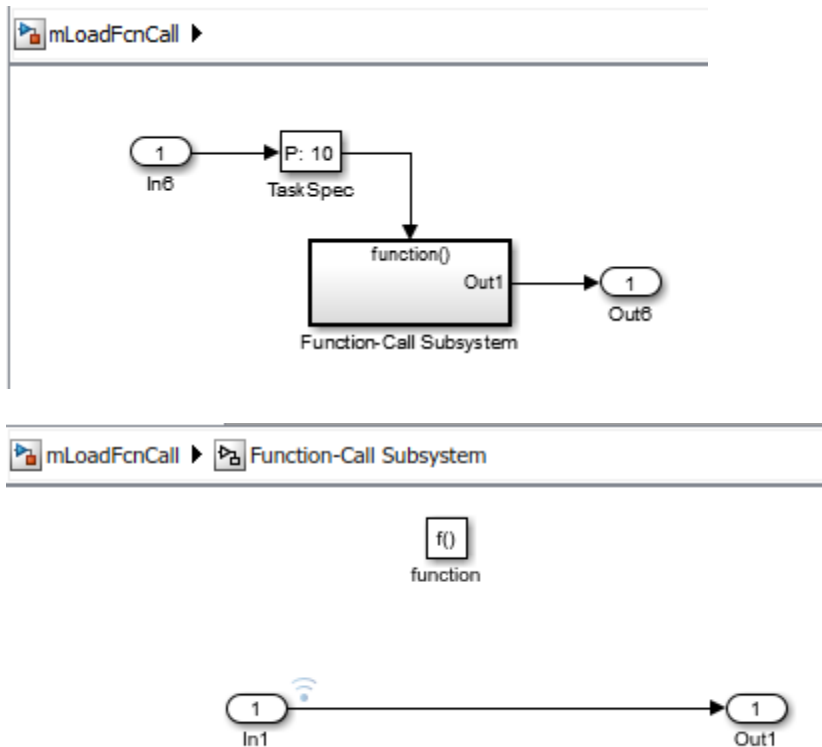

### Arrays for Input Ports Driving Function-Call Subsystems

You can use an array to drive a Function-Call Subsystem through a root-level input port. You can use an array or an array that is an element of a `Dataset` object. The array must be an  $n \times 1$  array. For the root-level Inport block, select the **Output function call** parameter.

For example, this `Dataset` object has an array element `x`:

```
ds = Simulink.SimulationData.Dataset;
x = [1 3 7 8]';
ds = ds.addElement(x, 'theElementName');
```

This model uses the `ds` data set in the **Configuration Parameters > Data Import/Export > Input** parameter.

When you simulate the model, the time values of the logged signal data in the Function-Call Subsystem show that the Function-Call Subsystem was triggered only for the times specified in an array stored in `ds`.

```
>> logouts{1}.Values.Time
```

```
ans =
```

```
1
3
7
8
```

## Loading MATLAB Time Expressions to Root Inports

### Specify the Input Expression

You can use a MATLAB time expression to load data from a workspace into a root-level input port. To use a time expression, enter the expression as a string (enclosed in single quotes) in the **Input** field of the **Data Import/Export** pane. The time expression can be any MATLAB expression that evaluates to a row vector equal in length to the number of signals entering the input ports of the model. Suppose that a model has one vector Inport that accepts two signals. Also, suppose that `timefcn` is a user-defined function that returns a row vector two elements long. Here are valid input time expressions for such a model:

```
'[3*sin(t), cos(2*t)]'
```

```
'4*timefcn(w*t)+7'
```

The expression is evaluated at each step of the simulation, applying the resulting values to the input ports of the model. Simulink defines the variable `t` when it runs the simulation. Also, you can omit the time variable in expressions for functions of one variable. For example, the expression `sin` is interpreted as `sin(t)`.

## Load Bus Data to Root-Level Input Ports

### In this section...

“Imported Bus Data Requirements” on page 75-58

“Open Example Materials” on page 75-59

“Import Bus Data to a Top-Level Inport” on page 75-60

“Get Information About Bus Objects” on page 75-61

“Create Structures of Timeseries Objects from Buses” on page 75-62

“Import Array of Buses Data” on page 75-62

You can import bus data to top-level input ports by manually specifying the data in the **Input** configuration parameter or by using the Root Inport Mapper tool. For information about importing bus data using the Root Inport Mapper tool, see “Import Bus Data” on page 76-14.

### Imported Bus Data Requirements

You can import bus (virtual, nonvirtual, or array of buses) data to a top-level input port defined by a bus object (see `Simulink.Bus`). In the top-level Inport block, set **Data type** to `Bus` and specify the name of a bus object. To specify data values for bus signals, use a structure of:

- MATLAB `timeseries` objects
- MATLAB `timetable` objects
- A combination of `timeseries` and `timetable` objects

Bus elements for which you do not include a field in the structure use ground values. You can use an empty matrix to specify to use ground values.

---

**Note** When you specify `timetable` data to load, the `timetable` must contain data for only one signal.

---

The structure of `timeseries` or `timetable` (or both) objects must match the bus elements in terms of:

- Hierarchy
- Name of the structure field, which must match the bus element name. (The name property of the `timeseries` object does not need to match the bus element name.)
- Data type
- Dimensions
- Complexity

The order of the structure fields does not have to match the order of the bus elements.

You can include the structure as an element of a `Dataset` object. You can use a structure in a comma-separated list. You can specify an empty matrix in a comma-separated list. The empty matrix uses the ground values for the bus signal.

For example, to load data for input ports `in1` and `in3`, and to use ground values for port `in2`, enter the following in the **Input** parameter:

```
in1, [], in3
```

### Initialize Bus Signals

You can initialize bus signals, including using partial specification of initialization data. For details, see “Specify Initial Conditions for Bus Elements” on page 81-64.

For details about importing array of bus data to a root Inport block, see “Import Array of Buses Data” on page 75-62.

### Limitations for Importing Bus Data to Top-Level Inputs

The signal data that you can use the Root Inport Mapper tool to import and map to a top-level Inport block can include bus data. You cannot use that tool to map bus signals to a top-level Enable or Trigger block.

You cannot use input ports to import buses in external modes. To import bus data in rapid accelerator mode, use `Dataset` format.

## Open Example Materials

This example uses these files:

- `InportLoadingBus`: Model that contains a top-level Inport block configured to load input data for a bus
- `LoadPartialAOB`: Model that loads partial input data for an array of buses
- `partialAOBData.m`: Function that creates `Simulink.Bus` objects and data for the model `LoadPartialAOB` to load
- `BasicColors.m`: Enumeration class definition to define data type used by `Simulink.Bus` objects in this example

For access to these files, click **Open Live Script**. Then, run the code that opens the file you need.

Open the model `InportLoadingBus`.

```
open_system("InportLoadingBus")
```

Open the model `LoadPartialAOB`.

```
open_system("LoadPartialAOB")
```

Open the MATLAB® file `partialAOBData.m`.

```
edit("partialAOBData.m")
```

Open the enumeration class definition file `BasicColors.m`.

```
edit("BasicColors.m")
```

## Import Bus Data to a Top-Level Inport

This model has two Inport blocks connected to Scope blocks. The data type of the In1 block is inherited (nonbus data) and the data type of the In2 block is defined by the bus object BusObject. The model has a callback that loads BusObject and its sub-bus BusObject1.

The BusObject bus object has two elements:

- c
- s1, which is a nested bus that has two elements:
  - a
  - b

- 1 Open the model InportLoadingBus.
- 2 Create a `timeseries` object that contains data for the first input port to load. This input port loads nonbus data.

```
t1 = (1:10)';
d1 = sin(t1);
in1 = timeseries(d1,t1);
```

- 3 Create an input structure, which can consist of `timeseries` objects or `timetable` objects, or a combination of those types of objects. Create one `timeseries` or `timetable` object for each leaf bus element for which you do not want to use ground values. This example uses ground values for the b bus element, so it does not need a `timeseries` or `timetable` object for that element.

```
t2 = (1:5)';
d2 = cos(t2);
in2.c = timeseries(d1,t1);
in2.s1.a = timetable(seconds(t2),d2);
```

The `timeseries` objects that you create must match the corresponding bus elements, as described in “Imported Bus Data Requirements” on page 75-58.

- 4 Create a `Dataset` object and add `in1` and `in2` the object.

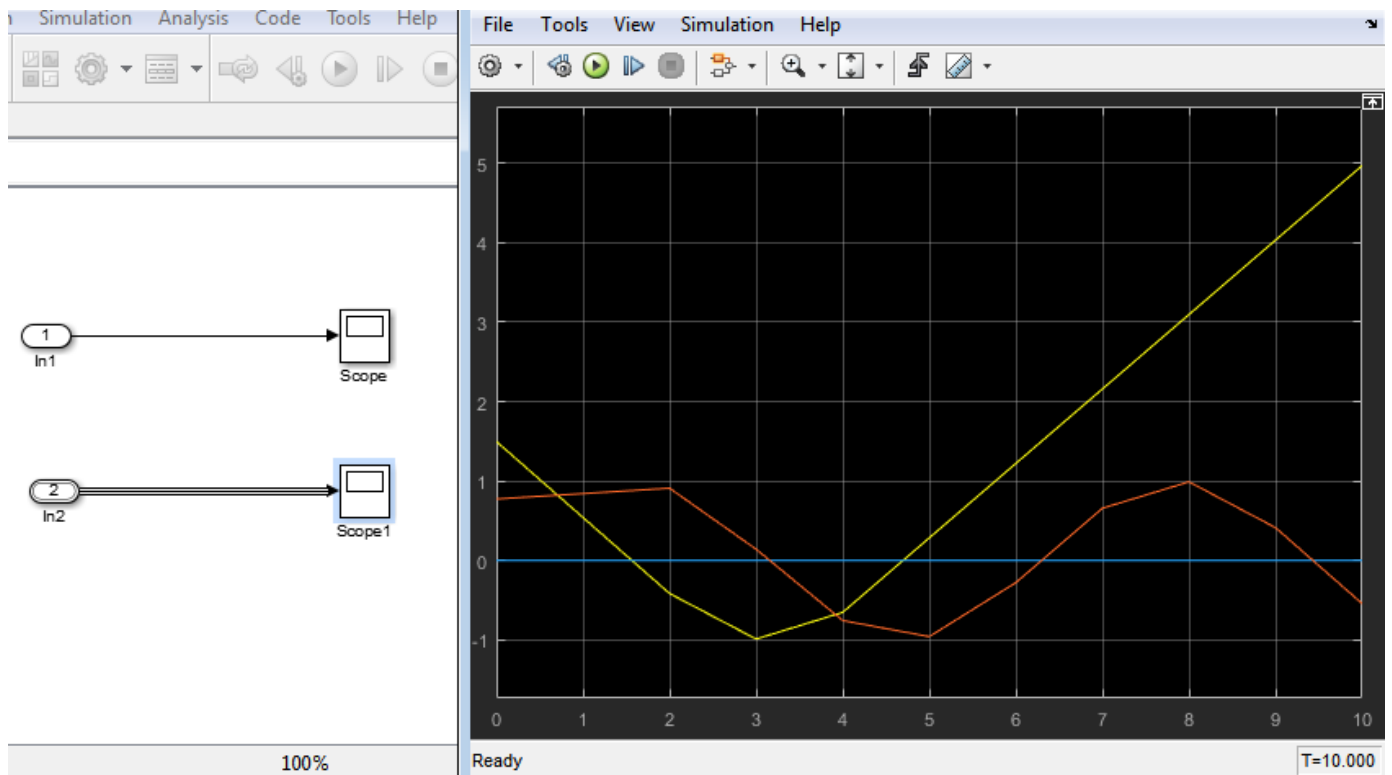

```
ds = Simulink.SimulationData.Dataset;
ds = ds.addElement(in1,'in1_signal');
ds = ds.addElement(in2,'in2_signal');
```

- 5 Open the Configuration Parameters dialog box. On the **Modeling** tab, click **Model Settings**.

- 6 On the **Data Import/Export** pane, select **Input**.
- 7 In the **Input** field, enter the name of the Dataset object `ds`.

- 8 Simulate the model. The Scope block connected to the second input port shows the imported bus data.

## Get Information About Bus Objects

To determine the number of `timeseries` objects and data type, complexity, and dimensions needed for creating a structure of `timeseries` objects from a bus, use these functions:

- `getNumLeafBusElements`
- `getLeafBusElements`

For example, for the bus object `BusObject`:

```
numElem = getNumLeafBusElements(BusObject)
```

```
numElem =
```

```
3
```

```
elemList = getLeafBusElements(BusObject)
```

```
elemList =  
  
    3x1 BusElement array with properties:  
  
        Min  
        Max  
        DimensionsMode  
        SampleTime  
        Description  
        Units  
        Name  
        DataType  
        Complexity  
        Dimensions  
  
elemList(1).Dimensions  
  
ans =  
  
    1
```

## Create Structures of Timeseries Objects from Buses

If you have `timeseries` objects defined, you can use them to create a structure of `timeseries` objects based on a bus object. Use the `Simulink.SimulationData.createStructOfTimeseries` function. For example, if you have defined `timeseries` objects `ts1`, `ts2`, and `ts3`, and you have a bus object `MyBusObject`, you can use this command to create a structure of `timeseries` objects.

```
input = Simulink.SimulationData.createStructOfTimeseries(...  
    'MyBusObject',{ts1,ts2,ts3});
```

The number of `timeseries` objects in the cell array must match the number of leaf elements in the bus object. The data type, dimensions, and complexity of each `timeseries` object must match those attributes of the corresponding bus object leaf node.

## Import Array of Buses Data

To load data for an array of buses using a top-level Inport block, use an array of structures of `timeseries` objects.

---

**Note** You cannot use an Enable, Trigger, or From File block to import data for an array of buses.

---

### Full Specification of Data

You can use logged data for an array of buses from a previous simulation as round trip input to a top-level Inport block in a subsequent simulation. The logged data is a full specification of data for the array of buses.

If you construct an array of structures of `timeseries` objects to specify the data to import:

- Specify the structure fields in the same order as the signals in the bus.
- Do not include more fields in the structure than there are signals in the bus.

For leaf fields, match exactly the data type, dimensions, and complexity of the corresponding signal in the bus.

### Partial Specification of Data

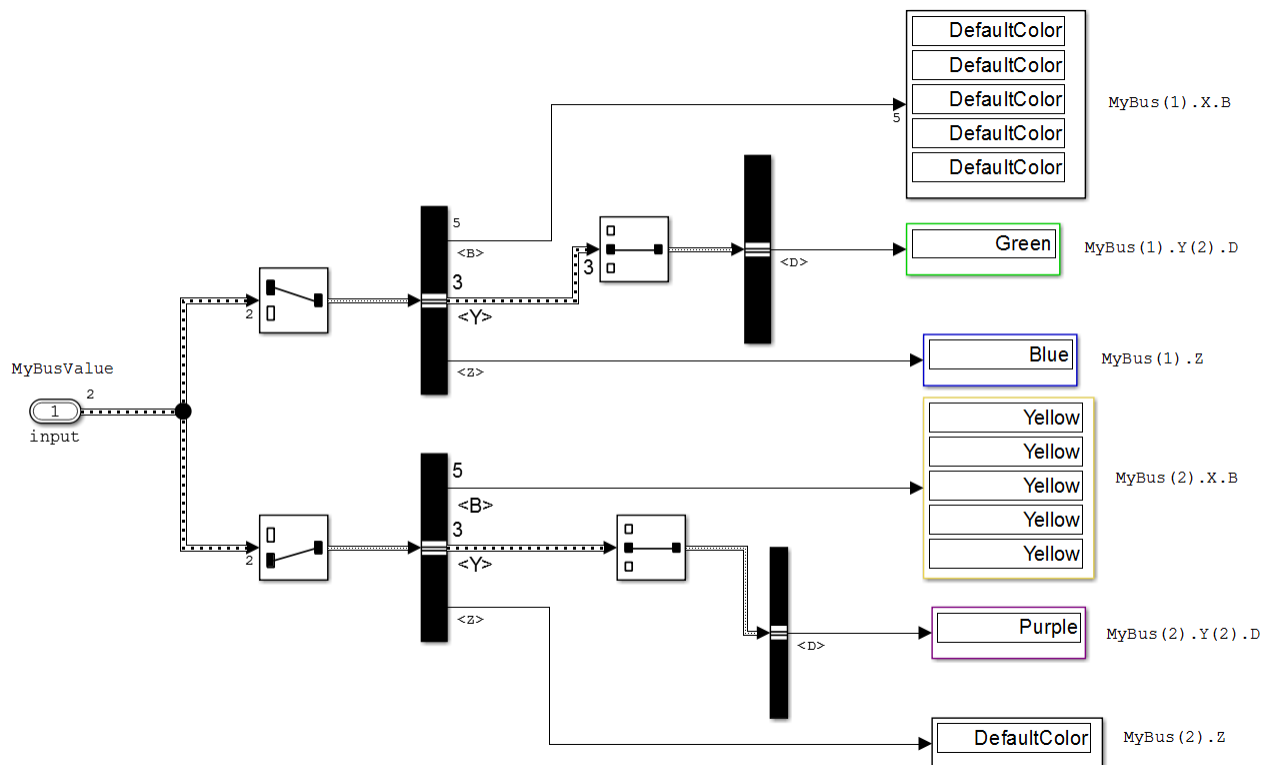

To specify partial data for array of buses, create an array of structures with `timeseries` objects at the leaf nodes.

The structure that you create to specify partial data must be consistent with these rules:

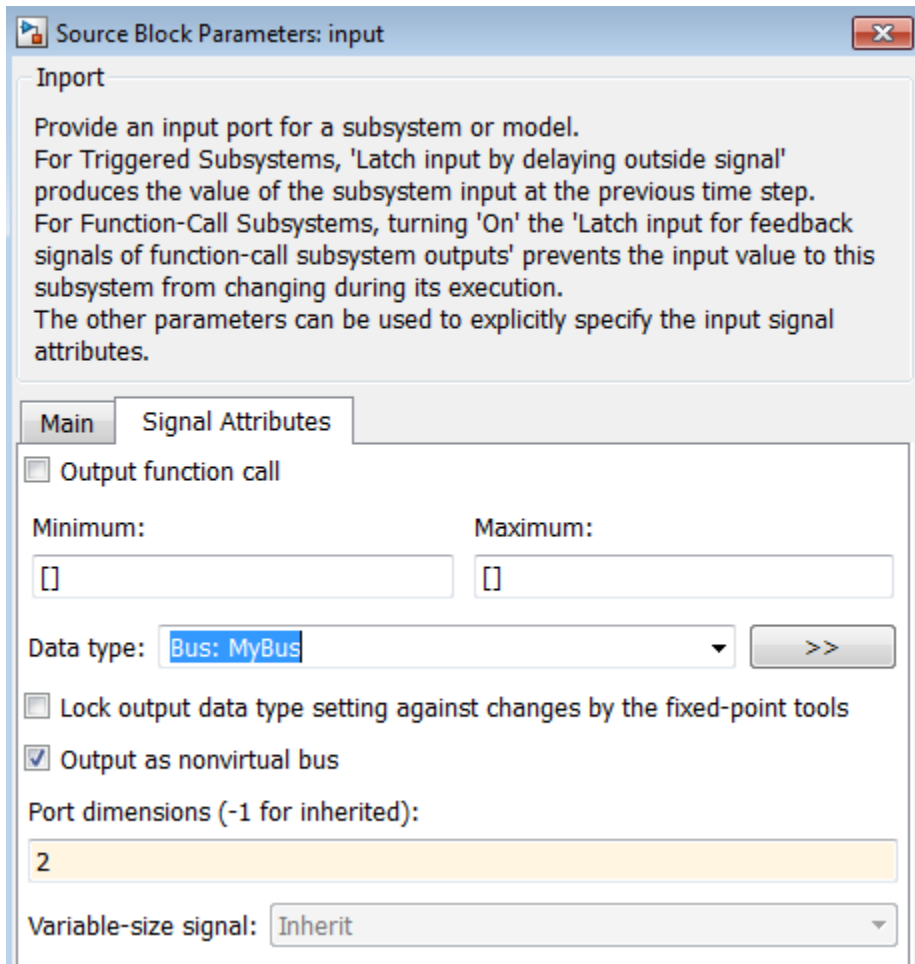

- You can omit fields, including leaf nodes and subbranches. You can also omit dimensions. If you do not specify a field, the software uses the ground value for that field.
- For nested bus nodes, make the dimension of each field equal to, or smaller than, the dimension for the corresponding node of the array of buses.

This example shows how you can specify partial data to be imported using a top-level Inport block whose data type is defined as the Simulink.Bus object `MyBus`. You can open the model `LoadPartialAOB` and the MATLAB code that defines the data to import `partialAOBData.m`.

When you simulate the model, you see that several of the Display blocks connected to elements of the array of buses display `DefaultColor`, the ground value for the bus. Other Display blocks connected to other array of buses elements display the value defined in the partial array of buses data.

The Inport block uses the `MyBus` bus object as its data type.

The MyBus array of buses includes MyBus (1) and MyBus (2). The port dimension is set to 2 to reflect the two buses in the array of buses, and **Output as nonvirtual bus** is enabled.

Here are the elements of the array of buses, which includes MyBus (1) and MyBus (2). The color highlighting shows the nodes of the array of buses for which data is being imported.

Here is MATLAB code that defines the data to import. The color that highlights the code matches the color of the corresponding node in the array of buses. To view the code used in this model, open the MATLAB code file `partialAODBData.m`.

```

7   %% Create timeseries data for leaf signals
8   N = 10; Ts = 1;
9   Time = ((0:N)*Ts)';
10  [m, n] = size(Time);
11
12  ZData = repmat(ex_partial_loading_aob_basicColors.Blue,m,n);
13  BData = repmat(ex_partial_loading_aob_basicColors.Yellow,m,5);
14  D1Data = repmat(ex_partial_loading_aob_basicColors.Green,m,n);
15  D2Data = repmat(ex_partial_loading_aob_basicColors.Purple,m,n);
16
17  % Create individual timeseries objects to represent Z, B, D1 and D2
18  ZT = timeseries(ZData, Time, 'Name', 'Z');
19  BT = timeseries(BData, Time, 'Name', 'B');
20  D1T = timeseries(D1Data, Time, 'Name', 'D1');
21  D2T = timeseries(D2Data, Time, 'Name', 'D2');
22
23  %% Construct MyBusValue(1)
24
25  % Y(2).D
26  Y(2) = struct('D',D1T);
27
28  % Set X.B to empty to allow the second element to support specification for
29  % this field
30  X = struct('B', []);
31
32  % MyBusValue(1)
33  MyBusValue(1) = struct('Z',ZT,'Y',Y,'X',X);
34  clear X Y;
35
36  %% Construct MyBusValue(2)
37
38  % Specify timeseries for MyBusValue(2).X.B
39  MyBusValue(2).X.B = BT;
40
41  % Specify timeseries for MyBusValue(2).Y(2).D
42  MyBusValue(2).Y(2).D = D2T;
43

```

In the code that defines the import data:

- The `timeseries` object `MyBusValue` specifies the data for the highlighted nodes.
- The `timeseries` object `BT` for `MyBus(2)`, because `BT` is a leaf node, it must match exactly the dimensions, data type, and complexity of the corresponding bus element.

- The structure specifies data for  $Y(2)$ . You can skip the first and last nested buses of  $Y$  (that is,  $Y(1)$  and  $Y(3)$ ).

This example specifies data for  $Y(2)$ ; you can skip the first and last nested buses of  $Y$  (that is,  $Y(1)$  and  $Y(3)$ ).

After you define the `MyBusValue` variable for the import data, set the **Configuration Parameters** > **Data Import/Export** > **Input** parameter to `MyBusValue`.

## Load Input Data for a Bus Using In Bus Element Blocks

You can use In Bus Element blocks to load external input data for a bus. Using In Bus Element blocks allows flexibility in the design and implementation of external interfaces for buses.

An In Bus Element block can load data for an element of a bus or an entire bus. To load data for an entire bus using an In Bus Element block, you must specify the data type for the block using a `Simulink.Bus` object.

Multiple In Bus Element blocks can select the same bus element.

This example shows how to use In Bus Element blocks to load input data for bus elements.

### Open and Inspect the Model

Open the `ex_load_inbuselement` model.

```
open_system('ex_load_inbuselement.slx')
```

One or more In Bus Element blocks can define a port in a model. The `ex_load_inbuselement` model has one port, **InBus**, defined by three In Bus Element blocks. The label for each In Bus Element block indicates the bus element the block selects. The **InBus** port corresponds to a bus containing a nested bus, **a**, with signals **x** and **y**, and an individual signal, **b**.

To specify workspace data to load as simulation input for the port in the model, in the Configuration Parameters dialog box, on the **Data Import/Export** pane, use the **Input** parameter. The **Input** parameter for the `ex_load_inbuselement` model loads the variable `struct1`, which maps to the port according to the **Port Number** defined in the In Bus Element block dialog box.

### Create Input Data

Ports that load bus data accept structures composed of individual `timeseries`, `timetable`, and `matlab.io.datastore.SimulationDatastore` objects. The hierarchy of the structure must match the hierarchy of the bus. Ports that use In Bus Element blocks to select bus elements allow partial specification and overspecification of data.

In Bus Element blocks interpolate loaded data for all data types except `string`, `enumerated`, and `fixed point`.

This example creates the structure using three `timeseries` signals that correspond to a sine wave, a line, and a constant.

```
time = linspace(0,10,11);
sineData = sin(time);
constData = 3*ones(11,1);
lineData = linspace(0,10,11);

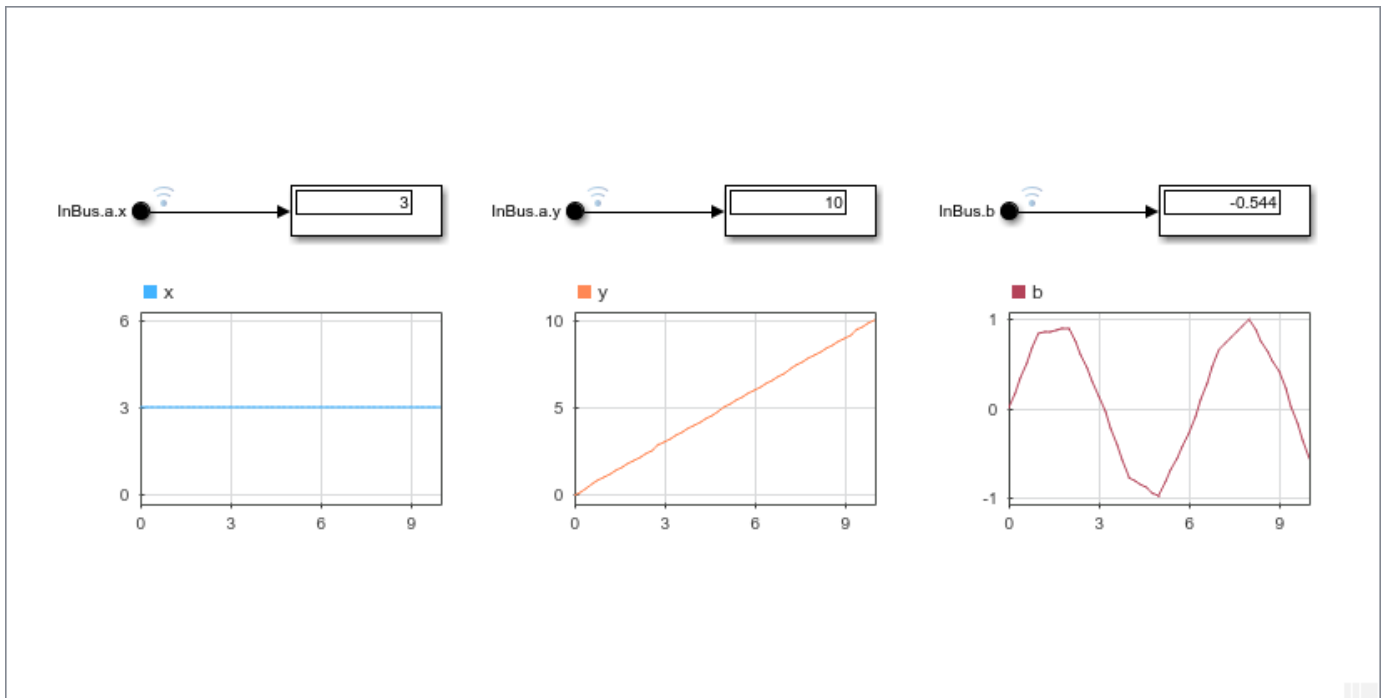

tsSine = timeseries(sineData,time);
tsConst = timeseries(constData,time);
tsLine = timeseries(lineData,time);
```

Construct the structure, `struct1`, to provide the input data for the port in the model. The structure field names must match the bus element names.

```
struct1.a.x = tsConst;
struct1.a.y = tsLine;
struct1.b = tsSine;
```

### Fully Specify Input Data

The data created in the previous section fully specifies data for the signals selected by the In Bus Element blocks in the model. Simulate the model and observe the signals on the Dashboard Scope blocks.

### Partially Specify Input Data

When you use In Bus Element blocks to select bus elements, you can partially specify data using a structure that does not include one or more selected elements. Elements without data defined in the structure use ground signal values for simulation.

For example, edit the label for the In Bus Element block that selects element `InBus.a.y` so that the In Bus Element block selects `InBus.a.z`. The structure that maps to the `InBus` port does not contain a field for `z` in the nested structure, `a`. When you simulate the model, without modifying the structure, the Dashboard Scope shows ground for `InBus.a.z`.

Change the In Bus Element port block that selects `InBus.a.z` back to select `InBus.a.y`.

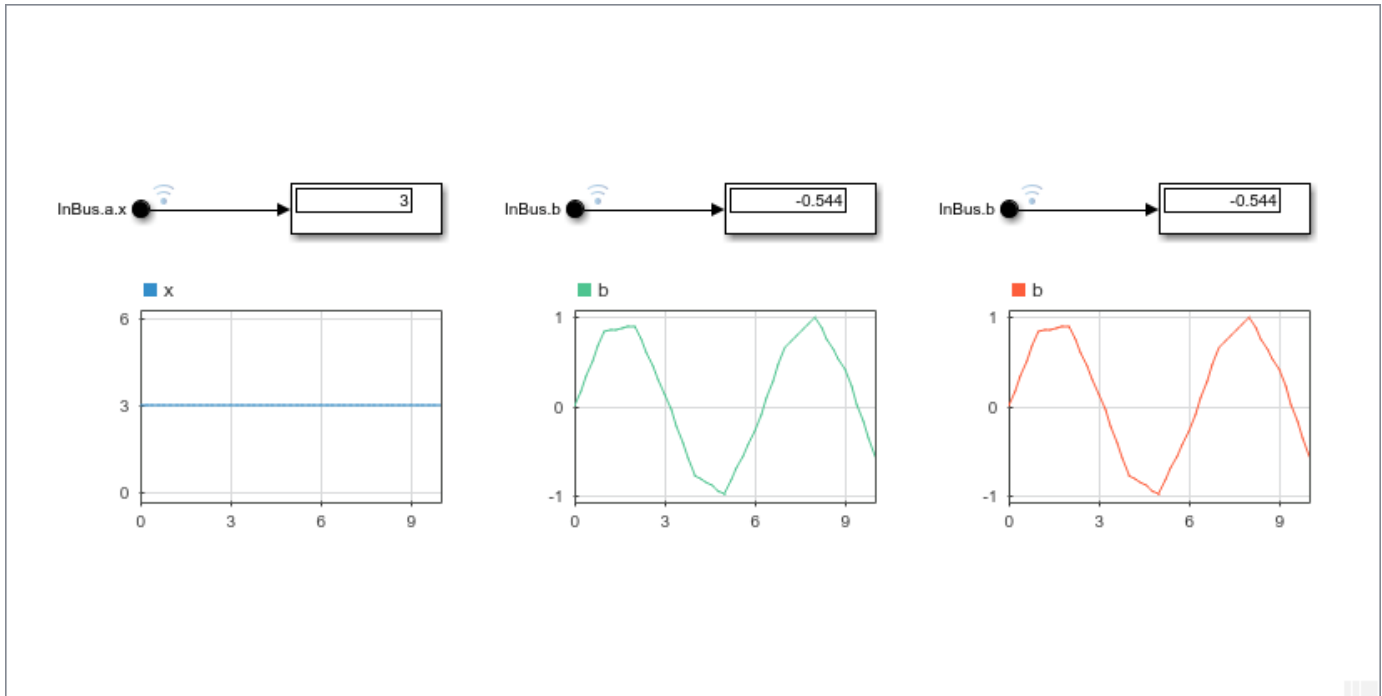

### Overspecify Input Data

When you use In Bus Element blocks to select bus elements, you can overspecify data for the port. Overspecified input data contains signals that are not selected by any of the In Bus Element blocks in the model.

For example, change the label for the In Bus Element block that selects `InBus.a.y` to select `InBus.b`. Now, none of the In Bus Element blocks selects `InBus.a.y`, while the structure still contains the data for that element.

Simulate the model and observe the signals on the Dashboard Scope blocks.

## Load Signal Data That Uses Units

Signal data logged in a previous simulation using signal logging or the To File or To Workspace block can include units information for `Dataset` or `Timeseries` logging formats.

Logging top-level model Outport block data from a previous simulation contains units information if:

- These **Data Import/Export** configuration parameter settings:
  - **Output** is enabled.
  - **Format** is `Dataset`.
- For the Outport blocks that you log, in the Block Parameters dialog box, you set the **Unit** parameter.

Otherwise, to include units in signal data that you load, for the `Units` property of the MATLAB `timeseries` objects that you want to load, specify a `Simulink.SimulationData.Unit` object.

## Loading Bus Signals That Have Units

When you input a bus signal to a root-level Inport or Outport block, or you use a From File or From Workspace block, the output data type of the block must be a bus object. When you load the data from these blocks, the units in loaded data must match the units specified for the bus elements in the bus object. If the units for the loaded data do not match the units for a bus element in the bus object, Simulink uses the units specified in the bus object.

## Load Data Using the From File Block

This example shows how to load simulation input data from a MAT file using the From File block, including how to create and format the input data. You can programmatically create the data you load, load data logged from another simulation, or load real-world data collected from sensors or in a lab. You can use the code from each format section as a template to understand how to format your own simulation input data.

### Examine the Model

This example uses a simple model. Two From File blocks load data from two different MAT files to create signals that are connected to two Output blocks. One From File block loads data for a scalar signal, and only the **File name** parameter for that block is changed from the default value. The other From File block is configured to load data for a bus. Two Dashboard Scope blocks display the output signals created by each From File block. The model also contains three Callback Button blocks you can use to generate the files with the input data using each format supported by the From File block.

#### Load Input Data for a Signal

#### Load Input Data for a Bus

The model uses the PreLoadFcn callback to:

- Create and save timeseries data in the file `inputData.mat`.
- Create and save input data for the bus in the file `busData.mat`.
- Create the `Simulink.Bus` object that defines the output data type for the From File block that loads data for a bus.

Use the Callback Button blocks to create data in the desired format prior to simulating the model. To create the data, click to select the Callback Button block and click again to run the code. You can view the code for each Callback Button block in the block dialog or Property Inspector.

### Create Time and Signal Data

The From File block supports loading data stored in `timeseries` objects and data stored in an array. Data you load using the From File block must contain a time value to correspond to each sample value. This example creates and loads ten seconds of data that represents a sine wave.

First, create a time vector. When you load data using the From File block, the data type for the time values must be `double`, and the time values must increase monotonically.

```
sampleTime = 0.01;  
numSteps = 1001;  
time = sampleTime*(0:numSteps-1);
```

Use the expression in this example to create an evenly spaced time vector for an input signal, especially when modeling discrete input signals. MATLAB® supports several other methods for creating an evenly spaced time vector, but other methods can introduce double-precision rounding errors in the time data, which can lead to unexpected simulation results.

Now, create the signal data using the `sin` function. The sample values you load using the From File block must not contain `NaN`, `Inf`, or `-Inf` values.

```
data = sin(2*pi/3*time);
```

### Load timeseries Data

Simulink® loading and logging both commonly use `timeseries` objects to pass time series data into and out of simulations. The From File block supports loading a variety of input data when you save the data in the MAT file as a `timeseries` object. The signal values you load can be:

- A built-in numeric data type other than `half`, `int64`, and `uint64`; a fixed-point data type with up to a 32-bit word length; or an enumerated data type.
- Real or complex.
- Scalar, vector, or multidimensional.

When you load data in a `timeseries` object using the From File block, you must save the `timeseries` data in a Version 7.3 MAT file. The To File block saves data to a Version 7.3 MAT file. When you load data from a file created using a To File block, you do not need to convert the version of the file.

The code for the Callback Button block labeled Create file with `timeseries` data to load:

- 1 Creates the time and signal data as row vectors.
- 2 Transposes the row vectors to column vectors, as required to create a `timeseries` object with scalar data values.
- 3 Creates a `timeseries` object to contain the data.
- 4 Saves the `timeseries` object in a Version 7.3 MAT file.

```
sampleTime = 0.01;  
numSteps = 1001;  
time = sampleTime*[0:(numSteps-1)];
```

```

data = sin(2*pi/3*time);
time = time';
data = data';
inputData = timeseries(data,time);
save("inputData.mat","inputData","-v7.3");

```

To load the `timeseries` data, you can run the code to create the `inputData.mat` file using the MATLAB Command Window or select then click the `Create file with timeseries data to load` Callback Button block. Then, simulate the model and view the loaded data on the Dashboard Scope block.

### Load Array Data

You can use the From File block to load scalar or vector signal data formatted as an array, where the first row contains time data and subsequent rows contain the sample values. When you load array data using the From File block, the sample values must be real and double. The From File block can load array data from any MAT file versions.

The code for the Callback Button block labeled `Create file with array data to load` creates the time and signal data, concatenates the row vectors into an array, and saves the array to a Version 7 MAT file.

```

sampleTime = 0.01;
numSteps = 1001;
time = sampleTime*[0:(numSteps-1)];
data = sin(2*pi/3*time);
inputData = [time;data];
save("inputData.mat","inputData")

```

To load the array data, you can run the code to create the `inputData.mat` file using the MATLAB Command Window or select then click the `Create file with array data to load` Callback Button block. Then, simulate the model and view the loaded data on the Dashboard Scope block.

### Load Bus Data

The From File block supports loading a structure that contains `timeseries` objects as input data for a bus. Each `timeseries` object in the structure can contain any kind of data supported when loading data from a single `timeseries` object.

When you load bus data using the From File block, you must specify the **Output data type** parameter as the `Simulink.Bus` object that defines the bus. The hierarchy and field names in the structure that contains the bus data must match the hierarchy and element names of the Bus object that defines the output data type.

The From File block that loads the bus data has its **Output data type** setting configured as `Bus:SinusoidBus`. The `PreLoadFcn` callback for the model and the code for the `Create file with bus data to load` Callback Button block both define the `SinusoidBus` object.

A Bus object defines the bus hierarchy as well as properties of the elements in the bus, such as name and data type. The Bus object in this example defines the bus hierarchy, the names for the signals contained in the bus, and the data type for a nested bus. The bus, `SinusoidBus`, contains one signal, `Cosine`, and a nested bus called `SineBus`, which contains two signals, `Sine` and `BigSine`.

```

elems(1) = Simulink.BusElement;
elems(1).Name = 'Sine';
elems(2) = Simulink.BusElement;

```

```
elems(2).Name = 'BigSine';
SineBus = Simulink.Bus;
SineBus.Elements = elems;

clear elems;
elems(1) = Simulink.BusElement;
elems(1).Name = 'SineBus';
elems(1).DataType = 'Bus: SineBus';
elems(2) = Simulink.BusElement;
elems(2).Name = 'Cosine';
SinusoidBus = Simulink.Bus;
SinusoidBus.Elements = elems;
```

For more information about defining buses using `Simulink.Bus` objects, see “Specify Bus Properties with `Simulink.Bus` Object Data Types” on page 81-58.

The `Create bus data to load Callback Button` block creates a structure of `timeseries` objects with a hierarchy and field names that match the hierarchy and element names of the `SinusoidBus` object and saves the structure to a Version 7.3 MAT file.

```
sampleTime = 0.01;
numSteps = 1001;
time = sampleTime*[0:(numSteps-1)];
time = time';

data = sin(2*pi/3*time);
cosdata = cos(2*pi/3*time);
ampdata = 2*data;

busData.Cosine = timeseries(cosdata,time);
busData.SineBus.Sine = timeseries(data,time);
busData.SineBus.BigSine = timeseries(ampdata,time);

save("busData.mat", "busData", "-v7.3");
```

To load the bus data, you can run the code to create the `busData.mat` file using the MATLAB Command Window or select then click the `Create bus data to load Callback Button` block. Then, simulate the model and view the loaded data on the `Dashboard Scope` block.

When you load input data for a bus using the `From File` block, you do not need to provide data for every element in the bus. To partially specify input data for a bus, you can omit the corresponding field in the structure or specify its value as `[]`. When you partially specify data for a bus that includes a nested bus, you can specify the entire nested bus as `[]` and the `From File` block provides ground values for all elements of the nested bus.

## Load Data Using the From Workspace Block

This example shows how to create and format data to load from the base workspace using the From Workspace block. To load data using the From Workspace block, you must create or save the data using a format the From Workspace block supports in the base, model, or mask workspace. You could programmatically create the data you load, load data logged in another simulation, or load real-world data collected from sensors or in a lab. You can use the code from each format section as a template to understand how to format your own simulation input data.

### Examine the Model

This example uses a simple model. Two From Workspace blocks load data from the base workspace to create signals that are connected to two Outport blocks. One From Workspace block uses default values for all block settings, and the other is configured to load data for a bus. Two Dashboard Scope blocks display the output signals created by each From Workspace block. The model also contains several Callback Button blocks you can use to generate the data in the base workspace using different formats supported by the From Workspace block.

The model uses the PreLoadFcn callback to:

- Create `timeseries` data stored in the variable `simin`.
- Create a structure of `timeseries` objects stored in the variable `busin`.
- Create the `Simulink.Bus` object that defines the output data type for the From Workspace block that loads data for a bus.

Use one of the Callback Button blocks to create data in the desired format prior to simulating the model. To create the data, click to select the Callback Button block and click again to run the code. You can view the code for each Callback Button block in the block dialog or Property Inspector.

### Create Time and Signal Data

Most data formats supported by the From Workspace block fundamentally consist of time values paired with signal values. You can use the `Structure without time` format to load only input data values with no corresponding time values, which is sometimes required for discrete simulations. (For more information, see “Control How Models Load Input Data” on page 75-27.) This example creates and loads ten seconds of time and signal data that represents a sine wave.

First, create a time vector. When you load data that includes time values using the From Workspace block, the data type for the time values must be `double`, and the time values must increase monotonically.

```
sampleTime = 0.01;
numSteps = 1001;
time = sampleTime*(0:numSteps-1);
time = time';
```

Use the expression in this example to create an evenly spaced time vector for an input signal, especially when modeling discrete input signals. MATLAB® supports several other methods for creating an evenly spaced time vector, but other methods can introduce double-precision rounding errors in the time data, which can lead to unexpected simulation results.

Now, create the signal data using the `sin` function.

```
data = sin(2*pi/3*time);
```

### Load timeseries Data

Simulink® loading and logging both commonly use `timeseries` objects to pass time series data into and out of simulations. The code for the Callback Button block labeled `Create timeseries data to load` creates the time and signal data, uses it to create a `timeseries` object, and assigns the `timeseries` object to the loading variable `simin`.

```
sampleTime = 0.01;
numSteps = 1001;
time = sampleTime*(0:numSteps-1);
time = time';
data = sin(2*pi/3*time);
simin = timeseries(data,time);
```

To load the `timeseries` data, you can run the code to create the `simin` loading variable in the MATLAB Command Window or select then click the `Create timeseries data to load` Callback Button block. Then, simulate the model and view the loaded data on the Dashboard Scope block.

### Load timetable Data

You can also store time series data in a MATLAB `timetable`. As the name suggests, the data is formatted as a table. When you load data using a `timetable`, the `timetable` must contain data for a single signal, in only one column.

The code for the Callback Button block labeled `Create timetable data to load` creates the time and signal data, formats the data as a `timetable`, and assigns the `timetable` to the loading

variable `simin`. To load a `timetable` using the From Workspace block, the input times must be a duration vector. This example creates the duration vector, `secs`, using the `seconds` function.

```
sampleTime = 0.01;
numSteps = 1001;
time = sampleTime*(0:numSteps-1);
time = time';
data = sin(2*pi/3*time);
secs = seconds(time);
simin = timetable(secs,data);
```

To load the `timetable` data, you can run the code to create the `simin` loading variable in the MATLAB Command Window or select then click the `Create timetable data to load Callback Button` block. Then, simulate the model and view the loaded data on the `Dashboard Scope` block.

### Load Structure Data

The From Workspace block supports loading data for a signal using a structure that matches the `Structure` or `Structure with time` logging formats. This example shows how to create data that matches the `Structure with time` format. The `Structure` format is the same as the `Structure with time` format, except the `Structure` format does not have a `time` field.

The structure has two top-level fields, `time` and `signals`. When you log data using the `Structure with time` format, the `signals` field may be an array of structures that each contain data for a different signal. When you load data using the `Structure with time` format, the `signals` field can only contain one structure with data for a single signal. The structure for the `signals` field contains a `values` field and must contain a `dimensions` field when the signal is not scalar.

The code for the `Callback Button` block labeled `Create structure with time data to load` creates the time and signal data and uses it to build the structure with the required fields and hierarchy. The code starts by clearing any existing variable with the name `simin` which could be an object with property names that match the names for the fields of the structure.

```
clear simin;
sampleTime = 0.01;
numSteps = 1001;
time = sampleTime*(0:numSteps-1);
time = time';
data = sin(2*pi/3*time);
simin.time = time;
simin.signals.values = data;
```

To load the structure data, you can run the code to create the `simin` loading variable in the MATLAB Command Window or select then click the `Create structure data to load Callback Button` block. Then, simulate the model and view the loaded data on the `Dashboard Scope` block.

When you load data for a multidimensional signal, add one more line of code to assign the signal dimensions to `simin.signals.dimensions`. When the signal data is scalar, set the `dimensions` field to 1, if you include it. When each signal value is a row vector, you can specify the dimensions as `[1 n]` or as `n`, where `n` is the number of elements in the row vector. When each signal value is an `M`-by-`N` matrix, specify the `dimensions` field value as `[M N]`.

When you want to load simulation input data without time data, use the `Structure` format, which does not include the `time` field and specify the desired sample rate using the **Sample time** parameter. For more information, see “Control How Models Load Input Data” on page 75-27.

## Load Array Data

You can use the From Workspace block to load signal data formatted as an array, where the first column of the array contains time data and subsequent columns contain the signal data. When you load data in the array format, the sample values must be scalars or vectors.

The code for the Callback Button block labeled `Create array data to load` creates the time and signal data, concatenates the two row vectors into an array, and assigns the array to the `simin` loading variable.

```
sampleTime = 0.01;
numSteps = 1001;
time = sampleTime*(0:numSteps-1);
time = time';
data = sin(2*pi/3*time);
simin = [time,data];
```

To load the array data, you can run the code to create the `simin` loading variable in the MATLAB Command Window or select then click the `Create array data to load` Callback Button block. Then, simulate the model and view the loaded data on the Dashboard Scope block.

## Load Bus Data

The From Workspace block supports loading a structure that contains `timeseries` objects or `timetables` as input data for a bus. Each `timeseries` object or `timetable` can contain any kind of data supported when loading data from a single `timeseries` object or `timetable`.

When you load input data for a bus using the From Workspace block, you must specify the **Output data type** setting as the `Simulink.Bus` object that defines the bus. The hierarchy and field names in the structure that contains the bus data must match the hierarchy and element names of the `Bus` object that defines the output data type.

The From Workspace block that loads the bus data has its **Output data type** setting configured as `Bus: SinusoidBus`. The `PreloadFcn` callback for the model and the code for the `Create bus data to load` Callback button both define the `SinusoidBus` object.

A `Bus` object defines the bus hierarchy as well as the properties of the elements in the bus, such as name and data type. The `Bus` object in this example defines the bus hierarchy, the names for the signals contained in the bus, and the data type for a nested bus. The bus, `SinusoidBus`, contains one signal, `Cosine`, and a nested bus called `SineBus`, which contains two signals, `Sine` and `BigSine`.

```
elems(1) = Simulink.BusElement;
elems(1).Name = 'Sine';
elems(2) = Simulink.BusElement;
elems(2).Name = 'BigSine';
SineBus = Simulink.Bus;
SineBus.Elements = elems;

clear elems;
elems(1) = Simulink.BusElement;
elems(1).Name = 'SineBus';
elems(1).DataType = 'Bus: SineBus';
elems(2) = Simulink.BusElement;
elems(2).Name = 'Cosine';
SinusoidBus = Simulink.Bus;
SinusoidBus.Elements = elems;
```

For more information about defining buses using `Simulink.Bus` objects, see “Specify Bus Properties with Simulink.Bus Object Data Types” on page 81-58.

The `Create bus data to load Callback Button` block creates a structure of `timeseries` objects with a hierarchy and field names that match the hierarchy and element names of the `SinusoidBus` object.

```
sampleTime = 0.01;
numSteps = 1001;
time = sampleTime*(0:numSteps-1);
time = time';

data = sin(2*pi/3*time);
cosdata = cos(2*pi/3*time);
ampdata = 2*data;

clear busin;
busin.Cosine = timeseries(cosdata,time);
busin.SineBus.Sine = timeseries(data,time);
busin.SineBus.BigSine = timeseries(ampdata,time);
```

To load the bus data, you can run the code to create the `busin` loading variable in the MATLAB Command Window or select then click the `Create bus data to load Callback Button` block. Then, simulate the model and view the loaded data on the `Dashboard Scope` block.

### Load Partially Specified Bus Data

When you load input data for a bus using the `From Workspace` block, you do not need to provide data for every bus element. To partially specify input data for a bus, you can omit the corresponding field in the structure or specify its value as `[]`.

The `Create partially specified bus data to load Callback Button` block creates a structure of `timeseries` objects with a hierarchy and field names that match the hierarchy and element names of the `SinusoidBus` object. It does not specify data for the `Cosine` bus element.

```
sampleTime = 0.01;
numSteps = 1001;
time = sampleTime*(0:numSteps-1);
time = time';

data = sin(2*pi/3*time);
ampdata = 2*data;

clear busin;
busin.Cosine = [];
busin.SineBus.Sine = timeseries(data,time);
busin.SineBus.BigSine = timeseries(ampdata,time);
```

To load the partially specified bus data, you can run the code to create the `busin` loading variable in the MATLAB Command Window or select then click the `Create partially specified bus data to load Callback Button` block. Then, simulate the model and view the loaded data on the `Dashboard Scope` block.

When you partially specify data for a bus that includes a nested bus or nested array of buses, you can specify the entire nested bus or nested array of buses as `[]` and the `From Workspace` block provides ground values for all elements of the nested bus or array of buses. You can also partially specify data for an array of buses by omitting data for one or more of the buses contained in the array of buses.

## Load Array of Buses Data

When you use the From Workspace block to load data for an array of buses, you must specify the **Output data type** parameter as the `Simulink.Bus` object that defines the buses the array of buses contains. All buses in an array of buses must be defined by the same `Simulink.Bus` object. The From Workspace block that loads data for the array of buses has its **Output data type** set to `Bus : SinusoidBus`. For details about defining the `Bus` object, see Load Bus Data.

The Create array of buses data to load Callback Button block creates an array that contains two structures of `timeseries` objects with hierarchy and field names that match the hierarchy and element names of the `SinusoidBus` object. The second structure, `bus2`, uses the same data as the first, shifted down by 1 so you can see all six signals on the Dashboard Scope block.

```
sampleTime = 0.01;
numSteps = 1001;
time = sampleTime*(0:numSteps-1);
time = time';

data = sin(2*pi/3*time);
cosdata = cos(2*pi/3*time);
ampdata = 2*data;

bus1.Cosine = timeseries(cosdata,time);
bus1.SineBus.Sine = timeseries(data,time);
bus1.SineBus.BigSine = timeseries(ampdata,time);

bus2.Cosine = timeseries((cosdata-1),time);
bus2.SineBus.Sine = timeseries((data-1),time);
bus2.SineBus.BigSine = timeseries((ampdata-1),time);

busin = [bus1,bus2];
```

To load the array of buses data, you can run the code to create the `busin` loading variable in the MATLAB Command Window or select then click the Create array of buses data to load Callback Button block. Then, simulate the model and view the loaded data on the Dashboard Scope block.

## Load Data Using Playback Block

This example shows how to use the Playback block to load data from a file. In this example you:

- Add data to the Playback block.
- Assign signal data to ports.
- Configure port parameters.
- Run a simulation to load the data into the model.

The model consists of a Playback block connected to a Record Block. The Playback block loads external data into the model. The Record block logs the data output by the Playback block. You can use the Playback block to visualize data before loading it into the model, and you can use the Record block to visualize the logged signal data.

### Add Data to Playback Block

Open the model `PlaybackRecord.slx`, which contains an empty Playback block connected to a Record block. You can use the Playback block to load data from the workspace, a file, and the Simulation Data Inspector.

```
open_system("PlaybackRecord")
```

To add data, double-click the Playback block. The Playback block presents three options to add data: add a workspace variable, add a file, or open the Add Signals dialog box for more options, such as adding runs from the Simulation Data Inspector. Suppose you collect data in the field and save the data to a Microsoft Excel® file named `TempDataFile.xlsx`, which contains two sets of indoor and outdoor temperature data. To add this signal data to the Playback block, select the file `TempDataFile.xlsx` from the file drop-down list.

### Visualize Signal Data Before Loading to Model

You can visually inspect the data in a sparkline plot before loading signals into the model. If you do not want to view a sparkline for a signal, you can clear the check box next to the signal name. Clearing the check box affects only which signals are plotted in the visualization, not which signals are loaded into the model during simulation.

### Assign Signals to Ports

You can set the number of ports on the Playback block and change which signal each port loads. The number of signals you add to the Playback block does not need to equal the number of ports. When you want to add a signal to the Playback block without loading the signal data into the model, do not assign the signal to a port. For example, to load only one set of temperature data, you can change the number of ports and the port assignments.

You can assign and unassign signals to ports using the Port column in the signals table:

- 1 Click the **Port** column in the same row as the signal you want to assign or unassign to a port.
- 2 Select the port number from the drop-down list. To assign a signal to no port, choose **Unassigned**.
- 3 If you unassign a signal from a port, the Unassign Port dialog box prompts you to choose to delete the port or keep the port with no signal assigned.

To load the first measurement of indoor and outdoor temperature into the model, assign the TempIndoor\_Run1 signal to port 1 and the TempOutdoor\_Run1 signal to port 2. Changing port assignments allows you to control the signal data the Playback block loads into the model.

	NAME	PORT	LINE	
	Sheet1			
<input checked="" type="checkbox"/>	TempIndoor_run1	1		
<input checked="" type="checkbox"/>	TempIndoor_run2	2		
<input checked="" type="checkbox"/>	TempOutdoor_run1	3		
<input checked="" type="checkbox"/>	TempOutdoor_run2	Unassigned		

To load a set of indoor and outdoor temperature data, the Playback block needs only two ports. One port loads the indoor temperature data. The second port loads the outdoor temperature data. You can use the **Port Editor** to add or delete ports.

To delete a port using the **Port Editor**:

- 1 On the **Simulation** tab, under **Port**, click **Port Editor**.
- 2 Select the row of the port you want to delete.
- 3 Click **Delete Port**.

Port Editor: PlaybackRecord/Playback

Number of Ports:

Port	Signal Source	Data Type	Comple...	Units	Sample ...	Dimensi...	Dimension M...
1	TempIndoor_run1	Inherit: auto	auto		-1		auto
2	TempOutdoor_run1	Inherit: auto	auto		-1		auto
3	TempIndoor_run2	Inherit: auto	auto		-1		auto
4	TempOutdoor_run2	Inherit: auto	auto		-1		auto

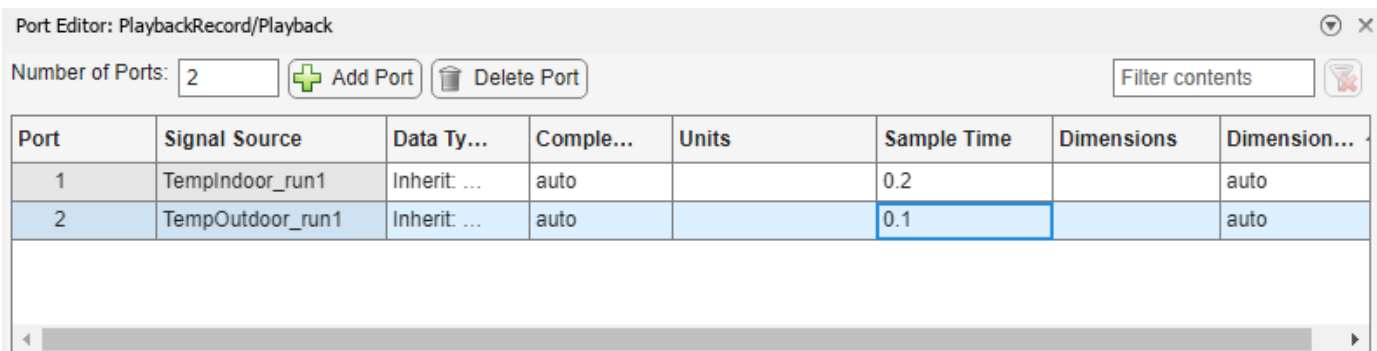

To delete port 3 and port 4, you can use the **Port Editor**, or you can unassign the signals from port 3 and port 4 in the signal table. Then, in the Unassign Port dialog box, select **Delete Port**. Notice that

all four signals are visible in the sparkline visualization even though only the TempIndoor\_run1 and TempOutdoor\_run1 signals are loaded into the model.

### Specify Port Parameters

You can change port properties using the **Port Editor**. By default, port properties are inherited from the signal. The Microsoft Excel® file format does not include sample time in the signal metadata, so the sample time for the signals added from the Excel file is inherited as continuous from the model. However, the physical measurement data is discrete. The indoor temperature data has a sample time of 0.2. The outdoor temperature data has a sample time of 0.1. In the **Sample Time** column of the **Port Editor**, specify the sample time for the TempIndoor\_run1 signal as 0.2 and the TempOutdoor\_run1 signal as 0.1 so the output signal reflects the discrete sample time with which the data was collected.

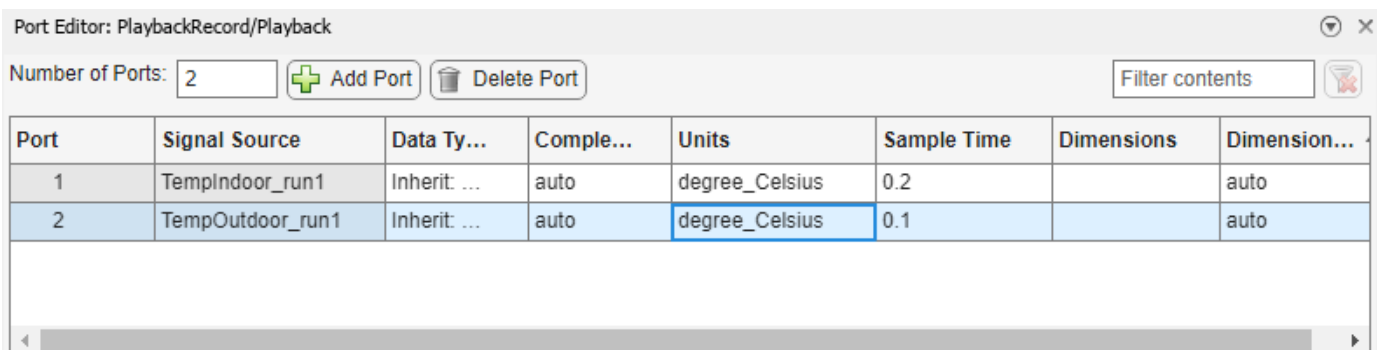

Port Editor: PlaybackRecord/Playback

Number of Ports: 2 + Add Port 🗑 Delete Port Filter contents

Port	Signal Source	Data Ty...	Comple...	Units	Sample Time	Dimensions	Dimension...
1	TempIndoor_run1	Inherit ...	auto		0.2		auto
2	TempOutdoor_run1	Inherit ...	auto		0.1		auto

You can also use the **Port Editor** to perform a unit conversion. The temperature data was measured in degrees Fahrenheit. You can use the Units port property to convert the data to Celsius. In the **Units** column of the **Port Editor**, change the units from degree\_Fahrenheit to degree\_Celsius.

Port Editor: PlaybackRecord/Playback

Number of Ports: 2 + Add Port 🗑 Delete Port Filter contents

Port	Signal Source	Data Ty...	Comple...	Units	Sample Time	Dimensions	Dimension...
1	TempIndoor_run1	Inherit ...	auto	degree_Celsius	0.2		auto
2	TempOutdoor_run1	Inherit ...	auto	degree_Celsius	0.1		auto

Changing the units on the port does not change the visualization in the Playback block because the signals added to the Playback block are in degrees Fahrenheit. The conversion to Celsius occurs when the data leaves the Playback block and enters the model.

### Simulate Model

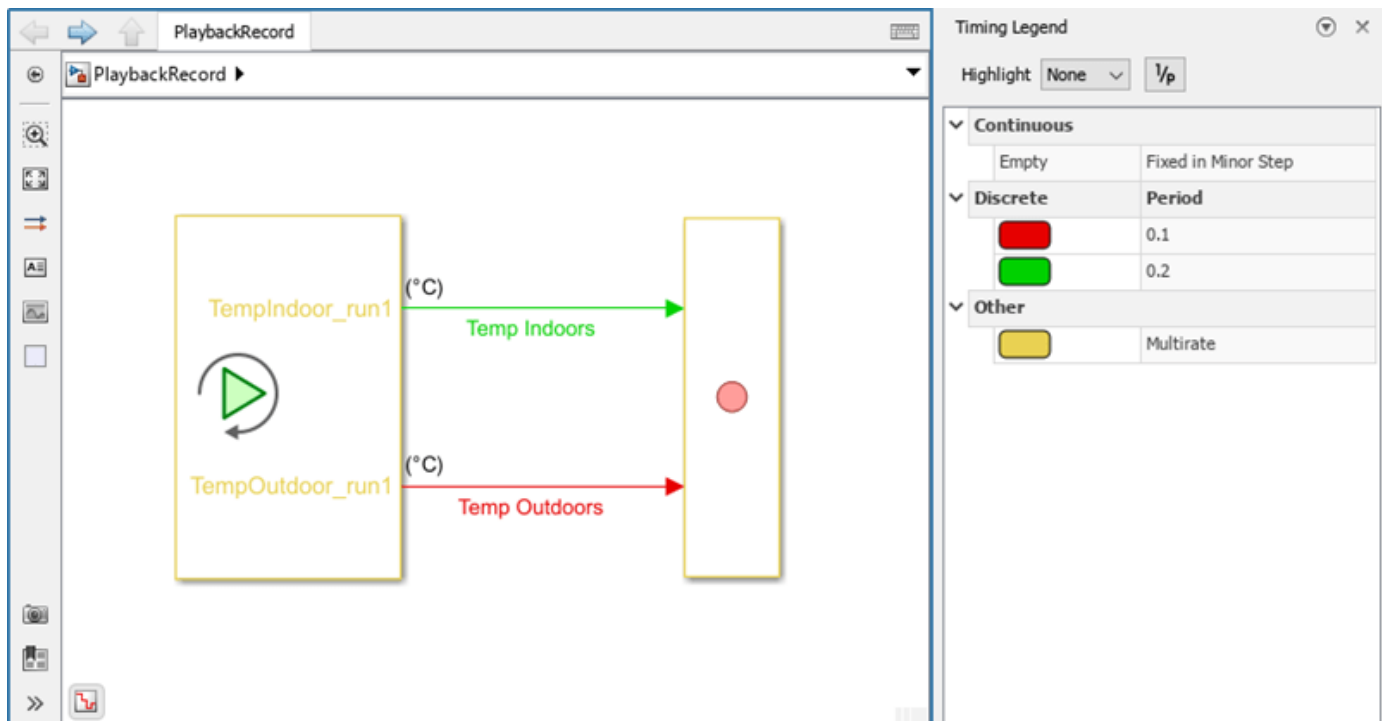

The Playback block loads data into the model when you run a simulation. Only the signals or messages assigned to ports are loaded into the model.

Add data into the model:

- 1 Click Up To Parent  to return to the model.
- 2 Connect the second port of the Playback block to the Record block.
- 3 Name the signals in the model so each signal is easy to identify in the Record block.
- 4 Run the simulation.
- 5 Double-click the Record block to view the data loaded by the Playback block.

You can use **Information Overlays** to view port units and color code the model based on sample times.

- To display signal units in the model, on the **Debug** tab, in the **Diagnostics** section, select **Information Overlays > Units**.
- To enable color coding, on the **Debug** tab, in the **Diagnostics** section, select **Information Overlays > Colors**. For more information, see “View Sample Time Information” on page 7-15.

### Visualize Logged Signal Data

To visualize the logged signal data, you can double-click the Record block. In the Record block sparkline visualization, you can see that the Playback block produced discrete signals and converted the temperature values to Celsius.

Because only the first measurements of indoor and outdoor temperature data are assigned to ports, the TempIndoor\_run1 and TempOutdoor\_run1 signals are the only ones loaded into the model. You can choose to assign different data to the existing ports or add more ports to load multiple sets of indoor and outdoor temperature data.

## Load State Information

### In this section...

“Import Initial States” on page 75-90

“Initialize a State” on page 75-90

“Initialize States in Referenced Models” on page 75-92

### Import Initial States

To initialize a simulation, you can use:

- Final state information (with or without `ModelOperatingPoint` object) from a previous simulation
- State information that you create in MATLAB

Use **Configuration Parameters > Data Import/Export** parameters to import initial states.

- 1 Enable the **Initial state** parameter.
- 2 In the **Initial state** edit box, enter the name of the variable for the state information that you want to use for initialization.

The initial values that the variable specifies override the initial state values that the blocks in the model specify in initial condition parameters.

You can specify `Dataset`, structure, or structure with time data.

### Initialize a State

You can initialize a specific state. This example creates an initial state structure for the x2 state of the `vdp` model. The x1 state is not initialized in the structure. Therefore, during simulation, Simulink uses the value in the Integrator block associated with the x1 state.

- 1 Open the model.
 

```
open_system('vdp');
```
- 2 Set the `SaveFormat` model argument to 'Structure'.
 

```
set_param('vdp','SaveFormat','Structure');
```
- 3 Obtain an initial state structure.
 

```
states = Simulink.BlockDiagram.getInitialState('vdp');
```
- 4 Set the initial value of the signals structure element associated with x2 to 2.
 

```
states.signals(2).values = 2;
```
- 5 Remove the signals structure element associated with x1.
 

```
states.signals(1) = [];
```
- 6 Use the `states` variable for the `vdp` model. Select the initial state configuration parameter.
 

```
set_param('vdp','LoadInitialState','on','InitialState','states');
```

- 7 Simulate the model and examine the initial values of x2 and x1.

```

sim('vdp');
states

states =

  struct with fields:

    time: 0
    signals: [1x1 struct]

states.signals

ans =

  struct with fields:

    values: 2
    dimensions: 1
    label: 'CSTATE'
    blockName: 'vdp/x2'
    stateName: ''
    inReferencedModel: 0
    sampleTime: [0 0]

```

When you simulate the model, both states have the initial value of 2. The initial value of the x2 state is assigned in the states structure, while the initial value of the x1 state is assigned in its Integrator block.

## Initialize States in Referenced Models

To initialize the states of a top model and the models that it references, use the structure or structure with time format or use operating point.

If the top model is in rapid accelerator mode, you cannot load discrete state data.

# Load Simulation Inputs Using the Root Inport Mapper

---

## Map Data Using Root Inport Mapper Tool

### In this section...

“The Model” on page 76-2

“Create Signal Data” on page 76-3

“Import and Visualize Workspace Signal Data” on page 76-3

“Map the Data to Inports” on page 76-5

“Save the Mapping and Data” on page 76-6

“Simulate the Model” on page 76-6

Use the Root Inport Mapper tool to import, visualize, and map signal and bus data to root-level inports.

Root-level inport mapping meets most modeling requirements and maintains model flexibility (for supported signal data, see “Create Signal Data for Root Inport Mapping” on page 76-9).

- Test your model with signals from the workspace and use your model as a referenced model in a larger context without any modification. Test signals in your model without disconnecting the inports and connecting sources to them.
- Use the Root Inport Mapper tool to update the **Input** parameter based on the signal data that you import and map to root-level inports.
- Visually inspect signal data without loading all the signal data into MATLAB memory.

To use the Root Inport Mapper tool:

- 1 Create signal data in the MATLAB workspace.
- 2 For a Simulink model, import the data from the workspace. You can visualize the data you import.
- 3 Map the data to root-level inports.
- 4 Simulate the model.
- 5 Save the Root Inport Mapper scenario.

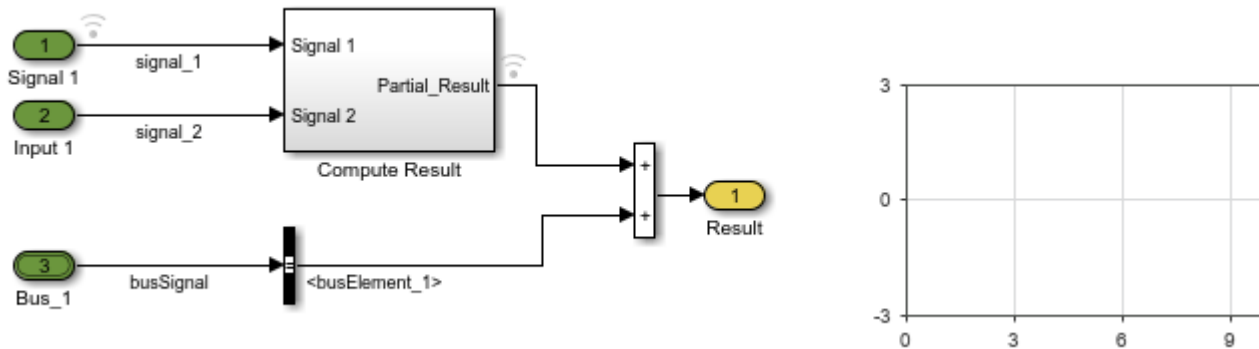

### The Model

This example shows how you can use the Root Inport Mapper tool to test the model with data. This approach can be useful for performing standalone testing of a model that another model references.

The example uses a model with three root-level Inport blocks. Two of the Inport blocks output scalar signals and the other Inport block outputs bus data.

```
model='ex_root_inport_mapping_example';  
open_system(model)
```

## Create Signal Data

You can define the signal data as MATLAB timeseries objects.

- 1 Define the time values for the signal data.

```
sampleTime = 0.01;
endTime = 10;
numberOfSamples = endTime * 1/sampleTime +1;
timeVector = (0:numberOfSamples) * sampleTime;
```

- 2 Create the data for the two scalar signals. Naming the data variable to match the name of the corresponding signal makes it easier to map data to signals.

```
signal_1 = timeseries(sin(timeVector)*10,timeVector);
signal_2 = timeseries(rand(size(timeVector)),timeVector);
```

- 3 Create the signals for the bus.

```
busSignal.busElement_1 = timeseries(cos(timeVector)*2,timeVector);
busSignal.busElement_2 = timeseries(randn(size(timeVector)),timeVector);
```

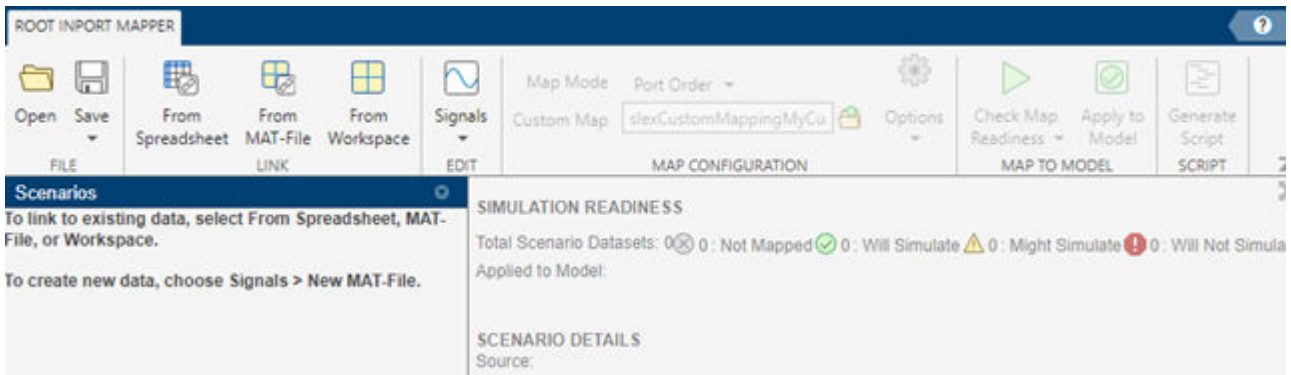

- 4 Create the bus object for the output data type of the Bus\_1 Inport block. You can create the bus object from the bus signal that you defined. Use a bus object for bus signals that cross model reference boundaries.

```
busInfo = Simulink.Bus.createObject(busSignal);
```

## Import and Visualize Workspace Signal Data

Import the signal data that you created from the workspace into the Root Inport Mapper tool. Then you can use the tool to visualize the imported data.

- 1 Open the Root Inport Mapper tool. Open the Block Parameters dialog box for one of the Inport blocks in the model and click **Connect Inputs**.
- 2 In the Root Inport Mapper tool, select the **From Workspace** button.

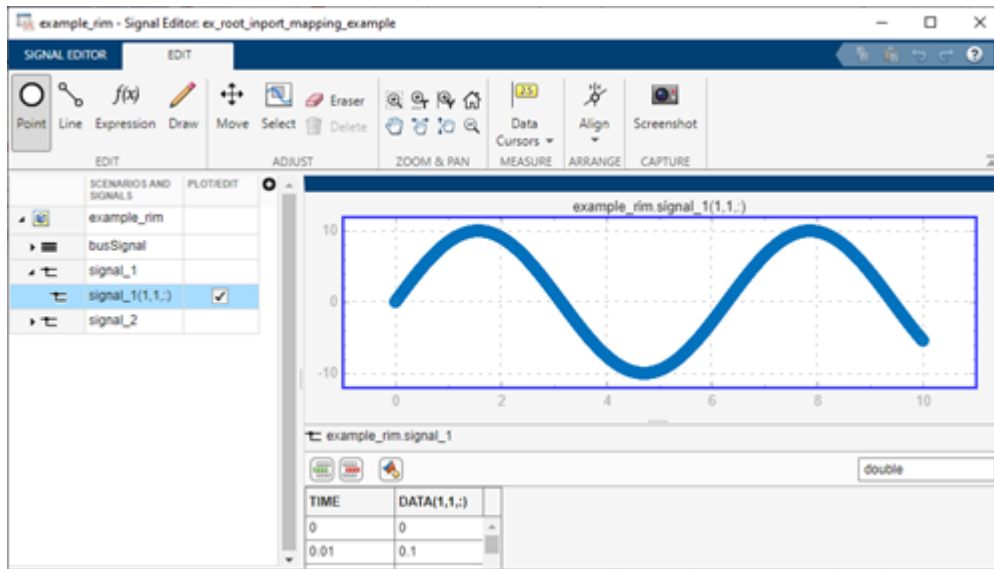

- 3 To clear the data variables, click the **Name** check box. Then click the check boxes for the busSignal, signal\_1, and signal\_2 signals.

<input checked="" type="checkbox"/> Name	Format	Unit	Interpolation	Block Path
<input checked="" type="checkbox"/> Signal	Signal		linear	-
<input checked="" type="checkbox"/> busSignal	Bus	-	-	-
<input checked="" type="checkbox"/> endTime	FunctionCall	-	-	-
<input checked="" type="checkbox"/> numberOfS	FunctionCall	-	-	-
<input checked="" type="checkbox"/> random	DataSet	-	-	-
<input checked="" type="checkbox"/> sampleTim	FunctionCall	-	-	-
<input checked="" type="checkbox"/> signal_1	MultiDimension...		linear	-
<input checked="" type="checkbox"/> signal_2	MultiDimension...		linear	-

Although in this example you select all the signals, you can select a subset of signals.

- 4 In the **Save As** dialog box, specify a MAT-file to save signals to.
- 5 You can visualize signals. In the Root Inport Mapper dialog box toolbar, click **Signals > Edit MAT-File**.
- 6 In the Select Linked MAT-file window, select the MAT-file to which you saved the signals and click **OK**.

The **Signal Editor** user interface appears. You can select signals to plot. For example, to see a plot of signal\_1, in the Navigation pane, expand the scenario data set (in this example, the top node, ex\_rootinportmappingexample) and then expand the signal\_1 entry. Select the check box for signal\_1(1,1,:) to plot the data.

- 7 Close the **Signal Editor** user interface by clicking **X**.

## Map the Data to Inports

After you import the data, you map which data to use for specific Inport blocks.

- 1 Select the map mode, which specifies the criteria the mapping uses. In the toolbar, select **Map Mode > Signal Name**.

The signals in this model have names, so mapping based on signal names makes it very clear which data is going to an Inport block.

- 2 You can specify options for the mapping. In the toolbar, select **Options > Update Model Automatically**, which updates the model after you do the mapping. Compiling the model verifies that signal dimensions and data types match between the data and the Inport blocks.
- 3 Map the data. In the Navigation pane, select the scenario data set. In the toolbar, click **Check Map Readiness > Map Selected**.
- 4 The dialog box shows the results of the mapped data.

**Tip** Alternatively, in the tree area, right-click and use the context menu to select **Check Map Readiness**.

Source	Scenario Dataset	Map Mode	Status
	example_rim	Signal Name	✔

Status	Scenario Signal	Port	Block Name	Mapped Signal
✔	signal_1	1	Signal 1	example_rm.getEle...
✔	signal_2	2	Input 1	example_rm.getEle...
✔	busSignal	3	Bus_1	example_rm.getEle...

## Save the Mapping and Data

If you want to reuse the mapping and data that you have set up, you can save it as a scenario. In the Root Inport Mapper tool, click **Save > Save As** and save the scenario as an `.mldatx` file.

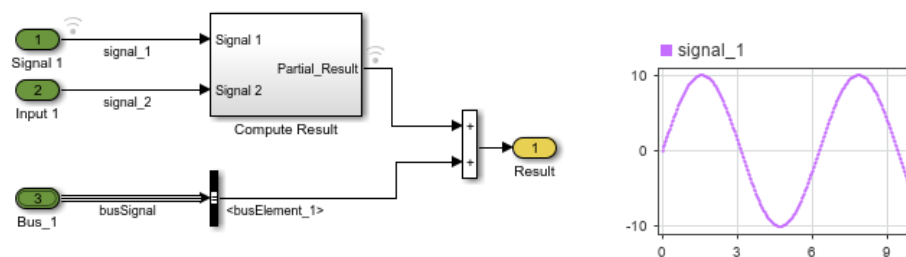

## Simulate the Model

- 1 In the Navigation pane, select the scenario data set.
- 2 In the toolbar, click **Apply to Model**.

The model is now set up to simulate using the workspace signal data that you mapped to root-level Inport blocks.

- 3 Simulate the model.

This model includes a Dashboard block that shows the data used during simulation for `signal_1`. The plot matches the plot you did when you visualized the data as part of the data import process.

# Map Root Inport Signal Data

## In this section...

“Command-Line Interface” on page 76-7

“Import and Mapping Workflow” on page 76-7

“View and Inspect Signal Data” on page 76-8

To import, visualize, and map signal and bus data to root-level input ports, use the Root Inport Mapper tool or the `getRootInportMap` function. At the top level of a model or referenced model, root-level input ports include:

- Inport blocks
- Enable blocks
- Trigger blocks

Root-level input ports import data from the MATLAB workspace based on the value of the **Configuration Parameters > Data Import/Export > Input** parameter.

Root-level inport mapping imports signal data in a way that meets most modeling requirements and maintains model flexibility. You can:

- Test your model with signals from the workspace and use your model as a referenced model in a larger context without any modification.
- Update the **Input** parameter based on the signal data you import and map to root-level inports.
- Visually inspect signal data without loading all the data into MATLAB memory.

**Tip** To determine whether another data import technique meets your specific modeling requirements (such as the amount of data or the storage location) better, see “Comparison of Signal Loading Techniques” on page 75-21.

## Command-Line Interface

You can use the `getRootInportMap` to create a custom object to map signals to root-level input ports and `getSlRootInportMap` to create a custom map mode. For more information, see “Create and Use Custom Map Modes” on page 76-25.

## Import and Mapping Workflow

- 1 Identify and possibly create signal data to import and map on page 76-9.
- 2 Import on page 76-13 and “View and Inspect Signal Data” on page 76-8.
- 3 Map the imported signal data on page 76-7. For example, you can map the signal data by block path or signal name.
- 4 Simulate the model using the mapped data. After associating a scenario with the model, you can generate scripts for simulation with scenarios on page 76-24 to perform batch simulations.

- 5 Optionally, save the current Root Inport Mapper scenario on page 76-27 for future reference or to share with other people.

---

**Tip** To extend the Root Inport Mapper tool map modes, you can create a custom mapping file function to map data to root-level inports.

---

## View and Inspect Signal Data

After you import signal or bus data, you can view and inspect signal data using tools such as:

- Signal Editor on page 74-2
- Simulation Data Inspector on page 31-2
- The `Simulink.SimulationData.Dataset` or `Simulink.SimulationData.DatasetRef` `plot` method, where the Signal Preview window contains an **Open Simulation Data Inspector** button. Click this button to plot the data using the Simulation Data Inspector.

For a summary of the other steps involved in using the Root Inport Mapper tool, see “Import and Mapping Workflow” on page 76-7.

- “Create Signal Data for Root Inport Mapping” on page 76-9

## Create Signal Data for Root Inport Mapping

### In this section...

- “Choose a Source for Data to Import and Map” on page 76-9
- “Choose a Naming Convention for Signals and Buses” on page 76-9
- “Choose a Base Workspace and MAT-File Format” on page 76-9
- “Bus Signal Data for Root Inport Mapping” on page 76-10
- “Create Signal Data in a MAT-File for Root Inport Mapping” on page 76-11

The first step for using the Root Inport Mapper tool is to know the source of signal data to import and map. You can use existing data (for example, in a Microsoft Excel spreadsheet), create data in a MAT-file, or use the Signal Editor interface to create signal data.

For a summary of the other steps involved in using the Root Inport Mapper tool, see “Import and Mapping Workflow” on page 76-7.

### Choose a Source for Data to Import and Map

You can import data from these sources.

- Base workspace — You can selectively import data from the base workspace. For more information about supported data formats, see “Choose a Base Workspace and MAT-File Format” on page 76-9.
- Data files — You can selectively import signals contained in MAT-files and Microsoft Excel files. Each time that you import the contents of the file, the contents overwrite data already loaded for the file in the Root Inport Mapper tool.

For more information, see “Choose a Base Workspace and MAT-File Format” on page 76-9 and “Supported Microsoft Excel File Formats”.

---

**Tip** To load input data for a simulation from a Microsoft Excel spreadsheet, consider using the From Spreadsheet block. The From Spreadsheet block incrementally loads data from the spreadsheet during simulation. If you use a From Spreadsheet block, you do not need to do anything to handle changes to sheet values.

---

You can also use the Signal Editor interface to create and edit signal data. For more information, see “Create and Edit Signal Data” on page 74-2.

### Choose a Naming Convention for Signals and Buses

When identifying signals to import, consider using a naming convention for signals and buses such that this grouping of data (scenario) is interchangeable. For example, you can have two MAT-files with the same set of variables named with the naming convention but different data values. Then, you can switch the scenarios of input data into and out of a model easily.

### Choose a Base Workspace and MAT-File Format

The Root Inport Mapper tool supports the MATLAB data types or formats described in the table for imported signal data. For each data type, you can use the map modes indicated in “Choose Map Mode”.

---

**Note** If your MAT-file or base workspace contains data in a format that the Root Inport Mapper tool does not support, the tool ignores that data.

---

---

**Note** Although the Root Inport Mapper tool accepts these formats, it can only link in a `Simulink.SimulationData.Dataset` object. To convert the data in your MAT-file to a `Simulink.SimulationData.Dataset` object, in the Root Inport Mapper From dialog box, select the **Convert signals into a scenario dataset and save to MAT-file** check box. Alternatively, use the `convertToSLDataset` function to convert your data.

---

---

**Note** When you specify a `timetable` as an element in the `Dataset` or a bus, the `timetable` must contain data for only one signal.

---

### Dataset Signal Data

If data sets have nonunique element names, use the **Port Order** map mode. For more information on map modes, see “Map Mode”.

### MATLAB Timeseries Signal Data

If you have MATLAB `timeseries` data that includes enumeration data, and the enumeration class is not on your MATLAB path, the tool ignores that timeseries data.

### Structure Signal Data

When converting structure signal data to datasets, the signals are named using the value contained in the label field of the signal field of the structure signal.

### Array Signal Data

The Root Inport Mapper tool tries to map the data array to a single input port. In this case, you can choose any of the map modes.

## Bus Signal Data for Root Inport Mapping

The signal data that you import and map to a root-level Inport block can include bus data. You cannot map bus signals to a root-level Enable or Trigger block.

- 1 In the MATLAB workspace, create or load a bus object on page 81-58 for the bus data you want to import and map.
- 2 If you create a bus object in the base workspace, save the bus object definition to a MAT-file, such as `d_myBusObj.mat`.
- 3 Create a separate MAT-file that contains the bus data you want to import for the bus object. Use one of these approaches:
  - Use an existing MAT-file that already contains a MATLAB struct or `Simulink.SimulationData.Dataset` object.

- Create the bus in the base workspace and then save it to a MAT-file.
- 4 Set up the model to load the bus object.
    - For root-level Inport blocks that you map signals to, set the **Data type** field to Bus. Specify the name of the variable for the bus object to be used for signal mapping.
    - Load into the model the MAT-file that includes the bus objects used for mapping. For example, use a `PreLoadFcn` callback function. For details, see “Alternative Workflows to Load Mapping Data” on page 76-20.

## Create Signal Data in a MAT-File for Root Inport Mapping

You can create signal data in a MAT-file to use for root-inport mapping. For example, you can import three signals (`signal1`, `signal2`, and `signal3`) and save the signals in a MAT-file. The `Simulink.SimulationData.Signal` objects include signal names, block names, block paths, and port order index values.

You can use the `convertToSLDataset` function to convert MAT-file contents to `Simulink.SimulationData.Dataset` objects.

- 1 In MATLAB, create three `Simulink.SimulationData.Signal` objects, specifying signal names, block paths, and port order index values.

```
signal1 = Simulink.SimulationData.Signal;
signal1.Name = 'signal1';
signal1.BlockPath = Simulink.SimulationData.BlockPath('Out1');
signal1.PortType = 'inport';
signal1.PortIndex = 1;

signal2 = Simulink.SimulationData.Signal;
signal2.Name = 'signal2';
signal2.BlockPath = Simulink.SimulationData.BlockPath('Out2');
signal2.PortType = 'inport';
signal2.PortIndex = 2;

signal3 = Simulink.SimulationData.Signal;
signal3.Name = 'signal3';
signal3.BlockPath = Simulink.SimulationData.BlockPath('Out3');
signal3.PortType = 'inport';
signal3.PortIndex = 3;
```

- 2 In the MATLAB workspace, select `signal1`, `signal2`, and `signal3`. Right-click the selection, and in the context menu, click **Save as**. Save the file as `mySigData.mat`.
- 3 Open the MAT-file.

```
open mySigData.mat
```

```
ans =
```

```
signal1: [1x1 Simulink.SimulationData.Signal]
signal2: [1x1 Simulink.SimulationData.Signal]
signal3: [1x1 Simulink.SimulationData.Signal]
```

You can use the **Signal Name**, **Block Name**, **Block Path**, or **Port Order** map mode with this MAT-file. Based on your map mode, the Root Inport Mapper tool maps the signal data from the MAT-file to corresponding ports.

## Import Signal Data for Root Inport Mapping

### In this section...

“Import Signal Data” on page 76-13

“Import Bus Data” on page 76-14

“Import Signal Data from Other Sources” on page 76-14

“Import Data from Signal Editor” on page 76-15

“Import Test Vectors from Simulink Design Verifier Environment” on page 76-15

### Import Signal Data

Before you can import data, identify the signals that you want to import and set up the data to use with root-level inport mapping. See “Create Signal Data for Root Inport Mapping” on page 76-9. For a summary of the other steps involved in using the Root Inport Mapper tool, see “Import and Mapping Workflow” on page 76-7.

For data import purposes, the Root Inport Mapper From MAT-File and From Workspace dialog boxes provide a **Convert signals into a scenario dataset and save to MAT-file** check box, selected by default. To convert the data in your MAT-file to a `Simulink.SimulationData.Dataset` object, select this check box. Alternatively, use the `convertToSLDataset` function to convert your data.

---

**Note** The Root Inport Mapper tool uses the term link to refer to the act of importing Simulink data. The sources from which you can link your data are in the LINK section of the tool.

---

To import signal data for root-inport mapping:

- 1 Open the Root Inport Mapper tool. For the model, click **Model Settings**. In the **Configuration Parameters > Data Import/Export** pane, click **Connect Inputs**.
- 2 In the LINK section, select the data source.
  - To browse to the MAT-file or spreadsheet file that contains the signals you want to import, select **From Spreadsheet** or **From MAT-File** and browse to the MAT-file or spreadsheet file. To return to the LINK section, click **OK**.

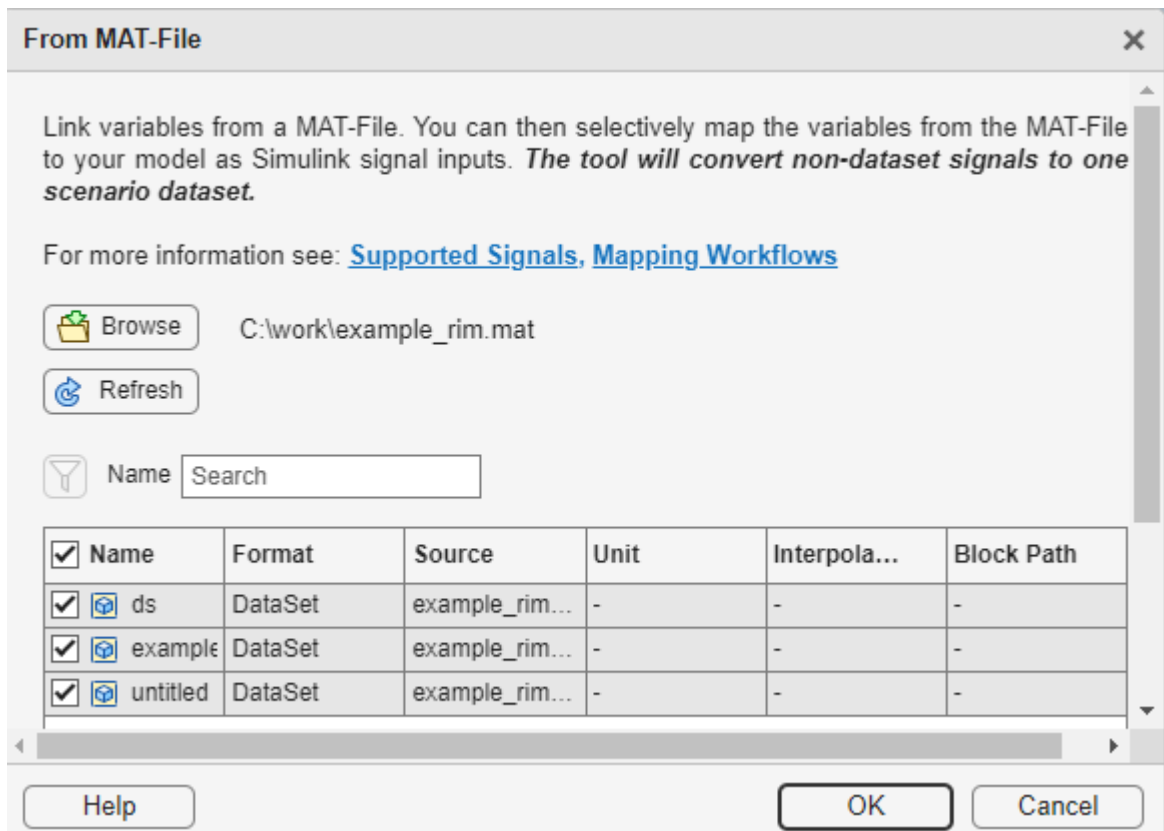

---

**Note** To import bus data for root inport mapping, see “Import Bus Data” on page 76-14.

---

- To display a list of base workspace variables that you can import, select **From Workspace**. Select the variables that you want to import and click **OK**.

The From dialog box displays the contents of the spreadsheet, MAT-file, or base workspace.

- 3 Select the data that you want to import, and then click **OK**.

The Root Inport Mapper tool displays the imported data.

Alternatively, you can create signal data to map using the **Signals > New MAT-File** option. For more information, see “Create and Edit Signal Data” on page 74-2.

## Import Bus Data

Use bus objects for bus data that you want to import and map to root inports or bus element ports.

Store the bus objects in a MAT-file. Use a different MAT-file that contains the bus data that you want to import for the bus object. This file can be an existing MAT-file that already contains a MATLAB `struct`. You can also create the bus in the base workspace and save it to a MAT-file. For more information, “Bus Signal Data for Root Inport Mapping” on page 76-10.

To import the bus data, in the LINK section of the Root Inport Mapper toolstrip, click **From MAT-File**. Select the MAT-file that contains the bus data and click **OK**.

## Import Signal Data from Other Sources

Use the Root Inport Mapper tool to import signals from other sources.

- To import signals from models that contain Signal Editor blocks, see “Import Data from Signal Editor” on page 76-15.

- You can import Excel spreadsheet data. The Root Inport Mapper tool imports a worksheet as a `Simulink.SimulationData.Dataset` object that contains timeseries elements.
- To import test vectors from Simulink Design Verifier, see “Import Test Vectors from Simulink Design Verifier Environment” on page 76-15.

## Import Data from Signal Editor

You can import and map data from the Signal Editor block in a MAT-file. For more information, see “Load Data with Interchangeable Scenarios Using Signal Editor Block” on page 76-30.

## Import Test Vectors from Simulink Design Verifier Environment

You can import and map Simulink Design Verifier test vectors. This workflow requires a Simulink Design Verifier license.

Before importing, use the Simulink Design Verifier `sldvsimdata` function to convert a Simulink Design Verifier test structure to a `Simulink.SimulationData.Dataset` object. This file contains a test vector structure `sldvData`. Save the output to a MAT-file and then import that file into the Root Inport Mapper tool.

## Map Signal Data to Root Input Ports

### In this section...

“Select Map Mode” on page 76-16

“Set Options for Mapping” on page 76-16

“Select Data to Map” on page 76-16

“Map Data” on page 76-16

“Understand Mapping Results” on page 76-18

“Alternative Workflows to Load Mapping Data” on page 76-20

After you import data, map signal data to root input ports by selecting map modes and options and selecting data.

For a summary of the other steps involved in using the Root Inport Mapper tool, see “Import and Mapping Workflow” on page 76-7.

### Select Map Mode

To map signal data to root-level ports, use one of these map modes in the **Map Configuration** section of the Root Inport Mapper toolstrip. The map mode you select from the toolstrip, such as **Block Name** or **Port Order**, is maintained between MATLAB sessions and models. You do not have to select the map mode each time you want to map signal data to root input ports.

For more information on map modes, see **Root Inport Mapper**.

### Set Options for Mapping

If you want to set up mapping options, in the **Map Configuration** section on the Root Inport Mapper toolstrip, click **Options**. The option you select from the toolstrip, such as **Update Model Automatically** or **Allow Partial Specification of Buses**, is maintained between MATLAB sessions and models. You do not have to select the option each time you want to map signal data to root inports.

To map the signals, see “Map Data” on page 76-16.

### Select Data to Map

To specify a subset of scenarios to map, click the down arrow on the **Check Map Readiness** button. You can choose different map modes for different scenarios. For more information on map modes, see **Root Inport Mapper**.

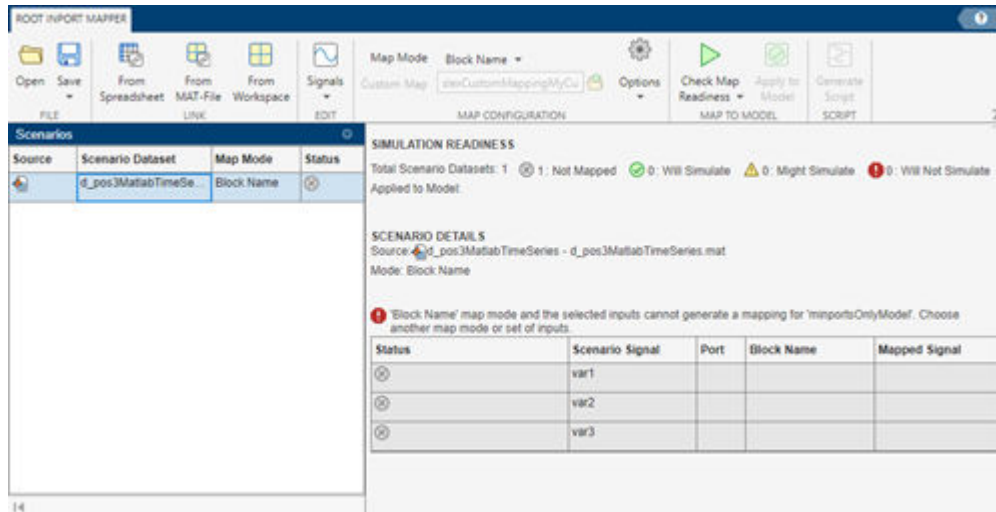

### Map Data

After you import signals or buses, you can map data.

- 1 On the Root Inport Mapper toolbar, to check if a data set is mappable, click **Check Map Readiness**.

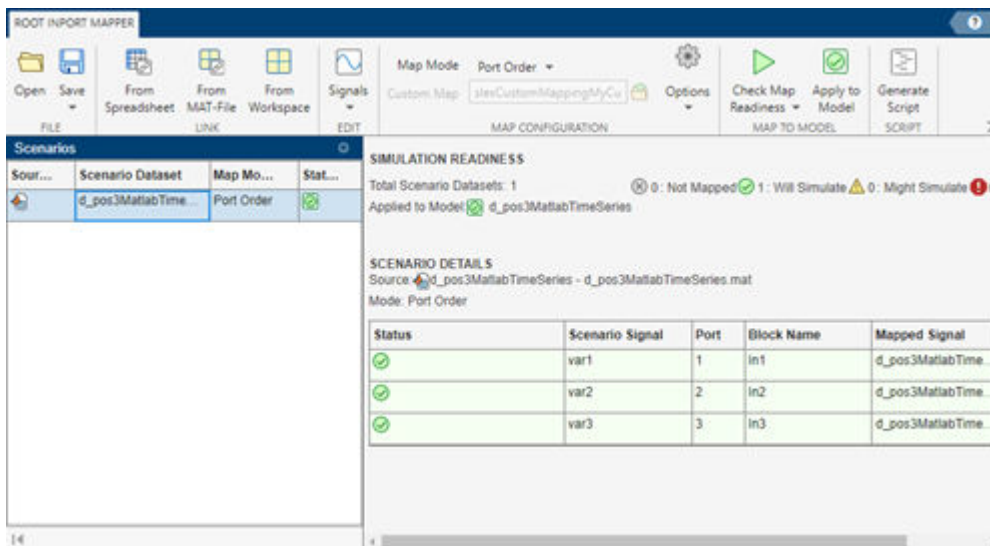

You can then select another map mode and check the readiness again. The results of a signal mapping appear in the **Scenario Dataset** tab.

If the map mode is not compatible with the mapping, Root Inport Mapper displays a message, such as:

You can then select another map mode and check the readiness again.

- 2 In the left pane, click a data set to see the mapping results

- The **Simulation Readiness** section lists the input data and the status of the mapping.

---

**Note** See “Understand Mapping Results” on page 76-18.

---

- The mapping definition for the input data is applied to the model.

After you save and close the model, when you load input data of the same scenario to the workspace, the model uses the mapping defined for that scenario.

For an example of mapping signal data to root-level inputs, see “Create Harness-Free Models with MAT File Input Data”.

After you save the mapping definition for a model, you can automate data loading. For more information, see “Alternative Workflows to Load Mapping Data” on page 76-20.

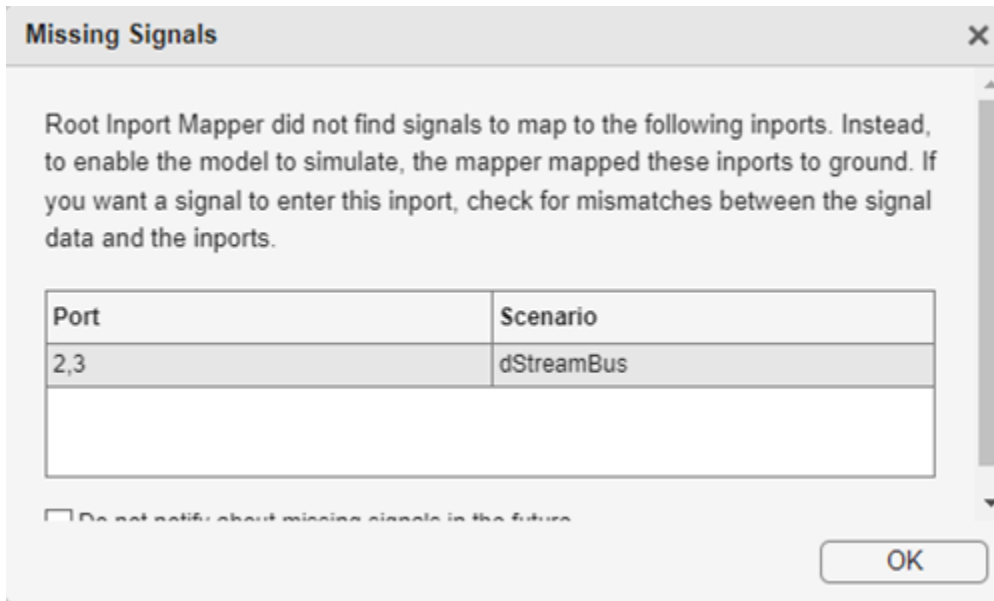

## Understand Mapping Results

When you complete the import and map process, the **Simulation Readiness** section displays the results in the status area. The results depend on whether you select the **Update Model Automatically** option when you set up the mapping.

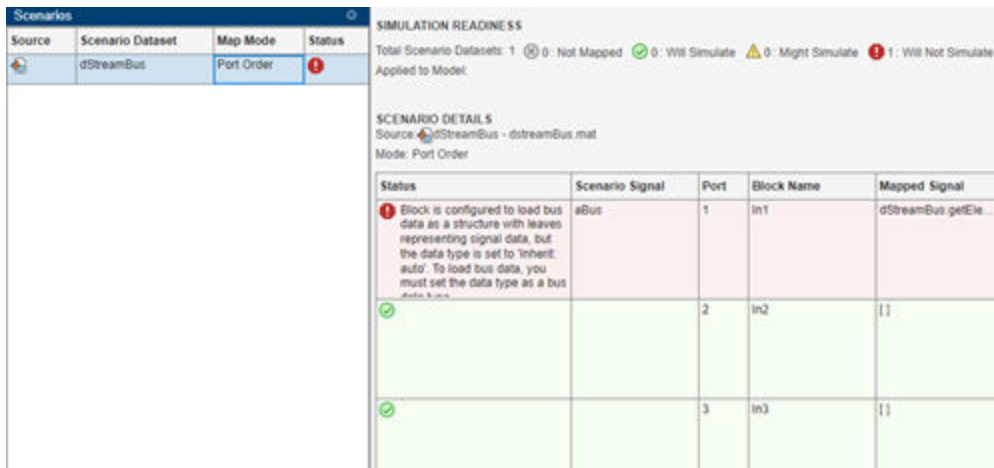

Status	Update Model Automatically	Continue Without Update Model Automatically
	The properties of the mapped data and the input port are appropriate for simulation.	The data type, dimension, and signal type properties of the data and input port are compatible.
	Not applicable	Comparison of data and root-level port data type, dimension, and signal type properties cannot determine whether there is a match. If you do not update the model before mapping, the tool cannot evaluate whether all the data types match unless you explicitly specify the input port data types. Confirm that you set these block parameters correctly:  Inport block parameter <b>Data type</b> is not set to <code>Inherit:auto</code> .  Inport block parameter <b>Dimension</b> is not set to <code>-1</code> .  Inport block parameter <b>Signal type</b> cannot be <code>auto</code> .
	The properties of the mapped data and the input port are not appropriate for simulation.	One or more of the data types, dimensions, or signal types of the signal data are not compatible with the root-level input port.

To enable the model to simulate, if Root Inport Mapper does not find input port signals to map, it maps these input ports to ground and displays a **Missing Signals** dialog box. An input port mapped to a ground signal displays as empty ([ ]).

This figure shows mapping successes, failures, and ground assignments. If there are issues, the status column displays suggested resolutions. Read through and diagnose the issues.

Sometimes the **Simulation Readiness** section shows a warning or error, but your investigation of the elements indicates that there is no problem with mapping the data. In these cases, if you did not select the **Update Model Automatically** check box from the **Options** menu, select it and click **Check Map Readiness** again.

In the Root Inport Mapper tool, clicking **Apply to Model** selects the **Input** check box in the **Data Import/Export** pane in the model Configuration Parameters dialog box. It also sets the value to the imported data variables. To apply the changes to the model configuration, in the **Data Import/Export** pane, click **OK**. Clicking **Apply to Model** also automatically identifies the first scenario to map.

If your model uses configuration references to reference configuration sets, you cannot mark the model for simulation. To use this data to simulate the model with the Root Inport Mapper tool, use the Model Explorer to activate a configuration set first.

This graphic illustrates the application of the changes to the model configuration for the model in “Map Data” on page 76-16.

To inspect the imported data, you can:

- Connect the output to a scope, simulate the model, and observe the data.
- Log the signals and use the Simulation Data Inspector tool to observe the data.

To highlight the Inport block that is associated with the signal, select an item in the **Simulation Readiness** section. The selected Inport block is outlined with blue.

---

**Note** When the input is a bus, click the levels of the bus object to see the individual elements in the bus.

---

## Alternative Workflows to Load Mapping Data

After you save the mapping definition to a model, you can automate data loading and simulation. Consider one of the following methods.

### Command Line or Script

To load data and simulate the model from the MATLAB command line, use commands similar to:

```
load('signaldata.mat');
simout = sim('model_name');
```

To automate testing and load different signal groups, consider using a script.

The following example code creates timeseries data and simulates a model after loading each signal group. It:

- Creates signal groups with variable names *In1*, *In2*, and *In3*, and saves these variables to MAT-files.
- Simulates a model after loading each signal group.

---

**Note** The variable names must match the import data variables in the **Configuration Parameters > Data Import/Export > Input** parameter.

---

```
% Create signal groups
fileName = 'testCase';
for k = 1 :3

    % Create the timeseries data
    var1 = timeseries(rand(10,1));
    var2 = timeseries(rand(10,1));
    var3 = timeseries(rand(10,1));

    %create a dataset
    ds = Simulink.SimulationData.Dataset();
    ds = ds.addElement( var1, 'var1');
    ds = ds.addElement( var2, 'var2');
    ds = ds.addElement( var3, 'var3');
```

```

    % Save the data
    save([fileName '_' num2str(k) '.mat' ],'ds');
end
clear all

% After mapping and saving the model loop over signal groups and simulate
% Set the filename to append testcase # to
fileName = 'testCase';
% Loop backwards to preallocate
for k=3:-1:1
    % Load the MAT-file.
    load([fileName '_' num2str(k) '.mat']);

    % Simulate the model
    simOut{k} = sim('model_name');
end

```

### Use the PreLoadFcn Model Callback

When you are satisfied with the data and mapping, you can configure your model to load a MAT-file containing the signal group into the MATLAB workspace. Call the `load` function in the `PreLoadFcn` callback for the model.

- 1 After saving the MAT-file, on the **Modeling** tab, click the **Model Settings** drop-down and select **Model Properties**.
- 2 In the Model Properties window, select the **Callbacks** tab and then the `PreLoadFcn` node.
- 3 Enter a command to load the MAT-file containing the signal data. For example:

```
load d_signal_data.mat;
```

- 4 Click **OK** and save the model.

## Preview Signal Data

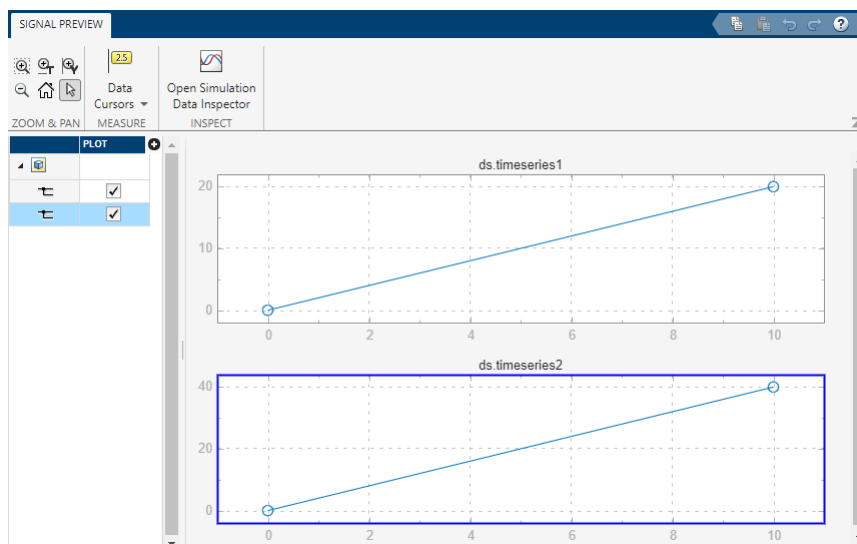

Preview input signal or bus data with the **Signal Preview** window or the Simulation Data Inspector. You can access these windows from the `Simulink.SimulationData.DatasetRef` and `Simulink.SimulationData.Dataset` plot methods. This topic describes using the **Signal Preview** window. For more information on the Simulation Data Inspector, see **Simulation Data Inspector**.

- 1 Preview input signal or bus data with the **Signal Preview** or Simulation Data Inspector windows.
  - For `Simulink.SimulationData.Dataset` or `Simulink.SimulationData.DatasetRef` elements, use the plot method on the dataset.

By default, the plot opens with the Simulation Data Inspector.

To use the **Signal Preview** window, use the 'preview' option.

- 2 In the **Signal Preview** window, explore the plots using the **Measure** and **Zoom & Pan** sections on the toolbar.

- In the **Measure** section, use the **Data Cursors** button to display one or two cursors for the plot. These cursors display the T and Y values of a data point in the plot. To view a data point, click a point on the plot line.
- In the **Zoom & Pan** section, select how you want to zoom and pan the signal plots. Zooming is only for the selected axis.

Type of Zoom or Pan	Button to Click
Zoom in along the T and Y axes.	
Zoom in along the time axis. After selecting the icon, on the graph, drag the mouse to select an area to enlarge.	
Zoom in along the data value axis. After selecting the icon, on the graph, drag the mouse to select an area to enlarge.	
Zoom out from the graph.	
Fit the plot to the graph. After selecting the icon, click the graph to enlarge the plot to fill the graph.	
Pan the graph up, down, left, or right. Select the icon. On the graph, hold the left mouse button and move the mouse to the area of the graph that you want to view.

## Generate MATLAB Scripts for Simulation with Scenarios

After associating a scenario with the model, you can generate a MATLAB script to perform batch simulations. These scripts enable you to connect multiple sets of input signals to your Simulink model for interactive or batch simulation. You can run simulations multiple times and quickly generate data. This topic assumes that you have a scenario ready to run (see “Root Inport Mapping Scenarios” on page 76-27).

- 1 Associate your scenario with the model.
- 2 In the **Script** section, click **Generate Script** and supply a script name when prompted. This command generates the batch simulation file and opens it in MATLAB Editor.
- 3 To run the script, in the MATLAB Editor, click **Run**.
- 4 To evaluate the results of the simulation, see the base workspace.

The resulting script uses the `Simulink.SimulationInput` object and `parsim` function.

### Related Examples

- “Root Inport Mapping Scenarios” on page 76-27

## Create and Use Custom Map Modes

You can create custom map modes to supplement the map modes that the Root Inport Mapper tool provides (see “Choose Map Mode”).

For a summary of the other steps involved in using the Root Inport Mapper tool, see “Import and Mapping Workflow” on page 76-7.

### Create Custom Mapping File Function

#### Files for Custom Mapping Workflow

This example shows how to create a custom mapping file function if you do not want to use the map modes in the Root Inport Mapper tool. For example, consider creating a custom mapping file function if:

- Your signal data contains a common prefix that is not in your model.
- You want to map a signal explicitly.

When the data contains a signal name that does not match one of the block names, a custom mapping function is useful for block name mapping.

To access the files for this example, click the open button. This example folder contains these files:

- BlockNameIgnorePrefixMap.m
- BlockNameIgnorePrefixData.mat
- ex\_block\_name\_ignore\_prefix.slx

#### Create Custom Mapping File Function

To create a custom mapping file function:

- 1 Create a MATLAB function with these input parameters:
  - Model name
  - Signal names specified as a cell array of character vectors
  - Signals specified as a cell array of signal data
- 2 In the function, call the `getRootInportMap` function to create a variable that contains the mapping object (for an example, see `BlockNameIgnorePrefixMap.m`).
- 3 Save and close the MATLAB function file.
- 4 Add the path for the new function to the MATLAB path.

#### Use Custom Mapping File Function

To use the custom mapping file function:

- 1 Open the model that you want to import data to (for example, `ex_block_name_ignore_prefix`).
- 2 Open the Configuration Parameters dialog box for the model and select the **Data Import/Export** pane.

- 3 In the **Load from workspace** section, click **Connect Inputs**.
- 4 Import your signal (for example, `BlockNameIgnorePrefixData.mat`).
- 5 In the **Map Configuration** section of the toolbar, select **Custom**.
- 6 In the **Custom Map** text box, select the MATLAB function file (for example, `BlockNameIgnorePrefixMap.m`) using the browser.

By default, this text box contains `slexcustomMappingMyCustomMap`, which is the custom function for “Attaching Input Data to External Inputs via Custom Input Mappings”.

---

**Tip** The Root Inport Mapper tool parses your custom code. Parsing reorders output alphabetically and verifies that data types are consistent.

---

- 7 Click **Options** and select the **Update Model Automatically** check box.
- 8 Click **Check Map Readiness**.

The model is compiled and the Root Inport Mapper tool gets updated.

To understand the mapping results, see “Understand Mapping Results” on page 76-18.

- 9 Save and close the model.

After you save the mapping definition for a model, you can automate data loading. The next time that you load input data of the same signal group into the workspace, the model uses the mapping definition during simulation. For more information, see “Alternative Workflows to Load Mapping Data” on page 76-20.

### Custom Map Modes Similar to Simulink Modes

If your custom map mode is similar to a Simulink map mode, use the `getSlRootInportMap` function in your custom mapping file function to perform the data mapping.

For an example of a custom mapping function that uses this function, see “Using Mapping Modes with Custom-Mapped External Inputs”.

### Command-Line Interface for Input Variables

Use the `getInputString` function to supply a set of input variables to:

- The `sim` command
- A list of input variables that you can paste in the **Configuration Parameters > Data Import/Export > Input** parameter

### See Also

## Root Inport Mapping Scenarios

### In this section...

“Open Scenarios” on page 76-27

“Save Scenarios” on page 76-27

“Open Existing Scenarios” on page 76-28

“Work with Multiple Scenarios” on page 76-28

Use the Root Inport Mapper tool to create scenarios, save scenarios, and load previously saved scenarios. The Root Inport Mapper tool uses scenarios to save a snapshot of the current state of the imported and mapped signals in an MLDATX file. A scenario file contains information about the:

- Location of signal files (MAT-file or Microsoft Excel files)
- Location of the model
- Map mode
- Mapping options
- Mapped state

When sharing scenario files, include the scenario file and signal files (MAT-file or Microsoft Excel). Place the signal files in the last known location (where you used the Root Inport Mapper tool most recently) or the MATLAB path.

### Open Scenarios

To open an existing scenario, click **Open**.

Click Yes, No, or Cancel. For more information on your options, see “Open”.

### Save Scenarios

When the **Save** icon turns blue or when the model name in the title bar has an asterisk (\*), you can save a scenario.

- 1 On the Root Inport Mapper toolbar, select **Save > Save As**.
- 2 In the Save As dialog box, browse to a writable folder, specify a scenario file name, and then click **Save**.

- To save the signals and the scenario file, click **Yes**.

If a MAT-file is already associated with the scenario, the tool appends the base workspace variables to this file.

Save a scenario to an existing file (the file from which the scenario was last loaded):

- 1 On the Root Inport Mapper tool toolbar, click **Save**.
- 2 Browse to the `.mldatx` file in which to save the scenario, and then click **Save**.

If you have not saved the signals from the scenario, the tool prompts you to save the signals to a MAT-file.

Goal	Action
Overwrite the existing <code>.mldatx</code> file.	<b>Yes</b>
Exit the dialog box. The tool does not save the scenario.	<b>No</b>

## Open Existing Scenarios

You can open previously saved scenario files in one of the following ways:

- Double-click the previously saved scenario file (`*.mldatx`). The Root Inport Mapper tool opens and loads the model. Alternatively, right-click the file and select **Open**.
- When loading scenario files, the tool looks for the associated model and MAT-file or Microsoft Excel file in the last known location, and then looks on the MATLAB path. If the tool cannot find the model or signal files in these two locations, an error occurs.
- If the previously saved scenario has mapped signals, when you open the scenario, the tool applies the mapping. Also, the tool adds the signals to the base workspace so that you can simulate the model.
- Open the Root Inport Mapper tool for the model, click **Open**, and select the previously saved scenario file.

If the model is already open, the new scenario overwrites the existing scenario for the model. If there are unsaved changes in the open scenario, respond to the prompt.

Goal	Click
Save the existing scenario and associated data before loading the new scenario.	<b>Yes</b>
Open the new scenario without saving the existing scenario. This option also removes the data in the existing scenario.	<b>No</b>

## Work with Multiple Scenarios

You can open and work with multiple scenario files simultaneously. Working with multiple scenario files lets you view, edit, group, and nest multiple scenario files. Use multiple scenario files to test more complex systems with interrelated components.

As you open each multiple scenario, the Root Inport Mapper tool adds its data set to the SCENARIO DATASET section. If the scenario contains only signals, convert the signals to the `Simulink.SimulationData.Dataset` format:

- 1 To convert the signals to a `Simulink.SimulationData.Dataset` format, use the `convertToSLDataset` function.
- 2 Link to the new data set. You do not need to reopen the scenario.

## Load Data with Interchangeable Scenarios

To easily exchange scenarios within models, use the Signal Editor block. This block displays, creates, edits, and switches scenarios, where scenarios contain information about groups of signals, such as:

- Location of signal files (MAT-file or Microsoft Excel files)
- Location of the associated model
- Map mode
- Mapping options
- Mapped state

Use scenarios to exchange groups of signals in your model, such as when running multiple simulations or working with test harnesses.

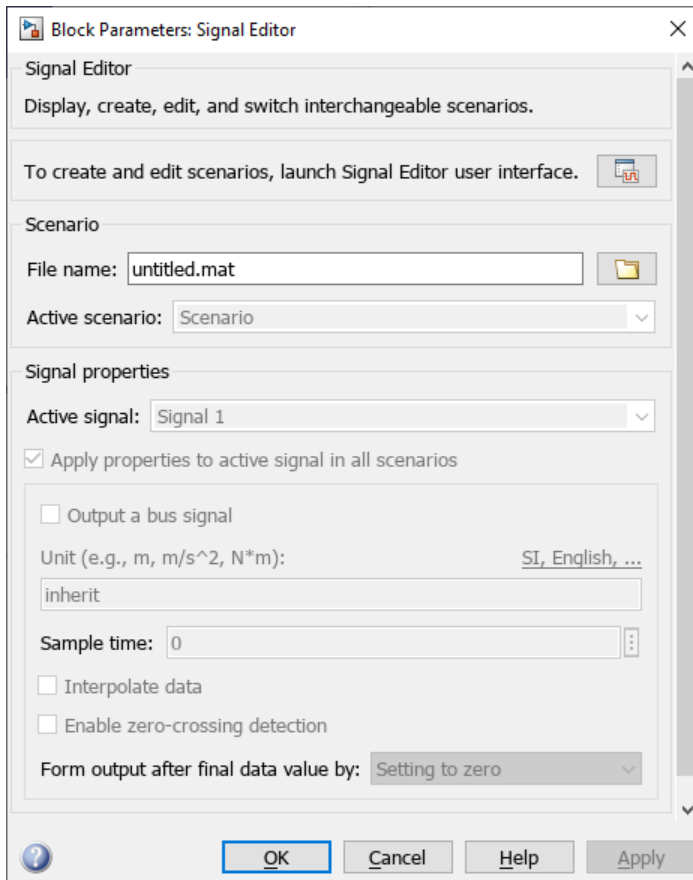

---

**Tip** The Signal Editor displays, creates, and edits interchangeable scenarios and is better integrated with other Simulink capabilities such as units, signals in MAT-files, and signal edit and creation. Consider using the Signal Editor block in models where you use the Signal Builder block. The Signal Builder block is not recommended to work with signal groups. For more information on benefits of the Signal Editor block, see “Replace Signal Builder Block with Signal Editor Block” on page 76-34.

---

### Load Data with Interchangeable Scenarios Using Signal Editor Block

The Signal Editor block gets groups of signals (scenarios) from MAT-files.

The block has these sections.

- Scenario — Set up a scenario by specifying the MAT-file containing the list of scenarios and selecting the active (current) scenario.
- Signal properties — Use the Signal Editor user interface to:
  - Examine, create, and edit scenarios and associated signals. The Signal Editor user interface organizes the signals according to the scenarios that contain them.
  - Select the active signal to be output and set up characteristics, such as unit, sample time, linear interpolation, and so forth, for the active signal. To change the active signal, use the drop-down list.

## Explore the Signal Editor Block

This example shows how to use the Signal Editor block with the “Parallel Simulations Using Parsim: Parameter Sweep in Normal Mode” example, which runs multiple simulations of a Monte Carlo study in parallel using Parallel Computing Toolbox. Parallel execution leverages the multiple cores of your host machine to run many simulations more quickly. If you do not have Parallel Computing Toolbox, this example runs the simulations in serial. The model simulates vehicle dynamics based on the interaction between road and suspension for different road profiles. This example stores its road profile scenarios in the `sldemo_suspn_3dof_sigData.mat` file.

- 1 In the `sldemo_suspn_3dof` model, open the Signal Editor (named Road Profiles) block.

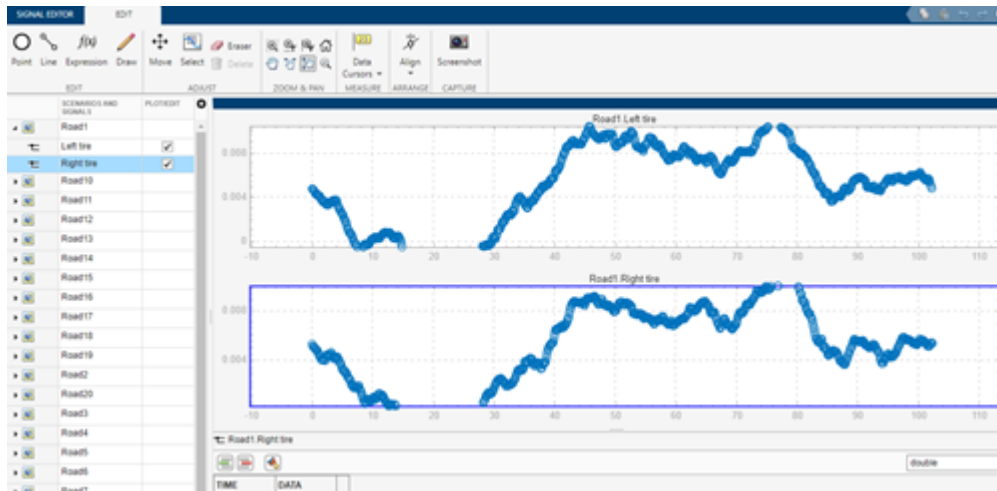

The Signal Editor block **File Name** parameter contains the MAT-file `sldemo_suspn_3dof_sigData.mat`.

Observe that:

- **Active scenario** automatically sets to the first scenario, `Road1`. This setting means that the remainder of the block parameters apply to the signals in that scenario. To change the active scenario, select a new scenario from the list of scenarios.
- **Active signal** automatically sets to the first signal `Left tire` in the active scenario, `Road1`. This setting means that the remainder of the settings in the **Parameter** section apply to the active signal. To change the active signal, select a new signal from the list of signals.

- 2 Explore and edit the scenarios in the MAT-file. Click .

The Signal Editor user interface displays a list of scenarios contained in the MAT-file. Explore and change the scenarios and associated signals. If you make changes, you can save them back to the MAT-file by clicking **Save**.

The output from the block is the active signal data. To simulate the model sequentially using each scenario and signal, use the `parsim` function. This function simulates dynamic systems multiple times in parallel or serial. For an example on how to use `parsim`, see “Parallel Simulations Using Parsim: Parameter Sweep in Normal Mode”.

## Get Number of Scenarios and Signals

To programmatically get the total number of scenarios and signals in the Signal Editor block, use the `get_param` `NumberOfScenarios` and `NumberOfSignals` properties. The values of these properties are character vectors. To convert these values to doubles, use the `str2double` function.

`NumberOfScenarios` and `NumberOfSignals` are read-only properties available only through `get_param`. The block dialog box does not provide these values.

## Migrate from Signal Builder Block to Signal Editor Block

The Signal Builder block and the `signalbuilder` function are not recommended. Consider replacing the Signal Builder block with the Signal Editor block. For more information, see “Replace Signal Builder Block with Signal Editor Block” on page 76-34.

For programmatic access to the Signal Editor block, use the `get_param` and `set_param` functions. For more information, see “Replace Programmatic Use of `signalbuilder`” on page 76-35.

### Replace Signal Builder Block with Signal Editor Block

The Signal Editor provides similar functionality to the Signal Builder block, but with greater flexibility. The benefits of the Signal Editor block include:

- Signal data storage in a MAT-file outside the model
- Signal editing and creation
- Support for Simulink signal attributes, such as dimension and complexity
- Support for standard Simulink data types, including bus and fixed-point
- Unique signal-level data types for outputs
- Multiple rates for outputs
- Support for Simulink units
- “Zero-Crossing Detection” on page 3-10 and data interpolation unique to each signal

To port signal data and properties from the Signal Builder block to the Signal Editor block, use the `signalBuilderToSignalEditor` function. For the current model, this function stores to a MAT-file the signal data and properties from an existing Signal Builder block, adds a Signal Editor block to the current model, and modifies the Signal Editor block to reference the new MAT-file.

For an example, see “Replace Signal Builder Block with Signal Editor Block”.

### Considerations

When you convert from the Signal Builder block to the Signal Editor block, take into account these considerations:

- Internal storage format and preprocessing of data differs between the Signal Builder and Signal Editor blocks. When using the variable step solver, different simulation time steps and mismatched output occur in the two blocks. To minimize the difference between the outputs of both blocks, you can:
  - Reduce the value of **Max step size** of the variable step solver.
  - Insert more data points in the input signal of the Signal Editor block to better represent its shape.
  - Use the fixed-step solver or set the sample time for both blocks to the same discrete sample time (greater than 0). For more information on discrete sample times, see “Discrete Sample Time” on page 7-19.
- The Signal Builder block supports only doubles. To change the data type or other signal properties after conversion, click the  button in the Signal Editor block to access the Signal Editor user interface.

- Scenario names must comply with valid MATLAB "Variable Names".

## Replace Programmatic Use of signalbuilder

The Signal Builder block and the `signalbuilder` function are not recommended. After replacing the Signal Builder block with the Signal Editor block, you can programmatically interact with the block using the `get_param` and `set_param` functions. These tables list the `signalbuilder` function and its equivalent functionality with `get_param`, `set_param`, and supporting code.

### Replace Group Usage with Scenarios

Action	Block	Programmatic Equivalents
Get scenario (group) names.	Signal Builder	<code>[~,~,~,groupNames] = signalbuilder(hBlk, 'options@ActiveScenario');</code>
	Signal Editor	<code>groupNames = get_param(hBlk, "options@ActiveScenario");</code>
Get number of scenarios (groups).	Signal Builder	<code>[~,~,~,groupNames] = signalbuilder(hBlk, 'options@ActiveScenario');</code> <code>numGroups = length(groupNames);</code>
	Signal Editor	<code>numGroups = str2double(get_param(hBlk, "NumberOfScenarios"));</code>
Get active scenario (group).	Signal Builder	<code>[idx, name] = signalbuilder(hBlk, 'ActiveScenario');</code>
	Signal Editor	<code>name = get_param(hBlk, "ActiveScenario");</code> <code>groupNames = get_param(hBlk, "options@ActiveScenario");</code> <code>idx = find(strcmp(groupNames, name));</code>
Set active scenario (group) by index.	Signal Builder	<code>signalbuilder(hBlk, 'activegroup', 2);</code>
	Signal Editor	<code>set_param(hBlk, "ActiveScenario", 2)</code>
Set active scenario (group) by name.	Signal Builder	N/A
	Signal Editor	<code>set_param(hBlk, "ActiveScenario", 'Hardwired');</code>

### Access Signals in Signal Editor and Signal Builder

Action	Block	Programmatic Equivalents
Get signal names.	Signal Builder	<code>[~,~,signalNames,~] = signalbuilder(hBlk, 'options@ActiveScenario');</code>
	Signal Editor	<code>signalNames = get_param(hBlk, "options@ActiveScenario");</code>
Get number of signals in active scenario (group).	Signal Builder	<code>[~,~,signalNames,~] = signalbuilder(hBlk, 'options@ActiveScenario');</code> <code>numSignals = length(signalNames);</code>
	Signal Editor	<code>numSignals = get_param(hBlk, "NumberOfSignals");</code>
Get active signal.	Signal Builder	N/A
	Signal Editor	<code>name = get_param(hBlk, "ActiveSignal");</code>
Set active signal by index.	Signal Builder	N/A
	Signal Editor	<code>set_param(hBlk, "ActiveSignal", 2)</code>
Set active signal by name.	Signal Builder	N/A
	Signal Editor	<code>set_param(hBlk, "ActiveSignal", 'Throttled');</code>

**Create Signal Editor in Model**

Action	Block	Programmatic Equivalents
Add block to model.	Signal Builder	<code>% Given array for time and data hBlk = signalbuilder([gcs,'/Signal Builder', time,data]);</code>
	Signal Editor	<code>% Given Simulink.SimulationData.Dataset fileName = 'scenarioMatFile.mat'; save(fileName,'ds'); hBlk = add_block('simulink/Sources/Signal Editor', [gcs,'/Signal Editor'],'MakeName', 'FileName',fileName);</code>

**Access Time and Data in Signal Editor Block**

Because the Signal Editor block stores its data in a MAT-file that is external to the model, the programmatic equivalents are less direct than in the Signal Builder block for getting and setting time and data. In these cases, you must get the time and data in Signal Builder format using code like this:

```
% Get MAT-file name, number of groups, and group names.
fileName = get_param(hBlk,"FileName");
numGroups = str2double(get_param(hBlk,"NumberofScenarios"));
groupNames = get_param(hBlk,"options@ActiveScenario");
% Load groups from MAT-file.
load(fileName);
time = {};
data = {};
% Get time and data from groups.
for id = 1:numGroups
    ds = eval(groupNames{id});
    timeThisScenario = {};
    dataThisScenario = {};
    for elementId = 1:ds.numElements
        % Timeseries in Simulink.SimulationData.Dataset, ds
        timeThisScenario{end+1} = ds{elementId}.Time';
        dataThisScenario{end+1} = ds{elementId}.Data';
    end
    % Put time and data into Signal Builder format.
    time(1:length(timeThisScenario),id) = timeThisScenario;
    data(1:length(dataThisScenario),id) = dataThisScenario;
end
```

Action	Block	Programmatic Equivalents
Get time and data in Signal Builder format.	Signal Builder	<code>[time, data] = signalbuilder(hBlk);</code>
	Signal Editor	Use the code "Access Time and Data in Signal Editor Block" on page 76-36 to get the time and data and then convert desired signals to Signal Builder time and data formats.
Get last time for data.	Signal Builder	<code>time = signalbuilder(hBlk); endTime = time{1,1}(end);</code>

Action	Block	Programmatic Equivalents
	Signal Editor	Use the code in “Access Time and Data in Signal Editor Block” on page 76-36 to get the time and data in Signal Builder format and then find the maximum time value for all time values.
Get time and data for specific signal.	Signal Builder	[time,data] = signalbuilder(hBlk,'get',
	Signal Editor	Use the code in “Access Time and Data in Signal Editor Block” on page 76-36 to get the time and data and then convert desired signals to Signal Builder time and data formats.
Set time and data to empty (delete) for all signals and groups. Both return error.	Signal Builder	signalbuilder(hBlk,'set',1:1:numSignals
	Signal Editor	fileName = get_param(hBlk,'FileName'); ds = Simulink.SimulationData.Dataset; save(fileName, 'ds');
Set time and data to empty (delete) for specific signals and groups.	Signal Builder	signalbuilder(hBlk,'set',[1,2],1,[],[])
	Signal Editor	Use the code in “Access Time and Data in Signal Editor Block” on page 76-36 to get the time and data and then set the desired signals with updated time and data and save the MAT-file in append mode.

**Append Scenarios and Groups**

Action	Block	Programmatic Equivalents
Add scenarios (groups).	Signal Builder append	time = {timeNew1 timeNew1; timeNew2 tim data = {dataNew1 dataNew1; dataNew2 dat [~,~,signalNames,~] = signalbuilder(hBl signalbuilder(hBlk, 'append', time, dat
	Signal Builder append group	time = {timeNew1 timeNew1; timeNew2 tim data = {dataNew1 dataNew1; dataNew2 dat signalbuilder(hBlk, 'appendgroup', time

Action	Block	Programmatic Equivalents
	Signal Editor	<pre> % Convert time and data formats to signals newSignal(1) = timeseries(dataNew1', timeNew1); newSignal(2) = timeseries(dataNew2', timeNew2); % Get MAT-file name. fileName = get_param(hBlk, "FileName"); % Load groups from MAT-file. load(fileName); % Add new scenarios (groups). numGroups = length(groupNames); numSignals = str2double(get_param(hBlk, "NumSignals")); signalNames = get_param(hBlk, "options@SignalNames"); for id = 1:numGroups     % create new dataset     ds(id) = Simulink.SimulationData.Dataset;     for idSig = 1:numSignals         element = Simulink.SimulationData.Element;         element.Name = signalNames{idSig};         element.Values = newSignal(idSig);         ds(id) = addElement(ds(id), element);     end     assignin('caller', groupNames{id}, id); % Save MAT-file using append mode. save(fileName, groupNames{id}, '-append'); end </pre>

**Append Signals**

Action	Block	Programmatic Equivalents
Add signal to all scenarios (groups).	Signal Builder	<pre> time = {timeNew1 timeNew1; timeNew2 timeNew2}; data = {dataNew1 dataNew1; dataNew2 dataNew2}; signalNames = {'signalNew1', 'signalNew2'}; signalbuilder(hBlk, 'appendSignal', time, data, signalNames); </pre>

Action	Block	Programmatic Equivalents
	Signal Editor	<pre> % Convert time and data formats to signals newSignal(1) = timeseries(dataNew1', timeNew1'); newSignal(2) = timeseries(dataNew2', timeNew2'); % Get MAT-file name. fileName = get_param(hBlk, "FileName"); % Load groups from MAT-file. load(fileName); % Use unique signal names. signalNames = {'signalNew1', 'signalNew2'}; % Append signals to scenarios (groups). numGroups = length(groupNames); numSignals = length(signalNames); for id = 1:numGroups     % Get dataset.     ds = eval(groupNames{id});     for idSig = 1:numSignals         element = Simulink.SimulationData.Element;         element.Name = signalNames{idSig};         element.Values = newSignal(idSig);         ds = addElement(ds, element);     end     assignin('caller', groupNames{id}, ds); % Save MAT-file using append mode. save(fileName, groupNames{id}, '-append'); end </pre>

### Print

Action	Block	Programmatic Equivalents
Print to Handle Graphics® figure.	Signal Builder	<code>hFig = signalbuilder(hBlk, 'print', config);</code>
	Signal Editor	Use the code in “Access Time and Data in Signal Editor Block” on page 76-36 to get the signals from the dataset and then plot the desired data.

## Save Simulation Data

### In this section...

“Choose Type of Simulation Data to Log” on page 77-2

“Choose Technique to Log Simulation Data” on page 77-3

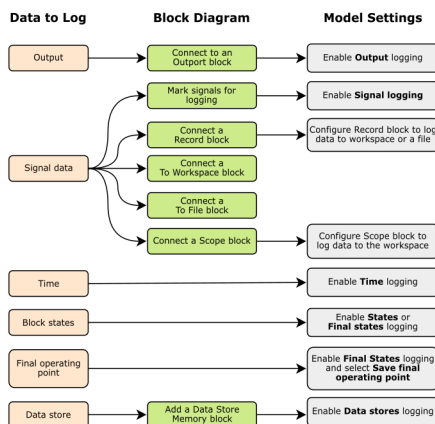

“Log Data” on page 77-8

Saving, or logging, simulation data provides a baseline for analyzing and debugging a model. You can save simulation data to the workspace or a file. Once simulation data is logged, you can later retrieve, analyze, and postprocess the data without rerunning the simulation. You can also use logged data as the input for simulating a model.

To log simulation data:

- 1 Choose the type or types of simulation data to log.
- 2 Choose one or more logging techniques based on the data you want to log.
- 3 Log the simulation data.

This flowchart provides an overview of the available techniques and necessary configuration settings based on the type of data you choose to log.

### Choose Type of Simulation Data to Log

Simulation data can include any combination of output, signal, time, state, and data store logging data.

- **Output** — Log output data to analyze signals connected to root-level Output blocks.
- **Signal data** — Log signal data to analyze a signal, bus, or array of buses connected to a block.
- **Time** — Log time data to save time values for a simulation.
- **State or final state** — Log state data to analyze how block states change throughout the simulation. Log model operating points during a simulation to resume the simulation from any of those operating points.

- Data store — Log data stores to save the values of a local or global data store for all the steps in a simulation. Data store logging is commonly used for model debugging or confirming a model modification.

## Choose Technique to Log Simulation Data

The available logging techniques and necessary configuration settings depend on the type of simulation data you want to log. You can log any combination of simulation data types and use multiple logging techniques to save simulation data within the same model.

You can use one or more of these techniques to log simulation data.

Goal	Logging Technique	More Information
Log output data.	Enable <b>Output</b> logging and connect a signal to a root-level Output block.	<p>Consider logging output data in a top-level model when your model already includes an Output block.</p> <p>Logged output data is stored in the workspace with the default variable name <code>yout</code>.</p> <p>Output data logged in <b>Dataset</b> format streams to the Simulation Data Inspector during simulation.</p>
Log signals throughout the model without adding blocks.	Enable <b>Signal logging</b> and mark signals for logging. For more information, see “Save Signal Data Using Signal Logging” on page 77-42.	<p>Use signal logging to avoid adding blocks to your model.</p> <p>Signal logging data is stored in the workspace with the default variable name <code>logout</code>.</p> <p>Signal logging streams data to the Simulation Data Inspector during simulation.</p> <p>Log signals using individual signal logging rates specified using the <b>Signal Properties</b> or <b>Instrumentation Properties</b>.</p> <p>Log subsets of marked signals programmatically or by using the Signal Logging Selector. For more information, see “Override Signal Logging Settings” on page 77-52</p>

Goal	Logging Technique	More Information
<p>Log signal data to the workspace, a file, and the Simulation Data Inspector.</p>	<p>Connect one or more signals to a Record block and configure the block to record data to the workspace or a file.</p>	<p>The Record block logs data to the workspace with the default variable name <code>recordout</code>.</p> <p>During simulation, the Record block streams data to the Simulation Data.</p> <p>You can configure the Record block to also log data to the workspace, a file, or both. For more information, see “Log Data to the Workspace and a File Using the Record Block” on page 77-83.</p> <p>The Record block supports logging data to a MAT file, an MLDATX file, or an Excel file.</p> <p>Visualize logged data in the Record block using several visualizations including sparklines plots, time plot, and XY plots.</p>
<p>Log signal data to the workspace.</p>	<p>Connect a signal to a To Workspace block.</p>	<p>The To Workspace block logs data to the workspace with the default variable name <code>simout</code>.</p> <p>During simulation, the To Workspace block streams logged data to the Simulation Data Inspector.</p> <p>Save data at a sample rate other than the base sample rate.</p> <p>For more information, see “Output Simulation Data with Blocks”</p>

Goal	Logging Technique	More Information
Log signal data to a MAT file.	Connect a signal to a To File block.	<p>The To File block saves data to a MAT file instead of saving it to a variable in the workspace.</p> <p>When you configure the model to <b>Record logged workspace data in Simulation Data Inspector</b>, data logged to a To File block is available in the Simulation Data Inspector when the simulation is paused, stopped, or completes. Data cannot be streamed to the Simulation Data Inspector during simulation.</p> <p>Save data at a sample rate other than the base sample rate.</p> <p>The To File block does not support logging variable-size signals.</p> <p>For more information, see “Output Simulation Data with Blocks”</p>
Log signal data displayed in a Scope block.	Connect one or more signals to a Scope and configure the block to log data to the workspace.	<p>Logged Scope data is saved to the workspace with the default variable name <code>ScopeData</code>.</p> <p>Save data at a sample rate other than the base sample rate.</p> <p>Scope blocks store data and can be memory intensive.</p> <p>For more information, see “Save Simulation Data Using Scope Block” on page 30-53.</p>
Log time values.	Enable <b>Time</b> logging.	<p>The software logs time data to the workspace at the base sample rate of the model.</p> <p>Logged time data is saved to the workspace with the default variable name <code>tout</code>.</p>

Goal	Logging Technique	More Information
<p>Log block state data to analyze how block states change throughout the simulation.</p>	<p>Enable <b>States</b> logging or <b>Final states</b> logging.</p>	<p>State data saved in Dataset format streams to the Simulation Data Inspector during simulation.</p> <p>To analyze how block states change throughout the simulation, configure the model to log <b>States</b>. States data is saved to the workspace with the default variable name <code>xout</code>.</p> <p>To log a snapshot of block states when the simulation is paused or when the simulation stops, configure the model to log <b>Final states</b>. Final states data is saved to the workspace with the default variable name <code>xFinal</code>.</p> <p>For more information, see “Save Block States and Simulation Operating Points” on page 77-73.</p>
<p>Log a complete model operating point to use as the starting point for future simulations.</p>	<p>Enable <b>Final states</b> logging and select <b>Save final operating point</b>.</p>	<p>The model operating point represents the complete set of block states and the state of the model, including the simulation time, the solver state, and the execution engine state. For more information, see “Save Block States and Simulation Operating Points” on page 77-73.</p> <p>Use model operating points to save time by not repeatedly running segments of a simulation that do not change from one scenario to the next. For more information, see “Use Model Operating Point for Faster Simulation Workflow” on page 27-44.</p>

Goal	Logging Technique	More Information
Log data stores, which share data throughout a model hierarchy, to debug a model or confirm a model modification.	Enable <b>Data stores</b> logging, add a Data Store Memory block to the model, and configure the block to log data.	Data stores are saved to the workspace using the default variable name <code>dmsout</code> .  Logged data stores stream to the Simulation Data Inspector during simulation.  For more information, see “Log Data Stores” on page 78-29.

### Choose Data Format

You can log data in several formats. This table shows the data formats available for each type of data and logging technique.

Logged Data	Data Format				
	Dataset	timeseries	Array	Structure with Time	Structure
Output	Yes (default)	No	Yes	Yes	Yes
Signal data using signal logging	Yes (default)	No	No	No	No
Signal data using a Record block	Yes (default)	No	No	No	No
Signal data using a To Workspace block	No	Yes (default)	Yes	Yes	Yes
Signal data using a To File block	No	Yes (default)	Yes	No	No
Signal data using a Scope block	Yes (default)	No	Yes	Yes	Yes
States and final states	Yes (default)	No	Yes	Yes	Yes
Data stores	Yes (default)	No	No	No	No

Time data is logged as a vector of the simulation times. For more information about the data formats, see “Data Format for Logged Simulation Data” on page 77-12.

Consider converting data logged in other formats to **Dataset** format to simplify post-processing. For more information, see “Convert Data to Dataset Format” on page 77-17.

## Log Data

Once you have chosen the types of data you want to log and chosen your logging technique, prepare the model to log data. Depending on the data and the chosen technique, use one or more of these steps:

- In the block diagram, add blocks or mark signals as specified by your chosen technique.
- Configure blocks to log data in the chosen format.
  - If using the Record block, a Scope block, or logging data stores, configure the blocks to log data.
  - If using the To Workspace, To File, or Scope block to log data, you can change the logged data format using the Block Parameters dialog box. Double-click a block to access the Block Parameters dialog box.
- Configure the model to log the chosen data.
  - 1 In the **Modeling** tab, in the **Setup** section, click **Model Settings**.
  - 2 Select the **Data Import/Export** pane.
  - 3 Select parameters to save data. For example, to save output data, select **Output**.

The parameters you select depend on the data you log.

Data	Configuration Parameter	Enabled by Default?
Output data	<b>Output</b>	Yes
Signal data marked for signal logging	<b>Signal logging</b>	Yes
Time data	<b>Time</b>	Yes
States	<b>States</b>	No
Final states	<b>Final states</b>	No
Data stores	<b>Data stores</b>	Yes
Data logged in a format other than Dataset and data logged using To File or Scope blocks that you want to view in the Simulation Data Inspector after simulation pauses or stops.	<b>Record logged workspace data in Simulation Data Inspector</b>	No

Once you have prepared your model to log the chosen data, click **Run** to simulate the model. Data is logged during simulation. To inspect logged simulation data interactively, consider using the **Simulation Data Inspector**. For more information, see “View Data in the Simulation Data Inspector” on page 31-2.

You can also access data logged to the workspace programmatically. By default, results are returned as a single `Simulink.SimulationOutput` object that contains complete simulation metadata and all simulation data logged to the workspace. Each logged data type is a property of the `SimulationOutput` object specified by the variable name of the logged data. For more information, see “View and Access Signal Logging Data” on page 77-63.

## View and Access Logged Simulation Data

Logged simulation data can include any combination of output, signal, time, state, and data store logging data. You can log data to a file or to the workspace. You can view logged data during simulation using the **Simulation Data Inspector**, or for paused or stopped simulations, by using other visualization interfaces. See “Decide How to Visualize Simulation Data” on page 33-2.

Alternatively, you can access simulation data that has been logged to the workspace programmatically, using MATLAB commands.

### View Logged Data Using Simulation Data Inspector

To inspect logged simulation data interactively, consider using the Simulation Data Inspector. Data logged in **Dataset** format is automatically logged in the Simulation Data Inspector. To view data logged using a format other than **Dataset**, open the Configuration Parameters dialog box. In the **Data Import/Export** pane, select the **Record logged workspace data in Simulation Data Inspector** parameter. For more information, see “View Data in the Simulation Data Inspector” on page 31-2.

Depending on the logging technique used and the format of the data, some logged data can also stream to the Simulation Data Inspector during simulation. For more information, see “View Streaming Data in the Simulation Data Inspector” on page 31-87.

### Access Logged Data Programmatically

You can access and analyze data logged to the workspace programmatically. By default, all simulation data logged to the workspace is returned as a single `Simulink.SimulationOutput` object in a variable with the default name `out`. The `Simulink.SimulationOutput` object contains complete simulation metadata and all simulation data logged to the workspace. Each logged data type becomes a property of the `Simulink.SimulationOutput`. The name of the property matches the name you specify for the logging variable. For example, when you log data using signal logging and use the default variable name `logsout`, the `Simulink.SimulationOutput` object has the property `logsout` that contains the logged signal data.

This table summarizes the default property name for several common logging techniques.

Logged Data	Default Variable Name in Workspace
Output data	<code>yout</code>
Signal logging data	<code>logsout</code>
Signal data logged using a Record block	<code>recordout</code>
Signal data logged using a To Workspace block	<code>simout</code>
Signal data logged using a Scope block	<code>ScopeData</code>
Time data	<code>tout</code>
States data	<code>xout</code>
Final states data	<code>xFinal</code>
Data stores	<code>dsmout</code>

When simulation results are returned as a single `Simulink.SimulationOutput` object, you can access logged data using a dot. For example, if output data is logged using the default name `yout`, then you can use the property `yout` to access logged output data .

```
outputData = out.yout
```

```
outputData =
```

```
Simulink.SimulationData.Dataset 'yout' with 1 element
```

	Name	BlockPath
1 [1x1 Signal]	Data from Output	LoggingTechniques/Out1

- Use braces `{ }` to access, modify, or add elements using index.

For an example of accessing signal logging data programmatically, see “View and Access Signal Logging Data” on page 77-63.

## Data Format for Logged Simulation Data

### In this section...

“Data Format for Block-Based Logged Data” on page 77-12

“Data Format for Model-Based Logged Data” on page 77-12

“Signal Logging Format” on page 77-12

“Logged Data Store Format” on page 77-12

“Time, State, and Output Data Format” on page 77-12

### Data Format for Block-Based Logged Data

You can use the Scope, To File, or To Workspace blocks to export simulation data. Each of these blocks has a data format parameter.

### Data Format for Model-Based Logged Data

The data format for model-based exporting of simulation data specifies how Simulink stores the exported data.

Simulink uses different data formats, depending on the kind of data that you export. For details, see:

- “Signal Logging Format” on page 77-12
- “Logged Data Store Format” on page 77-12
- “Time, State, and Output Data Format” on page 77-12

### Signal Logging Format

Signal logging always uses `Dataset` format. You can specify whether to log data for individual signals as `timeseries` or `timetable` objects.

To control how `Dataset` elements are saved, set the **Dataset signal format** configuration parameter. The default is `timeseries`. For details, see “Dataset signal format”.

The **Dataset signal format** parameter applies to signal logging, as well as output and states data when you set the **Format** parameter to `Dataset`.

### Logged Data Store Format

When you log data store data, Simulink uses a `Simulink.SimulationData.Dataset` object.

For details, see “Accessing Data Store Logging Data” on page 78-31.

### Time, State, and Output Data Format

For exported time, states, and output data, use one of the following formats:

- “Dataset” on page 77-13 (default)

- “Array” on page 77-13
- “Structure with Time” on page 77-14
- “Structure” on page 77-15

If you select the **Configuration Parameters > Data Import/Export > Output** check box, Simulink logs fixed-point data as double. To log fixed-point data, consider using one of these approaches:

- Signal logging — For details, see “Save Signal Data Using Signal Logging” on page 77-42.
  - 1 In the Simulink Editor, select one or more signals.
  - 2 Click **Log Signals**.
- To File block
- To Workspace block — In the To Workspace Block Parameters dialog box, enable the **Log fixed-point data as a fi object** parameter.

For information about the format for logged final state data, see “Save Block States and Simulation Operating Points” on page 77-73.

### Dataset

By default, time, states, and outputs are logged using the **Dataset** format. The **Dataset** format:

- Stores logged data in `timeseries` or `timetable` objects. You can work with data saved in a `timeseries` or `timetable` object in MATLAB without a Simulink license.
- Supports logging multiple data values for a given time step, which can be required for logging data in a For Iterator Subsystem, a While Iterator Subsystem, and Stateflow.
- Does not support logging states inside a function-call subsystem or during rapid accelerator simulations.
- Does not support code generation.

Signal logging always uses the **Dataset** format. Logging states and output data using the **Dataset** format allows you to post-process simulation data without writing custom code for different types of logged data. When you log states and outputs using the **Dataset** format, the data also automatically streams to the Simulation Data Inspector during simulation.

### Array

If you select this **Array** option, Simulink saves the states and outputs of a model in a state and in an output array, respectively.

The state matrix has the name specified in the **Configuration Parameters > Data Import/Export** pane (for example, `xout`). Each row of the state matrix corresponds to a time sample of the states of a model. Each column corresponds to an element of a state. For example, suppose that your model has two continuous states, each of which is a two-element vector. Then the first two elements of each row of the state matrix contain a time sample of the first state vector. The last two elements of each row contain a time sample of the second state vector.

The model output matrix has the name specified in the **Configuration Parameters > Data Import/Export** pane (for example, `yout`). Each column corresponds to a model output port, and each row to the outputs at a specific time.

**Note** Use array format to save your model outputs and states only if the logged data meets *all* these conditions:

- Data is all scalars or all vectors (or all matrices for states)
- Data is all real or all complex
- Data all has the same data type
- Data includes bus signals

If your model outputs and states do not meet these conditions, use the **Structure** or **Structure with time** output formats (see “Structure with Time” on page 77-14).

---

### Structure with Time

If you select this format, Simulink saves the model states and outputs in structures that have their names specified in the **Configuration Parameters > Data Import/Export** pane. By default, the structures are `xout` for states and `yout` for output.

The structure used to save outputs has two top-level fields:

- `time`  
Contains a vector of the simulation times.
- `signals`  
Contains an array of substructures, each of which corresponds to a model output port.

Each substructure has four fields:

- `values`  
Contains the outputs for the corresponding output port.
  - If outputs are scalars or vectors — `values` field is a matrix each of whose rows represent an output at the time specified by the corresponding time vector element.
  - If the outputs are matrix (2-D) values — `values` field is a 3-D array of dimensions M-by-N-by-T. M-by-N is the dimensions of the output signal and T is the number of output samples.
  - If  $T = 1$  — MATLAB drops the last dimension. Therefore, the `values` field is an M-by-N matrix.
- `dimensions`  
Specifies the dimensions of the output signal.
- `label`  
Specifies the label of the signal connected to the output port, S-Function block, or the type of state (continuous or discrete). The label is `DSTATE` or `CSTATE`, except for S-Function block state labels. For S-Function block state labels for discrete states, the label is the name of the state (instead of `DSTATE`).
- `blockName`  
Specifies the name of the corresponding output port or block with states.
- `inReferencedModel`

If the `signals` field records the final state of a block that resides in the referenced model, contains a value of 1. Otherwise, the value is false (0).

The following example shows the structure-with-time format for a nonreferenced model.

```
xout.signals(1)
ans =
    values: [296206x1 double]
 dimensions: 1
    label: 'CSTATE'
 blockName: 'vdp/x1'
inReferencedModel: 0
```

The structure used to save states has a similar organization. The states structure has two top-level fields:

- `time`

The `time` field contains a vector of the simulation times.

- `signals`

The field contains an array of substructures, each of which corresponds to one of the states of the model.

Each `signals` structure has four fields: `values`, `dimensions`, `label`, and `blockName`. The `values` field contains time samples of a state of the block specified by the `blockName` field. The `label` field for built-in blocks indicates the type of state: either `CSTATE` (continuous state) or `DSTATE` (discrete state). For S-Function blocks, the label contains whatever name is assigned to the state by the S-Function block.

The time samples of a state are stored in the `values` field as a matrix of values. Each row corresponds to a time sample. Each element of a row corresponds to an element of the state. If the state is a matrix, the matrix is stored in the `values` array in column-major order. For example, suppose that the model includes a 2-by-2 matrix state and that 51 samples of the state are logged during a simulation run.

The `values` field for this state would contain a 51-by-4 matrix. Each row corresponds to a time sample of the state, and the first two elements of each row correspond to the first column of the sample. The last two elements correspond to the second column of the sample.

---

**Note** Simulink can read back simulation data saved to the MATLAB workspace in the `Structure with time` output format. See “Examples of Specifying Signal and Time Data” on page 75-53 for more information.

---

## Structure

This format is the same as for `Structure with time` output format, except that Simulink does not store simulation times in the `time` field of the saved structure.

## Convert Data to Dataset Format

### In this section...

- “Why Convert to Dataset Format?” on page 77-17
- “Results of Conversion” on page 77-18
- “Convert timeseries object to Dataset object” on page 77-19
- “Convert Structure to Dataset Object” on page 77-20
- “Migrate Legacy Code That Uses ModelDataLogs” on page 77-22
- “Dataset Conversion Limitations” on page 77-24

### Why Convert to Dataset Format?

You can use the `Simulink.SimulationData.Dataset` constructor to convert a MATLAB workspace variable that contains data that was logged in one of these formats to `Dataset` format:

- Array
- Structure
- Structure with time
- MATLAB `timeseries` object
- `ModelDataLogs`

Converting data from other logging formats to `Dataset` format simplifies writing scripts to post-process data logged. For example, a model with multiple To Workspace blocks can use different data formats. Converting the logged data to `Dataset` format avoids the need to write special code to handle different formats.

Different simulation modes have different levels of support for data logging formats. Switching between normal and accelerator modes can require changes to the logging formats used.

The conversion to `Dataset` format also makes it easier to take advantage of features that require `Dataset` format. You can easily convert data logged in earlier releases that used a format other than `Dataset` to work well with `Dataset` data in a more recent release.

The `Dataset` format:

- Uses MATLAB `timeseries` objects to store logged data, which allows you to work with logging data in MATLAB without a Simulink license. For example, to manipulate the logged data, you can use MATLAB `timeseries` object functions such as `filter`, `detrend`, and `resample`.
- Supports logging multiple data values for a given time step, which is important for Iterator subsystem and Stateflow signal logging.

By default, the resulting `Dataset` object uses the variable name as the object name. You can use a name-value argument to specify a `Dataset` name.

You can also use the `concat` function to combine `Dataset` objects into one concatenated `Dataset` object.

## Results of Conversion

**Dataset** objects hold data as elements. To display the elements of a **Dataset** object variable, enter the variable name at the MATLAB command prompt. Each element is an object. The type of the object depends on the data each element contains. For example, signal logging stores data as `Simulink.SimulationData.Signal` elements, and state logging in **Dataset** format stores data as `Simulink.SimulationData.State` elements. Each element holds data as a MATLAB **timeseries** object. At conversion, the elements and **timeseries** field populate as much as possible from the converted object.

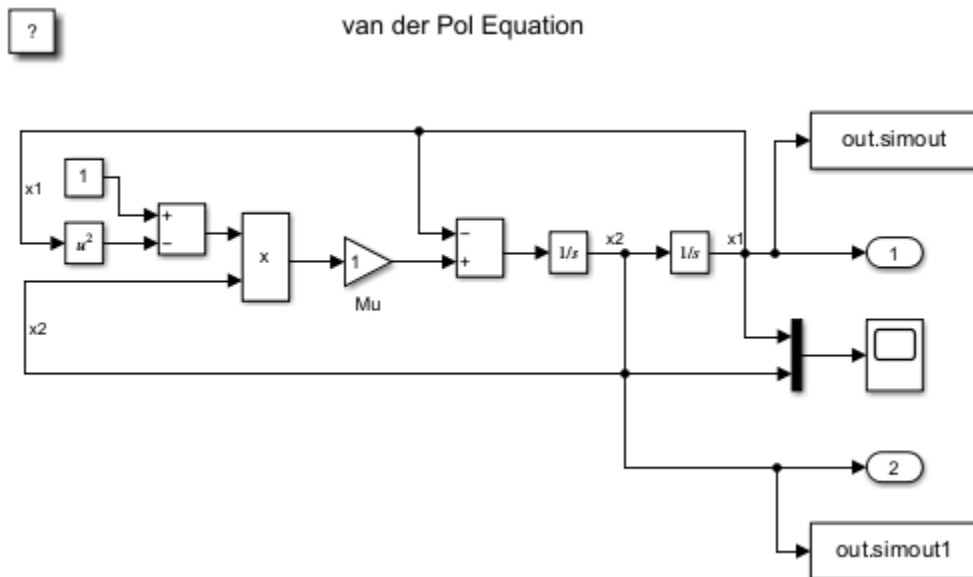

Format	Conversion Result Notes
MATLAB <b>timeseries</b> object	<p>If you log nonbus data, during conversion, the software first adds the data as a <code>Simulink.SimulationData.Signal</code> object. The software then adds that object as an element of the newly created <b>Dataset</b>.</p> <p>If you log bus data in <b>timeseries</b> format, one <b>timeseries</b> object corresponds to each element of a bus. Converting arranges the logged data as a structure with <b>timeseries</b> objects as leaf nodes where the structure hierarchy matches the bus hierarchy. Conversion of this type of structure adds the structure to a <code>Signal</code> object. Then, the <code>Signal</code> object is added as an element to the <b>Dataset</b> object.</p> <p><b>timeseries</b> objects hold relevant information such as block path and timestamps. The conversion tries to preserve this information.</p>
Structure and structure with time	<p>Structure and structure with time formats do not always contain as much information as if you log in <b>Dataset</b> format. However, before converting structure and structure with time formats, the data structure must have <b>time</b> and <b>signals</b> fields.</p> <p>Conversion populates a <code>Simulink.SimulationData.Signal</code> object with the structure and adds it as an element of the <b>Dataset</b> object. If other information is available, converting also adds that information to the element or <b>timeseries</b> object values. For example, if the structure has a field called <code>blockName</code>, converting adds the block name to the block path. Otherwise, the block path is empty.</p> <p>When scope data is logged in structure format, the logged structure has a <code>PlotStyle</code> field. The software uses this field to set the interpolation in the <b>Dataset</b> object.</p>

Format	Conversion Result Notes
Array	<p>Arrays contain little information. For example, there is no block path information.</p> <p>Conversion adds the array to a <code>Simulink.SimulationData.Signal</code> object, then adds the <code>Signal</code> object as an element of the <code>Dataset</code> object. The conversion treats unavailable information such as block path and timestamp fields as empty or uses default values.</p>
ModelDataLogs	<p>Converts data from ModelDataLogs format to Dataset format.</p> <p><b>Note</b> The ModelDataLogs format is no longer used for signal logging.</p>

## Convert timeseries object to Dataset object

Convert data from `timeseries` format to `Dataset` format. The model `vdpConvert` is the `vdp` model with two `To Workspace` blocks that log data to variables named `simout` and `simout1`.

Simulate the model. By default, `To Workspace` blocks log data as `timeseries` objects.

```
out = sim("vdpConvert")
```

```
out =
```

```
Simulink.SimulationOutput:
```

```
    simout: [1x1 timeseries]
    simout1: [1x1 timeseries]
```

```
SimulationMetadata: [1x1 Simulink.SimulationMetadata]
```

```
ErrorMessage: [0x0 char]
```

Use the `Simulink.SimulationData.Dataset` constructor to convert the timeseries objects to `Dataset` format.

```
ds = Simulink.SimulationData.Dataset(out.simout)
```

```
ds =  
Simulink.SimulationData.Dataset '' with 1 element
```

	Name	BlockPath
1 [1x1 Signal]	<u>x1</u>	<u>''</u>

- Use braces { } to access, modify, or add elements using index.

```
ds1 = Simulink.SimulationData.Dataset(out.simout1)
```

```
ds1 =  
Simulink.SimulationData.Dataset '' with 1 element
```

	Name	BlockPath
1 [1x1 Signal]	<u>x2</u>	<u>''</u>

- Use braces { } to access, modify, or add elements using index.

You can use the `concat` function to combine the two `Dataset` objects into one concatenated `Dataset` object.

```
dsFinal = concat(ds,ds1)
```

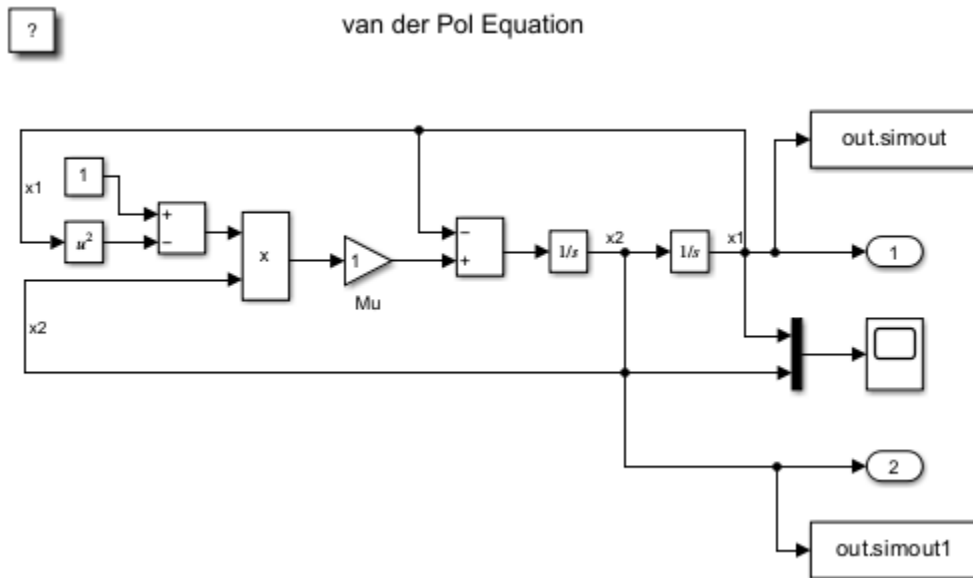

```
dsFinal =  
Simulink.SimulationData.Dataset '' with 2 elements
```

	Name	BlockPath
1 [1x1 Signal]	<u>x1</u>	<u>''</u>
2 [1x1 Signal]	<u>x2</u>	<u>''</u>

- Use braces { } to access, modify, or add elements using index.

## Convert Structure to Dataset Object

Convert a structure to `Dataset` format. The model `vdpConvertStructure` is the `vdp` model with two `To Workspace` blocks that log data to variables named `simout` and `simout1` in structure format.

Simulate the model.

```
out = sim("vdpConvertStructure");
```

The To Workspace block that saves data to the variable `simout` logs data as a structure with time. The To Workspace block that saves data to the variable `simout1` logs data as a structure without time.

```
simout = out.simout
```

```
simout = struct with fields:
    time: [64x1 double]
    signals: [1x1 struct]
    blockName: 'vdpConvertStructure/To Workspace'
```

```
simout1 = out.simout1
```

```
simout1 = struct with fields:
    time: []
    signals: [1x1 struct]
    blockName: 'vdpConvertStructure/To Workspace1'
```

Convert the structure data from both To Workspace blocks to Dataset format.

```
ds = Simulink.SimulationData.Dataset(simout);
ds1 = Simulink.SimulationData.Dataset(simout1);
```

Access the time values for the element `ds`.

```
get(ds,1).Values.time
```

```
ans = 64x1
```

```
    0
 0.0001
```

```
0.0006
0.0031
0.0157
0.0785
0.2844
0.5407
0.8788
1.2788
:
```

Notice that the time field for `simout1` is an empty array. When a structure without time or an array is converted to a `Dataset` object, the conversion inserts a time vector that starts at 0 and increments by 1.

Get the time values of the element in `ds1`. Because a time vector is not included in the structure `simout1`, the time steps for the `Dataset` object `ds1` do not match the simulation time steps.

```
get(ds1,1).Values.Time
```

```
ans = 64x1
```

```
0
1
2
3
4
5

9
:
```

## Migrate Legacy Code That Uses ModelDataLogs

For scripts that simulate a model created in a release earlier than R2016a that uses `ModelDataLogs` format for logging, update the code to log in `Dataset` format.

If you have already logged signal data in the `ModelDataLogs` format, you can use the `convertToDataset` function to update the `ModelDataLogs` signal logging data to use `Dataset` format. For example, update the `older_model_data` from `ModelDataLogs` format to `Dataset` format.

```
new_dataset = convertToDataset(logsout, "older_model_data")
```

Converting a model from using `ModelDataLogs` format to using `Dataset` format can require that you modify your existing models and code in callbacks, functions, scripts, or tests. This table identifies possible issues to address after converting to `Dataset` format.

Possible Issue After Conversion to Dataset Format	Solution
Code in existing callbacks, functions, scripts, or tests that used the <code>ModelDataLogs</code> programmatic interface to access data can result in an error.	<p>Check for code that uses <code>ModelDataLogs</code> format access methods. Update that code to use <code>Dataset</code> format access methods.</p> <p>For example, suppose that existing code includes this line.</p> <pre>logout.('Subsystem Name').X.data</pre> <p>Replace that code with a <code>Dataset</code> access function.</p> <pre>get(logout, "x").Values.data</pre>
Mux block signal names are lost.	The <code>Dataset</code> format treats Mux block signals as a vector. To identify signals by signal names, replace Mux blocks with Bus Creator blocks.
Signal Viewer cannot be used for signal logging.	<p>The software does not log signal logging data in the Signal Viewer.</p> <p>Use the signal logging output variable to view the logged data.</p>
The <code>unpack</code> function generates an error.	<p>The <code>unpack</code> function, which is supported for <code>Simulink.ModelDataLogs</code> and <code>Simulink.SubsysDataLogs</code> objects, is <i>not</i> supported for <code>Simulink.SimulationData.Dataset</code> objects.</p> <p>For example, suppose the data in <code>mlog</code> has three fields: <code>x</code>, <code>y</code>, and <code>z</code>.</p> <ul style="list-style-type: none"> <li>For <code>ModelDataLogs</code> format data, the <code>mlog.unpack</code> function creates three variables in the base workspace.</li> <li>For <code>Dataset</code> format data, the <code>get</code> function accesses data by name.</li> </ul> <pre>x = get(logout, "x").Values</pre>
The <code>ModelDataLogs</code> and <code>Dataset</code> formats have different naming rules for unnamed signals.	<p>If necessary, add signal names.</p> <p>In <code>ModelDataLogs</code> format, for an unnamed signal coming from a block, the software assigns a name in the form <code>SL_BlockName+&lt;portIndex&gt;</code>, for example, <code>SL_Gain1</code>.</p> <p>In <code>Dataset</code> format, elements do not need a name, so the software leaves the signal name empty.</p> <p>For both <code>ModelDataLogs</code> and <code>Dataset</code> formats, the software assigns the same name to unnamed signals that come from Bus Selector blocks.</p>
Test points in referenced models are not logged.	Consider enabling signal logging for test points in a referenced model.
Script uses <code>who</code> or <code>whos</code> functions.	Consider using <code>find</code> instead.

## Dataset Conversion Limitations

- Converting logged data to `Dataset` format results in a `Dataset` object that contains all the information that the original logged data included. However, if no corresponding information is available for the other `Dataset` properties, the conversion uses default values for that information.
- When you convert data for a variable-size signal logged using the `To Workspace` block, the information in the `valueDimensions` field of the structure is lost in the conversion.
- When you log a bus signal in array, structure, or structure with time formats, the logged data is organized with:
  - The first column containing the data for the first signal in the bus
  - The second column containing data for the second bus signal, and so on

When you convert that data to `Dataset` format, the `Dataset` object preserves that organization. However, if you log the bus signal in `Dataset` format without conversion, the conversion captures the bus data as a structure of `timeseries` objects.

- If the logged data does not include a time vector, when you convert that data to `Dataset` format, the conversion inserts a time vector. The time vector has one time step for each data value. However, the simulation time steps and the `Dataset` time steps can vary.
- `Dataset` format ignores the specification of frame signals. Conversion of structure or structure with time data to `Dataset` format reshapes the data for logged frame signals.

## Limit the Size of Logged Data

### In this section...

“Limit the Number of Runs Retained in the Simulation Data Inspector Archive” on page 77-25

“Specify a Minimum Disk Space Requirement or Maximum Size for Logged Data” on page 77-25

“View Data Only During Simulation” on page 77-26

“Reduce the Number of Data Points Logged from Simulation” on page 77-26

Logging simulation data can produce large amounts of data that fill up disk space. Such situations include logging many signals, logging data for long simulations, and running many simulations without deleting run data from the Simulation Data Inspector. You can choose among several options to limit the size of logged simulation data. You can:

- Limit the number of runs retained in the Simulation Data Inspector archive.
- Reduce the number of data points logged in each simulation.
- Specify a minimum disk space requirement or maximum size for logged data.
- Configure logging for only viewing data during simulation.

Depending on your requirements, you can use more than one strategy to limit the size of logged data.

### Limit the Number of Runs Retained in the Simulation Data Inspector Archive

When you run multiple simulations in a single MATLAB session, logged simulation data accumulates in the Simulation Data Inspector even if you overwrite the logging data in the MATLAB workspace. To reduce the amount of data the Simulation Data Inspector retains, you can configure a limit for the number of runs stored in the archive. When the number of runs in the archive reaches the size limit, the Simulation Data Inspector starts to delete runs from the archive on a first-in, first-out basis.

Configure the archive **Size** setting in the Simulation Data Inspector preferences. The size limit only applies to runs in the archive. For the Simulation Data Inspector to automatically limit data retention, select **Automatically archive** and specify the maximum number of runs to retain in the archive. By default, **Automatically archive** is enabled with an archive size limit of twenty runs. If you experience issues with logged data consuming too much disk space, consider adjusting the size limit for the archive in the Simulation Data Inspector preferences.

### Specify a Minimum Disk Space Requirement or Maximum Size for Logged Data

You can use preferences in the Simulation Data Inspector to directly limit the size of logged data by specifying a minimum amount of disk space to leave free or by specifying a maximum size for logged data on disk. Each setting accounts for all kinds of logged data. By default, logged data must leave at least 100 MB of free disk space with no maximum size limit. Specify the required disk space and maximum size in GB, and specify 0 to apply no disk space requirement or no maximum size limit.

When you specify a minimum disk space requirement or a maximum size for logged data, you can also specify whether to prioritize retaining data from the current simulation or data from prior simulations when approaching the limit. By default, the Simulation Data Inspector prioritizes

retaining data for the current run. As the free disk space or logged data size approaches the limit, prior runs are deleted first to free up space for data being logged in the current run. If deleting runs does not free up enough space, recording is disabled. To prioritize retaining prior data, change the **When low on disk space** setting to **Keep prior runs and stop recording**. You see a warning message when prior runs are deleted and when recording is disabled. If recording is disabled due to the size of logged data, you need to change the **Record Mode** back to **View and record data** to continue logging data, after you have freed up disk space.

## View Data Only During Simulation

In some situations, you may want to only view the data for logged signals and not save the values. For example, when using the Simulation Data Inspector to visualize data streaming from hardware, you may only want to view the data live and not record it. You can change the **Record mode** in the Simulation Data Inspector preferences to **View during simulation only** so that logged data is not saved and you can still view the data during simulation. The **Record mode** is reset to **View and record data** at the start of each MATLAB session.

When you change the **Record mode** to **View during simulation only**:

- Logged data is not available in the Simulation Data Inspector or workspace after simulation.
- You can view data using dashboard blocks, scopes, and the Simulation Data Inspector, but plots clear when you pan or zoom.
- You cannot access logged data during simulation using the Simulation Data Inspector programmatic interface.

## Reduce the Number of Data Points Logged from Simulation

Model configuration parameters and signal properties allow you to limit the number of data points logged in a simulation. Be sure to carefully consider data requirements when limiting logged data points. Limiting data can skip critical time points, and can lead to aliasing, if your effective sample rate is too low.

You can reduce the number of data points using:

- Decimation — Log every  $n$ th signal value.
- Limit data points to last — Only log the last  $n$  signal values.
- Logging intervals — Specify specific time intervals in which to log data.

For details, see “Specify Signal Values to Log” on page 77-27.

## Specify Signal Values to Log

### In this section...

“Decimation” on page 77-27

“Log Last n Signal Values” on page 77-28

“Specify Logging Intervals” on page 77-28

In some situations, you may not need to log signal values for every time step in a simulation. You can use several strategies to specify which signal data to log during simulation. Depending on your requirements, you can use more than one strategy for limiting the size of logged data. You can specify signal values to log using:

- Decimation — Log every  $n$ th signal value.
- Limit data points to last — Only log the last  $n$  signal values.
- Logging intervals — Specify specific time intervals in which to log data.

Carefully consider data requirements before you reduce the number of signal values logged in a simulation. Limiting data can skip critical time points, and decimation can cause aliasing if the effective sample rate is too low.

### Decimation

Decimation reduces the effective sample rate for logged data. To reduce the number of data points logged, specify a decimation factor greater than one. For example, a decimation of factor of 2 logs every other data point, reducing the number of logged points and effective sample rate by half. How you apply the decimation factor depends on the logged data you want to decimate.

Logging Method	How to Specify Decimation
Signal logging	<p>Use the Signal Properties dialog box or the Instrumentation Properties dialog box. Select <b>Decimation</b> and specify the decimation factor.</p> <p>To access the Signal Properties dialog, right-click a signal and select <b>Properties</b>.</p> <p>To access the Instrumentation Properties dialog, right-click the logging badge for a signal and select <b>Properties</b>.</p> <p>The decimation factor applies only to the selected signal. You can specify different decimation factors for different signals.</p>
Output, time, and states logging	<p>Use the <b>Decimation</b> parameter in the model configuration parameters on the <b>Data Import/Export</b> pane, under <b>Additional parameters</b>.</p> <p>The specified decimation factor applies for all logged time data, outputs, and states.</p>

Logging Method	How to Specify Decimation
Data store logging	Use the <b>Decimation</b> block parameter.
To Workspace block	The decimation factor applies only to that block.
To File block	

## Log Last $n$ Signal Values

When you only want to save or analyze the data from the end of a simulation, you can configure logging to capture only the last  $n$  signal values. How you specify the number of data points to log depends on how the data is logged.

Logging Method	How to Limit Logging to Last $n$ Points
Signal logging	<p>Use the Signal Properties dialog box or the Instrumentation Properties dialog box. Select <b>Limit data points to last</b> and specify the number of sample values to log.</p> <p>To access the Signal Properties dialog box, right-click a signal and select <b>Properties</b>.</p> <p>To access the Instrumentation Properties dialog box, right-click the logging badge for a signal and select <b>Properties</b>.</p> <p>The setting applies only to the selected signal.</p>
Output, time, and states logging	<p>Select the <b>Limit data points to last</b> parameter in the model configuration parameters on the <b>Data Import/Export</b> pane, under <b>Additional parameters</b> and specify the number of signal values to log.</p> <p>The setting applies for all logged time data, outputs, and states.</p>
Data store logging	Use the <b>Limit data points to last</b> block parameter.
To Workspace block	The setting applies only to that block.

When you only log the last simulation values, dashboard blocks and the Simulation Data Inspector do not display data during simulation.

## Specify Logging Intervals

When you only want to save and analyze data for particular time intervals, you can specify the time intervals in which to log data. Using logging intervals allows you to save specific data without changing or adding complexity to your model.

Specify logging intervals using the **Logging intervals** parameter on the model configuration parameters **Data Import/Export** pane, under **Additional parameters**. Specify the logging intervals

as an  $n$ -by-2 matrix where  $n$  is the number of intervals, the number in the first column indicates the start of the logging interval, and the number in the second column indicates the end. For example, when the **Logging intervals** setting is specified as [2, 4; 7, 9], logged data is saved between times 2 and 4 and again between times 7 and 9.

The specified logging intervals apply to:

- Time, states, and output logging.
- Signal logging.
- Data logged using the To Workspace block.
- Data logged using the To File block.
- Data logged to the workspace using the Record block.

Logging intervals do not apply to final state logging, data logged using scopes, or data logged to the Simulation Data Inspector.

When you use logging intervals, dashboard blocks only update the displayed value of a connected signal during the specified logging intervals.

## Work with Big Data for Simulations

Simulation of models with many time steps and signals can involve big data that is too large to fit into the RAM of your computer. Such situations include:

- Logging simulation data (signal logging, output port logging, and state logging)
- Loading input signal data for simulating a model
- Running multiple or parallel simulations

To work with big data for simulations, store the data to persistent storage in a MAT-file. Using big data techniques for simulations requires additional steps beyond what you do when the data is small enough to fit in workspace memory. As you develop a model, consider logging and loading simulation data without using persistent storage unless you discover that your model has big data requirements that overload memory.

### Big Data Workflow

This example is a high-level workflow for handling big data that one simulation produces and that another simulation uses as input. For more detailed information about the major workflow tasks, see:

- “Log Data to Persistent Storage” on page 77-32
- “Load Big Data for Simulations” on page 75-7
- “Analyze Big Data from a Simulation” on page 77-36

---

**Tip** This example uses a `SimulationDatastore` object for streaming data into a model. Alternatively, you can stream a `DatasetRef` object directly into a model.

---

- 1 Configure two models to log several signals.
- 2 Simulate the models, logging the data to persistent storage for each model.

```
sim(md11, 'LoggingToFile', 'on', 'LoggingFileName', 'data1.mat');
sim(md12, 'LoggingToFile', 'on', 'LoggingFileName', 'data2.mat');
```

Logging that involves big data requires saving the data to persistent storage as a v7.3 MAT-file. Only the data logged in `Dataset` format is saved to the file. Data logged in other formats, such as `Structure` with `time`, is saved in memory, in the base workspace.

The data that you log to persistent storage is streamed during the simulation in small chunks, to minimize memory requirements. The data is stored in a file that contains `Dataset` objects for each set of logged data (for example, `logout` and `xout`).

- 3 Create `DatasetRef` objects (`dsrc1` and `dsrc2`) for specific sets of logged signals. Then create `SimulationDatastore` objects (`dst1` and `dst2`) for values of elements of the `DatasetRef` objects. This example code creates a `SimulationDatastore` for the 12th element of `logout` for the first simulation. For the second simulation, the example code creates a signal with values being a `SimulationDatastore` object for the seventh element of `logout`. You can use curly braces for indexing.

```
dsrc1 = Simulink.SimulationData.DatasetRef('data1.mat', 'logout');
dsrc2 = Simulink.SimulationData.DatasetRef('data2.mat', 'logout');
```

```
dst1 = dsr1{12};
dst2 = dsr2{7};
```

- 4 Use `SimulationDatastore` objects as an external input for another simulation. To load the `SimulationDatastore` data, include it in a `Dataset` object. The datastore input is incrementally loaded from the MAT-file. The third input is a `timeseries` object, which is loaded into memory as a whole, not incrementally.

```
input = Simulink.SimulationData.Dataset;
input{1} = dst1;
input{2} = dst2;
ts = timeseries(rand(5,1),1, 'Name', 'RandomSignals');
input{3} = ts;
sim mdl3, 'ExternalInput', 'input');
```

- 5 Use MATLAB big data analysis to work with the `SimulationDatastore` objects. Create a `timetable` object by reading the values of a `SimulationDatastore` object. The `read` function reads a portion of the data. The `readall` function reads all the data.

```
tt = dst1.Values.read;
```

- 6 Set the MATLAB session as the global execution environment (`mapreducer`) for working with the tall `timetable`. Create a tall `timetable` from a `SimulationDatastore` object and read a `timetable` object with in-memory data.

```
mapreducer(0);
ttt = tall(dst1.Values);
```

---

**Tip** For another example showing how to work with big simulation data, see “Working with Big Data”.

## Log Data to Persistent Storage

### In this section...

“When to Log to Persistent Storage” on page 77-32

“Log to Persistent Storage” on page 77-33

“Enable Logging to Persistent Storage Programmatically” on page 77-33

“How Simulation Data Is Stored” on page 77-34

“Save Logged Data from Successive Simulations” on page 77-34

### When to Log to Persistent Storage

In some cases, logging simulation data can create large amounts of data that are too large for your computer to hold in working memory while also running efficiently. Such situations can include simulations that log many signals, simulations that run for a long time with many time steps, and parallel simulations. When your simulation configuration creates a large amount of data, you can log that data to persistent storage, rather than logging it to working memory.

You can store logged simulation data to persistent storage in a MAT-file. You control logging to persistent storage at the model level. You can enable and disable the feature by changing one model configuration parameter (**Log Dataset data to file**) without changing the model layout.

If you use **Dataset** format for logging, you can log each of these kinds of data to persistent storage:

- Signal logging — Uses **Dataset** format only.
- States — Defaults to **Dataset** format. You can use other formats.
- Final states — Requires that you clear the **Save final operating point** parameter
- Output — Defaults to **Dataset** format.
- Data stores — Uses **Dataset** format only.

By default, logging to persistent storage is disabled, so that logged data is stored in the MATLAB workspace. For most models, logging to the workspace is simpler because it avoids loading and saving logging files. Compared to accessing data logged to memory, accessing data logged to persistent storage requires some additional steps. For short simulations, logging to the MATLAB workspace can be faster and possibly use less memory than logging to persistent storage.

### Limitations for Logging to Persistent Storage

- Only data logged in **Dataset** format is stored in the MAT-file. Data logged in other formats is stored in the MATLAB workspace.
- To use persistent storage for logging final states data, you cannot enable the **Configuration Parameters > Data Import/Export + Save final operating point**.
- The Simulation Stepper and fast restart do not support logging to persistent storage.
- During simulation, you cannot load data from the persistent storage file directly into the model. Create objects that reference the data in the file and then load the referencing object.

### Alternative Approaches for Reducing Logging Memory Usage

When you need to simulate a model that creates a large amount of data and you do not want to log the simulation data to persistent storage, consider using one of these alternatives.

- Limit the amount of simulation data stored in the workspace.

You can limit the amount of simulation data stored in the workspace by using one or more of these techniques. For details, see “Specify Signal Values to Log” on page 77-27.

Technique	Description
Specify a decimation factor	Skip samples when exporting data.
Limit data points	Limit the number of samples saved to be only the most recent samples.
Specify intervals for logging	Specify ranges of time steps for logging.

If you limit the amount of simulation data stored in the workspace, the logged data may not contain some time steps that are critical for testing and analyzing the model.

- Use a To File block for each signal that you want to log.

Connecting a To File block to signals that you want to log stores the logged data in a MAT-file, rather than in the MATLAB workspace. However, this approach:

- Is a per-signal approach that can clutter a model with multiple To File blocks attached to individual signals.
- Creates a separate MAT-file for each To File block, instead of the single file created when you log to persistent storage.

## Log to Persistent Storage

- 1 Specify the kinds of logging to perform (for example, signal logging and output logging) and the variable names for the logging data.
- 2 In the model diagram, mark selected signals for signal logging.
- 3 Use **Dataset** format for logging the data. Data that is logged in any other format is stored in the workspace.
  - Signal logging and data store logging use **Dataset** format only. The default format for output, states, and final states logging is **Dataset**.
  - For final states logging, clear the **Save final operating point** configuration parameter.
- 4 Enable logging to persistent storage and specify an output MAT-file name.
  - Select the **Log Dataset data to file** configuration parameter.
  - Specify the MAT-file to use. Do not use a file name from one locale in a different locale.
- 5 To save the logged **Dataset** data using `timeseries` or `timetable` elements, set the **Dataset signal format** configuration parameter. The default format is `timeseries`. The `timetable` format is helpful for MATLAB combining logged data from multiple simulations. For details about the `timetable` format, see “Dataset signal format”.
- 6 Simulate the model.

## Enable Logging to Persistent Storage Programmatically

You can programmatically log to persistent storage. To enable logging to persistent storage, use the `LoggingToFile` and `LoggingFileName` name-value pairs with either the `sim` command or `set_param` command.

To enable the logging approaches that you want to use, set these parameters to 'on', as applicable:

- `SignalLogging`
- `SaveState`
- `SaveFinalState`
- `SaveOutput`
- `DSMLogging`

To log output, states, and final states data to persistent storage, set the `SaveFormat` parameter to 'Dataset'.

To log final states data to persistent storage, set the `SaveOperatingPoint` to 'off'.

## How Simulation Data Is Stored

Logging to persistent storage saves logged simulation data in the specified MAT-file. The data is stored as a `Simulink.SimulationData.Dataset` objects for each type of logging that uses `Dataset` format. The `Dataset` elements are stored as either `timeseries` or `timetable` objects, depending on how you set the **Dataset signal format** parameter. For details about the `timetable` format, see “Dataset signal format”.

The `Dataset` object name in the file is the name of the variable that you used for logging. For example, if you use the default signal logging variable `logsout`, the `Dataset` object in the MAT-file is `logsout`.

## Save Logged Data from Successive Simulations

The approach you use for saving data logged from successive simulations depends on whether you are performing parallel simulations.

### Without Using Parallel Simulations

Each time you simulate a model without using parallel simulation, Simulink overwrites the contents of the MAT-file unless you change the name of the file between simulations. When you use a `Simulink.SimulationData.DatasetRef` object that references data in the MAT-file to retrieve data in the file, it retrieves the most recent version of the data. To preserve data from an earlier simulation, use one of these approaches:

- Between simulations, use the **Configuration Parameters > Data Import/Export** pane to specify a different name for the MAT-file for logging.
- Between simulations, save a copy of the MAT-file. Use a different file name than the name that you specify as the MAT-file for persistent storage, or move the MAT-file.
- Programmatically specify a new file name for each simulation run.

If you run multiple simulations that overlap in time, use a unique MAT-file for each model that you log to persistent storage.

If you change the file name used for logging to persistent storage, then to access the logged data, use one of these approaches:

- Create a `Simulink.SimulationData.DatasetRef` object.

- To match the new file name, change the `Location` property of the `DatasetRef` objects.

For details about using `DatasetRef` objects to access logged data, see “Load Big Data for Simulations” on page 75-7.

### **With Parallel Simulations**

For parallel simulations, for which you specify an array of input objects, if you log to file, Simulink:

- Creates a MAT-file for each simulation
- Creates `Simulink.SimulationData.DatasetRef` objects to access output data in the MAT-file and includes those objects in the `SimulationOutput` object data
- Enables the `CaptureErrors` argument for simulation

For more information about parallel simulations, see “Running Multiple Simulations” on page 29-2.

## Analyze Big Data from a Simulation

### In this section...

“Create DatasetRef Objects to Access Logged Datasets” on page 77-36

“Use SimulationDatastore Objects to Access Signal Data” on page 77-36

“Create Timetables for MATLAB Analysis” on page 77-36

“Create Tall Timetables” on page 77-37

“Access Persistent Storage Metadata” on page 77-37

“Access Error Information” on page 77-37

To access data logged to a MAT-file for analysis in MATLAB, use references to the data in the MAT-file.

### Create DatasetRef Objects to Access Logged Datasets

When you log to a MAT-file, Simulink stores a `Simulink.SimulationData.Dataset` object in the specified MAT-file. The elements of the `Dataset` object in the file are `Dataset` objects. There is one `Dataset` object for each set of logged simulation data. For example, a file may contain a `Dataset` object that contains a `Dataset` object for logged signal data and another `Dataset` object for logged states data.

To access simulation `Dataset` format data for a set of logged simulation data, create `Simulink.SimulationData.DatasetRef` objects. You can access individual elements of the dataset using a `DatasetRef` object. For details, see “Load Individual Signals from a `DatasetRef` Object” on page 75-9.

### Use SimulationDatastore Objects to Access Signal Data

To access leaf signals in a logged `Dataset` object, create a `matlab.io.datastore.SimulationDatastore` object for the signal, based on the `DatasetRef` object for the `Dataset` object that contains the signal. For details, see

“Stream Individual Signals Using `SimulationDatastore` Objects” on page 75-7.

You can operate on data referenced by a `SimulationDatastore` object. For example, you can get the data in a chunk to be read into memory from the MAT-file. For an example, see `matlab.io.datastore.SimulationDatastore`.

### Create Timetables for MATLAB Analysis

When you read a `SimulationDatastore` object, using the `read` or `readall` method the output is in MATLAB timetable format. For details about the timetable format, see “Dataset signal format”.

You can use a `SimulationDatastore` object to create a timetable for the signal values and read a timetable object with in-memory data. For example, for `SimulationDatastore` object `dst1`:

```
tt = dst1.Values.read;
ttt = tall(dst1.Values);
```

## Create Tall Timetables

You can create a tall timetable:

```
mapreducer(0);
ttt = tall(dst1.Values);
```

## Access Persistent Storage Metadata

If you use persistent storage for several simulations, you can have multiple MAT-files. When you run multiple simulations using batch processing, you get multiple MAT-files if you specify a different persistent storage MAT-file for each simulation. For parallel simulations, Simulink produces a separate MAT-file for each simulation run. To help you identify and understand the context of the simulation data included in a MAT-file, Simulink stores metadata about logging to persistent storage.

A `Simulink.SimulationMetadata` object includes in its `ModelInfo` structure a `LoggingInfo` structure with two fields:

- `LoggingToFile` — Indicates whether logging to persistent storage is enabled ('on' or 'off')
- `LoggingFileName` — Specifies the resolved file name for the persistent storage MAT-file (if `LoggingToFile` is 'on').

The MAT-file used for persistent storage contains a `SimulationMetadata` variable that stores the same simulation metadata as the `Simulink.SimulationMetadata` object. The `SimulationMetadata` is a system-generated name, not a variable name that you specify.

To access the persistent logging storage metadata, use one of these alternatives:

- View simulation metadata by using the `SimulationOutput` object `SimulationMetadata` property.
- Use tab completion to access `SimulationMetadata` object properties such as `ModelInfo` and to access field names.
- Display simulation metadata in the Variable Editor. Click the `SimulationOutput` object and use one of these approaches:
  - Select the **Explore Simulation Metadata** check box (which displays the data in a tree structure).
  - Double-click the **SimulationMetadata** row.

## Access Error Information

You can view error message and information about the stack and causes for simulation data by using the `SimulationOutput` object `ErrorMessage` property. For parallel simulations, if you are logging to file, Simulink enables the `CaptureErrors` argument for simulation.

## Samples to Export for Variable-Step Solvers

### In this section...

“Output Options” on page 77-39  
 “Refine Output” on page 77-39  
 “Produce Additional Output” on page 77-39  
 “Produce Specified Output Only” on page 77-40

### Output Options

Use the **Output options** list under **Configuration Parameters > Data Import/Export > Additional parameters** to control how much output the simulation generates when your model uses a variable-step solver.

- Refine output (default)
- Produce additional output
- Produce specified output only

### Refine Output

The `Refine` output option provides additional output points when the simulation output does not include as many points as you would like. This parameter provides an integer number of output points between time steps. For example, a refine factor of 2 provides output midway between the time steps and at the steps. The default refine factor is 1.

Suppose that a sample simulation generates output at these times:

0, 2.5, 5, 8.5, 10

Choosing `Refine` output and specifying a refine factor of 2 generates output at these times:

0, 1.25, 2.5, 3.75, 5, 6.75, 8.5, 9.25, 10

To get smoother output more efficiently, change the refine factor instead of reducing the step size. When you change the refine factor, the solver generates additional points by evaluating a continuous extension formula at sample points. This option changes the simulation step size so that time steps coincide with the times that you specify for additional output.

The refine factor applies to variable-step solvers and is most useful when you are using `ode45`. The `ode45` solver can take large steps. However, when you graph simulation output, the output from this solver sometimes is not sufficiently smooth. In such cases, run the simulation again with a larger refine factor. A value of such as 4 for `ode45` can provide much smoother results.

---

**Note** This option helps the solver locate zero crossings, although it does not ensure that Simulink detects all zero crossings (see “Zero-Crossing Detection” on page 3-10).

---

### Produce Additional Output

Use the `Produce additional output` option to specify directly those additional times at which the solver generates output. When you select this option, the **Data Import/Export** pane displays an

**Output times** configuration parameter. In this parameter, enter a MATLAB expression that evaluates to an additional time or a vector of additional times. The solver produces hit times at the output times that you specify, in addition to the times it requires for accurate simulation.

Suppose that a sample simulation generates output at these times:

0, 2.5, 5, 8.5, 10

Choosing the **Produce additional output** option and specifying [0:10] generates output at these times:

0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10

and perhaps at additional times, depending on the step size chosen by the variable-step solver.

### Tips

- This option helps the solver locate zero crossings, although it does not ensure that Simulink detects all zero crossings (see “Zero-Crossing Detection” on page 3-10).
- Set the **Output times** configuration parameter to a value other than the default empty matrix ([ ]).
- For triggered subsystems and function-call subsystems, the calling function must inherit the sampling rate.

## Produce Specified Output Only

Simulink generates output at the start and stop times, in addition to the times that you specify.

Suppose that a sample simulation generates output at these times:

0, 2.5, 5, 8.5, 10

Choosing the **Produce specified output only** option and specifying [1:9] generates output at these times:

0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10

This option changes the simulation step size so that time steps coincide with the times that you specify for producing output. The solver can hit other time steps to accurately simulate the model. However, the output does not include these points. This option is useful when you are comparing different simulations to check that the simulations produce output at the same times.

### Tips

- This option helps the solver locate zero crossings, although it does not ensure that Simulink detects all zero crossings (see “Zero-Crossing Detection” on page 3-10).
- Set the **Output times** configuration parameter to a value other than the default empty matrix ([ ]).
- In normal, accelerator, and rapid accelerator modes, Simulink generates output at the start and stop times, as well as at the times that you specify.
- When you simulate a model in normal mode, triggered subsystems and function-call subsystems use:

- The times that you specify
- All the time steps in between the values that you specify
- The simulation start and stop times
- For triggered subsystems and function-call subsystems, the calling function must inherit the sampling rate.

## Save Signal Data Using Signal Logging

You can use signal logging to capture signal data from a simulation without adding blocks to your model. When signals are marked for logging, the software displays a logging badge . This example shows you how to use signal logging to log simulation data to the workspace and the Simulation Data Inspector.

To collect and use signal logging data:

- 1 “Enable Signal Logging for Model” on page 77-43.
- 2 “Mark Signals for Logging” on page 77-43.
- 3 “Simulate Model and View Data” on page 77-44.

You can also log subsets of marked signals. One approach for testing parts of a model as you develop it is to mark a superset of signals for logging and then override signal logging settings to select different subsets of signals for logging. You can use the Signal Logging Selector or a programmatic interface. For more information, see “Override Signal Logging Settings” on page 77-52.

For a summary of other approaches to capture simulation data, see “Save Simulation Data” on page 77-2.

---

**Note** Saving a custom library block with signals marked for logging can result in logging unnecessary data and is not recommended. Instead, place a custom library block with no logged signals in the model. Then, mark signals for logging only for that instance of the library block.

---

### Open Model

This example uses a model of a damped nonlinear spring given by the equation

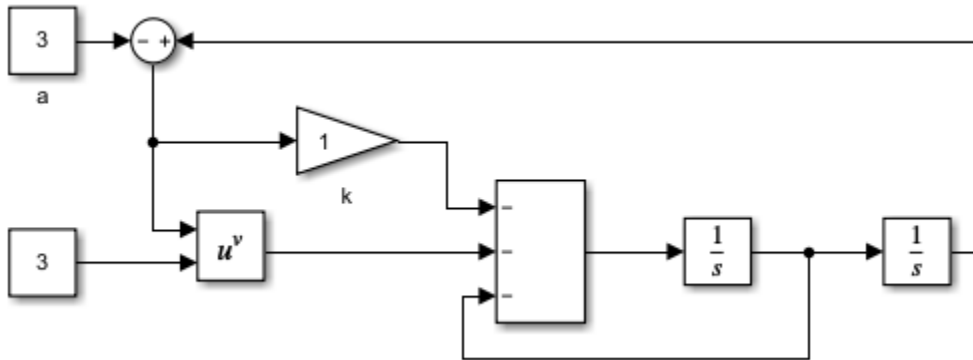

$$\ddot{x} + \dot{x} + k(x - a) + (x - a)^3 = 0,$$

where:

- $a = 3$  m is the resting length of the spring.
- $k = 1$  N/m is the spring constant.

The model does not contain any output blocks and has no signals marked for logging. This example shows how to turn on signal logging and specify signal logging names.

## Enable Signal Logging for Model

By default, signal logging is enabled. With signal logging enabled, the software logs data during simulation for signals you mark for logging. You can enable or disable signal logging for a model using the Configuration Parameters dialog box. For example, check whether signal logging is enabled for the model `damped_nonlin_spring`.

- 1 In the **Modeling** pane, select **Model Settings**.
- 2 In the **Data Import/Export** tab, make sure the **Signal logging** parameter is selected.

Signal logging is enabled, so when you mark signals in the model for logging, the software logs the signal data during simulation. If the **Signal logging** parameter is not selected, the software does not log signals that are marked for signal logging.

You can also use the `set_param` function to enable or disable signal logging for a model programmatically.

```
set_param("damped_nonlin_spring", 'SignalLogging', 'on')
```

## Mark Signals for Logging

To analyze the damped nonlinear spring dynamics, mark signals for logging. The signal coming from the Integrator block named `Integrator1` represents the position. The signal coming from the Integrator block named `Integrator` represents the velocity. To log signal data for the position and velocity of the spring, mark the signals for logging:

- 1 Select the signals in the model.
- 2 On the **Simulation** tab, click **Log Signals**.

A logging badge  indicates that the signals are marked for signal logging.

Alternatively, you can mark signals for logging programmatically using the `Simulink.sdi.markSignalForStreaming` function.

```
Simulink.sdi.markSignalForStreaming('damped_nonlin_spring/Integrator',1,'on')
Simulink.sdi.markSignalForStreaming('damped_nonlin_spring/Integrator1',1,'on')
```

You can use the **Model Data Editor** to simplify the process of marking signals for signal logging throughout a model hierarchy. The Model Data Editor displays a flat list of signals in your model that you can sort, group, and filter.

## Specify Signal Names

The signals in the `damped_nonlin_spring` model are unnamed. Naming signals that you log in a model allows you to more easily analyze the logged data. By default, the software uses the signal name in the workspace and the Simulation Data Inspector. If the signal does not have a name, the software uses a blank name when the data is logged to the workspace. The Simulation Data Inspector identifies unnamed signals by their block path and port number.

For example, to make the logged data easier to analyze, you can name the signals representing position and velocity interactively.

- 1 Double-click the signal output from the block named `Integrator1`. Then, type `position`.
- 2 Double-click the signal output from the block named `Integrator`. Then, type `velocity`.

Alternatively, you can specify signal names programmatically.

- 1 Get the port handle for the signal representing the position and the signal representing velocity.

```
posph = get_param('damped_nonlin_spring/Integrator1','PortHandles');
velph = get_param('damped_nonlin_spring/Integrator','PortHandles');
```

- 2 Use the `get_param` function to get the handle of the line connected to each port.

```
poslh = get_param(posph.Outport,'Line');
vellh = get_param(velph.Outport,'Line');
```

- 3 Use the `set_param` function to set the signal names.

```
set_param(poslh,'Name','position')
set_param(vellh,'Name','velocity')
```

You can also specify a signal logging name that is different than the signal name used in the model. Specifying a signal-level logging name can be useful for signals that you want to remain unnamed in the model or that share a duplicate name with another signal in the model hierarchy. To set a custom signal logging name, you can use the **Signal Properties** dialog box, the **Instrumentation Properties** dialog box, or the **Model Explorer**.

## Simulate Model and View Data

Because signal logging logs data to the Simulation Data Inspector, you can easily visualize simulation data. To view the logged position and velocity data in the Simulation Data Inspector:

- 1 Simulate the model.
- 2 On the **Simulation** tab, under **Review Results**, click **Data Inspector**.
- 3 In the Simulation Data Inspector, select the `position` and `velocity` signals to add the signal data to the plot area.

Initially, the spring is compressed. When released, the spring oscillates. Eventually, because the system is damped, the spring comes to rest at its resting spring length of 3 m.

For more information about viewing logged signal data in the Simulation Data Inspector, see “Inspect Simulation Data” on page 31-168 and “Create Plots Using the Simulation Data Inspector” on page 31-150.

## Access Signal Logging Data Programmatically

You can also analyze the logged workspace data using MATLAB. By default, all logged simulation data is returned as a single `Simulink.SimulationOutput` object in a variable named `out`.

`out`

`out =`

`Simulink.SimulationOutput:`

```
    logout: [1x1 Simulink.SimulationData.Dataset]
    tout: [59x1 double]
```

```
SimulationMetadata: [1x1 Simulink.SimulationMetadata]
ErrorMessage: [0x0 char]
```

Signal logging data is grouped in a `Simulink.SimulationData.Dataset` object with the default name of `logout`. When simulation results are returned as a single `Simulink.SimulationOutput` object, you can access the signal logging data using a dot.

```
out.logout
```

```
ans =
```

```
Simulink.SimulationData.Dataset 'logout' with 2 elements
```

		Name	BlockPath
1	[1x1 Signal]	velocity	damped_nonlin_spring/Integrator
2	[1x1 Signal]	position	damped_nonlin_spring/Integrator1

```
- Use braces { } to access, modify, or add elements using index.
```

When you log data to the workspace and return a single simulation output, the `Simulink.SimulationOutput` object contains a property for each logging type. For example, when you log data using signal logging and use the default workspace variable name for the `Dataset` object, the `Simulink.SimulationOutput` object has the property `logout` that contains the logged signal data. You can use the Configuration Parameters dialog box to enable or disable the **Single simulation output** parameter. For an example, see “Access Data in `Simulink.SimulationOutput` Object”.

Each signal logged using signal logging is stored as an element within the `Dataset` object. To change the workspace variable name of the signal logging `Dataset` object, you can use the text box next to the **Signal logging** parameter in the Configuration Parameters dialog box.

### Approaches for Viewing the Signal Logging Configuration

Signal Logging Configuration Viewing Approach	Usage	Documentation
In the Simulink Editor, view signal logging indicators.	<p>Consider using this approach for models that have few signals marked for signal logging and have a shallow model hierarchy.</p> <p>This approach avoids leaving the Simulink Editor.</p> <p>Open the Signal Properties dialog box for each signal.</p>	“View Signal Logging Configuration Using the Simulink Editor” on page 77-48
Use the Signal Logging Selector.	<p>Consider using this approach for models with deep hierarchies.</p> <p>View a model that has signal logging override settings for some signals.</p> <p>View the configuration as part of specifying a subset of signals for logging from all signals marked for signal logging.</p> <p>View signal logging configuration without displaying the signal logging indicators in the model.</p> <p>View signal logging configuration information such as decimation and output options in one window.</p>	“View Logging Configuration Using the Signal Logging Selector” on page 77-49
Use the Model Explorer.	<p>View signal logging configuration in the context of other model component properties.</p> <p>Adjust the column view to display signal logging properties, if necessary.</p>	“View Signal Logging Configuration Using the Model Explorer” on page 77-50

Signal Logging Configuration Viewing Approach	Usage	Documentation
Use MATLAB commands	Get the handles of the signals in the model and find the ones that have data logging enabled.	“Programmatically Find Signals Configured for Logging” on page 77-51

## View Signal Logging Configuration Using the Simulink Editor

By default, the Simulink Editor displays an indicator on each signal marked for logging. For example, this model logs the output signal of the Sine Wave block.

To view the signal properties, right-click the signal and select **Properties**.

If you programmatically override logging for a signal, the Simulink Editor continues to display the signal logging indicator for that signal. When you simulate the model, Simulink displays a red signal logging indicator for all signals marked to be logged, reflecting any overrides. For details about configuring a signal for logging, see “Mark Signals for Logging” on page 77-43.

A logged signal can also be a test point. See “Configure Signals as Test Points” on page 80-48 for information about test points.

To hide logging indicators, on the **Debug** tab, click to clear **Information Overlays > Log & Testpoint**.

## View Logging Configuration Using the Signal Logging Selector

In the **Modeling** tab, click **Model Settings**. Then, click **Configure Signals to Log**.

The **Contents** pane shows the signals marked for logging in the node selected in the **Model Hierarchy** pane. When no signals are marked for logging in a node, the **Contents** pane is empty. Use the arrow to the left of a hierarchical node to expand or collapse the contents of the node in the **Model Hierarchy** pane.

When a model includes referenced models, the check box in the **Model Hierarchy** pane indicates the override configuration for the model corresponding to the node.

Check Box	Signal Logging Configuration
<input checked="" type="checkbox"/>	For the top-level model node, logs all logged signals in the top model. For a Model block node, logs all logged signals in the model reference hierarchy for that block.
<input type="checkbox"/>	For the top-level model node, disables logging for all logged signals in the top-level model. For a Model block node, disables logging for all signals in the model reference hierarchy for that block.
<input checked="" type="checkbox"/>	For the top-level model node, logs all logged signals that have the DataLogging setting enabled. For a Model block node, logs all logged signals in the model reference hierarchy for that block that have the DataLogging setting enabled.

### View Configuration of Subsystems and Linked Libraries

The following table describes default **Model Hierarchy** pane display of subsystems, masked subsystems, and linked library nodes.

Node	Display Default
Subsystem	Displays all subsystems that include logged signals
Masked subsystem	Does not display masked subsystems

Node	Display Default
Linked library	Displays all subsystems that include logged signals

You can control how the **Model Hierarchy** pane displays subsystems, masked subsystems, and linked libraries. Use icons at the top of the **Model Hierarchy** pane or use the **View** menu, using the same approach as you use in the Model Explorer. For details, see **Model Explorer** and “Manage Existing Masks” on page 42-10.

- To display all subsystems, including subsystems that do not include signals marked for logging, select Show Subsystems with No Logged Signals  or **View > Show Subsystems with No Logged Signals**. This subsystem setting also applies to masked subsystems, if you choose to display masked subsystems.
- To display masked subsystems with logged signals, select Show Masked Subsystems  or **View > Show Masked Subsystems**
- To display linked libraries, select Show Library Links  or **View > Show Library Links**

### Filtering Signal Logging Selector Contents

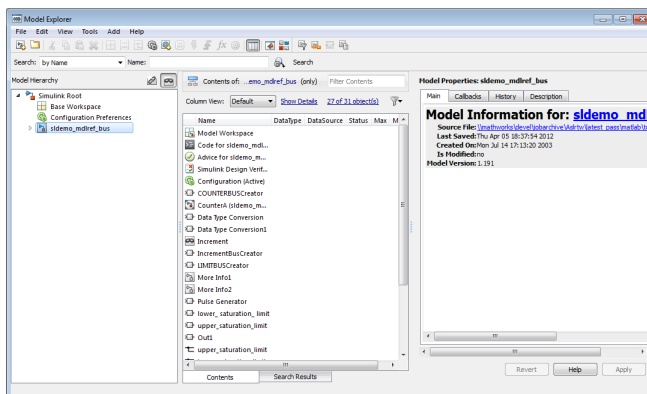

To find a specific signal or property value for a signal, use the **Filter Contents** edit box. Use the same approach as you use in the Model Explorer; for details, see **Model Explorer**.

### Highlighting a Block in a Model

To use the Model Hierarchy pane to highlight a block in model, right-click the block or signal and select **Highlight block in model**.

## View Signal Logging Configuration Using the Model Explorer

- 1 To access the logging configuration information for referenced models, open the model for which you want to view the signal logging configuration. Select the top-level model in a model reference hierarchy.
- 2 In the **Contents** pane, set **Column View** to the Signals view.

For further information, see **Model Explorer**.

## Programmatically Find Signals Configured for Logging

Use MATLAB commands to get the handles of the signals in the model and find the ones that have data logging enabled. For example:

```
mdlsignals = find_system(gcs, 'FindAll', 'on', 'LookUnderMasks', 'all', ...  
    'FollowLinks', 'on', 'type', 'line', 'SegmentType', 'trunk');  
ph = get_param(mdlsignals, 'SrcPortHandle')  
for i=1: length(ph)  
    get_param(ph{i}, 'datalogging')  
end
```

## Override Signal Logging Settings

### In this section...

“Benefits of Overriding Signal Logging Settings” on page 77-52

“Two Interfaces for Overriding Signal Logging Settings” on page 77-52

“Scope of Signal Logging Setting Overrides” on page 77-52

“Override Signal Logging Settings with Signal Logging Selector” on page 77-53

“Override Signal Logging Settings from MATLAB” on page 77-57

### Benefits of Overriding Signal Logging Settings

As you develop a model, you may want to override the signal logging settings for a specific simulation run. You can override signal logging properties without changing the model in the Simulink Editor.

To reduce memory overhead and to facilitate the analysis of simulation logging results, override signal logging properties. By overriding signal logging settings, you can avoid recompiling a model.

Overriding signal logging properties is useful when you want to:

- Focus on only a few signals by disabling logging for most of the signals marked for logging. You can mark a superset of signals for logging, and then select different subsets of them for logging.
- Exclude a few signals from the signal logging output.
- Override specific signal logging properties, such as decimation, for a signal.
- Collect only what you need when running multiple test vectors.

### Two Interfaces for Overriding Signal Logging Settings

Use either of two interfaces to override signal logging settings:

- “Override Signal Logging Settings with Signal Logging Selector” on page 77-53
- “Override Signal Logging Settings from MATLAB” on page 77-57

You can use a combination of the two interfaces. The Signal Logging Selector creates `Simulink.SimulationData.ModelLoggingInfo` objects when saving the override settings. The command-line interface has properties whose names correspond to the Signal Logging Selector interface. For example, the `Simulink.SimulationData.ModelLoggingInfo` object has a `LoggingMode` property, which corresponds to the **Logging Mode** parameter in the Signal Logging Selector.

### Scope of Signal Logging Setting Overrides

When you override signal logging settings, Simulink uses those override settings when you simulate the model.

Simulink saves in the model the signal logging override configuration that you specify. However, Simulink does not change the signal logging settings in the Signal Properties dialog box for each signal in the model.

In the Signal Logging Selector, if you override some signal logging settings, and then set the **Logging Mode** to **Log all signals as specified in model**, the logging settings defined in the model appear in the Signal Logging Selector. The override settings are greyed out, indicating that you cannot override these settings. To reactivate the override settings, set **Logging Mode** to **Override signals**. Using the Signal Logging Selector to override logging for a specific signal does not affect the signal logging indicator for that signal.

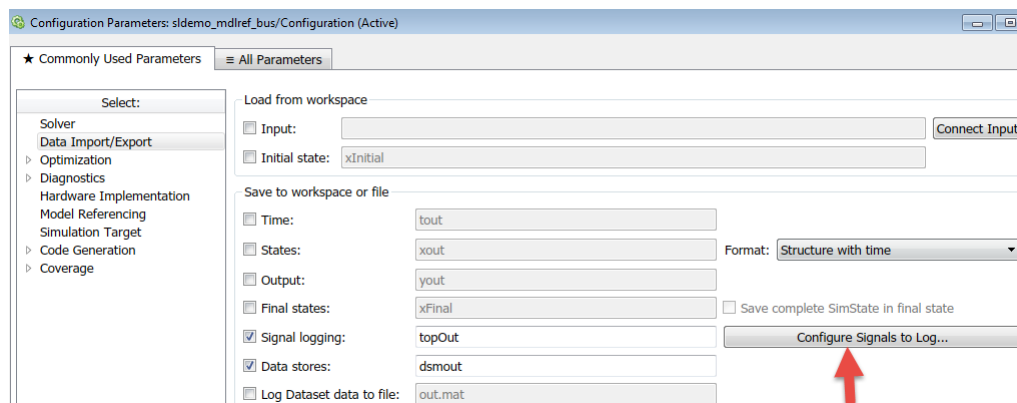

If you close and then reopen the model, the logging setting overrides that you made are in effect, if logging mode is set to override signals for that model. When the model displays the signal logging indicators, it displays the indicators for all logged signals, including logged signals that you have overridden.

**Note** The software rebuilds a model in the following situation:

- 1 The model contains one or more signals marked for signal logging.
- 2 You simulate the model in rapid accelerator mode.
- 3 You use the Signal Logging Selector or MATLAB command line to modify the signal logging configuration.
- 4 You simulate the model in rapid accelerator mode again.

## Override Signal Logging Settings with Signal Logging Selector

- 1 Open the Signal Logging Selector.
  - In the **Configuration Parameters > Data Import/Export** pane, click the **Configure Signals to Log** button.

**Tip** To enable the **Configure Signals to Log** button, select the **Signal logging** configuration parameter.

- 2 Set **Logging Mode** to **Override signals**.

**Note** The **Override signals** setting affects all levels of the model hierarchy. This setting can result in turning off logging for any signal throughout the hierarchy, based on existing settings. To review settings, select the appropriate node in the **Model Hierarchy** pane.

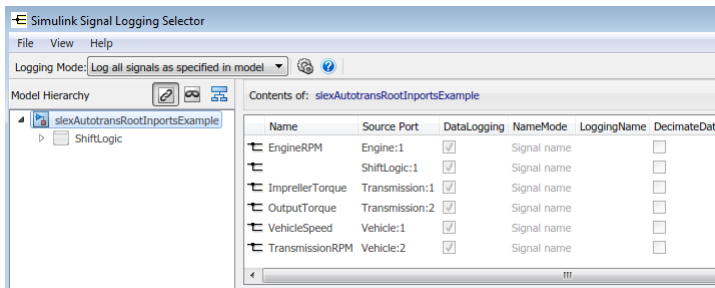

- 3 View the node containing the logged signals that you want to override. If necessary, expand nodes or configure the Model Hierarchy pane to display masked subsystems. See “View Logging Configuration Using the Signal Logging Selector” on page 77-49.
- 4 Override signal logging settings. Use one of the following approaches, depending on whether your model uses model referencing:
  - “Models Without Model Referencing: Overriding Signal Logging Settings” on page 77-54
  - “Models with Model Referencing: Overriding Signal Logging Settings” on page 77-54

**Tip** To open the **Configuration Parameters > Data Import/Export** pane from the Signal Logging Selector, use the  button.

### Models Without Model Referencing: Overriding Signal Logging Settings

If your model does not use model referencing (that is, the model does not include any Model blocks), override signal logging settings using the following procedure.

- 1 Open the Signal Logging Selector. In the **Configuration Parameters > Data Import/Export** pane, click the **Configure Signals to Log** button.
  - If necessary, select **Signal logging** to enable the **Configure Signals to Log** button.

- 2 Set **Logging Mode** to **Override signals**.
- 3 View the node containing the logged signals that you want to override. If necessary, expand nodes or configure the Model Hierarchy pane to display masked subsystems. See “View Logging Configuration Using the Signal Logging Selector” on page 77-49.
- 4 In the **Contents** pane table, select the signal whose logging settings you want to override.
- 5 Override logging settings:
  - To disable logging for a signal, clear the **DataLogging** check box for that signal.
  - To override other signal logging settings (for example, decimation), ensure that the **DataLogging** check box is selected. Then, edit values in the appropriate columns.

### Models with Model Referencing: Overriding Signal Logging Settings

If your model uses model referencing (that is, the model includes at least one Model block), override signal logging settings using one or more of these procedures:

- “Enable Logging for All Logged Signals” on page 77-55
- “Disable Logging for All Signals in Node” on page 77-55

- “Override Signal Logging for a Subset of Signals” on page 77-56
- “Override Other Signal Logging Properties” on page 77-56

### Enable Logging for All Logged Signals

By default, Simulink logs all the logged signals in a model, including the logged signals throughout model reference hierarchies.

If logging is disabled for any logged signals in the top-level model or in the top-level Model block in a model reference hierarchy, then in the **Model Hierarchy** pane, the check box to the left of that node is:

- Solid () , if logging is disabled for some of signals.
- Empty () , if logging is disabled for all the signals.

To enable logging of all logged signals for a node:

- 1 Open the Signal Logging Selector. In the **Configuration Parameters > Data Import/Export** pane, click the **Configure Signals to Log** button.
- 2 Set **Logging Mode** to **Override signals**.
- 3 View the node containing the logged signals that you want to override. If necessary, expand nodes or configure the Model Hierarchy pane to display masked subsystems. See “View Logging Configuration Using the Signal Logging Selector” on page 77-49.
- 4 In the **Model Hierarchy** pane, select the check box to the left of the node, so that the check box has a check mark ().
  - For the top-level model, logging is enabled for all logged signals in the top-level model, but not for logged signals in model reference hierarchies.
  - For a Model block at the top of a model referencing hierarchy, logging is enabled for the whole model reference hierarchy for the selected referenced model.

### Disable Logging for All Signals in Node

If signal logging is enabled for any signals in a model node, then in the **Model Hierarchy** pane, the check box to the left of the node is:

- Solid () , if logging is enabled for some signals.
- Checked () , if logging is enabled for all signals.

To disable logging for all logged signals in a node of a model:

- 1 Open the Signal Logging Selector. In the **Configuration Parameters > Data Import/Export** pane, click the **Configure Signals to Log** button.
- 2 Set **Logging Mode** to **Override signals**.
- 3 View the node containing the logged signals that you want to override. If necessary, expand nodes or configure the Model Hierarchy pane to display masked subsystems. See “View Logging Configuration Using the Signal Logging Selector” on page 77-49.
- 4 In the **Model Hierarchy** pane, clear the check box to the left of the node, so that the check box is empty ().

- For the top-level model, logging is disabled for all logged signals in the top-level model, but not for logged signals in model reference hierarchies.
- For a Model block at the top of a model referencing hierarchy, logging is disabled for the whole model reference hierarchy for the selected referenced model.

### Override Signal Logging for a Subset of Signals

To log some, but not all, logged signals in a model node:

- 1 Open the Signal Logging Selector. In the **Configuration Parameters > Data Import/Export** pane, click the **Configure Signals to Log** button.
- 2 Set **Logging Mode** to **Override signals**.
- 3 View the node containing the logged signals that you want to override. If necessary, expand nodes or configure the Model Hierarchy pane to display masked subsystems. See “View Logging Configuration Using the Signal Logging Selector” on page 77-49.
- 4 In the **Model Hierarchy** pane, ensure that the check box for the top-level model or Model block is either solid () , if logging is disabled for some of the signals, or empty () , if logging is disabled for all the signals. Click the check box to cycle through different states.
- 5 In the **Contents** pane table, for the signals that you want to log, select the check box in the **DataLogging** column.

To enable logging for multiple signals, hold the **Shift** or **Ctrl** key and select a range of signals or individual signals. Select the check box in the **DataLogging** column of one of the highlighted signals.

### Override Other Signal Logging Properties

In addition to overriding the setting for the **DataLogging** property for a signal, you can override other signal logging properties, such as decimation.

- 1 Open the Signal Logging Selector. In the **Configuration Parameters > Data Import/Export** pane, click the **Configure Signals to Log** button.
- 2 Set **Logging Mode** to **Override signals**.
- 3 View the node containing the logged signals that you want to override. If necessary, expand nodes or configure the Model Hierarchy pane to display masked subsystems. See “View Logging Configuration Using the Signal Logging Selector” on page 77-49.
- 4 In the **Model Hierarchy** pane, ensure that the check box for the top-level model or Model block is solid () if logging is disabled for some signals, or empty () , if logging is disabled for all signals. Click the check box to cycle through different states.
- 5 In the **Contents** pane table, for the signals for which you want to override logging properties, enable logging by selecting the check box in the **DataLogging** column.

To enable logging for multiple signals, hold the **Shift** or **Ctrl** key and select a range of signals or individual signals. Select the check box in the **DataLogging** column of one of the highlighted signals.

- 6 In the **Contents** pane table, modify the settings for properties, such as **DecimateData** and **Decimation**.

## Override Signal Logging Settings from MATLAB

You can use the MATLAB command-line interface for overriding signal logging settings.

- To query a model for its signal logging override status, use the `DataLoggingOverride` model parameter.
- To configure signal logging from the command line, use functions and properties of the following objects:
  - `Simulink.SimulationData.ModelLoggingInfo` — Override settings for a model. This object corresponds to the overall Signal Logging Selector interface.
  - `Simulink.SimulationData.SignalLoggingInfo` — Override settings for a specific signal. This object corresponds to a row in the logging property table in the Signal Logging Selector:
  - `Simulink.SimulationData.LoggingInfo` — Override settings for the `LoggingInfo` property of a `Simulink.SimulationData.SignalLoggingInfo`. This object corresponds to the editable columns in a row in the logging property table in the Signal Logging Selector.
- To apply the configuration, use the `set_param` function with the `DataLoggingOverride` model parameter.

You can control the kinds of systems from which to include logged signals. By default, the `Simulink.SimulationData.ModelLoggingInfo` object includes logged signals from:

- Libraries
- Masked subsystems
- Referenced models
- Active variants

The following sections describe how to use the command-line interface to perform some common signal logging configuration tasks.

- “Create Model Logging Override Object with Logged Signals” on page 77-57
- “Log Top-Level and Referenced Models as Specified in Model” on page 77-58
- “Set Logging Mode of Model Logging Override Object” on page 77-59
- “Override Signal Logging Settings for Specific Signal” on page 77-60
- “Log Subset of Sample Points” on page 77-61

### Create Model Logging Override Object with Logged Signals

You can create a model logging override object for the model `sldemo_mdhref_bus` and automatically add each logged signal in the model to that object. The model `sldemo_mdhref_bus` has four signals marked for logging.

```
mdl = 'sldemo_mdhref_bus';
open_system(mdl)
mdlInfo = Simulink.SimulationData.ModelLoggingInfo.createFromModel(mdl)

mdlInfo =
  ModelLoggingInfo with properties:
      Model: 'sldemo_mdhref_bus'
```

```

        LoggingMode: 'OverrideSignals'
LogAsSpecifiedByModels: {}
        Signals: [1x4 Simulink.SimulationData.SignalLoggingInfo]

```

The `LoggingMode` property is set to `'OverrideSignals'`, which configures the model logging override object to log only the signals specified in the `Signals` property.

Apply the model override object settings. The software saves the settings when you save the model.

```
set_param mdl, 'DataLoggingOverride', mdlInfo;
```

### Log Top-Level and Referenced Models as Specified in Model

You can control whether a top-level model and referenced models use override signal logging settings or use the signal logging settings specified by the model. This example shows how to log all signals as specified in the top model and all referenced models.

The model `sldemo_mdhref_bus` has four signals marked for logging. For more information about the model, see “Interface Specification Using Bus Objects”.

```
mdl = "sldemo_mdhref_bus";
open_system(mdl)
```

Create a model logging override object.

```
mdlInfo = Simulink.SimulationData.ModelLoggingInfo(mdl);
```

To specify whether to use the signal logging settings as specified in the model and all referenced models, or to override those settings, use the `LoggingMode` property of the model logging override object.

```
mdlInfo.LoggingMode = 'LogAllAsSpecifiedInModel'
```

```
mdlInfo =
```

```
ModelLoggingInfo with properties:
```

```

        Model: 'sldemo_mdhref_bus'
        LoggingMode: 'LogAllAsSpecifiedInModel'
LogAsSpecifiedByModels: {}
        Signals: [0x0 Simulink.SimulationData.SignalLoggingInfo]

```

Use the `set_param` function to apply the model override object settings. The software saves the settings when you save the model.

```
set_param(mdl, 'DataLoggingOverride', mdlInfo);
```

Simulate the model. The signal logging output is stored in `topOut`.

```
sim(mdl);
topOut
```

```
topOut =
Simulink.SimulationData.Dataset 'topOut' with 4 elements
```

	Name	BlockPath
1 [1x1 Signal]	COUNTERBUS	sldemo_mdref_bus/Concatenate
2 [1x1 Signal]	OUTERDATA	sldemo_mdref_bus/CounterA
3 [1x1 Signal]	INCREMENTBUS	sldemo_mdref_bus/IncrementBusCreator
4 [1x1 Signal]	INNERDATA	...erA\sldemo_mdref_counter_bus/COUNTER

- Use braces { } to access, modify, or add elements using index.

## Set Logging Mode of Model Logging Override Object

You can use the `setLogAsSpecifiedInModel` function to override signal logging settings specified in a model. For example, you can log only the top model or only a referenced model in a model hierarchy. The model `sldemo_mdref_bus` contains a Model block named `CounterA` that references the model `sldemo_mdref_counter_bus`. In total, four signals are marked for logging. The top model has three signals marked for logging: `COUNTERBUS`, `INCREMENTBUS`, and `OUTERDATA`. The referenced model has one signal marked for logging: `INNERDATA`.

```
mdl = 'sldemo_mdref_bus';
mdlInner = 'sldemo_mdref_bus/CounterA';
open_system(mdl)
```

Create an empty `Simulink.SimulationData.ModelLoggingInfo` object so that no signals are logged when the logging mode is set to the override settings specified in the `Signals` property.

```
mdlInfo = Simulink.SimulationData.ModelLoggingInfo(mdl);
```

You can use the `setLogAsSpecifiedInModel` function to log only signals in the top model using the logging settings specified in that model. Set the outer model to log signals as specified in the model. Then, set the inner model to use override settings. Since the `Signals` property vector is empty, no signals are logged when override settings are applied.

```
mdlInfo = setLogAsSpecifiedInModel(mdlInfo,mdl,true);
mdlInfo = setLogAsSpecifiedInModel(mdlInfo,mdlInner,false);
```

The `getLogAsSpecifiedInModel` function returns the logging mode.

```
outerLogMode = getLogAsSpecifiedInModel(mdlInfo,mdl)
```

```
outerLogMode = logical
    1
```

```
innerLogMode = getLogAsSpecifiedInModel(mdlInfo,mdlInner)
```

```
innerLogMode = logical
    0
```

Apply the model override object settings. Then, simulate the model. The software logs only those signals marked for logging in the top model.

```
set_param(mdl, 'DataLoggingOverride',mdlInfo);
sim(mdl);
topOut
```

```
topOut =
Simulink.SimulationData.Dataset 'topOut' with 3 elements
```

		Name	BlockPath
1	[1x1 Signal]	COUNTERBUS	sldemo_mdref_bus/Concatenate
2	[1x1 Signal]	OUTERDATA	sldemo_mdref_bus/CounterA
3	[1x1 Signal]	INCREMENTBUS	sldemo_mdref_bus/IncrementBusCreator

- Use braces { } to access, modify, or add elements using index.

You can also use the `setLogAsSpecifiedInModel` function to log only signals in the referenced model using the logging settings specified in that model. Set the outer model to use override settings. Then, set the inner model to log signals as specified in the model.

```
mdlInfo = setLogAsSpecifiedInModel(mdlInfo,mdl,false);
mdlInfo = setLogAsSpecifiedInModel(mdlInfo,mdlInner,true);
```

To verify that the logging mode for the top model and inner model have changed, you can use the `getLogAsSpecifiedInModel` function .

```
outerLogMode = getLogAsSpecifiedInModel(mdlInfo,mdl)
outerLogMode = logical
0
```

```
innerLogMode = getLogAsSpecifiedInModel(mdlInfo,mdlInner)
innerLogMode = logical
1
```

Apply the model override object settings. Then, simulate the model. This time, the software logs only the INNERDATA signal.

```
set_param(mdl, 'DataLoggingOverride',mdlInfo);
sim(mdl);
topOut
```

```
topOut =
Simulink.SimulationData.Dataset 'topOut' with 1 element
```

		Name	BlockPath
1	[1x1 Signal]	INNERDATA	...erA sldemo_mdref_counter_bus/COUNTER

- Use braces { } to access, modify, or add elements using index.

### Override Signal Logging Settings for Specific Signal

You can use `Simulink.SignalData.SignalLoggingInfo` objects to programmatically override logging settings for specific signals. For example, you can create a `Simulink.SimulationData.SignalLoggingInfo` object to override the signal logging settings such that only one of several signals marked for logging is logged.

This example uses a model of a rotating clutch system. In the model, ten signals are marked for logging. For more information about the model, see “Building a Clutch Lock-Up Model”.

```
mdl = "sldemo_clutch_override";
open_system(mdl);
```

You can use a `Simulink.SimulationData.SignalLoggingInfo` object to log only the `VehicleSpeed` signal. The `VehicleSpeed` signal is connected the second output port of the `Unlocked` subsystem. Create a `Simulink.SimulationData.SignalLoggingInfo` object for the `VehicleSpeed` signal by using the `BlockPath` and `OutputPortIndex` properties.

```
blkPath = "sldemo_clutch_override/Unlocked";
portNum = 2;
sigInfo = Simulink.SimulationData.SignalLoggingInfo(blkPath,portNum);
```

Create an empty `Simulink.SimulationData.ModelLoggingInfo` object. Then, assign the signal logging override settings `sigInfo` to the model logging information object.

```
mdlInfo = Simulink.SimulationData.ModelLoggingInfo(mdl);
mdlInfo.Signals(1) = sigInfo;
```

Use the `verifySignalAndModelPaths` function to ensure that you specified valid signal logging settings for the model.

```
verifiedObj = verifySignalAndModelPaths(mdlInfo)
```

```
verifiedObj =
  ModelLoggingInfo with properties:
      Model: 'sldemo_clutch_override'
  LoggingMode: 'OverrideSignals'
  LogAsSpecifiedByModels: {}
  Signals: [1x1 Simulink.SimulationData.SignalLoggingInfo]
```

Apply the model override object settings using the `set_param` function.

```
set_param(mdl, 'DataLoggingOverride',mdlInfo)
```

Simulate the model. Verify that `VehicleSpeed` is the only signal logged by accessing the `Simulink.SimulationData.Dataset` object `sldemo_clutch_output`.

```
sim(mdl);
sldemo_clutch_output

sldemo_clutch_output =
  Simulink.SimulationData.Dataset 'sldemo_clutch_output' with 1 element
```

	Name	BlockPath
1 [1x1 Signal]	VehicleSpeed	sldemo_clutch_override/Unlocked

- Use braces { } to access, modify, or add elements using index.

## Log Subset of Sample Points

You can use a `Simulink.SimulationData.LoggingInfo` object to create a set of signal logging override settings for a signal. For example, you can change the decimation settings to log a subset of sample points in a signal.

Open the model `sldemo_mdref_bus`. By default, the model does not decimate data. For more information about the model, see “Interface Specification Using Bus Objects”.

```
mdl = "sldemo_mdref_bus";  
open_system(mdl)
```

You can override signal logging settings so the software logs only a subset of sample points in the COUNTERBUS signal by specifying a decimation factor in the `LoggingInfo` property of a signal logging override object. First, create a `Simulink.SimulationData.LoggingInfo` object with default settings.

```
logInfo = Simulink.SimulationData.LoggingInfo;
```

Change the `DecimateData` and `Decimation` properties to log every tenth data point, starting with the first sample point.

```
logInfo.DecimateData = true;  
logInfo.Decimation = 10;
```

Create a `Simulink.SimulationData.SignalLoggingInfo` object for the COUNTERBUS signal. Then, to log only the subset of data points in the COUNTERBUS signal, set the `LoggingInfo` property of the signal logging override object to `logInfo`.

```
blkPath = "sldemo_mdref_bus/Concatenate";  
sigInfo = Simulink.SimulationData.SignalLoggingInfo(blkPath);  
sigInfo.LoggingInfo = logInfo;
```

Create an empty `Simulink.SimulationData.ModelLoggingInfo` object. Then, assign the signal logging override settings `sigInfo` to the model logging information object.

```
mdlInfo = Simulink.SimulationData.ModelLoggingInfo(mdl);  
mdlInfo.Signals = sigInfo;
```

Apply the model override object settings using the `set_param` function.

```
set_param(mdl, 'DataLoggingOverride', mdlInfo)
```

## View and Access Signal Logging Data

### In this section...

“Signal Logging Object” on page 77-63

“Access Data Programmatically” on page 77-63

“Handling Spaces and Newlines in Logged Names” on page 77-65

“Access Logged Signal Data in ModelDataLogs Format” on page 77-66

You can view logged signal data during simulation using the **Simulation Data Inspector**, or for paused or stopped simulations, using other visualization interfaces. See “Decide How to Visualize Simulation Data” on page 33-2.

Alternatively, you can access signal logging data programmatically, using MATLAB commands.

---

**Tip** If you do not see logging data for a signal that you marked in the model for signal logging, check the logging configuration. Use the Signal Logging Selector to enable logging for a signal whose logging is overridden. For details, see “View the Signal Logging Configuration” on page 77-47 and “Override Signal Logging Settings” on page 77-52.

---

### Signal Logging Object

The software saves signal logging data in a `Simulink.SimulationData.Dataset` object, which is a MATLAB workspace variable. The default name of the signal logging variable is `logouts`. You can change the variable name using the text box next to the **Signal logging** parameter in the Configuration Parameters dialog box.

You can specify whether you want the data for individual signals in a dataset to use MATLAB `timeseries` or `timetable` elements by setting the **Dataset signal format** configuration parameter. For details, see “Dataset signal format”.

Releases earlier than R2016a also supported a `ModelDataLogs` format. For details, see “Convert Data to Dataset Format” on page 77-17.

To search for specific elements in a `Dataset` object, use the `find` function. To return the names of the `Dataset` object elements, use the `getElementNames` function.

---

**Tip** To call a function on each specified MATLAB `timeseries` object, you can use the `Simulink.SimulationData.forEachTimeseries` function. For example, you can use this function to make it easy to resample every element of a structure of `timeseries` objects obtained by logging a bus signal.

---

### Access Data Programmatically

Access a `Simulink.SimulationData.Dataset` object and its elements.

Simulate the model `sldemo_clutch`, which models a rotating clutch system. Then, access the `Dataset` object `sldemo_clutch_output`, which contains the signal logging data. For more information about the model, see “Building a Clutch Lock-Up Model”.

```
sim("sldemo_clutch");
sldemo_clutch_output

sldemo_clutch_output =
Simulink.SimulationData.Dataset 'sldemo_clutch_output' with 10 elements
```

	Name	BlockPath
1 [1x1 Signal]	Fn	sldemo_clutch/Clutch Pedal
2 [1x1 Signal]	Tin	sldemo_clutch/Engine Torque
3 [1x1 Signal]	LockedFlag	sldemo_clutch/Friction Mode Logic
4 [1x1 Signal]	LockupFlag	sldemo_clutch/Friction Mode Logic
5 [1x1 Signal]	UnlockFlag	sldemo_clutch/Friction Mode Logic
6 [1x1 Signal]	Tfmaxk	sldemo_clutch/Friction Model
7 [1x1 Signal]	Tfmaxs	sldemo_clutch/Friction Model
8 [1x1 Signal]	ShaftSpeed	sldemo_clutch/Locked
9 [1x1 Signal]	EngineSpeed	sldemo_clutch/Unlocked
10 [1x1 Signal]	VehicleSpeed	sldemo_clutch/Unlocked

- Use braces `{ }` to access, modify, or add elements using index.

To access `Dataset` object elements, you can use indexing with curly braces. For example, access the `Tin` element of the signal logging `Dataset` object using the index 2.

```
e12 = sldemo_clutch_output{2}

e12 =
Simulink.SimulationData.Signal
Package: Simulink.SimulationData

Properties:
    Name: 'Tin'
    PropagatedName: ''
    BlockPath: [1x1 Simulink.SimulationData.BlockPath]
    PortType: 'outport'
    PortIndex: 1
    Values: [1x1 timeseries]
```

Methods, Superclasses

The signal data is stored in the `Values` property of the `Simulink.SimulationData.Signal` object as a `timeseries` object. The time values are in the `Time` property of the `timeseries` object. The signal values are in the `Data` property.

```
e12.Values

timeseries

Common Properties:
    Name: 'Tin'
    Time: [387x1 double]
    TimeInfo: tsdata.timemetadadata
```

```
Data: [387x1 double]
DataInfo: tsdata.datametadate
```

## Handling Spaces and Newlines in Logged Names

This example shows three signals that illustrate how signal logging names:

- A signal with a name that contains a space
- A signal with a name that contains a newline
- An unnamed signal that originates on a block with a name that contains a newline

Simulate the model and then look at the signal logging results in the `logouts` variable. You can see that the names in the `Dataset` object use a space where the signal name contained a space and a newline where the name contained a newline. The unnamed signal has an empty character array as its name.

```
logouts
```

```
logouts =
```

```
Simulink.SimulationData.Dataset 'logouts' with 3 elements
```

	Name	BlockPath
1 [1x1 Signal]	x y	ex_signal_names_with_spaces/Sine Wave
2 [1x1 Signal]	a b	ex_signal_names_with_spaces/Sine Wave1
3 [1x1 Signal]	' '	ex_signal_names_with_spaces/Sine Wave2

- Use braces `{ }` to access, modify, or add elements using index.

You can access a signal with a name that contains a space by name or by index. Include the space in the name you pass to the `getElement` function. To access a signal with a name that contains a newline, use the index.

```
>> logouts{2}
```

```
ans =
```

```
Simulink.SimulationData.Signal  
Package: Simulink.SimulationData
```

```
Properties:
```

```
    Name: 'a+b'  
PropagatedName: ''  
    BlockPath: [1x1 Simulink.SimulationData.BlockPath]  
    PortType: 'output'  
    PortIndex: 1  
    Values: [1x1 timeseries]
```

## Access Logged Signal Data in ModelDataLogs Format

Before R2016a, you could log signals in `ModelDataLogs` format. Starting in R2016a, you cannot log data in the `ModelDataLogs` format. Signal logging uses the `Dataset` format.

If you have already logged signal data in the `ModelDataLogs` format, you can use the `convertToDataset` function to update the signal logging data to use `Dataset` format. For more information, see “Migrate Legacy Code That Uses `ModelDataLogs`” on page 77-22.

## Log Signals in For-Each Subsystems

### In this section...

“Log Signal in Nested For-Each Subsystem” on page 77-67

“Log Bus Signals in For-Each Subsystem” on page 77-69

The approach you use to log data for a signal in a for-each subsystem depends on whether the signal is a:

- Nonbus signal — Log directly in a for-each subsystem.
- A bus or array of buses signal — Use one of these approaches:
  - Use a Bus Selector block to select the signals you want to log and mark those signals for signal logging. This approach works well for many models.
  - Attach the signal to an Outport block and log the signal outside of the for-each subsystem. Use this approach when you want to log a whole bus signal, and that bus signal includes many bus element signals.

---

**Note** You cannot log bus signals directly in a for-each subsystem.

You cannot log a signal inside a referenced model that is inside a for-each subsystem if either of these conditions exists:

- The for-each subsystem is in a model simulating in rapid accelerator mode.
  - The for-each subsystem is at the root-level of a model that is referenced by a Model block in accelerator mode.
- 

The data for each logged signal in a for-each subsystem is saved in a separate **Dataset** element as a `Simulink.SimulationData.Signal` object. The format of the logged signal data depends on how you set the **Dataset signal format** configuration parameter:

- If the setting is `timeseries`, then each signal object contains an array of MATLAB `timeseries` objects. The array keeps the data from different for-each iteration separate.
- If the setting is `timetable`, then each signal object contains a cell array of MATLAB `timetable` objects. The dimensions of this array match the number of for-each iterations. For example, if the for-each subsystem has three iterations, then the logged data has a 3x1 array of `timeseries` or `timetable` objects. Each layer of nesting adds another dimensions to the logged data if you use nested for-each subsystems.

### Log Signal in Nested For-Each Subsystem

Open the model `ex_loginsideforeach_nested`.

```
mdl = "ex_loginsideforeach_nested";
open_system(mdl)
```

In the Simulink® Editor, open the For Each Subsystem1 block. Inside that subsystem, open the For Each Subsystem2 block.

Simulate the model.

```
sim mdl;
```

Examine the signal logging data for the first iteration of the top subsystem and the third iteration of the bottom subsystem. The 2x3 timeseries results from two iterations at the first for-each level and three iterations at the second (nested) level.

```
logout.get('nestedDelay')
```

```
ans =
  Simulink.SimulationData.Signal
  Package: Simulink.SimulationData

  Properties:
    Name: 'nestedDelay'
    PropagatedName: ''
    BlockPath: [1x1 Simulink.SimulationData.BlockPath]
    PortType: 'outport'
    PortIndex: 1
    Values: [2x3 timeseries]
```

Methods, Superclasses

Return the values of the nestedDelay object.

```
logout.get('nestedDelay').Values(1,3)
```

```
timeseries
```

```
Common Properties:
  Name: 'nestedDelay'
  Time: [5x1 double]
  TimeInfo: tsdata.timemetadata
```

```
Data: [1x1x5 double]
DataInfo: tsdata.datametadate
```

## Log Bus Signals in For-Each Subsystem

This example logs two bus signals, LIMITBUS and COUNTERBUS, in a for-each subsystem using signal logging. The elements of LIMITBUS are logged individually inside the for-each subsystem. The COUNTERBUS data is logged outside the for-each subsystem.

Open the `ex_for_each_log_bus` model.

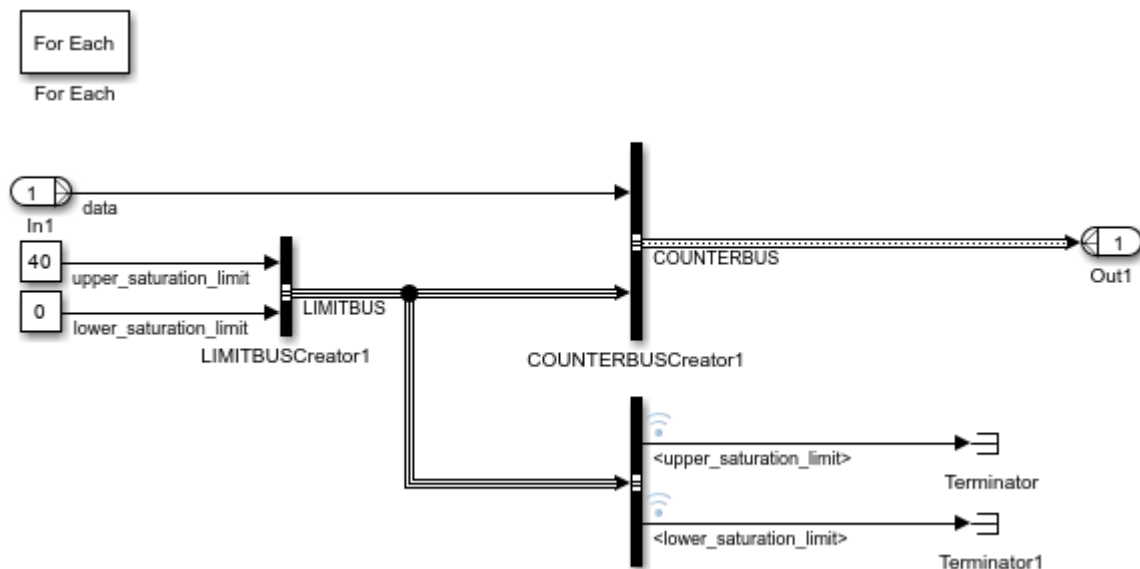

```
mdl = "ex_for_each_log_bus";
open_system(mdl)
```

In the Simulink® Editor, open the For Each Subsystem block.

To log the elements of LIMITBUS separately inside the for-each subsystem, the bus is connected to a Bus Selector block. Then, the individual signals are marked for logging.

To log COUNTERBUS outside the for-each subsystem, the bus data is output to the top-level model using an Outport block. Then, the `OutsideForEach` bus is marked for logging in the top-level model. To have the bus signal cross the subsystem boundary, the Bus Creator block that creates COUNTERBUS has the **Output data type** parameter set to `Bus: COUNTERBUS` and the **Output as nonvirtual bus** check box selected.

Simulate the model.

```
out1 = sim('ex_for_each_log_bus');
```

Examine the signal logging output `logout`. Signal logging logs data in `Dataset` format. By default, the data for each logged signal or bus element is stored in the `Dataset` object as a `timeseries`.

```
out1.logout
```

```
ans =
Simulink.SimulationData.Dataset 'logout' with 3 elements
```

		Name	BlockPath
1	[1x1 Signal]	OutsideForEach	ex_for_each_log_bus/For Each Subsystem
2	[1x1 Signal]	<lower_saturation_limit>	...g_bus/For Each Subsystem/Bus Selector
3	[1x1 Signal]	<upper_saturation_limit>	...g_bus/For Each Subsystem/Bus Selector

- Use braces `{ }` to access, modify, or add elements using index.

Access the `<lower_saturation_limit>` object, which is logged inside the for-each subsystem, using curly braces to get the second element in the `Dataset` object `logout`.

```
lowerLimTS = out1.logout{2}
```

```
lowerLimTS =
Simulink.SimulationData.Signal
Package: Simulink.SimulationData

Properties:
    Name: '<lower_saturation_limit>'
    PropagatedName: ''
    BlockPath: [1x1 Simulink.SimulationData.BlockPath]
    PortType: 'outport'
    PortIndex: 2
    Values: [3x1 timeseries]
```

Methods, Superclasses

```
lowerLimTS.Values
```

3x1 timeseries array with properties:

```
Events
Name
UserData
Data
DataInfo
Time
TimeInfo
Quality
QualityInfo
IsTimeFirst
TreatNaNasMissing
Length
```

Access the `OutsideForEach` object, which is logged outside the for-each subsystem, using curly braces to get the first element in the `Dataset` object `logout`.

```
outsideTS = out1.logout{1}
```

```
outsideTS =
  Simulink.SimulationData.Signal
  Package: Simulink.SimulationData

  Properties:
      Name: 'OutsideForEach'
      PropagatedName: ''
      BlockPath: [1x1 Simulink.SimulationData.BlockPath]
      PortType: 'outport'
      PortIndex: 1
      Values: [3x1 struct]
```

Methods, Superclasses

```
outsideTS.Values
```

```
ans=3x1 struct array with fields:
    data
    limits
```

If the `Dataset` signal format is `timetable`, then the software stores each logged signal or bus element in the `Dataset` object as a `timetable`. Specify the `Dataset` signal format as `timetable`. Then, simulate the model again.

```
out2 = sim('ex_for_each_log_bus', 'DatasetSignalFormat', 'timetable');
```

The data for the `<lower_saturation_limit>` object and the `OutsideForEach` object is now stored as a `timetable`.

```
lowerLimTT = out2.logout{2}
```

```
lowerLimTT =
  Simulink.SimulationData.Signal
  Package: Simulink.SimulationData

  Properties:
      Name: '<lower_saturation_limit>'
      PropagatedName: ''
      BlockPath: [1x1 Simulink.SimulationData.BlockPath]
      PortType: 'outport'
      PortIndex: 2
      Values: {3x1 cell}
```

Methods, Superclasses

```
lowerLimTT.Values
```

```
ans=3x1 cell array
    {1x1 timetable}
    {1x1 timetable}
```

```
{1x1 timetable}

outsideTT = out2.logout{1}

outsideTT =
  Simulink.SimulationData.Signal
  Package: Simulink.SimulationData

Properties:
  Name: 'OutsideForEach'
  PropagatedName: ''
  BlockPath: [1x1 Simulink.SimulationData.BlockPath]
  PortType: 'outport'
  PortIndex: 1
  Values: [3x1 struct]

Methods, Superclasses

outsideTT.Values

ans=3x1 struct array with fields:
  data
  limits
```

## Save Block States and Simulation Operating Points

During simulation, blocks in a model calculate an output value for each time step using the simulation time and inputs to the block. Some blocks also store information about their state and use that state information along with the block inputs and simulation time to calculate the output value for each time step. For example, the Unit Delay block stores the output signal value from the previous time step as its state and uses that information to calculate the output value for the current time step.

In addition to block states, other aspects of the model have state information that affects the simulation. The model operating point represents the complete set of block states and the state of the model, including the simulation time, the solver state, and the execution engine state.

Using logged block states, final states, and operating points, you can:

- Analyze changes in block states throughout a simulation.
- Specify initial states for blocks in the model.
- Run a set of simulations more quickly by simulating from an initial operating point.

### Choose Which State Information to Log

Depending on how you want to use the state information, you can configure your model to:

- Log block states for every simulation time step.
- Log a snapshot of block states when the simulation is paused or when the simulation stops.
- Log the complete model operating point when the simulation is paused or when the simulation stops.

To analyze how block states change throughout simulation, log block states for each simulation step using the **States** configuration parameter. To save a snapshot of the model for a given simulation time, log final states, with or without the complete model operating point.

You can log states and final states in the same simulation. When you log final states, you choose whether to save a snapshot of the simulation state that only includes block states or a snapshot that captures the complete model operating point. When the model is configured to return a single simulation output, logged states and final states are returned as part of the `Simulink.SimulationOutput` object.

To configure states logging for a model, use the Configuration Parameters dialog box. On the **Modeling** tab, click **Model Settings**, then select **Data Import/Export**.

Model Configuration Parameter	Type of State Information Saved	When State Information Is Saved	How State Information Is Saved	Default Variable Name
<b>States</b>	Block states	Each simulation time step	In format specified using <b>Format</b> parameter	xout
<b>Final states</b>	Block states	When simulation is paused or stopped	In format specified using <b>Format</b> parameter	xFinal

Model Configuration Parameter	Type of State Information Saved	When State Information Is Saved	How State Information Is Saved	Default Variable Name
<p><b>Final states and Save final operating point</b></p>	<p>Complete simulation state for the model, including:</p> <ul style="list-style-type: none"> <li>• Block states</li> <li>• Hidden states that are not captured by states logging, including states for: <ul style="list-style-type: none"> <li>• Transport Delay blocks</li> <li>• Variable Transport Delay blocks</li> <li>• From Workspace blocks</li> <li>• For Each Subsystem blocks</li> <li>• Conditionally executed subsystems</li> <li>• Stateflow charts</li> <li>• MATLAB System blocks</li> <li>• S-functions that implement custom operating point methods</li> <li>• Simscape Multibody second-generation blocks</li> </ul> </li> </ul>	<p>When simulation is paused or stopped</p>	<p>As a Simulink.op.ModelOperatingPoint object</p> <p>The <code>loggedStates</code> property of the <code>ModelOperatingPoint</code> object stores the block states in the format specified by the <b>Format</b> parameter.</p>	<p><code>xFinal</code></p>

Model Configuration Parameter	Type of State Information Saved	When State Information Is Saved	How State Information Is Saved	Default Variable Name
	<ul style="list-style-type: none"> <li>• Solver and execution engine states</li> <li>• Zero-crossing information</li> <li>• Output values for blocks where the output value is needed to restore the simulation state</li> </ul>			

Not all modeling patterns and workflows provide complete support for logging states and final states. Support for logging block states throughout the simulation depends on the format you use. For more information, see “Choose Format for Logged State Information” on page 77-78.

Support for saving final states depends on whether you save the model operating point and the format you use. When deciding how to save final states, consider your modeling requirements and how you want to use the final state.

Modeling Pattern or Workflow	Final States Without Operating Point	Final States with Operating Point
Faster simulation workflow	<p>Final states without operating point are not always sufficient to resume a simulation from a particular state and time without changing computed results.</p> <p>If you are unsure of the requirements for your model, use an operating point to simulate a model from a particular state.</p>	<p>Use model operating points to save time by not repeatedly running segments of a simulation that do not change from one scenario to the next. Results from a simulation that starts from an operating point match exactly the results from an uninterrupted simulation that runs from the start.</p> <p>When you use an operating point as the initial state:</p> <ul style="list-style-type: none"> <li>• The <b>Start time</b> for the simulation matches the <b>Start time</b> for the simulation that produced the operating point.</li> <li>• The simulation computes results starting from the time at which the operating point was created, saved in the <code>snapshotTime</code> property of the <code>ModelOperatingPoint</code> object.</li> </ul> <p>For more information, see “Use Model Operating Point for Faster Simulation Workflow” on page 27-44.</p>
Restore simulation time	<p>Simulations that use final state as initial state start from the start time you specify using the <b>Start time</b> configuration parameter for the model.</p>	<p>Simulations that use operating point as initial state start from the simulation time at which the operating point was saved, stored in the <code>snapshotTime</code> property for the <code>Simulink.op.ModelOperatingPoint</code> object.</p>

Modeling Pattern or Workflow	Final States Without Operating Point	Final States with Operating Point
Inspecting and modifying state values	<p>Can modify values for individual states between saving final states and using the state information as the initial state for another simulation.</p> <p>View and edit the contents of the final states variable, <code>xFinal</code> by default.</p>	<p>Can modify values for individual states between saving operating point and using it as the initial state for another simulation.</p> <p>View and edit the contents of the <code>loggedStates</code> property for the <code>Simulink.op.ModelOperatingPoint</code> object</p> <p>The <code>ModelOperatingPoint</code> object contains data for more states than when you log states without the operating point. Some of these additional states that you can view using the <code>loggedStates</code> property are read-only.</p>
Partial state restore	Can use subset of saved state information to specify initial state for simulation.	Must use complete operating point as initial state for simulation.
Specifying initial states that include bus data	Supported for final states saved using the <code>Dataset</code> format	Supported for all formats
Modifying model between simulations	Can use saved state information as initial state for simulation after modifying the model as long as the blocks that correspond to the states in the initial state exist in the model.	<p>Can use saved operating point as initial state for simulation when you do not modify the model and after making certain changes, including:</p> <ul style="list-style-type: none"> <li>• Changing tunable parameter values.</li> <li>• Modifying logging or visualization options.</li> <li>• Modifying solver settings, as long as the type of solver remains the same (fixed-step or variable-step).</li> </ul> <p>For details, see “Use Model Operating Point for Faster Simulation Workflow” on page 27-44.</p>

Modeling Pattern or Workflow	Final States Without Operating Point	Final States with Operating Point
Simulation mode	Supported for all simulation modes	Supported for all simulation modes  You can only use the model operating point as the initial state for a simulation run in the same simulation mode as the simulation that generated the operating point.
Model reference	Supported	Limitations apply when you simulate referenced models in accelerator mode. For details, see "Model Referencing" on page 27-50.
Code generation	Supported for state information saved using a format other than the Dataset format	Not supported

### Choose Format for Logged State Information

You can specify the format used to log state information using the **Format** parameter on the **Data Import/Export** pane of the Model Configuration Parameters dialog box. When you log block states for each simulation step or final states without the model operating point, the **Format** parameter specifies the format for the logged data. When you save final states with the model operating point, the **Format** parameter specifies the format for the data in the `loggedStates` property of the `Simulink.op.ModelOperatingPoint` object. The **Format** parameter also specifies the format for logged output data.

By default, states are logged using the `Dataset` format. Block states are returned in a `Simulink.SimulationData.Dataset` object that contains a `Simulink.SimulationData.State` object for each state. Logging states and outputs using the `Dataset` format can simplify postprocessing when you also use signal logging or log data stores, which are always logged using the `Dataset` format.

You can also use the `Structure` or `Structure with time` format. The `Dataset`, `Structure`, and `Structure with time` formats store similar metadata, including the block path, along with the numeric state data. The formats provide different levels of support for certain modeling patterns and workflows.

Modeling Pattern or Workflow	Dataset	Structure and Structure with time
Logging multiple sample values for a given time step	Supported  Can be important for logging Stateflow data or data inside a For Iterator Subsystem or While Iterator Subsystem.	Not supported

<b>Modeling Pattern or Workflow</b>	<b>Dataset</b>	<b>Structure and Structure with time</b>
Streaming data to the Simulation Data Inspector	Supported	Not supported
Rapid accelerator simulation	Logging states throughout simulation is not supported. Logging final states is supported.	Supported
Specifying initial states that include bus data	Supported for final states saved with and without operating point	Supported for final operating point Not supported for final states saved without operating point
Logging states inside function-call subsystems	Not supported	Supported
Code generation	Not supported	Supported

Logging states using the Array format is not recommended. The Array format does not include metadata. You use the order of the data in the array to determine which state value corresponds to which block in your model. The arrangement of block states in the array is based on the sorted order for blocks in the model, which can change from one simulation to the next, including when you modify the model or change the simulation or code generation mode.

## See Also

### Model Settings

**Initial state** | **Final states** | **Save final operating point**

### Objects

`Simulink.op.ModelOperatingPoint` | `Simulink.SimulationData.Dataset` | `Simulink.SimulationData.State`

## Related Examples

- “Load State Information” on page 75-90

## Save State Information

### In this section...

“Save State Information for Each Simulation Step” on page 77-80

“Save Partial Final State Information” on page 77-80

“Examine State Information Saved Without the Operating Point” on page 77-80

“Save Final State Information with Operating Point” on page 77-82

### Save State Information for Each Simulation Step

You can save state information for logged states for each simulation step during a simulation. That level of state information can be helpful for debugging.

- 1 Select the **Configuration Parameters > Data Import/Export > States** check box.
- 2 In the **States** edit box, you can specify a different variable for the state information, if you do not want to use the default `xout` variable.
- 3 Also in the **Data Import/Export** pane, set the **Format** parameter to `Dataset`, `Structure`, or `Structure with time`, unless you use array format for compatibility with a legacy model.

`Dataset` format does not support:

- Logging states information inside a function-call subsystem
- Logging states during rapid accelerator simulations
- Code generation

- 4 Click **Apply**.
- 5 Simulate the model.

### Save Partial Final State Information

To save just the logged states (the continuous and discrete states of blocks):

- 1 Select the **Configuration Parameters > Data Import/Export > Final states** check box.
- 2 In the **Final states** edit box, you can specify a different variable for the state information, if you do not want to use the default `xFinal` variable.
- 3 Clear the **Save final operating point** parameter.
- 4 Set the **Format** parameter to `Dataset`, `Structure`, or `Structure with time`.
- 5 Click **Apply**.
- 6 Simulate the model.

### Examine State Information Saved Without the Operating Point

If you enable the **Configuration Parameters > Data Import/Export > Final states** or **States** parameters, Simulink saves the state information in the format that you specify with the **Format** parameter. The default variable for **Final state** information is `xFinal`, and the variable for state information for **States** information is `xout`.

If a model has no states saved, then `xFinal` and `xout` are empty variables. To determine whether a model has states saved, use the `isempty(xout)` command.

### Final State Information in Dataset Format

For example, suppose that you saved final state information in `Dataset` format, and use the default `xFinal` variable for the saved state information.

```
xFinal
xFinal =
Simulink.SimulationData.Dataset 'xFinal' with 2 elements
```

		Name	BlockPath
1	[1x1 State]	CSTATE	vdp/x1
2	[1x1 State]	DSTATE	vdp/x2

- Use braces `{ }` to access, modify, or add elements using index.

Examine the first element of the state data set.

```
xFinal{1}
ans =
Simulink.SimulationData.State
Package: Simulink.SimulationData
Properties:
  Name: 'CSTATE'
  BlockPath: [1x1 Simulink.SimulationData.BlockPath]
  Label: CSTATE
  Values: [1x1 timeseries]
```

### Final State Information in Structure with Time Format

For example, suppose that you saved final state information in a structure with time format, and use the default `xFinal` variable for the saved state information.

To find the simulation time and number of states in the `vdp` model, enter the `xFinal` variable.

```
xFinal
xFinal =
    time: 20
  signals: [1x2 struct]
```

In this case, the simulation time is 20 and there are two states. To examine the first state, use this command.

```
xFinal.signals(1)
ans =
    values: 2.0108
```

```
        dimensions: 1
            label: 'CSTATE'
            blockName: 'vdp/x1'
            stateName: ''
inReferencedModel: 0
```

The `values` and `blockName` fields of the first state structure show that the final value for the output signal of the `x1` block is 2.018.

---

**Note** If you write a script to analyze state information, use a combination of `label` and `blockName` values to identify a specific state uniquely. Do not rely on the order of the states.

---

## Save Final State Information with Operating Point

To save complete state information, save the `ModelOperatingPoint` object for a simulation.

- 1 Select the **Configuration Parameters > Data Import/Export > Final states** check box.
- 2 Also in the Data Import/Export pane, select the **Save final operating point** parameter.
- 3 In the edit box next to the **Save final operating point** parameter, enter a variable name for the `ModelOperatingPoint` object and click **Apply**.
- 4 Simulate the model.

For more information about using the operating point, see “Use Model Operating Point for Faster Simulation Workflow” on page 27-44.

## Log Data to the Workspace and a File Using the Record Block

When you log data using the Record block, you can log data to the workspace, to a file, or to both the workspace and a file. You can modify the recording settings for the Record block between simulations as needed. This example shows how to access data in the workspace and in a file after simulation, how to configure the Record block properties, and how to modify the data visualization in the Record block. The model for the example is simple: a Record block logs data from a Sine Wave block, a Chirp Signal block, and a Square Wave Generator block.

```
open_system('RecordWorkspaceAndFile');
```

To log data to the workspace and to the MLDATX file, simulate the model.

```
out = sim('RecordWorkspaceAndFile');
```

### Access Data Logged to the Workspace

By default, model simulations return all logged data in a single `Simulink.SimulationOutput` object using the variable `out`. Type `out` in the Command Window to see the contents of the `Simulink.SimulationOutput` object.

```
out
```

```
out =
```

```
Simulink.SimulationOutput:
  recordout: [1x1 Simulink.SimulationData.Dataset]
  tout: [51x1 double]

SimulationMetadata: [1x1 Simulink.SimulationMetadata]
ErrorMessage: [0x0 char]
```

The logged workspace data for the Record block is inside the `out` workspace variable, stored in the `Simulink.SimulationData.Dataset` object `recordout`. Type `out.recordout` in the Command Window to view the contents of the `recordout` Dataset object.

```
out.recordout
```

```
ans =
```

```
Simulink.SimulationData.Dataset 'Run 1: RecordWorkspaceAndFile' with 3 elements
```

		Name	PropagatedName	BlockPath
1	[1x1 Signal]	Chirp Signal	Chirp Signal	RecordWorkspaceAndFile/Record
2	[1x1 Signal]	Sine Wave	Sine Wave	RecordWorkspaceAndFile/Record
3	[1x1 Signal]	Square Wave	Square Wave	RecordWorkspaceAndFile/Record

- Use braces { } to access, modify, or add elements using index.

The data for each signal connected to the Record block is stored in a `Simulink.SimulationData.Signal` object. The data and time values for the signal are stored as a `timeseries` object in the **Values** property of the `Signal` object. Access the data for the Square Wave signal.

```
recorddata = out.recordout;
sqsignal = get(recorddata,3);
sqts = sqsignal.Values;
sqWaveData = sqts.Data;
```

You can also access the data by combining all the steps into a single line of code.

```
sqWaveData = get(out.recordout,3).Values.Data;
```

### Access Data Logged to a File

This example logs data to a file in the working directory. After simulating the model, you see the `recording.mldatx` file in the Current Folder pane of the MATLAB® window. You can view the data in the MLDATX file using the Simulation Data Inspector. Double-click the file or open the file using the `open` function.

```
open('recording.mldatx');
```

In the Simulation Data Inspector, you can inspect the signal data using cursors or the replay controls, and you can build custom visualizations. You can use the Simulation Data Inspector programmatic interface to access the data from the MLDATX file in the workspace or a script, and you can export the data to the workspace, a MAT file, or an Excel® file.

You can also configure the Record block to log data to a MAT file or an Excel file. To access and analyze data logged to a MAT file, you can load the data into the base workspace, or you can import the data into the Simulation Data Inspector. You can access and analyze data logged to an Excel file in Excel, by reading the data into the base workspace, or by importing the data into the Simulation Data Inspector.

### Configure Recording Settings

View and modify the recording parameters for the Record block using the Property Inspector. To display the Property Inspector, on the **Modeling** tab, under **Design**, select **Property Inspector**. To view the parameters for the Record block in the model, select the Record block. The Record block in this example is configured to log data to the workspace using the variable `recordout` and to log data to the file `recording.mldatx`. Using the recording settings, you can disable logging to the

workspace or logging to file, and you can change the **File Type** parameter to log data to a MAT file or an Excel file and specify the location for the logged file.

### View Data Using the Record Block

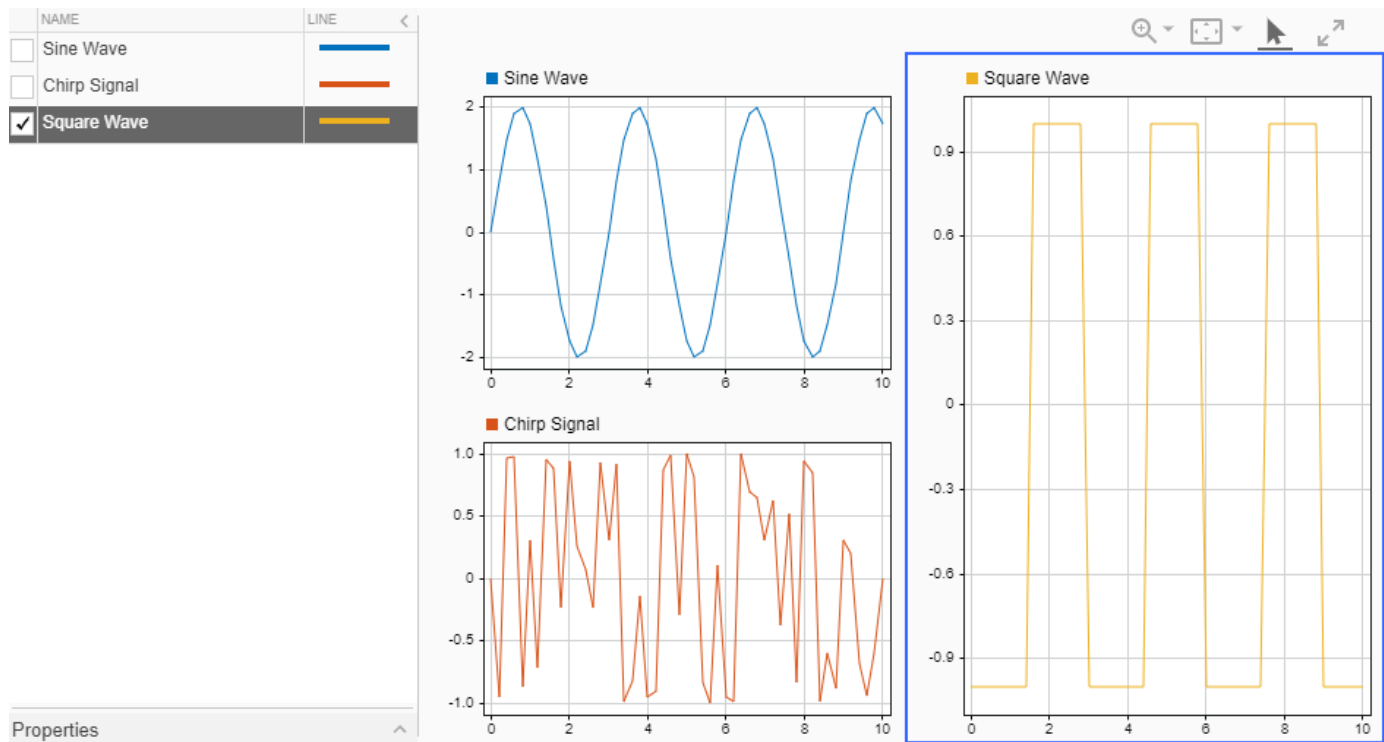

The Record block also visualizes the connected signals. To view the connected signal data, double-click the Record block. By default, the Record block displays each connected signal as a sparkline.

You can change the layout and display data on other types of visualizations, including an XY plot, a map, and time plots. For example, change the visualization to a time plot. On the **Simulation** tab, under **Prepare**, select **Sparklines** and then **Time Plot**. When you change to a different visualization, plotted signals are cleared from the subplot. Next, change the layout to include three subplots. From the **Layouts** menu, select the **Column Right** option.

To plot signals in the time plots, expand the signals table by clicking **Show Signals** in the upper-left. Check the box next to the signal you want to plot on the selected subplot, outlined in blue. For example, plot the **Sine Wave** signal in the first subplot. Then, select another subplot and plot the **Chirp** signal. Select the final subplot and plot the **Square Wave** signal.

When you save the model, the updated visualization is saved in the Record block. When you simulate the model, the Record block updates the plots with data from the current simulation.

# Working with Data Stores

---

- “Data Store Basics” on page 78-2
- “Model Global Data by Creating Data Stores” on page 78-10
- “Log Data Stores” on page 78-29

## Data Store Basics

A *data store* is a repository to which you can write data, and from which you can read data, without having to connect an input or output signal directly to the data store. Data stores are accessible across model levels, so subsystems and referenced models can use data stores to share data without using I/O ports.

### When to Use a Data Store

Data stores can be useful when multiple signals at different levels of a model need the same global values, and connecting all the signals explicitly would clutter the model unacceptably or take too long to be feasible. Data stores are analogous to global variables in programs, and have similar advantages and disadvantages, such as making verification more difficult.

To share data between the instances of a reusable algorithm (for example, a subsystem in a custom library or a reusable referenced model), you can use a data store. For more information about data sharing for a reusable referenced model, see “Share Data Among Referenced Model Instances” on page 8-34.

### Data Stores and Software Verification

Data stores can have significant effects on software verification, especially in the area of data coupling and control. Models and subsystems that use only input and output ports to pass data result in clean, well-specified, and easily verifiable interfaces in the generated code.

Data stores, like any type of global data, make verification more difficult. If your development process includes software verification, consider planning for the effect of data stores early in the design process.

For more information, see RTCA DO-331, “Model-Based Development and Verification Supplement to DO-178C and DO-278A,” Section MB.6.3.3.b.

### Goto and From Blocks as a Signal Routing Alternative

In some cases, you may be able to use a simpler technique, Goto blocks and From blocks, to obtain results similar to those provided by data stores. The principal disadvantage of data Goto/From links is that they generally are not accessible across nonvirtual subsystem boundaries, while an appropriately configured data store can be accessed anywhere. See the Goto and From block reference pages for more information about Goto/From links.

## Local and Global Data Stores

You can define two types of data stores:

- A *local data store* is accessible from anywhere in the model hierarchy that is at or below the level at which you define the data store, except from referenced models. You can define a local data store graphically in a model or by creating a model workspace signal object (`Simulink.Signal`).
- A *global data store* is accessible from throughout the model hierarchy, including from referenced models. Define a global data store only in the MATLAB base workspace, using a signal object. The only type of data store that a referenced model can access is a global data store.

In general, locate a data store at the lowest level in the model that allows access to the data store by all the parts of the model that need that access. Some examples of local and global data stores appear in “Data Store Examples” on page 78-10.

For information about using referenced models, see “Model References”.

## Data Store Diagnostics

- “About Data Store Diagnostics” on page 78-3
- “Detecting Access Order Errors” on page 78-3
- “Detecting Multitasking Access Errors” on page 78-5
- “Detecting Duplicate Name Errors” on page 78-6
- “Data Store Diagnostics in the Model Advisor” on page 78-8

### About Data Store Diagnostics

Simulink provides various run-time and compile-time diagnostics that you can use to help avoid problems with data stores. Diagnostics are available in the Model Configuration Parameters dialog box and the Data Store Memory block's parameters dialog box. The Simulink Model Advisor provides support by listing cases where data store errors are more likely because diagnostics are disabled.

### Detecting Access Order Errors

- “Data Store Diagnostics and Models Referenced in Accelerator Mode” on page 78-4
- “Data Store Diagnostics and the MATLAB Function Block” on page 78-5

You can use data store run-time diagnostics to detect unintended sequences of data store reads and writes that occur during simulation. You can apply these diagnostics to all data stores, or allow each Data Store Memory block to set its own value. The diagnostics are:

- **Detect read before write**
- **Detect write after read**
- **Detect write after write**

These diagnostics appear in the **Model Configuration Parameters > Diagnostics > Data Validity > Data Store Memory block** pane, where each can have one of the following values:

- **Disable all** — Disables this diagnostic for all data stores accessed by the model.
- **Enable all as warnings** — Displays the diagnostic as a warning in the MATLAB Command Window.
- **Enable all as errors** — Halts the simulation and displays the diagnostic in an error dialog box.
- **Use local settings** — Allow each Data Store Memory block to set its own value for this diagnostic (default).

The same diagnostics also appear in each Data Store Memory block parameters dialog box **Diagnostics** tab. You can set each diagnostic to **none**, **warning**, or **error**. The value specified by an individual block takes effect only if the corresponding configuration parameter is **Use local settings**. See “Model Configuration Parameters: Data Validity Diagnostics” and the Data Store Memory documentation for more information.

The most conservative technique is to set all data store diagnostics to **Enable all as errors** in **Model Configuration Parameters > Diagnostics > Data Validity > Data Store Memory block**. However, this setting is not best in all cases, because it can flag intended behavior as erroneous. For example, the next figure shows a model that uses block priorities to force the Data Store Read block to execute before the Data Store Write block:

An error occurred during simulation because the data store A is read from the Data Store Read block before the Data Store Write block updates the store. If the associated delay is intended, you can suppress the error by setting the global parameter **Detect read before write** to **Use local settings**, then setting that parameter to **none** in the **Diagnostics** pane of the Data Store Memory block dialog box. If you use this technique, set the parameter to **error** in all other Data Store Memory blocks aside from those that are to be intentionally excluded from the diagnostic.

#### Data Store Diagnostics and Models Referenced in Accelerator Mode

For models referenced in Accelerator mode, Simulink ignores the following **Configuration Parameters > Diagnostics > Data Validity > Data Store Memory block** parameters if you set them to a value other than **Disable all**.

- **Detect read before write** (ReadBeforeWriteMsg)
- **Detect write after read** (WriteAfterReadMsg)
- **Detect write after write** (WriteAfterWriteMsg)

You can use the Model Advisor to identify models referenced in Accelerator mode for which Simulink ignores the configuration parameters listed above.

- 1 In the Simulink Editor, in the **Modeling** tab, click **Model Advisor**.

- 2 Select **By Task**.
- 3 Run the **Check diagnostic settings ignored during accelerated model reference simulation** check.

### Data Store Diagnostics and the MATLAB Function Block

Diagnostics might be more conservative for data store memory used by MATLAB Function blocks. For example, if you pass arrays of data store memory to MATLAB functions, optimizations such as  $A = \text{foo}(A)$  might result in MATLAB marking the entire contents of the array as read or written, even though only some elements were accessed.

### Detecting Multitasking Access Errors

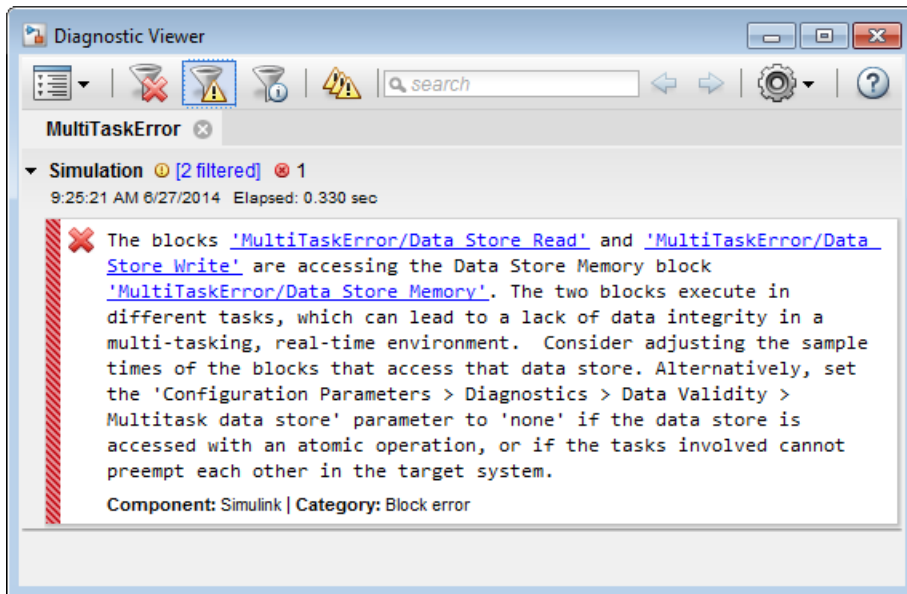

Data integrity may be compromised if a data store is read from in one task and written to in another task. For example, suppose that:

- 1 A task is writing to a data store.
- 2 A second task interrupts the first task.
- 3 The second task reads from that data store.

If the first task had only partly updated the data store when the second task interrupted, the resulting data in the data store is inconsistent. For example, if the value is a vector, some of its elements may have been written in the current time step, while the rest were written in the previous step. If the value is a multi-word, it may be left in an inconsistent state that is not even partly correct.

Unless you are certain that task preemption cannot cause data integrity problems, set the compile-time diagnostic **Model Configuration Parameters > Diagnostics > Data Validity > Data Store Memory block > Multitask data store** to warning (the default) or error. This diagnostic flags any case of a data store that is read from and written to in different tasks. The next figure illustrates a problem detected by setting **Multitask data store** to error:

Since the data store A is written to in the fast task and read from in the slow task, an error is reported, with suggested remedy. This diagnostic is applicable even in the case that a data store read or write is inside of a conditional subsystem. Simulink correctly identifies the task that the block is executing within, and uses that task for the purpose of evaluating the diagnostic.

The next figure shows one solution to the problem shown above: place a rate transition block after the data store read, which previously accessed the data store at the slower rate.

With this change, the data store write can continue to occur at the faster rate. This may be important if that data store must be read at that faster rate elsewhere in the model.

The **Multitask Data Store** diagnostic also applies to data store reads and writes in referenced models. If two different child models execute a data store's reads and writes in differing tasks, the error will be detected when Simulink compiles their common parent model.

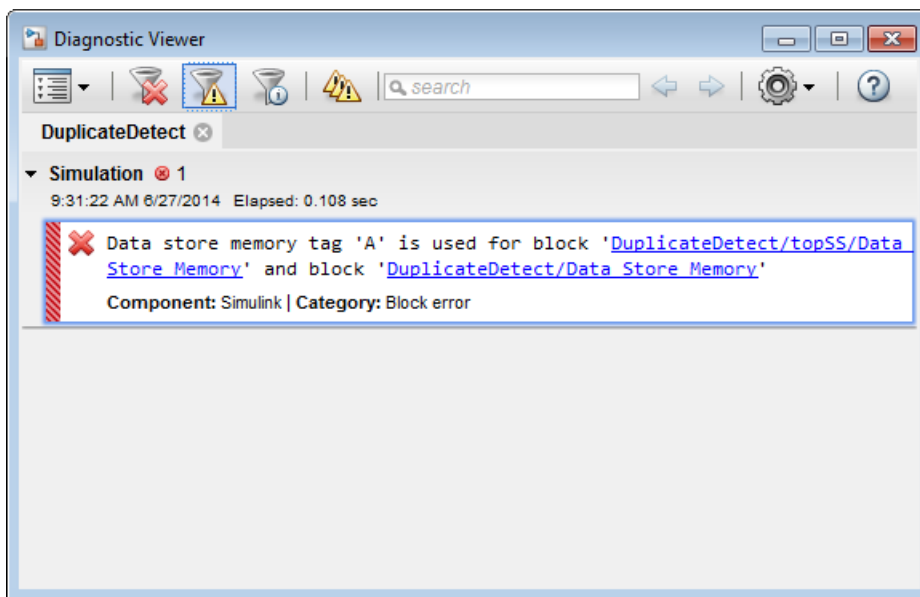

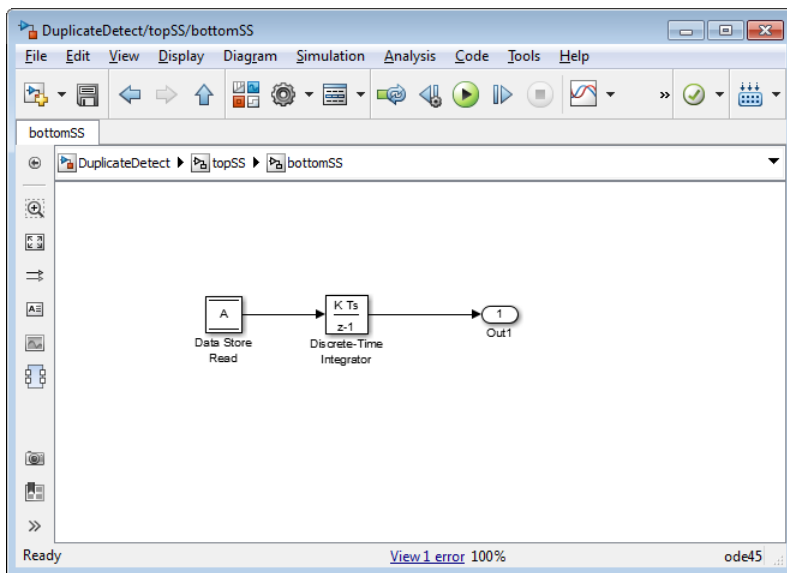

### Detecting Duplicate Name Errors

Data store errors can occur due to duplicate uses of a data store name within a model. For instance, data store shadowing occurs when two or more data store memories in different nested scopes have the same data store name. In this situation, the data store memory referenced by a data store read or write block at a low level may not be the intended store.

To prevent errors caused by duplicate data store names, set the compile-time diagnostic **Model Configuration Parameters > Diagnostics > Data Validity > Data Store Memory block > Duplicate data store names** to warning or error. By default, the value of the diagnostic is none,

suppressing duplicate name detection. The next figure shows a problem detected by setting **Duplicate data store names** to error:

The data store read at the bottom level of a subsystem hierarchy refers to a data store named A, and two Data Store Memory blocks in the same model have that name, so an error is reported. This diagnostic guards against assuming that the data store read refers to the Data Store Memory block in the top level of the model. The read actually refers to the Data Store Memory block at the intermediate level, which is closer in scope to the Data Store Read block.

### Data Store Diagnostics in the Model Advisor

The Model Advisor provides several diagnostics that you can use with data stores. See these sections for information about Model Advisor diagnostics for data stores:

“Check Data Store Memory blocks for multitasking, strong typing, and shadowing issues”

“Check data store block sample times for modeling errors”

“Check if read/write diagnostics are enabled for data store blocks”

## Specify Initial Value for Data Store

In general, to specify an initial value for a data store, you can use the same techniques that you use for other blocks. See “Initialize Signals and Discrete States” on page 80-42.

With most blocks, you can take advantage of scalar expansion to minimize the effort of specifying an initial value for a nonscalar signal. When you specify a scalar initial value, each element in the signal uses that scalar.

However, when you set the **Dimensions** parameter to -1 in a Data Store Memory block (the default), you cannot use scalar expansion. Instead, you must specify an initial value that has the same dimensions as the stored signal. To take advantage of scalar expansion of the initial value, set the **Dimensions** parameter to a specific value such as [1 2] or [1 myDim] (for symbolic dimensions).

A *data store* is a repository to which you can write data, and from which you can read data, without having to connect an input or output signal directly to the data store. Data stores are accessible across model levels, so subsystems and referenced models can use data stores to share data without using I/O ports. To decide whether to use data stores, see “Data Store Basics” on page 78-2.

### Data Store Examples

#### Overview

The following examples illustrate techniques for defining and accessing data stores. See “Order Data Store Access” on page 78-19 for techniques that control data store access over time, such as ensuring that a given data store is always written before it is read. See “Data Store Diagnostics” on page 78-3 for techniques you can use to help detect and correct potential data store errors without needing to run any simulations.

---

**Note** To use global data stores to share data among referenced models, see “Use Data Stores Across Multiple Models”.

---

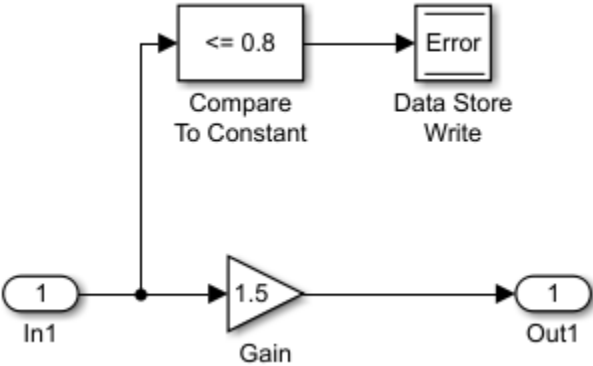

#### Local Data Store Example

The following model illustrates creation and access of a local data store, which is visible only in a model or particular subsystem.

This model uses a data store to permit subsystem A to signal that its output is invalid.

If subsystem A's output is invalid, the model uses the output of subsystem B.

**Global Data Store Example**

The following model replaces the subsystems of the previous example with functionally identical referenced models to illustrate use of a global data store to share data in a model reference hierarchy.

In this example, the top model uses a signal object in the MATLAB workspace to define the error data store. This is necessary because data stores are visible across model boundaries only if they are defined by signal objects in the MATLAB workspace or a data dictionary. The model specifies code for the `PreLoadFcn` model callback parameter that creates the signal object. This code executes before the model loads.

## Create and Apply Data Stores

**Note** To use buses and arrays of buses with data stores, perform *both* the following procedure and “Setting Up a Model to Use Data Stores with Buses and Arrays of Buses” on page 78-22.

The following is a general workflow for configuring data stores. You can perform the tasks in a different order, or separately from the rest, depending on how you use data stores.

- 1 Where applicable, plan your use of data stores to minimize their effect on software verification. For more information, see “Data Stores and Software Verification” on page 78-2.
- 2 Create data stores using the techniques described in “Data Stores with Data Store Memory Blocks” on page 78-13 or “Data Stores with Signal Objects” on page 78-16. For greater reliability, consider assigning rather than inheriting data store attributes, as described in “Specifying Data Store Memory Block Attributes” on page 78-14.
- 3 Add to the model Data Store Write and Data Store Read blocks to write to and read from the data stores, as described in “Access Data Stores with Simulink Blocks” on page 78-17.

- 4 Configure the model and the blocks that access each data store to avoid concurrency failures when reading and writing the data store, as described in “Order Data Store Access” on page 78-19.
- 5 Apply the techniques described in “Data Store Diagnostics” on page 78-3 as needed to prevent data store errors, or to diagnose them if they occur during simulation.
- 6 If you intend to generate code for your model, see “Data Stores in Generated Code” (Simulink Coder).

To create a data store, you create a Data Store Memory block or a `Simulink.Signal` object. The block or signal object represents the data store and specifies its properties. Every data store must have a unique name.

- A Data Store Memory block implements a local data store. See “Data Stores with Data Store Memory Blocks” on page 78-13.
- A `Simulink.Signal` object can act as a local or global data store. See “Data Stores with Signal Objects” on page 78-16.

Data stores implemented with Data Store Memory blocks:

- Support data store initialization
- Provide control of data store scope and options at specific levels in the model hierarchy
- Require a block to represent the data store
- Cannot be accessed within referenced models
- Cannot be in a subsystem that a For Each Subsystem block represents.

Data stores implemented with `Simulink.Signal` objects:

- Provide model-wide control of data store scope and options
- Do not require a block to represent the data store
- Can be accessed in referenced models, if the data store is global

Be careful not to equate local data stores with Data Store Memory blocks, and global data stores with `Simulink.Signal` objects. Either technique can define a local data store, and a signal object can define either a local or a global data store.

## Data Stores with Data Store Memory Blocks

- “Creating the Data Store” on page 78-13
- “Specifying Data Store Memory Block Attributes” on page 78-14

### Creating the Data Store

To use a Data Store Memory block to define a data store, drag an instance of the block into the model at the topmost level from which you want the data store to be visible. The result is a local data store, which is not accessible within referenced models.

- To define a data store that is visible at every level within a given model, except within Model blocks, drag the Data Store Memory block into the root level of the model.
- To define a data store that is visible only within a particular subsystem and the subsystems that it contains, but not within Model blocks, drag the Data Store Memory block into the subsystem.

Once you have added the Data Store Memory block, use its parameters to define the data store's properties. The **Data store name** property specifies the name of the data store that the Data Store Write and Data Store Read blocks access. See Data Store Memory documentation for details.

You can specify data store properties beyond those definable with Data Store Memory block parameters by selecting the **Data store name must resolve to Simulink signal object** option and using a signal object as the data store name. See “Specifying Attributes Using a Signal Object” on page 78-14 for details.

### Specifying Data Store Memory Block Attributes

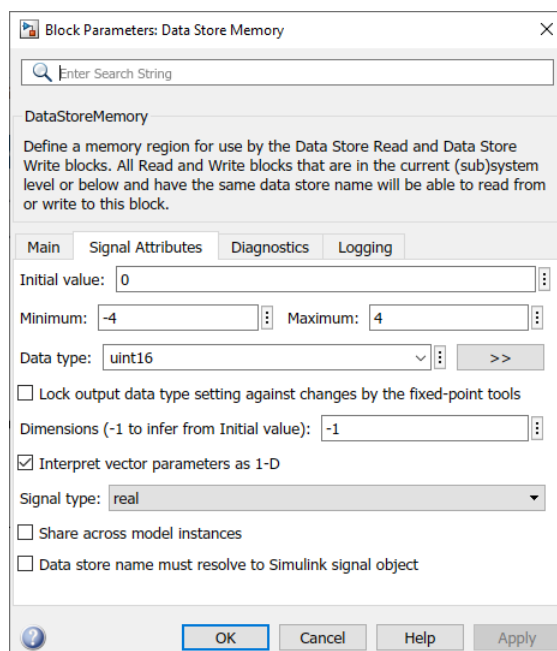

A Data Store Memory block can inherit three data attributes from its corresponding Data Store Read and Data Store Write blocks. The inheritable attributes are:

- Data type
- Complexity
- Sample time

However, allowing these attributes to be inherited can cause unexpected results that can be difficult to debug. To prevent such errors, use the Data Store Memory block dialog or a `Simulink.Signal` object to specify the attributes explicitly.

### Specifying Attributes Using Block Parameters

You can use the Data Store Memory block dialog box or the Model Data Editor **Data Stores** tab (in the **Modeling** tab, click **Model Data Editor**) to specify the data type and complexity of a data store. In the next figure, the block dialog box sets the **Data type** to `uint16` and the **Signal type** to `real`.

### Specifying Attributes Using a Signal Object

You can use a `Simulink.Signal` object to specify data store attributes for a Data Store Memory block.

**Tip** To establish an implicit data store, as described in “Data Stores with Signal Objects” on page 78-16, use the same general approach as when you explicitly associate a signal object with a Data Store Memory block.

The next figure shows a Data Store Memory block that specifies resolution to a Simulink.Signal object, named A. To use a signal object for the data store, set **Data store name** to the name of the signal object. For compile-time checking, open the **Signal Attributes** tab and select the **Data store name must resolve to Simulink signal object** parameter.

Alternatively, on the Model Data Editor **Data Stores** tab (on the **Modeling** tab, click **Model Data Editor**), while editing the data store name, click the nearby action button  and select **Create and Resolve**. In the Create New Data dialog box, set **Value** to Simulink.Signal.

The signal object specifies values for all three data attributes that the data store would otherwise inherit. In this example, which defines a local data store, the Simulink.Signal object A has the following inherited properties: `DataType`, `Complexity`, and `SampleTime`.

A =

```
Simulink.Signal (handle)
  CoderInfo: [1x1 Simulink.CoderInfo]
  Description: ''
  DataType: 'auto'
  Min: []
  Max: []
  Unit: ''
  Dimensions: 1
  DimensionsMode: 'auto'
  Complexity: 'auto'
  SampleTime: -1
  InitialValue: 0
```

For more information about specifying signal object attributes for local and global data stores, see “Signal Object Attributes for Data Stores” on page 78-16.

### **Use Model Data Editor to Configure Data Store Memory Blocks in a List**

Use the **Data Stores** tab in the Model Data Editor to configure the parameters of a Data Store Memory block. Use this technique to configure the data store without locating it in the model and to configure the data store together with other interface elements such as Inport and Outport blocks. The Model Data Editor also shows you information for Data Store Read and Data Store Write blocks in the same list.

To open the **Model Data Editor**, in the **Modeling** tab, click **Model Data Editor**.

## **Data Stores with Signal Objects**

- “Creating the Data Store” on page 78-16
- “Local and Global Data Stores” on page 78-16
- “Signal Object Attributes for Data Stores” on page 78-16

### **Creating the Data Store**

To use a `Simulink.Signal` object to define a data store without using a Data Store Memory block, create the signal object in a workspace that is visible to every component that needs to access the data store. The name of the associated data store is the name of the signal object. You can use this name in Data Store Read and Data Store Write blocks, just as if it were the **Data store name** of a Data Store Memory block. Simulink creates an associated data store when you use the signal object for data storage.

### **Local and Global Data Stores**

You can use a `Simulink.Signal` object to define either a local or a global data store.

- If you define the object in the MATLAB base workspace or a data dictionary, the result is a global data store, which is accessible in every model within Simulink, including all referenced models.
- If you create the object in a model workspace, the result is a local data store, which is accessible at every level in a model except any referenced models.

### **Signal Object Attributes for Data Stores**

Those data store attributes that a signal object does not define have the same default values that they do in a Data Store Memory block. The property values of a signal object used as a data store have different requirements, depending on whether the data store is local or global.

Once you have created the object, set the properties of the signal object to the values that you want the corresponding data store properties to have. For example, the following commands define a data store named `Error` in the MATLAB base workspace:

```
Error = Simulink.Signal;  
Error.Description = 'Use to signal that subsystem output is invalid';  
Error.DataType = 'boolean';  
Error.Complexity = 'real';  
Error.Dimensions = 1;  
Error.SampleTime = 0.1;
```

**Attributes for Local Data Stores**

For a local data store, for each parameter listed below, you can either set the value explicitly or you can have the data store inherit the value from the Data Store Write and Data Store Read blocks.

- DataType
- Complexity
- SampleTime

To define a local data store using a Data Store Memory block, you can use a signal object for the **Data store name** parameter. For compile-time checking, in the **Signal Attributes** tab, select the **Data store must resolve to Simulink signal object** parameter. The **Data store must resolve to Simulink signal object** parameter causes Simulink to display an error and stop compilation if Simulink cannot find the signal object or if the signal object properties are inconsistent with the signal object properties.

**Attributes for Global Data Stores**

The following table describes the parameter requirements for global data stores.

Parameter	Global Data Store Value
DataType	Must be set explicitly
Complexity	Must be set explicitly
Dimensions	Can be set or inherited
SampleTime	Can be set or inherited

**Modify Attributes of Data Store Defined by Signal Object**

You can use the Model Data Editor (in the **Modeling** tab, click **Model Data Editor**) to modify and inspect the attributes of data stores, Data Store Read, and Data Store Write blocks. On the **Data Stores** tab, to show the attributes of data stores that you define by using signal objects (such as Simulink.Signal), click the **Show/refresh additional information** button. Then, if a Data Store Read or Data Store Write block shown in the data table refers to a data store defined by a signal object, the table includes a row that corresponds to the object.

For more information, see **Model Data Editor**.

**Access Data Stores with Simulink Blocks**

- “Writing to a Data Store” on page 78-17
- “Reading from a Data Store” on page 78-18
- “Accessing a Global Data Store” on page 78-18

**Writing to a Data Store**

To set the value of a data store at each time step:

- 1 Create an instance of a Data Store Write block at the level of your model that computes the value.
- 2 Set the Data Store Write block **Data store name** parameter to the name of the data store to which you want it to write data.

- 3 Connect the output of the block that computes the value to the input of the Data Store Write block.

### Reading from a Data Store

To get the value of a data store at each time step:

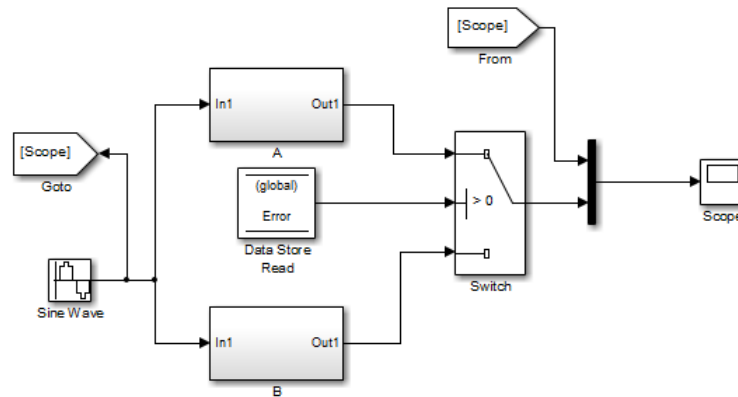

- 1 Create an instance of a Data Store Read block at the level of your model that needs the value.
- 2 Set the Data Store Read block **Data store name** parameter to the name of the data store from which you want it to read.
- 3 Connect the output of the Data Store Read block to the input of the block that needs the data store value.

### Accessing a Global Data Store

When connected to a global data store (one that is defined by a signal object in the MATLAB workspace), a Data Store Read or Data Store Write block displays the word `global` above the data store name.

## Order Data Store Access

- “About Data Store Access Order” on page 78-19
- “Ordering Access Using Function Call Subsystems” on page 78-19
- “Ordering Access Using Block Priorities” on page 78-21

### About Data Store Access Order

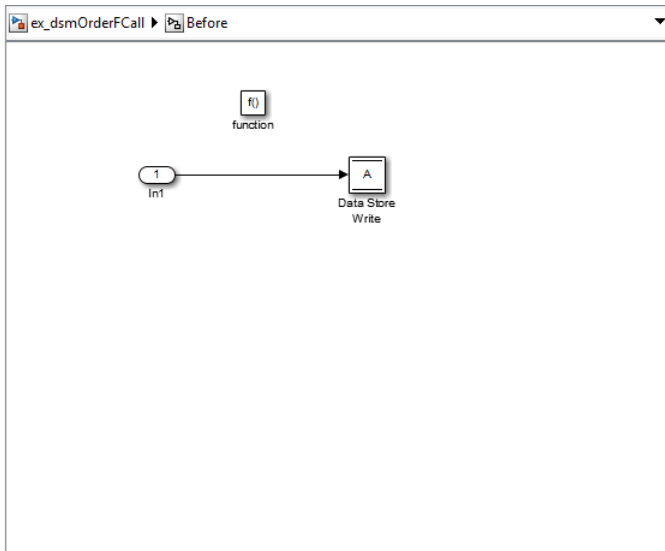

To obtain correct results from data stores, you must control the order of execution of the data store’s reads and writes. If a data store’s read occurs before its write, latency is introduced into the algorithm: the read obtains the value that was computed and stored in the previous time step, rather than the value computed and stored in the current time step.

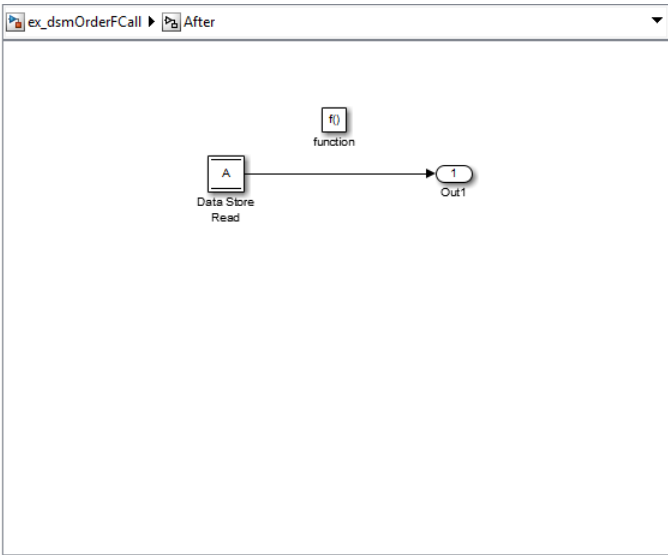

Such latency may cause the system to behave other than as designed, and in some cases may destabilize the system. Even if these problems do not occur, an uncontrolled access order could change from one release of Simulink to the next.

This section describes several strategies for explicitly controlling the order of execution of a data store’s reads and writes. See “Data Store Diagnostics” on page 78-3 for techniques you can use to detect and correct potential data store errors without running simulations.

### Ordering Access Using Function Call Subsystems

You can use function call subsystems to control the execution order of model components that access data stores. The next figure shows this technique:

The subsystem Before contains the Data Store Write, and the Stateflow chart calls that subsystem before it calls the subsystem After, which contains the Data Store Read.

**Ordering Access Using Block Priorities**

You can embed data store reads and writes inside atomic subsystems or Model blocks whose priorities specify their relative execution order.

The Model block `beforeDSM` has a lower priority than `afterDSM`, so it is guaranteed to execute first. Since `beforeDSM` is atomic, all of its operations, including the Data Store Write, will execute prior to `afterDSM` and all of its operations, including the Data Store Read.

## Data Stores with Buses and Arrays of Buses

Benefits of using data stores with buses and arrays of buses include:

- Simplifying the model layout by associating multiple signals with a single data store
- Producing generated code that represents the data in the store data as structures that reflect the bus hierarchy
- Writing to and reading from data stores without creating data copies, which results in more efficient data access

You cannot use a bus or array of buses that contains:

- Variable-dimension signals
- Frame-based signals

### Setting Up a Model to Use Data Stores with Buses and Arrays of Buses

This procedure applies to local and global data stores, and to data stores defined with a Data Store Memory block or a `Simulink.Signal` object. Before performing the procedure, you must understand how to use data stores in a model, as described in “Create and Apply Data Stores” on page 78-12.

To use buses and arrays of buses with data stores:

- 1 Use the Type Editor to define a bus object whose properties match the bus data that you want to write to and read from a data store. For details, see “Create and Specify `Simulink.Bus` Objects” on page 81-59.
- 2 Add a data store (using a Data Store Memory block or a `Simulink.Signal` object) for storing the bus data.
- 3 Specify the bus object as the data type of the data store. For details, see “Specify a Bus Object Data Type” on page 72-38.
- 4 If you use a MATLAB structure for the initial value of the data store, then set **Configuration Parameters > Diagnostics > Data Validity > Advanced parameters > Underspecified**

**initialization detection** to Simplified. For details, see “Specify Initial Conditions for Bus Elements” on page 81-64 and “Underspecified initialization detection”.

- 5 (Optional) Select individual bus elements to write to or read from a data store. For details, see “Accessing Specific Bus and Matrix Elements” on page 78-23.

## Accessing Specific Bus and Matrix Elements

### Selecting Specific Bus or Matrix Elements

By default, a model writes and reads all bus and matrix elements to and from a data store.

To select specific bus or matrix elements to write to or read from a data store, use the **Element Assignment** pane of the Data Store Write block and the **Element Selection** pane of the Data Store Read block . Selecting specific bus or matrix elements offers the following benefits:

- Reducing the number of blocks in the model. For example, you can eliminate a Data Store Read and Bus Selector block pair or a Data Store Write and Bus Assignment block pair for each specific bus element that you want to access).
- Faster simulation of models with large buses and arrays of buses.

### Writing Specific Elements to a Data Store

---

**Note** The following procedure describes how to use the Data Store Write block interface to write specific elements to a data store. You can also perform this task at the command line, using the `DataStoreElements` parameter to specify elements. For details, see “Specification using the command line” on page 78-26.

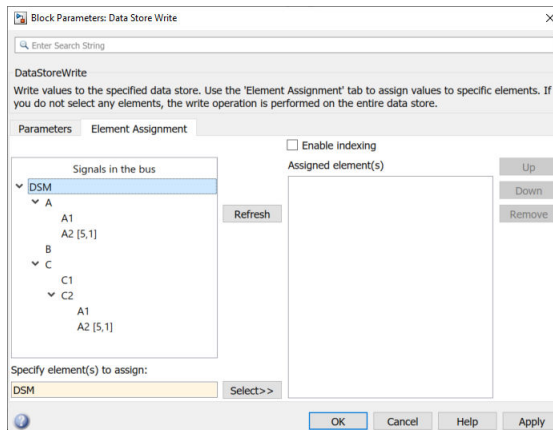

---

To assign specific bus or matrix elements to write to a data store:

- 1 Select the Data Store Write block and in the parameters dialog box, select the **Element Assignment** pane. For example, suppose you are using a bus with a data store named DSM:

- 2 Expand all the elements in the **Signals in the bus** list.

- 3 Specify the elements that you want to write to the data store. For example:
  - In the **Signals in the bus** list, click B. Then click **Select>>** to select the element B.
  - To write all the elements of A2 (in the A nested bus), select A2 [5, 1]. Then click **Select>>**.
  - To write the second element of A2 in the C2 nested bus, select the A2 [5, 1] element. In the **Specify element(s) to assign** text box, edit the text to say DSM.C.C2.A2(2, 1).

For more examples, see “Specifying Elements to Assign or Select” on page 78-25.

- 4 (Optional) Reorder the assigned elements, which changes the order of the ports of the Data Store Write block.
  - To reorder an assigned element, in the **Assigned element(s)** list, select the element that you want to move, and click **Up** or **Down**.
  - To remove an assigned element, click **Remove**.
- 5 To apply the assigned elements, click **OK**.

The Data Store Write block has a port for each assigned element. The names of the selected elements that correspond to each port appear in the block icon. If you assign several signals, these additions may diminish the readability of the model. To improve readability, you can expand the size of the block or create multiple Data Store Write blocks.

### Reading Specific Elements from a Data Store

Reading specific elements from a data store involves very similar steps as described in “Writing Specific Elements to a Data Store” on page 78-23. The Data Store Read block differs slightly from the Data Store Write block. A Data Store Read block has:

- An **Element Selection** pane instead of an **Element Assignment** pane
- A **Selected element(s)** list instead of an **Assigned element(s)** list

### Specifying Elements to Assign or Select

Use MATLAB matrix element syntax to specify specific elements. For details about specifying matrices in MATLAB, see “Creating, Concatenating, and Expanding Matrices”.

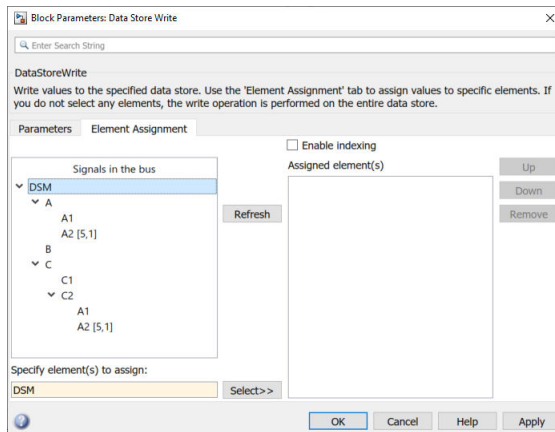

---

**Note** To select matrix elements with dynamic indexing with the Data Store Read and Data Store Write blocks, select **Enable indexing** on the **Element Selection / Element Assignment** pane of the block parameters dialog. You can select only one element at a time for dynamic indexing. See Data Store Read and Data Store Write.

---

### Valid element specifications

The following table shows examples of valid syntax for specifying elements to assign or select. These examples use the A2 nested bus of the A bus, as shown in the bus hierarchy used in “Writing Specific Elements to a Data Store” on page 78-23.

Valid Syntax	Description
DSM.A.A2 (: , :)	Selects all elements in every dimension
DSM.A.A2 ([ 1, 3, 5 ], 1)	Selects the first, third, and fifth elements
DSM.A.A2 (2 : 5, 1)	Selects the second through the fifth element

### Invalid element specifications

The following table shows examples of invalid syntax for specifying elements to assign or select. These examples use the A2 nested bus of the A bus, as shown in the bus hierarchy used in “Writing Specific Elements to a Data Store” on page 78-23.

Invalid Syntax	Reason the Syntax Is Invalid
DSM.A.A2(:)	You must specify a colon for each dimension. For the bus hierarchy used in these examples, you must use two colons.
DSM.A.A2(2:end,1)	You cannot use the end operator.
DSM.A.A2(idx,1)	You cannot use variables to specify indices. Consider using dynamic indexing by selecting <b>Enable indexing</b> on the <b>Element Selection / Element Assignment</b> pane of the block parameters dialog. See Data Store Read and Data Store Write.
DSM.A.A2(-1,1)	The dimension -1 is not within the valid dimension bounds.

### Specification using the command line

To set the elements to write to or read from, use the `DataStoreElements` parameter. Use a pound sign (#) to delimit multiple elements. For example, select the Data Store Write or Data Store Read block for which you want to specify elements and enter a command such as:

```
set_param(gcb, 'DataStoreElements', 'DSM.A#DSM.B#DSM.C(3,4)')
```

This specification results in the block now having three ports corresponding to the elements that you specified.

## Rename Data Stores

- “Rename Data Store Defined by Block” on page 78-26
- “Rename Data Store Defined by Signal Object” on page 78-26

### Rename Data Store Defined by Block

Rename a data store everywhere it is used by Data Store Read and Data Store Write blocks in a model.

- 1 In a Data Store Memory block dialog box, type a new name in the **Data store name** box, and click **Rename All**.
- 2 In the **Rename All** dialog box, confirm the new data store name in the **New name** field, and click **OK**.

---

**Note** You cannot use **Rename All** to rename a data store if you create a `Simulink.Signal` object in a workspace to control the code generated for the data store. Instead, you must rename the corresponding `Simulink.Signal` object using Model Explorer. For an example, see “Rename Data Store Defined by Signal Object” on page 78-26.

---

### Rename Data Store Defined by Signal Object

This example shows how to rename a data store defined by a `Simulink.Signal` object. You can use Model Explorer to rename the object everywhere it is used by Data Store Read and Data Store Write blocks in a model or in a model reference hierarchy.

- 1 Open the model `sldemo_mdhref_dsm`. The model creates a `Simulink.Signal` object `ErrorCond` in the MATLAB base workspace and uses the object as a global data store in a model reference hierarchy.

```
openExample('sldemo_mdhref_dsm')
```

- 2 Open Model Explorer.
- 3 In the **Model Hierarchy** pane, select the base workspace.
- 4 In the **Contents** pane, right-click the data store `ErrorCond` and select **Rename All**.
- 5 In the **Select a system** dialog box, click the name of the model `sldemo_mdhref_dsm` to select it as the context for renaming the data store `ErrorCond`.
- 6 Select **Search in referenced models** since `ErrorCond` is a global data store that is used in a referenced model. Click **OK**.

The **Update diagram to include recent changes** check box is cleared by default to save time by avoiding unnecessary model diagram updates. Select the check box to incorporate recent changes you made to the model by forcing a diagram update.

- 7 Click **OK** in response to the message to update the model diagram.

Since you just opened the model, you must update the model diagram at least once before renaming a variable such as `ErrorCond`. You could have selected **Update diagram to include recent changes** in the **Select a system** dialog box to force an initial diagram update, though you typically use that option when you make changes to the model while performing multiple variable renaming operations.

- 8 In the **Rename All** dialog box, type the new name for the data store in the **New name** box and click **OK**.

## Customized Data Store Access Functions in Generated Code

Embedded Coder provides a storage class that you can use to specify customized data store access functions in generated code. See “Organize Parameter Data into a Structure by Using Struct Storage Class” (Embedded Coder) and “Access Data Through Functions with Storage Class GetSet” (Embedded Coder).

## Log Data Stores

### In this section...

“Logging Local and Global Data Store Values” on page 78-29

“Supported Data Types, Dimensions, and Complexity for Logging Data Stores” on page 78-29

“Data Store Logging Limitations” on page 78-29

“Logging Data Stores Created with a Data Store Memory Block” on page 78-30

“Logging Icon for the Data Store Memory Block” on page 78-30

“Logging Data Stores Created with a Simulink.Signal Object” on page 78-30

“Accessing Data Store Logging Data” on page 78-31

### Logging Local and Global Data Store Values

You can log the values of a local or global data store data variable for all the steps in a simulation. Two common uses of data store logging are for:

- Model debugging - view the order of all data store writes
- Confirming a model modification - use the logged data to establish a baseline for comparing results to identify the impact of a model modification

For an example of logging a global data store, see “Use Data Stores Across Multiple Models”.

### Supported Data Types, Dimensions, and Complexity for Logging Data Stores

You can log data stores that use the following data types:

- All built-in data types
- Enumerated data types
- Fixed-point data types

You can log data stores that use any dimension level or complexity.

### Data Store Logging Limitations

Limitations for using data store logging in a model are:

- To log data for a data store memory:
  - Simulate the top-level model in Normal mode.
  - For local data stores, the model containing the Data Store Memory block must be in Model Reference Normal mode.
  - Any block in a referenced model that writes to the data store memory must be executed in model reference Normal mode.
- You cannot log data stores that use custom data types, including buses.

## Logging Data Stores Created with a Data Store Memory Block

To log a local data store that you create with a Data Store Memory block:

- 1 In the model, open the Model Data Editor. In the **Modeling** tab, click **Model Data Editor**.
- 2 On the **Data Stores** tab, set the **Change view** drop-down list to Instrumentation.
- 3 In the data table, for the target data store, select the check box in the **Log Data** column.

If the target data store does not appear in the table, click the **Change scope** button to display data stores that are defined in subsystems below your current system.

- 4 Optionally, to configure additional logging characteristics such as the maximum number of data points to log, open the Property Inspector (in the **Modeling** tab, under **Design**, click **Property Inspector**). Use the Property Inspector to open the block dialog box and inspect the **Logging** tab.
- 5 Enable data store logging with the **Model Configuration Parameters > Data Import/Export > Data stores** parameter.
- 6 Simulate the model.

## Logging Icon for the Data Store Memory Block

When you enable logging for a model, and you configure a local data store for logging, the Data Store Memory block displays a blue icon. If you do not enable logging for the model, then the icon is gray.

## Logging Data Stores Created with a Simulink.Signal Object

You can create local and global data stores using a `Simulink.Signal` object. See “Data Stores with Signal Objects” on page 78-16 for details.

To log a data store that you create with a `Simulink.Signal` object:

- 1 Create a `Simulink.Signal` object in a workspace that is visible to every component that needs to access the data store, as described in “Data Stores with Signal Objects” on page 78-16.
- 2 Use the name of the `Simulink.Signal` object in the **Data store name** block parameters of the Data Store Read and Data Store Write blocks that you want to write to and read from the data store.
- 3 From the MATLAB command line, set `DataLogging` (which is a property of the `LoggingInfo` property of `Simulink.Signal`) to 1.

For example, if you use a `Simulink.Signal` object called `DataStoreSignalObject` to create a data store, use the following command:

```
DataStoreSignalObject.LoggingInfo.DataLogging = 1
```

- 4 Optionally, specify limits for the amount of data logged, using the following properties, which are properties of the `LoggingInfo` property of the `Simulink.Signal` object: `Decimation`, `LimitDataPoints`, and `MaxPoints`.

- 5 Enable data store logging with the **Model Configuration Parameters > Data Import/Export > Data stores** parameter.
- 6 Simulate the model.

## Accessing Data Store Logging Data

The following Simulink classes represent data from data store logging and provide methods for accessing that data:

Class	Description
<code>Simulink.SimulationData.BlockPath</code>	Represents a fully specified Simulink block path; use for capturing the full model reference hierarchy
<code>Simulink.SimulationData.Dataset</code>	Stores logged data elements and provides searching capabilities; use to group <code>Simulink.SimulationData.Element</code> objects in a single object
<code>Simulink.SimulationData.DataStoreMemory</code>	Stores logging information from a data store during simulation

You can also convert data logged in formats other than Dataset. For more information, see “Convert Data to Dataset Format” on page 77-17.

### Viewing Data Store Data

To view data store logging data from the command line, view the output data set in the base workspace. The default variable for the data store logging data set is `dsmout`.

To view data store logging data, see “Use Data Stores Across Multiple Models”.

### Accessing Elements in the Data Store Logging Data

To find an element in the data store logging data, based on the `Name` or `BlockType` property, use the `getElement` method of `Simulink.SimulationData.Dataset`. For example:

```
dsmout.getElement('RefSignalVal')

ans =
Simulink.SimulationData.DataStoreMemory
Package: Simulink.SimulationData

Properties:
    Name: 'RefSignalVal'
    Blockpath: [1x1 Simulink.SimulationData.BlockPath]
    Scope: 'local'
    DSMWriterBlockPaths: [1x2 Simulink.SimulationData.BlockPath]
    DSMWriters: [101x1 uint32]
    Values: [101x1 timeseries]
```

To access an element by index, use the `Simulink.SimulationData.Dataset.getElement` method.

## What Is a Data Dictionary?

A data dictionary is a persistent repository of data that are relevant to your model. You can also use the base workspace to store design data that are used by your model during simulation. However, a data dictionary provides more capabilities.

The dictionary stores design data, which define parameters and signals, and include data that define the behavior of the model. The dictionary does not store simulation data, which are inputs or outputs of model simulation that enter and exit Inport and Output blocks.

A data dictionary is not associated with the MATLAB dictionary data type which is a data structure that associates each key with a corresponding value. For information on the MATLAB dictionary data type, see “Dictionaries”.

### Dictionary Capabilities

Dictionary Capability	Benefit
Dictionary as data source	Entries in a dictionary are persistent. You do not need to reload data during development.
Explicit data-model linkage	You can define a data dictionary as the data source for a model. During model simulation and code generation, the model retrieves data from the data dictionary.
Version handling	You can: <ul style="list-style-type: none"> <li>• Attach a data dictionary that includes model data saved in a previous version of Simulink to your model.</li> <li>• Continue using the data dictionary of a model saved in a previous version of Simulink with versions of the model saved in later versions of Simulink.</li> <li>• Export (save) a data dictionary for use in models created with a previous version of Simulink.</li> </ul>
Change tracking	When you modify an entry, its status is updated in the dictionary and stored as metadata that can be tracked. The dictionary also tracks who made the changes and when. You can also view or revert changes.
Entry comparison	Compare values of entries in two dictionaries.
Data grouping into reference dictionaries	Partition and organize data items into reference dictionaries.
Model-data dependency	Discover how entries are used in the model.

Dictionary Capability	Benefit
Options for fixing a missing variable	For a variable reported as undefined at compilation time: <ul style="list-style-type: none"> <li>• If the variable does not exist, create a new variable or load a file.</li> <li>• If the variable has been deleted, undo the deletion or create a new variable.</li> <li>• If the variable has been renamed, rename references to the variable or create a new variable by copying the renamed variable.</li> </ul>
Store and partition reference data	Store and partition data that are relevant to a model, such as equipment specifications, but not used by the model during simulation.
Unified interface for defining data	Use the Model Explorer to work with design data in a dictionary.
Incremental update in memory	Improved performance and scalability with minimal memory footprint.
Requirements traceability linking	Navigate from a data dictionary entry to a location in a requirements document.

## Sections of a Dictionary

A Simulink data dictionary consists of four sections:

- **Design Data:** Contains the variables and data types that define parameters, signals, and design data that determine the behavior of the model. Design data created or imported in a dictionary are stored in this section.

This section can store only certain classes and data types. See “Valid Design Data Classes” on page 79-10 for more information.

- **Configurations:** Contains configuration sets, which are objects of the `Simulink.ConfigSet` class, that determine how the model is configured during simulation. These objects control attributes such as sample time and simulation start time.

When you store configuration sets in a data dictionary, you use configuration references to access the configuration sets. Models with an attached data dictionary resolve configuration references to configuration sets in the dictionary. For more information about configuration references, see “Share a Configuration with Multiple Models” on page 13-11.

This section can also store variant configuration objects, which belong to the `Simulink.VariantConfigurationData` class. These objects store information about variant configurations, active and default variant settings, and definitions of the control variable associated with each configuration.

---

**Note** If you load a configuration set from the data dictionary that contains a component that is not available on your system, the parameters in the missing component are reset to their default values.

---

- **Embedded Coder Dictionary:** Contains code generation definitions for use with Embedded Coder. To inspect and modify code definitions stored in a data dictionary, use the **Embedded Coder Dictionary** not the Model Explorer.
- **Other Data:** Contains information that is relevant to your model but not used by the model during simulation. Use this section to store reference information such as data that describe physical equipment and processes that are represented by your model.

This section can store almost any built-in or custom class or data type. See “Invalid Other Data Classes” on page 79-11 for more information.

## Dictionary Usage for Models Created with Different Versions of Simulink

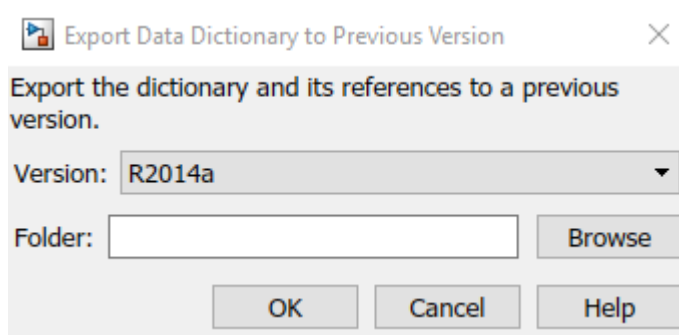

Simulink provides version handling for data dictionaries. When these events occur, Simulink synchronizes data in a dictionary for use with a model regardless of the Simulink version used to create the model:

- You attach a data dictionary that was saved in a previous version of Simulink to your model – for example, you attach a data dictionary saved in R2018a to a model that you develop in R2018b.
- You open a model with an attached data dictionary that was saved in a previous version of Simulink – for example, you developed a model that uses a data dictionary in R2018a and you open that model in R2018b to continue development.

To view the Simulink version in which a data dictionary is saved, in the Current Folder browser, click the data dictionary and find the **Saved in Simulink version** field in the **Details** pane. You also have the option to export (save) a data dictionary for use with models created using a different version of Simulink. To use a data dictionary you saved in a newer Simulink version in an older Simulink version, you need to export it first.

To export a data dictionary:

- 1 In the **Current Folder** pane of the MATLAB Command Window, navigate to the location of the data dictionary.
- 2 Double-click the name of the dictionary.
- 3 In the Model Explorer, right-click the name of the data dictionary. If you have made changes to the dictionary, in the context menu, select **Save Changes**.
- 4 Right-click the name of the data dictionary. In the context menu, select **Export to Previous Version**.
- 5 In the Export Data Dictionary to Previous Version dialog box, specify the previous version of Simulink in which you want to save the model. Specify the folder into which you want Simulink to place the new version of the dictionary. The folder that you specify cannot contain dictionaries that are part of the existing dictionary hierarchy. Then, click **OK**.

- 6 Verify that the new version of the data dictionary exists in the folder that you specified.

## Manage and Edit Entries in a Dictionary

To create, modify, and view the entries in a data dictionary, use the Model Explorer. For more information, see “Create, Edit, and Manage Workspace Variables” on page 72-100 and “View and Revert Changes to Dictionary Data” on page 79-24.

To manage entries in a dictionary programmatically, see “Store Data in Dictionary Programmatically” on page 79-40.

## Dictionary Referencing

You can reference one or more dictionaries in a parent dictionary. The data in the referenced dictionaries are visible in the parent dictionary. Use this technique to meaningfully partition data, especially for model reference hierarchies. For more information, see “Partition Dictionary Data Using Referenced Dictionaries” on page 79-28 and “Partition Data for Model Reference Hierarchy Using Data Dictionaries” on page 79-30.

## Import and Export File Formats

File Format	Import to Dictionary	Export from Dictionary
MAT-file	✓	✓
MATLAB script	✓	✓

## Allow Access to Base Workspace

For information about the **Enable model access to base workspace** property and the **Enable dictionary access to base workspace** property, see “Continue to Use Shared Data in the Base Workspace” on page 79-12.

## See Also

## Migrate Models to Use Simulink Data Dictionary

A Simulink data dictionary permanently stores model data including MATLAB variables, data objects, and data types. For basic information about data dictionaries, see “What Is a Data Dictionary?” on page 79-2.

### Migrate Single Model to Use Dictionary

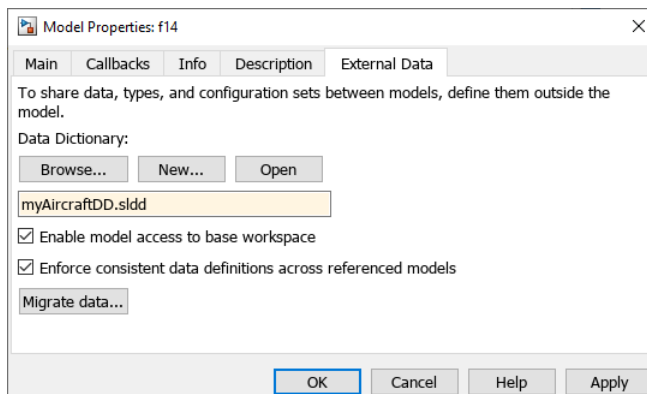

This example shows how to link a single standalone model to a single data dictionary.

---

**Note** Simulink does not import simulation data such as Timeseries objects into the data dictionary.

---

- 1 Open the f14 model, which loads design data into the base workspace.
- 2 Save a copy of the model to your current folder. Open the copy.
- 3 In the Simulink Editor, on the **Modeling** tab, under **Design**, click **Link to Data Dictionary**.
- 4 In the **Model Properties** dialog box, click **New** to create a data dictionary.

- 5 Name the data dictionary, save it, and click **Apply**.
- 6 Click **Migrate data**.
- 7 Click **Migrate** in response to the message about copying referenced variables.
- 8 (Optional) Clear **Enable model access to base workspace**.
- 9 Click **OK**.

10

To open the dictionary, in the Simulink Editor, click the model data badge  in the bottom left corner, then click the **External Data** link. To inspect the contents of the dictionary, in the Model Explorer **Model Hierarchy** pane, under the **External Data** node, expand the dictionary node.

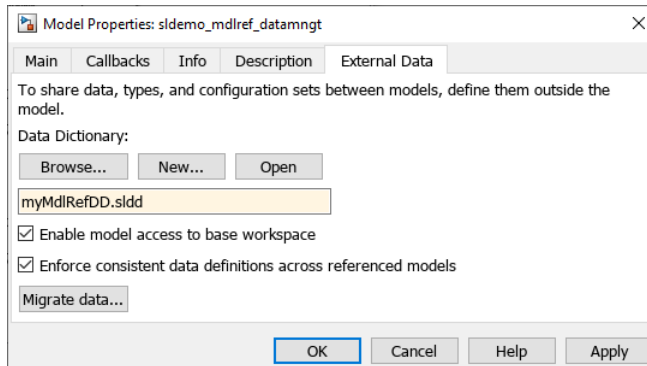

### Migrate Model Reference Hierarchy to Use Dictionary

This example shows how to link a parent model and all its referenced models to a single data dictionary.

- 1 Open the sldemo\_mdref\_datamngt model.

```
openExample('sldemo_mdref_datamngt')
```

- 2 The `sldemo_mdref_datamngt` model references `sldemo_mdref_counter_datamngt`.
- 2 Save copies of the models to your current folder.
- 3 Open the top model, `sldemo_mdref_datamngt`.
- 4 In the Simulink Editor, on the **Modeling** tab, under **Design**, click **Link to Data Dictionary**.
- 5 In the **Model Properties** dialog box, click **New** to create a data dictionary.

- 6 Name the data dictionary, save it, and click **Apply**.
- 7 Click **Change all models** in response to the message about linking referenced models that do not already use a dictionary.
- 8 Click **Migrate data**.
- 9 Click **Migrate** in response to the message about copying referenced variables.
- 10 (Optional) Clear **Enable model access to base workspace**.
- 11 Click **OK**.

## Considerations Before Migrating to Data Dictionary

After you link a model to a data dictionary, you can choose to migrate data from the base workspace into the dictionary. If you choose to migrate data, take these considerations into account.

### Check for Data-Loading Callbacks

You can use model callbacks such as the `PreLoadFcn` callback to load design data from a file into the base workspace when a model is loaded. For example, the following callback loads design data from the MAT file `myData.mat`.

```
load myData
```

After you migrate to a data dictionary, these callbacks will continue to load design data into the base workspace. Since the model then derives design data from the dictionary, manually remove or comment out these data-loading callbacks.

You can use the Dependency Analyzer to find data-loading callbacks. See “Analyze Model Dependencies” on page 17-41.

### Check Scripts

A new model has access to the base workspace by default, but does not lose access when it is linked to a data dictionary. Scripts must be written with the assumption that the model can have access to the base workspace, the data dictionary, or both.

If you make explicit references to the base workspace by using the `handle base` in your scripts, consider changing these references.

Consider this example. Here, the script searches the base workspace for variable `sensor` and sets the parameter `enable` depending on the value of `sensor.noiseEnable`.

```
if evalin('base','sensor.noiseEnable')
    enable = 'Enabled';
else
    enable = 'Disabled';
end
```

When you migrate to a data dictionary, replace these explicit references to `base` as follows:

```
if Simulink.data.evalInGlobal(myExampleModel,...
'sensor.noiseEnable')
    enable = 'Enabled';
else
    enable = 'Disabled';
end
```

The `Simulink.data.evalInGlobal` function evaluates an expression in the global scope of the specified model. Here, the global scope can be in a data dictionary or the base workspace, if the model is not linked to a dictionary.

### Check Tunable Parameters for Code Generation

- If your model is linked to a data dictionary, and the model does not have access to the base workspace (see “Continue to Use Shared Data in the Base Workspace” on page 79-12), Simulink ignores storage class information specified in the Model Parameter Configuration dialog box.
- If you use the Simulink interface to migrate a model to use a data dictionary, and you choose to migrate base workspace data, Simulink also migrates the storage class information of the model. If your model contains storage class information for variables in the base workspace, Simulink converts these variables into `Simulink.Parameter` objects during migration. Then, Simulink sets the storage class of these `Simulink.Parameter` objects using the storage class information from the model.
- If you migrate this model back to the base workspace, Simulink does not restore the storage class information in the model. To preserve the storage class for these variables, use the parameter objects from the data dictionary. You can also manually reset the storage class information in the model.
- If you set the `DataDictionary` property of a model from the command line, you can convert tunable variables to `Simulink.Parameter` objects using the `tunablevars2parameterobjects` function.

### Data Used by Model References

When you use model referencing to break a large system of models into smaller components and subcomponents, you can create data dictionaries to separate the data that the models use. Different models in a model hierarchy can connect to different dictionaries to view different sets of data.

Data dictionaries in a model hierarchy can contain multiple definitions of the same symbol. In this case, each of the symbol definitions visible to one model must be consistent for the model to update. Symbol definitions are consistent when their symbol name, class type, and property values are the same. These definitions can come from the base workspace, connected Simulink data dictionaries, or visible library dictionaries. If definitions for the same symbol are consistent, you can simulate the model in the normal, accelerator, and rapid accelerator modes, and generate code for the model. Duplicate symbols defined in the interface dictionary or in a data dictionary linked to an architecture model are not supported.

**Note** When a model can see multiple consistent definitions of a symbol, only one of the definitions is displayed by the Model Data Editor and returned by `Simulink.findVars`. It is this definition that is used by the model during simulation.

---

The current model and the models below it in the model hierarchy can use symbols with the same name but different values by setting the model parameter `EnforceDataConsistency` to `off`. In the Model Properties dialog box, on the **External Data** tab, clear the **Enforce consistent data definitions across referenced models** check box. Or set the parameter to `off` programmatically by using the `set_param` function.

```
set_param(bdroot, 'EnforceDataConsistency', 'off');
```

This setting allows you to more easily integrate Simulink models for large-scale simulations.

By default, the `EnforceDataConsistency` parameter is set to `on`. You cannot set `EnforceDataConsistency` to `on` for a model unless each of its referenced models and their variants also set `EnforceDataConsistency` to `on`.

Setting `EnforceDataConsistency` to `off` results in an error for:

- Code generation
- SIL and PIL simulations
- Simulation of a protected model

For more information, see “Determine Where to Store Variables and Objects for Simulink Models” on page 72-94.

### Valid Design Data Classes

You can import, store, or create MATLAB variables that use Simulink-supported data types, such as `boolean` and `int32`, and structures in the **Design Data** section of a Simulink data dictionary. You can also use objects of these classes and objects of most classes that subclass these classes:

- `Simulink.AliasType`
- `Simulink.Bus`
- `Simulink.NumericType`
- `Simulink.Parameter`
- `Simulink.LookupTable`
- `Simulink.Breakpoint`
- `Simulink.Signal`
- `Simulink.ValueType`
- `Simulink.Variant`
- `Simulink.data.dictionary.EnumTypeDefinition`
- `embedded.fi`
- `embedded.fimath`
- `numlti`

In addition, you can import, store, or create configuration objects of these classes in the **Configurations** section of a Simulink data dictionary:

- ConfigSet
- Simulink.VariantConfigurationData

### Invalid Other Data Classes

You can import, store, or create data objects of many built-in and custom classes or data types in the **Other Data** section of a Simulink data dictionary, except for the following:

- Arrays of objects created from built-in or custom classes
- Custom classes that have a property with any of these names:
  - LastModified
  - LastModifiedBy
  - DataSource
  - Status
  - Variant

### Migration With From Workspace Blocks

If a model contains a From Workspace block that refers to a variable in the base workspace, you can migrate the model to a data dictionary. However, the migration process takes different actions depending on the nature of the variable that the block refers to:

- If the value of the variable is not a `timeseries` object, the migration process imports the variable to the Design Data section of the data dictionary. The block can still refer to the variable.
- If the value of the variable is a `timeseries` object (which a data dictionary cannot store) or a structure with fields identical to a `timeseries` object, the migration process does not import the variable. Then, when you try to update the diagram or simulate the model, the From Workspace block cannot find the variable and issues an error. In such a case, you can configure the block to refer to the base workspace variable by using the `evalin` function. For more information, see From Workspace.

### Data Dictionary Limitations

- Simulink cannot automatically migrate variables used only by inactive variant models into a data dictionary.
- You cannot import certain kinds of design data such as meta class objects and `timeseries` objects into the Design Data section of a data dictionary.
- Simulink does not allow implicit signal resolution for a model linked to a data dictionary. To use a data dictionary, set the model configuration parameter **Signal resolution** to `Explicit` only or `None`.
- If a model reference hierarchy is already linked to a data dictionary, you can protect a referenced model that is part of the hierarchy. However, if you migrate a model reference hierarchy that includes a protected model, simulation will fail.

In other words, migrate a model to use a data dictionary before protecting it.

- Evaluation of expressions that include Simulink variables or data types that are stored in a data dictionary might not be supported.

## Continue to Use Shared Data in the Base Workspace

You can continue to store shared data in the base workspace and store model-specific data in the data dictionary by:

- Enabling access to the base workspace for the model.
- Enabling access to the base workspace from a data dictionary.

To enable access to the base workspace for a model, in the Model Properties dialog box, on the **External Data** tab, select **Enable model access to base workspace**. For a new model, this check box is selected by default. If the model is not linked to a data dictionary, this option must be selected.

You can also allow access to the base workspace from a data dictionary. For an existing dictionary, in the Model Explorer, select **Enable dictionary access to base workspace**.

When you allow base workspace access from a data dictionary, these limitations and ramifications apply:

- In general, you cannot interact with base workspace data through the dictionary.
  - When you inspect the contents of the dictionary in the Model Explorer, you cannot see base workspace data. To interact with base workspace data, in the **Model Hierarchy** pane, select the **Base Workspace** node.
  - With the programmatic interface of the data dictionary (see “Store Data in Dictionary Programmatically” on page 79-40), to interact with base workspace data, you can use only these functions with a `Simulink.data.dictionary.Section` object:
    - `assignin`
    - `exist`
    - `evalin`

Consider using functions such as `Simulink.data.assigninGlobal` instead. See “Transition to Using Data Dictionary” on page 79-43.

- Change-tracking features, such as the ability to view and revert changes to dictionary entries (see “View and Revert Changes to Dictionary Entries” on page 79-24), do not apply to base workspace data.
- When you export data from a dictionary (see “Import and Export Dictionary Data” on page 79-19), Simulink ignores base workspace data.
- Simulink treats the base workspace and the dictionary as a single namespace. However you can define two variables with the same name, one in the base workspace and one in the dictionary. In this case, the variables must be identical and the variable in the dictionary is used.

## Migrate Complicated Model Hierarchy with Shared Data

For examples, see “Partition Data for Model Reference Hierarchy Using Data Dictionaries” on page 79-30.

## Enumerations in Data Dictionary

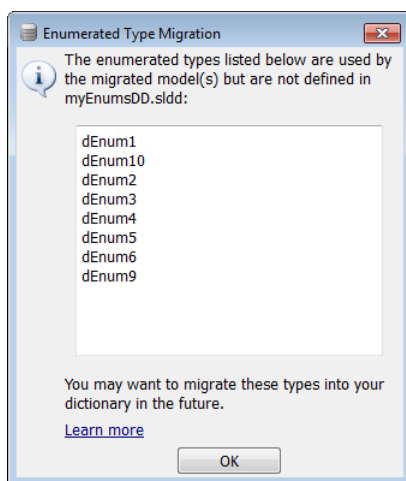

A Simulink data dictionary permanently stores model data including MATLAB variables, data objects, and data types including enumerated types. Enumeration classes defined in MATLAB by the data dictionary are owned by that dictionary and cannot be cleared by using `Simulink.clearIntEnumType`. To use an enumeration class defined in a data dictionary, the data dictionary must be open. When you close a data dictionary, the dictionary clears the enumeration classes that it owns. If an instance of an enumeration class exists when you close the dictionary, that enumeration class is not cleared and MATLAB becomes the owner of the class. The definition of the class remains in memory until you clear it by using `Simulink.clearIntEnumType`. To find the enumeration classes that remain in memory, call `Simulink.findIntEnumType`. For basic information about data dictionaries, see “What Is a Data Dictionary?” on page 79-2.

### Migrate Enumerated Types into Data Dictionary

This example shows how to migrate enumerated types that are used by a model into a data dictionary.

#### Import Design Data

- 1 Open a model that uses enumerated types for design data or for blocks in the model.
- 2 In the Simulink Editor, on the **Modeling** tab, in the **Design** section, under **Repositories**, click **Link to Data Dictionary**.
- 3 In the **Model Properties** dialog box, click **New** to create a data dictionary.
- 4 Name the data dictionary, save it, and click **Apply**.
- 5 Click **Migrate data**.
- 6 Click **Migrate** in response to the message about copying referenced variables.
- 7 Simulink reports the enumerated types that were not imported into the data dictionary.

- 8 Click **OK**.

A notification appears in the Simulink Editor, reporting that your model is now linked to the data dictionary.

## Import Enumerated Types

Import the definitions of enumerated types only after you import all the design data that were creating using the types. When you import enumerated types to a data dictionary, Simulink disables MATLAB files or P-files that contain the type definitions, causing variables that remain in the MATLAB base workspace to lose their definitions.

- 1 At the MATLAB command prompt, get the names of enumerated types that are used in model blocks.

```
% Find all variables and enumerated types used in model blocks
usedTypesVars = Simulink.findVars('EnumsReporting','IncludeEnumTypes',true);
% Here, EnumsReporting is the name of the model and
% usedTypesVars is an array of Simulink.VariableUsage objects

% Find indices of enumerated types that are defined by MATLAB files or P-files
enumTypesFile = strcmp({usedTypesVars.SourceType},'MATLAB file');

% Find indices of enumerated types that are defined using the function
% Simulink.defineIntEnumType
enumTypesDynamic = strcmp({usedTypesVars.SourceType},'dynamic class');

% In one array, represent indices of both kinds of enumerated types
enumTypesIndex = enumTypesFile | enumTypesDynamic;

% Use logical indexing to return the names of used enumerated types
enumTypeNames = {usedTypesVars(enumTypesIndex).Name}'

enumTypeNames =

    'dEnum1'
    'dEnum10'
    'dEnum2'
    'dEnum3'
    'dEnum4'
    'dEnum5'
    'dEnum6'
    'dEnum9'
```

- 2 Open the data dictionary, and represent it with a `Simulink.data.Dictionary` object.

```
ddConnection = Simulink.data.dictionary.open('myEnumsDD.sldd')

ddConnection =

    Dictionary with properties:

        DataSources: {0x1 cell}
        HasUnsavedChanges: 0
        NumberOfEntries: 3
```

- 3 Use the `importEnumTypes` method to import the enumerated types that are used by blocks in the model. The method saves changes made to the target dictionary, so before you use the method, confirm that unsaved changes are acceptable.

```
[successfulMigrations, unsuccessfulMigrations] = ...
importEnumTypes(ddConnection,enumTypeNames)

successfulMigrations =

    1x6 struct array with fields:

        className
```

```
renamedFiles
```

```
unsuccessfulMigrations =
```

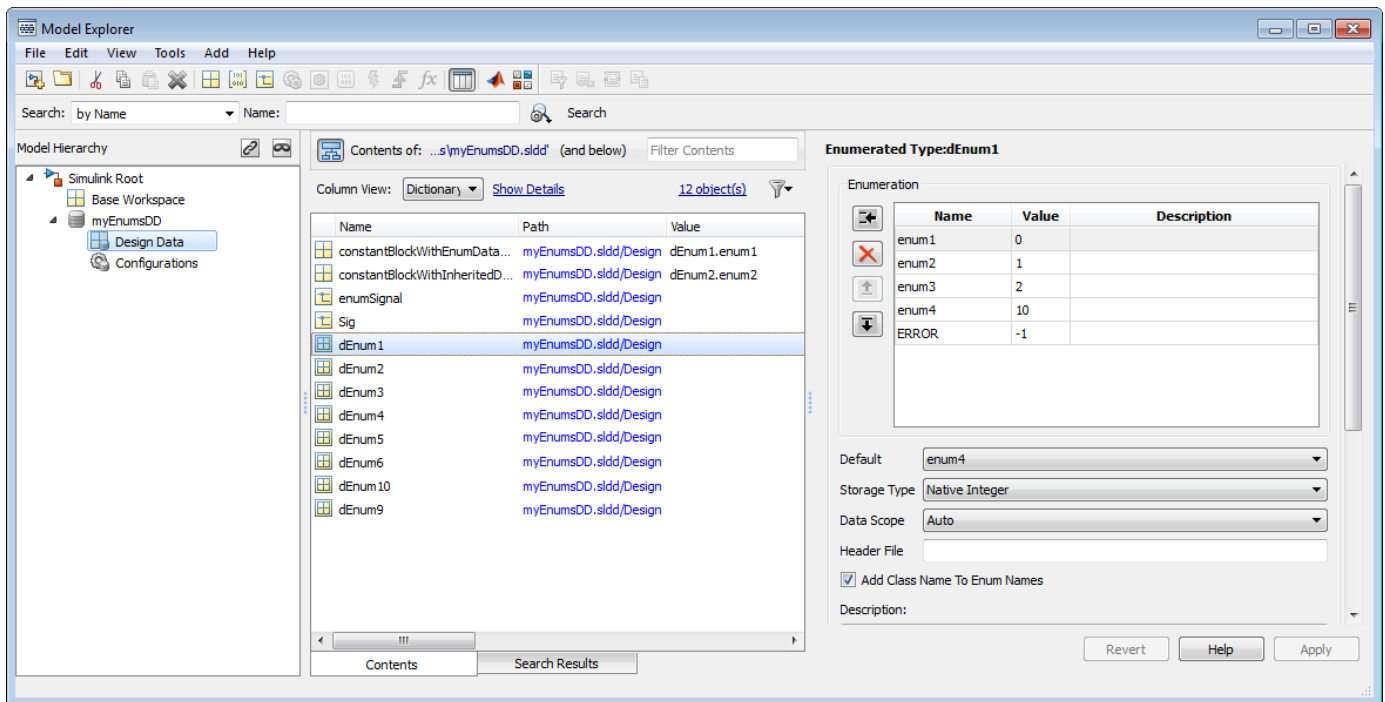

```
1x2 struct array with fields:
```

```
className
reasons
```

When enumerated types are imported, `importEnumTypes` renames the enumerated class definition file by appending `.save` to the file name. For example, if the original enumerated class definition is named `Enum1.m`, Simulink renamed the file as `Enum1.m.save`.

The structure `unsuccessfulMigrations` reports enumerated types that are not migrated. In this example, two enumerated type instances are defined in the model workspace and can be imported after closing the model. Close the model to import these enumerated types.

- 4 Open the dictionary to view the migrated enumerated types.

## Manipulate Enumerations in Data Dictionary

These examples show how to operate on existing enumerations in a data dictionary.

- “Rename Enumerated Type Definition” on page 79-17
- “Rename Enumeration Members” on page 79-17
- “Delete Enumeration Members” on page 79-17
- “Change Underlying Value of Enumeration Member” on page 79-17

### Rename Enumerated Type Definition

- 1 In the data dictionary, create a copy of the enumerated type, and rename the copy instead.
- 2 Find enumeration objects used by your model that are derived from the type with the old name.
- 3 Replace these objects with those derived from the renamed type.
- 4 Delete the type with the old name.

### Rename Enumeration Members

Use one of the following approaches.

- Select the enumeration within the dictionary, and rename one or more enumeration members.
- If your model references enumeration members, change these references to match the renamed member.

### Delete Enumeration Members

- 1 Find references in your model to an enumeration member you want to delete.
- 2 Replace these references with an alternate member.
- 3 Delete the original member from the enumeration.

### Change Underlying Value of Enumeration Member

You can change the values of enumeration members when you represent these values as MATLAB variables or by using `Value` field of `Simulink.Parameter` objects.

- 1 Find references in your model to an enumeration member whose value you want to change.
- 2 Make a note of these references.
- 3 Change the value of the enumeration member.
- 4 Manually update references to the enumeration member in your model.

## Remove Enumerated Types from Data Dictionary

If you decide that you no longer want to define an enumerated type in a dictionary, follow these steps.

- 1 Manually define the enumerated data type in MATLAB. See “Use Enumerated Data in Simulink Models” on page 73-5.
- 2 Delete instances of the enumeration class. If there is an instance of the enumeration class in existence when you delete the enumerated data type from the dictionary, the dictionary releases control of the enumeration class, but the class remains in memory as a dynamic enumeration class. You can then find or clear the class by using `Simulink.findIntEnumType` and `Simulink.clearIntEnumType`.
- 3 Delete the enumerated type from the dictionary.

### See Also

`Simulink.data.dictionary.EnumTypeDefinition`

### **Related Examples**

- “Use Enumerated Data in Simulink Models” on page 73-5
- “Simulink Enumerations” on page 73-2

## Import and Export Dictionary Data

A Simulink data dictionary permanently stores model data including MATLAB variables, data objects, and data types. For basic information about data dictionaries, see “What Is a Data Dictionary?” on page 79-2.

### Import Data to Dictionary from File

You can import data from a MATLAB file or MAT-file to a data dictionary using the Model Explorer window. Import variables and data objects that are used by a model during simulation to the Design Data section of a dictionary. Import variables and objects that you want to store with a model, but that are not used by the model during simulation, to the Other Data section of a dictionary.

#### Import Design Data from File

This example shows how to import design data from a file into the Design Data section of a dictionary.

- 1 In the Simulink Editor, in the **Modeling** tab, click **Model Explorer** to open the Model Explorer.
- 2 Select **File > Open**. Then browse to an existing dictionary.
- 3 In the **Model Hierarchy** pane, right-click the **Design Data** section of the dictionary and select **Import from File**. Then browse to and select the MAT-file or MATLAB file that contains the data to import.

Design data from the MAT-file populate the dictionary. Data appear with **DataSource** set to the name of the dictionary.

If you import from the same MAT-file again, Simulink only imports changed or new entries into the dictionary.

### Import Other Data from File

This example shows how to import data from a file into the Other Data section of a data dictionary. Use this section to store reference information that is not used by Simulink during simulation, such as data that describe physical equipment and processes that are represented by your model.

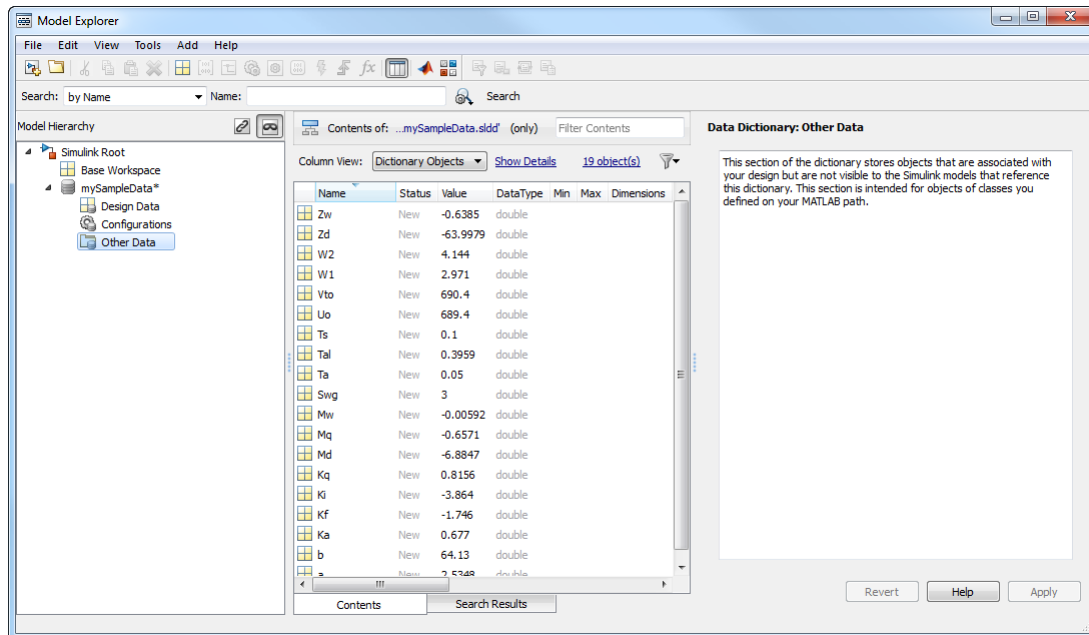

- 1 In the Simulink Editor, in the **Modeling** tab, click **Model Explorer** to open the Model Explorer.
- 2 Select **File > Open**. Then browse to an existing dictionary.
- 3 In the **Model Hierarchy** pane, right-click the dictionary node and select **Show Empty Sections**. Model Explorer reveals the **Other Data** and **Configurations** sections of the dictionary, even if they are empty, in addition to the **Design Data** section.

- 4 In the **Model Hierarchy** pane, right-click the **Other Data** section of the dictionary and select **Import from File**. Then browse to and select the MAT-file or MATLAB file that contains the reference data to import.

Data from the MAT-file populate the Other Data section of the dictionary. Data appear with **DataSource** set to the name of the dictionary.

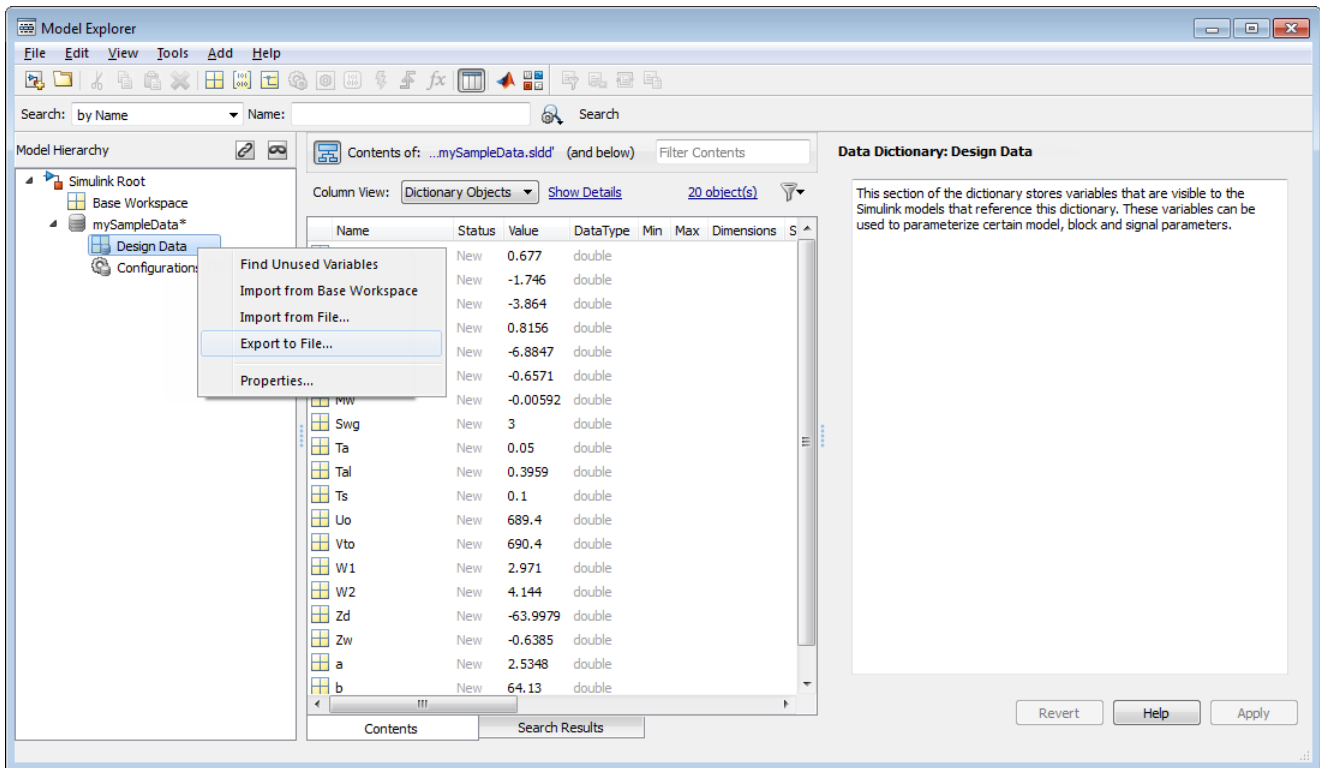

If you import from the same MAT-file again, Simulink only imports changed or new entries into the dictionary.

## Export Design Data from Dictionary

This example shows how to export model design data from a data dictionary into a MAT-file or MATLAB script.

- 1 In the Simulink Editor, in the **Modeling** tab, click **Model Explorer** to open the Model Explorer.
- 2 Open a data dictionary using **File > Open Data Dictionary**.
- 3 In the **Model Hierarchy** pane, expand the dictionary node and select **Design Data > Export to File**. Then save the design data to a MAT-file or MATLAB script.

The dictionary does not export enumerated data types (which are stored as `Simulink.data.dictionary.EnumTypeDefinition` objects). To transfer or copy an enumerated type from one dictionary to another, use the Model Explorer to cut or copy and paste the object.

## See Also

- “Migrate Models to Use Simulink Data Dictionary” on page 79-7

## View and Revert Changes to Dictionary Data

A Simulink data dictionary permanently stores model data including MATLAB variables, data objects, and data types. For basic information about data dictionaries, see “What Is a Data Dictionary?” on page 79-2.

### View and Revert Changes to Dictionary Entries

This example shows how to view unsaved changes to dictionary entries, who made them, and when. You can view changes to entries in any section, including data stored in the Other Data section and configuration sets stored in the Configurations section.

- 1 Open the `sldemo_fuelsys_dd_controller` model.

```
openExample('simulink_automotive/UseDDForFuelContSysExample','supportingfile','sldemo_fuelsys_dd_controller')
```

- 2

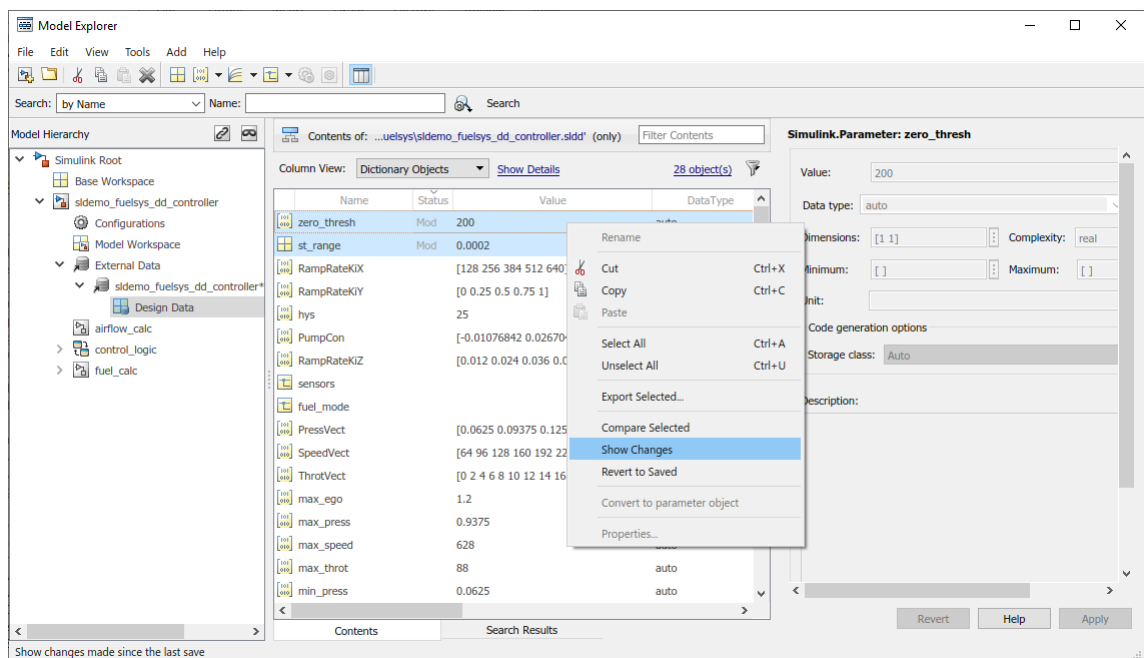

Open the data dictionary linked to this model. Click the model data badge  in the bottom left corner of the model, then click the **External Data** link.

- 3 In the Model Explorer **Model Hierarchy** pane, under the **External Data** node, select the **Design Data** node for `sldemo_fuelsys_dd_controller`.

- 4 In the **Contents** pane, change `st_range` to `0.0002` and `zero_thresh` to `200`.

The **Status** column of these entries changes to **Mod**, indicating that they have been modified.

- 5 Click the heading of the **Status** column to sort the entries. Then, select the modified entries, which are indicated by the **Mod** status.

- 6 Right-click and select **Show Changes**.

The Comparison Tool appears, displaying changed entries in separate tabs. The tool highlights changed values.

**Note** The Comparison Tool does not display changes to the data dictionary property **Enable dictionary access to base workspace**.

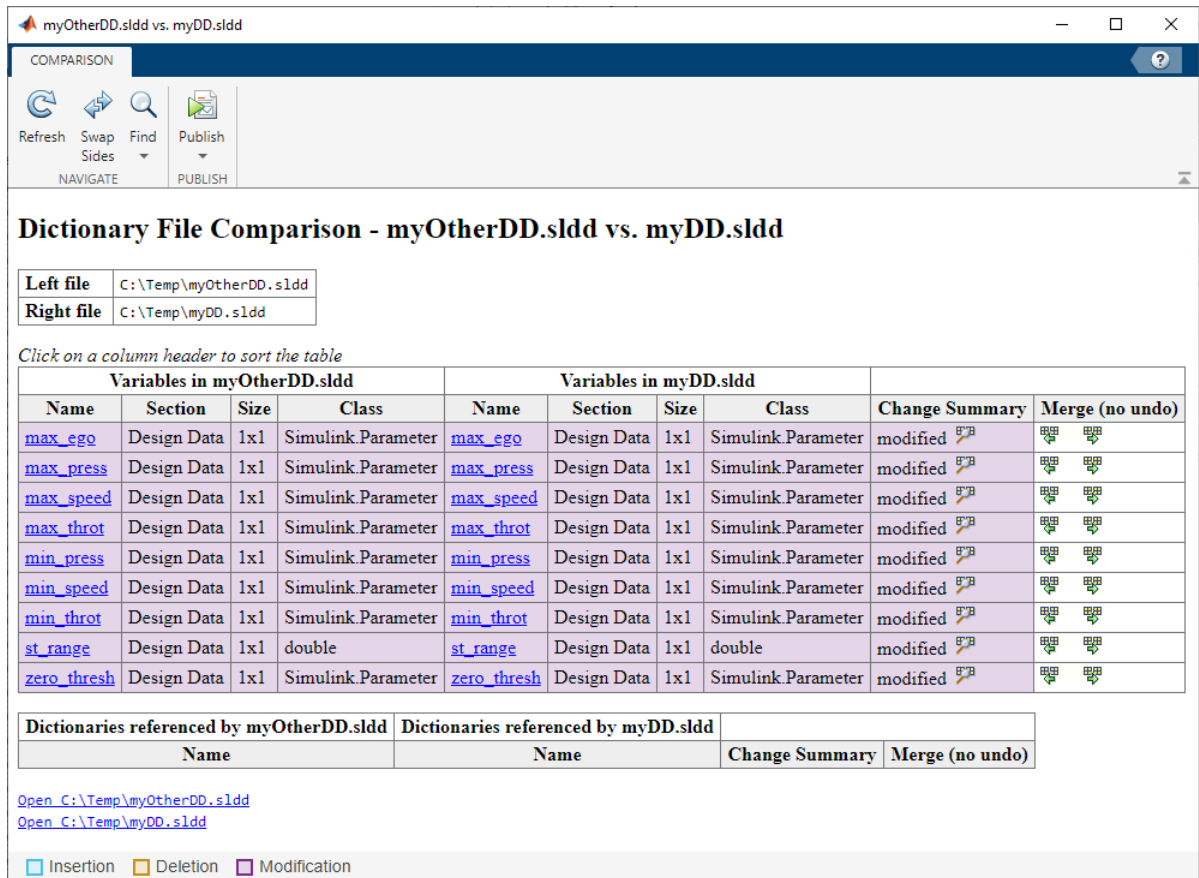

- 7 In the **Contents** pane of the Model Explorer, right-click `zero_thresh` and select **Revert to Saved**.

Simulink reverts `zero_thresh` to its value at the time of the last save action.

- 8 You can merge entries between dictionaries using the Comparison Tool. From the MATLAB desktop, on the **Home** tab, in the **File** section, click **Compare**.
- 9 Select the dictionaries to compare and merge.

- 10 In the comparison report, select the merge direction for each dictionary entry.

Insertion  Deletion  Modification

## View and Revert Changes to Entire Dictionary

If you store model variables in a data dictionary, you can view and manage the changes that you make while you work. You can use the Comparison Tool to see the changes made to a dictionary, which compares the modified dictionary with the most recent saved version.

When you view the changes to a dictionary, you can choose to discard changes to individual entries or dictionary references, which reverts to the last saved state. You can use this technique to recover entries that you delete in your modified version or dictionary references that you remove.

If you view changes to a dictionary that references other dictionaries, the Comparison Tool also reports changes made to the entries in the referenced dictionaries.

- 1 View the example data dictionary `sldemo_fuelsys_dd` in Model Explorer.

```
dictionary = Simulink.data.dictionary.open('sldemo_fuelsys_dd.sldd');
show(dictionary)
```

The dictionary contains entries that are defined in several referenced dictionaries, including `sldemo_fuelsys_dd_controller` and `sldemo_fuelsys_dd_plant`.

- 2 Make some changes to `sldemo_fuelsys_dd`.

```
section = getSection(dictionary, 'Design Data');
```

```
deleteEntry(section, 'PressVect');

entry = getEntry(section, 'min_throt');
entryValue = getValue(entry);
entryValue.DataType = 'int8';
entryValue.Value = 4;
setValue(entry, entryValue);
```

- In the **Model Hierarchy** pane of Model Explorer, right-click the node `sldemo_fuelsys_dd` and select **Show Changes**.

The Comparison Tool displays the changes made to the dictionary.

sldemo\_fuelsys\_dd.sldd

### Show Changes in Dictionary - sldemo\_fuelsys\_dd.sldd

*Click on a column header to sort the table*

Saved Entries				Unsaved Changes						
Name	Section	Data Source	Class	Name	Section	Data Source	Class	Change Summary	Last Modified	Action (no undo)
PressVect	Design Data	sldemo_fuelsys_dd_controller.sldd	Simulink Parameter					deleted	2013-10-22 04:05	<a href="#">Recover from Saved</a>
min_throt	Design Data	sldemo_fuelsys_dd_controller.sldd	Simulink Parameter	min_throt	Design Data	sldemo_fuelsys_dd_controller.sldd	Simulink.Parameter	modified ( <a href="#">compare</a> )	2015-03-11 09:05	<a href="#">Revert to Saved</a>

Dictionary references in sldemo_fuelsys_dd.sldd			
Saved References		Unsaved Changes	
Name	Name	Change Summary	Action (no undo)
sldemo_fuelsys_dd_plant.sldd		removed	<a href="#">Recover Reference</a>

- In the table at the top of the report, click **compare** in the Change Summary column of the row that corresponds to the entry `min_throt`.
 

A new tab shows the changes made to `min_throt`. The script changed the parameter data type from `auto` to `int8` and the parameter value from 3 to 4.
- Click the tab that shows the changes made to the dictionary. In the Action column of the row that corresponds to the entry `min_throt`, click **Revert to Saved**.
 

The entry reverts to the definition from the last saved version of the dictionary.
- The remaining row in the report shows that the script deleted the entry `PressVect`, which was defined in the referenced dictionary `sldemo_fuelsys_dd_controller`. Click **Recover from Saved**, which recovers the entry in the referenced dictionary.
- The table **Dictionary references in sldemo\_fuelsys\_dd.sldd** shows that the script removed the reference to the dictionary `sldemo_fuelsys_dd_plant`. In the Action column, click **Recover Reference**.

The report shows that there are no more unsaved changes to `sldemo_fuelsys_dd`.

## Partition Dictionary Data Using Referenced Dictionaries

This example shows how to partition a data dictionary into reference dictionaries that can be shared in a team. A Simulink data dictionary permanently stores model data including MATLAB variables, data objects, and data types.

### Open dictionary for partitioning

- 1 Open the Model Explorer. In the Simulink Editor, in the **Modeling** tab, click **Model Explorer**.
- 2 Select **File > Open**.

Browse and locate your dictionary.

### Create reference dictionary

Use a reference dictionary to store a subset of entries from the main dictionary.

- 1 Select **File > New > Data Dictionary**.

Name the reference dictionary and save it.

Both dictionaries appear as nodes in the **Model Hierarchy** pane.

- 2 In the **Model Hierarchy** pane, select the dictionary that serves as the parent.
- 3 In the dialog box pane, in the **Referenced Dictionaries** section, click **Add**. Browse to the location of the reference dictionary and add it as a reference.

The **Referenced Dictionaries** section displays each directly referenced data dictionary as a top level node and the indirectly referenced data dictionaries as a flat list below each top level node. To see the full dependency tree of referenced dictionaries in the Dependency Analyzer, click **View Hierarchy**.

### Move entries into reference dictionary

- 1 In the **Model Hierarchy** pane, select the **Design Data** node of the parent dictionary.
- 2 In the **Contents** pane, select the entries you want to move to the reference dictionary.
- 3 For one of the selected entries, set **DataSource** to the reference dictionary using the dropdown menu. You can also drag and drop entries between dictionaries.

To make the **DataSource** column visible, click **Show Details** in the **Contents** pane. In the text box, enter `DataSource`, and add `DataSource` to the list of displayed columns.

### Organize display of entries

- 1 Click the name of the **DataSource** column to sort the entries by the dictionaries that define them.
- 2 Right-click the name of the **DataSource** column and select **Group by This Column** to group the entries. The **Contents** pane creates a group for each dictionary that defines the entries.

## Partition Data for Model Reference Hierarchy Using Data Dictionaries

When you use model referencing to break a large system of models into smaller components and subcomponents, you can create data dictionaries to segregate the design data. Design data is the set of workspace variables that the models use to specify block parameters and signal characteristics. For basic information about data dictionaries, see “What Is a Data Dictionary?” on page 79-2.

To take this component-based approach to data management, create a shared dictionary that contains common data and a separate dictionary for each component that contains the data needed by that component.

### Open the Example Model and Load Design Data

Open the example model `ex_SystemModel`. This model is at the top of a reference hierarchy that includes the other example models.

Load the MAT-files contained in the working directory to create design data in the base workspace.

```
load ProjectData_Contr.mat
load ProjectData_ContrSub1.mat
load ProjectData_ContrSub2.mat
load ProjectData_ContrSubs.mat
load ProjectData_Plant.mat
load ProjectData_System.mat
```

### Create a Dictionary for Each Component

This example shows how to partition design data into dictionaries. When you finish, each component in the system has a dictionary, and dictionary references allow the components to share data.

#### Explore Example Model Hierarchy

- 1 In the model, update the diagram. Each bus signal in the model uses a `Simulink.Bus` object as a data type. The objects, `SensorBus` and `CtrlBus`, are in the base workspace.

The referenced models `ex_PlantComp_Lvl1` and `ex_ContrComp` use the bus objects for root-level inputs and outputs, which means the plant and controller components share the objects.

- 2 In the base workspace, double-click the `Simulink.NumericType` object named `FloatType`. Signals, parameters, and other data items in the controller component use this shared data type.
- 3 In the Model Explorer **Model Hierarchy** pane, expand the node `ex_SystemModel`.

Click the `Configurations` node. In the **Contents** pane, the node `Reference to SimConfigSet` appears. `SimConfigSet` is a `Simulink.ConfigSet` object in the base workspace. To maintain configuration parameter uniformity for simulation, all of the models in the hierarchy refer to `SimConfigSet`.

- 4 Right-click the node `Controller (ex_ContrComp)` and select **Open**.
- 5 In the Model Explorer **Model Hierarchy** pane, expand the new node `ex_ContrComp`. Click the `Configurations` node.

In the **Contents** pane, the node Reference to CodeGenConfigSet appears. CodeGenConfigSet is a Simulink.ConfigSet object in the base workspace. To maintain configuration parameter uniformity for code generation, the models in the controller component refer to CodeGenConfigSet. The models in the plant component do not use CodeGenConfigSet.

- 6 In the **Model Hierarchy** pane, select **Base Workspace**. In the **Contents** pane, right-click the variable `diff` and select **Find Where Used**. In the **Select a system** dialog box, select `ex_SystemModel` and click **OK**. If you see a message about updating the diagram, click **OK**.

In the **Contents** pane, the variable `diff` is used by Constant blocks in the models `ex_ContrComp_Sub1_Lvl1` and `ex_ContrComp_Sub1_Lvl2`, which make up the first controller subcomponent. Similarly, other models in the hierarchy share the base workspace variables `coeff`, `init`, `mu`, and `rho`.

The table shows the models that share each variable in the base workspace.

Variable Name	Models Using the Variable	Scope of Sharing
CtrlBus	Top-level models in the plant and controller components	Shared globally by entire system
SensorBus	Top-level models in the plant and controller components	Shared globally by entire system
SimConfigSet	All models in the hierarchy	Shared globally by entire system
rho	<code>ex_PlantComp_Lvl2</code> , <code>ex_ContrComp_Sub1_Lvl2</code> , and <code>ex_ContrComp_Sub2_Lvl2</code>	Shared globally by entire system
mu	<code>ex_PlantComp_Lvl1</code> and <code>ex_PlantComp_Lvl2</code>	Shared by models in the plant component
FloatType	All models in the controller component	Shared by controller component and subcomponents
CodeGenConfigSet	All models in the controller component	Shared by controller component and subcomponents
init	<code>ex_ContrComp_Sub1_Lvl2</code> and <code>ex_ContrComp_Sub2_Lvl1</code>	Shared by controller subcomponents
diff	<code>ex_ContrComp_Sub1_Lvl1</code> and <code>ex_ContrComp_Sub1_Lvl2</code>	Shared by models in the first controller subcomponent
coeff	<code>ex_ContrComp_Sub2_Lvl1</code> and <code>ex_ContrComp_Sub2_Lvl2</code>	Shared by models in the second controller subcomponent

Suppose that separate teams of developers maintain the plant component and the controller components. You can use data dictionaries to store and scope the shared design data.

### Create Shared Global Dictionary

Create a shared global data dictionary that contains the data shared globally by the entire system.

- 1 In the Model Explorer, select **File > New > Data Dictionary**.
- 2 Set the new dictionary name to `GlobalShare` and click **Save**.
- 3 In the **Model Hierarchy** pane, right-click the `GlobalShare` node and select **Show Empty Sections**.
- 4 In the **Model Hierarchy** pane, select **Base Workspace**. In the **Contents** pane, select the design data that are shared globally by the entire system: `CtrlBus`, `SensorBus`, and `rho`.
- 5 Right-click and select **Copy**.
- 6 In the **Model Hierarchy** pane, right-click the `Design Data` node under `GlobalShare` and select **Paste**.
- 7 Similarly, copy `SimConfigSet` from the **Base Workspace** and copy to the `Configurations` node under `GlobalShare`.

### Create Dictionary for Plant Component

Create a data dictionary for data shared by models in the Plant component. Add a reference from this dictionary to the shared global dictionary.

- 1 In the Model Explorer, select **File > New > Data Dictionary**.
- 2 Set the new dictionary name to `Plant` and click **Save**.
- 3 In the **Model Hierarchy** pane, select the node `Plant`. In the Dialog pane, under **Referenced Dictionaries**, click **Add**.
- 4 Double-click `GlobalShare.sldd`.
- 5 In the **Model Hierarchy** pane, right-click the node `Plant` and select **Save Changes**.

### Link Plant Component to Dictionary and Migrate Data

Link the Plant component to its component dictionary then migrate data shared by models in the Plant component from the base workspace to the dictionary.

- 1 Open the model `ex_PlantComp_Lvl1`.
- 2 In the model, update the diagram.
- 3 If the Diagnostic View displays an error for multiple inconsistent definitions of `SimConfigSet`, select **Delete others** next to the `GlobalShare` instance. This fix keeps the definition in the `GlobalShare` dictionary and removes other definitions that can be seen by the model.
- 4 In the **Modeling** tab, under **Design**, click **Link to Data Dictionary**.
- 5 In the dialog box, click **Browse**.
- 6 Double-click `Plant.sldd`.
- 7 In the **Model Properties** dialog box, click **Apply**. Click **Change all models** in response to the message about linking referenced models.
- 8 In the **Model Properties** dialog box, click **Migrate data**.
- 9 In the Migrate Data dialog box, select **Include data from referenced models** and then click **Migrate**.
- 10 (Optional) In the **Model Properties** dialog box, clear **Enable model access to base workspace**.
- 11 Remove the previous method for loading model data. In the **Model Properties** dialog box, on the **Callbacks** tab, clear the `PreLoadFcn` for the model.

- 12 Click **OK**.

### Create Dictionary for Controller Component

Create a data dictionary that contains the data shared by models in the controller component. This dictionary can also reference the shared global dictionary.

- 1 In the Model Explorer, select **File > New > Data Dictionary**.
- 2 Set the new dictionary name to **Controller** and click **Save**.
- 3 In the **Model Hierarchy** pane, select the node **Controller**. In the Dialog pane, under **Referenced Dictionaries**, click **Add**.
- 4 Double-click **GlobalShare.sldd**.
- 5 In the **Model Hierarchy** pane, right-click the node **Controller** and select **Save Changes**.

### Link Controller Component to Dictionary and Migrate Data

Link the Controller component to its component dictionary then migrate data shared by models in the Controller component from the base workspace to the dictionary.

- 1 Open the model **ex\_ContrComp**.
- 2 If the Diagnostic View displays an error for multiple inconsistent definitions of **SimConfigSet**, select **Delete others** next to the **GlobalShare** instance. This fix keeps the definition in the **GlobalShare** dictionary and removes other definitions that can be seen by the model.
- 3 In the **Modeling** tab, under **Design**, click **Link to Data Dictionary**.
- 4 In the dialog box, click **Browse**.
- 5 Double-click **Controller.sldd**.
- 6 In the **Model Properties** dialog box, click **Apply**. Click **Change all models** in response to the message about linking referenced models.
- 7 In the **Model Properties** dialog box, click **Migrate data**.
- 8 In the Migrate Data dialog box, select **Include data from referenced models** and then click **Migrate**.
- 9 (Optional) In the **Model Properties** dialog box, clear **Enable model access to base workspace**.
- 10 Remove the previous method for loading model data. In the **Model Properties** dialog box, on the **Callbacks** tab, clear the **PreLoadFcn** for the model.
- 11 Click **OK**.

### Link System to Global Dictionary

Finally, link the top model to the global dictionary.

- 1 Open the model **ex\_SystemModel**.
- 2 In the **Modeling** tab, under **Design**, click **Link to Data Dictionary**.
- 3 In the dialog box, click **Browse**.
- 4 Double-click **GlobalShare.sldd**.
- 5 In the **Model Properties** dialog box, click **OK**. Click **Change this model only** in response to the message about linking referenced models.

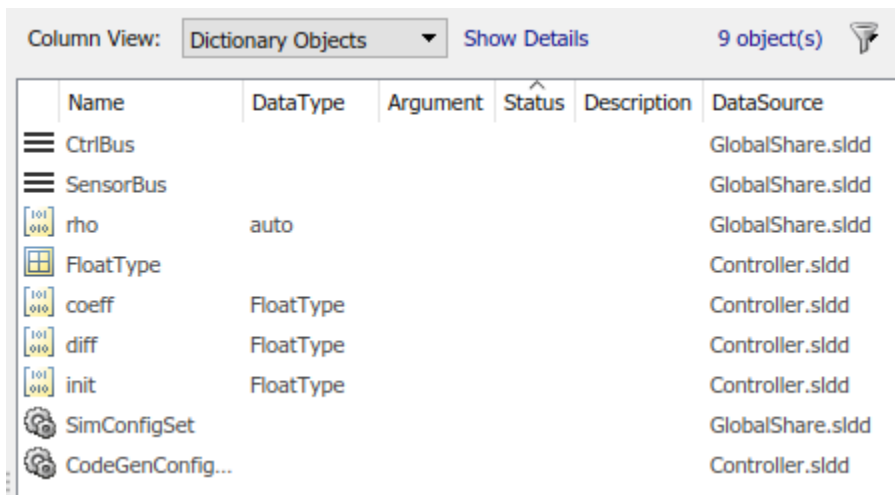

## Inspect Data Storage

In the Model Explorer **Model Hierarchy** pane, select the dictionary node `Plant`. In the **Contents** pane, to view the contents of `Plant.sldd`, click **Show Current System and Below** . The contents of the Design Data and Configurations sections appear.

Name	DataType	Argument	Status	Description	DataSource
CtrlBus					GlobalShare.sldd
SensorBus					GlobalShare.sldd
rho	auto				GlobalShare.sldd
mu	auto				Plant.sldd
SimConfigSet					GlobalShare.sldd

Similarly, view the contents of `Controller.sldd`.

Name	DataType	Argument	Status	Description	DataSource
CtrlBus					GlobalShare.sldd
SensorBus					GlobalShare.sldd
rho	auto				GlobalShare.sldd
FloatType					Controller.sldd
coeff	FloatType				Controller.sldd
diff	FloatType				Controller.sldd
init	FloatType				Controller.sldd
SimConfigSet					GlobalShare.sldd
CodeGenConfig...					Controller.sldd

The **DataSource** column shows the variables and objects that each dictionary stores.

All of the globally shared variables, such as `CtrlBus` and `SensorBus`, reside in `GlobalShare.sldd`. The variable `init`, which both of the controller subcomponents share, resides in `Controller.sldd`.

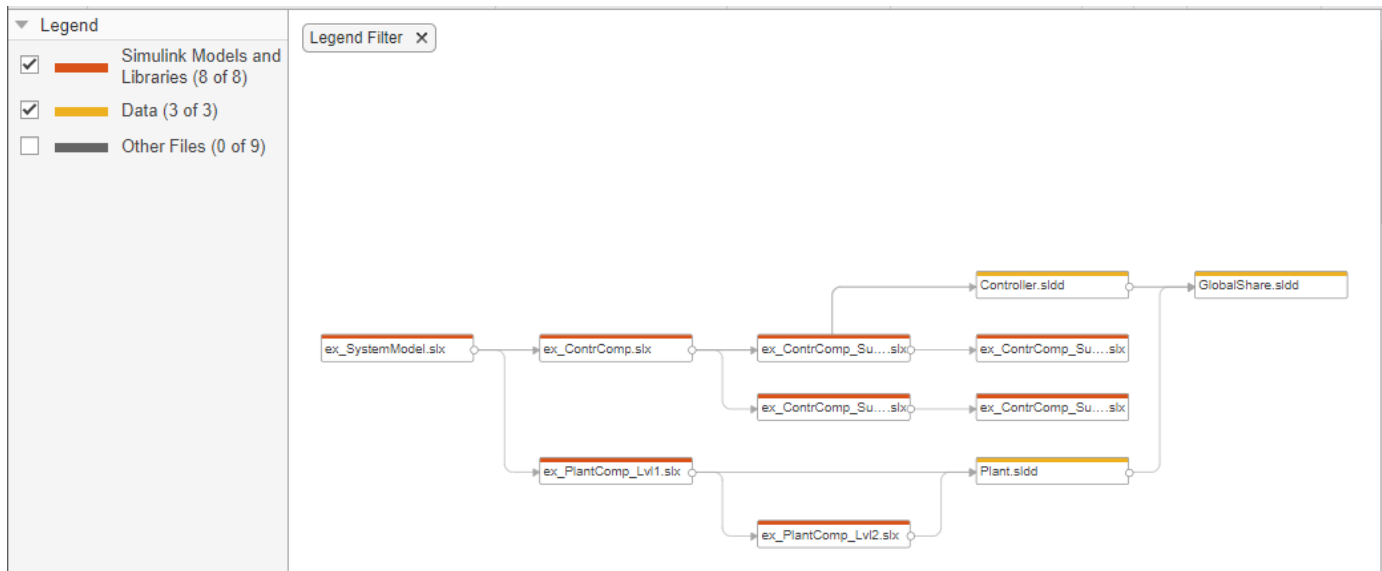

If the development team assigned to the controller component must make changes to the globally shared variables, they access the `GlobalShare` dictionary file. Similarly, if the team must make changes to the variable `init`, they must access the `Controller` dictionary file.

## Inspect Dictionary Hierarchy

To view the entire dictionary and model hierarchy, perform a dependency analysis.

- 1 Open your saved model `ex_SystemModel`.
- 2 On the **Modeling** tab, in the **Design** section, click **Dependency Analyzer**.

The system model, `ex_SystemModel`, is linked to the dictionary `GlobalShare.slidd`. The plant component and the controller component are each linked to a separate dictionary. To access the shared data, the component dictionaries reference the dictionary `GlobalShare.slidd`. These dictionaries form a reference hierarchy.

## Strategies to Discover Shared Data

To learn how the models in a model reference hierarchy share data, use these techniques:

- In an open model, on the Modeling tab, select **Find > Find Ref Variables**. The Model Explorer displays the variables that the model uses, as well as the variables that referenced models use. You can then right-click a variable and select **Find Where Used** to display all of the models that use the variable. For more information, see “Edit and Manage Workspace Variables by Using Model Explorer” on page 72-104.
- At the command prompt, use the function `Simulink.findVars` to determine the variables a model uses. You can then use the function `intersect` to determine the variables two models, components, or subcomponents share.

## Attach Data Dictionary to Custom Libraries

When you create a custom block library, you might define data objects — such as bus and enumeration types — to be used on block interfaces. You can make these data types available to library users by storing them in a Simulink data dictionary that is attached to the library. Library users automatically gain access to the data types contained in the dictionary when they drag a block from the library into their model.

### Author Library Blocks with Data Types Defined in Attached Data Dictionary

To define data and types for your library blocks in a data dictionary:

- 1 Create a new data dictionary or open an existing dictionary. To create a new dictionary, in the Model Explorer, select **File > New > Data Dictionary**. To open an existing dictionary, select **File > Open** and browse for your dictionary.
- 2 Add data and types, such as bus objects, to the data dictionary.

- 3 Save the data dictionary.

You can attach the data dictionary to your library by using the UI or programmatically by using the `set_param` function.

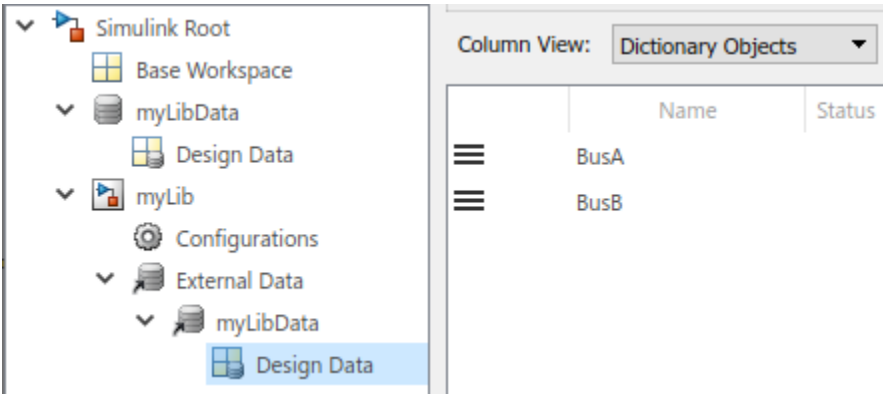

To attach the data dictionary by using the UI:

- 1 Unlock your library (see “Lock and Unlock Libraries” on page 44-6).
- 2 In the Simulink Editor, on the **Modeling** tab, click **Library Properties**.
- 3 In the Library Properties dialog box, on the **External Data** tab, click **Browse** to locate and open your data dictionary.
- 4 Click **OK** to attach the dictionary.

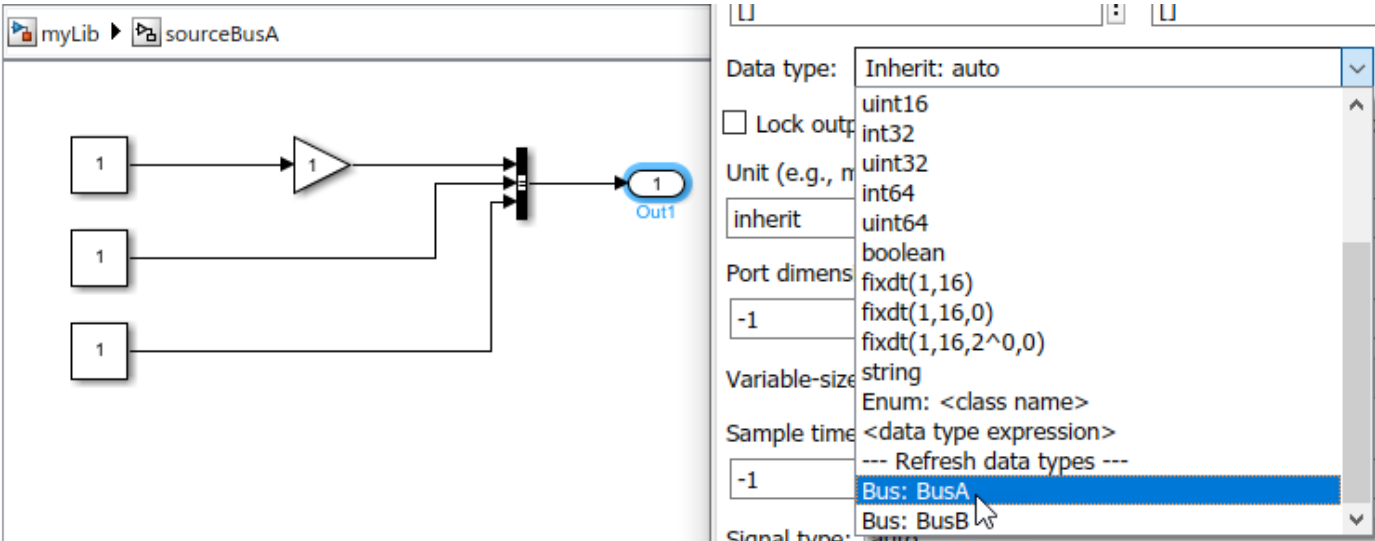

To attach the data dictionary by using the `set_param` function, use this command.

```
set_param('myLib', 'DataDictionary', 'myLibData.sldd');
```

After you have attached the dictionary and saved your library, the dictionary and its content appears in the Model Explorer as an external data source for the library.

As you develop blocks for your library, you can select the types contained in the library dictionary from the **Data type** list.

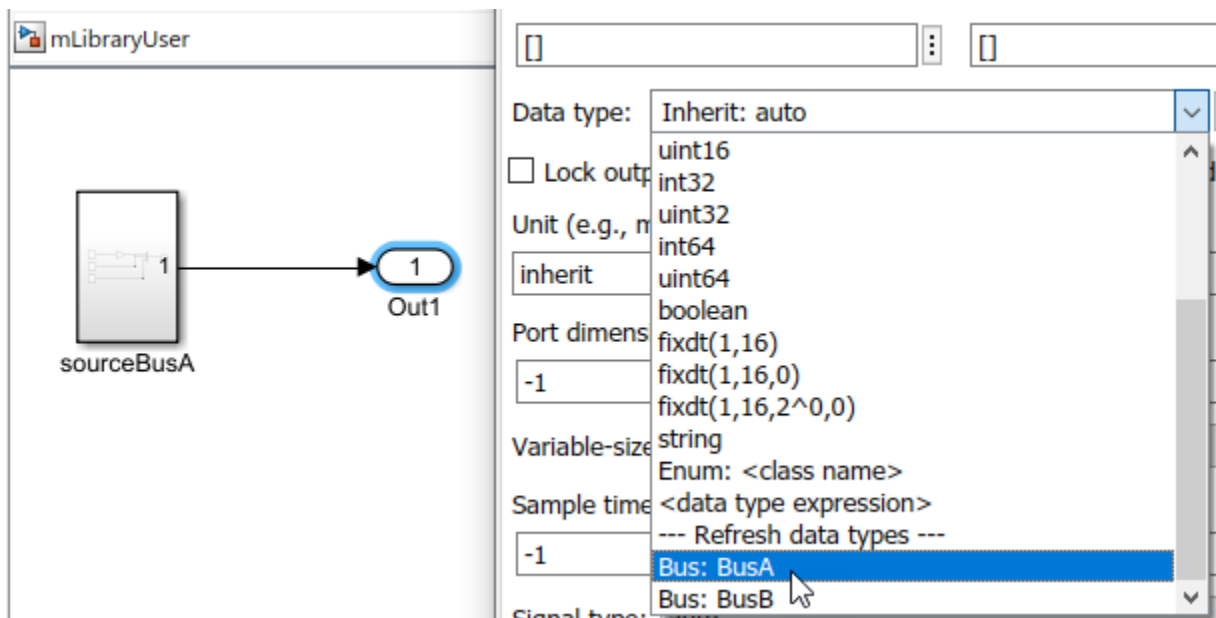

### Use Blocks From a Library with Attached Data Dictionary

When you drag a block from a library into your model, the model automatically gains access to data objects contained in the dictionary attached to that library. To see the dictionary in the Model

Explorer, in the Simulink Editor, click the model data badge  in the bottom left corner, then click **External Data**. The dictionary appears as an external data source to your model under the **From Libraries** node.

The data objects defined in the library are now available to the model for simulation and code generation without the need to bring those data objects into either the base workspace or another data dictionary.

When you update or save your model, if the model no longer contains a block from the library, the library dictionary is no longer available to your model and the dictionary is removed from the **From Libraries** node.

## Considerations When Using a Library Dictionary

There are several considerations when authoring or using a library with an attached data dictionary.

- In most cases, you will define bus or enumeration types in a library dictionary, but library authors can share any type of object with library users by adding objects to the dictionary.
- Items in the library dictionary are global in scope, and symbol resolution occurs as if the library dictionary is directly connected to the model.
- If a library link is broken, the data associated with the library is no longer available. To regain access to the data, you must manually attach the data dictionary to your model. Once the dictionary is attached, access to the data is also restored.
- If you are unable to manually attach data dictionary to your library, the cache that contains information about library dictionary links might be corrupted. To reset the cache, call the `Simulink.LibraryDictionary.resetLibraryLinks` function. After calling this function, the ability to attach a data dictionary to your library is restored, but information on previously attached library dictionaries is lost.
- In a model hierarchy, a model must directly or indirectly reference a library dictionary to use the data objects that the dictionary contains.
- Simulink stores library dictionary dependency information in the user preference folder. This information is persistent across MATLAB sessions. If you have moved a library to a different folder or machine, or if you have made changes to a library hierarchy, you can use the `Simulink.LibraryDictionary.refresh` function to perform a dependency analysis and update your stored dependencies. This dependency analysis can be expensive, so call the refresh function only if you have a missing dependency. To clear the previous dependency analysis, use the `Simulink.LibraryDictionary.clear` function.
- When you drag a block from a library into your model, the model gains access to the data dictionary attached to that library. However, if the block is from a sublibrary, access is only to the data dictionary attached to that sublibrary. In this case, to provide a model with access to both library and sublibrary dictionaries when it uses the block, the library author must contain the sublibrary block in a new subsystem.
- Subsystem reference does not support data dictionary attached to library. Library blocks which are dependent on the data dictionary attached to library may not function correctly inside the subsystem reference.
- If you store your library under the MATLAB root folder, you can attach a dictionary to the library, but a model does not have automatic access to the dictionary when you add a block from the library.
- Simulink does not support finding unused variables for a library with an attached data dictionary.

## Store Data in Dictionary Programmatically

### In this section...

“Add Entry to Design Data Section of Data Dictionary” on page 79-40  
 “Rename Data Dictionary Entry” on page 79-41  
 “Increment Value of Data Dictionary Entry” on page 79-41  
 “Data Dictionary Management” on page 79-41  
 “Dictionary Section Management” on page 79-42  
 “Dictionary Entry Manipulation” on page 79-43  
 “Transition to Using Data Dictionary” on page 79-43  
 “Programmatically Migrate Single Model to Use Dictionary” on page 79-44  
 “Import Directly From External File to Dictionary” on page 79-44  
 “Programmatically Partition Data Dictionary” on page 79-46  
 “Make Changes to Configuration Set Stored in Dictionary” on page 79-46

A data dictionary stores Simulink model data and offers more data management features than the MATLAB base workspace or the model workspace (see “What Is a Data Dictionary?” on page 79-2). To interact with the data in a dictionary programmatically:

- 1 Create a `Simulink.data.Dictionary` object that represents the target dictionary.
- 2 Create a `Simulink.data.dictionary.Section` object that represents the target section, for example the Design Data section. Use the object to interact with the entries stored in the section and to add entries.
- 3 Optionally, create `Simulink.data.dictionary.Entry` objects that each represent an entry in the target section. Use these objects to interact with individual entries in the target section.

To programmatically access variables for the purpose of sweeping block parameter values, consider using `Simulink.SimulationInput` objects instead of modifying the variables through the programmatic interface of the data dictionary. See “Optimize, Estimate, and Sweep Block Parameter Values” on page 40-38.

To programmatically interact with the **Embedded Coder** section of a data dictionary, see “Create Data Interface Configuration Programmatically” (Embedded Coder).

### Add Entry to Design Data Section of Data Dictionary

- 1 Represent the Design Data section of the data dictionary `myDictionary_ex_API.sldd` with a `Simulink.data.dictionary.Section` object named `dDataSectObj`.

```
myDictionaryObj = Simulink.data.dictionary.open('myDictionary_ex_API.sldd');
dDataSectObj = getSection(myDictionaryObj, 'Design Data');
```

- 2 In the Design Data section of `myDictionary_ex_API.sldd`, add entry `myNewEntry` with value 237.

```
addEntry(dDataSectObj, 'myNewEntry', 237)
```

## Rename Data Dictionary Entry

Rename an entry in the Design Data, Configurations, or Other Data section of a data dictionary.

- 1 Represent the data dictionary entry `fuelFlow` with a `Simulink.data.dictionary.Entry` object named `fuelFlowObj`. `fuelFlow` is defined in the data dictionary `myDictionary_ex_API.sldd`.

```
myDictionaryObj = Simulink.data.dictionary.open('myDictionary_ex_API.sldd');
dDataSectObj = getSection(myDictionaryObj, 'Design Data');
fuelFlowObj = getEntry(dDataSectObj, 'fuelFlow');
```

- 2 Rename the data dictionary entry.

```
fuelFlowObj.Name = 'fuelFlowNew';
```

## Increment Value of Data Dictionary Entry

- 1 Represent the data dictionary entry `fuelFlow` with a `Simulink.data.dictionary.Entry` object named `fuelFlowObj`. `fuelFlow` is defined in the data dictionary `myDictionary_ex_API.sldd`.

```
myDictionaryObj = Simulink.data.dictionary.open('myDictionary_ex_API.sldd');
dDataSectObj = getSection(myDictionaryObj, 'Design Data');
fuelFlowObj = getEntry(dDataSectObj, 'fuelFlow');
```

- 2 Store the value of the target entry in a temporary variable. Increment the value of the temporary variable by one.

```
temp = getValue(fuelFlowObj);
temp = temp+1;
```

- 3 Set the value of the target entry by using the temporary variable.

```
setValue(fuelFlowObj, temp)
```

## Data Dictionary Management

Use `Simulink.data.Dictionary` objects to interact with entire data dictionaries.

Goal	Use
Represent existing data dictionary with <code>Simulink.data.Dictionary</code> object	<code>Simulink.data.dictionary.open</code>
Create and represent data dictionary with <code>Simulink.data.Dictionary</code> object	<code>Simulink.data.dictionary.create</code>
Interact with data dictionary	<code>Simulink.data.Dictionary</code> class
Import variables to data dictionary from MATLAB base workspace	<code>importFromBaseWorkspace</code> method
Add reference dictionary to a data dictionary	<code>addDataSource</code> method
Remove reference dictionary from a data dictionary	<code>removeDataSource</code> method

Goal	Use
Save changes to data dictionary	<code>saveChanges</code> method
Discard changes to data dictionary	<code>discardChanges</code> method
View a list of entries stored in data dictionary	<code>listEntry</code> method
Import enumerated type definitions to data dictionary	<code>importEnumTypes</code> method
Return file name and path of data dictionary	<code>filepath</code> method
Show data dictionary in Model Explorer window	<code>show</code> method
Hide data dictionary from Model Explorer window	<code>hide</code> method
Close connection between data dictionary and <code>Simulink.data.Dictionary</code> object	<code>close</code> method
Identify data dictionaries that are open	<code>Simulink.data.dictionary.getOpenDictionaryPaths</code>
Close all connections to all open data dictionaries	<code>Simulink.data.dictionary.closeAll</code>

## Dictionary Section Management

Data dictionaries store data as entries contained in sections, and by default all dictionaries have at least three sections named Design Data, Other Data, and Configurations. Use `Simulink.data.dictionary.Section` objects to interact with data dictionary sections.

Goal	Use
Represent data dictionary section with <code>Section</code> object.	<code>getSection</code> method
Interact with data dictionary section	<code>Simulink.data.dictionary.Section</code> class
Import variables to data dictionary section from MAT-file or MATLAB file	<code>importFromFile</code> method
Export entries in data dictionary section to MAT-file or MATLAB file	<code>exportToFile</code> method
Delete entry from data dictionary section	<code>deleteEntry</code> method
Evaluate MATLAB expression in data dictionary section	<code>evalin</code> method
Search for entries in data dictionary section	<code>find</code> method
Determine whether entry exists in data dictionary section	<code>exist</code> method

## Dictionary Entry Manipulation

A variable that is stored in a data dictionary is called an entry of the dictionary. Entries have additional properties that store status information, such as the time and date the entry was last modified. Use `Simulink.data.dictionary.Entry` objects to manipulate data dictionary entries.

Goal	Use
Represent data dictionary entry with Entry object	<code>getEntry</code> method
Add data dictionary entry to section and represent with Entry object	<code>addEntry</code> method
Manipulate data dictionary entry	<code>Simulink.data.dictionary.Entry</code> class
Assign new value to data dictionary entry	<code>setValue</code> method
Display changes made to data dictionary entry	<code>showChanges</code> method
Save changes made to data dictionary	<code>saveChanges</code> method
Discard changes made to data dictionary entry	<code>discardChanges</code> method
Search in an array of data dictionary entries	<code>find</code> method
Return value of data dictionary entry	<code>getValue</code> method
Delete data dictionary entry	<code>deleteEntry</code> method
Store enumerated type definition in dictionary	<code>Simulink.data.dictionary.EnumTypeDefinition</code> class

## Transition to Using Data Dictionary

Using a data dictionary can complicate programmatic interaction with model data. If you link a model to a dictionary:

- You can no longer interact with the model data by using simple commands at the command prompt. Instead, you must use the programmatic interface of the dictionary (`Simulink.data.Dictionary`).
- When you select the dictionary property **Enable dictionary access to base workspace** (see “Continue to Use Shared Data in the Base Workspace” on page 79-12), depending on the storage location of the target data, you must use either simple commands or the programmatic interface.

To help transition from using the base workspace to using data dictionaries, consider using these functions. The functions operate on model data regardless of the storage location of the data.

Goal	Use
Change value of data dictionary entry or workspace variable in context of Simulink model	<code>Simulink.data.assigninGlobal</code>

Goal	Use
Evaluate MATLAB expression in context of Simulink model	<code>Simulink.data.evalInGlobal</code>
Determine existence of data dictionary entry or workspace variable in context of Simulink model	<code>Simulink.data.existsInGlobal</code>

## Programmatically Migrate Single Model to Use Dictionary

To change the data source of a Simulink model from the MATLAB base workspace to a new data dictionary, use this example code as a template.

```
% Define the model name and the data dictionary name
modelName = 'f14';
dictionaryName = 'myNewDictionary.slidd';

% Load the target model
load_system(modelName);

% Identify all model variables that are defined in the base workspace
varsToImport = Simulink.findVars(modelName,'SourceType','base workspace');
varNames = {varsToImport.Name};

% Create the data dictionary
dictionaryObj = Simulink.data.dictionary.create(dictionaryName);

% Import to the dictionary the model variables defined in the base
% workspace, and clear the variables from the base workspace
[importSuccess,importFailure] = importFromBaseWorkspace(dictionaryObj,...
    'varList',varNames,'clearWorkspaceVars',true);

% Link the dictionary to the model
set_param(modelName,'DataDictionary',dictionaryName);
```

---

**Note** This code does not migrate the definitions of enumerated data types that were used to define model variables. If you import model variables of enumerated data types to a data dictionary but do not migrate the enumerated type definitions, the dictionary is less portable and might not function properly if used by someone else. To migrate enumerated data type definitions to a data dictionary, see “Enumerations in Data Dictionary” on page 79-14.

---

## Import Directly From External File to Dictionary

This example shows how to use a custom MATLAB function to import data directly from an external file to a data dictionary without creating or altering variables in the base workspace.

- 1 Create a two-dimensional lookup table in one sheet of a Microsoft Excel workbook. Use the upper-left corner of the sheet to provide names for the two breakpoints and for the table. Use column B and row 2 to store the two breakpoints, and use the rest of the sheet to store the table. For example, your lookup table might look like this:

	A	B	C	D	E	F	G	H
1		bkpt2Name						
2	bkpt1Name	tableName	0.1	0.2	0.3	0.4	0.5	
3		0.25	0.35	0.6	0.85	1.1	1.35	
4		0.5	0.45	0.7	0.95	1.2	1.45	
5		0.75	0.55	0.8	1.05	1.3	1.55	
6		1	0.65	0.9	1.15	1.4	1.65	
7		1.25	0.75	1	1.25	1.5	1.75	
8								

Save the workbook in your current folder as `my2DLUT.xlsx`.

- Copy this custom function definition into a MATLAB file, and save the file in your current folder as `importLUTToDD.m`.

```
function importLUTToDD(workbookFile,dictionaryName)
% IMPORTLUTToDD(workbookFile,dictionaryName) imports data for a
% two-dimensional lookup table from a workbook directly into a data
% dictionary. The two-dimensional lookup table in the workbook can be
% any size but must follow a standard format.

% Read in the entire first sheet of the workbook.
[data,names,~] = xlsread(workbookFile,1,'');

% Divide the raw imported data into the breakpoints, the table, and their
% names.
% Assume breakpoint 1 is in the first column and breakpoint 2 is in the
% first row.
% Assume cells A2, B1, and B2 define the breakpoint names and table name.
bkpt1 = data(2:end,1);
bkpt2 = data(1,2:end);
table = data(2:end,2:end);
bkpt1Name = names{2,1};
bkpt2Name = names{1,2};
tableName = names{2,2};

% Prepare to import to the Design Data section of the target data
% dictionary.
myDictionaryObj = Simulink.data.dictionary.open(dictionaryName);
dDataSectObj = getSection(myDictionaryObj,'Design Data');

% Create entries in the dictionary to store the imported breakpoints and
% table. Name the entries using the breakpoint and table names imported
% from the workbook.
addEntry(dDataSectObj,bkpt1Name,bkpt1);
addEntry(dDataSectObj,bkpt2Name,bkpt2);
addEntry(dDataSectObj,tableName,table);

% Save changes to the dictionary and close it.
saveChanges(myDictionaryObj)
close(myDictionaryObj)
```

- At the MATLAB command prompt, create a data dictionary to store the lookup table data.

```
myDictionaryObj = Simulink.data.dictionary.create('myLUTDD.sldd');
```

- Call the custom function to import your lookup table to the new data dictionary.

```
importLUTToDD('my2DLUT.xlsx','myLUTDD.sldd')
```

- Open the data dictionary in Model Explorer.

```
show(myDictionaryObj)
```

Three new entries store the imported breakpoints and lookup table. These entries are ready to use in a 2-D Lookup Table block.

## Programmatically Partition Data Dictionary

To partition a data dictionary into reference dictionaries, use this example code as a template. You can use reference dictionaries to make large data dictionaries more manageable and to contain standardized data that is useful for multiple models.

```
% Define the names of a parent data dictionary and two
% reference data dictionaries
parentDDName = 'myParentDictionary.sldd';
typesDDName = 'myTypesDictionary.sldd';
paramsDDName = 'myParamsDictionary.sldd';

% Create the parent data dictionary and a
% Simulink.data.Dictionary object to represent it
parentDD = Simulink.data.dictionary.create(parentDDName);

% Create a Simulink.data.dictionary.Section object to represent
% the Design Data section of the parent dictionary
designData_parentDD = getSection(parentDD, 'Design Data');

% Import some data to the parent dictionary from the file partDD_Data_ex_API.m
importFromFile(designData_parentDD, 'partDD_Data_ex_API.m');

% Create two reference dictionaries
Simulink.data.dictionary.create(typesDDName);
Simulink.data.dictionary.create(paramsDDName);

% Create a reference dictionary hierarchy by adding reference dictionaries
% to the parent dictionary
addDataSource(parentDD, typesDDName);
addDataSource(parentDD, paramsDDName);

% Migrate all Simulink.Parameter objects from the parent data dictionary to
% a reference dictionary
paramEntries = find(designData_parentDD, '-value', '-class', 'Simulink.Parameter');
for i = 1:length(paramEntries)
    paramEntries(i).DataSource = 'myParamsDictionary.sldd';
end

% Migrate all Simulink.NumericType objects from the parent data dictionary
% to a reference dictionary
typeEntries = find(designData_parentDD, '-value', '-class', 'Simulink.NumericType');
for i = 1:length(typeEntries)
    typeEntries(i).DataSource = 'myTypesDictionary.sldd';
end

% Save all changes to the parent data dictionary
saveChanges(parentDD)
```

## Make Changes to Configuration Set Stored in Dictionary

You can store a configuration set (a `Simulink.ConfigSet` object) in the Configurations section of a dictionary. To change the setting of a configuration parameter in the set programmatically:

- 1 Create a `Simulink.data.dictionary.Entry` object that represents the configuration set (which is an entry in the dictionary). For example, suppose the name of the dictionary is `myData.sldd` and the name of the `Simulink.ConfigSet` object is `myConfigs`.

```
dictionaryObj = Simulink.data.dictionary.open('myData.sldd');
configsSectObj = getSection(dictionaryObj, 'Configurations');
entryObj = getEntry(configsSectObj, 'myConfigs');
```

- 2 Store a copy of the target `Simulink.ConfigSet` object in a temporary variable.

```
temp = getValue(entryObj);
```

- 3 In the temporary variable, modify the target configuration parameter (in this case, set **Stop time** to 20).

```
set_param(temp, 'StopTime', '20');
```

- 4 Use the temporary variable to overwrite the configuration set in the dictionary.

```
setValue(entryObj, temp);
```

- 5 Save changes made to the dictionary.

```
saveChanges(dictionaryObj)
```

## Attach Data Dictionary to Subsystem Reference

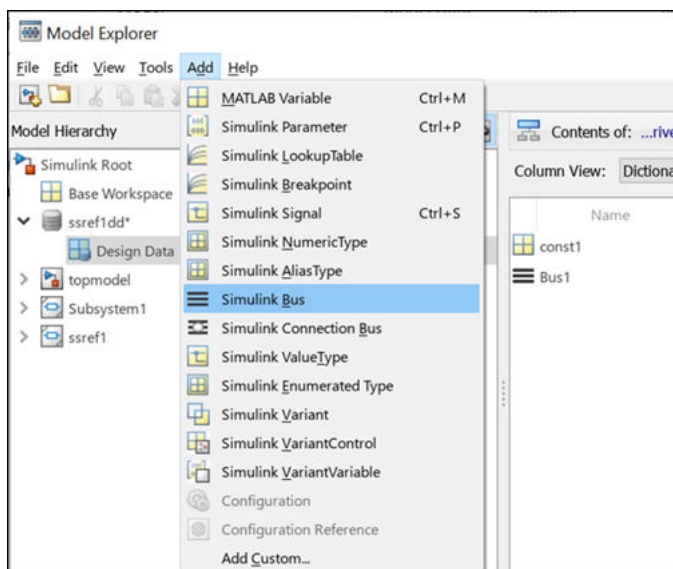

You can attach a data dictionary to a subsystem reference to store variables, objects, and interfaces. The scope of data you define in an attached data dictionary is the subsystem reference boundary. Using a data dictionary allows you to define all types of data and interfaces and reuse them in child blocks and instances of your subsystem reference.

### Attach Data Dictionary to a Subsystem File

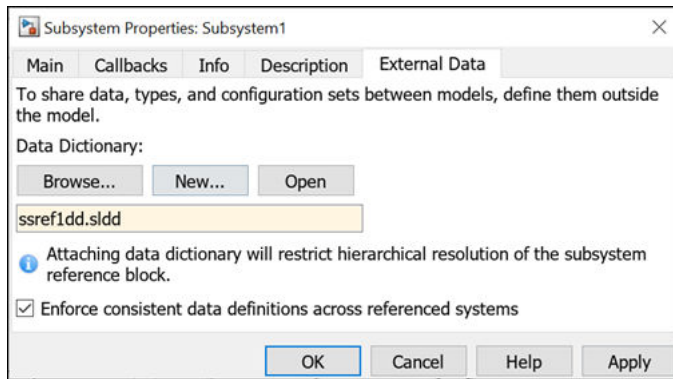

Attaching a data dictionary to a subsystem reference provides you with multiple capabilities, such as data storage, data-model linkage, and version handling. For more information, see “What Is a Data Dictionary?” on page 79-2

Create a new data dictionary or open an existing data dictionary.

- 1 To create a new data dictionary, in the **Model Explorer**, select **File > New > Data Dictionary**.
- 2 Click Add to add objects from the drop down list to the data dictionary.

- 3 Save the data dictionary.
- 4 To attach the data dictionary:
  - Open your subsystem file. In the Simulink Editor, on the **Modeling** tab, click **Subsystem Properties**.
  - In the **Subsystem Properties** dialog box, on the **External Data** tab, click **Browse** to locate and open your data dictionary.
  - Click **OK** to attach the data dictionary.

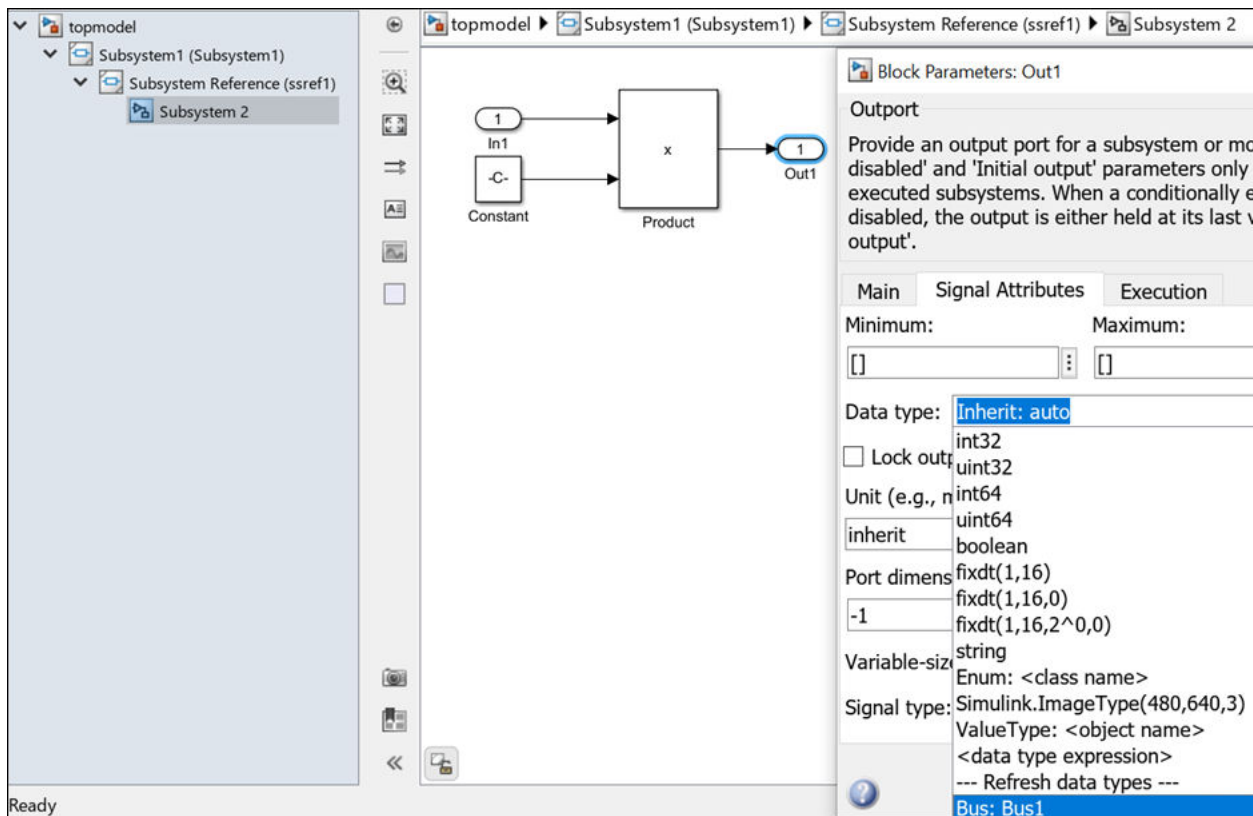

Alternatively, you can attach the data dictionary by using the `set_param` function.

```
set_param('ssref1', 'DataDictionary', 'ssref1dd.sldd')
```

After you have attached the data dictionary and saved your subsystem file, the data dictionary and its contents appear in the **Model Explorer** as an external data source for the subsystem file.

You can use variables and data types defined in the data dictionary within the subsystem reference boundary.

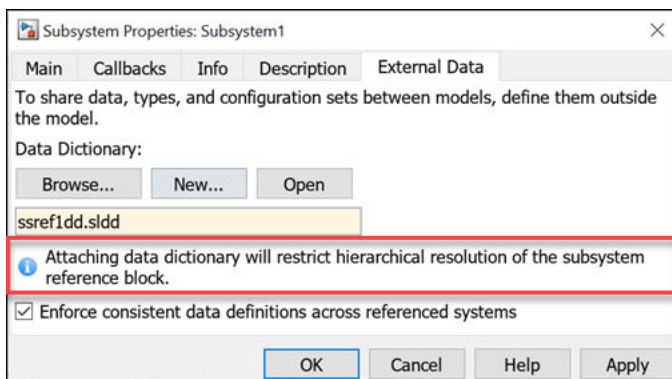

For example, select data types defined in the attached data dictionary from the **Data type** list in the child blocks and instances of your Subsystem Reference block.

## Symbol Resolution Process

To determine model behavior, Simulink tries to find the values of symbols used to define model entities. See “Symbol Resolution” on page 72-126 for more information. To resolve a symbol, Simulink searches through the accessible workspaces in hierarchical order for a variable or object whose name is same as the symbol's name.

When you attach a data dictionary with your subsystem file, the symbol resolution for any child block of a subsystem reference is restricted within the subsystem reference boundary. The dialog box displays the behavior change in symbol resolution when you attach a data dictionary.

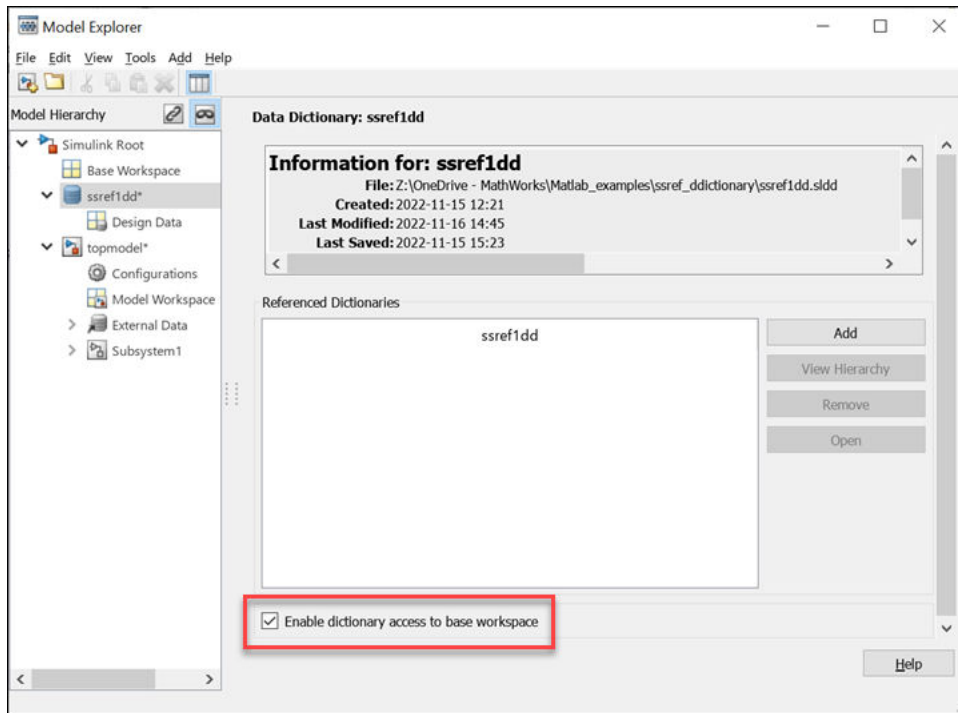

Symbol resolution for any child block of a subsystem reference is:

- 1 Mask workspaces of all blocks starting upward from the child block till the mask workspace of Subsystem Reference block (see “Masking Fundamentals” on page 42-3).
- 2 The data dictionary attached with the Subsystem Reference block.
- 3 MATLAB base workspace, only if the attached data dictionary has access to the base workspace.

To allow access to the MATLAB base workspace, in the **Model Explorer**, select your data dictionary and select **Enable dictionary access to base workspace**.

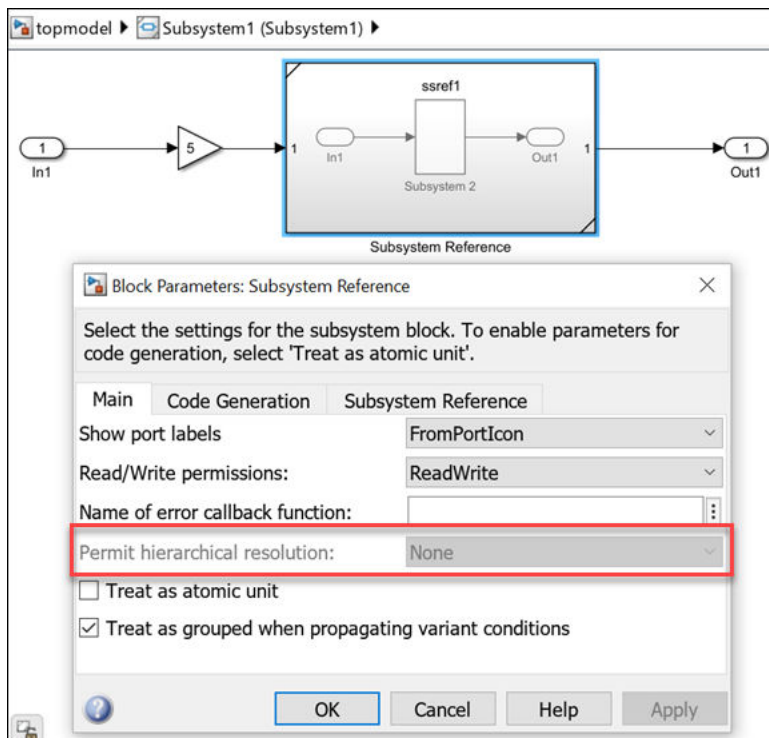

## Considerations and Limitations

There are some considerations when you attach a data dictionary with a subsystem reference.

- As the hierarchical symbol resolution is restricted, the **Permit Hierarchical Resolution** option on the Subsystem Reference block parameter dialog box is disabled and set to None.

- The enumerated data types defined in the data dictionary of a subsystem reference are available outside the subsystem reference boundary.

- “Specify Application-Specific Signal Properties” on page 80-50
- “Display Signal Attributes” on page 80-54
- “Signal Groups” on page 80-59

## Signal Basics

### In this section...

- “Signal Line Styles” on page 80-2
- “Signal Properties” on page 80-3
- “Signal Names and Labels” on page 80-4
- “Signal Display Options” on page 80-5
- “Store Design Attributes of Signals and States” on page 80-5
- “Test Signals” on page 80-6

A *signal* is a time-varying quantity that has values at all points in time. You can specify a wide range of signal attributes, including:

- Signal name
- Data type (for example, 8-bit, 16-bit, or 32-bit integer)
- Numeric type (real or complex)
- Dimensionality (one-dimensional, two-dimensional, or multidimensional array)

In Simulink, signals are the outputs of dynamic systems represented by blocks in a Simulink diagram and by the diagram itself. The lines in a block diagram represent mathematical relationships among the signals defined by the block diagram. For example, a line connecting the output of block A to the input of block B indicates that the signal output of B depends on the signal output of A.

Simulink block diagrams represent signals with lines that have an arrowhead. The source of the signal corresponds to the block that writes to the signal during evaluation of its block methods (equations). The destinations of the signal are blocks that read the signal during the evaluation of the block methods (equations). The destination of signals in a model do not necessarily represent the order of simulation of blocks in a model. The simulation order is determined by Simulink automatically.

---

**Note** Simulink signals are mathematical, not physical, entities. The lines in a block diagram represent mathematical, not physical, relationships among blocks. Simulink signals do not travel along the lines that connect blocks in the same way that electrical signals travel along a wire. Block diagrams do not represent physical connections between blocks.

---

You can create a signal by adding a source block to your model. For example, you can create a signal that varies sinusoidally with time by adding an instance of the Sine, Cosine block from the Simulink Sources library into your model. To see a list of the blocks that create signals in a model, see “Sources”. Alternatively, you can use the “Viewers and Generators Manager” on page 30-83 to create signals in your model without using blocks.

### Signal Line Styles

A Simulink model can include many different types of signals. As you construct a block diagram, all signal types appear as a thin, solid line. After you update the diagram or start simulation, the signals appear with the specified line styles. These signal types enable you to differentiate between different

signal types. From all signal types, you can only customize the nonscalar signal type. To learn more, see “Signal Types” on page 80-7.

Signal Type	Line Style
Scalar and nonscalar	
Nonscalar (with the <b>Wide nonscalar lines</b> option enabled—see “Wide Nonscalar Lines” on page 80-58)	
Control signal	
Virtual bus	
Nonvirtual bus	
Array of buses	
Variable-size	

## Signal Properties

You may want to specify signal properties in your model to give a name or a label to your signals, prepare data for logging, or to customize your signals in a model. Use the Property Inspector, the Model Data Editor, or the Signal Properties dialog box to specify properties for:

- Signal names and labels
- Signal logging
- Simulink Coder to use to generate code
- Documentation of the signal

To access the signal properties in the Property Inspector, first display the Property Inspector. On the **Modeling** tab, under **Design**, click **Property Inspector**. When you select a signal, the properties appear in the Property Inspector.

To open the Model Data Editor, on the **Modeling** tab, click **Model Data Editor**. Then, inspect the **Signals** tab and select a signal.

To use the Signal Properties dialog box, right-click a signal and select **Properties**.

To specify signal properties programmatically, use a function such as `get_param` to create a variable that holds the handle to the block output port that creates the signal line. Then, use `set_param` to set the programmatic parameters of the port. For example:

```
p = get_param(gcb, 'PortHandles')
l = get_param(p.Output, 'Line')
set_param(l, 'Name', 's9')
```

## Signal Names and Labels

You can name a signal interactively or programmatically in a model. The syntactic requirements for a signal name depend on how you use the name. The most common cases are:

- Do not use a less than character (<) to start a signal name.
- The signal name can resolve to a `Simulink.Signal` object. (See `Simulink.Signal`.) The signal name must then be a legal MATLAB identifier. This identifier starts with an alphabetic character, followed by alphanumeric or underscore characters up to the length given by the function `namelengthmax`.
- The signal has a name so the signal can be identified and referenced by name in a data log. (See “Save Signal Data Using Signal Logging” on page 77-42.) Such a signal name can contain space and newline characters. These characters can improve readability but sometimes require special handling techniques, as described in “Handling Spaces and Newlines in Logged Names” on page 77-65
- The signal name exists only to clarify the diagram and has no computational significance. Such a signal name can contain anything and does not need special handling.
- The signal is an element of a bus object. Use a valid C language identifier for the signal name.
- Inputs to a Bus Creator block must have unique names. If there are duplicate names, the Bus Creator block appends ( `signal#` ) to all input signal names, where `#` is the input port index.

Making every signal name a legal MATLAB identifier handles a wide range of model configurations. Unexpected requirements can require changing signal names to follow a more restrictive syntax. You can use the function `isvarname` to determine whether a signal name is a legal MATLAB identifier.

Name a signal interactively by using one of these options:

- The **Property Inspector** tool
- The **Model Data Editor** tool
- The **Signal Properties** dialog box

The signal name appears below a signal, displayed as a signal label.

To name a signal programmatically, use the `get_param` and `set_param` functions on the signal. The table below summarizes how to work with signal names and labels in the Simulink Editor.

Task	Action
Name a signal line	Double-click the signal and type its name.
Name a branch of a named signal line	Double-click the branch.
Name every branch of a signal	Right-click the signal, select <b>Properties</b> , and use the dialog box.
Delete signal label and name	Delete characters in the label or delete the name in Signal Properties dialog box.
Delete signal label only	Right-click the label and select <b>Delete Label</b> .

Task	Action
Open signal label text box for editing	Double-click the signal line. Click the label. Select the signal line (not the label) and use <b>F2</b> . On a Mac, select the signal line (not the label) and use <b>control+return</b> .
Move signal label	Drag the label to a new location on the same signal line.
Copy signal label	<b>Ctrl+drag</b> the signal label.
Change the label font	Select the signal line (not the label), and then on the <b>Format</b> tab, click the <b>Font Properties</b> button arrow, then click <b>Fonts for Model</b> .

## Signal Display Options

Displaying signal attributes in the model diagram can make the model easier to read. For example, in the Simulink Editor, on the **Debug** tab, use the **Information Overlays** menu to include in the model layout information about signal attributes, such as:

- Port data types
- Design ranges
- Signal dimensions
- Signal resolution

For details, see “Display Signal Attributes” on page 80-54.

You can also highlight a signal and its source or destination blocks. For details, see “Highlight Signal Sources and Destinations” on page 80-28.

## Store Design Attributes of Signals and States

You can use block parameters and signal properties to specify signal design attributes such as data type, minimum and maximum values, physical unit, and numeric complexity. To configure states, you can use block parameters. When you use these block parameters and signal properties, you store the specifications in the model file.

Alternatively, you can specify these attributes by using the properties of a `Simulink.Signal` or `Simulink.ValueType` object that you store in a workspace or data dictionary.

Choose which strategy to use based on your modeling goals.

Modeling Goal	Strategy
Improve model portability, readability, and ease of maintenance	Store signal attribute specifications in the model file. You do not need to save and manage external objects. Consider setting the model configuration parameter <b>Signal resolution</b> to None, which disables the use of <code>Simulink.Signal</code> objects by the model.
Separate signal attribute specifications from the model so that you can manage each signal independently	Use <code>Simulink.Signal</code> objects.
Separate signal attribute specifications from the model so that you can reuse an application-specific set of attributes	Use <code>Simulink.Valuetype</code> objects.

To configure design attributes and code generation settings for signals by using a list that you can sort, group, and filter, consider using the **Model Data Editor**. For objects, you can also use the **Model Explorer**.

To determine where to permanently store a `Simulink.Signal` or `Simulink.ValueType` object, see “Determine Where to Store Variables and Objects for Simulink Models” on page 72-94.

## Test Signals

You can perform the following kinds of tests on signals:

- **Minimum and Maximum Values** — For many Simulink blocks, you can specify a range of valid values for the output signals. Simulink provides a diagnostic for detecting when blocks generate signals that exceed their specified ranges during simulation. For details, see “Specify Signal Ranges” on page 80-36.
- **Connection Validation** — Many Simulink blocks have limitations on the types of signals that they accept. Before simulating a model, Simulink checks all blocks to ensure that the blocks can accommodate the types of signals output by the ports to which the blocks connect and reports errors about incompatibilities. To detect signal compatibility errors before running a simulation, update the diagram.

The Signal Editor block displays interchangeable groups of scenarios. Use the Signal Editor to display, create, edit, and switch interchangeable scenarios.

Scenarios can help with testing a model.

## Signal Types

Multiple types of signals can connect the blocks in a model. For example, a model may contain a control signal to initiate the execution of a block and buses to simplify line routing.

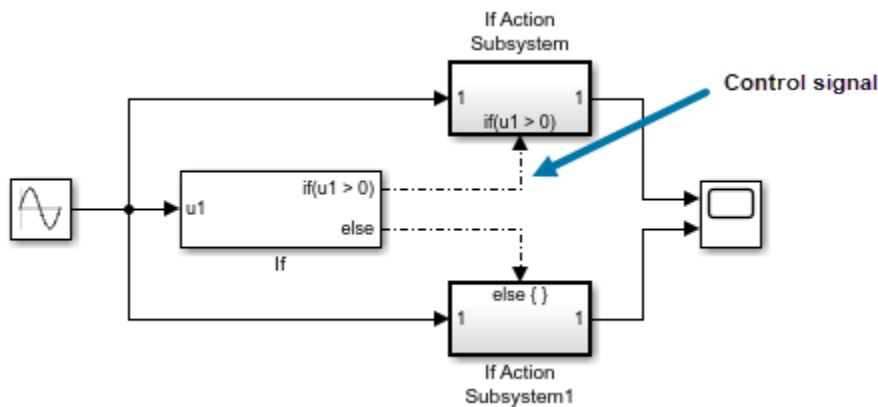

This table summarizes the types of Simulink signals.

Name	Description
Array	Nonscalar signal with one or more dimensions.
Array of buses	Array that contains nonvirtual buses.
Bus	Composite signal with name-based signal access.
Composite signal	Signal composed of other signals. See "Composite Signals" on page 80-8.
Concatenated signal	Nonvirtual vector, matrix, or array with index-based signal access.
Control signal	Signal used by a block to initiate the execution of another block. For example, a signal that executes a function-call subsystem or an action subsystem. See "Control Signals" on page 80-7.
Matrix	Two-dimensional nonscalar signal.
Multidimensional ( $N$ -D) signal	Array with three or more dimensions.
Mux signal	Virtual vector with index-based signal access.
Nonscalar signal	Signal with at least one dimension, such as a vector (1-D), matrix (2-D), or multidimensional array ( $N$ -D).
Nonvirtual signal	Signal that plays an active role in simulation and code generation. See "Virtual and Nonvirtual Signals" on page 80-8.
Scalar signal	Signal that supports only one value at a time.
Variable-size signal	Signal whose size (the number of elements in a dimension), in addition to its values, can change during a model simulation.
Vector	One-dimensional nonscalar signal.
Virtual signal	Signal that represents another signal or set of signals. See "Virtual and Nonvirtual Signals" on page 80-8.

**Note** Signals may also have application-specific types, such as a local wind velocity. To assign or validate the unit, minimum value, maximum value, dimensions, and other properties of a signal based on an application-specific type, see "Specify Application-Specific Signal Properties" on page 80-50.

### Control Signals

A *control signal* is a signal used by a block to initiate the execution of another block. For example, a signal that executes a function-call or action subsystem is a control signal. When you update or simulate a block diagram, Simulink uses a dash-dot pattern to draw lines that represent the control signals.

## Composite Signals

You can group multiple signals in a composite signal, route the signal from block to block, and extract the constituent signals where needed. When you have many parallel signals, composite signals can simplify the appearance of a model and clarify generated code. Composite signals can be virtual or nonvirtual.

For more information on composite signals, see “Composite Interface Guidelines” on page 81-2.

## Virtual and Nonvirtual Signals

A virtual signal is a signal that graphically represents other signals or parts of other signals. Virtual signals do not exist in generated code. Some blocks, such as the Mux block, always generate virtual signals. Others, such as the Bus Creator block, can generate either virtual or nonvirtual signals. A signal is virtual if the block that generates it is virtual.

A nonvirtual signal is a signal that plays an active role in simulation and code generation. Some blocks, such as the Vector Concatenate block, always generate nonvirtual signals. A signal is nonvirtual if the block that generates it is nonvirtual.

For information on virtual and nonvirtual blocks, see “Nonvirtual and Virtual Blocks” on page 39-2.

## Investigate Signal Values

In this section...
“Initialize Signal Values” on page 80-9
“View Signal Values” on page 80-9
“Display Signal Values in Model Diagrams” on page 80-10
“Signal Data Types” on page 80-10
“Complex Signals” on page 80-10
“Exporting Signal Data” on page 80-11

While transmitting valuable data about a model and between the blocks, signals may take different values. In this section, you learn how to initialize, display signals as well as more information on the data types and dimensions a signal can take.

### Initialize Signal Values

If a signal does not have an explicit initial value, the initial value that Simulink uses depends on the data type of the signal.

Signal Data Type	Default Initial Value
Numeric (other than fixed-point)	Zero
Fixed-point	Real-world ground value
Boolean	False
Enumerated	Default value

You can specify the non-default initial values of signals for Simulink to use at the beginning of simulation.

- For any signal, you can define a signal object (`Simulink.Signal`), and use that signal object to specify an initial value for the signal.
- For some blocks, such as `Outport`, `Data Store Memory`, and `Memory`, you can use either a signal object or a block parameter, or both, to specify the initial value of a block state or output.

For details, see “Initialize Signals and Discrete States” on page 80-42.

### View Signal Values

You can use either blocks or the signal viewers (such as the `Signal & Scope Manager`) to display the values of signals during a simulation. For example, you can use either the `Scope` block or the `Signal & Scope Manager` to graph time-varying signals on an oscilloscope-like display during simulation. For general information about options for viewing signal values, see “Scope Blocks and Scope Viewer Overview” on page 30-6. For detailed information about:

- Blocks that you can use to display signals in a model, see “Sinks”
- Signal viewers, “Floating Scope and Scope Viewer Tasks” on page 30-73
- The `Signal & Scope Manager`, see “Viewers and Generators Manager” on page 30-83

- Test points, which are signals that Simulink guarantees to be observable when using a Floating Scope block in a model, see “Configure Signals as Test Points” on page 80-48.

## Display Signal Values in Model Diagrams

To include graphical displays of signal values in a model diagram, use one of the following approaches:

- “Display Data Tips During Simulation” on page 80-10
- “Display Signal Value After Simulation” on page 80-10

### Display Data Tips During Simulation

For many blocks, Simulink can display block output (port values) as data tips on the block diagram while a simulation is running.

- 1 In the Simulink Editor, on the **Debug** tab, select **Output Values**, go to the **Signal** tab, and toggle on the **Output Value Label > Toggle Value Displays** button.
- 2 To change display options, use the **Options** submenu.

For details, see “Display Port Values for Debugging” on page 39-7.

### Display Signal Value After Simulation

To display, below a specific signal, the signal value after simulation:

- 1 Right-click the signal.
- 2 In the context menu, select **Show Value Label of Selected Port**.

## Signal Data Types

Data type refers to the format used to represent signal values internally. By default, the data type of Simulink signals is double. You can create signals of other data types. Simulink signals support the same range of data types as MATLAB. See “About Data Types in Simulink” on page 72-2 for more information.

## Complex Signals

The values of signals can be complex numbers or real numbers. A signal whose values are complex numbers is a complex signal. Create a complex-valued signal using one of the following approaches:

- Load complex-valued signal data from the MATLAB workspace into the model via a root-level Inport block.
- Create a Constant block in your model and set its value to a complex number.
- Create real signals corresponding to the real and imaginary parts of a complex signal, then combine the parts into a complex signal, using the Real-Imag to Complex conversion block.

Manipulate complex signals via blocks that accept them. If you are not sure whether a block accepts complex signals, see the documentation for the block.

## Exporting Signal Data

You can save signal values to the MATLAB workspace during simulation, for later retrieval and postprocessing. For a summary of different approaches, see “Save Simulation Data” on page 77-2.

“Display Propagated Signal Labels” on page 80-16

“Special Cases of Signal Propagation” on page 80-17

You can give signals signal names and configure propagating the signal names in a Simulink model to track a signal label through one block or many blocks. For a list of supported blocks, see “Blocks That Support Signal Label Propagation” on page 80-12.

When you name a signal and enable the display of signal label propagation for output signals of allowed blocks:

- If there is a user-specified signal name that Simulink can propagate, the propagated signal label includes the name in angle brackets (for example, `<sig1>`).
- If there is no signal name to propagate, Simulink displays an empty set of angle brackets (`<>`) for the label.

Simulink does not propagate signal labels for commented out blocks.

For example, in the following model, the output signal from the Subsystem block is configured for signal label propagation. The propagated signal label (`<const>`) is based on the name of the upstream output signal of the Constant block (`const`).

For more information on how Simulink creates propagated signal labels, see “How Simulink Propagates Signal Labels” on page 80-13.

### Blocks That Support Signal Label Propagation

You can use signal label propagation with output signals for several *connection* blocks, which route signals through the model without changing the data. Connection blocks perform no signal transformation.

Also, Model blocks support signal label propagation.

The connection blocks that support signal label propagation are:

- Enable
- From
- Function-Call Split
- Goto

- Inport (subsystem only; not model input ports)
- Signal Specification
- Subsystem (through subsystem Inport and Outport blocks)
- Trigger

The Bus Creator and Bus Selector blocks do *not* support signal label propagation. However, if you want to view the hierarchy for any bus, use the “Display Bus Hierarchy” on page 81-41.

The Signal Properties dialog box for a signal indicates whether that signal supports signal label propagation. The **Show propagated signals** parameter is available only for blocks that support signal label propagation. For details, see “Display Propagated Signal Labels” on page 80-16.

## How Simulink Propagates Signal Labels

In general, Simulink performs signal label propagation consistently:

- For different modeling constructs (for example, non-bus and bus signals, virtual and nonvirtual buses, subsystem and model variants, model referencing, and libraries)
- In models with or without hidden blocks, which Simulink inserts in certain cases to enable simulation
- At model load, edit, update, and simulation times

For information about some special cases, see:

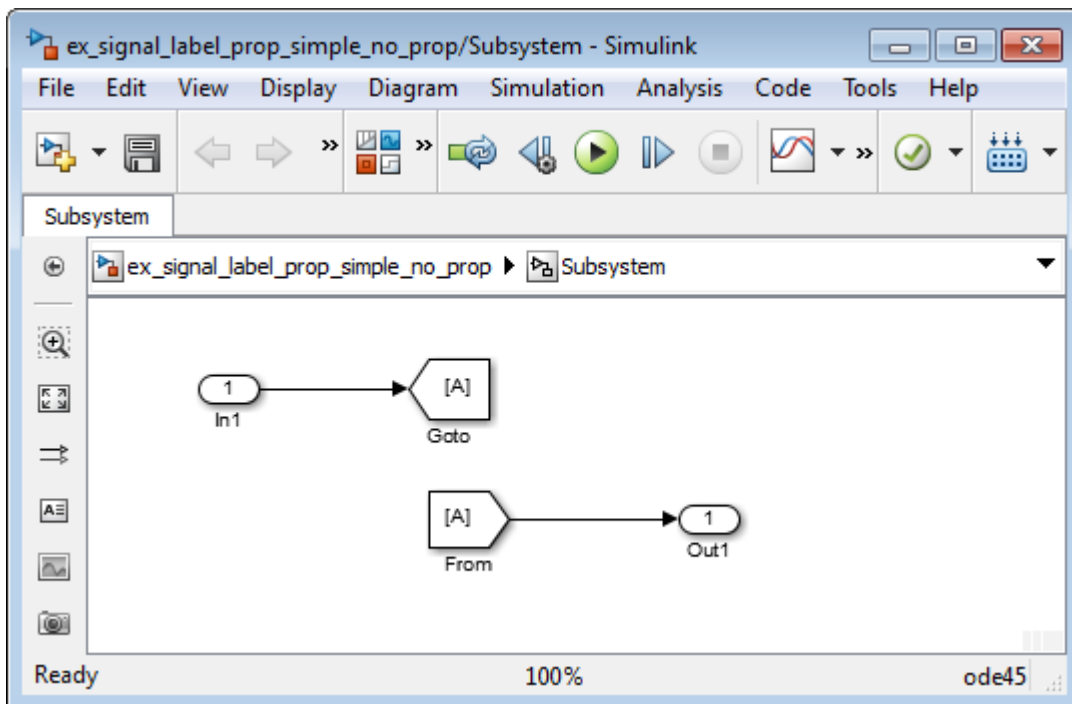

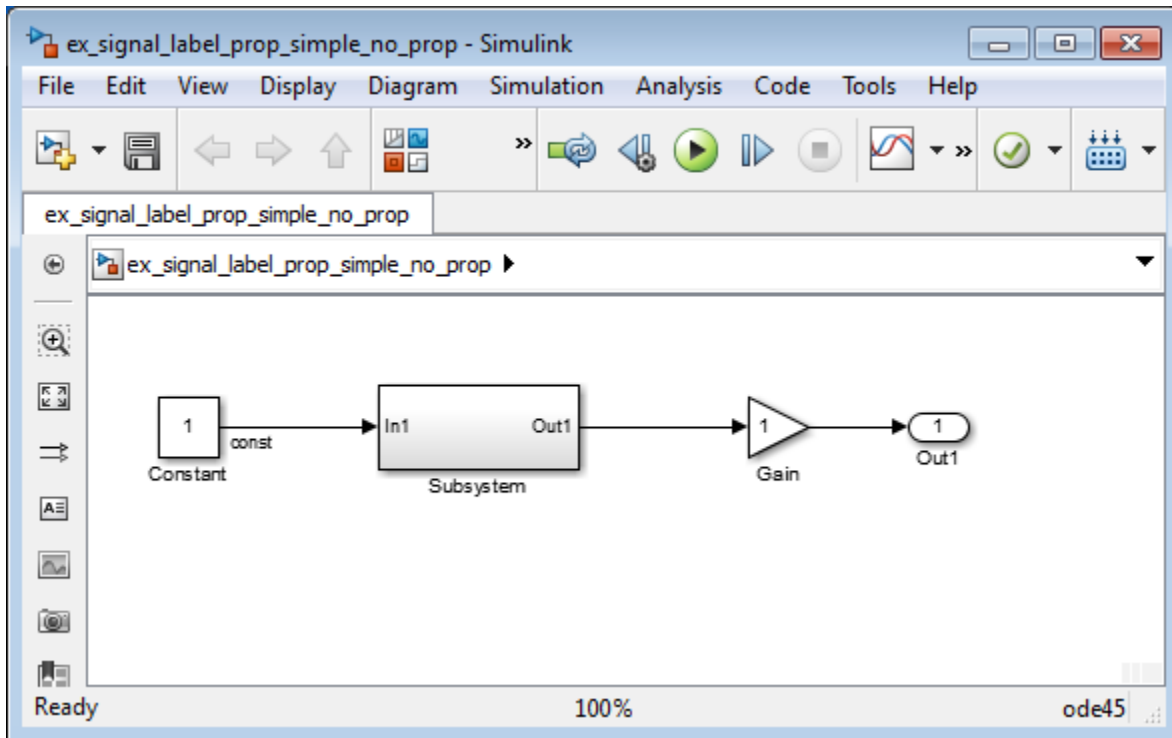

- “Processing for Referenced Models” on page 80-17
- “Processing for Variants and Configurable Subsystems” on page 80-18

### General Signal Label Propagation Processing

In general, when you enable signal label propagation for an output signal of a block (for example, BlockA), Simulink performs the following processing to find the source signal name to propagate:

- 1 Checks the block whose output signal connects to BlockA, and if necessary, continues checking upstream blocks, working backward from the closest block to the farthest block.
- 2 Stops when it encounters a block that either:
  - Supports signal label propagation and has a signal name
  - Does not support signal label propagation
- 3 Obtains the signal name, if any, of the output signal for the block at which Simulink stops.
- 4 Uses that signal name for the propagated signal label of any output signals of downstream blocks for which you enable signal label propagation.

For example, in the following model, suppose that you enable signal label propagation for the output signal for the Subsystem block (that is, the signal connected to the Out1 port).

Simulink checks inside the subsystem, checks upstream from the From and GoTo blocks (which support signal label propagation and do not have a name), and then checks farther upstream, to the Constant block, which does not support signal label propagation.

Simulink uses the signal name of the Constant block output signal, `const`. The propagated signal label for the Subsystem block output signal is `<const>`.

If the output signal from the Constant block did not have a signal name, then the propagated signal label would be an empty set of angle brackets (`<>`).

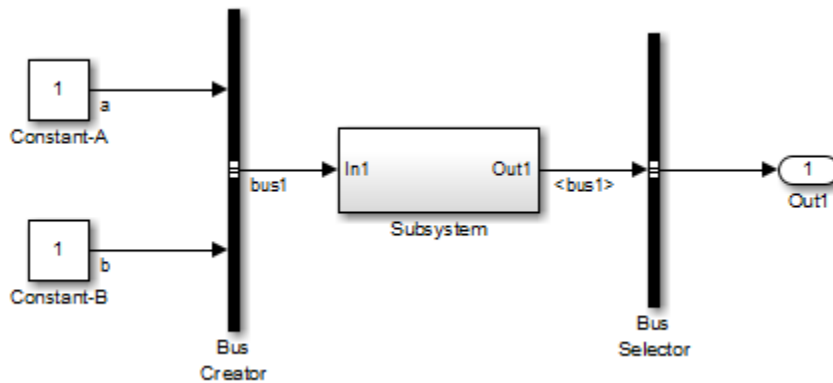

Suppose that in the Subsystem block you enable signal label propagation for the output signal from the In1 block, and you use the Signal Properties dialog box to specify the signal name `const - from` for the output signal of the From block, as shown below.

The propagated signal label for the Subsystem block output signal changes to `<const - from>`, because that is the first named signal that Simulink encounters in its signal label propagation processing.

In the following model, the signal label propagation for the output signal of the Subsystem block uses the signal name `bus1`, which is the name of the output bus of the Bus Creator block. The propagated signal label does not include the names of the bus element signals (a and b).

## Display Propagated Signal Labels

You can display propagated signal labels for individual signals, or display the propagated signal labels for all signals in a model. To display the labels for all signals, in the Simulink Editor, on the **Debug** tab, select **Information Overlays > Propagated Signal Labels**.

To display a propagated signal label for an individual signal:

- 1 Right-click the signal for which you want to display a propagated signal label and select **Properties**.
- 2 In the Signal Properties dialog box, select **Show propagated signals**.

The **Show propagated signals** parameter is available only for output signals from blocks that support signal label propagation.

To configure a signal to display its propagated name programmatically, use the `set_param` function to specify the value of the `ShowPropagatedSignals` property for the port handle that corresponds to the block output port that produces the signal. For example, to enable signal label propagation for the output signal on the first output port of Subsystem block Subsystem in the model MyModel:

- 1 Use the `get_param` function to get the port handles for the block.
 

```
portHandles = get_param("MyModel/Subsystem", "PortHandles");
```
- 2 Access the handle for the first output port by index. The block port handles are returned as a structure that contains a field for each type of port the block might have.
 

```
outport1 = portHandles.Outputport(1);
```
- 3 Use the `set_param` function to specify the value for the `ShowPropagatedSignals` parameter for the output port as on.
 

```
set_param(outport1, ShowPropagatedSignals="on")
```

If a signal already has a label, then an *alternative* approach for displaying a propagated signal label is:

- 1 In the model diagram, click the signal label.
- 2 Remove the label text.
- 3 In the signal label text box, enter an angle bracket (<).
- 4 Click outside the signal label.

Simulink displays the propagated signal label.

## Special Cases of Signal Propagation

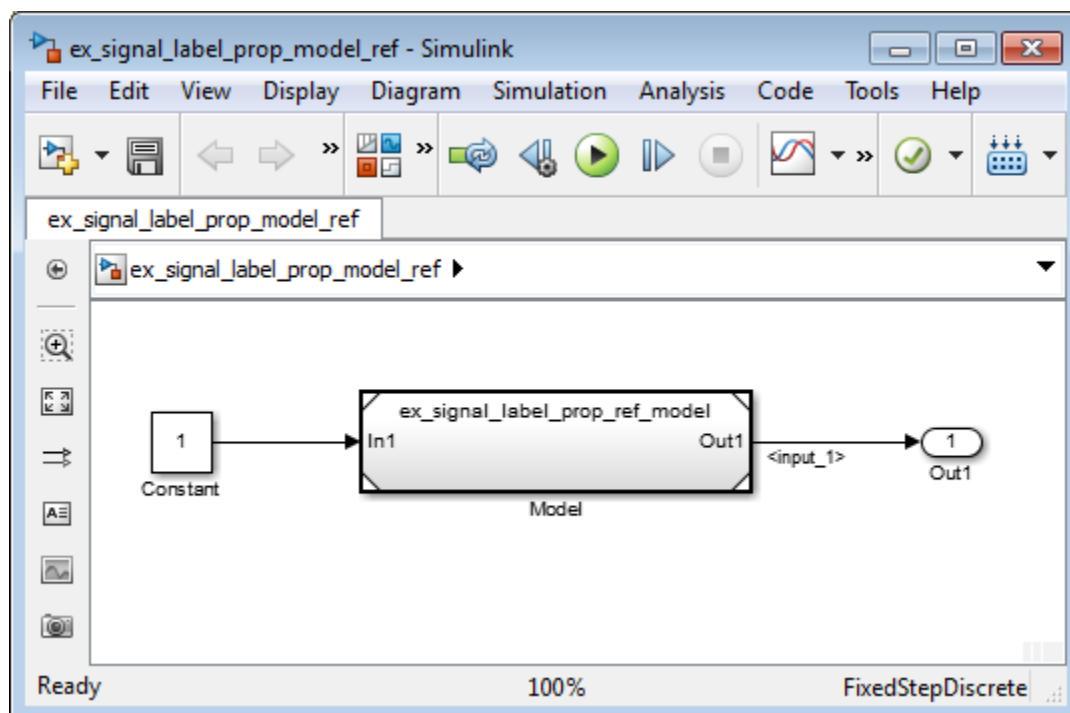

### Processing for Referenced Models

To enable signal label propagation for referenced models, in addition to the steps described in “Display Propagated Signal Labels” on page 80-16, use the default setting for the **Model Configuration Parameters > Model Referencing > Propagate all signal labels out of the model** parameter. In other words, make sure the parameter is enabled.

If you make a change inside a referenced model that affects signal label propagation, the propagated signal labels outside of the referenced model do not reflect those changes until after you update the diagram or simulate the model.

For example, the model `ex_signal_label_prop_model_ref` has a referenced model that includes an output signal from the In1 block that has a signal name of `input_1`.

If you enable signal label propagation for the signal from the Out1 port of the Model block, that signal does *not* reflect the name `input_1` until after you update the diagram or simulate the model.

### Processing for Variants and Configurable Subsystems

Simulink updates the propagated signal label (if enabled) for the output signal of the Subsystem or Model block, when *both* of these conditions occur:

- The output signals for variant models have different signal names.
- You change the active variant model or variant subsystem.

For Subsystem blocks, the signal label updates at edit time. For Model blocks, the update occurs when you update diagram or simulate the model.

## Determine Signal Dimensions

### In this section...

“Simulink Blocks that Support Multidimensional Signals” on page 80-20

“Determine the Output Dimensions of Source Blocks” on page 80-20

“Determine the Output Dimensions of Nonsource Blocks” on page 80-21

“Signal and Parameter Dimension Rules” on page 80-21

“Scalar Expansion of Inputs and Parameters” on page 80-21

Simulink blocks can output one-dimensional, two-dimensional, or multidimensional signals. The Simulink user interface and documentation generally refer to 1-D signals as *vectors* and 2-D or multidimensional signals as *matrices*. A one-element array is frequently referred to as a *scalar*. A *row vector* is a 2-D array that has one row. A *column vector* is a 2-D array that has one column.

- A one-dimensional (1-D) signal consists of a series of one-dimensional arrays output at a frequency of one array (vector) per simulation time step.
- A two-dimensional (2-D) signal consists of a series of two-dimensional arrays output at a frequency of one 2-D array (matrix) per block sample time.
- A multidimensional signal consists of a series of multidimensional (two or more dimensions) arrays output at a frequency of one array per block sample time. You can specify multidimensional arrays with any valid MATLAB multidimensional expression, such as [4 3]. See “Multidimensional Arrays” for information on multidimensional arrays.

Simulink blocks vary in the dimensionality of the signals they can accept or output. Some blocks can accept or output signals of any dimension. Some can accept or output only scalar or vector signals.

---

**Note** Simulink does not support dynamic signal dimensions during a simulation. That is, the dimension of a signal must remain constant while a simulation is executing. However, you can change the size of a signal during a simulation. See “Variable-Size Signal Basics” on page 82-2.

---

If a block can emit nonscalar signals, the dimensions of the signals that the block outputs depend on the block parameters, if the block is a source block; otherwise, the output dimensions depend on the dimensions of the block input and parameters.

To determine the dimensions that a signal ultimately uses for simulation, first update the block diagram (for example, by pressing **Ctrl+D**). Then, choose one of these techniques:

- Display the dimensions directly on the block diagram. Use this technique to trace signal dimensions along a path of blocks. In the model, on the **Debug** tab, select **Information Overlays > Signal Dimensions**.
- Inspect the dimensions in the **Model Data Editor**, which shows you information in a searchable, sortable table. In the table, the right side of each cell in the **Dimensions** column shows the true dimensions of the corresponding signal line in the model.

## Simulink Blocks that Support Multidimensional Signals

The Simulink Block Data Type Support table includes a column identifying the blocks with multidimensional signal support.

- 1 In the MATLAB command line, enter `showblockdatatypetable`.

A separate window with the Simulink Block Data Type Support table opens.

- 2 In the Block column, locate the name of a Simulink block. Columns to the right are data types or features. An **X** in a column indicates support for that feature.

Simulink supports signals with up to 32 dimensions. Do not use signals with more than 32 dimensions.

## Determine the Output Dimensions of Source Blocks

A *source* block is a block that has no inputs. Examples of source blocks include the Constant block and the Sine Wave block. See “Sources” for a complete listing of Simulink source blocks. The output dimensions of a source block are the same as those of its output value parameters if the block **Interpret vector parameters as 1-D** parameter is off (that is, not selected in the block parameter dialog box). If the **Interpret vector parameters as 1-D** parameter is on, the output dimensions equal the output value parameter dimensions unless the parameter dimensions are N-by-1 or 1-by-N. In the latter case, the block outputs a vector signal of width N.

As an example of how the output value parameters and **Interpret vector parameters as 1-D** parameter of a source block determine the dimensionality of its output, consider the Constant block. This block outputs a constant signal equal to its **Constant value** parameter. The following table illustrates how the dimensionality of the **Constant value** parameter and the setting of the **Interpret vector parameters as 1-D** parameter determine the dimensionality of the block output.

Constant Value	Interpret vector parameters as 1-D	Output
scalar	off	one-element array
scalar	on	one-element array
1-by-N matrix	off	1-by-N matrix
1-by-N matrix	on	N-element vector
N-by-1 matrix	off	N-by-1 matrix
N-by-1 matrix	on	N-element vector
M-by-N matrix	off	M-by-N matrix
M-by-N matrix	on	M-by-N matrix

Simulink source blocks allow you either to specify the dimensions of the signals that they output or specify values from which Simulink infers the dimensions. You can therefore use the source blocks to introduce signals of various dimensions into your model.

## Determine the Output Dimensions of Nonsource Blocks

If a block has inputs, the dimensions of its outputs are, after scalar expansion, the same as those of its inputs. (All inputs must have the same dimensions, as discussed in “Signal and Parameter Dimension Rules” on page 80-21).

## Signal and Parameter Dimension Rules

When creating a Simulink model, you must observe the following rules regarding signal and parameter dimensions.

### Input Signal Dimension Rule

All nonscalar inputs to a block must have the same dimensions.

A block can have a mix of scalar and nonscalar inputs as long as all the nonscalar inputs have the same dimensions. Simulink expands the scalar inputs to have the same dimensions as the nonscalar inputs (see “Scalar Expansion of Inputs and Parameters” on page 80-21).

### Block Parameter Dimension Rule

In general, block parameters must have the same dimensions as the dimensions of the inputs to the block. Simulink performs some processing that provides flexibility relating to that general rule.

- A block can have scalar parameters corresponding to nonscalar inputs. In this case, Simulink expands a scalar parameter to have the same dimensions as the corresponding input (see “Scalar Expansion of Inputs and Parameters” on page 80-21).
- If an input is a vector, the corresponding parameter can be either an N-by-1 or a 1-by-N matrix. In this case, Simulink applies the N matrix elements to the corresponding elements of the input vector. This exception allows use of MATLAB row or column vectors, which are actually 1-by-N or N-by-1 matrices, respectively, to specify parameters that apply to vector inputs.

### Vector or Matrix Input Conversion Rules

Simulink converts vectors to row or column matrices and row or column matrices to vectors under the following circumstances:

- If a vector signal is connected to an input that requires a matrix, Simulink converts the vector to a one-row or one-column matrix.
- If a one-column or one-row matrix is connected to an input that requires a vector, Simulink converts the matrix to a vector.
- If the inputs to a block consist of a mixture of vectors and matrices and the matrix inputs all have one column or one row, Simulink converts the vectors to matrices having one column or one row, respectively.

---

**Note** You can configure Simulink to display a warning or error message if a vector or matrix conversion occurs during a simulation. See “Vector/matrix block input conversion” for more information.

---

## Scalar Expansion of Inputs and Parameters

*Scalar expansion* is the conversion of a scalar value into a nonscalar array. Many Simulink blocks support scalar expansion of inputs and parameters. Block-specific descriptions indicate whether Simulink applies scalar expansion to block inputs and parameters.

Scalar expansion of inputs refers to the expansion of scalar inputs to match the dimensions of other nonscalar inputs or nonscalar parameters. When the input to a block is a mix of scalar and nonscalar signals, Simulink expands the scalar inputs into nonscalar signals having the same dimensions as the other nonscalar inputs. For example, a scalar of 4 is expanded to the vector [4 4 4] if the associated nonscalar has a dimension of 3.

Scalar expansion of parameters refers to the expansion of scalar block parameters to match the dimensions of nonscalar inputs.

Input(s)	Associated Block Parameter	Scalar Expansion
Scalar	Nonscalar	Input expanded to match parameter dimensions.  See “Scalar Input and Nonscalar Parameter” on page 80-22.
Nonscalar	Scalar	Scalar parameter expanded to match number of elements of input.  See “Nonscalar Input and Scalar Parameter” on page 80-23.
Combination of scalar and nonscalar	No corresponding parameter	Scalar inputs expanded to match dimensions of largest nonscalar input.  See “Scalar and Nonscalar Inputs and No Associated Parameter” on page 80-23.

### Scalar Input and Nonscalar Parameter

In this example, the Constant block input to the Gain block is scalar. The Gain block **Gain** parameter is a nonscalar. Simulink expands the scalar input to match the dimensions of a nonscalar **Gain** parameter, as reflected in the simulation results in the Display block.

### Nonscalar Input and Scalar Parameter

In this example, the Constant block input to the Gain block is nonscalar. The Gain block **Gain** parameter is a scalar. Simulink expands the scalar parameter to match the dimensions of a nonscalar input from the Constant block, as reflected in the simulation results in the Display block.

### Scalar and Nonscalar Inputs and No Associated Parameter

In this example, the Constant1 block input to the Sum block is nonscalar, and the Constant2 block input is scalar. The Sum block has no associated parameter. Simulink expands the scalar input from Constant2 to match to the dimensions of the nonscalar Constant1 block input. The input is expanded to the vector  $[3 \ 3 \ 3]$ .

### Get Compiled Port Dimensions

These examples show how to use the `CompiledPortDimensions` parameter to obtain dimensions of port signals of blocks in a Simulink model during compilation. For nonbus signals, dimensions of port signals represent dimensions of signals associated with the querying port. For bus signals, dimensions of port signals consist of the type of bus associated with the querying port, the number of signals carried by the bus, and the dimensions of those signals. To display signal dimensions, in the Simulink Editor, on the **Debug** tab, click **Information Overlays > Signals > Signal Dimensions**. For more information on signal dimensions, see “Signal Dimensions” on page 80-56.

### Get Compiled Port Dimensions for Nonbus Signal

Get the dimensions of port signals of a Constant block when querying the output port of the Constant block. As the block outputs a nonbus signal, `OutSig`, the dimensions of the port signals represented by the `dim` array are the dimensions of the nonbus output signal.

Step through the `ex_nonBusPortDim` model programmatically using `SimulationCommand`.

```
open_system('ex_nonBusPortDim.slx')
set_param('ex_nonBusPortDim', 'SimulationCommand', 'start')
set_param('ex_nonBusPortDim', 'SimulationCommand', 'pause')
```

Store the block name in a variable programmatically using the `PortHandles` parameter. Then, use the `CompiledPortDimensions` parameter to obtain the dimensions.

```
gcb='ex_nonBusPortDim/Constant';
ph= get_param(gcb, 'PortHandles');
dim= get_param(ph.Outport, 'CompiledPortDimensions')
```

```
dim = 1x3
```

```
    2    2    3
```

For nonbus signals, the result is an array where the first element is 2, which is the number of dimensions of `OutSig`. The next two elements are 2 and 3, which are the values of dimensions.

To stop the simulation programmatically, use `SimulationCommand`.

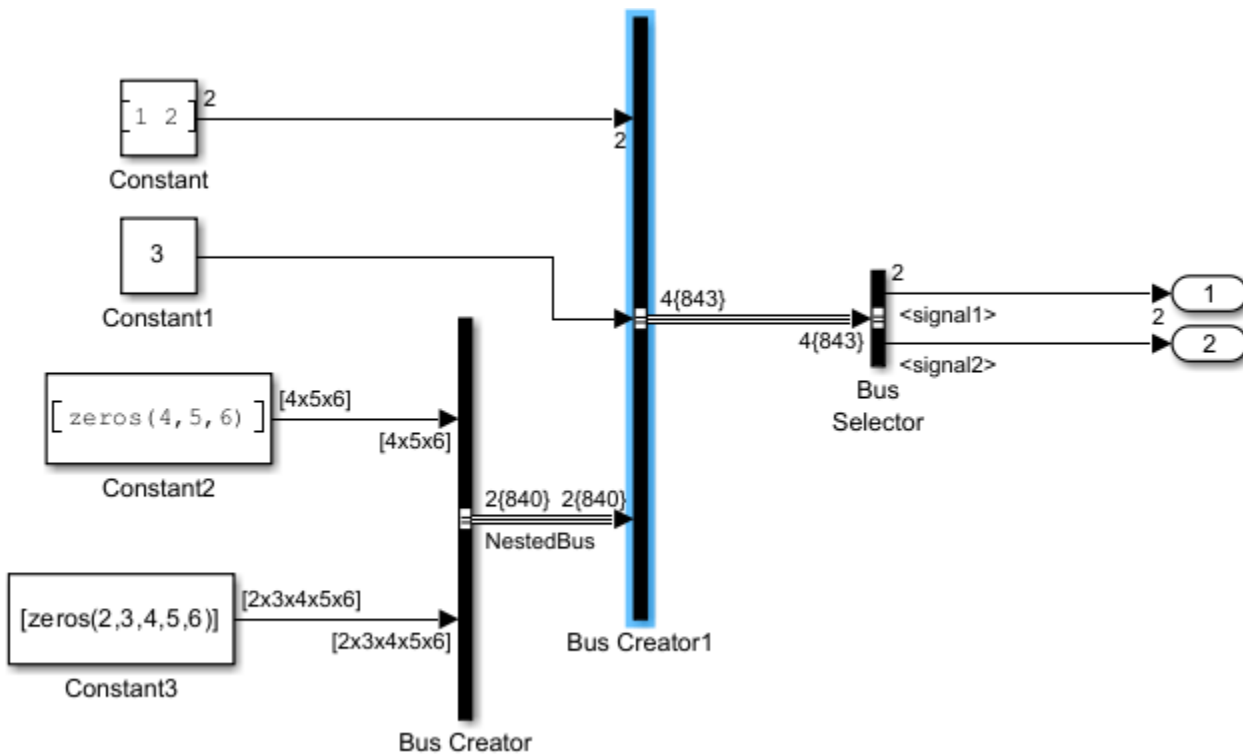

```
set_param('ex_nonBusPortDim', 'SimulationCommand', 'stop')
```

### Get Compiled Port Dimensions for Virtual Bus Signal

Get the dimensions of port signals of a Bus Creator block when querying the output port of Bus Creator1 block. As the block outputs a virtual bus signal, the dimensions of the port signals represented by the `dim` array consist of the type of bus signal associated with the output port of Bus Creator1 block, the number of signals carried by the bus, and the dimensions of those signals.

Step through the `ex_virtualBusPortDim` model programmatically using `SimulationCommand`.

```
open_system('ex_virtualBusPortDim.slx')
set_param('ex_virtualBusPortDim', 'SimulationCommand', 'start')
set_param('ex_virtualBusPortDim', 'SimulationCommand', 'pause')
```

Store the block name in a variable programmatically using the `PortHandles` parameter. Then, use the `CompiledPortDimensions` parameter to obtain the dimensions.

```
gcb='ex_virtualBusPortDim/Bus Creator1';
ph= get_param(gcb, 'PortHandles');
dim= get_param(ph.Outport, 'CompiledPortDimensions')
```

```
dim = 1x16
```

```
-2    4    1    2    1    1    3    4    5    6    5    2    3    4    5    6
```

For buses, the results include extra elements. The first element is -2, which indicates that the port corresponds to a virtual bus. The second element is 4, which is the number of leaf nodes. The subsequent elements follow the same pattern as nonbus signals.

- The output port of the first leaf node has 1 dimension, and the value in that dimension is 2.
- The output port of the second leaf node has 1 dimension, and the value in that dimension is 1.
- The output port of the third leaf node has 3 dimensions, and the values in those dimensions are 4 5 6.
- The output port of the fourth leaf node has 5 dimensions, and the values in those dimensions are 2 3 4 5 6.

To stop the simulation programmatically, use `SimulationCommand`.

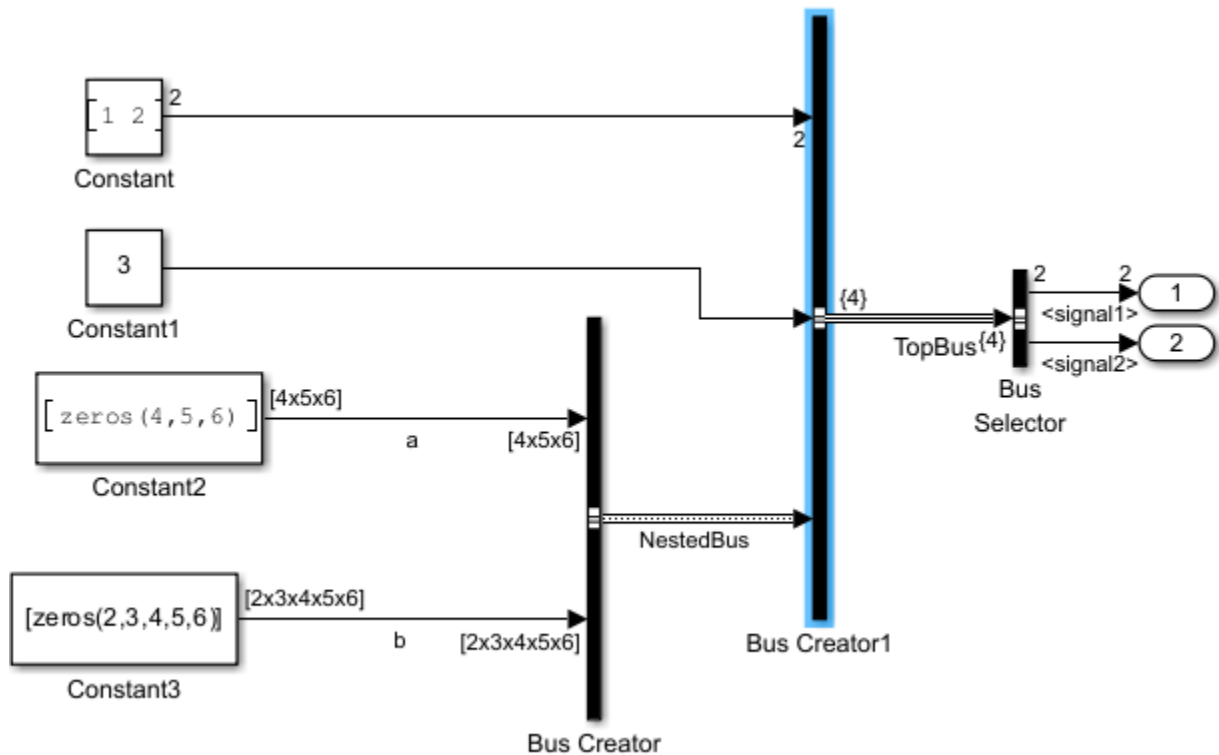

```
set_param('ex_virtualBusPortDim', 'SimulationCommand', 'stop')
```

## Get Compiled Port Dimensions for Nonvirtual Bus Signal

Get the dimensions of port signals of a Bus Creator block when querying the output port of Bus Creator1 block. Bus Creator1 block receives a nonvirtual bus signal at one of its input ports and outputs a virtual bus signal. As the block outputs a virtual bus signal, the dimensions of the port signals represented by the dim array consist of the type of bus signal associated with the output port of Bus Creator1 block, the number of signals carried by the bus, and the dimensions of those signals.

Step through the `ex_nonvirtualBusPortDim` using `SimulationCommand`.

```
open_system('ex_nonvirtualBusPortDim.slx')
set_param('ex_nonvirtualBusPortDim','SimulationCommand','start')
set_param('ex_nonvirtualBusPortDim','SimulationCommand','pause')
```

Store the block name in a variable programmatically using the `PortHandles` parameter. Then, use the `CompiledPortDimensions` parameter to obtain the dimensions.

```
gcb='ex_nonvirtualBusPortDim/Bus Creator1';
ph= get_param(gcb,'PortHandles');
dim= get_param(ph.Outputport,'CompiledPortDimensions')
```

```
dim = 1x8
      -2   3   1   2   1   1   1   1
```

When querying dimensions, nonvirtual buses are treated as scalars. The second element in the `dim` array is 3, which indicates three leaf nodes instead of four leaf nodes because the nonvirtual bus is treated as scalar. The subsequent elements follow the same pattern as nonbus signals.

- The output port of the first leaf node has 1 dimension, and the value in that dimension is 2.
- The output port of the second leaf node has 1 dimension, and the value in that dimension is 1.
- The third leaf node corresponds to the Bus Creator block that outputs the nonvirtual bus, `NestedBus`. The output port of the third leaf node has 1 dimension, and the value in that dimension is 1.

To stop the simulation programmatically, use `SimulationCommand`.

```
set_param('ex_nonvirtualBusPortDim', 'SimulationCommand', 'stop')
```

## Highlight Signal Sources and Destinations

### In this section...

“Highlight Signal Source” on page 80-28  
 “Highlight Signal Destination” on page 80-29  
 “Choose the Path of a Trace” on page 80-29  
 “Trace a Signal To and From Subsystems” on page 80-30  
 “Show All Possible Paths of a Trace” on page 80-31  
 “Display Port Values Along a Trace” on page 80-31  
 “Remove Highlighting” on page 80-32  
 “Resolve Incomplete Highlighting to Library Blocks” on page 80-33  
 “Signal Highlighting in Variant Systems” on page 80-33  
 “Limitations” on page 80-34  
 “Bus Element Tracing and Highlighting” on page 80-34

You can highlight a signal and its source or destination blocks in Simulink, and then remove the highlighting when it is not required any more. Signal highlighting crosses subsystem and model reference boundaries, allowing you to trace a signal across multiple subsystem levels. If a signal is composite, all source or destination blocks are highlighted. For more information on composite signals, see “Composite Interface Guidelines” on page 81-2.

To continue the trace towards the source or destination of the signal, use the left and right arrow keys of your keyboard, respectively.

### Highlight Signal Source

To begin a trace to the source blocks of a signal, select the **Highlight Signal to Source** option from the context menu for the signal. The

badge identifies the start of the trace. This option highlights:

- All branches of the signal anywhere in the model
- All virtual blocks through which the signal passes
- The nonvirtual blocks that write the value of the signal

To continue tracing towards the source of the signal, press the **Left** arrow key.

## Highlight Signal Destination

To begin a trace to the destination blocks of a signal, select the **Highlight Signal to Destination** option from the context menu for the signal. Press the **Right** arrow key to move the trace towards the final destination. The

badge identifies the start of the trace. This option highlights:

- All branches of the signal anywhere in the model
- All virtual blocks through which the signal passes
- The nonvirtual blocks that read the value of the signal
- The signal and destination block for all blocks that are duplicates of the Inport block for the line that you select

In this example, the selected trace shows a path of the signal from the Stick Input to the Elevator Command in the Controller subsystem of the f14 model.

In the next example, selecting the signal from In2 and choosing the **Highlight Signal to Destination** option highlights the signal and destination block for In2 and In1, because In1 and In2 are duplicate Inport blocks.

## Choose the Path of a Trace

In some situations, a signal trace can take multiple viable paths in the next segment of the trace. This can be seen when a signal is combined or split through a Mux or Demux block, or if it is branched out as an input to another block. In such cases, the options are highlighted in blue and can be cycled using the **Up** and **Down** arrow keys on the keyboard. Once you have highlighted the block to which you would like to move, proceed as normal.

In the figure above, the trace to source has reached the Sum block where it can take one of three possible paths. The first option to Gain  $Zd$  is highlighted in blue.

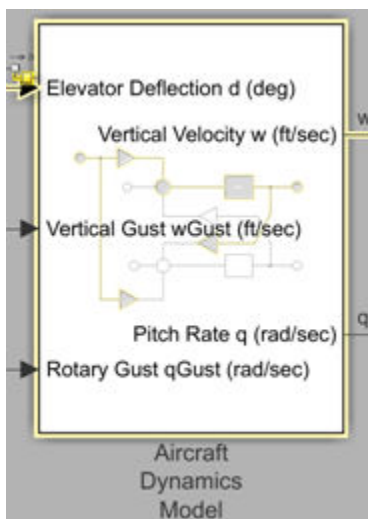

## Trace a Signal To and From Subsystems

When the trace reaches a subsystem, it does not automatically trace in. Instead, the trace highlights the target subsystem and you are able to see a preview of the trace within the subsystem.

In this example, the selected signal trace to destination has reached the Controller subsystem of the f14 model. You can see that the contents of the subsystem are visible and the next segment of the trace is highlighted within the preview.

When the trace comes out of a subsystem, the subsystem preview also displays the path of the trace inside it. The next example shows the path of a trace through the Aircraft Dynamics Model subsystem from the input  $wGust$  to vertical velocity  $w$  output.

**Note** You cannot jump over a subsystem or a referenced model in your trace. You need to trace the signal path through them.

## Show All Possible Paths of a Trace

To highlight all possible paths a trace can take, press **Ctrl** key along with the **Left** (towards source) or the **Right** (towards destination) key. You can continue to trace as before.

To clear the highlighting, simultaneously press the **Ctrl** key and the arrow key in the direction opposite to the trace.

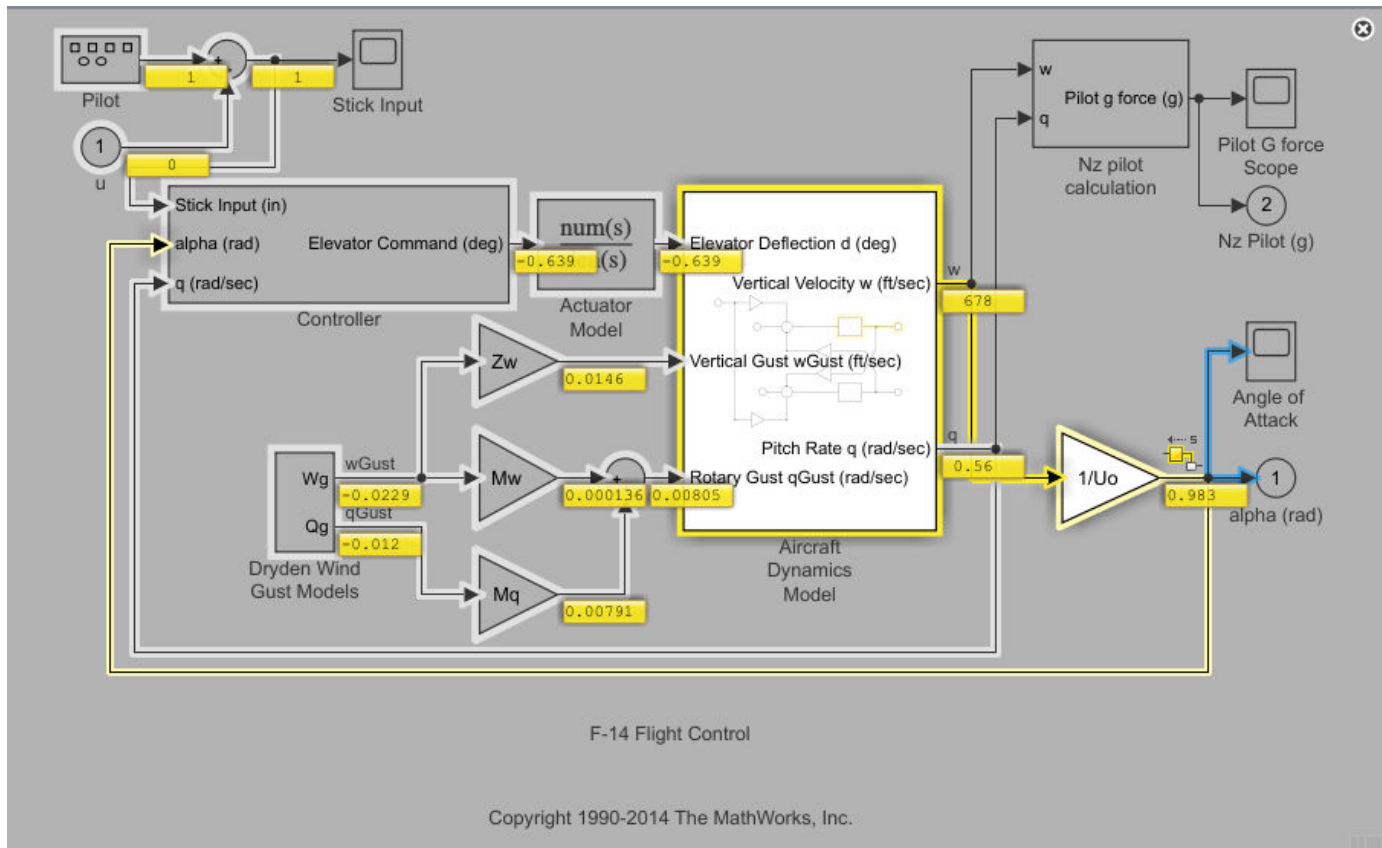

## Display Port Values Along a Trace

After you trace the path of a signal, press the **L** key to display the values of a signal at the output port of each block.

If you highlight all the possible paths of the trace as described in “Show All Possible Paths of a Trace” on page 80-31, press the **Ctrl + L** to view the signal values at all the output ports.

## Remove Highlighting

To remove all highlighting, right-click the model, and then select **Remove Highlighting**, or, on the **Signal** tab, click **Remove Trace**. You can also press **Ctrl+Shift+H** or click the  icon at the top right corner of the editor.

To back up a trace, press the arrow key opposite to the original intent of the trace. For example, if you would like to back up a trace to the destination of the signal, press the left arrow key. To back up a trace to the source of a signal, press the **right arrow** key.

## Resolve Incomplete Highlighting to Library Blocks

If the path from a source block or to a destination block includes an unresolved reference to a library block, the highlighting options highlight the path from or to the library block, respectively. To display the complete path, press **Ctrl+D** to update the diagram. The diagram update resolves all library references and displays the complete path to a destination block or from a source block.

## Signal Highlighting in Variant Systems

Tracing a signal that passes through inline variant blocks such as Variant Source and Variant Sink highlights the path of the active variant choice. In this example, the selected signal trace to its source shows the path of the active variant passing through the **Variant Source2** block.

For a Variant Subsystem block, the trace highlights the active choice within the subsystem by default.

If the **Variant activation time** parameter of the Variant Subsystem block is set to code compile, the trace highlights both the active and inactive choices within the subsystem.

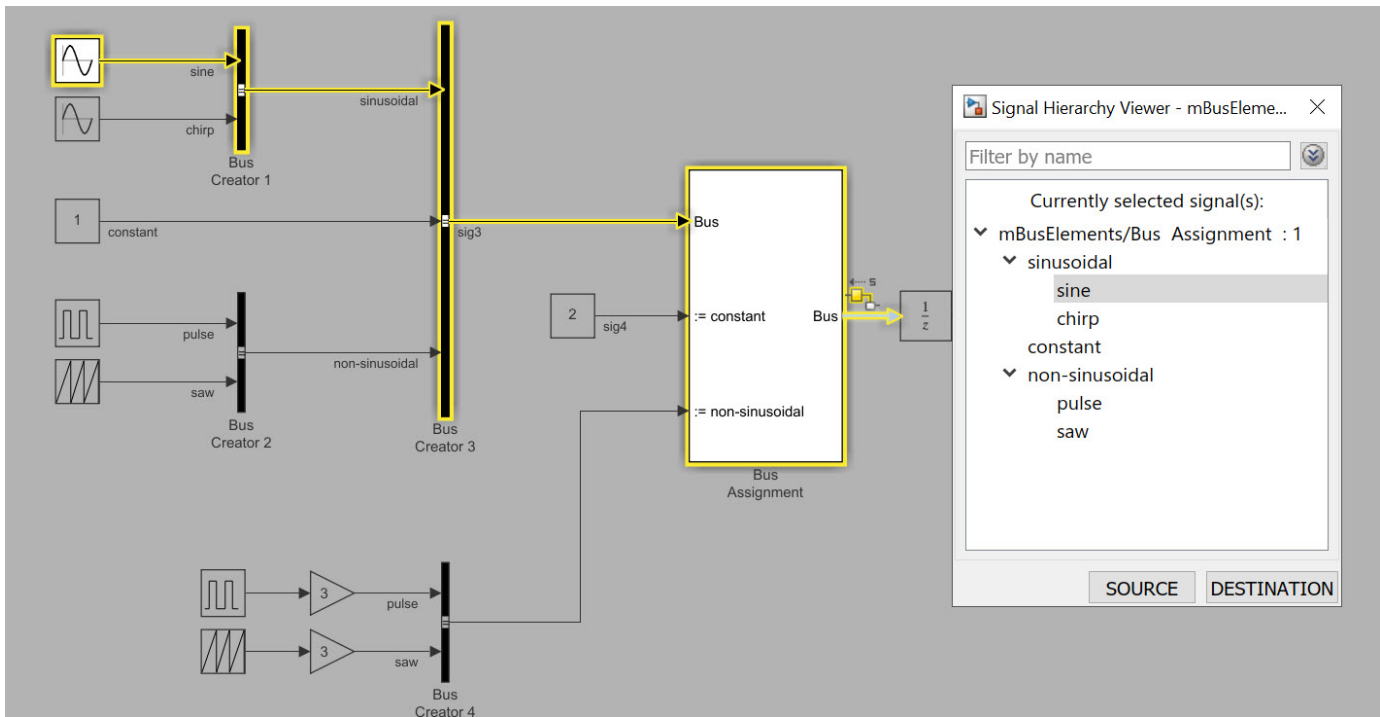

## Limitations

The signal tracing tool has the following limitations in its usage:

- The signal trace does not preserve bus information when tracing into or out of a referenced model.
- Tracing past a Goto block changes the active level to that containing the matching From block. However, this does not guarantee that the matching From block is the active block if there are other valid blocks at the same level.
- Signal tracing is unsupported by certain blocks. Unsupported blocks are blocks where:
  - You cannot trace into them to highlight their contents. Examples of such blocks include but are not limited to Stateflow charts, Simscape subsystems, and function blocks,.
  - You cannot cross them and continue tracing (e.g. Simscape blocks).
- The styling of the signal does not update with modifications to the model when signal tracing is enabled.
- The operation to “Show All Possible Paths of a Trace” on page 80-31 does not traverse through referenced models in the same way as it does subsystems. Referenced models are treated as non-virtual blocks and the impact region will not highlight their contents.

## Bus Element Tracing and Highlighting

You can trace the source or destination of a bus element signal in the model using **Signal Hierarchy Viewer**. This figure shows how to trace the source blocks of the bus element named `sine`. The tracing starts from the output port of the block named `mBusElements/Bus Assignment`. In the **Signal Hierarchy Viewer**, select the bus element `sine`, which belongs to the bus signal `sinusoid`, then click **Source**. All source blocks containing `sine` will be highlighted.

There are three methods to activate the **Signal Hierarchy Viewer**:

- Right-click a signal line and select **Signal Hierarchy** from the list.
- If the currently selected signal line contains the bus signal, the **Signal Hierarchy Viewer** opens automatically.
- If the currently selected signal line does not contain the bus signal but the tracing reaches a line that contains the bus signal, the **Signal Hierarchy Viewer** opens automatically.

The **Signal Hierarchy Viewer** displays the signal that is currently selected. If a different signal line is selected while **Signal Hierarchy Viewer** is open, the **Signal Hierarchy Viewer** updates to the corresponding selection. If no signal is selected, the **Signal Hierarchy Viewer** is blank. Thus, tracing the signal via **Signal Hierarchy Viewer** requires at least one signal line selected.

## Specify Signal Ranges

### In this section...

“Blocks That Allow Signal Range Specification” on page 80-36

“Work with Signal Ranges in Blocks” on page 80-37

“Troubleshoot Signal Range Errors” on page 80-38

“Unexpected Errors or Warnings for Data with Greater Precision or Range than double” on page 80-40

Simulink blocks allow you to specify a range of valid values for their output signals. Specifying signal ranges help you to optimize data types and improve generated code.

If you have Embedded Coder, Simulink Coder can optimize the code that you generate from the model by taking into account the minimum and maximum values that you specify for signals and parameters. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see [Optimize using the specified minimum and maximum values \(Embedded Coder\)](#).

### Blocks That Allow Signal Range Specification

The following blocks allow you to specify ranges for their output signals:

- Abs
- Constant
- Data Store Memory
- Data Type Conversion
- Difference
- Discrete Derivative
- Discrete-Time Integrator
- Gain
- In Bus Element
- Inport
- Interpolation Using Prelookup
- 1-D Lookup Table
- 2-D Lookup Table
- n-D Lookup Table
- Math Function
- MinMax
- Multiport Switch
- Out Bus Element
- Outport
- Product, Divide, Product of Elements
- Relay

- Repeating Sequence Interpolated
- Repeating Sequence Stair
- Saturation
- Saturation Dynamic
- Signal Specification
- Sum, Add, Subtract, Sum of Elements
- Switch

## Work with Signal Ranges in Blocks

To specify signal ranges for most blocks, use the **Output minimum** and **Output maximum** parameters of a block to specify a range of valid values for the block output signal. Exceptions include the Data Store Memory, Inport, In Bus Element, Outport, Out Bus Element, and Signal Specification blocks, for which you use their **Minimum** and **Maximum** parameters to specify a signal range. See “Blocks That Allow Signal Range Specification” on page 80-36 for a list of applicable blocks.

To access these parameters, use the Property Inspector (on the **Modeling** tab, under **Design**, click **Property Inspector**), the Model Data Editor (on the **Modeling** tab, click **Model Data Editor**), or the block dialog box.

Specify a minimum or maximum as an expression that evaluates to a scalar, real number with double data type. For example, you can use:

- A literal number such as `98.884`. Implicitly, the data type is `double`.
- A numeric workspace variable (see “Share and Reuse Block Parameter Values by Creating Variables” on page 40-9) whose data type is `double`. Use this technique to share a minimum or maximum value between multiple data items.

When you use a variable to set the `Min` or `Max` property of a `Simulink.ValueType`, `Simulink.Signal`, or `Simulink.BusElement` object, the current value of the variable is assigned to the object. The `Min` and `Max` properties of the object are not affected by future changes to the variable.

The scalar value that you specify applies to each element of a composite signal (for example, when the signal is nonscalar or a bus). For information about scalar expansion, see “Scalar Expansion of Inputs and Parameters” on page 80-21.

To leave the minimum or maximum of a signal unspecified, use an empty matrix `[]`, which is the default value.

### Specify Ranges for Modeling Constructs

If you use modeling constructs such as buses, data stores, and Stateflow charts, you can use different techniques to specify design range information. Use the information in the table.

Description of Target Signal	Technique and More Information
Numerically complex signal	When you specify an <b>Output minimum</b> or <b>Output maximum</b> for a signal that is numerically complex, the specified minimum and maximum values apply separately to the real part and to the imaginary part of the complex number. If the value of either part of the number is less than the minimum, or greater than the maximum, the complex number is outside the specified range. No range checking occurs against any combination of the real and imaginary parts, such as $(\sqrt{a^2+b^2})$ .
Signal elements in a bus	If you assemble the bus by using a Bus Creator block, you can specify range information on the upstream blocks that feed the Bus Creator block.  Regardless of the technique you use to assemble the bus, you can create a <code>Simulink.Bus</code> object and use it as the data type of the bus. In this case, consider specifying range information by using the <code>Min</code> and <code>Max</code> properties of the <code>Simulink.BusElement</code> objects that reside in the bus object. For more information, see “Specify Bus Properties with Simulink.Bus Object Data Types” on page 81-58.
Signal in a MATLAB Function block	Use the <b>Symbols</b> pane and Property Inspector to specify the <b>Minimum</b> and <b>Maximum</b> properties of the variables. See “Set General Variable Properties” on page 49-31.
Signal in a Stateflow chart	Set the <b>Minimum</b> and <b>Maximum</b> properties of the corresponding Stateflow data. See “Limit range” (Stateflow).
Signal that you associate with an object (such as a <code>Simulink.Signal</code> or <code>Simulink.ValueType</code> object)	Set the <code>Min</code> and <code>Max</code> properties of the <code>Simulink.Signal</code> or <code>Simulink.ValueType</code> object.
Data store (Data Store Memory block or <code>Simulink.Signal</code> object)	For a Data Store Memory block, set the <b>Minimum</b> and <b>Maximum</b> block parameters. For a signal object, set the <code>Min</code> and <code>Max</code> properties.

## Troubleshoot Signal Range Errors

Simulink provides a diagnostic named **Simulation range checking**, which you can enable to detect when signals exceed their specified ranges during simulation. When enabled, Simulink compares the signal values that a block outputs with both the specified range (see “Work with Signal Ranges in Blocks” on page 80-37) and the block data type. That is, Simulink performs the following check:

$$\text{DataTypeMin} \leq \text{MinValue} \leq \text{VALUE} \leq \text{MaxValue} \leq \text{DataTypeMax}$$

where

- `DataTypeMin` is the minimum value representable by the block data type.
- `MinValue` is the minimum value the block should output, specified by, e.g., **Output minimum**.
- `VALUE` is the signal value that the block outputs.
- `MaxValue` is the maximum value the block should output, specified by, e.g., **Output maximum**.

- `DataTypeMax` is the maximum value representable by the block data type.

**Note** It is possible to overspecify how a block handles signals that exceed particular ranges. For example, you can specify values (other than the default values) for both signal range parameters and enable the **Saturate on integer overflow** parameter. In this case, Simulink displays a warning message that advises you to disable the **Saturate on integer overflow** parameter.

### Enable Simulation Range Checking

To enable the **Simulation range checking** diagnostic:

- 1 In your model window, on the **Modeling** tab, click **Model Settings**.  
Simulink displays the Configuration Parameters dialog box.
- 2 In the **Select** tree on the left side of the Configuration Parameters dialog box, click the **Diagnostics > Data Validity** category. On the right side under **Signals**, set the **Simulation range checking** diagnostic to error or warning.

- 3 Click **OK** to apply your changes and close the Configuration Parameters dialog box.

See “Simulation range checking” for more information.

### Simulate Models with Simulation Range Checking

To check for signal range errors or warnings:

- 1 Enable the **Simulation range checking** diagnostic for your model (see “Enable Simulation Range Checking” on page 80-39).
- 2 In your model window, click **Run** to simulate the model.

Simulink simulates your model and performs signal range checking. If a signal exceeds its specified range when the **Simulation range checking** diagnostic specifies **error**, Simulink stops the simulation and generates an error (for example, in the Diagnostic Viewer).

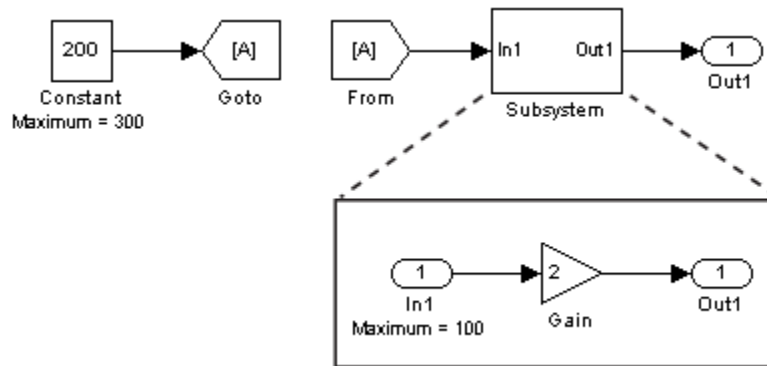

Otherwise, if a signal exceeds its specified range when the **Simulation range checking** diagnostic specifies **warning**, Simulink generates a warning message in the MATLAB Command Window. Each message identifies the block whose output signal exceeds its specified range, and the time step at which this violation occurs.

### Signal Range Propagation for Virtual Blocks

Some virtual blocks (see “Nonvirtual and Virtual Blocks” on page 39-2) allow you to specify ranges for their output signals, for example, the Inport and Outport blocks. When the **Simulation range**

**checking** diagnostic is enabled for a model that contains such blocks, the signal range of the virtual block propagates backward to the first instance of a nonvirtual block whose output signal it receives. If the nonvirtual block specifies different values for its own range, Simulink performs signal range checking with the tightest range possible. That is, Simulink checks the signal using the larger minimum value and the smaller maximum value.

For example, consider the following model:

In this model, the Constant block specifies its **Output maximum** parameter as 300, and that of the Inport block is set to 100. Suppose you enable the **Simulation range checking** diagnostic and simulate the model. The Inport block back propagates its maximum value to the nonvirtual block that precedes it, i.e., the Constant block. Simulink then uses the smaller of the two maximum values to check the signal that the Constant block outputs. Because the Constant block outputs a signal whose value (200) exceeds the tightest range, Simulink generates an error.

## Unexpected Errors or Warnings for Data with Greater Precision or Range than double

When a data item (signal or parameter) uses a data type other than `double`, before comparison, Simulink casts the data item and each design limit (minimum or maximum value that you specify) to the nondouble data type. This technique helps prevent the generation of unnecessary, misleading errors and warnings.

However, Simulink stores design limits as `double` before comparison. If the data type of the data item has higher precision than `double` (for example, a fixed-point data type with a 128-bit word length and a 126-bit fraction length) or greater range than `double`, and `double` cannot exactly represent the value of a design limit, Simulink can generate unexpected warnings and errors.

If the nondouble type has higher precision, consider rounding the design limit to the next number furthest from zero that `double` can represent. For example, suppose that a signal generates an error after you set the maximum value to `98.8847692348509014`. At the command prompt, calculate the next number furthest from zero that `double` can represent.

```
format long
98.8847692348509014 + eps(98.8847692348509014)
```

```
ans =
```

```
98.884769234850921
```

Use the resulting number, `98.884769234850921`, to replace the maximum value.

## Initialize Signals and Discrete States

### In this section...

“Using Block Parameters to Initialize Signals and Discrete States” on page 80-42

“Use Signal Objects to Initialize Signals and Discrete States” on page 80-43

“Using Signal Objects to Tune Initial Values” on page 80-45

“Initialization Behavior Summary for Signal Objects” on page 80-45

Simulink allows you to specify the initial values of signals and discrete states, i.e., the values of the signals and discrete states at the **Start time** of the simulation. You can use signal objects to specify the initial values of any signal or discrete state in a model. In addition, for some blocks, e.g., Outport, Data Store Memory, or Memory, you can use either a signal object or a block parameter or both to specify the initial value of a block state or output. In such cases, Simulink checks to ensure that the values specified by the signal object and the parameter are consistent. For information about initializing bus signals, see “Specify Initial Conditions for Bus Elements” on page 81-64

When you specify a signal object for signal or discrete state initialization, or a variable as the value of a block parameter, Simulink resolves the name that you specify to an appropriate object or variable, as described in “Symbol Resolution” on page 72-126.

A given signal can be associated with at most one signal object under any circumstances. The signal can refer to the object more than once, but every reference must resolve to exactly the same object. A different signal object that has exactly the same properties will not meet the requirement for uniqueness. A compile-time error occurs if a model associates more than one signal object with any signal. For more information, see `Simulink.Signal` and the Merge block.

### Using Block Parameters to Initialize Signals and Discrete States

For blocks that have an initial value or initial condition parameter, you can use that parameter to initialize a signal. For example, the following Block Parameters dialog box initializes the signal for a Unit Delay block with an initial condition of 0.

To access these block parameters, choose one of these techniques:

- Use the **Model Data Editor** (on the **Modeling** tab, click **Model Data Editor**) to configure multiple signals and states with a searchable, sortable table. To initialize a block state or data store, you can use the appropriate tab (**States** or **Data Stores**). To initialize a signal, state, or data store, you can use the **Parameters** tab and find the row that corresponds to the relevant block parameter.
- Use the **Property Inspector** (on the **Modeling** tab, under **Design**, click **Property Inspector**) to configure one signal or state at a time. Select the block that maintains the target state or generates the target signal and find the relevant block parameter.
- Use the block parameter dialog box. Use this technique to configure one signal or state at a time or to compare the configurations of a few signals or states side by side.

For more information about techniques to access block parameters (including the parameters that control signal and state initialization), see “Set Properties and Parameters”.

## Use Signal Objects to Initialize Signals and Discrete States

You can use signal objects that have a storage class other than 'auto' or, when you set the default storage class of the corresponding data category to `Default` (the default setting) in the Code Mapping Editor, 'Model default' to initialize:

- Discrete states with an initial condition parameter
- Signals in a model except bus signals and blocks that output constant value

To specify an initial value, use the Model Explorer or MATLAB commands to do the following:

- 1 Create the signal object.

On the Model Explorer toolbar, select **Add > Simulink Signal**. The signal object appears in the base workspace with a default name. Rename the object as `S1`. Alternatively, use this command at the command prompt:

```
S1 = Simulink.Signal;
```

The name of the signal object must be the same as the name of the signal that the object is initializing. Although not required, consider setting the **Signal name must resolve to Simulink signal object** option in the Signal Properties dialog box. This setting makes signal objects in the MATLAB workspace consistent with signals that appear in your model.

Consider using the Data Object Wizard to create signal objects. The Data Object Wizard searches a model for signals for which signal objects do not exist. You can then selectively create signal objects for multiple signals listed in the search results with a single operation. For more information about the Data Object Wizard, see “Create Data Objects for a Model Using Data Object Wizard” on page 72-68.

- 2 Set the signal object storage class to a value other than `Auto` or `Model default`. In the Model Explorer **Contents** pane, select the signal object. In the Dialog pane, set **Storage class** to `ExportedGlobal`. Alternatively, use this command at the command prompt:

```
S1.CoderInfo.StorageClass = 'ExportedGlobal';
```

- 3 Set the initial value. You can specify a MATLAB expression, including the name of a workspace variable, that evaluates to a numeric scalar value or array.

The Simulink engine converts the initial value so the type, complexity, and dimension are consistent with the corresponding block parameter value. If you specify an invalid value or expression, an error message appears when you update the model.

In the Model Explorer Dialog pane, set **Initial value** to 0.5. Alternatively, use this command at the command prompt:

```
S1.InitialValue = '0.5'
```

If you can also use a block parameter to set the initial value of the signal or state, you should set the parameter either to empty ([]) or to the same value as the initial value of the signal object. If you set the parameter value to empty, Simulink uses the value specified by the signal object to initialize the signal or state. If you set the parameter to any other value, Simulink compares the parameter value to the signal object value and displays an error if they differ.

The following example shows a signal object specifying the initial output of an enabled subsystem.

Signal `s` is initialized to 4.5. To avoid a consistency error, the initial value of the enabled subsystem Output block must be [] or 4.5.

If you need a signal object and its initial value setting to persist across Simulink sessions, see “Create Persistent Data Objects” on page 72-75.

Some initial value settings may depend on the initialization mode. For more information, see “Underspecified initialization detection”.

**Classic initialization mode:** In this mode, initial value settings for signal objects that represent the following signals and states override the corresponding block parameter initial values if undefined (specified as []):

- Output signals of conditionally executed subsystems and Merge blocks
- Block states

**Simplified initialization mode:** In this mode, initial values of signal objects associated with the output of the following blocks are ignored. The initial values of the corresponding blocks are used instead.

- Output signals of conditionally executed subsystems
- Merge blocks

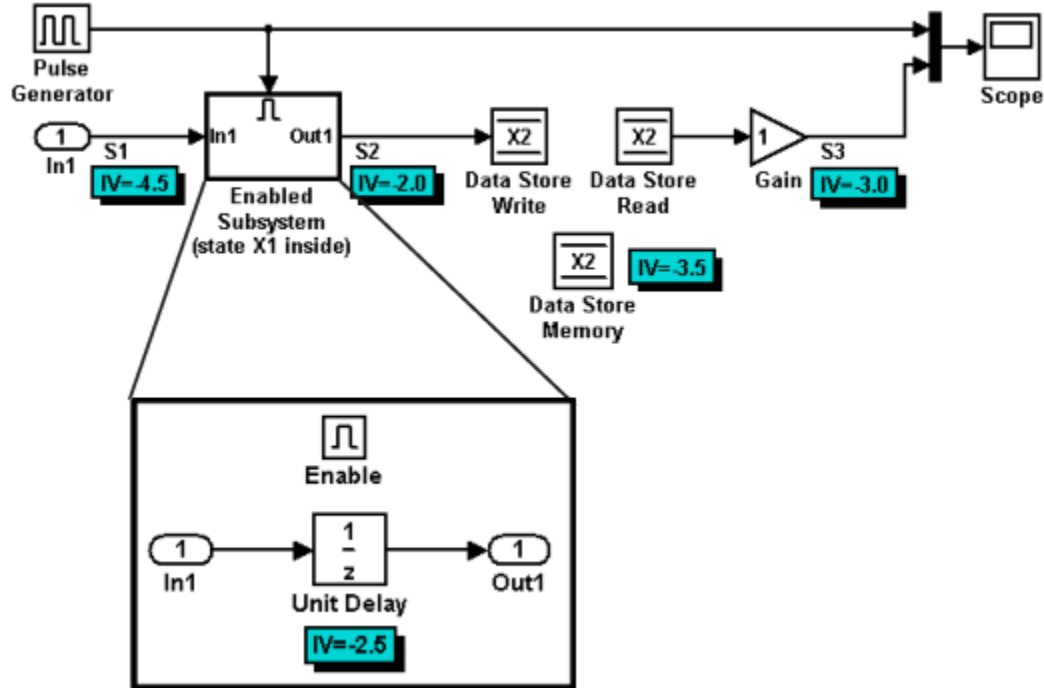

## Using Signal Objects to Tune Initial Values

Simulink allows you to use signal objects as an alternative to parameter objects (see `Simulink.Parameter`) to tune the initial values of block outputs and states that can be specified via a tunable parameter. To use a signal object to tune an initial value, create a signal object with the same name as the signal or state and set the signal object initial value to an expression that includes a variable defined in the MATLAB workspace. You can then tune the initial value by changing the value of the corresponding workspace variable during the simulation.

For example, suppose you want to tune the initial value of a Memory block state named M1. To do this, you might create a signal object named M1, set its storage class to 'ExportedGlobal', set its initial value to K (`M1.InitialValue = 'K'`), where K is a workspace variable in the MATLAB workspace, and set the corresponding initial condition parameter of the Memory block to [] to avoid consistency errors. You could then change the initial value of the Memory block state any time during the simulation by changing the value of K at the MATLAB command line and updating the block diagram (e.g., by typing **Ctrl+D**).

## Initialization Behavior Summary for Signal Objects

The following model and table show different types of signals and discrete states that you can initialize and the simulation behavior that results for each.

Signal or Discrete State	Description	Behavior
S1	Root input port	<ul style="list-style-type: none"> <li>Initialized to <code>S1.InitialValue</code>.</li> <li>If you use the <b>Data Import/Export</b> pane of the Configuration Parameters dialog to specify values for the root inputs, the initial value is overwritten and may differ at each time step. Otherwise, the value remains constant.</li> </ul>
X1	Unit Delay block — Block with a discrete state that has an initial condition	<ul style="list-style-type: none"> <li>Initialized to <code>X1.InitialValue</code>.</li> <li>Simulink checks whether <code>X1.InitialValue</code> matches the initial condition specified for the block and displays an error if a mismatch occurs.</li> <li>At first write, the output equals <code>X1.InitialValue</code> and the state equals S1.</li> <li>At each time step after the first write, the output equals the state and the state is updated to equal S1.</li> <li>If the block is inside an enabled subsystem, you can use the initial value as a reset value if the subsystem Enable block parameter <b>States when enabling</b> is set to reset.</li> </ul>
X2	Data Store Memory block	<ul style="list-style-type: none"> <li>Data type work (DWork) vector initialized to <code>X2.InitialValue</code>. For information on work vectors, see “DWork Vector Basics”.</li> <li>Simulink checks whether <code>X2.InitialValue</code> matches the initial condition specified for the block, and displays an error if a mismatch occurs.</li> <li>Data Store Write blocks overwrite the value.</li> </ul>

Signal or Discrete State	Description	Behavior
S2	Output of an enabled subsystem	<ul style="list-style-type: none"> <li>• Initialized to <code>S2.InitialValue</code> or the value of the Outport block. If multiple initial values are specified for the same signal, all initial values must be the same.</li> <li>• The first write occurs when the subsystem is enabled. The block feeding the subsystem output sets the value.</li> <li>• The initial value is also used as a reset value if the subsystem Enable block parameter <b>States when enabling</b> or Outport block parameter <b>Output when disabled</b> is set to reset.</li> </ul>
S3	Persistent signals	<ul style="list-style-type: none"> <li>• Initialized to <code>S3.InitialValue</code>.</li> <li>• The output value is reset by the block at each time step.</li> <li>• Affects code generation only. For simulation, setting the initial value for S3 is irrelevant because the values are overwritten at model simulation start time.</li> </ul>

## Configure Signals as Test Points

### In this section...

“What Is a Test Point?” on page 80-48

“Displaying Test Point Indicators” on page 80-49

### What Is a Test Point?

A *test point* is a signal that Simulink guarantees to be observable when using a Floating Scope block in a model. Simulink allows you to designate any signal in a model as a test point.

Designating a signal as a test point exempts the signal from model optimizations, such as signal storage reuse (see Signal storage reuse (Simulink Coder)) and block reduction (see “Implement logic signals as Boolean data (vs. double)”). These optimizations render signals inaccessible and hence unobservable during simulation.

Signals designated as test points will not have algebraic loops minimized, even if **Minimize algebraic loop occurrences** is selected (for more information about algebraic loops, see “Algebraic Loop Concepts” on page 3-39).

Test points are primarily intended for use when generating code from a model with Simulink Coder. For more information about test points in the context of code generation, see “Appearance of Test Points in the Generated Code” (Simulink Coder).

Marking a signal as a test point has no impact on signal logging that uses the Dataset logging format. For information about logging signals, see “Save Signal Data Using Signal Logging” on page 77-42.

Use one of the following ways to designate a signal as a test point:

- Open the **Signal Properties** dialog for the signal and check **Test Point** in the **Logging and accessibility** section.
- Use the Model Data Editor for batch configuration and for signals that are difficult to locate in a large model or hierarchy of subsystems. On the **Signals** tab, set the **Change view** drop-down list to **Instrumentation** and use the **Test Point** column. For more information, see **Model Data Editor**.
- To configure Stateflow data in a chart as test points, see “Monitor Test Points in Stateflow Charts” (Stateflow).

To configure a signal as a test point programmatically:

- 1 Get handles to the ports of the block.

```
portHandles = get_param('myModel/myBlock', 'portHandles');
```

`portHandles` is a structure. Each field stores a handle to a block port.

- 2 Extract a handle to the output port that creates the target signal line.

```
outportHandle = portHandles.Outport;
```

- 3 Set the port parameter `TestPoint` to 'on'.

```
set_param(outportHandle, 'TestPoint', 'on')
```

## Displaying Test Point Indicators

By default, Simulink displays an indicator on each signal whose **Signal Properties > Test point** option is enabled. For example, in the following model signals s2 and s3 are test points:

---

**Note** Simulink does not display an indicator on a signal that is specified as a test point by a `Simulink.Signal` object, because such a specification is external to the graphical model.

---

A signal that is a test point can also be logged. See “Save Signal Data Using Signal Logging” on page 77-42 for information about signal logging. The appearance of the indicator changes to indicate signals for which logging is also enabled.

To turn display of test point indicators on or off, in the Simulink Editor, on the **Debug** tab, select **Information Overlays > Log & Testpoint** to enable or disable the option.

- “Save Signal Data Using Signal Logging” on page 77-42

## Specify Application-Specific Signal Properties

When a signal represents a recurring type of value, you can define the signal properties once and reuse that specification for each signal that represents the same value type. For example, you can specify the unit, minimum value, maximum value, and dimensions of wind velocity, tire pressure, or water temperature.

A `Simulink.ValueType` object specifies this fundamental set of signal properties for a value type:

- Data type
- Minimum value
- Maximum value
- Unit
- Complexity
- Dimensions
- Dimensions mode (fixed-size or variable-size)
- Description

The property specifications for a value type are relevant wherever the type of value appears in a model. `ValueType` objects do not include instance-specific properties, such as initial values or sample times.

### Determine Whether To Use Value Types

You can specify signal properties individually or with a predefined set of property specifications. Depending on your modeling requirement, the way you define a set of signal properties differs.

Modeling Requirement	Source of Property Specifications
Assign or validate the properties of signals based on a set of properties that is fundamental to the application-specific value type of the signal, such as wind velocity.	Use a <code>Simulink.ValueType</code> object.
Assign or validate the properties of a signal based on a set of instance-specific properties, including the initial value and sample time.	Use a <code>Simulink.Signal</code> object or a Signal Specification block.
Assign or validate the properties of a signal that is an element of a bus.	Use a <code>Simulink.BusElement</code> object in a <code>Simulink.Bus</code> object.

A `ValueType` object can define the properties of a signal at an interface. When the ports of model components directly connect to each other, specify the same `ValueType` object for the blocks that represent those ports. If you specify different `ValueType` objects that have the same properties but different names, you receive an error. By specifying the same value type at both sides of the interface, you enforce consistency at the interface between the two components. For more information about interface design, see “Define Interfaces of Model Components” on page 23-19.

The `ValueType` object propagates through the model until it reaches a block that produces new data as output. For example, the object passes through In Bus Element and Out Bus Element blocks, but it does not pass through Sum or Gain blocks.

Information overlays display the properties specified by the `ValueType` object. Information overlays do not specify the `ValueType` object itself. Suppose your value type has units. To see the units, in the Simulink Toolstrip, on the **Debug** tab, select **Information Overlays > Units**. The units specified by the `ValueType` object appear on the signal lines.

`ValueType` objects do not appear in the generated code. The signal properties that the `ValueType` objects specify appear in the generated code.

## Create Value Types

To interactively create or edit `Simulink.ValueType` objects, use the **Type Editor** or **Model Explorer**. `ValueType` objects created with these tools are initially stored in the base workspace or a data dictionary.

To create a `ValueType` object in the Type Editor:

- 1 Open a model.
- 2 In the Simulink Toolstrip, on the **Modeling** tab, in the **Design** gallery, click **Type Editor**.
- 3 In the **Sources** pane of the Type Editor, select the storage location for the `Simulink.ValueType` object. For example, if the model uses a data dictionary, select the data dictionary. Otherwise, select the base workspace.
- 4 In the Type Editor toolstrip, in the **Add** gallery, select **Value Type**.

A new `ValueType` object appears in the **Contents** pane.

- 5 Use the table or **Property Inspector** pane to specify the desired property values for the value type.

To programmatically create and edit `ValueType` objects, see `Simulink.ValueType`. `ValueType` objects created programmatically are initially stored in the base workspace.

## Specify Value Types

After you create a `ValueType` object and specify its properties, use it to specify signal properties:

- At an interface with Inport, Outport, In Bus Element, or Out Bus Element blocks
- In a model with Signal Specification blocks
- In a `Simulink.BusElement`, `Simulink.Signal`, or `Simulink.Parameter` object

To associate a block or object with a value type, set the data type of the block or object to `ValueType: <object name>` and replace `<object name>` with the `ValueType` object name.

You can specify the `ValueType` object as the data type either before or after defining the `ValueType` object. However, before you simulate the model, the `ValueType` object must be defined and loaded.

The property values specified by the `ValueType` object override the property values specified by the block, object, or signal. For example, suppose an Inport block sets **Unit** to `ft/s`. When you set the **Data type** of the Inport block to a `ValueType` object that has `m/s` as its unit, the block uses `m/s` as the unit.

During model development, you can modify signals to match `ValueType` objects or modify `ValueType` objects to match signals. If you do not want to change the `ValueType` object, you can:

- Create a `ValueType` object that matches the changes to the signal and use the new `ValueType` object for the blocks that the changed signal connects to.
- Revert the signal changes so that the signal continues to match the associated `ValueType` object.

When `ValueType` objects do not match at an interface, you can:

- Specify the same `ValueType` object at both ports.
- Remove the `ValueType` object specification from one of the ports.
- Insert a Signal Specification block between the ports. The Signal Specification block returns a mismatch warning instead of an error when it receives a different `ValueType` object than the one it specifies.

## Save Value Types

You can save `Simulink.ValueType` objects to these locations:

- Data dictionary
- Script
- Function
- MAT file

If you do not save `ValueType` objects, then when you reopen a model that uses the `ValueType` objects, you need to recreate the `ValueType` objects.

Choose where to store `ValueType` object based on your modeling requirements.

Modeling Requirement	Location
Store data for large models and model hierarchies.	Use a data dictionary.  When you save to a data dictionary from the base workspace, you get all the variables used by the model, not just the <code>ValueType</code> objects.  For more information, see “Migrate Models to Use Simulink Data Dictionary” on page 79-7.
Use MATLAB for traceability and model differencing.	Use a script or function.  Create a script or function that programmatically defines one or more <code>ValueType</code> objects.  For more information, see “Create Scripts” and “Create Functions in Files”.
Save and load <code>ValueType</code> objects faster.	Use a MAT file.  To create a MAT file that contains either the specified <code>ValueType</code> objects from the base workspace or everything in the base workspace, use the <code>save</code> function.

To save `ValueType` objects stored in the base workspace, you can use any MATLAB technique that saves the contents of the base workspace. However, the resulting file contains everything in the base workspace, not just `ValueType` objects.

When you modify saved `ValueType` objects, you must resave them to keep the changes.

## Map Value Types to Models

Before you simulate a model, all the `ValueType` objects that the model uses must be loaded into the base workspace or a data dictionary used by the model. Mapping `ValueType` objects to models is important for automation and consistency across models.

- By identifying all of the `ValueType` objects that a model requires, you can ensure that those objects are loaded before model execution.
- By identifying all models that use a `ValueType` object, you can ensure that changes to a `ValueType` object do not cause unexpected changes in any of the models that use the `ValueType` object.

To ensure the necessary `ValueType` objects load before model execution, consider:

- **Projects** — Automatically load or run files that define `ValueType` objects by configuring the files to run when you open a project. For details, see “Project Management”.
- **Data dictionaries** — Store `ValueType` objects with variables and other objects for one or more models.

To share a `ValueType` object among models, you can link each model to a dictionary and create a common referenced dictionary to store the object. For an example, see “Partition Dictionary Data Using Referenced Dictionaries” on page 79-28.

- **Databases** — Capture mapping information in an external data source, such as a database.
- **Model callbacks** — Load or run files that define `ValueType` objects by using a model callback, such as `PreLoadFcn`. For more information, see “Model Callbacks” on page 4-54.

If a model uses only a few `ValueType` objects, consider copying the `ValueType` object code directly into the callback, instead of loading a file.

To find where a `ValueType` object is used in an open model, see “Finding Blocks That Use a Specific Variable” on page 72-105.

## Related Examples

- “Specify Signal Ranges” on page 80-36
- “Determine Signal Dimensions” on page 80-19
- “Investigate Signal Values” on page 80-9
- “Display Signal Attributes” on page 80-54

## Display Signal Attributes

### In this section...

“Ports & Signals Menu” on page 80-54  
 “Port Data Types” on page 80-55  
 “Design Ranges” on page 80-56  
 “Signal Dimensions” on page 80-56  
 “Signal to Object Resolution Indicator” on page 80-57  
 “Wide Nonscalar Lines” on page 80-58

A signal line in a model has attributes such as data type, dimensions, and numeric complexity. When you display these attributes on the block diagram, you can:

- Make the model easier to understand by others.
- Determine the value of the attribute that the signal ultimately uses for simulation (for example, when a signal uses an inherited data type).
- Plan your strategy to control these attributes along a data path (a series of connected blocks).

Additionally, to inspect and specify these attributes in a searchable, sortable table, you can use the **Model Data Editor**.

### Ports & Signals Menu

In the Simulink Editor, on the **Debug** tab, the **Information Overlays** menu offers the following options for displaying signal properties on the block diagram:

- Linearization Indicators
- Port Data Types (See “Port Data Types” on page 80-55)
- Design Ranges (See “Design Ranges” on page 80-56)
- Signal Dimensions (See “Signal Dimensions” on page 80-56)
- Storage Class
- Testpoint/Logging Indicators
- Signal Resolution Indicators (See “Signal to Object Resolution Indicator” on page 80-57)
- Viewer Indicators
- Wide Nonscalar Lines (See “Wide Nonscalar Lines” on page 80-58)

In addition, you can display sample time information. In the Simulink Editor, on the **Debug** tab, the **Information Overlays** menu provides the choices of **Colors** and **Text**. The **Colors** option allows the block diagram signal lines and blocks to be color-coded based on the sample time types and relative rates. The **Text** option provides black codes on the signal lines which indicate the type of sample time. If you select both **Colors** and **Text**, then both the colors and the annotations display. All of these options cause a Sample Time Legend to appear. The legend contains a description of the type of sample time and the sample time rate. If **Colors** is enabled, color codes also appear in the legend. The same is true if **Text** is enabled.

## Port Data Types

Displays the data type that each signal uses for simulation and code generation. The data type appears next to the output port that emits the signal.

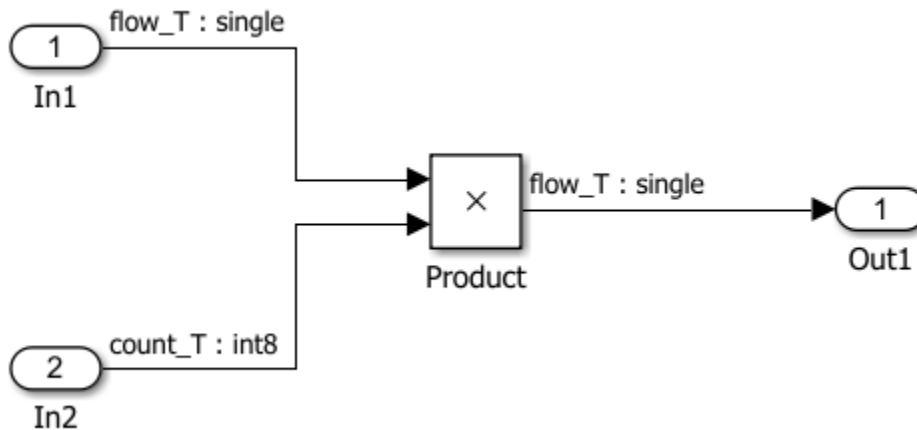

The notation (c) indicates that the signal is numerically complex (i).

If you use data type aliases (such as a `Simulink.AliasType` objects in the base workspace or a data dictionary) to set output data types in your model, by default, the diagram displays the aliases.

If you create a chain of aliases (for example, by using one `Simulink.AliasType` object as the base type of another `Simulink.AliasType` object), the diagram displays only the alias that you use to set the output data type of each signal. The diagram does not display the underlying aliases in the chain.

To display the lowest underlying base data type (such as `int8`, `single`, or `s16En14`) as well as the alias, in the **Debug** tab, open the **Information Overlays** drop-down. Under **Ports** click **Base Data Types** and **Alias Data Types**.

Alternatively, you can display the base type and not the alias by selecting **Base Data Types**.

When you use a fixed-point data type, the diagram displays the base type by using a standard notation that indicates the characteristics of the type (such as signedness and binary fraction length). To interpret this notation, see “Fixed-Point Data Type and Scaling Notation” (Fixed-Point Designer).

When you save a model with **Base Data Types** enabled, the next time you load the model, it displays the data type and complexity signal attributes.

## Design Ranges

Displays the compiled design range of a signal next to the output port that emits the signal. The ranges are computed during an update diagram.

Ranges are displayed in the format [min..max]. In the above example, the design range at the output port of the Mux block is displayed as [-10..mixed], because the two signals the Mux block combines have the same design minimum but different design maximums.

You can also use command-line parameters `CompiledPortDesignMin` and `CompiledPortDesignMax` to access the design minimum and maximum of port signals, respectively, at compile time. For more information, see “Common Block Properties”.

## Signal Dimensions

Display the dimensions of nonscalar signals next to the line that carries the signal.

The format of the display depends on whether the line represents a single signal or a bus. If the line represents a single vector signal, Simulink displays the width of the signal. If the line represents a single matrix signal, Simulink displays its dimensions as  $[N_1 \times N_2]$  where  $N_i$  is the size of the  $i$ th dimension of the signal. If the line represents a bus carrying signals of the same data type, Simulink displays  $N\{M\}$  where  $N$  is the number of signals carried by the bus and  $M$  is the total number of signal elements carried by the bus. If the bus carries signals of different data types, Simulink displays only the total number of signal elements  $\{M\}$ .

When you save a model with this option enabled, the next time you load the model, it displays signal dimensions.

## Signal to Object Resolution Indicator

The Simulink Editor by default graphically indicates signals that must resolve to signal objects. For any labeled signal whose **Signal name must resolve to signal object** property is enabled, a signal resolution icon appears to the left of the signal name. The icon looks like this:

A signal resolution icon indicates only that the **Signal name must resolve to signal object** property for a signal is enabled. The icon does not indicate whether the signal is actually resolved, and does not appear on a signal that is implicitly resolved without its **Signal name must resolve to signal object** property being enabled.

Where multiple labels exist, each label displays a signal resolution icon. No icon appears on an unlabeled branch. In the next figure, signal x2 must resolve to a signal object, so a signal resolution icon appears to the left of the signal name in each label:

To suppress the display of signal resolution icons, in the model window, on the **Debug** tab, select **Information Overlays > Signal Resolves to Object** to disable. This option is enabled default. To restore signal resolution icons, enable **Signal Resolves to Object**. Individual signals cannot be set to show or hide signal resolution indicators independently of the setting for the whole model. For additional information, see:

- “Symbol Resolution” on page 72-126
- “Initialize Signals and Discrete States” on page 80-42
- `Simulink.Signal`

## Wide Nonscalar Lines

Draws lines that carry vector or matrix signals wider than lines that carry scalar signals.

For more information on vector and matrix signals, see “Signal Types” on page 80-7.

### About Signal Groups

To display, create, and edit interchangeable groups of signal sources and quickly switch the groups into and out of a model, use the Signal Builder block. You can define any piecewise linear signal shape (waveform).

---

**Note** The Signal Builder block is not recommended to work with signal groups. Instead, use the Signal Editor block to display, create, edit, and switch interchangeable scenarios. For more information, see “Load Data with Interchangeable Scenarios” on page 76-30.

---

Use signal groups when testing a model, especially when using them in conjunction with the Simulink Assertion block and the Model Coverage Tool from the Simulink Coverage.

**Solver** pane settings in Model Configuration Parameters can affect the Signal Builder block output. See “Simulation Phases in Dynamic Systems” on page 3-2 and “Compare Solvers” on page 3-6 for a description of how solvers affect simulation.

---

**Note** The Signal Builder block adds a port for each signal you create. The block **Position** parameter limits the number of ports the Signal Builder block can have, and therefore the number of signals you can create. For more information, see the **Position** parameter at “Common Block Properties”.

---

You can also use the `signalbuilder` function to populate a Signal Builder block.

### Supported Waveforms

The Signal Builder block supports these waveforms.

## Using the Signal Builder Block with Fast Restart

After you turn on fast restart:

- In between runs, you can change data, rename signals and signal groups, and add new groups. You cannot:
  - Import signals or signal groups
  - Change signal output settings
- You can click the **Run all** button once. To reenale the **Run all** button, toggle the fast restart button on the Simulink Editor tool bar. However, **Run all** does not use fast restart.

## Editing Signal Groups

The Signal Builder window allows you to create, rename, move, then delete signal groups from the set of groups represented by a Signal Builder block.

### Creating and Deleting Signal Groups

To create a signal group:

- 1 In Signal Builder, copy an existing signal group.
- 2 Modify it to suit your needs.

To copy an existing signal group:

- 1 In Signal Builder, select the group from the list.
- 2 Select **Group > Copy**.

A new group is created.

To delete a group, select the group from the list, and select **Group > Delete**.

### Renaming Signal Groups

To rename a signal group:

- 1 In Signal Builder, select the group from the list.
- 2 Select **Group > Rename**.
- 3 Edit the existing name in the dialog box or enter a new name. Click **OK**.

### Moving Signal Groups

To reposition a group in the stack of group panes:

- 1 In Signal Builder, select the pane.
- 2 To move the group lower in the stack, select **Group > Move Down**.
- 3 To move the pane higher in the stack, select **Group > Move Up**.

## Editing Signals

Signal Builder allows you to create, cut and paste, hide, and delete signals from signal groups.

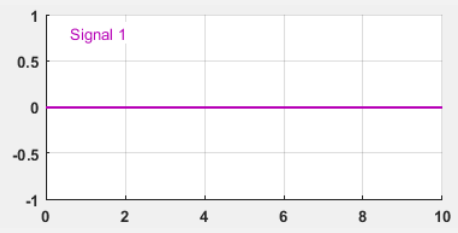

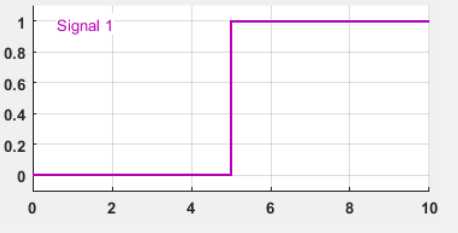

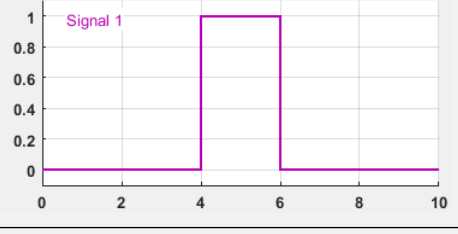

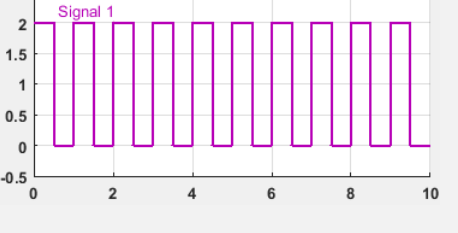

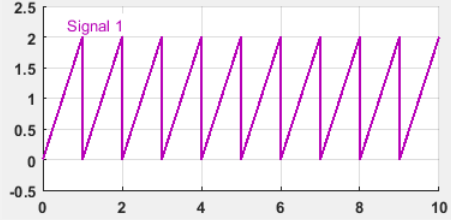

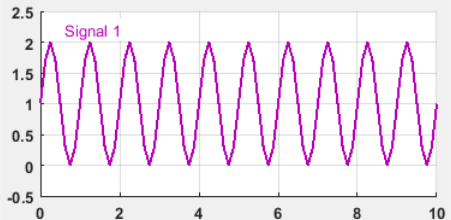

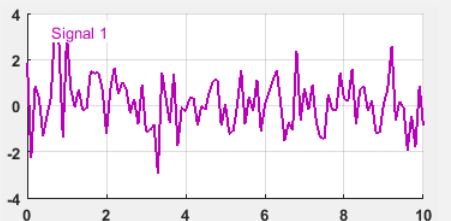

## Creating Signals

To create a signal in the currently selected signal group:

- 1 In Signal Builder, from the Active Group list, select the group you want to add the signal to.
- 2 Select **Signal > New**.

The menu lists the waveforms you can add.

Waveform	Description	Inputs	Output
Constant	Constant waveform	None	 <p>A graph showing a constant signal at 0 over a time interval from 0 to 10. The y-axis ranges from -1 to 1, and the x-axis ranges from 0 to 10. The signal is a horizontal purple line at y=0.</p>
Step	Step waveform	None	 <p>A graph showing a step waveform. The signal is at 0 until time 5, then jumps to 1 and remains constant until time 10. The y-axis ranges from 0 to 1, and the x-axis ranges from 0 to 10.</p>
Pulse	Pulse waveform	None	 <p>A graph showing a pulse waveform. The signal is at 0 until time 4, jumps to 1, stays at 1 until time 6, and then returns to 0 until time 10. The y-axis ranges from 0 to 1, and the x-axis ranges from 0 to 10.</p>
Square	Square waveform	<ul style="list-style-type: none"> <li>• <b>Frequency (Hz)</b> Waveform frequency, in hertz</li> <li>• <b>Amplitude</b> Waveform amplitude</li> <li>• <b>Y Offset</b> Waveform vertical offset</li> <li>• <b>% Duty cycle</b> Percent of the period the signal is positive (a value between 0 and 100)</li> </ul>	 <p>A graph showing a square wave signal. The signal oscillates between 0 and 2 with a period of 1 unit. The y-axis ranges from -0.5 to 2.5, and the x-axis ranges from 0 to 10.</p>

Waveform	Description	Inputs	Output
Sawtooth	Sawtooth waveform	<ul style="list-style-type: none"> <li>• <b>Frequency (Hz)</b> Waveform frequency, in hertz</li> <li>• <b>Amplitude</b> Waveform amplitude</li> <li>• <b>Y Offset</b> Waveform vertical offset</li> </ul>	
Sampled Sin	Sampled sine waveform	<ul style="list-style-type: none"> <li>• <b>Frequency (Hz)</b> Waveform frequency, in hertz</li> <li>• <b>Amplitude</b> Waveform amplitude</li> <li>• <b>Y Offset</b> Waveform vertical offset</li> <li>• <b>Samples Per Period</b> Number of samples per waveform period</li> </ul>	
Sampled Gaussian Noise	Sampled Gaussian noise waveform based on a Gaussian distribution with input mean and standard deviation at input frequency	<ul style="list-style-type: none"> <li>• <b>Frequency (Hz)</b> Waveform frequency, in hertz</li> <li>• <b>Mean</b> The mean value of the random variable output</li> <li>• <b>Standard Deviation</b> The standard deviation squared of the random variable output</li> <li>• <b>Seed (empty to use current state)</b> The initial seed value for the random number generator</li> </ul>	

Waveform	Description	Inputs	Output
Pseudorandom Noise	Pseudorandom noise waveform based on a binomial distribution with upper and lower values at input frequency	<ul style="list-style-type: none"> <li>• <b>Frequency (Hz)</b> Frequency with which waveform fluctuates between <b>Upper value</b> and <b>Lower value</b>, in hertz</li> <li>• <b>Upper value</b> Upper limit of signal</li> <li>• <b>Lower value</b> Lower limit of signal</li> <li>• <b>Seed</b> The initial seed value for the random number generator</li> </ul>	
Poisson Random Noise	Poisson random noise waveform that alternates between 0 and 1	<ul style="list-style-type: none"> <li>• <b>Avg rate (1/sec)</b> Average rate of transition between 0 and 1</li> <li>• <b>Seed (empty to use current state)</b> The initial seed value for the random number generator</li> </ul>	

Waveform	Description	Inputs	Output
Custom	Custom piecewise linear waveform; custom values must fit within the display area	<ul style="list-style-type: none"> <li>• <b>Time values</b> Vector of two or more time coordinates</li> <li>• <b>Y values</b> Vector of two or more signal amplitudes that correspond to the values in <b>Time values</b></li> </ul> <p>The entries in either field can be any MATLAB expression that evaluates to a vector, including the results from the evaluation of a MATLAB workspace variable. The resulting vectors must be of equal length.</p> <hr/> <p><b>Note</b> Signal Builder displays a warning if you add a custom waveform with a large number of data points (100,000,000 or more).</p>	

- 3 Select the waveform you want to add.
- 4 Specify the inputs (in the prompt), and click **OK**.

If you select a standard waveform, Signal Builder adds a signal with that waveform to the group. If you select a custom waveform, you are prompted for **Time values** and **Y values**.

You can also use MATLAB workspace variables to create new signals.

- 1 In the MATLAB Command Window, create data for two variables,  $t$  and  $y$ .

```
t = 1:10
y = 1:10
```

These vectors must be the same size.

- 2 Create a model and add a Signal Builder block.
- 3 Double-click the Signal Builder block.
- 4 Select **Signal > New > Custom**.
- 5 In the Custom Waveform window, enter  $t$  in the **Time values** field and  $y$  in the **Y values** field and then click **OK**.

The Signal Builder block window displays the new signal as Signal 2.

## Defining Signal Output

To specify the type of output to use for sending test signals:

- 1 In Signal Builder, select **Signal > Output**.
- 2 From the list, select:

- **Ports**

Default. Sends individual signals from the block. An output port named Signal *N* appears for each Signal *N*.

- **Bus**

Sends single, virtual, nonhierarchical bus of signals from the block. An output port named Bus appears.

---

### Tip

- You cannot use the **Bus** option to create a bus of nonvirtual signals.
  - The **Bus** option enables you to change your model layout without having to reroute Signal Builder block signals. Use the Bus Selector block to select the signals from this bus.
  - If you create a Signal Builder block using the Viewers & Generators Manager or using the **Create & Connect Generator** option from a signal line context menu, you cannot define signal output. In these cases, the block sends individual signals.
-

### Copying and Pasting Signals

To copy a signal from one group and paste it into another group as a new signal:

- 1 In Signal Builder, select the signal you want to copy.
- 2 Select **Edit > Copy**.
- 3 Select the group you want to paste the signal into.
- 4 Select **Edit > Paste**.

To copy a signal from one axis and paste it into another axis to replace its signal:

- 1 Select the signal you want to copy.
- 2 Select **Edit > Copy**.
- 3 Select the signal on the axis that you want to update.
- 4 Select **Edit > Paste**.

### Deleting Signals

To delete a signal, in Signal Builder, select the signal and choose **Delete** or **Cut** from the **Edit** menu. Signal Builder deletes the signal from the current group. Because each signal group must contain the same number of signals, Signal Builder also deletes all signals sharing the same index in the other groups.

### Renaming a Signal

To rename a signal:

- 1 In Signal Builder, select **Signal > Rename**.

A dialog box appears with an edit field that displays the current name of the signal.

- 2 Edit or replace the current name with a new name.
- 3 Click **OK**.

You can also edit the signal name in the **Name** field in the lower-left corner of the Signal Builder window.

### Replacing a Signal

To replace a signal:

- 1 In Signal Builder, select the signal, then select **Signal > Replace with** .

A menu of waveforms appears. It includes a set of standard waveforms (**Constant**, **Step**, and so on) and a **Custom** waveform option.

- 2 Select one of the waveforms.

If you select a standard waveform, Signal Builder replaces a signal in the currently selected group with that waveform. For other waveforms, the Signal Builder displays a dialog to allow you to provide input for the requested waveform.

Waveform	Description	Inputs
Constant	Constant waveform.	None
Step	Step waveform.	None
Pulse	Pulse waveform	None
Square	Square waveform	<ul style="list-style-type: none"> <li>• <b>Frequency (Hz)</b> Waveform frequency, in hertz</li> <li>• <b>Amplitude</b> Waveform amplitude</li> <li>• <b>Y Offset</b> Waveform vertical offset</li> <li>• <b>% Duty cycle</b> Percent of the period in which the signal is positive. Enter a value between 0 and 100.</li> </ul>
Sawtooth	Sawtooth waveform	<ul style="list-style-type: none"> <li>• <b>Frequency (Hz)</b> Waveform frequency, in hertz</li> <li>• <b>Amplitude</b> Waveform amplitude</li> <li>• <b>Y Offset</b> Waveform vertical offset</li> </ul>
Sampled Sin	Sampled sine waveform	<ul style="list-style-type: none"> <li>• <b>Frequency (Hz)</b> Waveform frequency, in hertz</li> <li>• <b>Amplitude</b> Waveform amplitude</li> <li>• <b>Y Offset</b> Waveform vertical offset</li> <li>• <b>Samples Per Period</b> Number of samples per waveform period</li> </ul>

Waveform	Description	Inputs
Sampled Gaussian Noise	Sampled Gaussian noise waveform based on a Gaussian distribution with input mean and standard deviation at input frequency.	<ul style="list-style-type: none"> <li>• <b>Frequency (Hz)</b> Waveform frequency, in hertz</li> <li>• <b>Mean</b> The mean value of the random variable output</li> <li>• <b>Standard Deviation</b> The standard deviation squared of the random variable output</li> <li>• <b>Seed (empty to use current state)</b> The initial seed value for the random number generator</li> </ul>
Pseudorandom Noise	Pseudorandom noise waveform based on a binomial distribution with upper and lower values at input frequency.	<ul style="list-style-type: none"> <li>• <b>Frequency (Hz)</b> Frequency with which waveform fluctuates between <b>Upper value</b> and <b>Lower value</b>, in hertz</li> <li>• <b>Upper value</b> Upper limit of signal</li> <li>• <b>Lower value</b> Lower limit of signal</li> <li>• <b>Seed</b> The initial seed value for the random number generator</li> </ul>
Poisson Random Noise	Poisson random noise waveform that alternates between 0 and 1	<ul style="list-style-type: none"> <li>• <b>Avg rate (1/sec)</b> Average rate of transition between 0 and 1</li> <li>• <b>Seed (empty to use current state)</b> The initial seed value for the random number generator</li> </ul>
Custom	Custom piecewise linear waveform. Custom values must fit within the display area.	<ul style="list-style-type: none"> <li>• <b>Time values</b> Vector of two or more time coordinates</li> <li>• <b>Y values</b> Vector of two or more signal amplitudes that correspond to the values in <b>Time values</b></li> </ul> <p>The entries in either field can be any MATLAB expression that evaluates to a vector. The resulting vectors must be of equal length.</p> <p><b>Note</b> Signal Builder returns a warning if you add a custom waveform with a large number of data points (100,000,000 or more). You can then cancel the action.</p>

You can also edit the signal name in the **Name** field in the lower-left corner of the Signal Builder window.

### Changing a Signal Index

To change a signal index:

- 1 In Signal Builder, select the signal, then select **Signal > Change Index**.

A dialog box appears with a drop-down list field containing the existing index of the signal.

- 2 From the drop-down list, select another index and select **OK**. Or select an index from the **Index** list in the lower-left corner of the Signal Builder window.

### Hiding Signals

By default, the Signal Builder window displays the group waveforms in the group pane. To hide a waveform:

- 1 In Signal Builder, select the waveform, then select **Signal > Hide**.
- 2 To redisplay a hidden waveform, select the **Group** pane, then select **Signal > Show**.
- 3 Select the signal from the list. Alternatively, you can hide and redisplay a hidden waveform by double-clicking its name in the Signal Builder signal list.

### Creating Signal Group Sets Manually

This topic describes how to create signal group sets manually. If you have signal data files, such as those from test cases, consider importing this data as described in “Importing Signal Group Sets” on page 80-70.

To create an interchangeable set of signal groups:

- 1 Drag an instance of the Signal Builder block from the Simulink Sources library and drop it into your model.

By default, the block represents a single signal group containing a single signal source that outputs a square wave pulse.

- 2 Use the block signal editor to create additional signal groups, add signals to the signal groups, modify existing signals and signal groups, and select the signal group that the block outputs.

---

**Note** Each signal group must contain the same number of signals.

---

- 3 Connect the output of the block to your diagram.

The block displays an output port for each signal that the block can output.

You can create as many Signal Builder blocks as you like in a model, each representing a distinct set of interchangeable groups of signal sources. When a group has multiple signals, the signals might have different end times. However, Signal Builder block requires the end times of signals within a group to match. If a mismatch occurs, Signal Builder block matches the end times by holding the last value of the signal with the smaller end time.

See “Simulating with Signal Groups” on page 80-90 for information on using signal groups in a model.

## Signal Data Files and Data Reformatting Function for Following Procedures

The procedures in the following sections use these three files: `3Grp_3Sig.xls`, `SigBldCustomFile.xls`, and `createSignalBuilderSupportedFormat.m`. To access these files, open the live script.

### Importing Signal Group Sets

The topics in this section describe how to import signal data into the Signal Builder block. You should already have a signal data file whose contents you want to import. For example, you might have signal data from previously run test cases. See “Importing Signal Groups from Existing Data Sets” on page 80-70 for a description of the data formats that the Signal Builder block accepts.

Signal Builder accepts signals only of type double.

If you import a `Simulink.SimulationData.Dataset` data set, the block imports it as its own group.

### Importing Signal Groups from Existing Data Sets

You might have existing signal data sets that you want to enter into the Signal Builder block. The **File > Import from File** command on the Signal Builder window starts the Import File dialog box. This dialog box is modal, which means that focus cannot change to another MATLAB window while the dialog box is running. If you want to see changes in the Signal Builder window after you import data, do one of the following:

- Close the Import File dialog box.
- Set up the Import File dialog box and Signal Builder window side by side.

---

**Note** You cannot undo the results of importing a signal data file. In addition, you cannot undo the last action performed before opening the Import File dialog box. When you close the Import File dialog box, the **Undo last edit** and **Redo last edit** buttons on the Signal Builder window are grayed out. These buttons are grayed out regardless of whether you imported a data file.

---

The Import File dialog box accepts the following appropriately formatted file types:

- Microsoft Excel (.xls, .xlsx)
- Comma-separated value (CSV) text files (.csv)
- MAT-files (.mat)

---

**Tip** To import signal data from a Microsoft Excel spreadsheet, consider using the From Spreadsheet block. The From Spreadsheet block incrementally loads data from the spreadsheet during simulation. If you use a From Spreadsheet block, you do not need to do anything to handle changes to sheet values.

---

You can import your data set file only if it is appropriately formatted.

For Microsoft Excel spreadsheets:

- The Signal Builder block interprets the first row as signal name. If you do not specify a signal name, the Signal Builder block assigns a default one with the format `Imported_Signal #`, where # increments with each additional unnamed signal.
- The Signal Builder block interprets the first column as time. In this column, the time values must increase.
- The Signal Builder block interprets the remaining columns as signals.
- If there are multiple sheets:
  - Each sheet must have the same number of signals (columns).
  - Each sheet must have the same set of signal names (if any).
  - Each column on each sheet must have the same number of rows.
- Signal Builder block interprets each worksheet as a signal group.

This example `3Grp_3Sig.xls` contains an acceptably formatted Microsoft Excel spreadsheet. It has three worksheets named Group1, Group2, and Group3, representing three signal groups.

Time must be first column

1	Time	DC In	Trigger	AC In	← Signal names (optional)
2	0	1	2	3	
3	1	2	3	4	
4	2	3	4	5	
5	3	4	5	6	
6	4	5	6	7	
7	5	6	7	8	
8	6	7	8	9	
9	7	8	9	10	
10	8	9	10	11	
11	9	10	11	12	
12	10	11	12	13	
13	11	12	13	14	
14	12	13	14	15	
15	13	14	15	16	
16	14	15	16	17	
17	15	16	17	18	
18					

Worksheets - equivalent to signal group

For CSV text files:

- Each file contains only numbers. Do not name signals in a CSV file.
- The Signal Builder block interprets the first column as time. In this column, the time values must increase.
- The Signal Builder block interprets the remaining columns as signals.
- Each column must have the same number of entries.
- The Signal Builder block interprets each file as one signal group.
- The Signal Builder block assigns a default signal name to each signal with the format Imported\_Signal #, where # increments with each additional signal.

This example contains an acceptably formatted CSV file. The contents represent one signal group.

```
0,0,0,5,0
1,0,1,5,0
2,0,1,5,0
3,0,1,5,0
4,5,1,5,0
5,5,1,5,0
6,5,1,5,0
7,0,1,5,0
8,0,1,5,1
9,0,1,5,1
10,0,1,5,0
```

For MAT-files:

- The Signal Builder block supports data store logging that the `Simulink.SimulationData.Dataset` object represents and interprets this data as a single group.
- The Signal Builder block supports Simulink output saved as a structure with time.
- The Signal Builder block supports the Signal Builder data format. This format is a group of cell arrays that must be labeled.
- Signal Builder block does not support:
  - Simulink output as only a structure
  - Simulink output as only an array

---

**Note** Signal Builder returns a warning if you import a large number of data points (100,000,000 or more). You can then cancel the action.

---

This example contains an acceptably logged MATLAB workspace. Use the MATLAB workspace **Save** command to save the variables to a MAT-file. Import this file to the Signal Builder block.

### Replacing All Signal Data with Selected Data

Simulink software creates a default Signal Builder block with one signal. To replace this signal and all other signal data that the block might display:

- 1 Create a model and drag a Signal Builder block into that model.
- 2 Double-click the block.

The Signal Builder window appears with its default Signal 1.

- 3 In Signal Builder, select **File > Import from File**.

The Import File dialog box appears.

- 4 In the **File to Import** field, enter a signal data file name or click **Browse**.

The file browser appears.

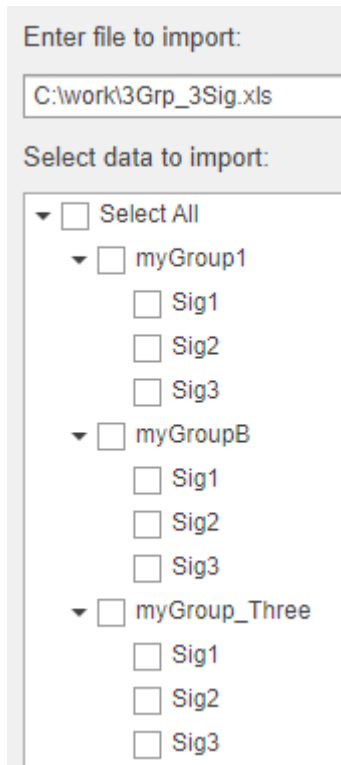

- 5 If you select the file browser, navigate to and select a signal data file. Select `3Grp_3Sig.xls`.

---

**Note** If you try to import an improperly formatted data file, an error message pops up.

---

The **Select data to import** pane contains the signal data from the file. Click the expanders to display all the signals.

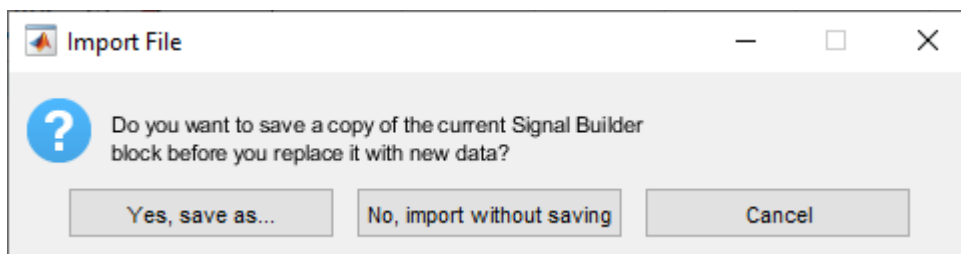

- 6 Select the signals you want to import. To import all the signals, click **Select All**.
- 7 From the **Select placement of data** list, select the action to take on the signal data. Select **Replace existing dataset**.

The **Confirm Selection** button is activated. Validate your signal selection before the Signal Builder block performs the specified action. If the dialog detects an error, it displays an error message.

- 8 Click the **Confirm Selection** button.
- 9 Click **Apply** to replace the existing signal data with the contents of this file.

When selecting **Replace existing dataset**, the software gives you the opportunity to save the existing contents of the Signal Builder block.

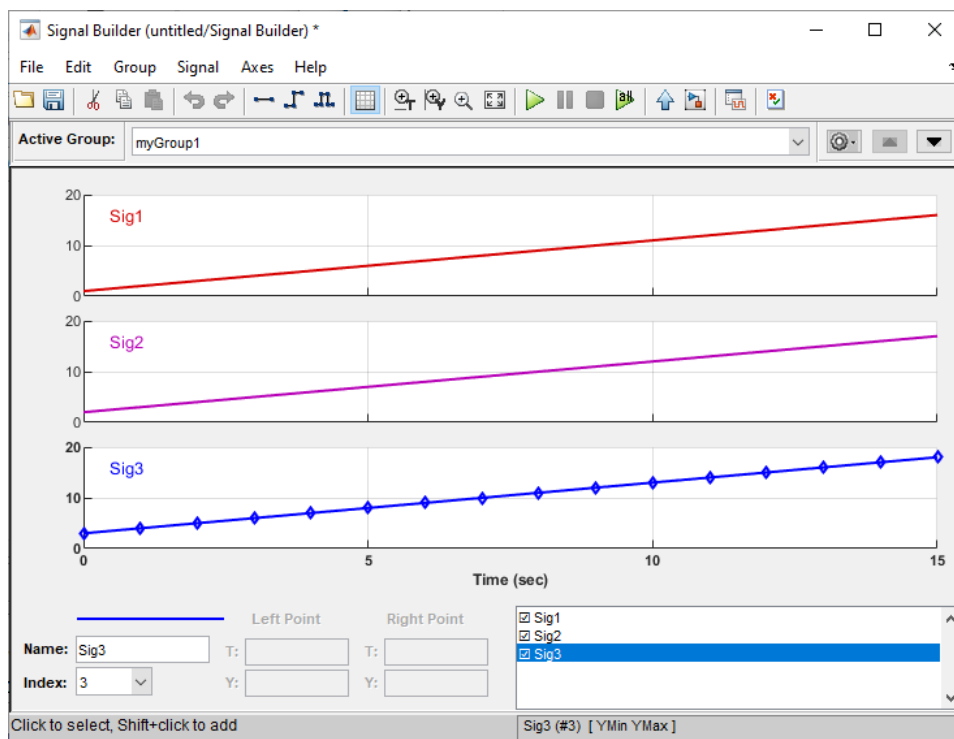

- 10 Click a button, as follows:

To...	Click...
Save the contents of the Signal Builder block before replacing it with the new signal data.	<b>Yes, save as</b>
<b>Note</b> This selection prompts you to save the Signal Builder block in a model name of your choice. The software saves only the Signal Builder block and no other model content.	
Replace the contents of the Signal Builder block without saving them first.	<b>No, import without saving</b>
Stop the replacement process.	<b>Cancel</b>

For this example, select **No, import without saving** to replace the contents of the Signal Builder block.

- The Signal Builder block updates with the new signal data. Click **OK** to close the Import File dialog box and inspect the Signal Builder block.

- Click **OK**.
- Inspect the updated Signal Builder window to confirm that your signal data is intact.
- Close the Signal Builder window and save and close the model. For example, save the model as signalbuilder1.

### Appending Selected Signals to All Existing Signal Groups

You can import signals from a signal data file and append selected signals to the end of all existing signal groups. If the signal names to be appended are not unique, the software renames them by

incrementing each name by 1 or higher until it is a unique signal name. For example, if the block and data file contain signals named `thermostat`, the software renames the imported signal to `thermostat1` upon appending. If you add another signal named `thermostat`, the software names that latest version `thermostat2`.

This topic uses `signalbuilder1` from the procedure in “Replacing All Signal Data with Selected Data” on page 80-73.

- 1 In the MATLAB Command Window, type `signalbuilder1`.
- 2 Double-click the Signal Builder block.

The Signal Builder window appears.

- 3 In the Signal Builder window, select **File > Import from File**.

The Import File dialog box appears.

- 4 In the **File to Import** field, enter a signal data file name or click **Browse**.

The file browser is displayed.

- 5 If you select the file browser, navigate to and select a signal data file. Select `3Grp_3Sig.xls`.

---

**Note** If you try to import an improperly formatted signal data file, an error message pops up.

---

The **Select data to import** pane contains the signal data from the file. Click the expander to display all the signals.

- 6 Select the signals you want to import. In this example, there are three groups, `myGroup1`, `myGroupB`, and `myGroup_Three`. Select all the signals in `myGroup1`.

- 7 From the **Select placement of data** list, select the action to take on the signal data. Select **Append selected signals to all groups**.

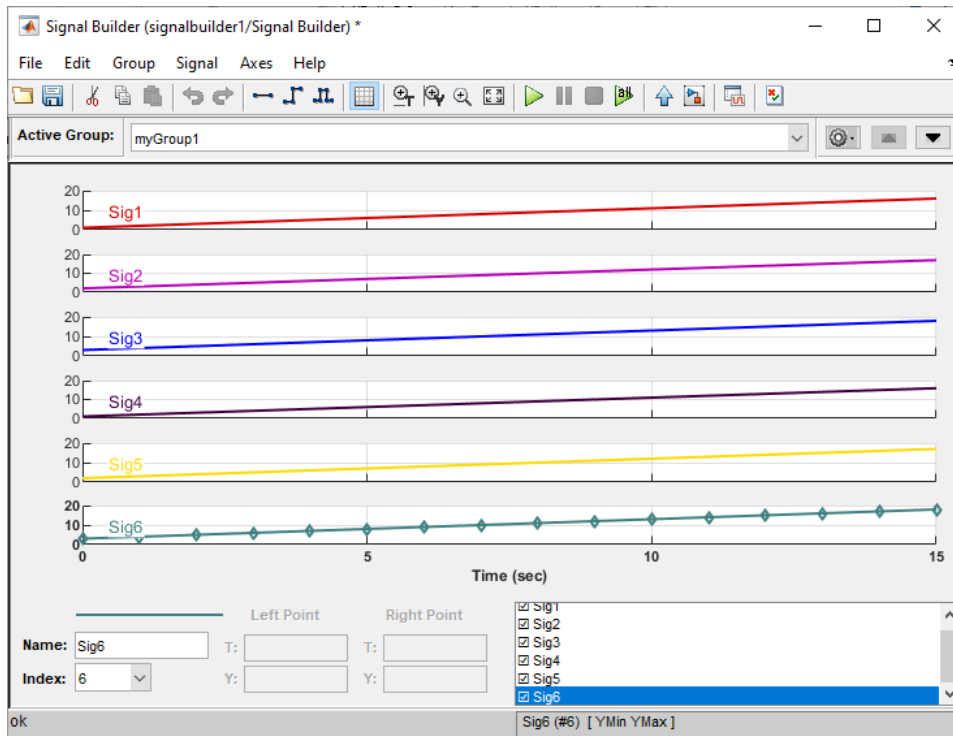

The **Confirm Selection** button is activated. Validate your signal selection before the Signal Builder block performs the specified action. If the signal data selection is not appropriate, **Confirm Selection** remains grayed out. For example, **Confirm Selection** remains grayed out if the number of signals you select is not the same as the number of signals in the Signal Builder group that you want to replace.

- 8 Click the **Confirm Selection** button.

The confirmation also enables the **OK** and **Apply** buttons.

- 9 Click **Apply** to append the selected signals to all the signal groups in the Signal Builder block.
- 10 The Signal Builder block updates with the new signal data. Click **OK** to close the Import File dialog box and inspect the Signal Builder block.

- 11 Click **OK**.
- 12 Inspect the updated Signal Builder window to confirm that your signal data is intact. Notice that the software has renamed the signals Sig1, Sig2, and Sig3 from the signal data file to Sig4, Sig5, and Sig6 in the Signal Builder block.
- 13 Close the Signal Builder window and save and close the model. For example, save the model as `signalbuilder2`.

### Appending Selected Signals to Sequential Existing Signal Groups

You can append signals, in the order in which they are selected, to the end of sequential signal groups. This statement means that you select the same number of signals as there are signal groups, and sequentially append each signal to a different group. The software renames each appended signal to the name of the last appended signal.

This topic uses `signalbuilder1` from the procedure in “Replacing All Signal Data with Selected Data” on page 80-73.

- 1 In the MATLAB Command Window, type `signalbuilder1`.
- 2 Double-click the Signal Builder block.
- 3 Note how many groups exist in the Signal Builder block. For example, this Signal Builder block has three groups, `myGroup1`, `myGroupB`, and `myGroup_Three`.

- 4 In the Signal Builder window, select **File > Import from File**.
- 5 In the **File to Import** field, enter a signal data file name or click **Browse**.
- 6 If you select the file browser, navigate to and select a signal data file. Select 3Grp\_3Sig.xls.

---

**Note** If you try to import an improperly formatted signal data file, an error message pop-up window appears.

---

The **Select data to import** pane contains the signal data from the file. Click the expander to display all the signals.

- 7 Select the signals you want to import. In this example, there are three groups, myGroup1, myGroupB, and myGroup\_Three. Select all the signals in myGroup1.

- 8 From the **Placement for Selected Data** list, select the action to take on the signal data. Select **Append selected signals to different groups (in order)**.

The **Confirm Selection** button is activated. Validate your signal selection before the Signal Builder block performs the specified action.

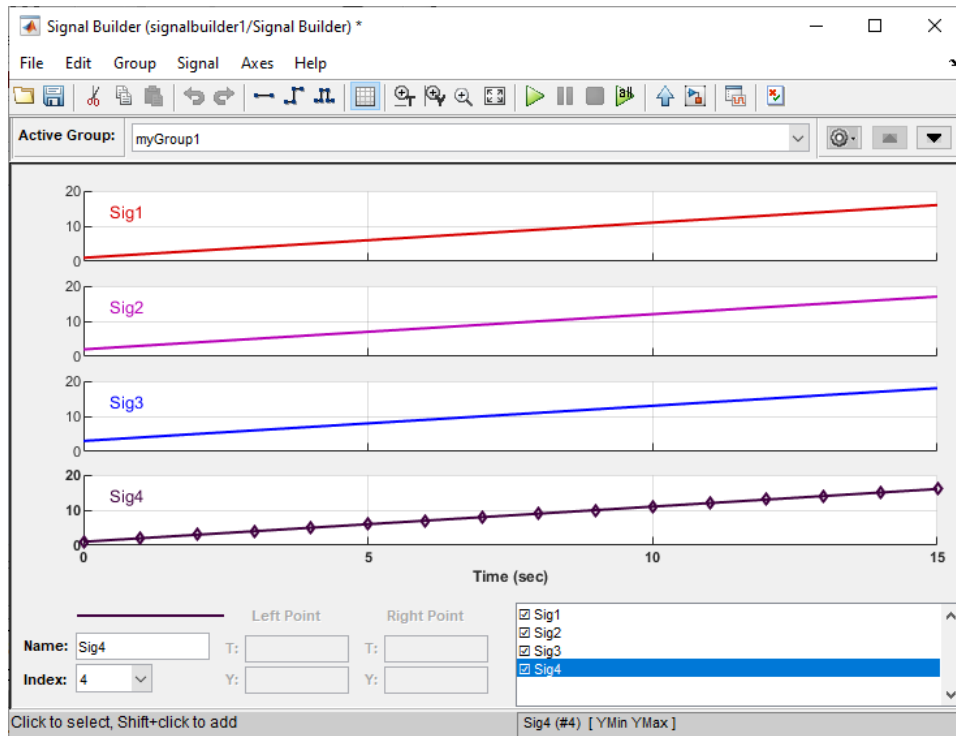

- 9 Click the **Confirm Selection** button.

The confirmation also enables the **OK** and **Apply** buttons.

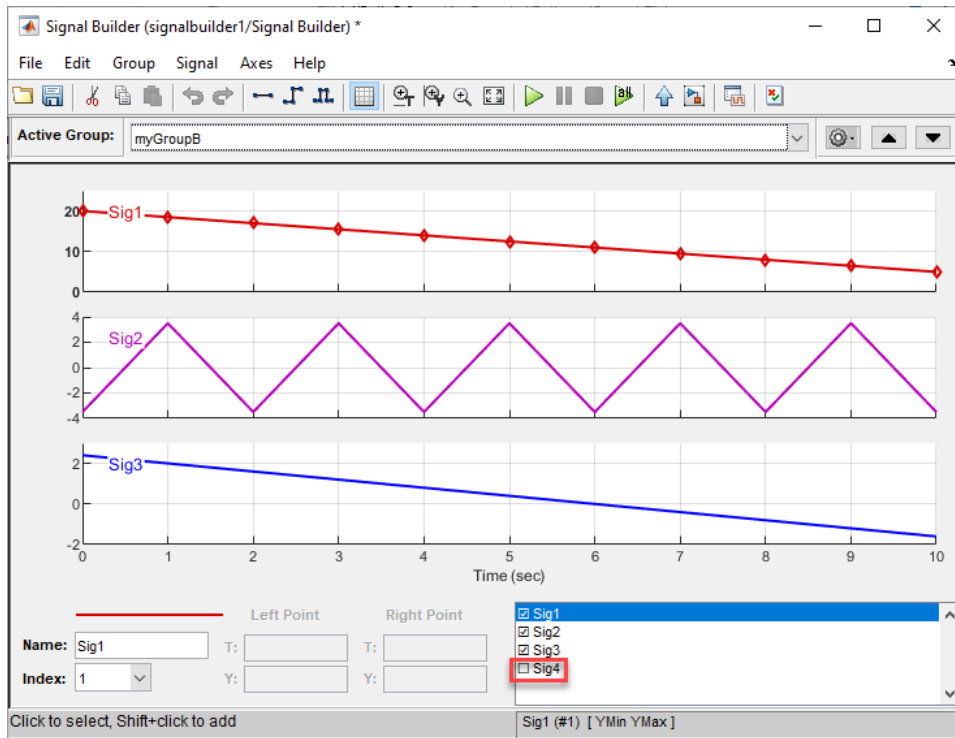

- 10** Click **Apply** to append the signals.

The Signal Builder block updates with the new signal data. Click **OK** to close the Import File dialog box and inspect the three groups of the Signal Builder block.

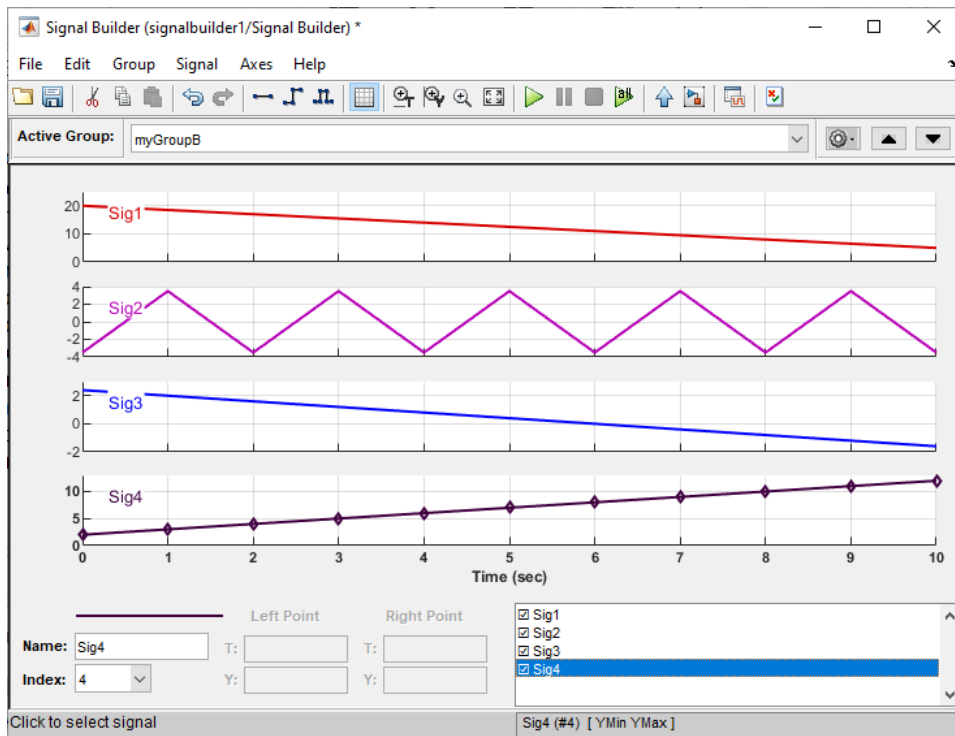

The topmost signal group, myGroup1, shows all signals by default, including the new Sig4.

- 11** Click another group name, for example, myGroupB. Notice that Sig4 exists for the group, hidden by default.

- 12** To show Sig4 on this pane, double-click Sig4 in the Selection Status area of the pane. The graph is updated to reflect Sig4.

- 13** Close the Signal Builder window and save and close the model. For example, save the model as signalbuilder3.

## Appending Signal Groups to Existing Groups

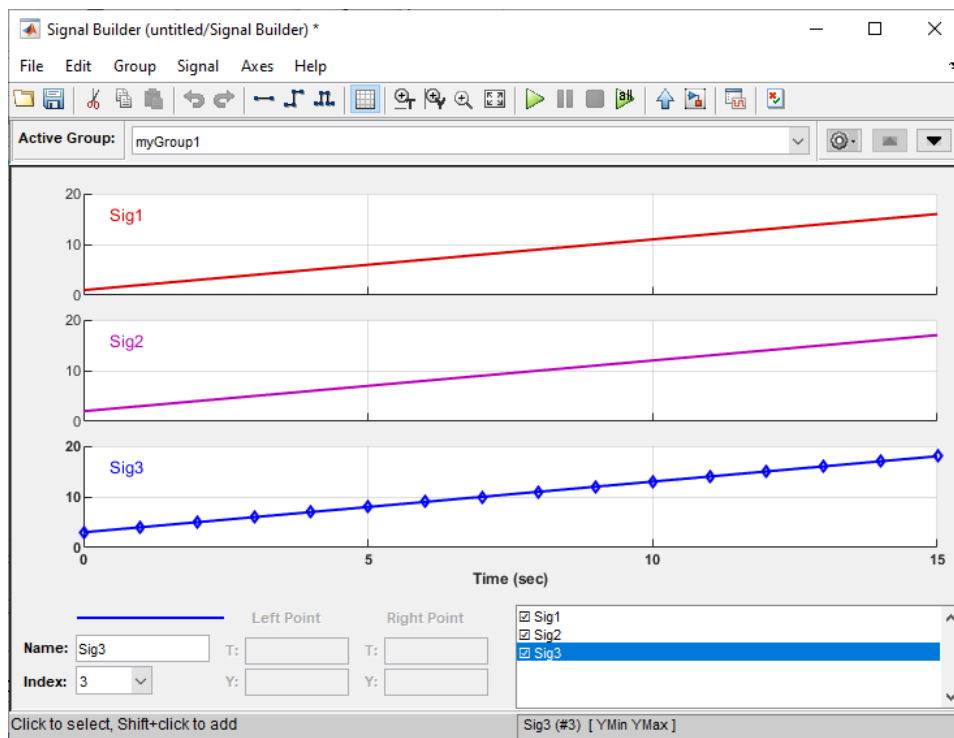

You can append one or more signal groups to the end of the list of existing signal groups. If the block already has a signal group with the same name as the one you are adding, the software increments the group name by 1 or higher until it is unique before adding it. For example, if the block and data file contain groups named MyGroup1, the software renames the imported group to MyGroup2 upon appending. If you add another group named MyGroup1, the software names that latest version MyGroup3.

This topic uses `signalbuilder1` from the procedure in “Replacing All Signal Data with Selected Data” on page 80-73.

- 1 In the MATLAB Command Window, type `signalbuilder1`.
- 2 Double-click the Signal Builder block.

The Signal Builder window appears.

- 3 Note how many groups exist in the Signal Builder block, and how many signals exist in each group. The Signal Builder block requires that all groups have the same number of signals. For example, this Signal Builder block has three groups, `myGroup1`, `myGroupB`, and `myGroup_Three`. Three signals exist in each group.

- 4 Double-click the block.
- 5 In the **File to Import** text field, enter a signal data file name or click **Browse**.
- 6 If you select the file browser, navigate to and select a signal data file. Select `3Grp_3Sig.xls`.

The **Data to Import** pane contains the signal data from the file. Click the expander to display all the signals.

- 7 Evaluate the number of signals in the groups of this data file. If the number of signals in each group equals the number of signals in the groups that exist in the block, you can append one of these groups to the block.
- 8 Select the group you want to import. In this example, there are three groups, myGroup1, myGroupB, and myGroup\_Three. Select myGroupB.

- 9 From the **Placement for Selected Data** list, select the action to take on the signal group. Select **Append groups**.

The **Confirm Selection** button is activated. Validate your signal selection before the Signal Builder block performs the specified action.

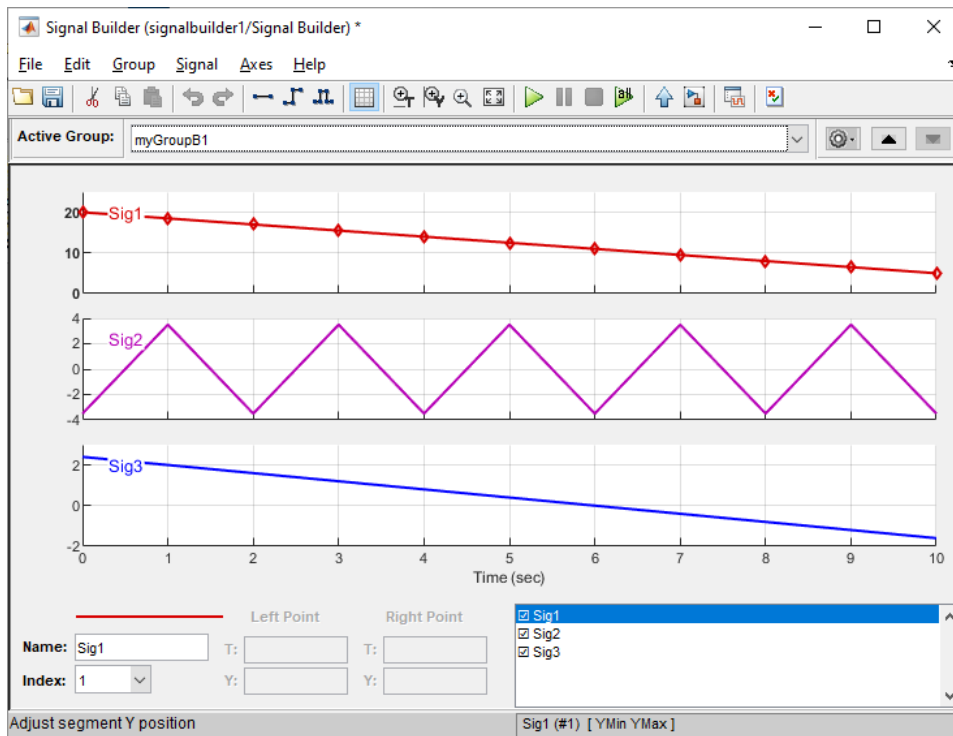

- 10 Click the **Confirm Selection** button.

The confirmation also enables the **OK** and **Apply** buttons.

- 11 Click **Apply** to append the signals.

The Signal Builder block updates with the new signal data. Click **OK** to close the Import File dialog box and inspect the groups of the Signal Builder block.

Notice the addition of the new signal group as the last pane. Because there is already a signal group named myGroupB, the software automatically increments the new signal group name by 1. Select myGroupB1.

- 12 Close the Signal Builder window and save and close the model. For example, save the model as `signalbuilder4`.

### Appending Signals with the Same Name to Existing Signal Groups

If you append a signal whose name is the same as a signal that exists in the Signal Builder block, the software increments the name of the appended signal by 1. The software repeats incrementing until the appended signal name is unique. For example:

- 1 Assume your Signal Builder block has a signal group, `myGroup1`, with the signals `Sig1`, `Sig2`, and `Sig3`.
- 2 Append a signal named `Sig1` to `myGroup1`.
- 3 Observe that the software increments `Sig1` to `Sig4` before appending it to `myGroup1`.

### Appending a Group of Signals with Different Signal Names

If you append a signal group whose signal names differ from those that exist in the Signal Builder block, the software changes the names of the existing signals to be the same as the appended signals. For example,

- 1 Assume your Signal Builder block has a signal group, `myGroup1`, with the signals `Sig1`, `Sig2`, and `Sig3`.
- 2 Append a signal group named `myGroup2` whose signal names are `SigA`, `SigB`, and `SigC`.
- 3 Observe that the software:
  - Appends `myGroup2`.
  - Renames the signals in `myGroup1` to be the same as those in `myGroup2`.

## Importing Data with Custom Formats

This topic describes how to import signal data formatted in a custom format. You should already have the signal data from a file whose contents you want to import. See “Importing Signal Groups from Existing Data Sets” on page 80-70 for a description of the data formats that the Signal Builder block accepts. If your data is not formatted using one of these data formats, use the following workflow to import the custom formatted data. This workflow uses the following files, located in the folder `matlabroot\help\toolbox\simulink\examples` (open), as examples:

- `SigBldCustomFile.xls` — Signal data Microsoft Excel file using a format that Signal Builder block does not accept, for example:

<b>Group1</b>	Time	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
	Signal1	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16
	Signal2	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16
	Signal3	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16
	Signal4	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16
<b>Group2</b>	Signal1	1.6	2.6	3.6	4.6	5.6	6.6	7.6	8.6	9.6	10.6	11.6	12.6	13.6	14.6	15.6	16.6
	Signal2	1.8	2.8	3.8	4.8	5.8	6.8	7.8	8.8	9.8	10.8	11.8	12.8	13.8	14.8	15.8	16.8
	Signal3	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17
	Signal4	2.2	3.2	4.2	5.2	6.2	7.2	8.2	9.2	10.2	11.2	12.2	13.2	14.2	15.2	16.2	17.2

- `createSignalBuilderSupportedFormat.m` — Custom MATLAB function that reads Microsoft Excel spreadsheets. This example function reformats the custom data, in a format that the Signal Builder block supports, as follows:
  - `grpNames` — Cell array that contains group name character vectors with number of rows = 1, number of columns = number of groups.

- *sigNames* — Cell array that contains signal name character vectors with number of rows = 1, columns = number of signals.
- *time* — Cell array that contains time data with number of rows = number of signals, columns = number of groups.
- *data* — Cell array that contains signal data with number of rows = number of signals, columns = number of groups.

Signal Builder has the following requirements for this custom function:

- Number of signals in each group must be the same.
- Signal names in each group must be the same.
- Number of data points in each signal must be the same.
- Each element in the *time* and *data* cell array holds a matrix of real numbers. This matrix can be [1xN] or [Nx1], where *N* is the number of data points in every signal.

- 1 Identify the format of your custom signal data, for example:

```
SigBldCustomFile.xls
```

- 2 Create a custom MATLAB function that:

- a Uses a MATLAB I/O function to read your custom formatted signal data. For example, `createSignalBuilderSupportedFormat.m`.
- b Formats the custom formatted signal data to one that the Signal Builder block accepts, for example, a MAT-file.

- 3 Use your custom MATLAB function to write your custom formatted signal data to a file that Signal Builder block accepts. For example:

```
createSignalBuilderSupportedFormat('SigBldCustomFile.xls', 'OutputData.mat')
```

- 4 Import the reformatted signal data file, `OutputData.mat`, into the Signal Builder block (see “Importing Signal Group Sets” on page 80-70).

## Editing Waveforms

Signal Builder allows you to change the shape, color, and line style and thickness of the waveforms output by a group.

### Reshaping a Waveform

Signal Builder allows you to change the waveform by selecting and dragging its line segments and points with the mouse or arrow keys or by editing the coordinates of segments or points.

### Selecting a Waveform

To select a waveform, left-click the mouse on any point on the waveform.

The Signal Builder displays the waveform points to indicate that the waveform is selected.

To deselect a waveform, left-click any point on the waveform axis that is not on the waveform itself or press the **Esc** key.

### Working with Points

You can work with points in a waveform:

- To select a point in a waveform, first select the waveform. Then, position the mouse cursor over the point. The cursor changes shape to indicate that it is over a point.

Left-click the point with the mouse. The Signal Builder draws a circle around the point to indicate your selection.

- To insert a point, select the waveform and **Shift+click** the section for the point.
- To deselect the point, press the **Esc** key.
- To delete a point, select the point and press the **Backspace** or **Delete** keys.
- To edit a point with the `signalbuilder` function, use the `signalbuilder set` function to replace the waveform. You cannot programmatically remove a point.

### Selecting Segments

To select a line segment, first select the waveform that contains it. Then, left-click the segment. The Signal Builder thickens the segment to indicate that it is selected.

To deselect the segment, press the **Esc** key.

### Moving Waveforms

To move a waveform, select it and use the arrow keys on your keyboard to move the waveform in the desired direction. Each key stroke moves the waveform to the next location on the snap grid (see “Snap Grid” on page 80-87) or by  $0.1$  inches if the snap grid is not enabled.

## Dragging Segments

To drag a line segment to a new location, position the mouse cursor over the line segment. The mouse cursor changes shape to show the direction in which you can drag the segment.

Press the left mouse button and drag the segment in the direction indicated to the desired location. You can also use the arrow keys on your keyboard to move the selected line segment.

## Dragging points

To drag a point along the signal amplitude (vertical) axis, move the mouse cursor over the point. The cursor changes shape to a circle to indicate that you can drag the point. Drag the point parallel to the y-axis to the desired location. To drag the point along the time (horizontal) axis, press the **Shift** key while dragging the point. You can also use the arrow keys on your keyboard to move the selected point.

## Snap Grid

Each waveform axis contains an invisible snap grid that facilitates precise positioning of waveform points. The origin of the snap grid coincides with the origin of the waveform axis. When you drop a point or segment that you have been dragging, the Signal Builder moves the point or the segment points to the nearest point or points on the grid, respectively. The Signal Builder **Axes** menu allows you to specify the grid horizontal (time) axis and vertical (amplitude) axis spacing independently. The finer the spacing, the more freedom you have in placing points but the harder it is to position points precisely. By default, the grid spacing is 0, which means that you can place points anywhere on the grid; i.e., the grid is effectively off. Use the **Axes** menu to select the spacing that you prefer.

## Inserting and Deleting points

To insert a point, first select the waveform. Then hold down the **Shift** key and left-click the waveform at the point where you want to insert the point. To delete a point, select the point and press the **Del** key.

## Editing Point Coordinates

To change the coordinates of a point, first select the point. The Signal Builder displays the current coordinates of the point in the **Left Point** edit fields at the bottom of the Signal Builder window. To change the amplitude of the selected point, edit or replace the value in the **Y** field with the new value and press **Enter**. The Signal Builder moves the point to its new location. Similarly edit the value in the **T** field to change the time of the selected point.

### Editing Segment Coordinates

To change the coordinates of a segment, first select the segment. The Signal Builder displays the current coordinates of the endpoints of the segment in the **Left Point** and **Right Point** edit fields at the bottom of the Signal Builder window. To change a coordinate, edit the value in its corresponding edit field and press **Enter**.

### Changing the Color of a Waveform

To change the color of a waveform, select the waveform and then select **Color** from the Signal Builder **Signal** menu. The Signal Builder displays the MATLAB color chooser. Choose a new color for the waveform. Click **OK**.

### Changing a Waveform Line Style and Thickness

The Signal Builder can display a waveform as a solid, dashed, or dotted line. It uses a solid line by default. To change the line style of a waveform, select the waveform, then select **Line Style** from the Signal Builder **Signal** menu. Select a line style from the menu.

To change the line thickness of a waveform, select the waveform, then select **Line Width** from the **Signal** menu. Edit the thickness value and click **OK**.

## Signal Builder Time Range

The Signal Builder time range determines the span of time over which its output is explicitly defined. By default, the time range runs from 0 to 10 seconds. You can change both the beginning and ending times of a block time range (see “Changing a Signal Builder Time Range” on page 80-88).

If the simulation starts before the start time of a block time range, the block extrapolates its initial output from its first two defined outputs. If the simulation runs beyond the block time range, the block by default outputs values extrapolated from the last defined signal values for the remainder of the simulation. The Signal Builder **Simulation Options** dialog box allows you to specify other final output options (see “Signal values after final time” on page 80-91 for more information).

---

**Note** When you click the **Start simulation** button on the Signal Builder block toolbar, the simulation uses the stop time of the model. The end of the time range specified in the waveform is not the stop time for the model.

---

### Changing a Signal Builder Time Range

To change the time range, select **Change Time Range** from the Signal Builder **Axes** menu.

In the dialog box, edit the **Min time** and **Max time** fields as necessary to reflect the beginning and ending times of the new time range, respectively.

## Exporting Signal Group Data

You can export data that defines Signal Builder block signals groups to a MAT-file, the MATLAB Workspace, or the Signal Editor block.

To export Signal Builder signal data, formatted as `Simulink.SimulationData.Dataset`, to a MAT-file, select **File > Export Data > To MAT-file**.

- **File name** — Enter a name for the MAT-file to contain the data.
- **Group indices** — Enter one or signal group numbers for which you want to export the data, specified as a scalar or vector. Numbers must correspond to an existing group in the block.

Alternatively, you can use the `signalbuilder get` function to return one or more data sets. For example:

```
[ds1 ds2]=signalbuilder(block,'get',[group1 group2])
```

To export signal data to the MATLAB workspace, select **File > Export Data > To Workspace**.

The Signal Builder exports the data by default to a workspace variable named `channels`. To export to a differently named variable, enter the variable name in the **Variable name** field. The Signal Builder exports the data to the workspace as the value of the specified variable.

The exported data is an array of structures. The structure `xData` and `yData` fields contain the coordinate points defining signals in the currently selected signal group.

To access all the data in the signal groups of a Signal Builder block, use the `signalbuilder get` function:

```
[time, data]=signalbuilder(block,'get',signal,group)
```

For example:

```
% For time 0 to 5, create three signal groups.
block = signalbuilder([], 'create', [0 5], {[2 2] [4 4] [7 8]};[0 2] [0 4] [7 10]);
% Get the signals for all three groups.
[time, data]=signalbuilder(block,'get',[1 2],[1:3])
```

```
time =
```

```
2×3 cell array
```

```
 [1×2 double] [1×2 double] [1×2 double]
 [1×2 double] [1×2 double] [1×2 double]
```

```
data =
```

```
2×3 cell array
```

```
 [1×2 double] [1×2 double] [1×2 double]
 [1×2 double] [1×2 double] [1×2 double]
```

To access signal data from the Signal Builder block and export it to the Signal Editor block, select **File > Export Data > To Signal Editor block**.

- 1 From the Signal Builder block, select **File > Export > To Signal Editor block**.

---

**Tip** Alternatively, click .

---

- 2 In the file browser, specify a file name to contain the saved signal data.

A Signal Editor block appears in the model.

- 3 To export the signal data to the Signal Editor block, double-click the block and verify the exported file name in the **File name** parameter.
- 4 To view the imported signal data in the Signal Editor user interface, click **Launch Signal Editor** ()

## Simulating with Signal Groups

You can use standard simulation commands to run models containing Signal Builder blocks or you can use the **Run** or **Run all** button in the Signal Builder window (see “Running All Signal Groups” on page 80-90).

If you want to capture inputs and outputs that the **Run all** button generates, consider using the SystemTest™ software.

### Activating a Signal Group

During a simulation, a Signal Builder block always outputs the active signal group. The active signal group is the group selected in the Signal Builder window for that block, if the dialog box is open. Otherwise, the active group is the group that was selected when the dialog box was last closed. To activate a group, open the group Signal Builder window and select the group.

### Running Different Signal Groups in Succession

The Signal Builder toolbar includes the standard Simulink buttons for running a simulation. This facilitates running several different signal groups in succession. For example, you can open the dialog box, select a group, run a simulation, select another group, run a simulation, and so on, all from the Signal Builder window.

### Running All Signal Groups

To run all the signal groups defined by a Signal Builder block, open the block dialog box and click the

 button from the Signal Builder toolbar. The **Run all** button runs a series of simulations, one for each signal group defined by the block. If you installed Simulink Coverage on your system and are using the Model Coverage Tool, the **Run all** button configures the tool to collect and save coverage data for each simulation in the MATLAB workspace and display a report of the combined coverage results at the end of the last simulation. This allows you to quickly determine how well a set of signal groups tests your model.

---

**Note** To stop a series of simulations started by the **Run all** command, enter **Ctrl+C** at the MATLAB command line.

---

## Simulation from Signal Builder Block

To control simulations from the Signal Builder block, select **File > Simulation Options**.

### Signal values after final time

The setting of this control determines the output of the Signal Builder block if a simulation runs longer than the period defined by the block.

- To output the last defined value of each signal in the currently active group for the remainder of the simulation, select **Hold final value**. For example:

- To output values extrapolated from the last defined value of each signal in the currently active group for the remainder of the simulation, select **Extrapolate**. For example:

- To output zero for the remainder of the simulation, select **Set to zero**. For example:

### Sample time

To output a continuous signal, enter 0 in the **Sample time** parameter. For example, the following display shows the output of a Signal Builder block set to output a continuous Gaussian waveform over a period of 10 seconds.

To output a discrete signal, enter the sample time of the signal in this parameter. The following example shows the output of a Signal Builder block set to emit a discrete Gaussian waveform having a 0.5 second sample time.

### **Enable zero crossing**

To have the Signal Builder block detect zero-crossing events, set **Enable zero crossing** On (default). The Signal Builder block sets the zero-crossing detection on the From Workspace block that you use to create the Signal Builder signal groups. For more information, see “Zero-Crossing Detection” on page 3-10.

# Using Composite Interfaces

---

## Composite Interface Guidelines

To simplify model appearance, you can group signals, messages, or conserving connections to create composite interfaces for model components and blocks. Composite interfaces reduce the number of ports on a model component and the number of lines in a block diagram. Elements of a composite interface retain their separate identities.

Virtual buses meet most modeling requirements for composite interfaces, and they give you the flexibility to group different types of elements. They reduce line complexity and clutter in a block diagram and make it easier to change the interface incrementally. For example, if you must add or remove elements from a component interface, modifying a bus can be simpler than adding or removing ports.

When you create a composite interface, such as a virtual bus, group lines based on their functionality. By organizing signals, messages, or connections into logical groupings, you reduce the likelihood of significant refactoring in the future.

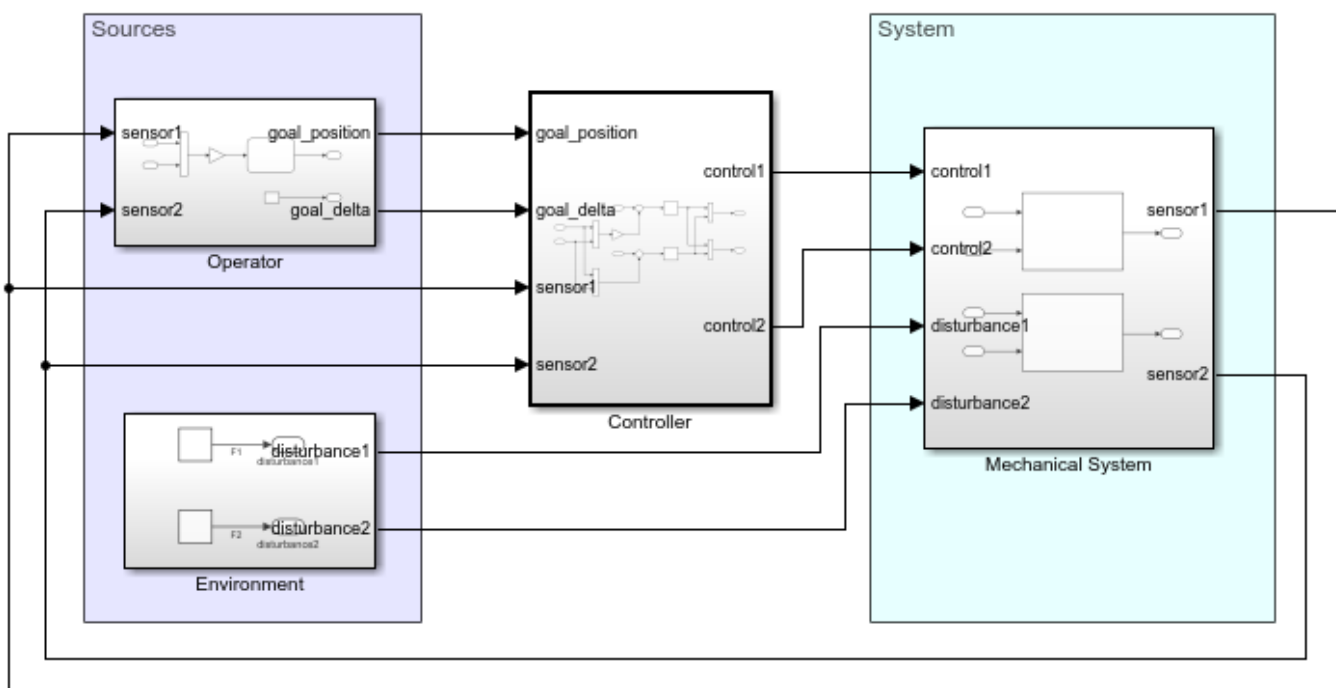

At component interfaces, use In Bus Element and Out Bus Element blocks. In Bus Element blocks let you extract bus elements by name at their point of use. Out Bus Element blocks let you build an output bus by connecting elements to multiple Out Bus Element blocks for the same output port.

To enforce the composition of a bus at an interface, use a `Simulink.Bus` object.

To implement the bus definition as a structure in generated code or to iteratively process buses in a subsystem such as a for-each subsystem, consider making the virtual buses into nonvirtual buses.

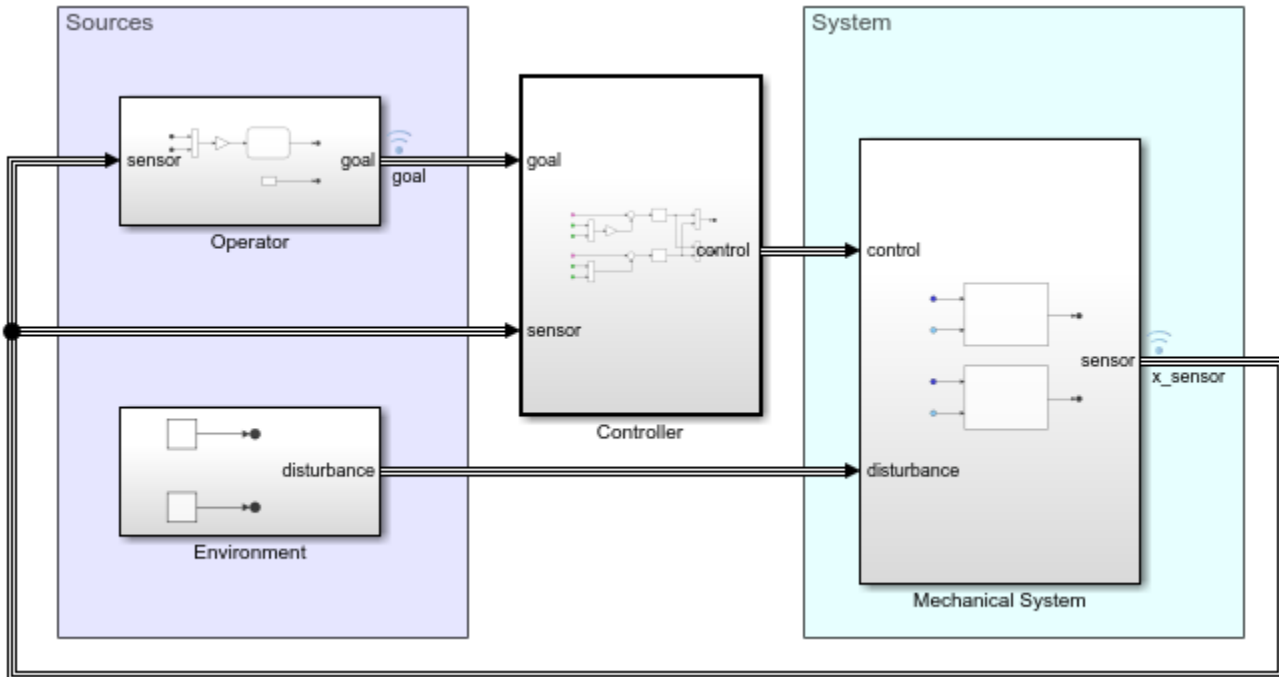

### Visualize Composite Interfaces

Suppose you have this relatively simple model.

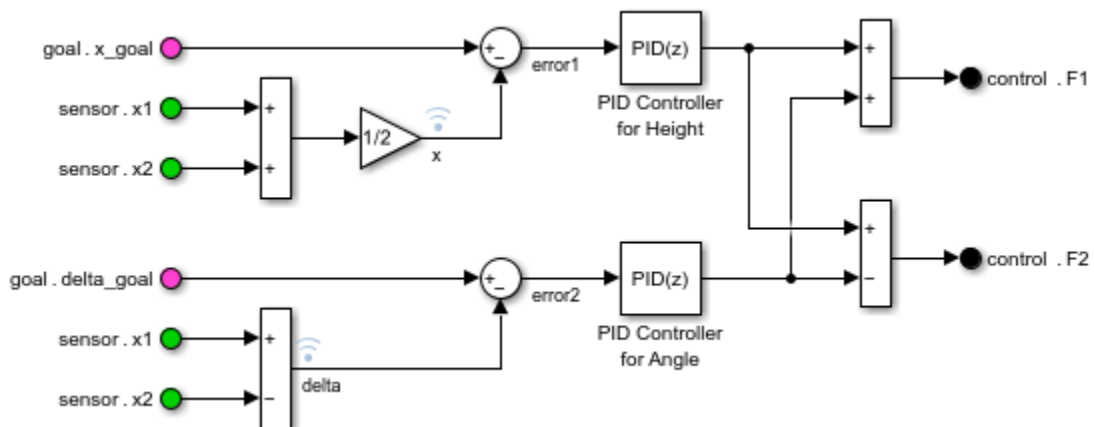

Each component interface in this model has multiple ports, and the signal lines clutter the model.

With composite interfaces, you can simplify the block diagram by reducing the number of lines.

Virtual buses simplify the signal lines in the block diagram based on four different types of functionality: sensor data, system goals, control signals, and system disturbances.

The components use In Bus Element and Out Bus Element blocks at their interface. For example, consider the contents of the subsystem named Controller.

Each In Bus Element and Out Bus Element block has a label that displays the corresponding element, for example, `sensor . x1`. In this example, `sensor` is the name of the port, and `x1` is the name of the bus element. Two In Bus Element blocks select this element to avoid a branched signal line.

## Define Composite Interfaces

Before you create composite interfaces, consider your high-level and low-level modeling requirements.

1. "Choose Among Composite Interfaces" on page 81-5	Decide how to group signals, messages, or conserving connections based on your high-level modeling requirements.
2. "Compare Capabilities of Composite Interfaces" on page 81-9	Compare virtual buses, nonvirtual buses, and arrays of buses against low-level modeling requirements.

---

**Tip** To identify the boundaries, scope of data, and interface attributes of your model component, see "Define Interfaces of Model Components" on page 23-19.

---

## Choose Among Composite Interfaces

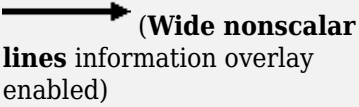

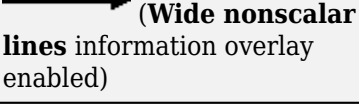

To reduce visual complexity in a model, you can group multiple signals, messages, or conserving connections into a composite interface for a block or model component. The grouped elements retain their separate identities, and you can extract them.

As you create composite interfaces, consider these potential requirements:

- Name-based element access — Meaningful element names and hierarchy can simplify element selection and mapping.
- Reusability — Bus objects provide a reusable interface definition that you can apply as long as the definition is available to the model.
- Code generation — The type of composite interface can make a significant difference in the efficiency, size, and readability of the generated code. For a bus to appear in the generated code, it must be nonvirtual. Only the elements of a virtual bus appear in the generated code.

### Composite Interfaces

The different types of composite interfaces serve a variety of modeling requirements.

Type of Composite Interface	Definition	Appearance in Model
Virtual bus	A virtual bus is a flexible group of named elements.  A virtual bus is analogous to a bundle of wires held together by tie wraps.	
Nonvirtual bus	A nonvirtual bus is a defined group of named elements.  A nonvirtual bus is analogous to a struct in C code.	
Array of buses	An array of buses is an array of nonvirtual buses that have the same interface definition.	
Mux signal	A mux signal is a virtual vector.	 
Concatenated signal	A concatenated signal is a nonvirtual vector, matrix, or array.	 

Models can use any combination of these interfaces.

You can identify composite interfaces by their line style after you compile the model. When you create a composite interface or open a model that contains composite interfaces, the composite interfaces have the same line style as scalar signals. To compile the model and show the composite interface line styles, in the Simulink Toolstrip, on the **Modeling** tab, select **Update Model**.

## High-Level Composite Interface Selection Guidelines

Each type of composite interface has an ideal use case:

- Virtual bus — Ideal for flexible interfaces and incremental changes
- Nonvirtual bus — Ideal for defined interfaces in code generation
- Array of buses — Ideal for iterative processing of multiple elements
- Mux signal — Ideal for grouping multiple callers to function-call subsystems
- Concatenated signal — Ideal for iterative processing of individual elements

The ideal use cases are a subset of the possible use cases for each type of composite interface. For example, you can use a virtual bus that specifies a `Simulink.Bus` object to define an interface.

---

**Tip** While mux signals support additional use cases, virtual buses and concatenated signals address those use cases more effectively.

---

This flow chart helps you choose a composite interface type to consider.

The flow chart identifies whether you have one of these specialized use cases for a composite interface:

- If the interface will provide multiple signals for a subsystem to iteratively process, consider an array of buses.
- If the interface will provide one signal for a subsystem to iteratively process, consider a concatenated signal.
- If the interface will provide multiple callers to a function-call subsystem, consider a mux signal.
- If you will require the generated code to use a data structure to represent the interface, consider a nonvirtual bus.

For all other use cases, consider a virtual bus.

## **Modeling Requirement Considerations**

Before implementing a composite interface based on the high-level guidelines, consider additional modeling requirements. For example, if you want to group messages, you must use a virtual bus.

When possible, use buses instead of mux signals and concatenated signals. To determine whether a virtual bus, nonvirtual bus, or array of buses meets your modeling requirements, see “Compare Capabilities of Composite Interfaces” on page 81-9.

## Compare Capabilities of Composite Interfaces

Before you implement a piece of your system using a specific type of composite interface, consider whether the type satisfies your requirements for composite interface elements, modeling, and code generation.

**Tip** To identify which composite interfaces to consider based on high-level guidelines and ideal use cases, see “Choose Among Composite Interfaces” on page 81-5.

For physical conserving connections, see Simscape Bus (Simscape).

Based on best practices for composite interfaces, these comparison tables focus on buses.

### Composite Interface Elements

Composite Interface Elements Requirement	Virtual Buses	Nonvirtual Buses	Arrays of Buses
<b>Hierarchical elements</b>	<b>Supported</b> Elements of virtual buses can have hierarchy.	<b>Supported</b> Elements of nonvirtual buses can have hierarchy.	<b>Supported</b> While the array of buses is flat, the nested buses can have hierarchy.
<b>Elements with different sample times</b>	<b>Supported</b> Elements of virtual buses can have different sample times.	<b>Not supported</b> All elements of a nonvirtual bus must use the same sample time.  Use a Rate Transition block to change the sample time of signals in a bus. For more information, see “Modify Sample Times for Nonvirtual Buses” on page 81-56.	<b>Not supported</b> All elements of an array of buses must use the same sample time.
<b>Elements with different data types</b>	<b>Supported</b> Elements of virtual buses can have different data types.	<b>Supported</b> Elements of nonvirtual buses can have different data types.	<b>Supported</b> Top-level elements of arrays of buses must specify the same <code>Simulink.Bus</code> object data type. Elements of the nested buses can have different data types.

<b>Composite Interface Elements Requirement</b>	<b>Virtual Buses</b>	<b>Nonvirtual Buses</b>	<b>Arrays of Buses</b>
<b>Variable-size signals</b>	<p><b>Supported</b></p> <p>Virtual buses can contain variable-size signals as long as they are not used as inputs to or outputs from a referenced model.</p>	<p><b>Supported</b></p> <p>Nonvirtual buses can contain variable-size signals.</p> <p>Signal logging is supported for nonvirtual buses with variable-size signals when running a simulation in normal or accelerator mode.</p>	<p><b>Supported</b></p> <p>Arrays of buses can contain variable-size signals only for simulations in normal mode.</p> <p>Signal logging is supported for arrays of buses with variable-size signals only when running a simulation in normal mode.</p>
<b>Function-call signals</b>	<p><b>Supported</b></p> <p>Virtual buses can contain function-call signals. The virtual bus must not be defined by a <code>Simulink.Bus</code> object.</p>	<p><b>Not supported</b></p> <p>Nonvirtual buses cannot contain function-call signals.</p>	<p><b>Not supported</b></p> <p>Arrays of buses cannot contain function-call signals.</p>
<b>Messages</b>	<p><b>Supported</b></p> <p>Virtual buses can have message elements as long as they do not also have signal elements.</p>	<p><b>Not supported</b></p> <p>Nonvirtual buses can contain only signal elements.</p> <p>Messages can have nonvirtual bus payloads.</p>	<p><b>Not supported</b></p> <p>The nested nonvirtual buses in arrays of buses cannot have message elements.</p>

## Composite Interface Modeling

<b>Composite Interface Modeling Requirement</b>	<b>Virtual Buses</b>	<b>Nonvirtual Buses</b>	<b>Arrays of Buses</b>
<b>Name-based element access</b>	<p><b>Supported</b></p> <p>Access elements of virtual buses by name.</p>	<p><b>Supported</b></p> <p>Access elements of nonvirtual buses by name.</p>	<p><b>Supported</b></p> <p>Access top-level elements of arrays of buses by index. Then, access elements of the nested buses by name.</p>

Composite Interface Modeling Requirement	Virtual Buses	Nonvirtual Buses	Arrays of Buses
<b>Element access at component input ports</b>	<b>Supported</b> To select elements of a virtual bus at an input port, use In Bus Element blocks.	<b>Supported</b> To select elements of a nonvirtual bus at an input port, use In Bus Element blocks.	<b>Not supported</b> In Bus Element blocks can pass arrays of buses through the interface, but they cannot select the index-based elements of arrays of buses.
<b>Composite interface definition at component input ports</b>	<b>Supported</b> To define an input virtual bus for a model component, specify the virtual bus and its elements with one or more In Bus Element blocks.	<b>Supported</b> To define an input nonvirtual bus for a model component, specify the nonvirtual bus with one or more In Bus Element blocks.  For the element that you want to be a nonvirtual bus: <ol style="list-style-type: none"> <li><b>1</b> Set <b>Data type</b> to a Simulink.Bus object.</li> <li><b>2</b> Set <b>Bus virtuality</b> to nonvirtual.</li> </ol>	<b>Supported</b> To define an input array of buses for a model component, specify the array of buses with an In Bus Element block.  For the element that you want to be an array of buses: <ol style="list-style-type: none"> <li><b>1</b> Set <b>Data type</b> to a Simulink.Bus object.</li> <li><b>2</b> Set <b>Bus virtuality</b> to nonvirtual.</li> <li><b>3</b> Set <b>Dimensions</b> to an integer greater than 1.</li> </ol>
<b>Composite interface creation at component output ports</b>	<b>Supported</b> To create a virtual bus at an output port, connect the desired elements of the virtual bus to Out Bus Element blocks that correspond to the same output port.	<b>Supported</b> To create a nonvirtual bus at an output port, connect the desired elements of the nonvirtual bus to Out Bus Element blocks that correspond to the same output port. Then, edit the signal attributes of the bus. <ol style="list-style-type: none"> <li><b>1</b> Set <b>Data type</b> to a Simulink.Bus object.</li> <li><b>2</b> Set <b>Bus virtuality</b> to nonvirtual.</li> </ol>	<b>Not supported</b> Out Bus Element blocks can pass arrays of buses through the interface, but they cannot create arrays of buses.

Composite Interface Modeling Requirement	Virtual Buses	Nonvirtual Buses	Arrays of Buses
<b>Incremental interface changes</b>	<p><b>Supported</b></p> <p>Virtual buses support incremental interface changes. Use In Bus Element and Out Bus Element blocks to modify the bus at the interface.</p>	<p><b>Not supported</b></p> <p>Nonvirtual buses are defined by <code>Simulink.Bus</code> objects. ## Group Signals or Messages into Virtual Buses

You can combine signals or messages into a bus and then access the bus as a whole or select specific elements from the bus. A virtual Simulink bus is analogous to a bundle of wires held together by tie wraps. For comparison, a nonvirtual Simulink bus is analogous to a struct in C code.

Not all blocks can accept buses and some blocks implicitly convert buses to vectors. To learn which blocks support which types of buses, see “Bus-Capable Blocks” on page 81-45. To identify bus conversions, see “Manage Bus-to-Vector Conversions”.

How you create virtual buses differs based on the location of the signals or messages that you want to group.

- Within a component — Use Bus Creator blocks, which you can implement with automated actions. See “Group Signal Lines Within a Component” on page 81-14.
- At the output interface of a component — Use Out Bus Element blocks. See “Connect Multiple Output Signals to a Port” on page 81-17.
- At subsystem interfaces — Use automated actions to implement In Bus Element and Out Bus Element blocks. See “Combine Multiple Subsystem Ports into One Port” on page 81-19.

To extract elements from a bus, use a Bus Selector block within a component or an In Bus Element block at a component interface.

To focus on fundamental steps, the following examples are simple, however, buses are most useful when you have many signals or messages to combine.

---

**Tip** When you open a model or create a bus, the Simulink Editor does not display bus line styles. To update the line styles, you must compile the model. On the **Modeling** tab of the Simulink Toolstrip, click **Update Model** or **Run**.

---

### Group Signal Lines Within a Component

You can group signals into a virtual bus within a component by using Bus Creator blocks.

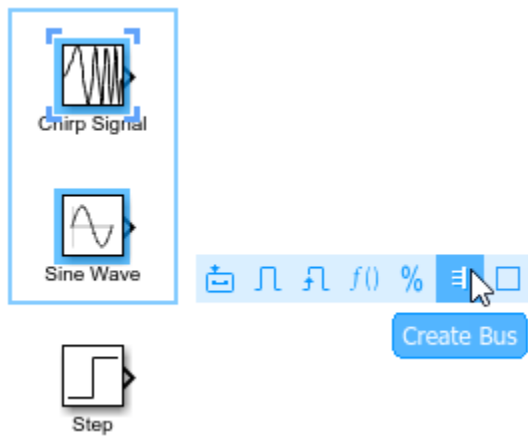

Open the example model, which contains three blocks.

Copyright 2019 The MathWorks, Inc.

To create a bus that contains the outputs from multiple blocks, drag to select the blocks. For this example, select the Chirp Signal and Sine Wave blocks. In the action bar that appears, click **Create Bus**.

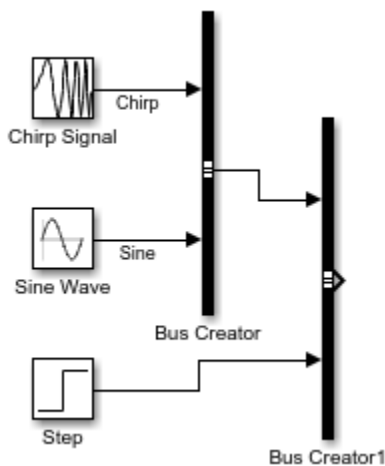

Simulink adds a Bus Creator block and connects the inputs to that block. The output of the Bus Creator block is a virtual bus.

To make identifying the elements of the bus easier, label the inputs to the Bus Creator block. Label the output of the Chirp Signal block by double-clicking the line and entering `Chirp`. Similarly, label the output of the Sine Wave block `Sine`.

To create a second bus that contains the first bus and the output of the Step block, drag to select the Bus Creator and Step blocks. In the action bar that appears, click **Create Bus**. Since the `Sine` and `Chirp` signals are elements of the input bus, Simulink creates the same bus regardless of whether your selection includes the Sine Wave and Chirp Signal blocks.

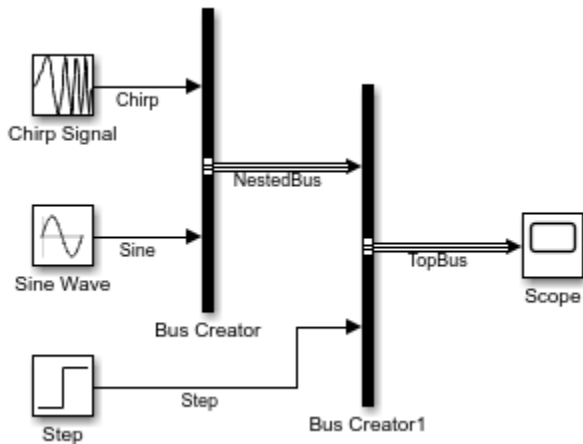

Simulink adds another Bus Creator block and connects the inputs to that block. The output of the Bus Creator block is a virtual bus that contains a nested bus.

You can nest buses to any depth. If one of the inputs to a Bus Creator block is a bus, then its output is a bus hierarchy that contains at least one nested bus.

Label the output of the Step block `Step` and the output of the first Bus Creator block `NestedBus`. Optionally, arrange the blocks to improve the readability of the model.

Connect the output of the second Bus Creator block to a Scope block and label the output `TopBus`. To visually identify the buses, compile the model by clicking **Update Model** or **Run** on the **Modeling** tab of the Simulink Toolstrip. Compiling the model updates the line styles.

## Connect Multiple Output Signals to a Port

This example shows how to group the output signals of a subsystem or model into a virtual bus using Out Bus Element blocks.

Open the example model, which contains three source blocks.

Copyright 2019-2020 The MathWorks, Inc.

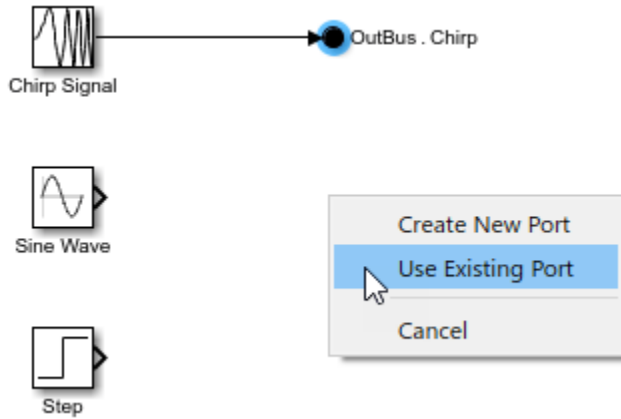

Add an Out Bus Element block to the model. An Out Bus Element block is similar to a Bus Creator block connected to an Output port block. Connect the output of the Chirp Signal block to the Out Bus Element block.

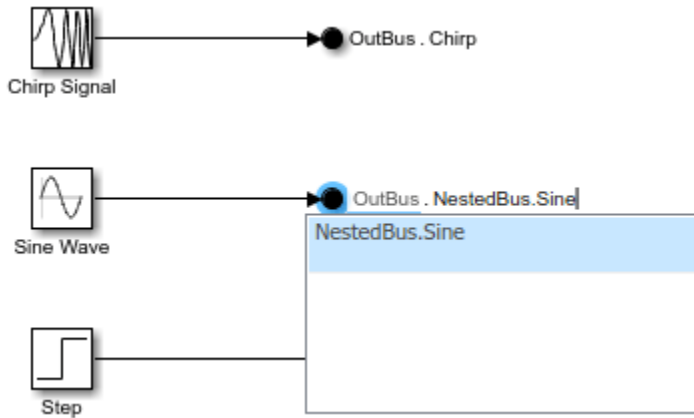

The label next to the Out Bus Element block has two parts. The first part of the label describes the bus (`OutBus`), and the second part of the label describes the bus element (`signal1`). To make identifying elements of the bus easier, rename the element by double-clicking `signal1` and entering `Chirp`.

**Ctrl**+drag the Out Bus Element block twice to make two copies of the block. When copying the block this way, specify whether to create a new port or use the existing port. To create one output bus that contains all of the signals, choose **Use Existing Port** each time you copy the block, then connect the signals.

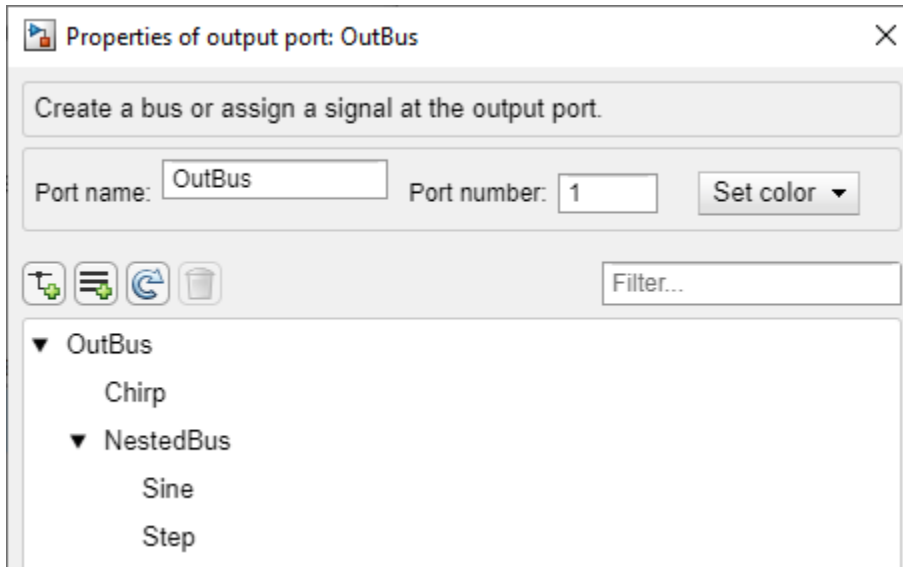

To create hierarchy in the output bus, use dots in the part of the label that describes the bus element. Each dot creates a new level of hierarchy. Create a nested bus named `NestedBus` by defining the bus elements as `NestedBus . Sine` and `NestedBus . Step`, respectively.

Alternatively, you can connect a bus to an Out Bus Element block. If other Out Bus Element blocks correspond to the same port, the bus is nested in the output bus. The part of the label that describes the bus element provides the name of this nested bus.

Inspect the bus hierarchy in the dialog box for the port by double-clicking any of the Out Bus Element blocks.

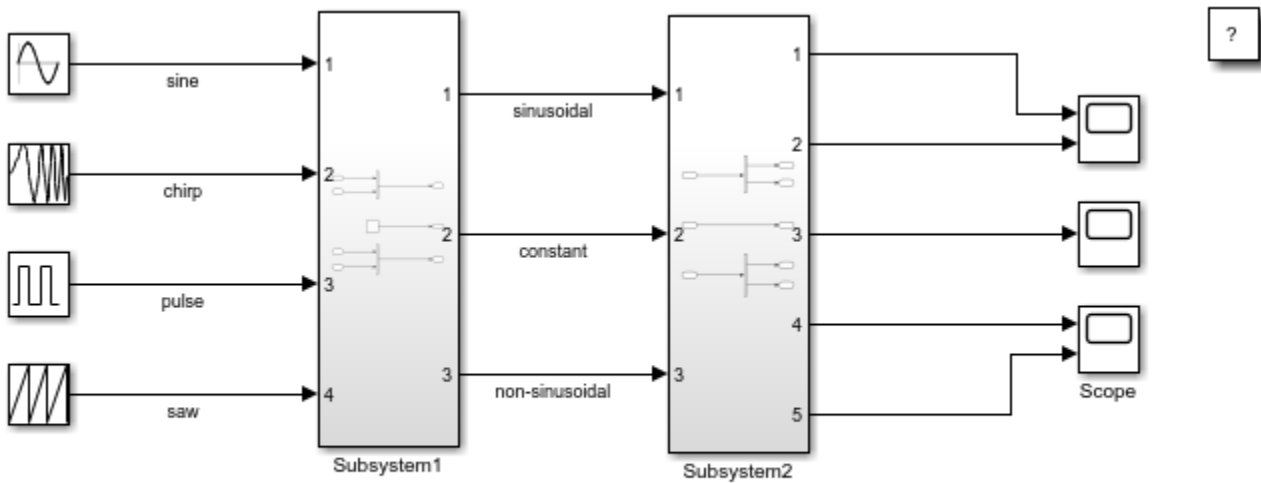

The three Out Bus Element blocks create a virtual bus at the output port of the model. To see the virtual bus, reference the model in another model or move the Out Bus Element blocks into a subsystem. The line styles update when you compile the model. To compile the model, on the **Modeling** tab of the Simulink Toolstrip, click **Update Model** or **Run**.

## Combine Multiple Subsystem Ports into One Port

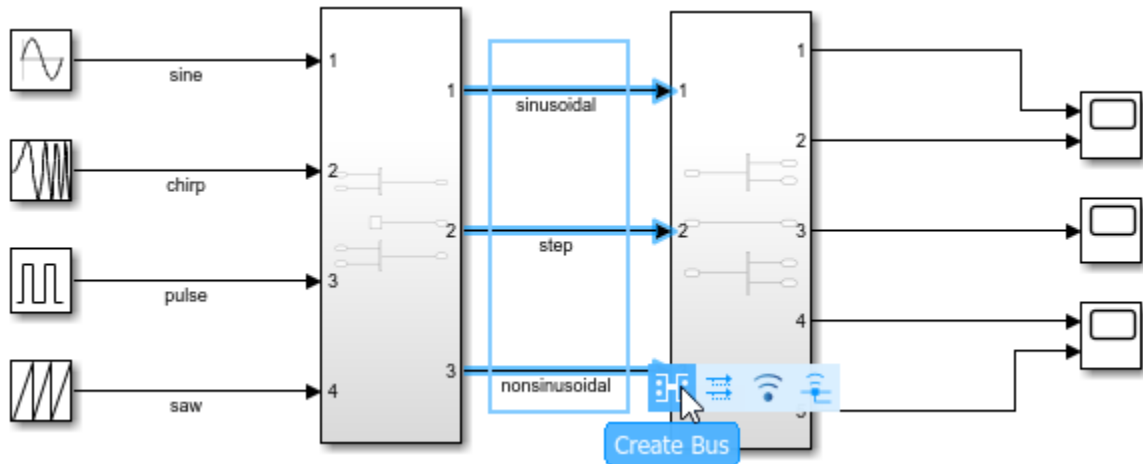

This example shows three ways to simplify a subsystem interface by converting multiple ports and their connected signals into one port and a bus. Model interfaces do not support this automated conversion.

Open the example model, which contains two subsystems with multiple input and output ports.

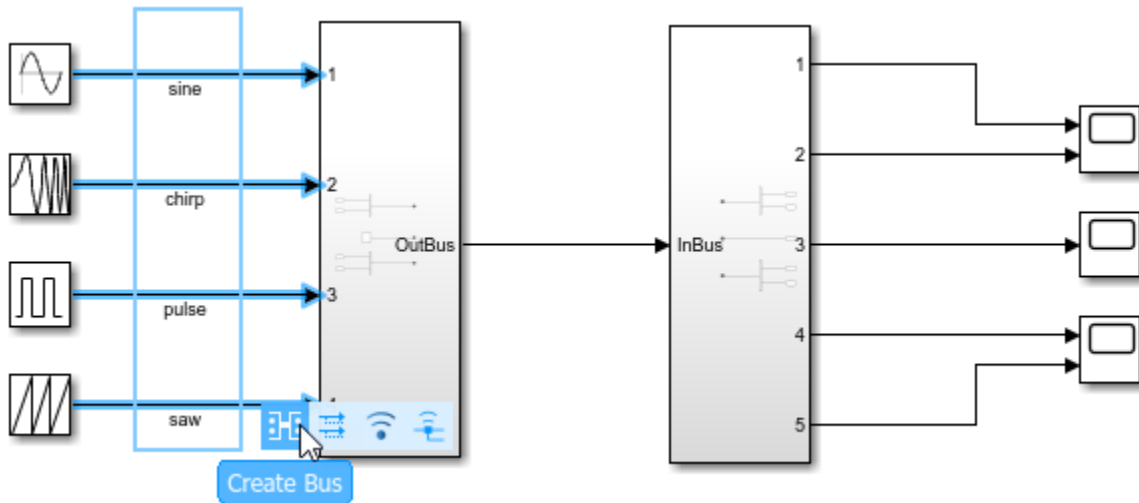

Copyright 2019 The MathWorks, Inc.

Drag a selection box around the signal lines between the two subsystems. From the action bar that appears, click **Create Bus**.

Simulink replaces the Inport and Outport blocks in the source and destination subsystems with In Bus Element and Out Bus Element blocks.

Drag a selection box around the signal lines between the source blocks and first subsystem. From the action bar that appears, click **Create Bus**.

Simulink adds a Bus Creator block before the first subsystem and replaces the Inport blocks in the first subsystem with In Bus Element blocks.

Drag a selection box around the signal lines between the second subsystem and Scope blocks. From the action bar that appears, click **Create Bus**.

Simulink replaces the Outport blocks in the second subsystem with Out Bus Element blocks and adds a Bus Selector block after the second subsystem.

The resulting model uses virtual buses at the subsystem interfaces.

## Simplify Subsystem and Model Interfaces with Bus Element Ports

Buses simplify subsystem and model interfaces by letting you associate multiple signals or messages with one port. They reduce line complexity and clutter in a block diagram, make it easier to change the interface incrementally, and allow access to elements closer to their point of usage.

For an overview of how to use buses to simplify composite interfaces, see [Reduced Bus Wiring: Bus Element Ports](#) (2 min, 7 sec).

For example, this model contains subsystems where each subsystem interface has multiple ports.

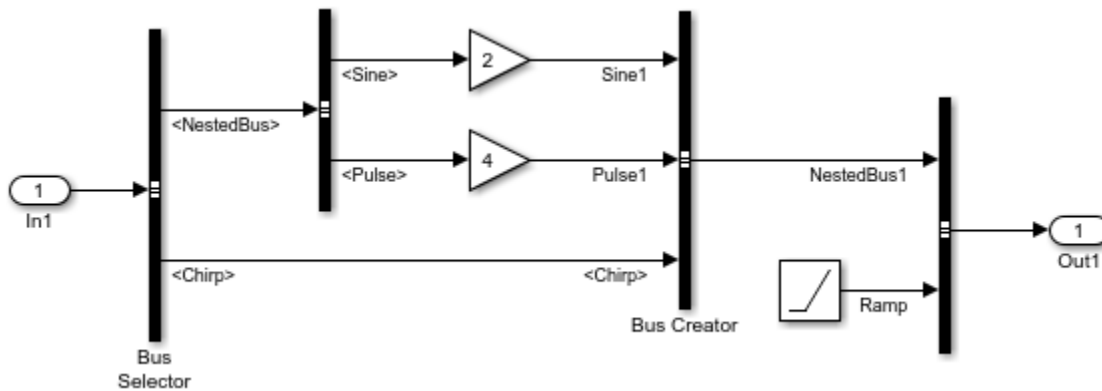

This equivalent model uses buses and has one port per subsystem interface.

For buses at interfaces, use In Bus Element and Out Bus Element blocks instead of Inport and Bus Selector blocks for inputs and Outport and Bus Creator blocks for outputs. In Bus Element and Out Bus Element blocks support multirate virtual buses and do not require `Simulink.Bus` objects at model interfaces, unlike Inport and Outport blocks. They also provide cleaner bus interfaces.

For example, this model uses Inport, Bus Selector, Bus Creator, and Outport blocks.

This equivalent model uses In Bus Element and Out Bus Element blocks.

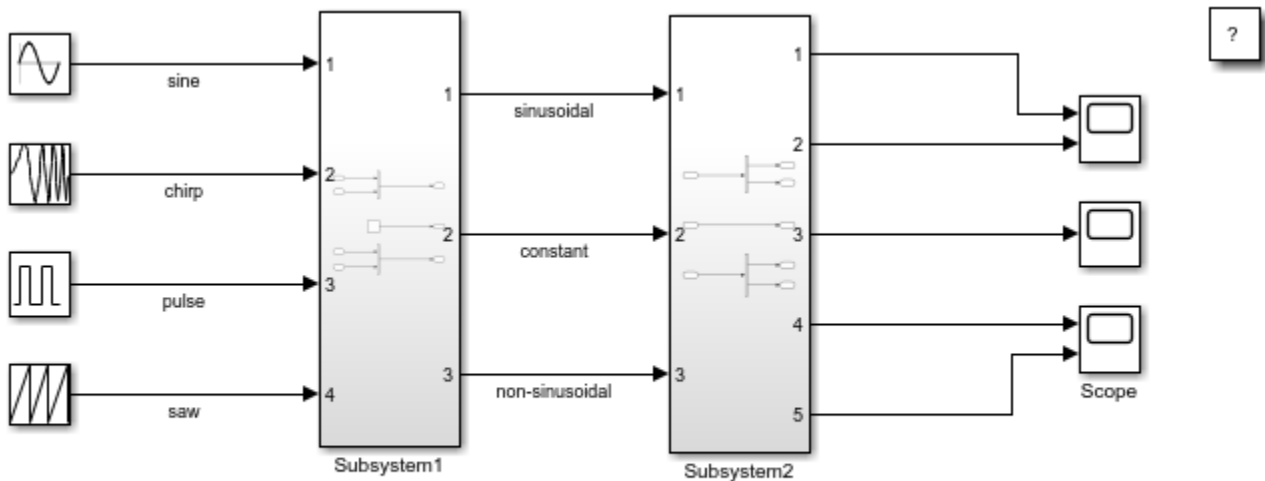

At the interface you want to update, the lines and blocks must not have nondefault specifications that could cause conflicts. For example, the line between a Bus Creator block and an Outport block must not be named or marked for signal logging. Similarly, while you can specify a `Simulink.Bus` object data type for an output port, you must not specify a nondefault data type for an element of the output port, such as `TopBus1.NestedBus1`.

The following examples demonstrate how to update interfaces to use In Bus Element and Out Bus Element blocks. The example models are simple, however, buses are most useful when you have many elements to combine.

## Combine Multiple Subsystem Ports into One Port

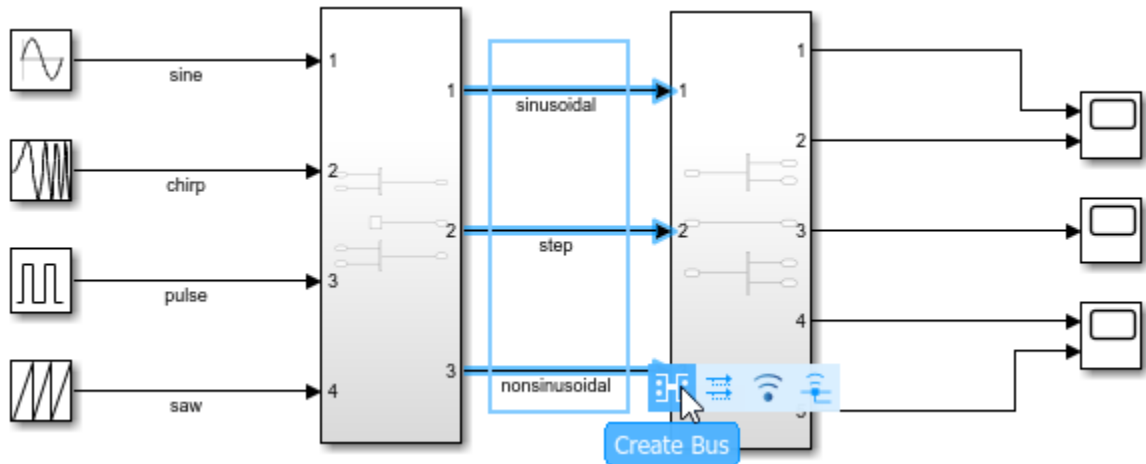

This example shows three ways to simplify a subsystem interface by converting multiple ports and their connected signals into one port and a bus. Model interfaces do not support this automated conversion.

Open the example model, which contains two subsystems with multiple input and output ports.

Copyright 2019 The MathWorks, Inc.

Drag a selection box around the signal lines between the two subsystems. From the action bar that appears, click **Create Bus**.

Simulink replaces the Inport and Outport blocks in the source and destination subsystems with In Bus Element and Out Bus Element blocks.

Drag a selection box around the signal lines between the source blocks and first subsystem. From the action bar that appears, click **Create Bus**.

Simulink adds a Bus Creator block before the first subsystem and replaces the Inport blocks in the first subsystem with In Bus Element blocks.

Drag a selection box around the signal lines between the second subsystem and Scope blocks. From the action bar that appears, click **Create Bus**.

Simulink replaces the Outport blocks in the second subsystem with Out Bus Element blocks and adds a Bus Selector block after the second subsystem.

The resulting model uses virtual buses at the subsystem interfaces.

## Simplify Bus Interfaces in Subsystems and Models

This example shows how to convert a subsystem or model interface that uses Inport, Bus Selector, Bus Creator, and Outport blocks to use In Bus Element and Out Bus Element blocks.

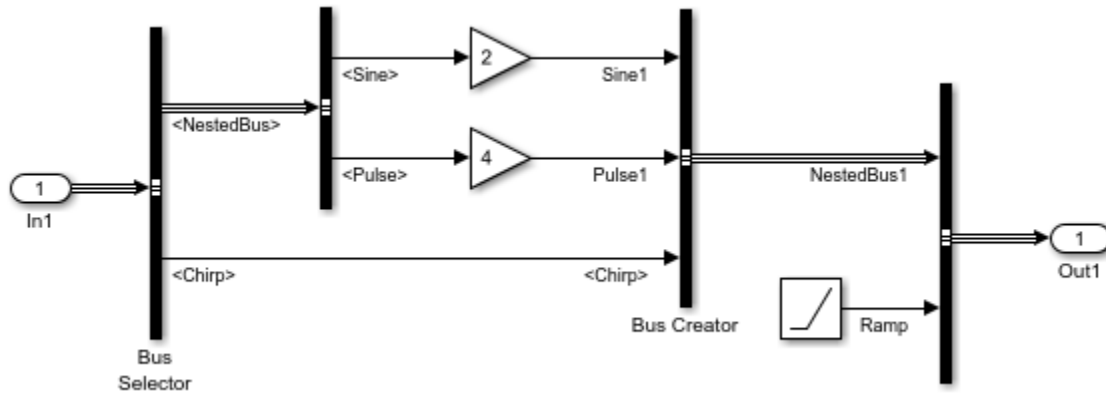

Open the example model, which contains a subsystem that modifies an input bus hierarchy using Bus Selector and Bus Creator blocks. The subsystem uses Inport and Outport blocks for input and output.

Compile the model to update line styles, which you can use to visually identify buses. In the Simulink Toolstrip, on the **Modeling** tab, click **Update Model** or **Run**.

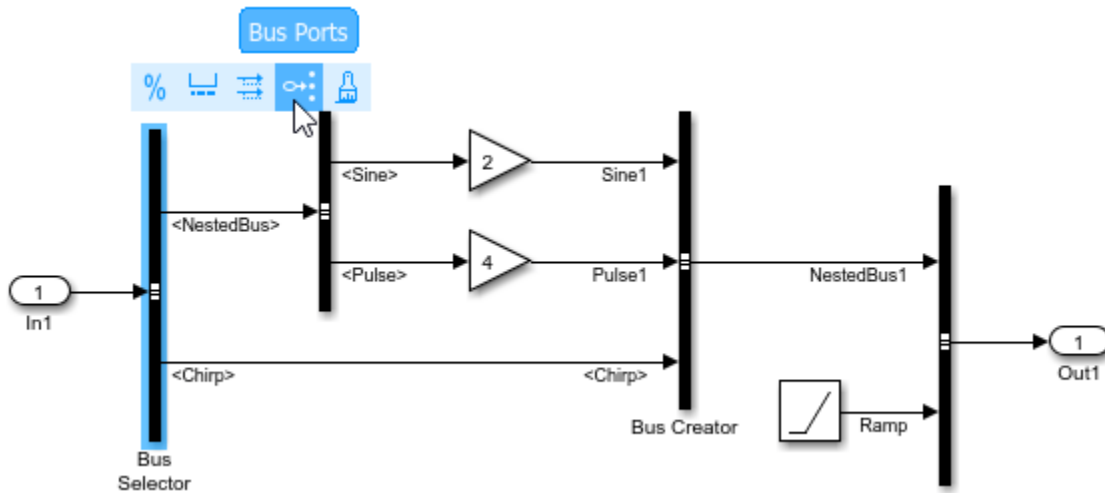

Copyright 2019 The MathWorks, Inc.

Open the subsystem.

To convert Inport and Bus Selector blocks to In Bus Element blocks:

- 1 Click a Bus Selector block that directly connects to an Inport block.
- 2 In the action bar that appears when you pause over the ellipsis, click **Bus Ports**.

You can similarly convert an In Bus Element and Bus Selector block.

To convert Outport and Bus Creator blocks to Out Bus Element blocks:

- 1 Click a Bus Creator block that directly connects to an Outport block without branching.
- 2 In the action bar that appears when you pause over the ellipsis, click **Bus Ports**.

You can similarly convert Out Bus Element and Bus Creator blocks.

The resulting model simplifies line routing, makes it easier to incrementally change the interface, and lets you access elements closer to their point of usage.

You can change the name of a bus and its elements by double-clicking the block labels and editing them.

To easily identify elements of the same nested bus or bus port, specify block colors.

- 1 Double-click an In Bus Element or Out Bus Element block to open the dialog box for the related port.
- 2 Select an element or the top bus.
- 3 Specify the background color with the **Set color** dropdown menu.

## Use Buses at Model Interfaces

Bus input for a Model block must be consistent with the bus expected by the referenced model.

If you use a bus as an input to or an output from a referenced model:

- Only a nonvirtual bus can contain variable-size signal elements.
- For code generation, you can only configure the I/O arguments `step` method style of the C++ class interface for the referenced model when using a nonvirtual bus or when using the `Default` style of the C++ class interface.
- For code generation, you can only configure function prototype control for the referenced model when using a nonvirtual bus.

## See Also

In Bus Element | Out Bus Element

- “Group Signals or Messages into Virtual Buses” on page 81-14
- “Create Nonvirtual Buses” on page 81-34
- “Load Input Data for a Bus Using In Bus Element Blocks” on page 75-67
- “Load Bus Data to Root-Level Input Ports” on page 75-58

## Modify Bus Hierarchy

To view the hierarchy of a bus, right-click on the associated line and click **Signal Hierarchy** in the context menu. You can also see the bus hierarchy in the block parameter dialog box for the Bus Creator, Bus Assignment, Bus Selector, In Bus Element, and Out Bus Element blocks.

To change the hierarchy of elements in a bus, you can:

- Separate a bus into its constituent elements with a Bus Selector block, then reassemble the elements with one or more Bus Creator blocks.
- For an Out Bus Element block, edit the second part of the label, which corresponds to the bus element. Suppose you have a bus element named `signal1` and you want to move `signal1` into a nested bus named `NestedBus`. You would change the part of the label that corresponds to the bus element from `signal1` to `NestedBus.signal1`.
- In the Out Bus Element block parameter dialog box, click and drag elements to different hierarchy levels.

To change the order of elements in a bus:

- In the Bus Creator block parameter dialog box, select one element or adjacent elements, then click the **Up** or **Down** button.
- In the Out Bus Element block parameter dialog box, click and drag elements within their existing hierarchy level.

When you change the bus hierarchy, Simulink automatically handles most of the complexities involved. For example, Simulink repairs broken selections in the Bus Selector and Bus Assignment block parameter dialog boxes due to upstream bus hierarchy changes. By default, the related **Repair bus selections** configuration parameter is set to `Warn` and `repair`. The repairs occur when you update a model.

---

**Tip** To change the value of elements in a bus, use a Bus Assignment block. For details, see “Assign Signal Values to Bus Elements” on page 81-51.

---

## Resolve Circular Dependencies in Buses

Nesting buses can produce a loop of blocks where a bus is an element of itself. This circular definition cannot be resolved and therefore causes an error. To trace the loop, you can use the location cited in the error message.

- 1 Select a line associated with the location cited in the error message.
- 2 Right-click a line and choose **Highlight Signal to Source** or **Highlight Signal to Destination**. See “Highlight Signal Sources and Destinations” on page 80-28 for more information.
- 3 Continue choosing lines and highlighting their sources and destinations until the loop becomes clear.
- 4 Restructure the model to eliminate the circular bus definition.

Because the problem is a circular definition, rather than a circular computation, the cycle cannot be broken by inserting additional blocks. For example, you cannot fix a circular definition the way that you break an algebraic loop by inserting a Unit Delay block. You must restructure the model to eliminate the circular bus definition.

- “Specify Initial Conditions for Bus Elements” on page 81-64

## Create Nonvirtual Buses

A nonvirtual bus is analogous to a struct in C code. Use nonvirtual buses to:

- Construct an array of buses.
- Have bus data cross MATLAB Function block or Stateflow chart boundaries.
- Package bus data as structures in generated C code.
- Interface with external code through an S-function.
- Reduce the number of function arguments passed to a subcomponent in generated code.

A `Simulink.Bus` object data type must define the bus you want to make nonvirtual. A bus becomes nonvirtual when you select a block parameter such as **Output as nonvirtual bus**. Making the bus nonvirtual causes simulation and code generation to apply the structure defined by the `Bus` object. When the bus is virtual, the `Bus` object only validates the properties of the bus.

To simulate a model that contains nonvirtual buses, the referenced `Bus` objects must be in the base workspace or a data dictionary used by the model. For more information, see “Specify Bus Properties with `Simulink.Bus` Object Data Types” on page 81-58.

Nonvirtual buses also require all elements of the bus to have the same sample time. For more information, see “Modify Sample Times for Nonvirtual Buses” on page 81-56.

The way to create nonvirtual buses differs based on the location of the bus and the block that creates the bus:

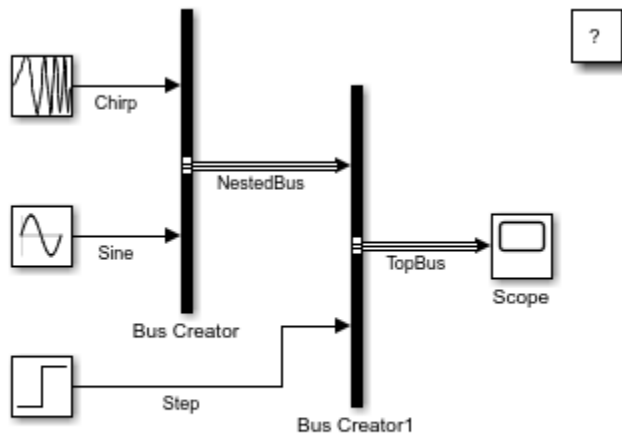

- “Create Nonvirtual Buses Within a Component” on page 81-34
- “Create Nonvirtual Buses at Interfaces” on page 81-36
- “Convert Virtual Bus to Nonvirtual Bus” on page 81-38
- “Create Nonvirtual Bus from MATLAB Structure” on page 81-39

To focus on fundamental steps, these examples are simple. However, buses are most useful when you have many signals to combine.

### Create Nonvirtual Buses Within a Component

You can use `Bus Creator` blocks to create nonvirtual buses within components.

Open and compile the example model, which uses `Bus Creator` blocks to create a hierarchy of virtual buses. To compile the model, on the **Modeling** tab of the Simulink Toolstrip, click **Update Model** or **Run**. Compiling the model updates the line styles, which you can use to visually identify buses.

Copyright 2019-2020 The MathWorks, Inc.

To create this model, see “Group Signal Lines Within a Component” on page 81-14.

The virtual buses in this model are not defined by `Simulink.Bus` objects. To change the output of the Bus Creator blocks to nonvirtual buses, you must have Bus objects that match the bus hierarchy.

To create the Bus objects that correspond to `TopBus` and `NestedBus`, use the `Simulink.Bus.createObject` function. In the MATLAB Command Window, enter:

```
Simulink.Bus.createObject('NonvirtualBusCreationModel',...
    'NonvirtualBusCreationModel/Bus Creator1');
```

This function creates the Bus object that corresponds to the output bus of the specified block. If the output bus contains nested buses, the function also creates Bus objects that correspond to the nested buses. In this example, the function creates two Bus objects that are named after the corresponding buses, `TopBus` and `NestedBus`.

To view the Bus objects, open the **Type Editor**. In the MATLAB Command Window, enter:

```
typeeditor
```

Now that you have Bus objects that correspond to the nonvirtual buses you want to create, create the nonvirtual buses. In the Simulink Editor, double-click the Bus Creator block named `Bus Creator1`. In the Block Parameters dialog box, set **Output data type** to `Bus: TopBus`, select the **Output as nonvirtual bus** check box, and click **OK**. `TopBus` is now a nonvirtual bus, while `NestedBus` remains a virtual bus. To identify the nonvirtual bus by line style, compile the model.

Double-click the block named `Bus Creator`. In the Block Parameters dialog box, set **Output data type** to `Bus: NestedBus`, select the **Output as nonvirtual bus** check box, and click **OK**. `NestedBus` is now a nonvirtual bus. To update its line style, compile the model.

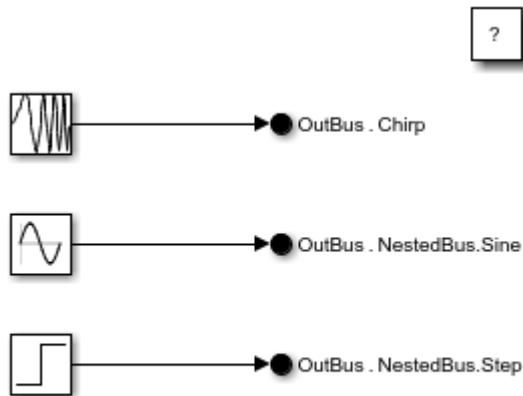

If you do not save the Bus objects, then you must recreate the Bus objects when you reopen the model. For information on how to save the Bus objects, see “Specify Bus Properties with Simulink.Bus Object Data Types” on page 81-58.

## Create Nonvirtual Buses at Interfaces

To create a nonvirtual bus at an interface, connect the bus elements to Out Bus Element blocks and specify that the output bus is nonvirtual.

Open the example model, which uses three Out Bus Element blocks to create a virtual bus at the output port, `OutBus`.

Copyright 2019-2020 The MathWorks, Inc.

To create this model, see “Connect Multiple Output Signals to a Port” on page 81-17.

Nonvirtual buses require a `Simulink.Bus` object data type. Create the `Bus` object that corresponds to the output bus.

- 1 In the Simulink Toolstrip, on the **Modeling** tab, in the **Design** gallery, select **Type Editor**.
- 2 In the Type Editor, create two `Bus` objects. In the toolstrip, click **Bus** twice.
- 3 Name the `Bus` objects. Select one of the `Bus` objects, and set **Name** to `OutBus`. Select the other `Bus` object, and set **Name** to `NestedBus`.
- 4 For each `Bus` object, create the `Simulink.BusElement` objects that correspond to the elements of the buses. Select `NestedBus`, then, in the toolstrip, click **Bus Element** twice. Name the elements `Sine` and `Step`. Select `OutBus`, then click **Bus Element** twice. Name the elements `Chirp` and `NestedBus`.
- 5 Specify a `Bus` object data type for any nested buses. With the `NestedBus` object selected, set **Data type** to `Bus: NestedBus`.

To output a nonvirtual bus, specify the `Bus` object data type and bus virtuality.

- 1 Open the dialog box for the port by double-clicking one of the `Out Bus Element` blocks.
- 2 In the tree hierarchy of the dialog box, pause on `OutBus`, and click the pencil icon that appears next to `OutBus`.
- 3 Specify the `Bus` object data type. Set **Data type** to `Bus: OutBus`.
- 4 In the tree hierarchy of the dialog box, click the signal attributes that now appear next to `OutBus`.
- 5 Specify the bus virtuality. Set **Bus virtuality** to `nonvirtual`, then close the dialog box.

The output of the model is a nonvirtual bus. To see the nonvirtual bus, reference the model in another model or move the `Out Bus Element` blocks into a subsystem. The line styles update when you compile the model. To compile the model, on the **Modeling** tab of the Simulink Toolstrip, click **Update Model** or **Run**.

If you do not save the Bus objects, then you must recreate the Bus objects when you reopen the model. For information on how to save the Bus objects, see “Specify Bus Properties with Simulink.Bus Object Data Types” on page 81-58.

Root (top-level) Inport and Outport blocks can also create nonvirtual buses at interfaces. To specify the bus virtuality:

- For a root Inport block, on the **Signal Attributes** tab of the dialog box, select **Output as nonvirtual bus**.
- For a root Outport block, on the **Signal Attributes** tab of the dialog box, select **Output as nonvirtual bus in parent model**.

In Bus Element blocks use the **Bus virtuality** parameter to determine whether they inherit or define the bus virtuality. If the block defines the bus virtuality and the virtuality of the input bus does not match, compiling the model produces an error.

## Convert Virtual Bus to Nonvirtual Bus

You can convert a virtual bus to a nonvirtual bus anywhere within a model by using a Signal Conversion block.

Open and compile the example model, which contains a virtual bus hierarchy created by Bus Creator blocks. To compile the model, on the **Modeling** tab of the Simulink Toolstrip, click **Update Model** or **Run**. Compiling the model updates the line styles, which you can use to visually identify buses.

Copyright 2019-2020 The MathWorks, Inc.

To define the buses and support conversion to nonvirtual buses, the Bus Creator blocks specify `Simulink.Bus` object data types. To create the Bus objects in the base workspace when the model is loaded, the model uses the `PreLoadFcn` callback.

To view the callback, in the Simulink Toolstrip, on the **Modeling** tab, click **Model Settings > Model Properties**. In the Model Properties dialog box, open the **Callbacks** tab and select the **PreLoadFcn** model callback.

To convert a virtual bus to a nonvirtual bus, use a To Nonvirtual Bus block, which is a preconfigured version of the Signal Conversion block that has **Output** set to `Nonvirtual bus`.

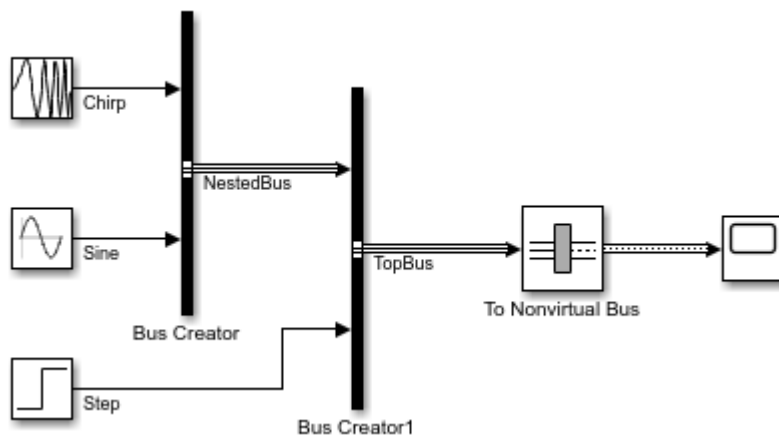

In the example model:

- 1 Add a To Nonvirtual Bus block to the model.
- 2 Drag the To Nonvirtual Bus block onto the line between the Bus Creator1 and Scope blocks. When you drag the block onto the line, the block connects to the line at both ends.

Suppose the data type of the bus you want to convert is not specified by a Bus object. You would need to perform these additional actions:

- 1 Creating the corresponding Bus objects.
- 2 Specifying the Bus object data type for the bus. For example, setting the **Data type** parameter of the To Nonvirtual Bus block to the Bus object that corresponds to the input bus.

The input to the To Nonvirtual Bus block is a virtual bus, and the output is a nonvirtual bus. To see the nonvirtual bus line style, compile the model.

## Create Nonvirtual Bus from MATLAB Structure

You can use a Constant block to compactly represent a nonvirtual bus with constant-valued elements.

On the Constant block, specify:

- A MATLAB structure for **Constant value**.
- A `Simulink.Bus` object as the **Output data type**.

Constant blocks only support MATLAB structures when the output data type is a Bus object.

For example, define a MATLAB structure named `const_param_struct` with elements named `Offset`, `Gain`, and `Threshold`.

```
const_param_struct.Offset = 197;
const_param_struct.Gain = 4.32;
const_param_struct.Threshold = 795.68;
```

Define the corresponding Bus object data type.

```
Simulink.Bus.createObject(const_param_struct)
```

The new Bus object uses the default name `slBus1`.

Open and simulate the example model, which contains a Constant block with **Constant value** set to `const_param_struct` and **Output data type** set to Bus: `slBus1`.

```
open_system('NonvirtualBusFromStructModel')
sim('NonvirtualBusFromStructModel');
```

The output of the Constant block is a nonvirtual bus.

- “Inspect Generated Code for Nonvirtual Buses” on page 81-93
- “Create Structures in MATLAB Function Blocks” on page 49-68

## Display Bus Information

You can display bus information using multiple approaches.

- To display whether a bus is virtual or nonvirtual, update or simulate the model. A virtual bus appears as three solid lines () and a nonvirtual bus appears as two solid lines on either side of a dashed line ()
- To interactively display the hierarchy of a bus, see “Display Bus Hierarchy” on page 81-41.
- To interactively display the value of bus elements at a port, see “Display Value of Bus Elements” on page 81-42.
- To programmatically display the virtuality and hierarchy of a bus, see “Programmatically Get Bus Hierarchy and Virtuality” on page 81-43.

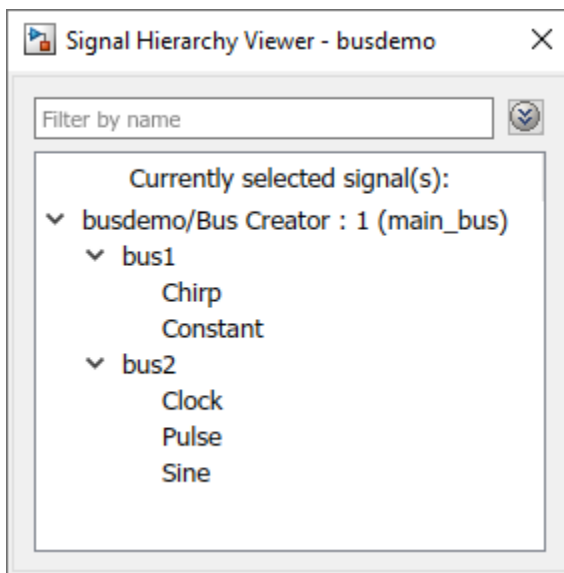

### Display Bus Hierarchy

To interactively display bus hierarchy:

- 1 Click a signal line.
- 2 On the **Signal** tab, select **Signal Hierarchy**.

A Signal Hierarchy Viewer opens, showing the signal hierarchy for the selected signal.

For example, this Signal Hierarchy Viewer shows the signal hierarchy for a bus named `main_bus`.

Each Signal Hierarchy Viewer is associated with a specific model. If you edit a model while the associated Signal Hierarchy Viewer is open, the Signal Hierarchy Viewer reflects those updates.

---

**Note** To produce accurate results at edit time in the Signal Hierarchy Viewer, your model must compile successfully.

---

To filter the displayed signals, click the **Show filtering options** button  on the right side of the **Filter by name** edit box.

- To use MATLAB regular expressions for filtering signal names, select **Enable regular expression**. For example, to display all signals whose names end with a lowercase r (and their immediate parents), enter r\$ in the **Filter by name** edit box. For more information, see “Regular Expressions”.
- To display a flat list of the filtered results, select **Show filtered results as a flat list**. The flat list uses dot notation to indicate the hierarchy of buses. This example shows a filtered set of nested buses.

## Display Value of Bus Elements

To interactively display the values of bus elements at a port:

- 1 Click a signal line.
- 2 On the **Signal** tab, select **Output Value Label**.
- 3 Click the port value label, and select the signals you want to display.

For example, in this model, you can select which signals to display from the signals that are contained in ModelBus.

For more information, see “Display Value for a Specific Port” on page 39-10.

## Programmatically Get Bus Hierarchy and Virtuality

To programmatically get the hierarchy and virtuality of a bus in a compiled model, query these parameters using the `get_param` function:

- `'SignalHierarchy'` — If the signal is a bus, returns the name and hierarchy of the signals in the bus.
- `'CompiledBusType'` — For a model that has run the `'compile'` phase, returns information about whether the signal connected to a port is a bus and whether the signal is a virtual or nonvirtual bus. Before you query the `CompiledBusType` parameter value, use the model name programmatic interface to compile the model. For more information, see “Use Model Name as Programmatic Interface” on page 3-65.

For example, open and simulate the `busdemo` model.

```
open_system('busdemo')
sim('busdemo');
```

Obtain the handle of the port for which you want bus information.

```
ph = get_param('busdemo/Bus Creator', 'PortHandles');
```

Get the signal hierarchy at the port.

```
sh = get_param(ph.Outport, 'SignalHierarchy')
```

```
sh = struct with fields:
  SignalName: 'main_bus'
  BusObject: ''
  Children: [2x1 struct]
```

Get the compiled bus type at the port.

```
busdemo([],[],[],'compile');
bt = get_param(ph.Outport, 'CompiledBusType')
```

```
bt =
'VIRTUAL_BUS'
```

Terminate the simulation that was started by compiling the model.

```
busdemo([],[],[],'term');
```

## Bus-Capable Blocks

Blocks that support buses or arrays of buses can accept them as input, produce them as output, store them in memory, or perform a combination of these options. Block support for buses and arrays of buses can depend on block parameter settings.

This table describes whether a block supports virtual buses, nonvirtual buses, and arrays of buses.

**Note** Buses that contain signals of enumerated data types do not pass through a block that requires a nonzero scalar initial value (such as a Unit Delay block). Use a structure value to initialize signals with enumerated types.

Block	Virtual Bus Support	Nonvirtual Bus Support	Array of Buses Support
All virtual blocks (see “Nonvirtual and Virtual Blocks” on page 39-2)	<b>Supported</b> Inport and Outport blocks at the top-level of a model must specify <code>Simulink.Bus</code> object data types.	<b>Supported</b>	<b>Supported with limitations</b> All virtual blocks except Demux, Enable, Mux, and Trigger blocks support arrays of buses.

## Assign Signal Values to Bus Elements

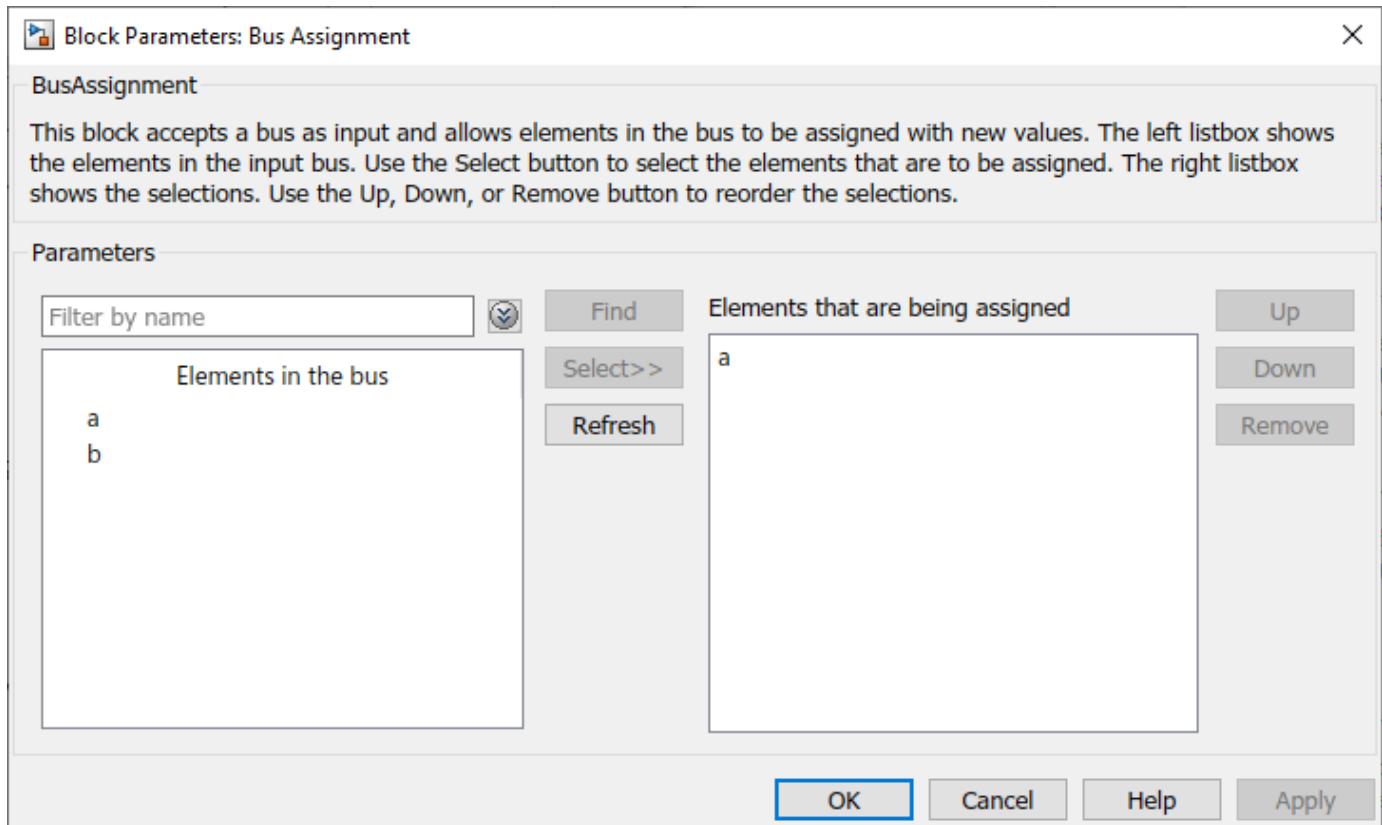

This example shows how to use a Bus Assignment block to replace the value of a bus element. You do not need to add Bus Selector and Bus Creator blocks to change the value of a bus element.

Open and simulate the example model.

The Bus Assignment block has two input ports. The first input port receives the bus that contains an element to which you want to assign a new value. The bus can be virtual or nonvirtual. The second input port receives the signal whose value you want to assign to the bus element.

Double-click the Bus Assignment block to open a dialog box with assignment options. The Block Parameters dialog box lists the elements available for assignment in the **Elements in the bus** list.

In this model, bus elements **a** and **b** are available for assignment. Element **a** also appears in the **Elements that are being assigned** list, which indicates that it is selected for assignment.

To assign a new value to the bus element, connect the signal that provides the new value to the corresponding port on the Bus Assignment block. The elements to which you assign values can be nonbus signals or buses. The new values must match the attributes of the elements in the original bus.

In this model, signal **c** connects to the port that assigns a new value to element **a**. The port label indicates the bus element. For element **a**, the port label is **:=a**.

The Bus Assignment block replaces the value of bus element **a**, which is 1, with the value of signal **c**, which is 3.

To display the new value of element **a** and the unchanged value of element **b**, the Bus Selector block selects elements **a** and **b** and connects them to Display blocks. The Display blocks show the value of these elements after assignment.

- Element **a** has a value of 3, which is the new, assigned value from the Bus Assignment block.
- Element **b** has a value of 2, which is its original value.

You can select additional elements for assignment by selecting an element under **Elements in the bus** then clicking **Select**. The Bus Assignment block adds an input port for each additional element to

which you want to assign a new value. The new input ports let you connect the signals that you want to assign to the additional bus elements.

## Identify Automatic Bus Conversions

To comply with composite signal requirements and limitations, Simulink may add hidden Bus to Vector and Signal Conversion blocks to your model. These additions help you avoid manually converting or refactoring your models, which can be time consuming and error prone.

### Bus-to-Vector Conversions

When a block requires a vector but receives a virtual bus, a hidden Bus to Vector block may convert the bus to a vector. Bus to Vector blocks are virtual and do not affect simulation results, code generation, or performance. However, when a bus is treated as a vector, the elements of the bus become inaccessible.

To receive warnings or errors when a bus is treated as a vector, set the **Bus signal treated as vector** configuration parameter to `warning` or `error`, respectively. These settings allow you to identify potential problems at the source, instead of at downstream blocks that expect a bus.

To correct buses used as vectors:

- In the Model Advisor for the top model, run the “Check bus signals treated as vectors” check and perform the recommended actions.
- Use the `Simulink.BlockDiagram.addBusToVector` function to add Bus To Vector blocks where Simulink would implicitly convert buses to vectors. For an example, see “Manage Bus-to-Vector Conversions”.
- Replace the related Bus Creator block with a Mux block, which creates a vector.

### Virtual and Nonvirtual Bus Conversions

When updating a diagram before simulation or code generation, Simulink might automatically convert a virtual bus to a nonvirtual bus or a nonvirtual bus to a virtual bus. For example, Simulink implicitly converts a bus when:

- A block, such as an S-Function block or a Stateflow chart, receives a virtual bus but requires a nonvirtual bus.
- A referenced model receives a nonvirtual bus, but the corresponding Inport block specifies a virtual bus.
- A root-level Outport block receives a nonvirtual bus but specifies a virtual bus.

Simulink inserts hidden Signal Conversion blocks into the model where needed. If a `Simulink.Bus` object is not specified for a virtual bus, the conversion to a nonvirtual bus fails, and you receive an error.

Unlike Bus to Vector blocks, Signal Conversion blocks do not affect the structure of the output bus.

By default, In Bus Element and Out Bus Element blocks inherit the bus virtuality from the bus. When they specify either a virtual or nonvirtual bus, they produce an error instead of automatically converting the bus virtuality.

## Modify Sample Times for Nonvirtual Buses

Unlike virtual buses, which can combine signals that have different sample times, all of the signals in a nonvirtual bus must have the same sample time.

To group signals with different sample times in a nonvirtual bus, make the sample times of the input signals the same by inserting Rate Transition blocks.

Suppose a model creates a nonvirtual bus using a Bus Creator block. To standardize the sample time of the input signals, the model uses three Rate Transition blocks before the Bus Creator block.

Suppose another model converts a virtual bus to a nonvirtual bus using a root-level Outport block. To standardize the sample time of the elements of the virtual bus, the model uses a single Rate Transition block before the Outport block.

Alternatively, specify the same sample time at each block that generates an element of the bus.

**Tip** To output a multirate virtual bus from a model, use Out Bus Element blocks.

## Specify Bus Properties with Simulink.Bus Object Data Types

A bus can be associated with a `Simulink.Bus` object, which specifies properties that Simulink uses to validate the bus. Bus objects are optional for virtual buses, but required for nonvirtual buses.

A Bus object specifies only the architectural properties of a bus, as distinct from the values of the signals it contains. For example, a Bus object can specify the number of elements in a bus, the order of those elements, whether and how elements are nested, and the data types of constituent signals; but not the signal values.

A Bus object is analogous to a structure definition in C: it defines the members of the bus, but does not create the bus. A Bus object is also similar to a cable connector. The connector defines all the pins and their configuration and controls what types of wires can be connected to it. Similarly, a Bus object defines the configuration and properties of the signals that the associated bus must have.

### Simulink.Bus Object Workflow

Using Bus objects in a model involves performing these tasks, in many cases iteratively.

- 1 “Determine Whether to Use Simulink.Bus Objects” on page 81-58
- 2 “Determine How to Manage Simulink.Bus Objects” on page 81-59
- 3 “Create and Specify Simulink.Bus Objects” on page 81-59
- 4 “Save Simulink.Bus Objects” on page 81-60
- 5 “Map Simulink.Bus Objects to Models” on page 81-60

### Determine Whether to Use Simulink.Bus Objects

You must use Bus objects for these modeling configurations:

- Nonvirtual buses
- Stateflow charts with bus input or output
- S-function or Legacy Code Tool interface with external code

You can associate a Bus object with multiple blocks. Some blocks require that you specify a Bus object if the block has a bus input or output. For more information, see “Bus-Capable Blocks” on page 81-45.

When a Bus object governs a signal input or output for a block, the signal must be a bus that has the properties specified by the object. Any variance causes an error.

If you use Bus Creator or In Bus Element block parameters to specify bus properties, all blocks downstream from the bus inherit the same properties.

You can use Bus Creator block parameters to define virtual buses and perform limited error checking. To perform thorough error checking on a bus, associate a Bus object with that bus. Using Bus objects to check buses for errors is important when you want to create reusable and shareable model components.

To make tracing the correspondence between the model and the generated code for a bus easier, use a nonvirtual bus. The generated code for a nonvirtual bus produces a structure. Nonvirtual buses can result in multiple copies of some buses.

## Determine How to Manage Simulink.Bus Objects

You can save Bus objects to these locations:

- Data dictionary
- Function
- MAT-file
- Database or other external files

If you do not save Bus objects, then when you reopen a model that uses the Bus objects, you need to recreate the Bus objects.

Different Bus object storage locations provide different advantages.

Location	Usage Considerations
Data dictionary	Use for large model componentization.  When you save to a data dictionary from the base workspace, you get all the variables used by the model, not just the Bus objects.  Before you save to a data dictionary, read “Considerations Before Migrating to Data Dictionary” on page 79-8.
Function	Use for when you want to use MATLAB for traceability and model differencing.
MAT-file	Use for faster Bus object saving and loading.
Database or other external files	Use for comparing bus interface information with design documents stored in an external data source.

## Create and Specify Simulink.Bus Objects

To create or edit Bus objects interactively, use the **Type Editor** or **Model Explorer**. Bus objects created with these tools are initially stored in the base workspace or data dictionary. To visualize bus hierarchy and access capabilities such as import and export, use the **Type Editor**. When you have multiple types of objects to update, use the **Model Explorer**. The **Model Explorer** lets you update additional types of objects, such as Simulink.Parameter objects.

To create and edit Bus objects programmatically, see “Programmatically Create Simulink Bus Objects” on page 81-62. Bus objects are initially stored in either the base workspace, a data dictionary, or a function.

After you create a Bus object and specify its attributes, you can associate it with any block that needs to use the bus definition that the object provides. To associate a block with a bus, in the Block Parameters dialog box, set **Output data type** or **Data type** to Bus: <object name> and replace <object name> with the Bus object name.

You can specify the Bus object as the data type of a block either before or after defining the Bus object. However, before you simulate the model, the Bus object and the corresponding bus must have the same number of bus elements, in the same order. Also, each element in the Bus object and in the corresponding bus must have the same data type and dimensions.

During model development, you can modify buses to match Bus objects or modify Bus objects to match buses.

If you do not want to change the Bus object, you can:

- Create a Bus object that matches the changes to the bus and use the new Bus object for the blocks that the changed bus connects to.
- Revert the bus changes so that the bus continues to match the associated Bus object.

## Save Simulink.Bus Objects

To save Bus objects stored in the base workspace, you can use any MATLAB technique that saves the contents of the base workspace. However, the resulting file contains everything in the base workspace, not just Bus objects.

You can save Bus objects in a variety of locations.

Location	File Creation Method	File Contents
Data dictionary	See “Migrate Models to Use Simulink Data Dictionary” on page 79-7.	Bus objects and other base workspace variables used by a model
Function	Use the Type Editor or <code>Simulink.Bus.save</code> function.	Bus objects
MAT file	Use the Type Editor.	Bus objects
Database or other external files	Use the <code>Simulink.importExternalCTypes</code> function, scripts, or Database Toolbox™ functionality on C code structure ( <code>struct</code> ) definitions. In preparation for integrating existing algorithmic C code for simulation (for example, by using the Legacy Code Tool), you can package signal or parameter data in the definitions according to structure type.	Bus objects

When you modify saved Bus objects, you must resave them to keep the changes.

## Map Simulink.Bus Objects to Models

Before you simulate a model, all the Bus objects it uses must be loaded into the base workspace or a data dictionary used by the model. For automation and consistency across models, mapping Bus objects to models is important.

- By identifying all of the Bus objects that a model requires, you can ensure that those objects are loaded before model execution.
- By identifying all models that use a Bus object, you can ensure that changes to a Bus object do not cause unexpected changes in any of the models that use the Bus object.

To ensure the necessary Bus objects load before model execution, consider:

- **Projects** — Automatically load or run files that define Bus objects by configuring the files to run when you open a project. For details, see “Project Management”.
- **Data dictionaries** — Store Bus objects with variables and other objects for one or more models.

To share a Bus object among models, you can link each model to a dictionary and create a common referenced dictionary to store the object. For an example, see “Partition Dictionary Data Using Referenced Dictionaries” on page 79-28.

- **Databases** — Capture mapping information in an external data source, such as a database.
- **Model callbacks** — Load or run files that define Bus objects by using a model callback, such as `PreLoadFcn`. For more information, see “Model Callbacks” on page 4-54.

If a model uses only a few Bus objects, consider copying the Bus object code directly into the callback, instead of loading a file.

To find where a Bus object is used in an open model, see “Finding Blocks That Use a Specific Variable” on page 72-105.

---

**Tip** Using a rigorous and standard naming convention is very helpful for mapping Bus object usage. For example, consider the model and data required for an actuator control function. Naming the model `Actuator` and the input and output ports `Actuator_bus_in` and `Actuator_bus_out`, respectively, makes the connection between the Bus objects and the model clear.

Note that this approach can cause issues if the output from one model is fed directly to another model. In this case, the naming mismatch results in an error.

## Programmatically Create Simulink Bus Objects

You can programmatically create a `Simulink.Bus` object and its `Simulink.BusElement` objects from arrays, blocks, cell arrays, structures, or C code.

As you create Bus objects programmatically, you can store them in the MATLAB workspace or a data dictionary or save their definitions in a function. For Bus objects in the base workspace, you can programmatically save their definitions in a function using the `Simulink.Bus.save` function.

To simulate a block that uses a Bus object, that Bus object must be in the base workspace or in a data dictionary.

### Create Bus Objects from Bus Element Objects

Create a hierarchy of `Simulink.Bus` objects using arrays of `Simulink.BusElement` objects.

Create an array that contains two `BusElement` objects, named `Chirp` and `Sine`, in the base workspace.

```
elems(1) = Simulink.BusElement;  
elems(1).Name = 'Chirp';
```

```
elems(2) = Simulink.BusElement;  
elems(2).Name = 'Sine';
```

Array indexing lets you create and access the elements of the array. Dot notation lets you access property values of the elements.

Create a `Bus` object, named `Sinusoidal`, that contains the elements defined in the `elems` array.

```
Sinusoidal = Simulink.Bus;  
Sinusoidal.Elements = elems;
```

To create a hierarchy of `Bus` objects, create another `Bus` object to reference the `Bus` object named `Sinusoidal`.

Create an array that contains two `BusElement` objects, named `NestedBus` and `Step`. Specify the `Bus` object named `Sinusoidal` as the data type of the `NestedBus` element.

```
clear elems  
  
elems(1) = Simulink.BusElement;  
elems(1).Name = 'NestedBus';  
elems(1).DataType = 'Bus: Sinusoidal';
```

```
elems(2) = Simulink.BusElement;  
elems(2).Name = 'Step';
```

Create a `Bus` object, named `TopBus`, that contains the elements defined in the `elems` array.

```
TopBus = Simulink.Bus;  
TopBus.Elements = elems;
```

You can view the hierarchy of the created objects in the **Type Editor**.

typeeditor

## Create Bus Objects from Blocks

To programmatically create a `Simulink.Bus` object based on a block in a model, use the `Simulink.Bus.createObject` function.

If you specify a Bus Creator block that is at the highest level of a bus hierarchy, the function creates Bus objects for all of the buses in the hierarchy, including nested buses.

## Create Bus Objects from MATLAB Data

To create a `Simulink.Bus` object from a cell array, use the `Simulink.Bus.cellToObject` function. Each subordinate cell array represents another Bus object.

To create a Bus object from a MATLAB structure, use the `Simulink.Bus.createObject` function. The structure can contain MATLAB timeseries, MATLAB timetable, and `matlab.io.datastore.SimulationDatastore` objects or be a numeric structure.

## Create Bus Objects from External C Code

You can create a `Simulink.Bus` object that corresponds to a structure type (`struct`) that your existing C code defines. Then, in preparation for integrating existing algorithmic C code for simulation (for example, by using the Legacy Code Tool), you can use the Bus object to package signal or parameter data according to the structure type. To create the object, use the `Simulink.importExternalCTypes` function.

## Related Examples

- “Specify Bus Properties with `Simulink.Bus` Object Data Types” on page 81-58

## Specify Initial Conditions for Bus Elements

Bus initialization is a special form of signal initialization. For general information about initializing signals, see “Initialize Signals and Discrete States” on page 80-42. For details about initializing arrays of buses, see “Initialize Arrays of Buses” on page 81-77.

Bus initialization specifies the bus element values that Simulink uses for the first execution of a block that uses that bus. By default, the initial value for a bus element is the ground value (represented by 0). Bus initialization involves specifying nonzero initial conditions.

You can use bus initialization features to:

- Specify initial conditions for signals that have different data types.
- Apply a different initial condition for each element in the bus.
- Specify initial conditions for a subset of elements in a bus without specifying initial conditions for all the elements.
- Use the same initial conditions for multiple blocks, signals, or models.

### Blocks That Support Bus Initialization

You can initialize bus values that input to a block if that block meets both of these conditions:

- Has an initial value or initial condition block parameter
- Supports buses

These blocks support bus initialization:

- Data Store Memory
- IC
- Memory
- Merge
- Output (when the block is inside a conditionally executed context)
- Receive
- Rate Transition
- Unit Delay

For example, the Unit Delay block is a bus-capable block. Its Block Parameters dialog box has an **Initial conditions** parameter.

You cannot initialize a bus that has:

- Variable-size signals
- Frame-based signals

### Set Diagnostics to Support Bus Initialization

To enable bus initialization, before you start a simulation, set the **Underspecified initialization detection** configuration parameter to `simplified`.

## Create Initial Condition Structures

You can create partial or full initial condition structures to represent initial values for a bus. To create an initial condition structure, use one of these approaches:

- Define a MATLAB structure in the MATLAB base or Simulink model workspace. You can manually define the structure, or alternatively for full structures, you can use the `Simulink.Bus.createMATLABStruct` function.
- In the Block Parameters dialog box for a block that supports bus initialization, for the initial condition parameter specify an expression that evaluates to a structure.

For information about defining MATLAB structures, see “Structure Arrays”.

The field that you specify in an initial condition structure must match these data attributes of the bus element exactly:

- Name
- Dimension
- Complexity

For example, if you define a bus element to be a real [2x2] double array, then in the initial condition structure, define the value to initialize that bus element to be a real [2x2] double array.

Explicitly specify fields in the initial condition structure for every bus element that has an enumerated (enum) data type.

## Control Data Types of Structure Fields

If any of the elements of the target bus use a data type other than `double`, you can use different techniques to control the data types of the fields of initial condition structures. The technique that you choose can influence the efficiency and readability of the generated code. See “Control Data Types of Initial Condition Structure Fields” on page 81-86.

## Create Full Structures for Initialization

A full initial condition structure provides an initial value for every element of a bus. The initial condition structure mirrors the bus hierarchy and reflects the attributes of the bus elements.

Specifying full structures during code generation offers these advantages:

- Generates more readable code
- Supports a modeling style that explicitly initializes all signals

Use the `Simulink.Bus.createMATLABStruct` function to streamline the creation of a full MATLAB initial condition structure with the same hierarchy, names, and data attributes as a bus. This function fills all of the elements that you do not specify with ground values for those elements.

You can use several different kinds of input with the function, including:

- A `Simulink.Bus` object name
- An array of port handles

You can invoke the function from the **Type Editor**. Select the Bus object for which you want to create a full MATLAB structure. Then, click **MATLAB Structure**. For an example, see “Initialize Buses and Arrays of Buses Using Type Editor”.

To detect when structure parameters are not consistent in shape (hierarchy and names) with the associated bus, use the Model Advisor.

- 1 On the **Modeling** tab, click **Model Advisor**.
- 2 Click **OK**.
- 3 Under **By Task > Modeling Signals and Parameters using Buses**, select **Check structure parameter usage with bus signals**.
- 4 Click the **Run This Check** button.

The Model Advisor identifies partial initial condition structures.

After you create the structure, you can edit it in the MATLAB Editor.

## Create Partial Structures for Initialization

A partial initial condition structure provides initial values for a subset of the elements of a bus. If you use a partial initial condition structure, during simulation, Simulink creates a full initial condition structure to represent all the bus elements. Simulink assigns the respective ground value to each element for which the partial initial condition structure does not explicitly assign a value.

Specifying partial structures for block parameter values can be useful during the iterative process of creating a model. Partial structures enable you to focus on a subset of signals in a bus. When you use partial structures, Simulink initializes unspecified signals implicitly.

When you define a partial initial condition structure:

- Include only fields that are in the bus.
- Omit one or more fields that are in the bus.
- Make the field in the initial condition structure correspond to the nesting level of the bus element.
- Within the same nesting level in both the structure and the bus, optionally specify the structure fields in a different order than the bus elements.

---

**Note** The value of an initial condition structure must lie within the design minimum and maximum range of the corresponding bus element. Simulink performs this range checking when you do an update diagram or simulate the model.

---

Suppose that you have a bus, Top, composed of three elements: A, B, and C, with these characteristics:

- A is a nested bus, with two signal elements.
- B is a single signal.
- C is a nested bus that includes bus A as a nested bus.

The `ex_bus_initial_conditions` model includes the Top bus.

Copyright 2004-2018 The MathWorks, Inc.

Here is a summary of the Top bus hierarchy and the data type, dimension, and complexity of the bus elements.

Top

```

A (sub1)
  A1 (double)
  A2 (int8, 5x1, complex)
B (double)
C (sub2)
  C1 (int16)
  C2 (sub1)
    A1 (double)
    A2 (int8, 5x1, complex)
  
```

In these examples, K is an initial condition structure specified for the initial value of the Unit Delay block. The initial condition structure corresponds to the Top bus in the `ex_bus_initial_conditions` model. Here are some valid initial condition specifications.

Valid Syntax	Description
<code>K.A.A1 = 3</code>	Initialize the bus element Top.A.A1 using the value 3.
<code>K = struct('C',struct('C1',int16(4)))</code>	The bus element Top.C.C1 is int16. The corresponding structure field explicitly specifies <code>int16(4)</code> . Alternatively, you could specify the field value as 4 without specifying an explicit data type.
<code>K = struct('B',3,'A',struct('A1',4))</code>	Bus elements Top.B and Top.A are at the same nesting level in the bus. For bus elements at the same nesting level, the order of corresponding structure fields does not matter.

### Invalid Partial Initial Condition Structures

In the following examples, K is an initial condition structure specified for the initial value of the Unit Delay block. The initial condition structure corresponds to the Top bus in the `ex_bus_initial_conditions` model.

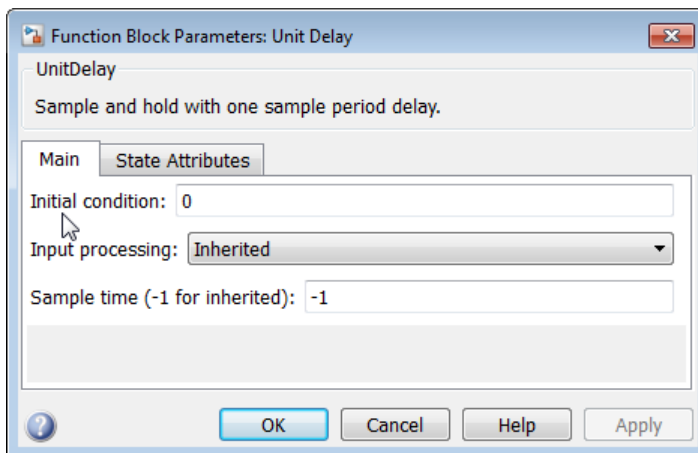

These three initial condition specifications are *not* valid:

Invalid Syntax	Reason the Syntax Is Invalid
<code>K.A.A2 = 3</code>	Value dimension and complexity do not match. The bus element <code>Top.A.A2</code> is $5 \times 1$ , but <code>K.A.A2</code> is $1 \times 1$ ; <code>Top.A.A2</code> is complex, but <code>K.A.A2</code> is real.
<code>K.C.C2 = 3</code>	You cannot use a scalar value to initialize initial condition substructures.
<code>K = struct('B',3,'X',4)</code>	You cannot specify fields that are not in the bus (X does not exist in the bus).

### Initialize Buses Using Block Parameters

Initialize a bus by setting the initial condition parameter for a block that receives a bus as input and that supports bus initialization (see “Blocks That Support Bus Initialization” on page 81-64).

For example, the Block Parameters dialog box for the Unit Delay block has an **Initial condition** parameter.

For a block that supports bus initialization, you can replace the default value of 0 using one of these approaches:

- “MATLAB Structure for Initialization” on page 81-69
- “MATLAB Variable for Initialization” on page 81-69
- “Simulink.Parameter Object For Initialization” on page 81-70

All three approaches require that you define an initial condition structure (see “Create Initial Condition Structures” on page 81-65). You cannot specify a nonzero scalar value or any other type of value other than 0, an initial condition structure, or `Simulink.Parameter` object to initialize a bus.

Defining an initial condition structure as a MATLAB variable, rather than specifying the initial condition structure directly in the Block Parameters dialog box offers several advantages, including:

- Reuse of the initial condition structure for multiple blocks
- Using the initial condition structure as a tunable parameter in the generated code

### MATLAB Structure for Initialization

You can initialize a bus using a MATLAB structure that explicitly defines the initial conditions for the bus.

For example, in the **Initial condition** parameter of the Unit Delay block, you could type in a structure.

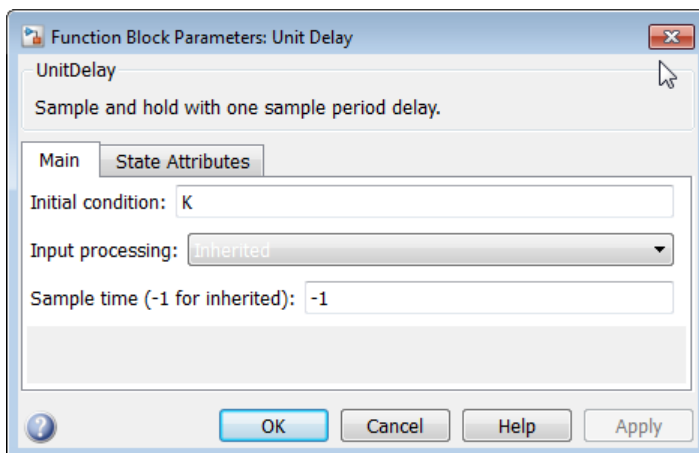

### MATLAB Variable for Initialization

You can initialize a bus using a MATLAB variable that you define as an initial condition structure with the appropriate values.

For example, you could define the following partial structure in the base workspace:

```
K = struct('A', struct('A1', 3), 'B', 4);
```

You can then specify the K structure as the **Initial condition** parameter of the Unit Delay block:

## Simulink.Parameter Object For Initialization

You can initialize a bus using a `Simulink.Parameter` object that uses an initial condition structure for the `Value` property.

For example, you could define the partial structure `P` in the base workspace (reflecting the `ex_bus_initial_conditions` model discussed in the previous section):

```
P = Simulink.Parameter;
P.DataType = 'Bus: Top';
P.Value = Simulink.Bus.createMATLABStruct('Top');
P.Value.A.A1 = 3;
P.Value.B = 5;
```

You can then specify the `P` structure as the **Initial condition** parameter of the Unit Delay block:

## Group Nonvirtual Buses in Arrays of Buses

An array of buses is an array whose elements are nonvirtual buses defined by the same `Simulink.Bus` object. An array of buses is equivalent to an array of structures in MATLAB.

Use an array of buses to:

- Reduce maintenance by centralizing algorithms used for processing multiple buses.
- Streamline iterative processing of multiple buses of the same type, for example, by using a for-each subsystem with the array of buses.
- Change the number of buses being processed without having to restructure the parts of the model that use the array of buses.
- Use built-in blocks, such as the Assignment or Selector blocks, to manipulate arrays of buses just like arrays of any other type. Using an array of buses avoids the need for you to create custom S-functions to manage packing and unpacking structure signals.
- Generate code that has an array of C structures, which you can integrate with legacy C code that uses arrays of structures. This approach simplifies indexing into an array for Simulink computations, using a for loop on indexed structures.

For example, you can model a multi-channel system, such as a communications system, as an array of buses. While all the channels have the same properties, each of the channels may have a different value.

For a model that demonstrates multiple ways to use an array of buses, see “Model Arrays of Buses”.

Arrays of buses with variable-size signals are supported, subject to certain limitations. See “Variable-Size Signal Limitations” on page 82-6.

### Requirements of Arrays of Buses

All buses combined into an array of buses must:

- Be nonvirtual
- Specify the same `Simulink.Bus` object data type (that is, the same name, hierarchies, and bus element attributes)

For information on creating nonvirtual buses, see “Create Nonvirtual Buses” on page 81-34.

For information on which blocks support arrays of buses, see “Bus-Capable Blocks” on page 81-45.

### Create Array of Buses from Nonvirtual Buses

You can use a Vector Concatenate or Matrix Concatenate block to group nonvirtual buses into an array of buses. Simulink treats nonvirtual buses as scalars. Therefore, you can use either of these blocks regardless of the bus element data types.

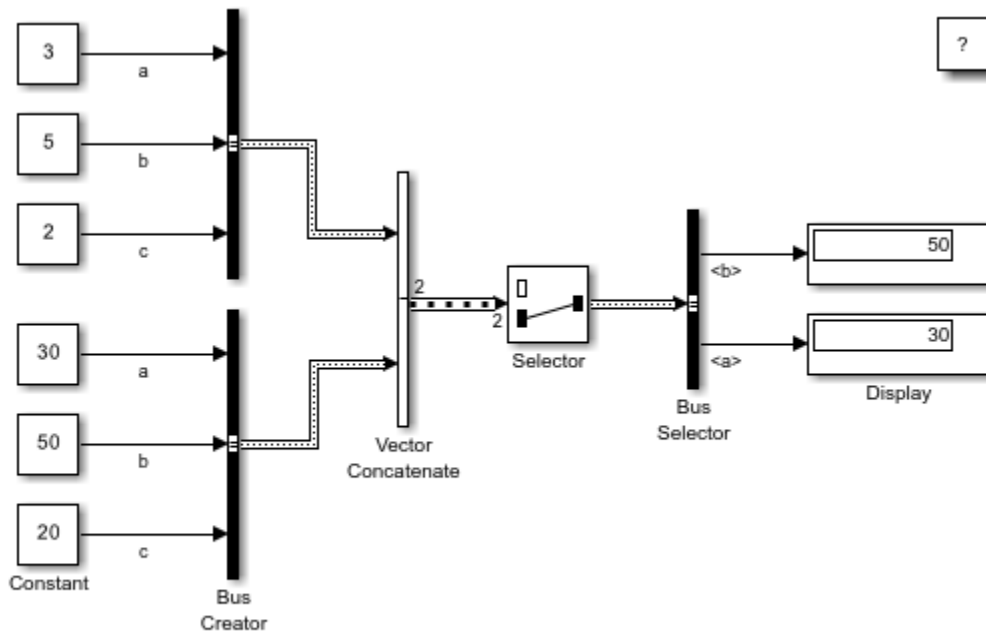

To create an array of buses with one of these blocks:

- 1 Define one `Simulink.Bus` object data type for all of the nonvirtual buses that you want to group in the array of buses.

- 2 In the Block Parameters dialog box for the Vector Concatenate or Matrix Concatenate block, set **Number of inputs** to the number of buses you want in the array of buses. The block icon displays the number of input ports that you specify.
- 3 Connect the nonvirtual buses to the block inputs.

The block output is the array of buses.

Open and compile the example model. To compile the model, on the **Modeling** tab of the Simulink Toolstrip, click **Update Model** or **Run**. Compiling the model updates the line styles, which you can use to visually identify arrays of buses.

Copyright 2019-2020 The MathWorks, Inc.

To demonstrate how to create arrays of buses from nonvirtual buses, the model uses:

- Two Bus Creator blocks to create two nonvirtual buses that have the same Bus object data type (Bus: BusObject).
- A Vector Concatenate block with **Number of inputs** set to 2 to group the two nonvirtual buses in an array of buses.

To demonstrate how to select elements from the array of buses, the model uses:

- A Selector block to extract one of the buses from the array of buses based on the specified **Index** in the dialog box. Because arrays of buses are concatenated signals that provide index-based access to their elements, the Selector block uses `Index vector (dialog)` for the **Index Option**.
- A Bus Selector block to extract the elements of the nonvirtual bus using name-based access.

The **Signal Dimensions** information overlay shows that the array of buses contains two buses. To enable the **Signal Dimensions** overlay, in the Simulink Toolstrip, on the **Debug** tab, select **Information Overlays > Signal Dimensions**.

## Create Array of Buses from MATLAB Structures

You can use a Constant block to compactly represent an array of buses with constant-valued bus elements. This technique can reduce the number of lines in a model and the number of variables used by the model, especially when the model repeats an algorithm with different parameter values.

On the Constant block, specify:

- **Constant value** as an array of MATLAB structures or a `Simulink.Parameter` object that specifies an array of MATLAB structures
- **Output data type** as a `Simulink.Bus` object

Constant blocks only support MATLAB® structures when the output data type is a `Bus` object.

Define an array of structures named `const_struct_array`. Compose each structure of the same elements: `Offset`, `Gain`, and `Threshold`.

```
const_struct_array(1).Offset = 197;
const_struct_array(1).Gain = 4.32;
const_struct_array(1).Threshold = 795.68;
```

```
const_struct_array(2).Offset = 158;
const_struct_array(2).Gain = 3.83;
const_struct_array(2).Threshold = 1039.77;
```

To create an array of structures for a bus hierarchy with many elements, consider using the `Simulink.Bus.createMATLABStruct` function.

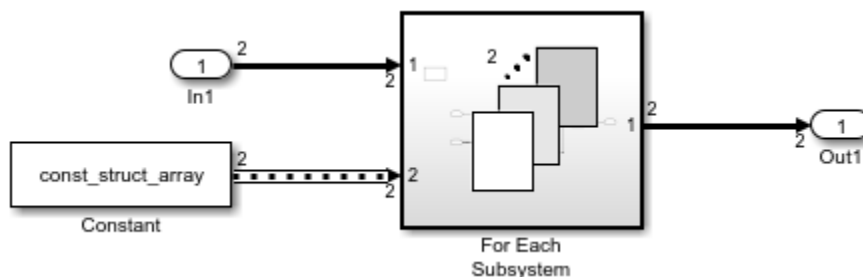

Define the corresponding `Bus` object data type.

```
Simulink.Bus.createObject(const_struct_array)
```

The new `Bus` object uses the default name `s1Bus1`.

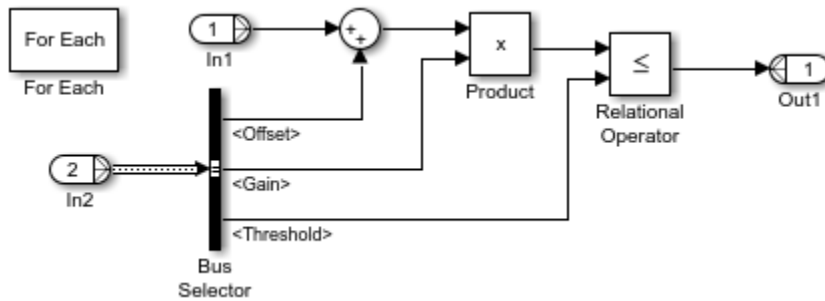

Open and simulate the example model, which contains a Constant block with **Constant value** set to `const_struct_array` and **Output data type** set to `Bus: s1Bus1`.

```
open_system('ArrayOfBusesFromStructModel')
sim('ArrayOfBusesFromStructModel');
```

The output of the Constant block is an array of buses.

The For Each Subsystem block iteratively processes the constant values for each nonvirtual bus in the array. The subsystem contents display the nonvirtual bus instead of the array of buses that connects to the port.

- “Specify Initial Conditions for Bus Elements” on page 81-64
- “Access Bus Data Logged Using Dataset Format”

## Work with Arrays of Buses

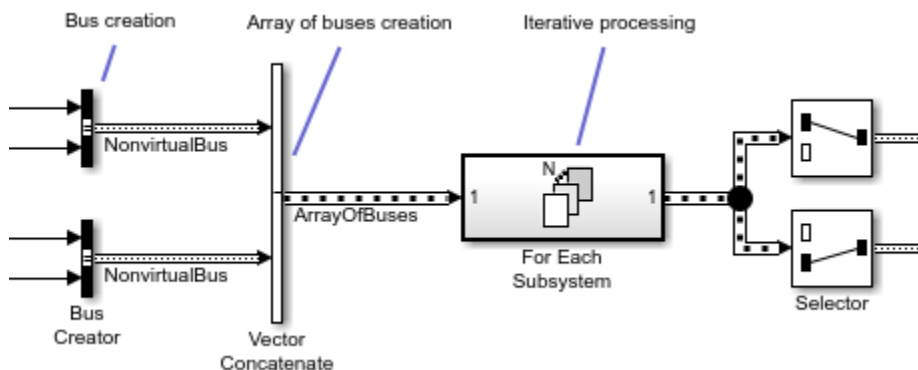

Setting up a model to use an array of buses usually involves these tasks:

- 1 Define the array of buses. See “Create Array of Buses from Nonvirtual Buses” on page 81-71.
- 2 Add a subsystem for performing iterative processing on each element of the array of buses. See “Perform Iterative Processing” on page 81-75.
- 3 Model your scalar algorithm within the iterative processing subsystem.
  - a Operate on the array of buses (using Selector and Assignment blocks).
  - b Use the Bus Selector and Bus Assignment blocks to select elements from, or assign elements to, a nonvirtual bus within the subsystem.

See “Assign Values into Arrays of Buses” on page 81-75 and “Select Bus Elements from Array of Buses” on page 81-76.

- 4 Optionally, import or log array of buses data. See “Import Array of Buses Data” on page 81-76 and “Log Arrays of Buses” on page 81-76.

The resulting model creates the array of buses and uses a subsystem to iteratively process the elements of the array.

### Perform Iterative Processing

You can perform iterative processing on the bus data of an array of buses using blocks such as the For Each Subsystem, While Iterator Subsystem, and For Iterator Subsystem blocks. You can use one of these blocks to perform the same kind of processing on:

- Each bus in the array of buses
- A selected subset of buses in the array of buses

### Assign Values into Arrays of Buses

How you assign values to one or more elements in an array of buses depends on your modeling requirement.

- To assign values to specified buses in an array of buses, use an Assignment block. For an example, see “Model Arrays of Buses”.

- To assign values to specified elements in a bus, use a Bus Assignment block. Access the bus in a subsystem such as a for-each subsystem or by selecting a bus from the array of buses with a Selector block. For an example, see “Assign Signal Values to Bus Elements” on page 81-51.

A Bus Assignment block can also assign or fully replace an array of buses that is an element of a bus.

- To assign values to elements of a bus in an array of buses, you can use a MATLAB Function block. For an example, see “Assign into Elements of Array of Buses” on page 81-80.

## Select Bus Elements from Array of Buses

To select a bus element from an array of buses:

- 1 Use a Selector block to select a bus from the array of buses. The input array of buses can have any dimension. The output bus of the Selector block is a selected or reordered set of elements from the input array of buses.
- 2 Use a Bus Selector block to select a bus element from the bus. The input for the Bus Selector block must be a bus.

For an example, see “Model Arrays of Buses”.

## Import Array of Buses Data

Use a root Import block to import (load) an array of structures of MATLAB `timeseries` objects for an array of buses. You can import partial data into the array of buses. For more information, see “Import Array of Buses Data” on page 75-62.

You cannot use a From Workspace or From File block to import data for an array of buses.

## Log Arrays of Buses

To export an array of buses, mark the signal for signal logging. For more information, see “Save Run-Time Data from Simulation”.

---

**Note** Simulink does not log signals inside referenced models in rapid accelerator mode.

---

To access the signal logging data for a specific signal in an array of buses, navigate through the structure hierarchy and specify the index to the specific signal. For details, see “Access Bus Data Logged Using Dataset Format”.

Root level bus outputs are not logged when you select the **Output** configuration parameter. Use standard signal logging instead, as described in “Save Signal Data Using Signal Logging” on page 77-42.

Do not use signal logging for buses or arrays of buses directly from within a for-each subsystem. Either use a Bus Selector block to select the bus element signals to log or add an Output block outside of the subsystem and then log that signal. For details, see “Log Signals in For-Each Subsystems” on page 77-67.

---

**Note** Signal logging is supported for arrays of buses with variable-size signals only when running a simulation in normal mode.

---

## Initialize Arrays of Buses

To specify a unique initial value for each of the individual signals in an array of buses, you can use an array of initial condition structures. Each structure in the array initializes one of the buses.

To initialize an array of buses with structure parameters, you can use:

- The number `0`. In this case, all the individual signals in the array of buses use the initial value `0`.
- A scalar `struct` that represents the same hierarchy of fields and field names as the bus type. In this case, the scalar structure expands to initialize each of the individual signals in the array of buses.
- An array of structures that specifies an initial value for each of the individual signals in the array of buses.

If you use an array of structures, all the structures in the array must have the same hierarchy of fields. Each field in the hierarchy must have the same characteristics across the array:

- Field name
- Numeric data type, such as `single` or `int32`
- Complexity
- Dimensions

You cannot use partial structures.

For examples, see “Initialize Buses and Arrays of Buses Using Type Editor” and “Programmatically Initialize Arrays of Buses” on page 81-78.

## Code Generation

Code generation for arrays of buses produces structures with a specific format. See “Code Generation for Arrays of Buses” on page 81-92.

---

**Note** Code generation is not supported for arrays of buses with variable-size signals.

---

## Programmatically Initialize Arrays of Buses

This example shows how to initialize an array of buses. Suppose that you define `Simulink.Bus` objects named `MyData` and `PressureBus`.

```
% Bus object: MyData
clear elems;
elems(1) = Simulink.BusElement;
elems(1).Name = 'temperature';
elems(1).DataType = 'int16';

elems(2) = Simulink.BusElement;
elems(2).Name = 'pressure';
elems(2).DataType = 'Bus: PressureBus';

MyData = Simulink.Bus;
MyData.Elements = elems;

% Bus object: PressureBus
clear elems;
elems(1) = Simulink.BusElement;
elems(1).Name = 's1';

elems(2) = Simulink.BusElement;
elems(2).Name = 's2';

PressureBus = Simulink.Bus;
PressureBus.Elements = elems;
clear elems;
```

The object named `MyData` has two elements, named `temperature` and `pressure`. The `pressure` element uses `Bus` object `PressureBus`, which has two elements, named `s1` and `s2`.

The data type of `temperature` is `int16`, and the data types of `s1` and `s2` are `double`.

To specify initial conditions for an array of buses, create a variable whose value is an array of initial condition structures.

```
initValues(1).temperature = int16(5);
initValues(1).pressure.s1 = 9.87;
initValues(1).pressure.s2 = 8.71;

initValues(2).temperature = int16(20);
initValues(2).pressure.s1 = 10.21;
initValues(2).pressure.s2 = 9.56;

initValues(3).temperature = int16(35);
initValues(3).pressure.s1 = 8.98;
initValues(3).pressure.s2 = 9.17;
```

The variable `initValues` provides initial conditions for an array of three buses. You can use `initValues` to specify the **Initial condition** parameter of a block such as a `Unit Delay` block.

Alternatively, you can use a scalar structure to specify the same initial conditions for all the buses in the array.

```
initStruct.temperature = int16(15);
initStruct.pressure.s1 = 10.32;
initStruct.pressure.s2 = 9.46;
```

If you specify `initStruct` in the **Initial condition** parameter of a block, each bus in the array uses the same initial value, 15, for the signal element `temperature`. Similarly, the buses use the initial value 10.32 for the element `pressure.s1` and the value 9.46 for the element `pressure.s2`.

To create an array of structures for a bus that uses a large hierarchy of signal elements, consider using the `Simulink.Bus.createMATLABStruct` function.

Suppose `pressure` represents a nested array of buses with dimensions [1 3]. To programmatically set this value, access the `Dimensions` property of the second element of the `Elements` property of the `MyData` object.

```
MyData.Elements(2).Dimensions = '[1 3]';
```

Create an array of four initialization structures by using the function `Simulink.Bus.createMATLABStruct`. Store the array in the variable `initStruct`. Initialize all the individual signals to the ground value, 0.

```
initStruct = Simulink.Bus.createMATLABStruct('MyData', [], [1 4])
```

```
initStruct =
```

```
1×4 struct array with fields:
```

```
temperature
pressure
```

Inspect the created structure.

- 1 In the base workspace, double-click the variable `initStruct` to view it in the variable editor.

The four structures in the array each have the fields `temperature` and `pressure`.

- 2 To inspect a `pressure`, double-click one of the fields.

The value of each of the four `pressure` fields is an array of three substructures. Each substructure has the fields `s1` and `s2`.

To provide unique initialization values for the signals in an array of buses, you can interactively specify the values using the variable editor.

Alternatively, you can programmatically specify the values. For example, to assign value of 15.35 to the field `s1` of the second substructure `pressure` in the third structure of `initStruct`, enter:

```
initStruct(3).pressure(2).s1 = 15.35;
```

## Assign into Elements of Array of Buses

This example shows how to assign data for the buses in an array of buses. MATLAB Function blocks can directly assign the data for a bus in an array of buses. They can also make a partial assignment to certain elements in the array of buses.

Open the example model, which contains a MATLAB Function block that receives a nonvirtual bus.

Copyright 2021 The MathWorks, Inc.

The In Bus Element and Out Bus Element blocks specify a `Simulink.Bus` object named A. To view the hierarchy and specified attributes of the input bus, double-click the In Bus Element block named InBus.

- ▼ InBus (dt: Bus: A, nonvirtual, dims: 1)
  - a (dt: boolean, dims: [1], Fixed, real)
  - ▼ a1 (dt: Bus: B, nonvirtual, dims: [10], Fixed ...)
    - b (dt: int32, dims: [5], Fixed, real)
    - b1 (dt: single, dims: [1], Fixed, real)

The top-level bus is a nonvirtual bus defined by the `Simulink.Bus` object named A. The bus element named a1 is an array of buses. It contains ten nonvirtual buses defined by the Bus object named B.

The MATLAB Function block specifies Bus object A as the data type for the block input and output. To view this specification, double-click the MATLAB Function block. In the toolstrip, on the **Function** tab, click **Ports & Data Manager**.

	Name	Scope	DataType
	u	Input	Bus: A
	y	Output	Bus: A

The MATLAB Function block uses a function to iteratively assign new values to element b of each nonvirtual bus in the array of buses. The function also assigns a new value to bus element a.

```
function y = fcn(u)

y = u;
y.a = false;
for idx = 1:length(y.a1)
    y.a1(idx).b = int32(zeros(5,1));
end
```

## Iteratively Process Nonvirtual Buses with Arrays of Buses

Update a model to use an array of buses when:

- The model contains many subsystems that perform the same kind of processing.
- The model has grown in complexity.

For example, compare the following modeling patterns.

In the original modeling pattern:

- Three nonvirtual buses specify a `Simulink.Bus` object data type named `BusObject`.
- Each of these nonvirtual buses connects to a Subsystem block.

- The Subsystem blocks, named `ScalarAlgorithm1`, `ScalarAlgorithm2`, and `ScalarAlgorithm3`, have the same content.

The original modeling pattern is inefficient. To process each nonvirtual bus, the model has copies of the subsystem that encapsulates the algorithm. To process another nonvirtual bus with the same `BusObject` data type, the model requires another copy of the subsystem.

To convert the original modeling pattern to use an array of buses:

- 1 Identify the buses and associated algorithm that you want to convert.
  - The buses that you concatenate in an array of buses must be nonvirtual. If the buses are virtual and all their elements have the same sample time or inherit their sample time, convert the virtual buses to nonvirtual buses.
  - The nonvirtual buses cannot have variable-dimensioned and frame-based elements.
- 2 Use a Vector Concatenate block to group the nonvirtual buses into an array of buses.
- 3 Replace all identical copies of the subsystem with a for-each subsystem that encapsulates the algorithm.
- 4 Connect the array of buses to the for-each subsystem.
- 5 Configure the For Each Subsystem block to iterate over the input array of buses and concatenate the output.

The scalar algorithm within the for-each subsystem cannot have continuous states.

The array of buses lets you replace multiple identical subsystems with one subsystem that supports iterative processing.

For more information on creating arrays of buses, see “Group Nonvirtual Buses in Arrays of Buses” on page 81-71.

## Share and Reuse Bus-Routing Blocks

With custom libraries, you can share and reuse blocks that input or output buses. For a block linked to a parent library block that expects a bus input, you must provide the appropriate input bus. For example, the input bus for a Bus Selector block that is linked to a library must contain signals that have the same name as the signals that the parent library block selects.

To modify the parent library block, perform these steps. For details about modifying library links, see “Linked Blocks” on page 44-12.

- 1 Copy the parent library block to a model.
- 2 Connect a bus to the input port of the block.
- 3 Disable the link to the parent library block.
- 4 Edit the block within the context of the model.
- 5 Resolve the link to the library.
- 6 In the Link Tool, in **Push/Restore Mode**, select Push to place the edited content in the library.
- 7 Save the library.

To lock the interface of a parent library block, set its data type to a `Simulink.Bus` object.

With subsystem references, you can share and reuse a subsystem containing blocks that input or output buses and their associated signal lines. For more information, see “Subsystem Reference” on page 4-26.

## Generate Code for Nonvirtual Buses

If you have Simulink Coder, whether you use a virtual or nonvirtual bus can make a significant difference in the efficiency, size, and readability of generated code.

- A virtual bus does not appear as a structure or any other coherent unit in generated code. A separate copy of any algorithm that manipulates the bus exists for each element. In general, virtual buses do not affect the generated code.
- A nonvirtual bus appears as a structure in generated code, and only one copy exists of any algorithm that uses the bus. The use of a structure in the generated code can be helpful when tracing the correspondence between the model and the code.

For example, suppose a bus passes through a Unit Delay block. For simplicity, the bus contains only three elements: a, b, and c.

Virtual buses do not require type definitions. The generated *model.h* file defines one Unit Delay block for each element of the virtual bus.

```
typedef struct {
    real_T UnitDelay_1_DSTATE; /* '<Root>/Unit Delay' */
    real_T UnitDelay_2_DSTATE; /* '<Root>/Unit Delay' */
    real_T UnitDelay_3_DSTATE; /* '<Root>/Unit Delay' */
} DW_model_T;
```

Nonvirtual buses require type definitions. `Simulink.Bus` objects appear in the generated *model\_types.h* file as structures for nonvirtual buses.

```
typedef struct {
    real_T a;
    real_T b;
    real_T c;
} BusObject;
```

The generated *model.h* file defines one Unit Delay block for the nonvirtual bus, using the `BusObject` structure.

```
typedef struct {
    BusObject UnitDelay_DSTATE; /* '<Root>/Unit Delay' */
} DW_model_T;
```

To group signals into structures in the generated code, use nonvirtual buses. See “Organize Data into Structures in Generated Code” (Simulink Coder).

To efficiently generate code for a model that uses buses, see “Generate Efficient Code for Bus Signals” (Simulink Coder). Generating code for nonvirtual buses can result in multiple copies of some buses.

If you use a nonvirtual bus as an input to or an output from a referenced model:

- You can only configure the `I/O arguments step method` style of the C++ class interface for the referenced model when using a nonvirtual bus or when using the `Default` style of the C++ class interface.
- You can only configure function prototype control for the referenced model when using a nonvirtual bus.

## Control Data Types of Initial Condition Structure Fields

You can use a MATLAB structure to initialize the signal elements in a bus. See “Specify Initial Conditions for Bus Elements” on page 81-64.

When you create a MATLAB structure to initialize a bus that contains elements that use numeric data types other than `double`, you need to set the values of structure fields. The technique that you choose to set the values can influence the efficiency and readability of the generated code.

- To avoid manually matching the field data types with the data types of the signal elements, use untyped expressions to set the field values. As you develop and rapidly prototype a model, use this technique for convenience.
- To generate more efficient production code and to avoid floating-point storage in the code, match the data types of the structure fields with the data types of the corresponding signal elements.

For examples and more information about tunable initial conditions in the generated code, see “Control Signal and State Initialization in the Generated Code” (Simulink Coder).

### Inline Numeric Values of Structure Fields in the Generated Code

If you set the **Default parameter behavior** configuration parameter to `Inlined`, by default, the field values of the initial condition structure appear in the generated code as inlined numbers (non-tunable). For these structures, use untyped expressions to set the field values in Simulink. The field values do not require data types because the structure is not tunable in the generated code.

However, if you later set **Default parameter behavior** to `Tunable` or apply a storage class to the structure by using a `Simulink.Parameter` object, the code can contain floating-point storage and inefficient explicit typecasts and bit shifts. To avoid these issues, consider matching the data types of the structure fields with the data types of the corresponding signal elements.

### Generate Tunable Structure Specified Directly in a Block Dialog Box

Suppose that you specify an initial condition structure directly in a block dialog box, or in a `Simulink.Signal` object, with an expression such as `struct('signal1',5,'signal2',7.2)` (instead of storing the structure in a variable or `Simulink.Parameter` object). In this case, to generate a tunable structure in the code, you set **Default parameter behavior** to `Tunable`.

Use the table to decide how to control the data types of the fields in these initial condition structures.

Goal		Technique
Use a nonvirtual bus.		Use untyped expressions to set the field values.
Use a virtual bus.	Avoid manually matching the field data types with those of the signal elements.	Use untyped expressions to set the field values.
	Generate more efficient code and avoid floating-point storage.	Match the structure field data types with the signal element types. Store the data type information in the <code>struct</code> by using typed expressions to set the field values.

## Generate Tunable Structure Stored in a Variable or Parameter Object

Suppose that you store an initial condition structure in a variable or `Simulink.Parameter` object that you create in the base workspace or a data dictionary. For example, you use this technique to share the structure between multiple blocks, or to generate a tunable structure when you set **Default parameter behavior** to `Inlined`. In this case, use the table to decide how to control the data types of the fields in the initial condition structure.

Goal	Technique
Avoid manually matching the field data types with those of the signal elements.	Use untyped expressions to set the field values. In the generated code, the structure fields use the data type <code>double</code> . The generated algorithm uses explicit typecasts to reconcile the data type mismatches.
Generate more efficient code and avoid floating-point storage.	Match the structure field data types with the signal element types. Store the data type information in the structure fields or use a <code>Simulink.Bus</code> object to control the data types of the fields and the signal elements simultaneously.  To use the Model Advisor to check your model for potentially expensive data type mismatches, see “Check structure parameter usage with bus signals”.
Initialize an array of buses in a referenced model by using an array of structures. Pass the array of structures to the referenced model as the value of a model argument in the Model block.	Match the structure field data types with the signal element types. Store the data type information in the structure fields or use a <code>Simulink.Bus</code> object to control the data types of the structure fields and the signal elements simultaneously.  If you do not pass the structure to the referenced model as a model argument, follow the other guidelines for nonvirtual buses to decide how to control the data types.

### Use Untyped Expressions to Set Field Values

You can use untyped expressions to set the structure field values. The fields implicitly use the data type `double`. Set the field values to represent the ideal, real-world initialization values.

You avoid manually matching the field data types with the data types of the corresponding signal elements. However, depending on the virtuality of the bus, the method that you use to apply the initial condition, and other factors, you can introduce floating-point storage and potentially inefficient typecasts in the generated code.

Suppose that you create a bus `myBusSig` with these signal elements. Each element uses a specific data type.

```
myBusSig
    signalElement1 (int32)
    signalElement2 (boolean)
    signalElement3 (single)
```

Create an initial condition structure `initStruct`. Use untyped expressions to specify the field values. Optionally, to enhance readability of the Boolean field `signalElement2`, use the value `false` instead of `0`.

```
initStruct.signalElement1 = 3;  
initStruct.signalElement2 = false;  
initStruct.signalElement3 = 17.35;
```

If you use the function `Simulink.Bus.createMATLABStruct` to create the structure, the function stores data type information in the structure fields. After you create the structure, you can optionally use untyped expressions to change the field values. See “Use `Simulink.Bus.createMATLABStruct` to Create Structure” on page 81-89.

### Store Data Type Information in Structure Fields

To store data type information in the structure fields, use typed expressions to set the field values, or use the function `Simulink.Bus.createMATLABStruct` to create the structure. Use these techniques to generate efficient code by eliminating floating-point storage and potentially inefficient explicit typecasts.

To avoid manually applying new data types to the structure fields when you change the data types of the corresponding signal elements, consider using a `Simulink.Bus` object to control the data types in the structure and the bus simultaneously.

### Use Typed Expressions to Set Field Values

Suppose that you create a bus `myBusSig` with these elements, which use specific data types.

- `signalElement1` (`int32`)
- `signalElement2` (`boolean`)
- `signalElement3` (`single`)

Create an initial condition structure `initStruct` by using typed expressions to set the field values. Match the data types of the fields with the data types of the corresponding signal elements.

```
initStruct.signalElement1 = int32(3);  
initStruct.signalElement2 = false;  
initStruct.signalElement3 = single(17.35);
```

The structure fields store data type information. If you later change the data type of a signal element, manually apply the new data type to the corresponding structure field.

To match a fixed-point data type, set the field value by using a `fi` object.

### Change Field Value by Preserving Data Type Information

Suppose that you change the value of a field in an existing initial condition structure. To preserve the data type information in the field you can use subscripted assignment, with the syntax `(:)`.

```
initStruct.signalElement3(:) = 16.93;
```

If you do not use subscripted assignment, you must remember to preserve the data type by using a typed expression.

```
initStruct.signalElement3 = single(16.93);
```

If you do not use either of these techniques, the field loses the data type information.

```
initStruct.signalElement3 = 16.93; % Field data type is now 'double'.
```

### Use `Simulink.Bus.createMATLABStruct` to Create Structure

You can use the function `Simulink.Bus.createMATLABStruct` to create a structure whose fields all have ground values, typically `0`. If you configure the data types of the signal elements before using the function, for example by setting the output data types of the blocks that generate the signal elements, each field in the output structure uses the same data type as the corresponding signal element. The fields store the data type information as if you use typed expressions to set the values.

You can initialize some of the signal elements with a value other than ground by passing a partial structure to the function. When you create this partial structure, match the data type of each field with the data type of the corresponding signal element by using typed expressions. For more information and examples, see `Simulink.Bus.createMATLABStruct`.

When you later change the value of a field in the structure, choose one of these techniques to set the new value:

- Untyped expression. The field value no longer stores the data type information.
- Typed expression or subscripted assignment. The field value continues to store the data type information.

### Use Bus Object as Data Type of Initial Condition Structure

Whether you store data type information in the structure fields or use untyped expressions to set the field values, you can use a `Simulink.Bus` object as the data type of the entire initial condition structure. You can then manage the field values and data types independently.

If you use this technique, consider using untyped expressions to set the field values. Then, you do not need to match the field data types manually when you change the data types of the signal elements. To control the data types of the fields and the signal elements, use the `DataType` property of the elements in the `Bus` object.

Suppose that you use a Bus Creator block to create a bus `myBusSig` with these elements:

- `signalElement1` (`int32`)
- `signalElement2` (`boolean`)
- `signalElement3` (`single`)

- 1 Open the Type Editor.

```
typeeditor
```

- 2 Create a Bus object, `myBus`, that corresponds to the bus.

Name	Type
myBus	
— signalElement1	int32
— signalElement2	boolean
— signalElement3	single

- 3 Create an initial condition structure `initStruct`. Used untyped expressions to set the field values. To enhance readability of the field `signalElement2`, use the Boolean value `false` instead of `0`.

```

initStruct.signalElement1 = 3;
initStruct.signalElement2 = false;
initStruct.signalElement3 = 17.35;

```

- 4 To represent the structure, create a `Simulink.Parameter` object.

```
initStruct = Simulink.Parameter(initStruct);
```

- 5 Use the parameter object to specify an initial condition for the bus. For example, in a Unit Delay block dialog box, set **Initial condition** to `initStruct`.

- 6 Use the `Bus` object to specify the data type of the parameter object.

```
initStruct.DataType = 'Bus: myBus';
```

- 7 Use the `Bus` object to specify the data type of the bus. For example, in the Bus Creator block dialog box, set **Output data type** to `Bus: myBus`.

During simulation and in the generated code, the structure fields and the signal elements use the data types that you specify in the `Bus` object. Before simulation and code generation, the parameter object casts the structure fields to the data types that you specify in the `Bus` object.

For basic information about `Bus` objects, see “Specify Bus Properties with `Simulink.Bus` Object Data Types” on page 81-58.

### Configure Data Types for Existing Structure

To remove data type information from all the fields of a structure, you can write a custom function that replaces the field values with `double` numbers. Use the example function `castStructToDbl` as a template.

```

function outStruct = castStructToDbl(inStruct)
%outStruct = castStructToDbl(inStruct) casts the leaf fields of inStruct to
% doubles and returns the resulting structure as outStruct. This function
% operates on nested structures and one-dimensional arrays of structures.
%
% Use this function on a structure parameter that you previously created for
% bus signal initialization. The resulting structure contains only doubles,
% logicals, and instances of enumerated types. When you simulate, the bus
% elements cast the values of the structure fields.
%
% To prevent loss of data, save the original structure in
% a MAT-file or .m file.
%
% This function casts only leaf fields whose data types are floating-point,
% integer, and fixed-point types.

% Copy the input struct.
outStruct = inStruct;

% Get a list of all of the field names. Even if the structure contains
% nested structures, this list includes only the names of the fields of
% inStruct.
fieldNamesList = fieldnames(inStruct);

% If this structure is an array of structures, iterate through the
% structures.
for j = 1:length(inStruct)

for i = 1:length(fieldNamesList)

tempField = inStruct(j).(fieldNamesList{i});

% If this field is another structure, use castStructToDbl().
if isstruct(tempField)
outStruct(j).(fieldNamesList{i}) = castStructToDbl(tempField);

% If this field is not a structure, a Boolean, or an
% enum, but is numeric, then cast it to double.
elseif ~isenum(tempField) && ~islogical(tempField) && isnumeric(tempField)
outStruct(j).(fieldNamesList{i}) = cast(tempField,'double');

```

```

    end % if
end % for
end % for
end % function

```

To convert a structure that uses doubles to one that stores data type information, you can create a reference structure using the function `Simulink.Bus.createMATLABStruct`. You can then write a custom function to cast the field values to the data types in the reference structure. Use the example function `castStructFromDbl` as a template.

```

function outStruct = castStructFromDbl(inStruct,refStruct)
%outStruct = castStructFromDbl(inStruct,refStruct) casts the leaf fields of
%inStruct to the data types used by the corresponding fields of refStruct
%and returns the resulting structure as outStruct.
%
%Use this function on a structure parameter, inStruct, that you previously
%created for bus signal initialization. The fields of outStruct
%use the ideal values specified in inStruct and the data types specified in
%refStruct.
%
%To create refStruct, use the function Simulink.Bus.createMATLABStruct to
%generate a structure from a bus signal in a model or from a bus object.
%Each field in the generated structure uses the same data type as the
%corresponding bus element.
%
%To prevent loss of data, save the original structure inStruct in
%a MAT-file or .m file.
%
%This function casts only leaf fields of inStruct whose data types are floating-point,
%integer, and fixed-point types.

% Copy the input struct.
outStruct = inStruct;

% Get a list of all of the field names. Even if the structure contains
% nested structures, this list includes only the names of the fields of
% inStruct.
fieldNamesList = fieldnames(inStruct);

% If this structure is an array of structures, iterate through the
% structures.
for j = 1:length(inStruct)
    for i = 1:length(fieldNamesList)
        tempField = inStruct(j).(fieldNamesList{i});

        % If this field is another structure, use castStructFromDbl().
        if isstruct(tempField)
            tempfieldref = refStruct.(fieldNamesList{i});
            outStruct(j).(fieldNamesList{i}) = castStructFromDbl(tempField,tempfieldref);

            % If this field is not a structure, a Boolean, or an
            % enum, but is numeric, then cast it to the corresponding type in
            % refStruct.
            elseif ~isenum(tempField) && ~islogical(tempField) && isnumeric(tempField)
                outStruct(j).(fieldNamesList{i}) = cast(tempField,'like',...
                    refStruct.(fieldNamesList{i}));

        end % if
    end % for
end % for
end % function

```

### Check for Mismatched Data Types with Model Advisor

To detect when the data types of structure fields are not consistent with associated bus elements, use the Model Advisor.

- 1 On the **Modeling** tab, click **Model Advisor**.
- 2 Click **OK**.
- 3 Under **By Task > Modeling Signals and Parameters using Buses**, select **Check structure parameter usage with bus signals**.

- 4 Click the **Run This Check** button.

## Code Generation for Arrays of Buses

When you generate code for a model that includes an array of buses, a `typedef` that represents the underlying bus type appears in the `*_types.h` file.

Code generation produces an array of C structures that you can integrate with legacy C code that uses arrays of structures. As necessary, code for bus variables (arrays) is generated in the following structures:

- Block IO
- States
- External inputs
- External outputs

Here is a simplified example of some generated code for an array of buses.

```
typedef struct {  
    real_T a;  
    real_T b;          /* Block signals (auto storage) */  
} BusObject;  
typedef struct {  
    BusObject ForEachSubsystem_IterInp_0[2];  
} BlockIO_aob1;
```

For basic information about code generation for nonvirtual buses, which appear in the code as structures, see “Organize Data into Structures in Generated Code” (Simulink Coder).

- “Use Buses at Model Interfaces” on page 81-31
- “Inspect Generated Code for Nonvirtual Buses” on page 81-93

## Inspect Generated Code for Nonvirtual Buses

This example shows how nonvirtual buses appear in the generated code for a model. The steps require a Simulink® Coder™ license.

Open and simulate the example model, which contains a nonvirtual bus.

Copyright 2019 The MathWorks, Inc.

Open the **Simulink Coder** app. On the **Apps** tab, click the arrow on the far right of the **Apps** section. Under **Code Generation**, click **Simulink Coder**.

To generate code for the model, on the **C Code** tab, click **Generate Code**.

To see the generated files, open the `NonvirtualBusCodeGenModel_grt_rtw` folder.

`NonvirtualBusCodeGenModel_types.h` defines the `Simulink.Bus` object as a struct.

```
typedef struct {
    real_T a;
    real_T b;
    real_T c;
} BusObject;
```

`NonvirtualBusCodeGenModel.h` defines the Unit Delay block using the `BusObject` struct.

```
typedef struct {
    BusObject UnitDelay_DSTATE;          /* '<Root>/Unit Delay' */
} DW_NonvirtualBusCodeGenModel_T;
```

`NonvirtualBusCodeGenModel.c` implements the Unit Delay block, which passes the nonvirtual bus to the Output block.

```
NonvirtualBusCodeGenModel_Y.Out1 =  
NonvirtualBusCodeGenModel_DW.UnitDelay_DSTATE;
```

## Trace Connections Using Interface Display

In the Simulink Editor, you can turn on and off the display of interfaces in a model. When you are building large, complex models, you can connect or add signal lines between blocks or buses that are at different levels. The interface view allows you to trace signals through the nested levels. This capability helps you to:

- Identify inputs and outputs.
- Trace signal lines and bus elements to sources and terminations.
- Annotate signal characteristics such as data type, dimensions, and sample time.
- View units associated with signals, where applicable.

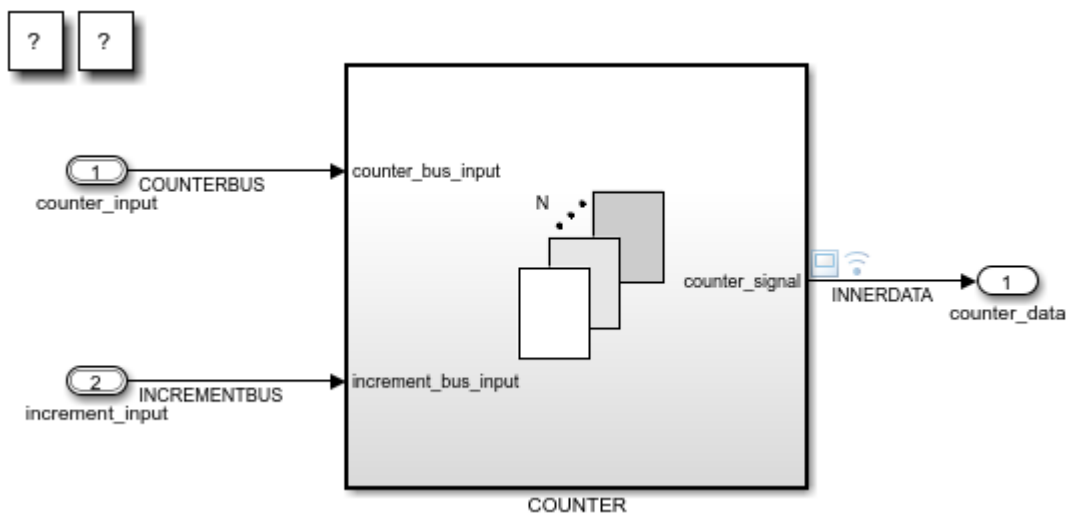

When you build a model, transition block pairs such as Inport and Outport and From and Goto help you to simplify connections of the crossovers among many signal lines. The interface view enables you to trace the hand-off and receipt between such blocks by way of colored highlights.

### Trace Connections in a Subsystem

This example shows how to use the display of model interfaces to examine, trace, and understand the flow of signals and buses. This model propagates buses into referenced models.

- 1 Open the model `sldemo_md\ref_counter_bus`.

The **counter\_bus\_input** port channels the data and saturation limits of the counter to count and sets the upper and lower limit values. The **increment\_bus\_input** port channels a bus to change the increment and reset the counter.

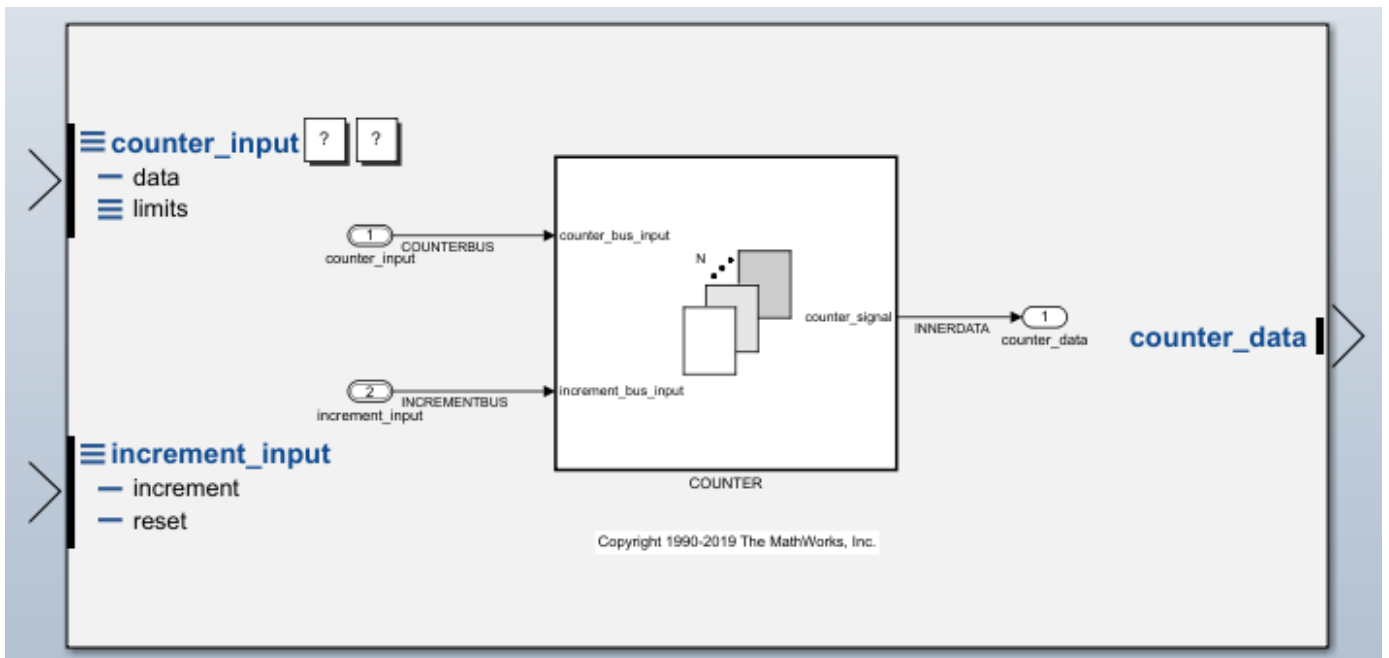

- 2 On the **Modeling** tab, under **Design**, click **Model Interface** to enable the interface view.

**Tip** Use the perspectives control in the lower-right corner of the model to toggle the display of interfaces.

The three bars next to the `counter_input` and `increment_input` interfaces indicate the bus input signals. The single bars indicate data lines, such as counts per second, or command lines, such as reset, to start a new counting sequence. The three bars next to `limits` indicate that buses are nested inside the subsystem named `COUNTER`.

- 3 Under `counter_input`, click `data`.

The path for the `data` element appears in blue. The subsystem named `COUNTER` is highlighted, indicating the path continues within it.

4 Double-click the subsystem named COUNTER.

The continuation of the path for the data signal appears in blue.

5 On the **Modeling** tab, click **Update Model**.

---

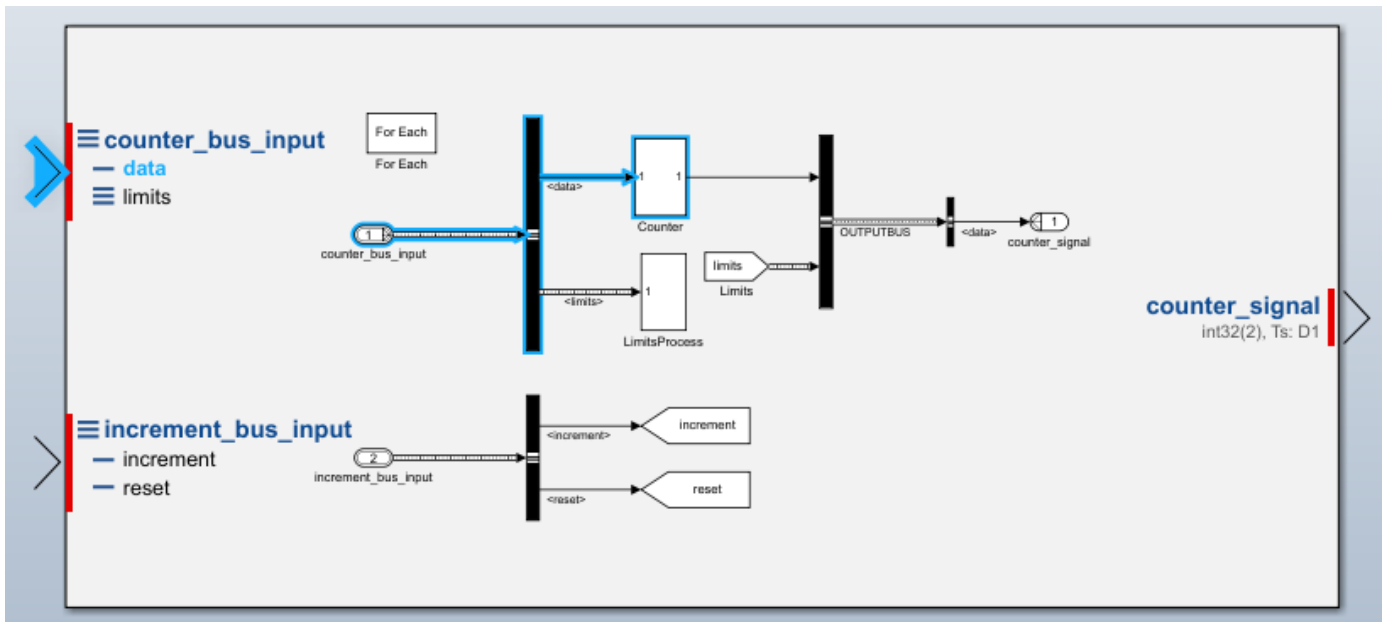

**Note** This model requires values from a parent model to simulate completely.

---

The counter\_signal interface displays these signal attributes, which help you to synchronize signals between blocks during simulation:

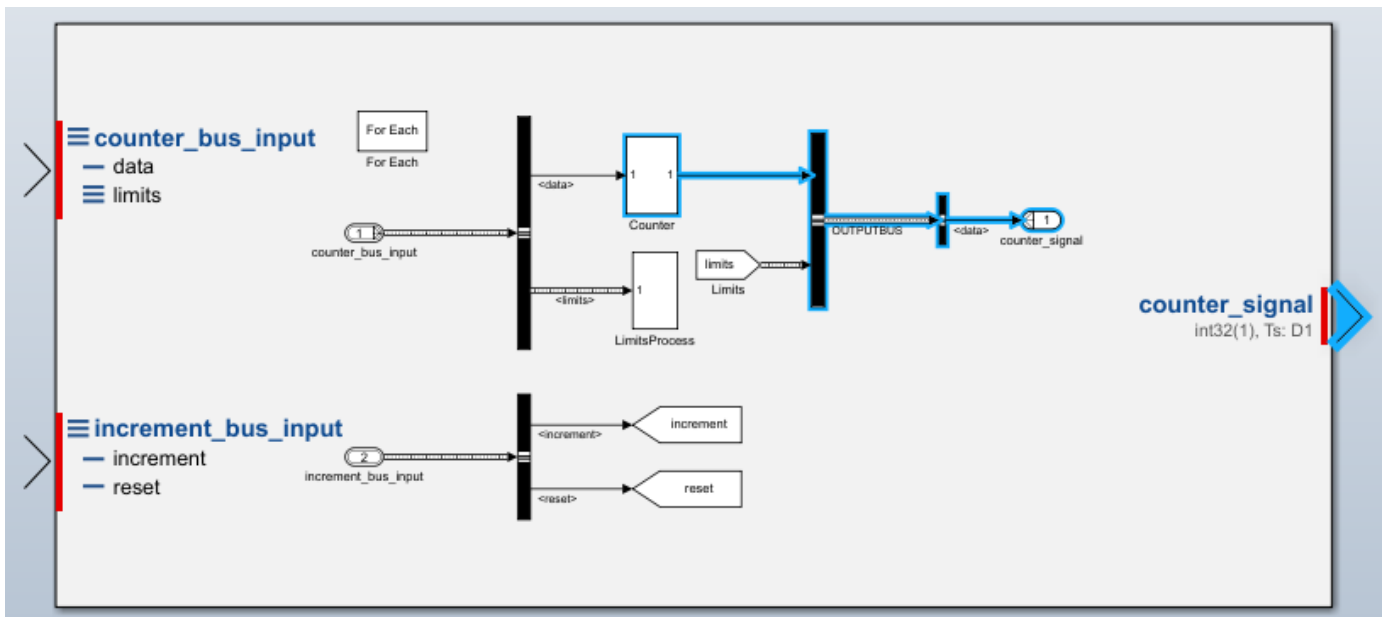

- Data type: int32 (signed 32-bit integer)
- Dimensions: (2) (a 1-D Simulink representation of a scalar)
- Sample time: Ts:D1 (a discrete sample time of D1, which is the highest speed)

In addition, when you update the diagram with interfaces displayed, the model displays the color code for sample time at each interface. For example, this model displays a red bar at each interface to indicate a sample time of D1.

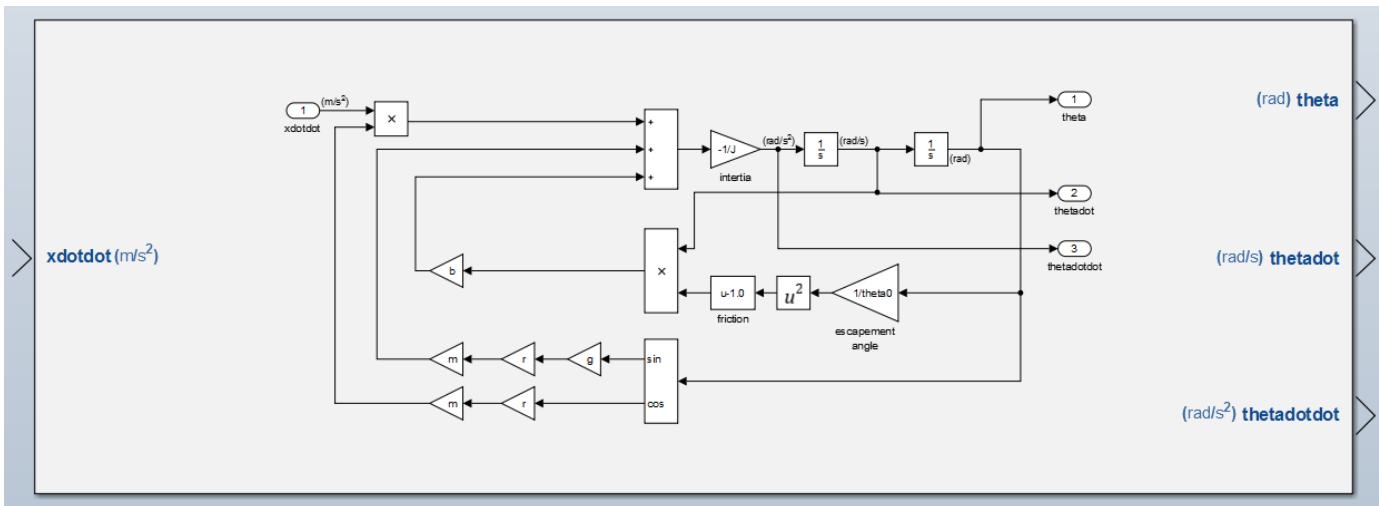

**Tip** To display a legend of the meaning of sample time colors, on the **Debug** tab, select **Information Overlays > Colors**.

- Click the `counter_signal` output interface to see the output of the bus outlined in blue, where the path ends.

- If you want to print this diagram with the interfaces displayed, in the **Simulation** tab, click **Print**.

When signals in your model have units associated with them, you see the units in the interface view. For example, in the `sldemo_metro` model, the subsystem named `Metronome1` shows units for inputs and outputs of the subsystem in the interface view.

To modify the attributes of the existing interface (such as signal names, data types, and dimensions), consider using the **Model Data Editor**. On the **Modeling** tab, click **Model Data Editor**.

## Variable-Size Signal Basics

### In this section...

“How Variable-Size Signals Propagate” on page 82-2  
 “Determine Whether Signal Line Has Variable Size” on page 82-3  
 “Empty Signals” on page 82-4  
 “Simulink Block Support for Variable-Size Signals” on page 82-4  
 “Variable-Size Signal Limitations” on page 82-6

A Simulink signal can be a scalar, vector (1-D), matrix (2-D), or N-D. A Simulink variable-size signal is a signal whose size (the number of elements in a dimension), in addition to its values, can change during a model simulation. However, during a simulation, the number of dimensions cannot change. This capability allows you to model systems with varying resources, constraints, and environments.

You can create variable-size signals in your Simulink model by using:

- Switch or Multiplex blocks with different input ports having fixed-size signals with different sizes. The output is a variable-size signal.
- A Selector block with the **Starting and ending indices (port)** indexing option. The index port signal can specify different subregions of the input data signal which produce an output signal of variable size as the simulation progresses.
- An S-Function block with the output port configured for a variable-size signal. The output includes not only the values but also the dimension of the signal.
- A MATLAB Function block with the output configured for a variable-size signal.

### How Variable-Size Signals Propagate

In the Simulink environment, variable-size signals can change their size during model execution in one of two ways:

- **At every step of model execution.**

Various blocks in the model modify the sizes of the signals during execution of the output method.

- **Only during initialization of conditionally executed subsystems.**

Size changes occur during distinct mode-switching events in subsystems such as Action, Enable, and Function-Call subsystems.

You can see the key difference by considering a Discrete 2-Tap Filter block with states.

### Discrete 2-Tap Filter

Assume that the input signal dimension to this filter changes from 4 to 1 during simulation. It is ambiguous when and how the states of the Unit Delay blocks should adapt from 4 to 1 to continue processing the input. To ensure consistency, both Unit Delay blocks must change their state behavior synchronously. To prevent ambiguity, Simulink generally disallows blocks whose number of states depends on input signal sizes in contexts where signal sizes change at any point during execution.

In contrast, consider the same Discrete 2-Tap Filter block in a Function-Call subsystem. Assume that this subsystem is using the second way to propagate variable-size signals. In this case, the size of the input signal changes from 4 to 1 only at the initialization of the subsystem. At initialization, the subsystem resets all of its states (including the states of the two Unit Delay blocks) to their initial values. Resetting the subsystem ensures no ambiguity on the assignment of states to the input signal of the filter.

“Mode-Dependent Variable-Size Signals” on page 82-14 shows how you can use the two ways of propagating variable-size signals in a complementary fashion to model complex systems.

### Determine Whether Signal Line Has Variable Size

The following example demonstrates how to use commands at the command prompt or in a script to determine whether a signal line has a variable size. In a large model or hierarchy of subsystems or referenced models, use this technique to determine whether a signal has a variable size due to an upstream block.

The example model `sldemo_varsize_basic` contains a signal `a` that is downstream of a Switch block.

- 1 Open the example model.
- 2 Select the Sum block whose output signal is labeled `a`.
- 3 Type the following at the command window to set the model to a compiled state (similar to a diagram update).

```
sldemo_varsize_basic([],[],[],'compile')
```

- 4 Get a handle to the block output port.

```
portHandles = get_param(gcf,'portHandles');
outPortHandle = portHandles.Outputport;
```

- 5 Query the programmatic parameter `CompiledPortDimensionsMode` of the output port.

```
varSize = get_param(outPortHandle,'CompiledPortDimensionsMode')
```

```
varSize =
    1
```

The value of the variable `varSize` is 1, which indicates that the signal `a` has variable size.

The value 0 indicates that a signal does not have variable size.

- 6 Terminate the model compilation.

```
sldemo_varsize_basic([],[],[],'term')
```

## Empty Signals

An empty signal is a signal with a length of 0. For example, signals with size [0], [0×3], [2×0], and [2×0×3] are all empty signals. Simulink allows empty signals with variable-size signals and supports most element-wise operations. However, Simulink does not support empty signals for blocks that modify signal dimensions. Unsupported blocks include Reshape, Permute, and Sum along a specified dimension.

## Simulink Block Support for Variable-Size Signals

The Simulink Block Data Type Support table includes a complete list of blocks that support variable-size signals.

To view the table:

- 1 Open a Simulink model.
- 2 In the MATLAB command line, enter `showblockdatatypetable`.

A separate window with the Simulink Block Data Type Support table opens.

An X in the **Variable-Size Support** column indicates support for that block.

---

**Tip** You can also view the table by entering `showblockdatatypetable` at the command prompt.

---

### Subsystem Initialization of Variable-Size Signals

The initial signal size from an Output block in a conditionally executed subsystem varies depending on the parameters you select.

If you set the **Propagate sizes of variable-size signals** parameter in the parent subsystem to **During execution**, the **Initial output** parameter for the Output block must not exceed the maximum size of the input port. If the **Initial output** parameter value is:

Initial output parameter	Initial output signal size
A nonscalar matrix	The initial output signal size is the size of the <b>Initial output</b> parameter.
A scalar	The initial output signal size is a scalar.

Initial output parameter	Initial output signal size
The default []	The initial output size is an empty signal (dimensions are all zeros).

If you set the **Propagate sizes of variable-size signals** parameter in the parent subsystem to **Only when enabling**, the **Initial output** parameter for the Output block must be a scalar value.

- When size is repropagated for the input of the Output block, the initial output value is set using scalar expansion from the scalar parameter value.
- If the **Initial output** parameter is the default value [], Simulink treats the initial output as a grounded value.
- If the model does not activate the parent subsystem at start time ( $t = 0$ ), the current size of the subsystem output corresponding to the Output block is set to maximum size.
- When its parent subsystem repropagates signal sizes, the values of the subsystem variable-size output signals are also reset to their initial output parameter values.

### Conditionally Executed Subsystem Blocks

Control port blocks are in conditionally executed subsystems. You can set the **Propagate sizes of variable-size signals** parameter for these blocks to **During execution**, **Only when execution is resumed** (Action Port), and **Only when enabling** (Enable and Trigger or Function-Call).

- Action Port
- Enable
- Trigger — **Trigger type** set to function-call

### Switching Blocks

Switching blocks support variable-size signals by allowing input signals with different sizes and propagating the size of the input signal to the output signal. You can set the **Allow different data input sizes** parameter for these blocks on the Signal Attributes pane to either on or off.

- Switch
- Multiport Switch
- Manual Switch

### Variable-Size Signal Limitations

The following table describes variable-size signal limitations.

Limitation	Workaround
Array format logging does not support variable-size signals.	Use a <b>Structure</b> , <b>Structure With Time</b> , or <b>Dataset</b> format for logging variable-size signals.
Variable-size signals must have a discrete sample time.	—
Embedded Coder does not support variable-size signals with ERT S-functions, custom storage classes, function prototype control, the AUTOSAR model interface, the C++ interface, and the ERT reusable code interface.	—
Simulink does not support variable-size parameter or DWork vectors.	—
Rapid accelerator mode does not support models having root-level input ports with variable-size signals.	—
Virtual buses that you use as inputs to or outputs from a referenced model (Model block) do not support variable-size signals.	Configure the bus signal as nonvirtual. For more information about using buses as inputs to or outputs from a referenced model, see “Use Buses at Model Interfaces” on page 81-31. For more information about controlling bus virtuality, see “Composite Interface Guidelines” on page 81-2.
Referenced models configured to use a local solver do not support variable-size signals on the model interface.	—
Variable-size signals are not supported for blocks that specify an initial condition as a MATLAB structure.	—
Variable-size signals are supported for arrays of buses only in normal simulation mode.	—
Some simulation modes do not support signal logging for arrays of buses with variable-size signals.	Simulate the model in normal mode to log arrays of buses with variable-size signals using signal logging.
Some simulation modes do not support signal logging for nonvirtual buses with variable-size signals.	Simulate the model in normal mode or accelerator mode to log: <ul style="list-style-type: none"> <li>• Nonvirtual buses that contain variable-size signals directly or in nested buses</li> <li>• Buses with nested nonvirtual buses that contain variable-size signals</li> </ul>
Signal logging is not supported for virtual buses with variable-size signals that are not contained within a nested nonvirtual bus.	—

<b>Limitation</b>	<b>Workaround</b>
You cannot apply a storage class to a root-level Outport block (see “C Code Generation Configuration for Model Interface Elements” (Simulink Coder)) if the signal that enters the block has a variable size.	Apply the storage class to the signal line instead of the Outport block.

## Inspect Variable-Size Signals on Simulink Models

### In this section...

“Variable-Size Signal Generation and Operations” on page 82-9

“Variable-Size Signal Length Adaptation” on page 82-11

“Mode-Dependent Variable-Size Signals” on page 82-14

“S-Functions Using Variable-Size Signals” on page 82-18

### Variable-Size Signal Generation and Operations

This example model shows how to create a variable-size signal from multiple fixed-size signals and from a single data signal. It also shows some of the operations you can apply to variable-size signals.

For a complete list of blocks that support variable-size signals, see “Simulink Block Support for Variable-Size Signals” on page 82-4.

- In the MATLAB Command Window, type
 

```
openExample('sldemo_varsize_basic')
varSize = get_param(outPortHandle,'CompiledPortDimensionsMode')
```
- In the Simulink Editor, on the **Debug** tab, select **Information Overlays > Signal Dimensions**. Run a simulation or press **Ctrl-D**.

The Simulink Editor displays the signal dimensions and line styles. See “Signal Basics” on page 80-2 for an interpretation of signal line styles.

- So that you can see the names of the blocks in the model, on the **Format** tab, clear **Auto > Hide Automatic Block Names**.

### Create a Variable-Size Signal from Fixed-Size Signals

One way to create a variable-size signal is to use the Switch block. The input signals to the Switch block can differ in their number of dimensions and in their size.

Output from the Switch block is a 2-D variable-size signal with a maximum size of 3x2. When you select the **Allow different data input sizes** parameter on the Switch block, Simulink does not expand the scalar value from the Constant1 block.

### Save Variable-Size Signal Data

You could add a To Workspace block to the output from the Switch block. Since the model already has a To Workspace block, the second To Workspace block would save data to a signal array named `simout2`. The `values` field logs the actual signal values. If logged signal data is smaller than the maximum size, values are padded with NaNs or appropriate values. To obtain these signal values, type:

```
simout2.signals.values
```

```
ans(:,:,1) =
```

```
    1    -1
   -2     2
   -3     3
```

```
ans(:,:,2) =
```

```
    1    -1
   -2     2
   -3     3
```

```
ans(:,:,3) =
```

```
    0    NaN
   NaN  NaN
   NaN  NaN
```

The `valueDimensions` field logs the dimensions of a variable-size signal. To obtain the dimensions, type:

```
simout2.signals.valueDimensions
```

The signal dimensions for the first three time steps are shown.

ans =

```

3     2
3     2
1     1

```

### Create a Variable-Size Signal from a Single Data Signal

The data signal (Constant5) is a 3x4 matrix. The Pulse Generator represents a control signal that selects a starting and ending index value ( [1 2] or [1 3] ). The Selector block then uses the index values to select different parts of the data signal at each time step and output a variable-size signal.

### View Changes in Signal Size

The output from the Selector block is either a 2x2 or 3x3 matrix. Because the maximum dimension for a variable-size signal is the 3x4 matrix from the data signal, the logged output signals are padded with NaNs.

Use the Probe or Width blocks to inspect the current dimensions and width of a variable-size signal. In addition, you can display variable-size signals on Scope blocks and save variable-size signals to the workspace using the To Workspace block.

### Process Variable-Size Signals

The remainder of the model shows various operations that are possible with variable-size signals. Operations include using the Gain, Sum, Math Function, and Matrix Concatenate blocks. You can connect variable-size signals with the From, Goto, Bus Assignment, Bus Creator, and Bus Selector blocks.

### Variable-Size Signal Length Adaptation

This example model corresponds to a hypothetical system where the model adapts the length of a signal over time. Length adaptation is based on the value of a control signal. When the control signal falls within one of three predefined ranges, the fixed-size raw data signal changes to a variable-size data signal.

The variable-size signal connects to a processing block, where blocks that support variable-size signals operate on it. A MATLAB Function block with both input and output signals of variable size allow more flexibility than other blocks supporting variable-size signals. See “Simulink Block Support for Variable-Size Signals” on page 82-4.

To open the example model, in the MATLAB Command Window, type:

```
openExample('sldemo_varsize_dataLengthAdapt')
```

So that you can see the names of the blocks, in the model, on the **Format** tab, clear **Auto > Hide Automatic Block Names**.

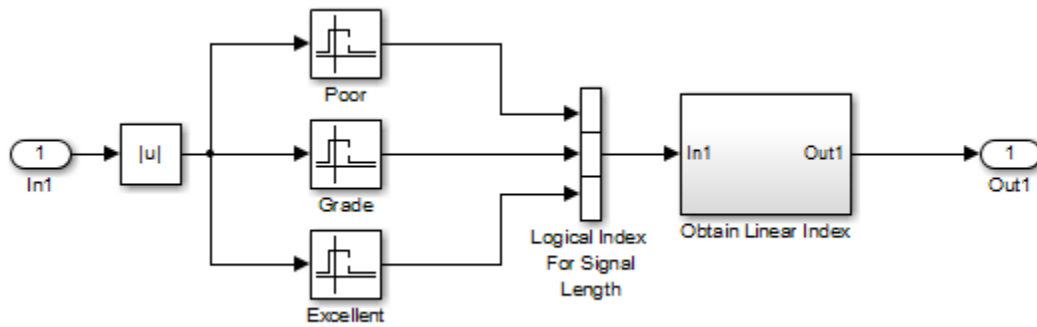

### Creating a Variable-Size Signal by Adapting the Length of a Data Signal

This model generates a data signal and converts the signal to a variable-size signal. The size of the signal depends on the value of a control signal. The raw data signal is a column vector with values from 1 to 9.

```
[1:9].'
```

```
ans =
     1
     2
     3
     4
     5
     6
     7
     8
     9
```

The Size Selection subsystem determines the quality of the data signal and outputs a quality value ( 1, 2, or 3). This value helps to select the length of the data signal in the Length Adaptation subsystem.

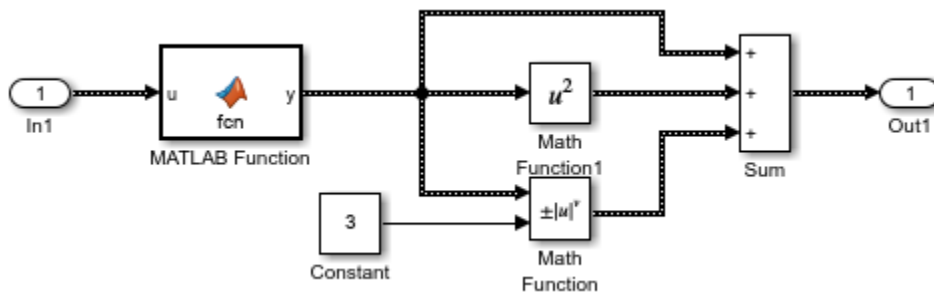

In the Length Adaptation subsystem, the Signal Size subsystem generates an index based on the quality value from the Size Selection subsystem (In2). The Data Selector block uses the starting and ending indices to adapt the length of the data signal (In1) and output a variable-size signal.

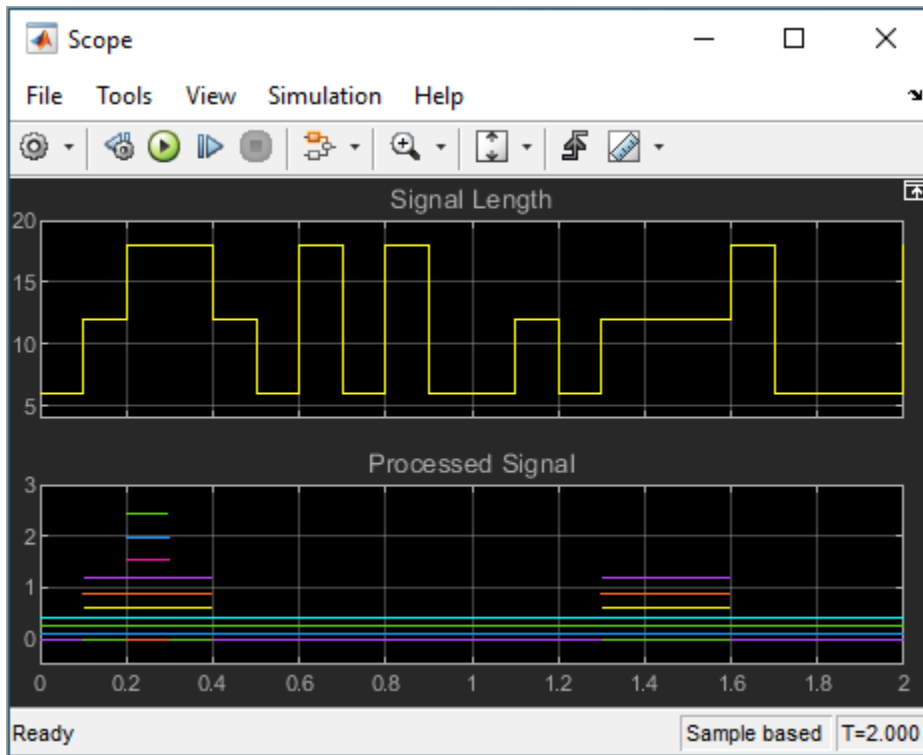

### Processing a Variable-Size Signal

The center section of the model processes the variable-size signal. The MATLAB Function block adds zeros between the data values in a way that is similar to upsampling a signal. The dimension of the signal changes from 9 to 18. The Math Function blocks show various manipulations you can do with variable-size signals.

### Visualizing a Variable-Size Signal

The right section of the model determines the signal width (size) and uses a scope to visualize the width and the processed data signal.

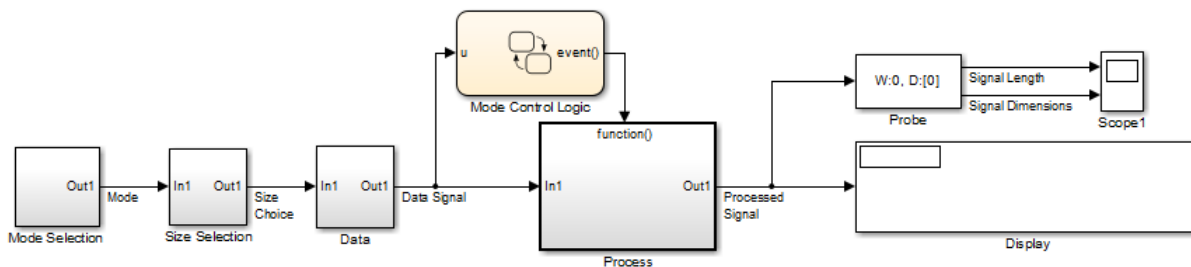

## Mode-Dependent Variable-Size Signals

This example model represents a system that has three operation modes. For each mode, the data signal to process has a different size.

The Process subsystem in this model receives a variable-size signal where the size of the signal depends on the operation mode of the system. For each mode change, the Stateflow chart, Mode Control Logic, detects when the data signal size changes. It then generates a function call to reset the blocks in the Process subsystem.

To open the model, In the MATLAB Command Window, type:

```
openExample('sldemo_varsize_multimode')
```

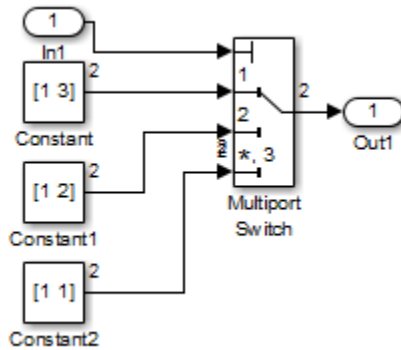

So that you can see the names of the blocks, in the model, on the **Format** tab, clear **Auto > Hide Automatic Block Names**.

## Creating a Variable-Size Signal Based on Mode

The Mode Selection subsystem determines the mode for processing a data signal and outputs a mode value ( 1, 2, or 3). This value helps to select the length of the data signal using the Size Selection and Data subsystems.

The Size Selection subsystem creates an index value from the mode value. In this example, the index values are [1 3], [1 2], and [1 1].

The Data subsystem takes a data signal (Constant block) and selects part of the data signal dependent on the mode. The output is a variable-size signal with a matrix size of 3x3, 2x2, and 1x1.

The dimensions of the raw data signal (Constant block) is a 3x3. After connecting a To Workspace block to a signal line, you can view the signal in the MATLAB Command Window by typing:

```
simout.signals.values
```

```
ans(:,:,1) =
```

```

1     4     7
2     5     8
3     6     9
```

The variable-size signal generated from the Data subsystem is also a 3x3 matrix. For shorter signals, the matrix is padded with NaNs.

```
simout.signals.values
```

```
ans(:,:,1) =
```

```
    1   NaN   NaN
   NaN   NaN   NaN
   NaN   NaN   NaN
```

```
ans(:,:,2) =
```

```
    1    4   NaN
    2    5   NaN
   NaN   NaN   NaN
```

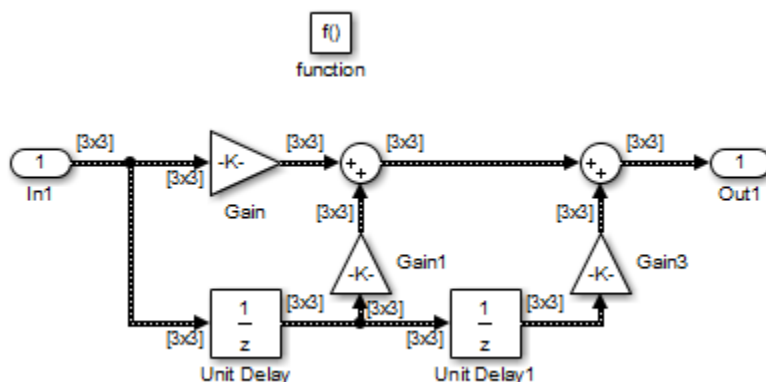

```
ans(:,:,3) =
```

```
    1    4    7
    2    5    8
    3    6    9
```

### Processing a Variable-Size Signal with a Conditionally Executed Subsystem

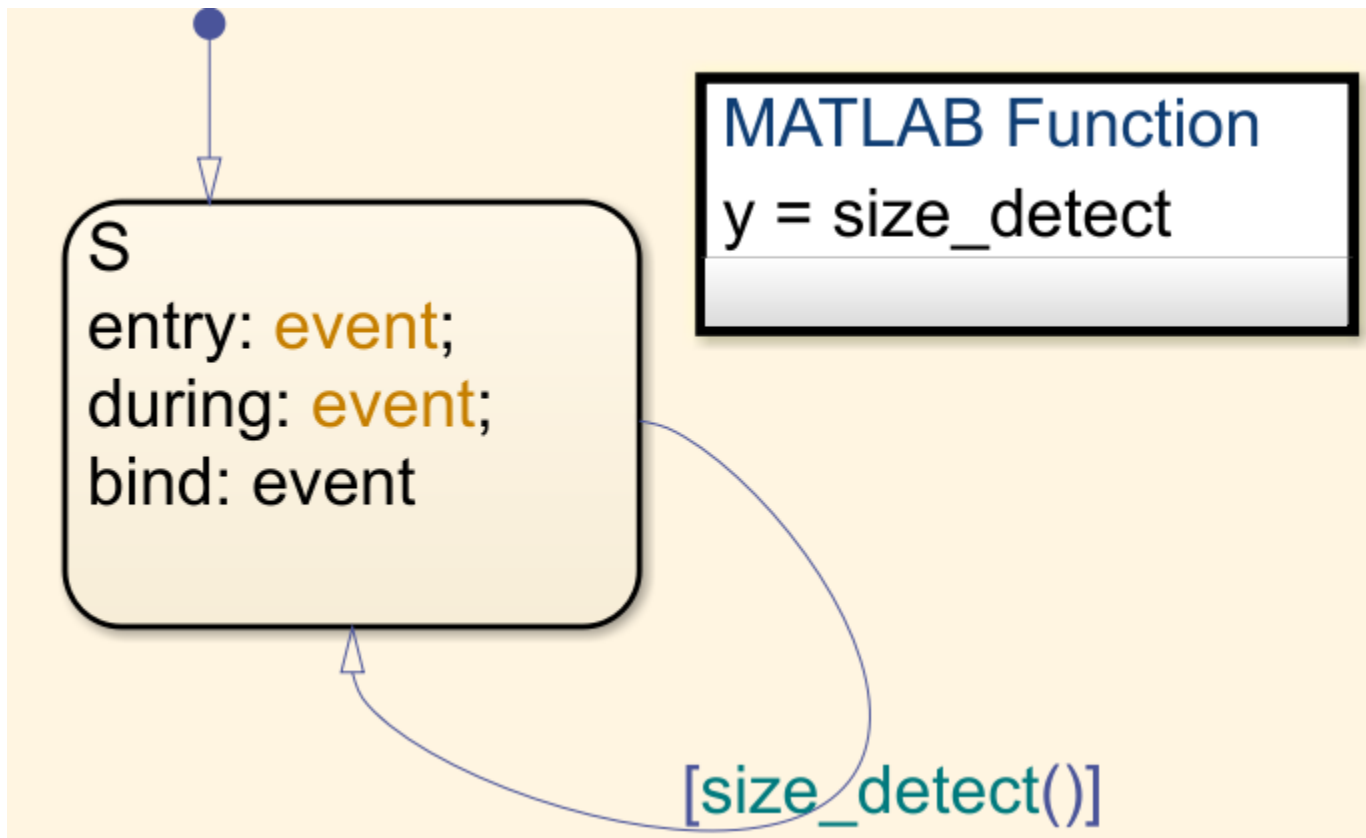

Because the Process subsystem contains a Delay block, the subsystem resets and repropagates the signal at each time step. This model uses a Stateflow chart to detect a signal size change and reset the Process subsystem.

In the function block dialog, and from the **Propagate sizes of variable-size signals** list, choose **Only when enabling**. When the model enables this subsystem, selecting this option directs the Simulink software to propagate sizes for variable-size signals inside the conditionally executed subsystem. Signal sizes can change only when they transition from disabled to enabled. For an explanation of handling signal-size changes with blocks containing states, see “How Variable-Size Signals Propagate” on page 82-2.

The Stateflow chart determines if there is a change in the size of the signal. The function `size_detect` calculates the width of the variable-size signal at each time step, and compares the

current width to the previous width. If there is a change in signal size, the chart outputs a function-call output event that resets and repropagates the signal sizes within the Process subsystem.

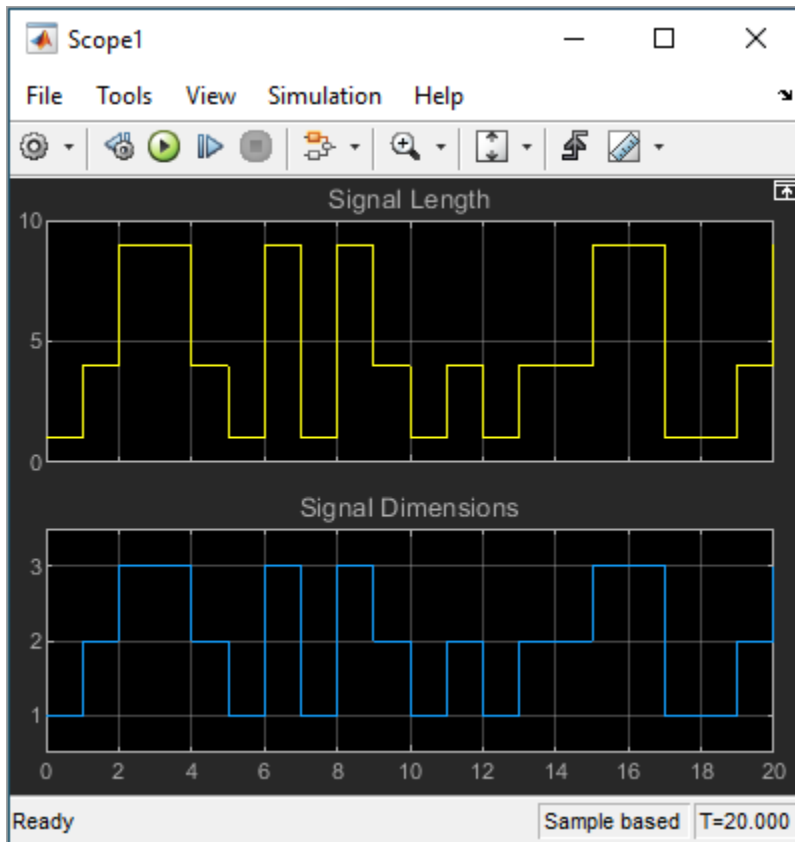

### Visualizing Data

Use the Probe block to visualize signal size and signal dimension.

Since the signals are  $n \times n$  matrices, the signal dimension lines overlap in the Scope display.

You can use a Display block and the Simulink Debugger to visualize signal values at each time step.

## S-Functions Using Variable-Size Signals

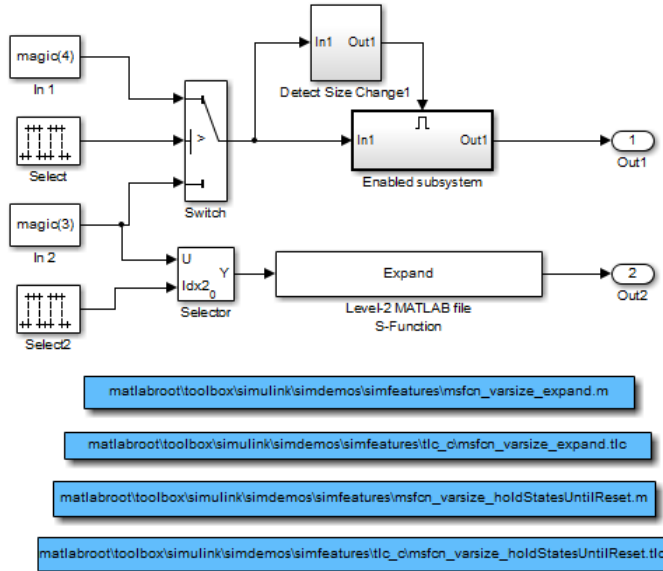

### Level-2 MATLAB S-Function with Variable-Size Signals

Both Level-2 MATLAB S-Functions and C S-Functions support variable-size signals when you set the **DimensionMode** for the output port to **Variable**. You also need to consider the current dimension of the input and output signals in the input and output update methods.

To open this example model, in the MATLAB Command Window, type:

```
msfcdemo_varsize
```

The Enabled subsystem includes a Level-2 MATLAB S-Function which shows how to implement a block that holds its states until reset. Because this block contains states and delays the input signal, the input size can change only when a reset occurs.

The Expand block is a Level-2 MATLAB S-Function that takes a scalar input and outputs a vector of length indicated by its input value. The output is by 1 : n where n is the input value.

### C S-Function with Variable-Size Signals

To open this example model, in the MATLAB Command Window, type:

```
sfcn_demo_varsize
```

The enabled subsystems have two S-Functions:

- `sfun_varsize_holdStatesUntilReset` is a C S-Function that has states and requires its DWorks vector to reset whenever the sizes of the input signal changes.
- `sfun_varsize_concat1D` is a C S-Function that implements the concatenation of two unoriented vectors. You can use this function within an enabled subsystem by itself.

## Access Frequently Used Features and Commands in Simulink

The Simulink quick access toolbar provides access to frequently used operations and favorite commands. This toolbar is always visible, even when you navigate between different Simulink Toolstrip tabs.

To customize the quick access toolbar, you can:

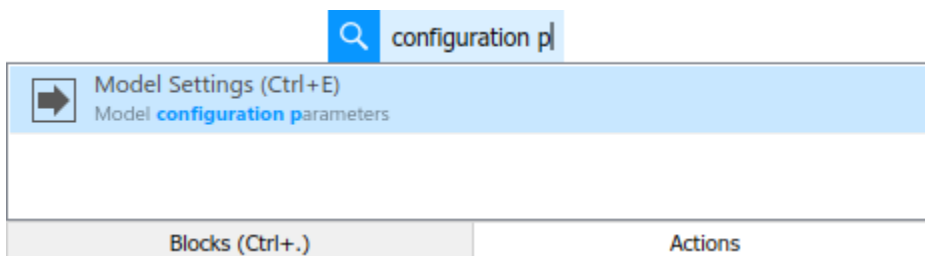

- Right-click an item in the toolstrip and select **Add to Quick Access Toolbar**. To remove a toolstrip item you have added, right-click the item and select **Remove from Quick Access Toolbar**.
- Drag items to change their position.
- Show item labels by right-clicking the item icon and selecting **Show Label**.
- Show or hide common items by clicking the **Common Controls** button  and selecting or clearing the corresponding check boxes.

To restore default settings for the quick access toolbar, use one of these options:

- Right-click an item and select **Restore Defaults**.
- Click the **Common Controls** button  and select **Restore Defaults**.

## Search for Simulink Toolstrip Actions

To search for Simulink Toolstrip actions, click the **Search Toolstrip** button . In the search box that appears, start typing the name or description of the toolstrip item, then select it from the quick action search menu.

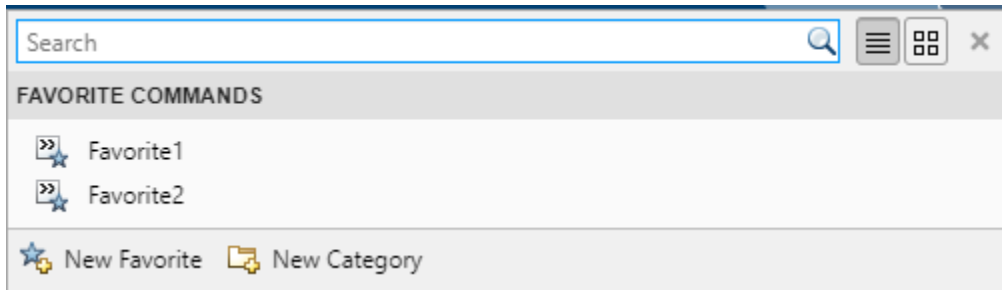

If the **Search Toolstrip** button  is not in the quick access toolbar, click the **Common Controls** button  and select the **Search Toolstrip** check box.

Alternatively, you can open the quick action search menu by double-clicking the Simulink Editor canvas and selecting the **Actions** tab or by pressing the **Ctrl + . (period)** keyboard shortcut. For more information, see “Keyboard Shortcuts and Mouse Actions for Simulink Modeling” on page 1-8.

## Rerun Favorite Commands for Simulink

The Simulink quick access toolbar provides you with a place to access your favorite MATLAB commands. Click the **Favorites** button  to open the **Favorite Commands** gallery.

The list of favorite commands is independent of the list of favorite commands in the MATLAB quick access toolbar.

To create a favorite command:

- 1 Click **New Favorite**. The Favorite Command Editor dialog box opens.
- 2 In the **Label** box, enter a name for the favorite command.
- 3 In the **Type** box, specify whether the favorite command is a script or function. Functions run in a limited scope and receive callback information from the *cbinfo* variable.
- 4 In the **Code** box, type the statements you want the favorite command to run.
- 5 Set **Category** to an existing category from the drop-down list.
- 6 Optionally, set **Icon** to one of the options provided or a custom icon. Custom icons must be PNG files. If you rename, move, or delete a custom icon, the icon no longer appears in the icon list, and any favorite commands that used the icon revert to the default icon.
- 7 Optionally, select **Add to quick access toolbar** and **Show label on quick access toolbar**.
- 8 Click **OK**.
- 9 To run the statements in the **Code** box and ensure that they perform the desired actions, click the button for the new command. All the statements in the **Code** box of the Favorite Command Editor execute as if you ran those statements from the Command Window, although they do not appear in the Command History window.

To edit or delete a favorite command, right-click the command and choose the corresponding option.

To create a new category for your favorite commands:

- 1 Click **New Category**. The Favorite Category Editor dialog box opens.
- 2 In the **Label** box, enter a name for the category.
- 3 Click **OK**.

To reorder categories, click the **Move category to top**  and **Move category to bottom**  buttons to the right of the category names.

To edit or delete a category, right-click the category and choose the corresponding option.

To reset the Simulink **Favorite Commands** gallery, use the `slResetFavoriteCommands` function.

## Share Favorite Commands for Simulink

To export the contents of your Simulink **Favorite Commands** gallery to a file that you can share with team members, use the `slExportFavoriteCommands` function. The generated file saves the contents of the gallery, including the categories and their order.

To import favorite commands from a file, use the `slImportFavoriteCommands` function. During import, you can merge the imported content with existing content or completely overwrite the content of the gallery.

When you merge content:

- Imported content appears after existing content.
- If the category of an imported command matches an existing category, the imported command is added to the existing category.
- Commands can have the same name and properties as each other. A command will not overwrite another command.

- “Improve Quick Block Insert Results” on page 83-54

## Create Custom Simulink Toolstrip Tabs

The Simulink Toolstrip provides a set of built-in actions to support a variety of workflows. You can customize the toolstrip by adding tabs that focus on workflows specific to you and your team. Custom tabs provide a platform for performing custom actions that you develop. You can also populate custom tabs with built-in actions from the default Simulink Toolstrip tabs.

Before you create a custom tab, consider how you want elements of the tab to appear and behave.

For an example of a prepopulated custom tab, see “Add Prepopulated Custom Tab to Simulink Toolstrip” on page 83-28.

The following sections describe how to create a custom tab that has the **Info** and **File** sections from the prepopulated custom tab example.

1. “Start Simulink” on page 83-5
2. “Create Simulink Toolstrip Component” on page 83-6
3. “Add Blank Tab to Simulink Toolstrip” on page 83-6
4. “Open JSON File to Develop Custom Tab” on page 83-7
5. “Define Custom Tab Layout” on page 83-8
6. “Choose Among Types of Controls” on page 83-10
7. “Get Built-In Simulink Actions” on page 83-11
8. “Specify Built-In Simulink Actions” on page 83-12
9. “Define Custom Actions” on page 83-13
10. “Choose Among Pop-Up List Elements” on page 83-17
- .
11. “Define Pop-Up Lists” on page 83-18
- .
12. “Share Custom Tabs” on page 83-27
- .

### Start Simulink

To work with the Simulink Toolstrip, start Simulink. For example, in the MATLAB Command Window, enter:

```
start_simulink
```

## Create Simulink Toolstrip Component

A Simulink Toolstrip component contains the definition for one or more custom tabs. Before you create a custom tab, you must create the component to contain it.

Create one or more custom Simulink Toolstrip components by using the `slCreateToolstripComponent` function.

For example, create a component named `custom`.

```
slCreateToolstripComponent("custom");
```

This command creates a `resources` folder in your current folder and adds your current folder to the MATLAB path. The `resources` folder contains two folders and one JSON file.

- `icons` folder — Location of icons used by custom tab elements
- `json` folder — Location of JSON files that define custom tabs
- `sl_toolstrip_plugins.json` — JSON file that must not be edited

Each component name must be unique. If multiple components have the same name, only one of the components with that name loads. You can see the component name in the `sl_toolstrip_plugins.json` file.

---

**Tip** Use a component name that is likely to be unique from other component names. For example, name the component after the workflow it supports.

---

To load a Simulink Toolstrip component, the folder that contains the `resources` folder must be on the MATLAB path.

To get the loaded custom Simulink Toolstrip components, use the `slLoadedToolstripComponents` function.

When you want to change whether a custom Simulink Toolstrip component persists across MATLAB sessions, use the `slPersistToolstripComponent` function.

To destroy a custom Simulink Toolstrip component, use the `slDestroyToolstripComponent` function.

## Add Blank Tab to Simulink Toolstrip

Create one or more custom tabs with the `slCreateToolstripTab` function.

For example, create the tab `customTab` in the `custom` component, and title the tab `CUSTOM TAB`.

```
slCreateToolstripTab("customTab","custom",Title="CUSTOM TAB");
```

The function creates a JSON file named `customTab.json` in the `json` folder that defines the tab.

To see the custom tabs you create, open a model. For example, open the `vdp` model.

`vdp`

The Simulink Toolstrip displays a blank tab titled `CUSTOM TAB`.

## Open JSON File to Develop Custom Tab

The JSON file that defines the custom tab uses:

- Curly braces to define JSON objects
- Quotation marks to identify JSON properties and values
- Colons to specify values for JSON properties
- Commas to separate like elements, such as JSON objects or properties
- Square brackets to define JSON properties with arrays of JSON objects

To modify a JSON file, consider using a JSON editor that checks for syntax errors, helps you format the code, and lets you collapse parts of the code. For example, use Visual Studio Code to open and edit your JSON files.

Open `customTab.json` from the `json` folder.

```
{
  "version": "1.0",
  "entries": [
    {
      "type": "Tab",
      "id": "customTab",
      "title": "CUSTOM TAB",
    }
  ]
}
```

The file defines a tab as a JSON object ("type": "Tab") with the specified ID ("id": "customTab") and title ("title": "CUSTOM TAB"). You can modify the tab ID and title.

After you modify a JSON file, use the `slReloadToolstripConfig` function to reload the toolstrip configuration with your changes. In the MATLAB Command Window, enter:

```
slReloadToolstripConfig;
```

The function searches the MATLAB path for `resources` folders that contain a valid `sl_toolstrip_plugins.json` file.

To temporarily modify the toolstrip configuration, perform one of these actions before you call this function:

- Add folders that contain `resources` folders to the MATLAB path.
- Remove folders that contain `resources` folders from the MATLAB path.

If the custom tab does not appear:

- Debug and correct errors in the JSON code.
- Add the folder that contains the corresponding resources folder to the MATLAB path.

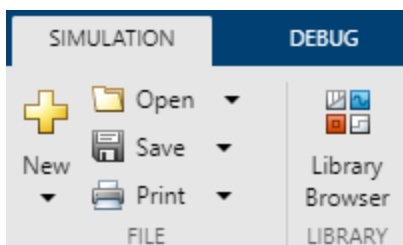

## Define Custom Tab Layout

The Simulink Toolstrip is composed of many elements in a hierarchy. Each tab is a collection of sections. Sections contain columns. Controls, such as push buttons, populate the columns.

On a toolstrip tab, vertical lines indicate section boundaries. If a section has a title, the title appears at the bottom of the section in all uppercase letters. Columns are visible only when they contain at least one control. The size of the control depends on how many controls are in the column. Each column supports a maximum of three controls.

For example, the **Simulation** tab of the Simulink Toolstrip contains multiple sections, such as the **File** section. The **File** section contains two columns. The first column contains one control, titled **New**. The second column contains three controls, titled **Open**, **Save**, and **Print**.

To create a hierarchy in the custom tab, the tab must have a `children` property. To support controls, the tab must have a child section, and the section must have a child column.

For each tab, specify:

- `type` — Type of JSON object (Tab), specified as a string
- `id` — Unique identifier within the toolstrip component, specified as a string
- `title` — Text that appears as the tab label, specified as a string
- `children` — Sections within the tab, specified as an array of JSON objects

For each section, specify:

- `type` — Type of JSON object (Section), specified as a string
- `id` (optional) — Unique identifier within the tab, specified as a string
- `title` — Text that appears as the section label, specified as a string
- `children` — Columns within the section, specified as an array of JSON objects

For each column, specify:

- `type` — Type of JSON object (Column), specified as a string
- `id` (optional) — Unique identifier within the section, specified as a string
- `width` (optional) — Width of the column in pixels, specified as a number
- `children` — Controls within the column, specified as an array of JSON objects

For example, create the layout for the **Info** and **File** sections from the prepopulated custom tab example, and title the sections.

Update the `customTab.json` file.

```
{
  "version": "1.0",
  "entries": [
    {
      "type": "Tab",
      "id": "customTab",
      "title": "CUSTOM TAB",
      "children": [
        {
          "type": "Section",
          "title": "Info",
          "children": [
            {
              "type": "Column",
              "children": []
            }
          ]
        },
        {
          "type": "Section",
```

```

        "title": "File",
        "children": [
            {
                "type": "Column",
                "children": []
            },
            {
                "type": "Column",
                "children": []
            }
        ]
    }
]
}

```

To display the changes on the custom tab, reload the toolstrip configuration.

```
slReloadToolstripConfig;
```

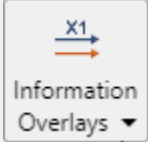

The two sections and their titles appear. The columns are not visible because they are empty.

## Choose Among Types of Controls

Different types of controls serve different goals. The default Simulink Toolstrip tabs contain a variety of controls. When a column has more than one control, the controls resize so that each control uses one third of the vertical space in the column.

Custom tabs support the subset of controls described in this table.

Control	Appearance	Description	JSON Object Type
Push button	Full size:  Reduced size: 	A push button performs an action.	PushButton

Control	Appearance	Description	JSON Object Type
Drop-down button	Full size:  Reduced size: 	A drop-down button displays a pop-up list.	DropDownButton
Split button	Full size:  Reduced size: 	A split button is a combination of a push button and a drop-down button. The push button part performs an action, and the button arrow shows a pop-up list.	SplitButton
Empty control	Same appearance as empty parts of the toolstrip	An empty control adds a blank space where a control would otherwise be.	EmptyControl

Add up to three controls to the `children` property of each column. The order of the controls in the JSON file determines the order in which they appear in the column.

For each control, specify:

- `type` — Type of JSON object, specified as a string.
- `id` (optional) — Unique identifier within the column, specified as a string.
- `action` (conditional) — Appearance and behavior of the control, specified as a string. Omit this property for empty controls.
- `popupName` (conditional) — Name of a pop-up list for a drop-down or split button, specified as a string. Omit this property for push buttons and empty controls.

## Get Built-In Simulink Actions

To get the name and icon for a built-in action from the Simulink Toolstrip, use the `slToolstripDeveloperMode` function.

In the MATLAB Command Window, enter this command:

```
slToolstripDeveloperMode('on')
```

```
ans =
```

```
logical
0
```

The command enables developer mode for the Simulink Toolstrip. The returned value indicates that developer mode was disabled before you entered the command.

Pause on an item in the Simulink Toolstrip and press **Ctrl**. On a Mac, press **command** (⌘) instead of **Ctrl**.

For example, pause on the **Open** button and press **Ctrl**.

```
Action: openModelAction
Icon: open
-----
```

The names of the corresponding action and icon appear in the MATLAB Command Window.

## Specify Built-In Simulink Actions

After you get the name of a built-in Simulink action, specify it as the action for a control by using it to define the `action` property of the control.

For example, create the **Open** push button from the prepopulated custom tab example.

On the **Simulation** tab, get the built-in action for the **Open** button.

```
Action: openModelAction
Icon: open_24
-----
```

Update the `customTab.json` file.

```
{
  "version": "1.0",
  "entries": [
    {
      "type": "Tab",
      "id": "customTab",
      "title": "CUSTOM TAB",
      "children": [
        {
          "type": "Section",
          "title": "Info",
          "children": [
            {
              "type": "Column",
```

```

        "children": []
      }
    ]
  },
  {
    "type": "Section",
    "title": "File",
    "children": [
      {
        "type": "Column",
        "children": []
      },
      {
        "type": "Column",
        "children": [
          {
            "type": "PushButton",
            "action": "openModelAction"
          }
        ]
      }
    ]
  }
]
}

```

To see the push button, reload the toolstrip configuration.

```
slReloadToolstripConfig;
```

## Define Custom Actions

To define a custom appearance and behavior for controls:

- 1 Create a MATLAB script or function that performs the action. The file must be on the MATLAB path.
- 2 Optionally, get a built-in icon or save 16-by-16 and 24-by-24 pixel versions of a custom icon to the icon folder in the resources directory. Custom icons must be saved as PNG files.
- 3 In the `json` folder of the resources directory, create a JSON file that defines actions and icons. For example, create a JSON file named `customTab_actions.json`.
- 4 Populate the new file with the required JSON properties: `version` and `entries`. For example:

```
{
  "version": "1.0",
```

```
    "entries": []
  }
}
```

- 5 Define your custom actions and icons as JSON objects in the `entries` property.
- 6 Reference the custom action from a JSON object.

For each action, specify:

- `type` — Type of JSON object (`Action`), specified as a string.
- `id` — Unique identifier within the toolstrip component, specified as a string.
- `text` (optional) — Text that appears on the control as a label, specified as a string. When a control is alone in a column, its text can span two lines. Use `\n` to start a new line. When the control shares its column with other controls, a space replaces the line break.
- `description` (optional) — Text that provides additional information, specified as a string. When the action defines a control, the text appears as a tooltip when you pause on the control. When the action defines a list item for a pop-up list, the text appears underneath the title of the list item.
- `icon` (optional) — Built-in or custom icon that appears on the control, specified as a string.
- `command` — Name of a MATLAB file that executes when you click the control, specified as a string. The file must be on the MATLAB path.
- `commandType` (conditional) — Specification that the MATLAB file is a script, specified as a string. Omit this property when the MATLAB file is a function.

Use functions instead of scripts if you want to use information about the current window in which the command is being executed. For more information, see “Callback Info Object” on page 83-41.

For each icon, specify:

- `type` — Type of JSON object (`Icon`), specified as a string.
- `id` — Unique identifier within the toolstrip component, specified as a string.
- `icon16` (conditional) — 16-by-16 pixel version of a custom icon for a reduced-size control, specified as a string. The icon must be saved as a PNG file.
- `icon24` (conditional) — 24-by-24 pixel version of a custom icon for a full-size control, specified as a string. The icon must be saved as a PNG file.

For example, create the **MathWorks Website** button from the prepopulated custom tab example.

Create a script named `openMathWorksWebsite.m` that opens the MathWorks website. Make sure the script is on the MATLAB path.

```
web('https://www.mathworks.com')
```

Add 16-by-16 and 24-by-24 pixel versions of a custom icon to the icon folder in the resources directory. This example uses two PNG files that indicate their size in their file names (openMathWorksWebsite\_16.png and openMathWorksWebsite\_24.png).

Create the customTab\_actions.json file. In this file, define the custom action (openMathWorksWebsiteAction) and icon (openMathWorksWebsiteIcon).

```
{
  "version": "1.0",
  "entries": [
    {
      "type": "Action",
      "id": "openMathWorksWebsiteAction",
      "text": "MathWorks\nWebsite",
      "description": "Open the MathWorks website",
      "icon": "openMathWorksWebsiteIcon",
      "command": "openMathWorksWebsite",
      "commandType": "Script"
    },
    {
      "type": "Icon",
      "id": "openMathWorksWebsiteIcon",
      "icon16": "openMathWorksWebsite_16.png",
      "icon24": "openMathWorksWebsite_24.png"
    }
  ]
}
```

In the customTab.json file, add the push button and reference the openMathWorksWebsiteAction action.

```
{
  "version": "1.0",
  "entries": [
    {
      "type": "Tab",
      "id": "customTab",
      "title": "CUSTOM TAB",
      "children": [
        {
          "type": "Section",
          "title": "Info",
          "children": [
            {
              "type": "Column",
              "children": [
                {
                  "type": "PushButton",
                  "action": "openMathWorksWebsiteAction"
                }
              ]
            }
          ]
        },
        {
          "type": "Section",
          "title": "File",
          "children": [

```

```

    {
      "type": "Column",
      "children": []
    },
    {
      "type": "Column",
      "children": [
        {
          "type": "PushButton",
          "action": "openModelAction"
        }
      ]
    }
  ]
}

```

To see the custom push button, reload the toolstrip configuration.

```
slReloadToolstripConfig;
```

Using developer mode, you can get the fully qualified names of custom actions and icons on a custom tab. For more information, see `slToolstripDeveloperMode`.

```
Action: custom:openMathWorksWebsiteAction
Icon: custom:openMathWorksWebsiteIcon
-----
```

You can also define a custom icon in a custom action, a custom action in a control, and a MATLAB command in a JSON file. For example, this push-button control uses nested JSON objects to define the custom action and icon and the command no longer references an external script.

```

{
  "type": "PushButton",
  "action": {
    "text": "MathWorks\nWebsite",
    "description": "Open the MathWorks website",
    "icon": {
      "icon16": "openMathWorksWebsite_16.png",
      "icon24": "openMathWorksWebsite_24.png"
    },
    "command": "web('https://www.mathworks.com')",
    "commandType": "Script"
  }
}

```

Nesting JSON objects and defining commands in the JSON file add complexity to the JSON file. Debugging is easier when you have fewer levels of hierarchy and use MATLAB functions or scripts to define and debug commands.

## Choose Among Pop-Up List Elements

Pop-up lists display multiple actions in a menu. You can use them to simplify the appearance of your custom tab by grouping similar actions under one control. Drop-down and split buttons support pop-up lists.

The order in which you add elements to the pop-up list determines the order in which they appear in the list. This table describes the elements you can add to a pop-up list.

List Control	Appearance	Description	JSON Object Type
List item	 Blank Model Ctrl+N	A list item performs an action, similar to a push button.	ListItem
List item with pop-up list	 Project	A list item with a pop-up list displays a pop-up list, similar to a drop-down button.	ListItemWithPopup
List header	FROM TEMPLATE	A list header adds a titled heading to the list.	ListHeader
List separator	 Architecture...  Project	A list separator adds a horizontal line to separate items in the list.	ListSeparator

For each list item, specify:

- `type` — Type of JSON object (`ListItem` or `ListItemWithPopup`), specified as a string.
- `id` (optional) — Unique identifier within the pop-up list, specified as a string.
- `action` — Appearance and behavior of the list item, specified as a string.
- `showDescription` (optional) — Option to display the text from the `description` property of the action on the list item, specified as a Boolean (`true` or `false`). By default, the list item displays the description.
- `popupName` (conditional) — Name of another pop-up list, specified as a string. Omit this property for `ListItem` JSON objects.

For each list header, specify:

- `type` — Type of JSON object (`ListHeader`), specified as a string
- `id` (optional) — Unique identifier within the pop-up list, specified as a string
- `text` — Text to appear in the heading, specified as a string

For each list separator, specify:

- `type` — Type of JSON object (`ListSeparator`), specified as a string
- `id` (optional) — Unique identifier within the pop-up list, specified as a string

## Define Pop-Up Lists

To create pop-up lists:

- 1 Define any custom actions the pop-up lists use.
- 2 Get the built-in actions that the pop-up lists use.
- 3 In the `json` folder of the `resources` directory, create a JSON file that defines pop-up lists. For example, create a JSON file named `customTab_popups.json`.
- 4 Populate the new file with the required JSON properties: `version` and `entries`. For example:

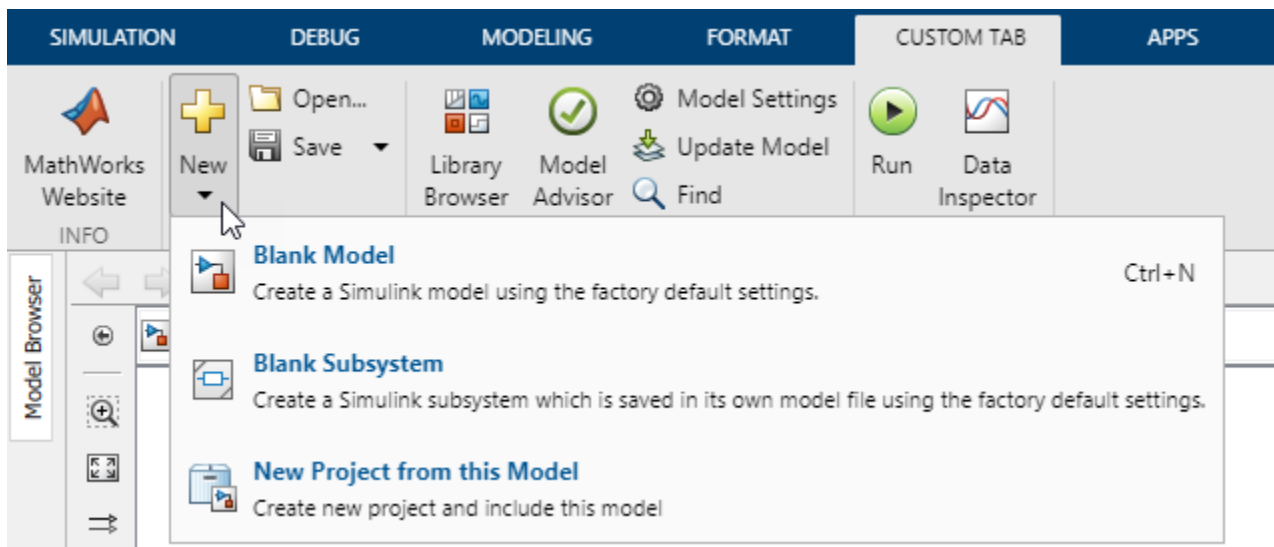

```
{
  "version": "1.0",
  "entries": []
}
```

- 5 Define the pop-up lists as JSON objects in the `entries` property.
- 6 Reference each pop-up list from a JSON object for a drop-down button, split button, or list item with a pop-up list.

For each pop-up list, specify:

- `type` — Type of JSON object (`PopupMenu`), specified as a string
- `id` (optional) — Unique identifier within the toolstrip component, specified as a string
- `children` — Elements within the pop-up list, specified as an array of JSON objects

For example, create the **New** drop-down button from the prepopulated custom tab example.

Get the built-in icon for the **New** button on the **Simulation** tab.

```
Action: createNewBlankModelAction
Icon: new_24
-----
```

The built-in icon has a suffix (`_24`) to indicate the icon size. When you reference the icon for a custom action, drop this suffix.

In the `customTab_actions.json` file, add a custom action (`newPopUpAction`) that defines the icon and text for the drop-down button.

```
{
  "version": "1.0",
  "entries": [
    {
      "type": "Action",
      "id": "newPopUpAction",
      "text": "New",
      "icon": "new"
    },
    {
      "type": "Action",
      "id": "openMathWorksWebsiteAction",
      "text": "MathWorks\nWebsite",
      "description": "Open the MathWorks website",
      "icon": "openMathWorksWebsiteIcon",
      "command": "openMathWorksWebsite",
      "commandType": "Script"
    },
    {
      "type": "Icon",
      "id": "openMathWorksWebsiteIcon",
      "icon16": "openMathWorksWebsite_16.png",
      "icon24": "openMathWorksWebsite_24.png"
    }
  ]
}
```

Get the built-in actions for these buttons on the **Simulation** tab:

- **New > Blank Model**
- **New > Blank Subsystem**
- **New > Project > New Project from this Model**

Action: `createNewBlankModelAction`

Icon: `model_24`

-----  
Action: `createNewBlankReferenceableSubsystemAction`

Icon: `referenceableSubsystem_24`

-----  
Action: `createNewProjectFromModelAction`

Icon: `projectNewFromModel_24`

Create the `customTab_popups.json` file. In this file, define the pop-up list (`newPopUpList`) for the button.

```
{
  "version": "1.0",
  "entries": [
    {
      "type": "PopUpList",
      "id": "newPopUpList",
      "children": [
        {
          "type": "ListItem",
          "action": "createNewBlankModelAction"
        },
        {

```

```

        "type": "ListItem",
        "action": "createNewBlankReferenceableSubsystemAction"
      },
      {
        "type": "ListItem",
        "action": "createNewProjectFromModelAction"
      }
    ]
  }
}

```

In the `customTab.json` file, add the **New** drop-down button and reference the corresponding action (`newPopUpAction`) and pop-up list (`newPopUpList`).

```

{
  "version": "1.0",
  "entries": [
    {
      "type": "Tab",
      "id": "customTab",
      "title": "CUSTOM TAB",
      "children": [
        {
          "type": "Section",
          "title": "Info",
          "children": [
            {
              "type": "Column",
              "children": [
                {
                  "type": "PushButton",
                  "action": "openMathWorksWebsiteAction"
                }
              ]
            }
          ]
        },
        {
          "type": "Section",
          "title": "File",
          "children": [
            {
              "type": "Column",
              "children": [
                {
                  "type": "DropDownButton",
                  "action": "newPopUpAction",
                  "popupName": "newPopUpList"
                }
              ]
            }
          ]
        },
        {
          "type": "Column",
          "children": [
            {
              "type": "PushButton",
              "action": "openModelAction"
            }
          ]
        }
      ]
    }
  ]
}

```

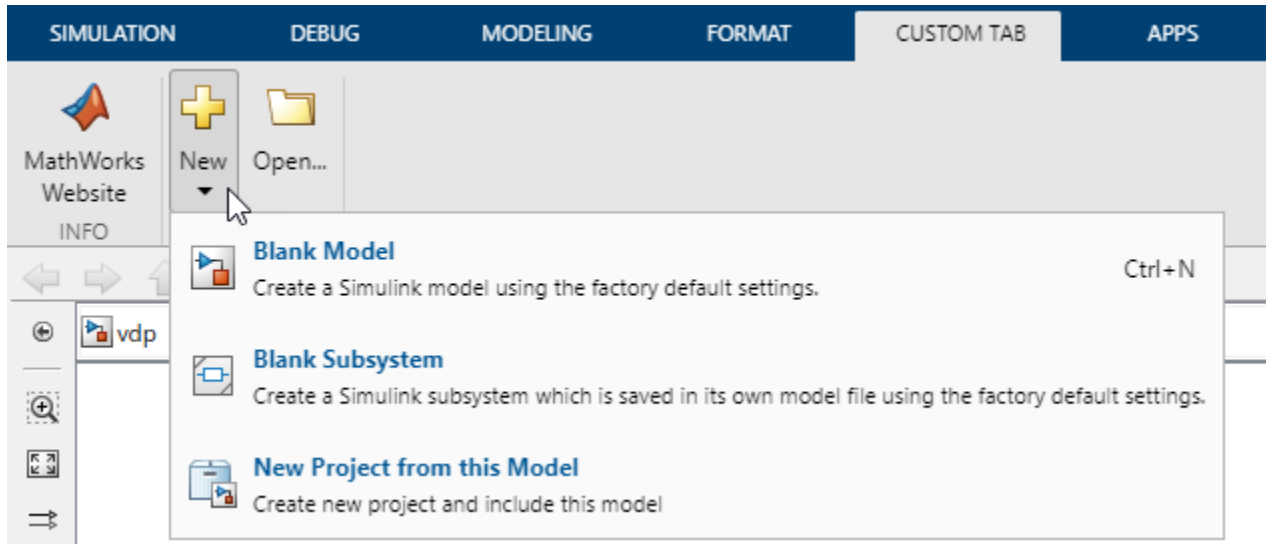

```

    }
  }
}

```

To see the **New** drop-down button and its pop-up list, reload the toolstrip configuration.

```
slReloadToolstripConfig;
```

For a more complicated example, create the **Save** split button from the prepopulated custom tab example.

In the `customTab_actions.json` file, add a custom action (`exportPopUpAction`) that defines the text for the list item with a pop-up list.

```
{
  "version": "1.0",
  "entries": [
    {
      "type": "Action",
      "id": "newPopUpAction",
      "text": "New",
      "icon": "new"
    },
    {
      "type": "Action",
      "id": "exportPopUpAction",
      "text": "Export model to..."
    },
    {
      "type": "Action",
      "id": "openMathWorksWebsiteAction",
      "text": "MathWorks\nWebsite",
      "description": "Open the MathWorks website",
      "icon": "openMathWorksWebsiteIcon",
      "command": "openMathWorksWebsite",
      "commandType": "Script"
    },
    {
      "type": "Icon",
      "id": "openMathWorksWebsiteIcon",
      "icon16": "openMathWorksWebsite_16.png",
      "icon24": "openMathWorksWebsite_24.png"
    }
  ]
}
```

```

    }
  ]
}

```

Get the built-in actions for these buttons on the **Simulation** tab:

- **Save**
- **Save > Save As**
- **Save > Protected Model**
- **Save > Template**
- **Save > Previous Version**

```

Action: saveModelAction
Icon: save_24
-----
Action: saveModelAsAction
Icon: save_as_16
-----
Action: createProtectedModelAction
Icon: referencedModelProtect_16
-----
Action: exportModelToTemplateAction
Icon: exportModelToTemplate_16
-----
Action: exportModelToPreviousVersionAction
Icon: export_16
-----

```

In the `customTab_popups.json` file, define the two additional pop-up lists:

- `savePopUpList` — Pop-up list for the **Save** split button
- `exportPopUpList` — Pop-up list for the **Export model to** list item

For the list item that has a pop-up list, reference the corresponding action (`exportPopUpAction`) and pop-up list (`exportPopUpList`).

```

{
  "version": "1.0",
  "entries": [
    {
      "type": "PopupList",
      "id": "newPopUpList",
      "children": [
        {
          "type": "ListItem",
          "action": "createNewBlankModelAction"
        },
        {
          "type": "ListItem",
          "action": "createNewBlankReferenceableSubsystemAction"
        },
        {
          "type": "ListItem",
          "action": "createNewProjectFromModelAction"
        }
      ]
    },
    {
      "type": "PopupList",
      "id": "savePopUpList",
      "children": [
        {
          "type": "ListHeader",
          "text": "Save"
        }
      ]
    }
  ]
}

```

```

    },
    {
      "type": "ListItem",
      "action": "saveModelAction"
    },
    {
      "type": "ListItem",
      "action": "saveModelAsAction"
    },
    {
      "type": "ListHeader",
      "text": "Export"
    },
    {
      "type": "ListItemWithPopup",
      "action": "exportPopUpAction",
      "popupName": "exportPopUpList"
    }
  ]
},
{
  "type": "PopupList",
  "id": "exportPopUpList",
  "children": [
    {
      "type": "ListItem",
      "action": "createProtectedModelAction"
    },
    {
      "type": "ListItem",
      "action": "exportModelToTemplateAction"
    },
    {
      "type": "ListSeparator"
    },
    {
      "type": "ListItem",
      "action": "exportModelToPreviousVersionAction"
    }
  ]
}
]
}
}
}

```

In the `customTab.json` file, add the **Save** split button after the **Open** button. Reference the corresponding action (`saveModelAction`) and pop-up list (`savePopUpList`).

```

{
  "version": "1.0",
  "entries": [
    {
      "type": "Tab",
      "id": "customTab",
      "title": "CUSTOM TAB",
      "children": [
        {
          "type": "Section",
          "title": "Info",
          "children": [

                "type": "EmptyControl"
            }
        ]
    }
}

```

To see the effect of the empty control, reload the toolstrip configuration.

```
slReloadToolstripConfig;
```

## Share Custom Tabs

To share a custom tab with team members, share the `resources` folder and the supporting files referenced by custom actions.

The `resources` folder must be in a folder that is on the MATLAB path. If multiple `resources` folders use the same component name, only one of the components with that name loads.

If a team member does not have a license or product installation required by one of the controls on the custom tab, the control appears as a button with no text, icon, tooltip, or action.

## Add Prepopulated Custom Tab to Simulink Toolstrip

This example provides the `resources` folder contents for a prepopulated custom tab. When you add custom tabs to the Simulink® Toolstrip, you might find modifying a prepopulated tab easier than starting with a blank tab.

A custom tab provides a single location for the actions you use most often. Use custom tabs to collect built-in actions that span multiple tabs on the default Toolstrip, such as the **Open** and **Model Advisor** buttons. While this example focuses on Simulink actions, you can also add actions from other products to your custom tab, such as the **Build** button from Simulink Coder™. If you do not have a product installed or do not have a license for a product, the built-in actions from that product appear as empty buttons on the custom tab.

Custom tabs also support custom actions. In this example, the **MathWorks Website** button uses a custom action defined by a script.

The prepopulated custom tab provides one or more examples of each type of control that custom tabs support.

- The **New** button is a *drop-down button* that expands to show additional items in a pop-up list.
- The **Open** button is a *push button* that you click to perform an action.
- The **Save** button is a *split button* that consists of a push button and drop-down button.
- An *empty control* adds space below the **Save** button.

You can distinguish a drop-down button from a split button by pausing on the button. The split button has two interactive parts separated by a line, while a drop-down button has only one part.

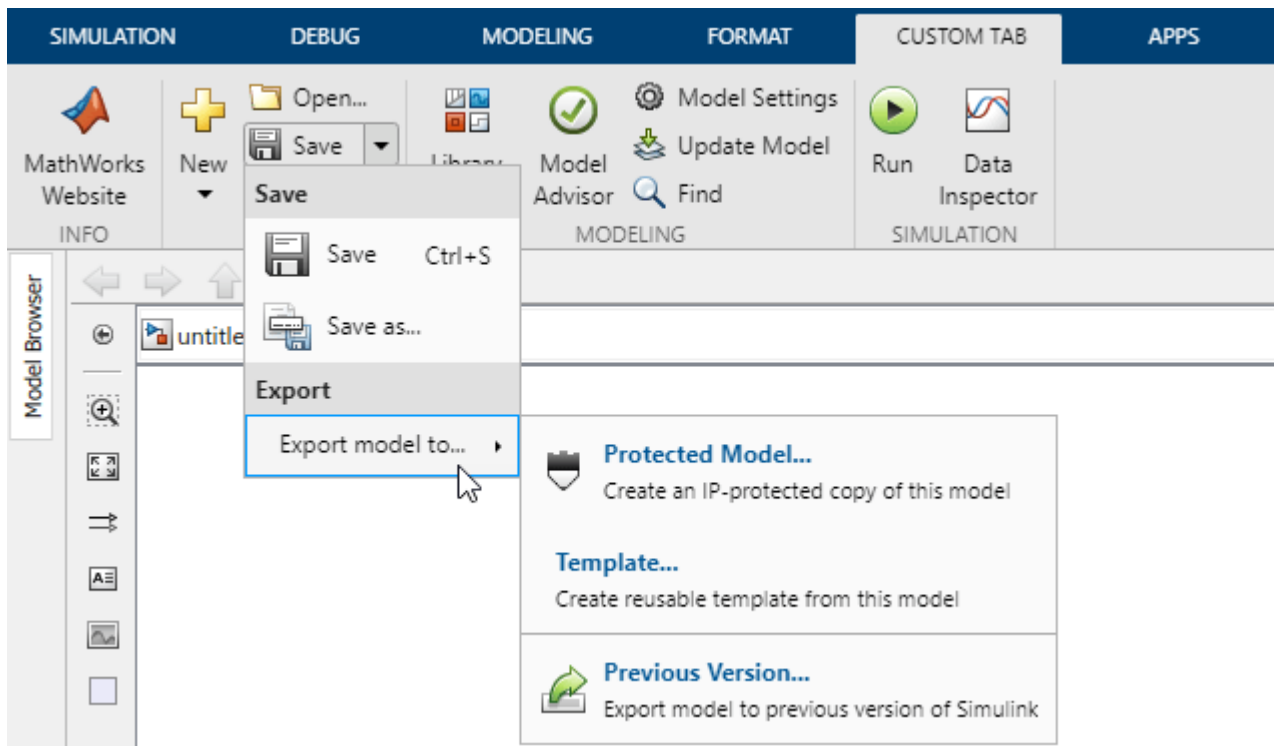

The **New** button expands to show a pop-up list with three *list items* that you click to perform an action.

The **Save** button expands to show a pop-up list with more features.

- **Save** and **Export** are *list headers* that provide headings.
- The line between **Template** and **Previous Version** is a *list separator*.
- **Export model to** is a *list item with a pop-up list* that expands to show additional items in a nested pop-up list.

### Examine Files That Define Custom Tab Appearance and Behavior

The files that define the prepopulated custom tab are in the `resourcesExample` folder. To view the custom tab in the Simulink Toolstrip, you must rename the folder from `resourcesExample` to `resources` and add its parent folder to the MATLAB path.

The `sl_toolstrip_plugins.json` file defines the Simulink Toolstrip component. Do not edit this file.

```
file0 = fullfile(pwd,"resourcesExample","sl_toolstrip_plugins.json");
type(file0)
```

```
{"entries":[{"content":{"Name":"custom"},"type":"config.ComponentData"},"packageUri":[],"version":1}
```

The two images in the `icons` folder of the `resourcesExample` folder provide the 16-by-16 and 24-by-24 pixel versions of a custom icon.

Three JSON files in the `json` folder of the `resourcesExample` folder define the custom tab.

- `customTab.json` — JSON file that defines the tab, layout, and controls.
- `customTab_actions.json` — Optional JSON file that defines custom actions. One of the actions references the `openMathWorksWebsite.m` script in the example folder.
- `customTab_popups.json` — Optional JSON file that defines the pop-up lists for drop-down buttons, split buttons, and list items with pop-up lists.

```
file1 = fullfile(pwd,"resourcesExample","json","customTab.json");
type(file1)
```

                }
            ]
        }
    ]
}

```

```

        {
            "type": "ListItem",
            "action": "saveModelAsAction"
        },
        {
            "type": "ListHeader",
            "text": "Export"
        },
        {
            "type": "ListItemWithPopup",
            "action": "exportPopUpAction",
            "popupName": "exportPopUpList"
        }
    ]
},
{
    "type": "PopupList",
    "id": "exportPopUpList",
    "children": [
        {
            "type": "ListItem",
            "action": "createProtectedModelAction"
        },
        {
            "type": "ListItem",
            "action": "exportModelToTemplateAction"
        },
        {
            "type": "ListSeparator"
        },
        {
            "type": "ListItem",
            "action": "exportModelToPreviousVersionAction"
        }
    ]
}
]
}

```

The script that the action references must be on the MATLAB path. The script cannot be in the resources folder for the custom tab.

```
type openMathWorksWebsite.m
```

```
web('https://www.mathworks.com')
```

### Edit Prepopulated Custom Tab

- 1 Copy the `resourcesExample` folder and the `openMathWorksWebsite.m` script to a folder on the MATLAB® path.
- 2 Rename the folder from `resourcesExample` to `resources`. For a custom tab to register as a Simulink Toolstrip customization, the folder name must be `resources`.
- 3 In the MATLAB Command Window, enter `slReloadToolstripConfig`.
- 4 To interact with the custom tab, open a Simulink model.
- 5 To edit the custom tab, edit the JSON files in the `json` folder.

- 6 To see your changes, reload the Simulink Toolstrip configuration by entering `slReloadToolstripConfig`.

For more information, see “Create Custom Simulink Toolstrip Tabs” on page 83-5.

## **See Also**

`slReloadToolstripConfig`

## **Related Examples**

- “Disable Simulink Toolstrip and Context Menu Actions” on page 83-44

## Add Items to Model Editor Menus

### In this section...

“Code for Adding Menu Items” on page 83-36  
 “Define Menu Items” on page 83-37  
 “Register Menu Customizations” on page 83-41  
 “Callback Info Object” on page 83-41  
 “Debugging Custom Menu Callbacks” on page 83-42  
 “Menu Tags” on page 83-42

You can add commands and submenus to context menus for the Simulink Editor and Stateflow Editor. Menu bar customization will be removed in a future release. To customize the Simulink Toolstrip, use custom tabs. For more information on custom tabs, see “Create Custom Simulink Toolstrip Tabs” on page 83-5. To convert an existing toolbar menu into a toolstrip tab, use `slConvertCustomMenus`.

To add an item to a menu:

- 1 For each item, create a function, called a schema function, that defines the item (see “Define Menu Items” on page 83-37).
- 2 Register the menu customizations with the Simulink customization manager at startup, e.g., in an `sl_customization.m` file on the MATLAB path (see “Register Menu Customizations” on page 83-41).
- 3 Create callback functions that implement the commands triggered by the items that you add to the menus.

### Code for Adding Menu Items

The following `sl_customization.m` file adds four items to the bottom of the context menu that appears when you right-click the Simulink Editor canvas.

```
function sl_customization(cm)

    %% Register custom menu function.
    cm.addCustomMenuFcn('Simulink:ContextMenu', @getMyMenuItems);
end

%% Define the custom menu function.
function schemaFcns = getMyMenuItems(callbackInfo)
    schemaFcns = {@getItem1, ...
                 @getItem2, ...
                 {@getItem3,3}, ... %% Pass 3 as user data to getItem3.
                 @getItem4};
end

%% Define the schema function for first menu item.
function schema = getItem1(callbackInfo)
    schema = sl_action_schema;
    schema.label = 'Item One';
    schema.userdata = 'item one';
    schema.callback = @myCallback1;
end

function myCallback1(callbackInfo)
    disp(['Callback for item ' callbackInfo.userdata ' was called']);
end

function schema = getItem2(callbackInfo)
```

```

% Make a submenu label 'Item Two' with
% the menu item above three times.
schema = sl_container_schema;
schema.label = 'Item Two';
schema.childrenFcns = {@getItem1, @getItem1, @getItem1};
end

function schema = getItem3(callbackInfo)
% Create a menu item whose label is
% 'Item Three: 3', with the 3 being passed
% from getMyItems above.

schema = sl_action_schema;
schema.label = ['Item Three: ' num2str(callbackInfo.userdata)];
end

function myToggleCallback(callbackInfo)
if strcmp(get_param(gcs, 'ScreenColor'), 'red') == 0
    set_param(gcs, 'ScreenColor', 'red');
else
    set_param(gcs, 'ScreenColor', 'white');
end
end

%% Define the schema function for a toggle menu item.
function schema = getItem4(callbackInfo)
schema = sl_toggle_schema;
schema.label = 'Red Screen';
if strcmp(get_param(gcs, 'ScreenColor'), 'red') == 1
    schema.checked = 'checked';
else
    schema.checked = 'unchecked';
end
schema.callback = @myToggleCallback;
end

```

## Define Menu Items

You define a menu item by creating a function that returns an object, called a *schema* object, that specifies the information needed to create the menu item. The menu item that you define may trigger a custom action or display a custom submenu. See the following sections for more information.

- “Defining Menu Items That Trigger Custom Commands” on page 83-37
- “Defining Custom Submenus” on page 83-39

### Defining Menu Items That Trigger Custom Commands

To define an item that triggers a custom command, your schema function must accept a callback info object (see “Callback Info Object” on page 83-41) and create and return an action schema object (see “Action Schema Object” on page 83-38) that specifies the item label and a function, called a *callback*, to be invoked when the user selects the item. For example, the following schema function defines a menu item that displays a message when selected by the user.

```

function schema = getItem1(callbackInfo)

%% Create an instance of an action schema.
schema = sl_action_schema;

%% Specify the menu item label.
schema.label = 'My Item 1';
schema.userdata = 'item1';

%% Specify the menu item callback function.

```

```

    schema.callback = @myCallback1;
end

function myCallback1(callbackInfo)
    disp(['Callback for item ' callbackInfo.userdata
        ' was called']);
end

```

### Action Schema Object

This object specifies information about menu items that trigger commands that you define, including the label that appears on the menu item and the function to be invoked when the user selects the menu item. Use the function `sl_action_schema` to create instances of this object in your schema functions. Its properties include:

Property	Description
tag	Optional character vector that identifies this action, for example, so that it can be referenced by a filter function.
label	Character vector specifying the label that appears on a menu item that triggers this action.
state	Property that specifies the state of this action. Valid values are: <ul style="list-style-type: none"> <li>'Enabled' (default) - The action appears in the menu and can be selected</li> <li>'Disabled' - The action appears in the menu but cannot be selected</li> <li>'Hidden' - The action does not appear in the menu</li> </ul>
statustip	Character vector specifying text to appear in the editor status bar when the user selects the menu item that triggers this action.
userdata	Data that you specify, which can be of any type.
accelerator	Character vector specifying a <b>Ctrl</b> and key combination to use to trigger this action. You can add a keyboard shortcut only for custom menu items that appear on menu bar menus (to be removed) and cannot redefine accelerators that come with the Simulink Editor. For example, <b>Ctrl+D</b> is an accelerator for <b>Update Diagram</b> in the Simulink Editor, so you cannot redefine it. <p>To specify this value, use the form 'Ctrl+K', where <i>K</i> is the shortcut key. For example, use 'Ctrl+Alt+T' for an accelerator invoked by holding down <b>Ctrl</b> and <b>Alt</b> and pressing <b>T</b>.</p>
callback	Character vector specifying a MATLAB expression to be evaluated or a handle to a function to be invoked when a user selects the menu item that triggers this action. This function must accept one argument: a callback info object.
autoDisableWhen	Property that controls when a menu item is automatically disabled. <ul style="list-style-type: none"> <li>'Locked' (default) - When the active editor is locked or when the model is busy</li> <li>'Busy' - Only if the model is busy</li> <li>'Never' - Never</li> </ul>

### Toggle Schema Object

This object specifies information about a menu item that toggles some object on or off. Use the function `sl_toggle_schema` to create instances of this object in your schema functions. Its properties include:

Property	Description
<code>tag</code>	Optional character vector that identifies this toggle action, for example, so that it can be referenced by a filter function.
<code>label</code>	Character vector specifying the label that appears on a menu item that triggers this toggle action.
<code>checked</code>	Specify whether the menu item displays a check mark. Valid values are 'unchecked' (default) and 'checked'
<code>state</code>	Property that specifies the state of this toggle action. Valid values are: <ul style="list-style-type: none"> <li>'Enabled' (default) - The action appears in the menu and can be selected</li> <li>'Disabled' - The action appears in the menu but cannot be selected</li> <li>'Hidden' - The action does not appear in the menu</li> </ul>
<code>statustip</code>	Character vector specifying text to appear in the editor status bar when the user selects the menu item that triggers this toggle action.
<code>userdata</code>	Data that you specify, which can be of any type.
<code>accelerator</code>	Character vector specifying a <b>Ctrl</b> and key combination to use to trigger this action. You can add a keyboard shortcut only for custom menu items that appear on menu bar menus (to be removed) and cannot redefine accelerators that come with the Simulink Editor. For example, <b>Ctrl+D</b> is an accelerator for <b>Update Diagram</b> in the Simulink Editor, so you cannot redefine it. <p>To specify this value, use the form 'Ctrl+K', where <i>K</i> is the shortcut key. For example, use 'Ctrl+Alt+T' for an accelerator invoked by holding down <b>Ctrl</b> and <b>Alt</b> and pressing <b>T</b>.</p>
<code>callback</code>	Character vector specifying a MATLAB expression to be evaluated or a handle to a function to be invoked when a user selects the menu item that triggers this action. This function must accept one argument: a callback info object.
<code>autoDisableWhen</code>	Property that controls when a menu item is automatically disabled. <ul style="list-style-type: none"> <li>'Locked' (default) - When the active editor is locked or when the model is busy</li> <li>'Busy' - Only if the model is busy</li> <li>'Never' - Never</li> </ul>

### Defining Custom Submenus

To define a submenu, create a schema function that accepts a callback info object and returns a container schema object (see "Container Schema Object" on page 83-40) that specifies the schemas that define the items on the submenu. For example, the following schema function defines a submenu that contains three instances of the menu item defined in the example in "Defining Menu Items That Trigger Custom Commands" on page 83-37.

```
function schema = getItem2( callbackInfo )
    schema = sl_container_schema;
    schema.label = 'Item Two';
```

```

    schema.childrenFcns = {@getItem1, @getItem1, @getItem1};
end

```

### Container Schema Object

A container schema object specifies a submenu label and its contents. Use the function `sl_container_schema` to create instances of this object in your schema functions. Properties of the object include:

Property	Description
<code>tag</code>	Optional character vector that identifies this submenu.
<code>label</code>	Character vector specifying the submenu label.
<code>state</code>	Character vector that specifies the state of this submenu. Valid values are 'Enabled' (default), 'Disabled', and 'Hidden'.
<code>statustip</code>	Character vector specifying text to appear in the editor status bar when the user selects this submenu.
<code>childrenFcns</code>	<p>Cell array that specifies the contents of the submenu. Each entry in the cell array can be:</p> <ul style="list-style-type: none"> <li>• A pointer to a schema function that defines an item on the submenu (see “Define Menu Items” on page 83-37).</li> <li>• A two-element cell array whose first element is a pointer to a schema function that defines an item entry and whose second element is data to be inserted as user data in the callback info object (see “Callback Info Object” on page 83-41) passed to the schema function.</li> <li>• 'separator', which causes a separator to appear between the item defined by the preceding entry in the cell array and the item defined in the following entry. The case is ignored for this entry (for example, 'SEPARATOR' and 'Separator' are both valid entries). A separator is also suppressed if it appears at the beginning or end of the submenu and separators that would appear successively are combined into a single separator (for example, as a result of an item being hidden).</li> </ul> <p>For example, this cell array specifies two submenu entries:</p> <pre>{@getItem1, 'separator', {@getItem2, 1}}</pre> <p>In this example, a 1 is passed to <code>getItem2</code> via a callback info object.</p>
<code>generateFcn</code>	<p>Pointer to a function that returns a cell array defining the contents of the submenu. The cell array must have the same format as that specified for the container schema objects <code>childrenFcns</code> property.</p> <p>The <code>generateFcn</code> property takes precedence over the <code>childrenFcns</code> property. If you set both, the <code>childrenFcns</code> property is ignored and the cell array returned by the <code>generateFcn</code> is used to create the submenu.</p>
<code>userdata</code>	Data of any type that is passed to <code>generateFcn</code> .

Property	Description
<code>autoDisableWhen</code>	Property that controls when a menu item is automatically disabled. <ul style="list-style-type: none"> <li>'Locked' (default) - When the active editor is locked or when the model is busy</li> <li>'Busy' - Only if the model is busy</li> <li>'Never' - Never</li> </ul>

## Register Menu Customizations

You must register custom items to be included on a Simulink menu with the customization manager. Use the `sl_customization.m` file for a Simulink installation (see “Register Customizations with Simulink” on page 83-55) to perform this task. In particular, for each menu that you want to customize, your system `sl_customization` function must invoke the customization manager `addCustomMenuFcn` method. Each invocation should pass the tag of the menu (see “Menu Tags” on page 83-42) to be customized and a custom menu function that specifies the items to be added to the menu (see “Creating the Custom Menu Function” on page 83-41). For example, the following `sl_customization` function adds custom items to the Simulink Tools menu.

```
function sl_customization(cm)
    %% Register custom menu function.
    cm.addCustomMenuFcn('Simulink:ToolsMenu', @getMyItems);
```

### Creating the Custom Menu Function

The custom menu function returns a cell array of schema functions that define custom items that you want to appear on the model editor menus (see “Define Menu Items” on page 83-37 ). The custom menu function returns a cell array similar to that returned by the `generateFcn` function.

Your custom menu function should accept a callback info object (see “Callback Info Object” on page 83-41) and return a cell array that lists the schema functions. Each element of the cell array can be either a handle to a schema function or a two-element cell array whose first element is a handle to a schema function and whose second element is user-defined data to be passed to the schema function. For example, the following custom menu function returns a cell array that lists three schema functions.

```
function schemas = getMyItems(callbackInfo)
    schemas = {@getItem1, ...
              @getItem2, ...
              {@getItem3,3} }; % Pass 3 as userdata to getItem3.
end
```

## Callback Info Object

Instances of these objects are passed to menu customization functions. Methods and properties of these objects include:

Method or Property	Description
<code>uiObject</code>	Method to get the handle to the owner of the menu for which this is the callback. The owner can be the Simulink Editor or the Stateflow Editor.
<code>model</code>	Method to get the handle to the model being displayed in the editor window.

Method or Property	Description
userdata	User data property. The value of this property can be any type of data.

## Debugging Custom Menu Callbacks

On systems using the Microsoft Windows operating system, selecting a custom menu item whose callback contains a breakpoint can cause the mouse to become unresponsive or the menu to remain open and on top of other windows. To fix these problems, use the MATLAB code debugger keyboard commands to continue execution of the callback.

## Menu Tags

A menu tag identifies a Simulink Editor menu, a Stateflow Editor menu, or a context menu. You need to know the tag for a menu to add custom items to it (see “Register Menu Customizations” on page 83-41).

Tag	What It Adds
Simulink tags	
Simulink:MenuBar (to be removed)	Menu to the Simulink Editor menu bar
Simulink:PreContextMenu	Item to the beginning of a Simulink Editor context menu
Simulink:ContextMenu	Item to the end of a Simulink Editor context menu
Simulink:FileMenu (to be removed)	Item to the end of a Simulink Editor <b>File</b> menu
Simulink>EditMenu (to be removed)	Item to the end of a Simulink Editor <b>Edit</b> menu
Simulink:ViewMenu (to be removed)	Item to the end of a Simulink Editor <b>View</b> menu
Simulink:DisplayMenu (to be removed)	Item to the end of a Simulink Editor <b>Display</b> menu
Simulink:DiagramMenu (to be removed)	Item to the end of a Simulink Editor <b>Diagram</b> menu
Simulink:SimulationMenu (to be removed)	Item to the end of a Simulink Editor <b>Simulation</b> menu
Simulink:AnalysisMenu (to be removed)	Item to the end of a Simulink Editor <b>Analysis</b> menu
Simulink:CodeMenu (to be removed)	Item to the end of a Simulink Editor <b>Code</b> menu
Simulink:ToolsMenu (to be removed)	Item to the end of a Simulink Editor <b>Tools</b> menu
Simulink:HelpMenu (to be removed)	Item to the end of a Simulink Editor <b>Help</b> menu
Stateflow tags	
Stateflow:MenuBar (to be removed)	Menu to the Stateflow Editor menu bar
Stateflow:PreContextMenu	Item to the beginning of a Stateflow Editor context menu.
Stateflow:ContextMenu	Items to the end of a Stateflow Editor context menu.
Stateflow:FileMenu (to be removed)	Item to the end of a Stateflow Editor <b>File</b> menu
Stateflow>EditMenu (to be removed)	Item to the end of a Stateflow Editor <b>Edit</b> menu

<b>Tag</b>	<b>What It Adds</b>
Stateflow:ViewMenu (to be removed)	Item to the end of a Stateflow Editor <b>View</b> menu
Stateflow:DisplayMenu (to be removed)	Item to the end of a Stateflow Editor <b>Display</b> menu
Stateflow:ChartMenu (to be removed)	Item to the end of a Stateflow Editor <b>Chart</b> menu
Stateflow:SimulationMenu (to be removed)	Item to the end of a Stateflow Editor <b>Simulation</b> menu
Stateflow:AnalysisMenu (to be removed)	Item to the end of a Stateflow Editor <b>Analysis</b> menu
Stateflow:CodeMenu (to be removed)	Item to the end of a Stateflow Editor <b>Code</b> menu
Stateflow:ToolsMenu (to be removed)	Item to the end of a Stateflow Editor <b>Tools</b> menu
Stateflow:HelpMenu (to be removed)	Item to the end of a Stateflow Editor <b>Help</b> menu

### **Simulink and Stateflow Editor Menu Customization**

Use the same general procedures to customize Stateflow Editor menus as you use for Simulink Editor. The addition of custom menu functions to the ends of top-level menus depends on the active editor:

- Menus bound to `Simulink:FileMenu` only appear when the Simulink Editor is active.
- Menus bound to `Stateflow:FileMenu` only appear when the Stateflow Editor is active.
- To have a menu to appear in both of the editors, call `addCustomMenuFcn` twice, once for each tag. Check that the code works in both editors.

#### **Related Examples**

- “Disable Simulink Toolstrip and Context Menu Actions” on page 83-44
- “Disable and Hide Dialog Box Controls” on page 83-47
- “Customize Library Browser Appearance” on page 83-51
- “Register Customizations with Simulink” on page 83-55

## Disable Simulink Toolstrip and Context Menu Actions

You can disable items that appear in the Simulink Toolstrip and context menus. For context menus, you can also hide actions. To disable or hide an action, you must:

- 1 Get the name of the built-in action that you want to disable or hide.
- 2 Create or edit a customization file.
- 3 Create a filter function that disables or hides the item.
- 4 Register the filter function with the customization manager.
- 5 Refresh the Simulink customization file (`sl_customization.m`).

For example, this code creates and registers a filter function to disable the **New Model** button in the Simulink Toolstrip.

```
function sl_customization(cm)
    cm.addCustomFilterFcn('Simulink:NewModel',@myFilter);
end

function state = myFilter(callbackInfo)
    state = 'Disabled';
end
```

### Get Built-In Simulink Actions

To get the name and icon for a built-in action from the Simulink Toolstrip, use the `slToolstripDeveloperMode` function.

In the MATLAB Command Window, enter this command:

```
slToolstripDeveloperMode('on')

ans =

    logical

     0
```

The command enables developer mode for the Simulink Toolstrip. The returned value indicates that developer mode was disabled before you entered the command.

Pause on an item in the Simulink Toolstrip and press **Ctrl**. On a Mac, press **command** (⌘) instead of **Ctrl**.

For example, pause on the **Open** button and press **Ctrl**.

```
Action: openModelAction
Icon: open
-----
```

The names of the corresponding action and icon appear in the MATLAB Command Window.

## Set Up Customization File

To register customizations, use a MATLAB function file named `sl_customization.m`. Place the function on the MATLAB path of the Simulink installation that you want to customize or in the current folder.

You can have more than one `sl_customization.m` file. The customizations in each file take effect, with conflicts handled by each customization. For example, if you specify priorities for libraries in multiple `sl_customization.m` files, only one takes effect. If you add the same menu item twice, it appears twice. To ensure that customizations load as expected, refresh the customizations as described in “Read and Refresh Customization Files” on page 83-46.

The `sl_customization` function accepts one argument: a handle to the customization manager object (`cm`). For example:

```
function sl_customization(cm)
```

## Create Filter Functions

In the `sl_customization.m` file, create a filter function. Your filter function must accept a callback info object and return the state that you want to assign to the item. Valid states are:

- 'Hidden' — Hide the item.
- 'Disabled' — Disable the item.
- 'Enabled' — Enable the item.

For example, this filter function assigns the 'Disabled' state.

```
function state = myFilter(callbackInfo)
    state = 'Disabled';
end
```

Your filter function may have to compete with other filter functions and with Simulink to assign a state to an item. Which one succeeds depends on the strength of the state that each assigns to the item.

- 'Hidden' is the strongest state. If any filter function or Simulink assigns 'Hidden' to a menu item, it is hidden. For Simulink Toolstrip items, specifying 'Hidden' disables the item instead of hiding it.
- 'Disabled' overrides 'Enabled', but is itself overridden by 'Hidden'.
- 'Enabled' is the weakest state. For an item to be enabled, all filter functions and the Simulink or Stateflow products must assign 'Enabled' to the item.

## Register Filter Functions

Use the customization manager `addCustomFilterFcn` method to register a filter function. The `addCustomFilterFcn` method takes two arguments: a tag that identifies the menu or item to be filtered and a pointer to the filter function itself.

For example, the following code registers a filter function for the **New Model** item on the Simulink Toolstrip.

```
function sl_customization(cm)
    cm.addCustomFilterFcn('Simulink:NewModel',@myFilter);
end
```

## Read and Refresh Customization Files

The `sl_customization.m` file is read when Simulink starts. If you change the `sl_customization.m` file, either restart Simulink or enter this command to see the changes:

```
sl_refresh_customizations
```

This command runs all `sl_customization.m` files on the MATLAB path and in the current folder. Some side effects of running `sl_refresh_customizations` include:

- Rebuilding the Simulink Toolstrip
- Rebuilding all Simulink Editor menus
- Rebuilding the Library Browser menus and toolbars
- Clearing the Library Browser cache and refreshing the Library Browser
- Reloading the Viewers and Generators Manager data

## Disable and Hide Dialog Box Controls

### In this section...

“About Disabling and Hiding Controls” on page 83-47

“Disable a Button on a Dialog Box” on page 83-47

“Write Control Customization Callback Functions” on page 83-48

“Dialog Box Methods” on page 83-48

“Widget IDs” on page 83-48

“Register Control Customization Callback Functions” on page 83-49

### About Disabling and Hiding Controls

Simulink includes a customization API that allows you to disable and hide controls (also referred to as widgets), such as text fields and buttons, on most dialog boxes. The customization API allows you to disable or hide controls on an entire class of dialog boxes, for example, parameter dialog boxes, by way of a single method call.

Before you customize a Simulink dialog box or class of dialog boxes, first make sure that the dialog box or class of dialog boxes is customizable. Any dialog box that appears in the dialog pane of Model Explorer is customizable. In addition, any dialog box that has dialog and widget IDs is customizable. To determine whether a dialog box is customizable, open the dialog box, enable dialog and widget ID display (see “Widget IDs” on page 83-48), and hover over a widget. If a widget ID appears, you can customize the dialog box.

Once you have determined that a dialog box or class of dialog boxes is customizable, write MATLAB code to customize the dialog boxes. This entails writing callback functions that disable or hide controls for a specific dialog box or class of dialog boxes (see “Write Control Customization Callback Functions” on page 83-48) and registering the callback functions using the customization manager (see “Register Control Customization Callback Functions” on page 83-49). Simulink invokes the callback functions to disable or hide the controls whenever you open the dialog boxes.

### Disable a Button on a Dialog Box

This `sl_customization.m` file disables the **Browse** button on the **Code Generation** pane of the Configuration Parameters dialog box for any model whose name contains `engine`.

```
function sl_customization(cm)

% Disable for standalone Configuration Parameters dialog box
configset.dialog.Customizer.addCustomization(@disableRTWBrowseButton,cm);

end

function disableRTWBrowseButton(dialogH)
    hSrc = dialogH.getSource; % Simulink.RTWCC
    hModel = hSrc.getModel;
    modelName = get_param(hModel,'Name');

    if ~isempty(strfind(modelName,'engine'))
        % Takes a cell array of widget Factory ID.
        dialogH.disableWidgets({'STF_Browser'})
    end
end

end
```

To test this customization:

- 1 Save the `sl_customization.m` file on the MATLAB path.
- 2 Refresh the customizations by entering `sl_refresh_customizations` at the command line or by restarting MATLAB (see “Register Customizations with Simulink” on page 83-55).
- 3 Open the `sldemo_engine` model in the “Modeling Engine Timing Using Triggered Subsystems” example.
- 4 Open the Configuration Parameters dialog box and look at the **Code Generation** pane to see if the **Browse** button is disabled.

## Write Control Customization Callback Functions

A callback function for disabling or hiding controls on a dialog box accepts one argument: a handle to the dialog box object that contains the controls you want to disable or hide. The dialog box object provides methods that the callback function can use to disable or hide the controls that the dialog box contains.

The dialog box object also provides access to objects containing information about the current model. Your callback function can use these objects to determine whether to disable or hide controls. For example, this callback function uses these objects to disable the **Browse** button on the **Code Generation** pane of the Configuration Parameters dialog box for any model whose name contains `engine`.

```
function disableRTWBrowseButton(dialogH)

    hSrc = dialogH.getSource; % Simulink.RTWCC
    hModel = hSrc.getModel;
    modelName = get_param(hModel, 'Name');

    if ~isempty(strfind(modelName, 'engine'))
        % Takes a cell array of widget Factory ID.
        dialogH.disableWidgets({'STF_Browser'})
    end
```

## Dialog Box Methods

Dialog box objects provide these methods for enabling, disabling, and hiding controls:

- `disableWidgets(widgetIDs)`
- `hideWidgets(widgetIDs)`

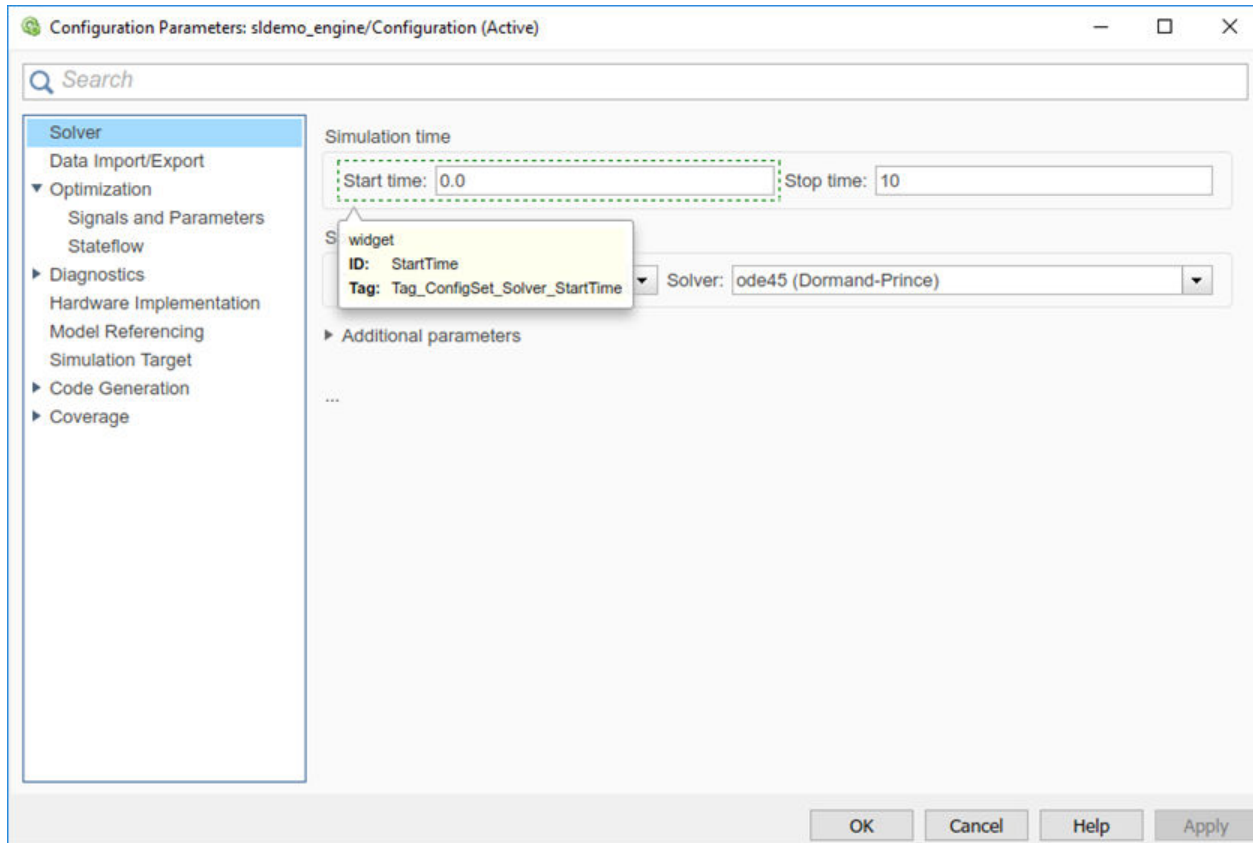

`widgetIDs` is a cell array of widget identifiers (see “Widget IDs” on page 83-48) that specify the widgets to disable or hide.

## Widget IDs

Widget IDs identify a control on a Simulink dialog box. To determine the widget ID for a particular control, execute the following code at the command line:

```
cm = sl_customization_manager;
cm.showWidgetIdAsToolTip = true
```

Open the dialog box that contains the control and hover over the control to display a tooltip listing the widget ID. For example, hovering over the **Start time** field on the **Solver** pane of the Configuration Parameters dialog box shows that the widget ID for the **Start time** field is `StartTime`.

---

**Note** The tooltip displays not customizable for controls that are not customizable.

---

## Register Control Customization Callback Functions

To register control customization callback functions for an installation of Simulink, include code in the installation `sl_customization.m` file (see “Register Customizations with Simulink” on page 83-55) that invokes the `configset.dialog.Customizer.addCustomization` method on the callbacks.

This method takes as an argument a pointer to the callback function to register. Invoking this method causes the registered function to be invoked before the dialog box is opened.

This example registers a callback that disables the **Browse** button on the **Code Generation** pane of the Configuration Parameters dialog box (see “Write Control Customization Callback Functions” on page 83-48).

```
function sl_customization(cm)

% Disable for standalone Configuration Parameters dialog box
configset.dialog.Customizer.addCustomization(@disableRTWBrowseButton,cm);

end
```

**Note** Registering a customization callback causes Simulink to invoke the callback for every instance of the class of dialog boxes specified by the method dialog box ID argument. You can therefore use a single callback to disable or hide a control for an entire class of dialog boxes. In particular, you can use a single callback to disable or hide the control for a parameter that is common to most built-in blocks. Most built-in block dialog boxes are instances of the same dialog box super class.

- “Register Customizations with Simulink” on page 83-55

## Customize Library Browser Appearance

### In this section...

“Reorder Libraries” on page 83-51

“Disable and Hide Libraries” on page 83-51

“Expand or Collapse Library in Browser Tree” on page 83-52

### Reorder Libraries

The library name and sort priority determines its order in the tree view of the Library Browser. Libraries appear in ascending order of priority. Libraries that have the same priority are sorted alphabetically.

The Simulink library has a sort priority of -1 by default. All other libraries have a sort priority of 0 by default. These sort priorities cause the Simulink library to display first in the Library Browser by default.

You can reorder libraries by changing their sort priorities. To change library sort priorities, add code in this form to an `sl_customization.m` file on the MATLAB path:

```
cm.LibraryBrowserCustomizer.applyOrder({'LIBNAME1',PRIORITY1, ...
                                       'LIBNAME2',PRIORITY2, ...
                                       .
                                       .
                                       'LIBNAMEN',PRIORITYN});
```

`LIBNAMEn` is the name of the library (or its model file) and `PRIORITYn` is an integer indicating the library sort priority. For example, this code moves the Simulink Extras library to the top of the Library Browser tree view.

```
cm.LibraryBrowserCustomizer.applyOrder({'Simulink Extras',-2});
```

After adding or modifying the `sl_customization.m` file, enter `sl_refresh_customizations` at the MATLAB command prompt to see the customizations take effect.

For more information on the customization functions, see “Register Customizations with Simulink” on page 83-55.

### Disable and Hide Libraries

To disable or hide libraries, sublibraries, or library blocks, insert code in this form in an `sl_customization.m` file (see “Register Customizations with Simulink” on page 83-55) on the MATLAB path. Blocks that you disable or hide in a library also do not appear on the quick insert menu that you invoke in the model.

```
cm.LibraryBrowserCustomizer.applyFilter({'Item1','State', ...
                                       'Item2','State', ...
                                       .
                                       .
                                       'ItemN','State'});
```

- `ItemN` is the library, sublibrary, or block to disable or hide. Specify the item in the form `'LibraryName/Sublibrary/Block'`.

- `LibraryName` is the library name as it appears in the browser. For a custom library, you set this value in the `slblocks.m` file with the `Browser.Name` property.
- `Sublibrary` is the name of the sublibrary or, for a custom library, a `Subsystem` block. You can specify a block inside the subsystem in your library or in a library that you open by way of the `Subsystem OpenFcn` callback. See “Create Custom Library” on page 44-2.
- `Block` is the block name.
- `'State'` is `'Disabled'` or `'Hidden'`.

For example, this code hides the `Sources` sublibrary of the `Simulink` library and disables the `Sinks` sublibrary.

```
cm.LibraryBrowserCustomizer.applyFilter({'Simulink/Sources','Hidden'});
cm.LibraryBrowserCustomizer.applyFilter({'Simulink/Sinks','Disabled'});
```

This code disables the `Sqrt` block in the sublibrary opened by way of the `Subsystem2` block in the custom library `'My Library'`.

```
cm.LibraryBrowserCustomizer.applyFilter(...
{'My Library/Subsystem2/Sqrt','Disabled'});
```

After adding or modifying the `sl_customization.m` file, enter `sl_refresh_customizations` at the MATLAB command prompt to see the customizations take effect.

## Expand or Collapse Library in Browser Tree

When you use the Library Browser in Standalone Mode, you can add a customization to expand or collapse any library in the Library Browser tree. For example, the `Simulink` library is expanded by default. You can specify to instead collapse it by default. Add code in this form to your `sl_customization.m` file:

```
cm.LibraryBrowserCustomizer.applyNodePreference(...
{'libraryName',logical});
```

---

**Note** To open the Library Browser in standalone mode, in the Library Browser window, click the Launch standalone library browser button .

---

Use `true` to expand the library and `false` to collapse it.

For example, this code collapses the `Simulink` library and expands the `Simscape` library:

```
function sl_customization(cm)
    cm.LibraryBrowserCustomizer.applyNodePreference(...
{'Simulink',false,'Simscape',true});
end
```

This code collapses a custom library named `'My Library'`.

```
function sl_customization(cm)
    cm.LibraryBrowserCustomizer.applyNodePreference(...
{'My Library',false});
end
```

After adding or modifying the `sl_customization.m` file, enter `sl_refresh_customizations` at the MATLAB command prompt to see the customizations take effect.

## Improve Quick Block Insert Results

You can double-click the end of a signal line that you draw from an existing block to add a block. A menu of possible blocks to insert appears. For example, at the end of a signal line out of a Gain block, the quick insert menu suggests other math blocks. Simulink comes with default suggestions.

You can improve the suggestions on this menu by updating the engine with information about your models. To do so, run a command on a single model or on all the models in a folder. Information about your model designs updates the engine. You can also remove this customization using a command.

Goal	Command
Improve results based on one model	<code>slblocksearchdb.trainfrommodel</code>
Improve results based on all the models in a folder	<code>slblocksearchdb.trainfrommodelsindir</code>
Remove the effects of a single model from the results	<code>slblocksearchdb.untrainmodel</code>
Remove the effects of all the models in a folder from the results	<code>slblocksearchdb.untrainmodelsindir</code>
Revert to the default results that come with Simulink	<code>slblocksearchdb.untrainall</code>

# Register Customizations with Simulink

In Simulink, you can register multiple customizations with an `sl_customization` function.

## Set Up Customization File

To register customizations, use a MATLAB function file named `sl_customization.m`. Place the function on the MATLAB path of the Simulink installation that you want to customize or in the current folder.

You can have more than one `sl_customization.m` file. The customizations in each file take effect, with conflicts handled by each customization. For example, if you specify priorities for libraries in multiple `sl_customization.m` files, only one takes effect. If you add the same menu item twice, it appears twice. To ensure that customizations load as expected, refresh the customizations as described in “Read and Refresh Customization Files” on page 83-55.

The `sl_customization` function accepts one argument: a handle to the customization manager object (`cm`). For example:

```
function sl_customization(cm)
```

## Edit the Customization File

In your `sl_customization` function, use customization manager object properties and methods specific to your application to register customizations. You can use customization properties and methods to:

- “Add Items to Model Editor Menus” on page 83-36
- “Disable Simulink Toolstrip and Context Menu Actions” on page 83-44
- “Disable and Hide Dialog Box Controls” on page 83-47
- “Add Libraries to Library Browser” on page 44-8
- “Customize Library Browser Appearance” on page 83-51
- “Import Lookup Table Data from MATLAB” on page 41-39

Additional MathWorks products use the customization manager object and the `sl_customization.m` file. Refer to the product documentation to learn about the methods and properties that apply to a product other than Simulink.

## Read and Refresh Customization Files

The `sl_customization.m` file is read when Simulink starts. If you change the `sl_customization.m` file, either restart Simulink or enter this command to see the changes:

```
sl_refresh_customizations
```

This command runs all `sl_customization.m` files on the MATLAB path and in the current folder. Some side effects of running `sl_refresh_customizations` include:

- Rebuilding the Simulink Toolstrip

- Rebuilding all Simulink Editor menus
- Rebuilding the Library Browser menus and toolbars
- Clearing the Library Browser cache and refreshing the Library Browser
- Reloading the Viewers and Generators Manager data

## Frames for Printed Models

---

## Create Print Frames for Printed Pages

Print frames are borders of a printed page that contain information about a block diagram, such as the model name or the date of printing. After you create a print frame, use the Simulink or Stateflow Editor to print a block diagram or chart with that print frame.

The default print frame has two rows:

Rows contain one or more cells. You can add content entries to cells. You can also add new rows and cells. Within cells, you can include text (such as the name and address of your organization) and variable content (such as the current date).

For example, the print frame below includes:

- An additional row at the top of the frame for a title
- A middle row, which includes the block diagram
- A bottom row, in which one cell has the path to the subsystem and another cell has the page number

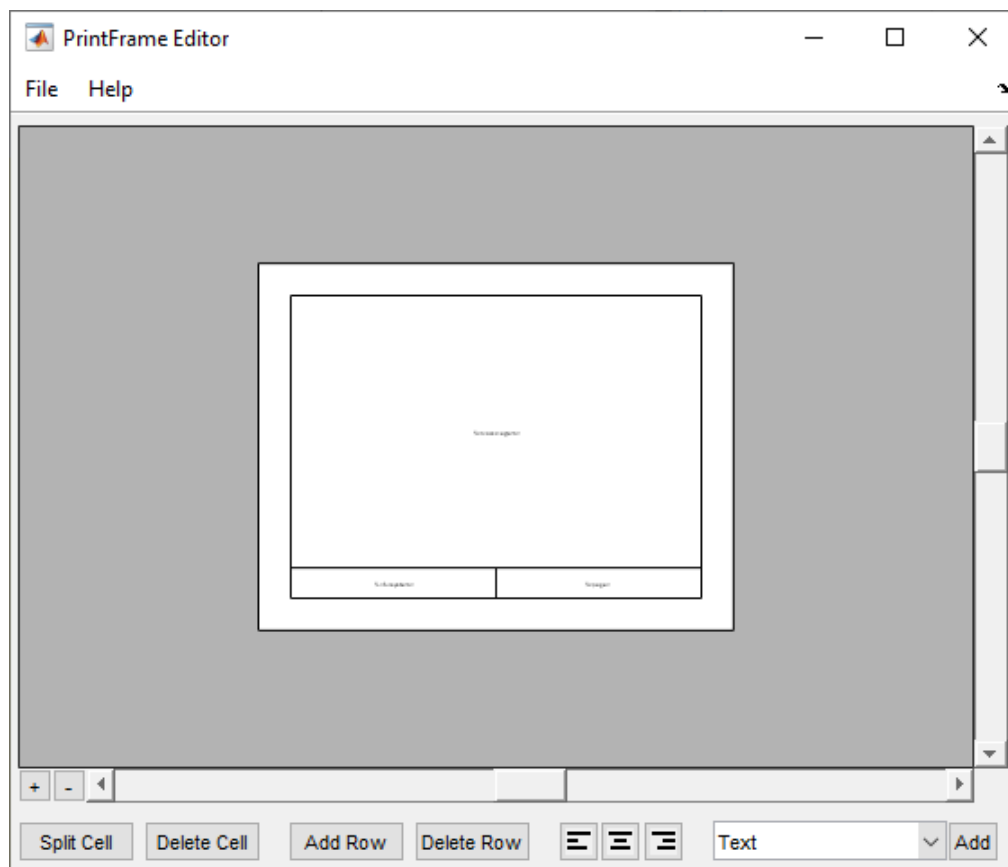

You can design a print frame for one particular block diagram, or you can design a more generic print frame for printing multiple block diagrams.

## PrintFrame Editor

Use the **PrintFrame Editor** to create and edit print frames.

To open the **PrintFrame Editor**, at the MATLAB Command Window, enter the `frameedit` command.

Use the **PrintFrame Editor** to:

- Set up the printed page.
- Add or remove rows and cells in the print frame.
- Add content to cells, such as text, the date, and page numbers.
- Format cell content.

To open an existing print frame, use `frameedit` with the `filename` parameter, where `filename` is an existing print frame (a `.fig` file).

## Create a Print Frame

- 1 At the MATLAB prompt, type `frameedit` to open the **PrintFrame Editor**.
- 2 In the **PrintFrame Editor**, select **File > Page Setup**.

If necessary, change default page setup for the print frame, which is:

- Paper type — `usletter`
- Orientation — **landscape**

---

**Note** The paper orientation you specify does not control the paper orientation used for printing. For example, assume you specify a landscape-oriented print frame in the

**PrintFrame Editor.** If you want the printed page to have a landscape orientation, you must specify that using the Print Model dialog box.

---

- Margins — 0.75 inches on all sides
- 3 Set up the layout of the print frame and add content.
  - 4 Save the print frame as a .fig file. Select **File > Save As**.

## Add Rows and Cells to Print Frames

To add a row above the row that you select:

- 1 Click in a cell to select a row.

When you select a row, handles appear on all four corners. If you select only a line, handles appear on two corners.

- 2 Click **Add Row**.

The new row appears above the row that you selected.

To remove a row, select the row and click **Delete Row**.

To add cells within a row:

- 1 Select the cell that you want to split.
- 2 Click **Split Cell**.

The cell splits into two cells.

To remove a cell, select the cell and click **Delete Cell**.

To change the dimensions of a row or cell by selecting the bordering line:

- 1 Click the line you want to move.

A handle appears on both ends of the line.

- 2 Drag the line to resize the row or cell.

For example, to make a row taller, click the top line that forms the row. Drag the line up, and the height of the row increases.

## Add Content to Print Frame Cells

You can add text, variables, or both to a cell.

To add content to print frame cells:

- 1 Select the cell that you want to add content to.
- 2 From the list, select the type of content that you want to add.
- 3 Click **Add**.

The type of content that you added appears in the cell.

---

**Tip** If you click **Add** and nothing happens, it might be because you did not select a cell first.

---

- 4 If you add text, select the edit box and type in the text.

---

**Tip** To make it easier to read and edit the content that you add, you can click the **Zoom in +** button.

---

To include multiple entries in a cell:

- 1 Select a cell that has a content entry.
- 2 Add another content type item from the list.

The new entry is added after the last entry in that cell.

Every print frame must include one **Block Diagram** variable. If you do not specify a **Block Diagram** in one of the cells, you cannot save the print frame and cannot print a block diagram with it. In addition to the **Block Diagram** variable, you can add other variables, such as the current date, to cells. Simulink supplies variable content at the time of printing.

The following table describes the variables you can add to cells.

Variable Entries	Description
Block Diagram	Add this variable in the cell in which you want the block diagram to print.  You cannot include multiple entries or text in the cell that contains the <b>Block Diagram</b> variable. %<blockdiagram> must be the only content in that cell.
Date	The date that the block diagram and print frame are printed, in dd-mmm-yyyy format.
Time	The time that the block diagram and print frame are printed, in hh:mm format.
Page Number	The page of the block diagram being printed.
Total Pages	The total number of pages being printed for the block diagram, which depends on the printing options specified.
System Name	The name of the block diagram being printed.
Full System Name	The name of the block diagram being printed, including its position from the root system through the current system, for example, engine/Throttle & Manifold.
File Name	The file name of the block diagram, for example, sldemo_engine.slx.
Full File Name	The full path and file name for the block diagram, for example, \\matlab\matlab\examples\simulink_automotive\main\sldemo_engine.slx.

Variable Entries	Description
Text	<p>The text that you want to include in that cell, for example, the name of your organization. To type additional text on a new line, press the <b>Enter</b> key. When you are finished editing, click outside of the edit box.</p> <p>You can copy and paste text from another document into a cell. Any formatting of the copied text is lost.</p> <p>To type special characters (for example, superscripts and subscripts, Greek letters, and mathematical symbols), use embedded TeX sequences. For a list of allowable sequences, see the <code>text</code> command <code>String</code> property (in <code>Text</code>).</p>

When you enter a variable, the cell displays the type of content in brackets, `<>`, preceded by a percent sign, `%`. For example, if you add a `Page Number` variable, it appears as `%<page>`.

---

**Note** Do not edit the text of a variable entry, because then the variable content does not print. For example, if you accidentally remove the `%` from the `%<page>` entry, the text `<page>` prints instead of the actual page number.

---

You can also add descriptive text to any of the variable entries without using the **Text** item.

- 1 Double-click in the cell.
- 2 Type text in the edit box before or after the entry.
- 3 To end editing mode, click outside of the cell.

## Format Content in Cells

You can align cell contents using the left, center, and right alignment buttons.

---

**Note** Block diagrams are always center aligned.

---

You can change font properties such as size or style (for example, italics or bold). To change font properties, select the cell, then right-click the contents and use the context menu to format the text.

# Running Models on Target Hardware

# About Run on Target Hardware Feature

---

- “Simulink Supported Hardware” on page 85-2
- “Block Produces Zeros or Does Nothing in Simulation” on page 85-3

## Simulink Supported Hardware

As of this release, Simulink supports the following hardware.

Support Package	Vendor	Earliest Release Available	Last Release Available
Android Devices	Android	R2014a	Current
Apple iOS Devices	Apple	R2015a	Current
Arduino Hardware	Arduino	R2013a	Current
BeagleBoard Hardware	BeagleBoard	R2012a	R2016a
LEGO MINDSTORMS EV3 Hardware	LEGO	R2014a	Current
Raspberry Pi Hardware	Raspberry Pi	R2013a	Current
Parrot Minidrones	Parrot®	R2017a	Current

For a complete list of supported hardware, see Hardware Support.

## Block Produces Zeros or Does Nothing in Simulation

If you simulate a model on your host computer without running it on your target hardware:

- Input blocks produce zeros.
- Output blocks do nothing.

This is the expected behavior.

For example, in a model, on the **Simulation** tab, if you select `Normal` in the **Simulate** section, and then click **Run**, the following happens:

- The sensor block and Digital Input block send zeros to the model.
- The Digital Output block does nothing.

To see the blocks work normally, run your model on target hardware or use External mode.

To run the model on target hardware, on the **Modeling** tab, click **Model Settings**. In the Configuration Parameters dialog box, open the **Hardware Implementation** pane, select your hardware board from the list, and click **Apply**. Then, in the Simulink Editor, on the **Hardware** tab, click **Build, Deploy & Start**.

To use External mode, on the **Modeling** tab, click **Model Settings**. In the Configuration Parameters dialog box, open the **Hardware Implementation** pane, select your hardware board from the list, and click **Apply**. Then expand **Target hardware resources**, and under **Groups** select **External mode**. Review the configuration parameter settings, such as the **Communication interface**. Then, in the Simulink Editor, on the **Modeling** tab, change the simulation mode to `External`, and click **Run**.

# Running Simulations in Fast Restart

---

- “How Fast Restart Improves Iterative Simulations” on page 86-2
- “Get Started with Fast Restart” on page 86-5

## How Fast Restart Improves Iterative Simulations

In a typical simulation, when you simulate a model, the software:

- 1 Compiles the model
- 2 Simulates the model
- 3 Terminates the simulation

While developing a model, you typically simulate a model repeatedly as you iterate the design. For example, you might calibrate input values or block parameters for a particular response. Changing these values or parameters does not always require compiling the model before simulating again. However, in the classic workflow, each simulation compiles the model, even if the changes do not alter the model structurally. Each compile slows down the process and increases overall simulation time.

Fast restart allows you to perform iterative simulations without compiling a model or terminating the simulation each time. Using fast restart, you compile a model only once. You can then change values for root inputs, values for model initial state, and from Workspace block data, tune parameters and root inputs and simulate the model again without spending time on recompiling. Fast restart associates multiple simulation phases to a single compile phase to make iterative simulations more efficient.

Use fast restart when your workflow does not require structural changes to the model. Also, fast restart is better suited if the workflow involves any of these factors:

- The model requires multiple simulations in which simulation inputs or parameters change in every iteration.
- The compile time of the model is several seconds or longer.
- You need to switch solvers during runtime to pick the appropriate solvers without having to go through an expensive recompilation process.

You can use fast restart in normal and accelerator simulation modes. When you use fast restart in accelerator mode, you reduce simulation time and perform only a single compilation.

### Limitations

- Fast restart is not supported for rapid accelerator or external mode simulations.
- Fast restart is not supported for model hierarchies that contain one or more referenced models configured to use a local solver. For more information, see “Use Local Solvers in Referenced Models” on page 27-5.
- When a model is in the reinitialized state, you cannot:
  - Make structural changes.
  - Make changes to nontunable parameters such as sample time.
  - Save changes to the model. You must turn off fast restart to save any changes to the model.
- You cannot turn on fast restart in a model if it contains blocks that do not support saving and restoring the model operating point. These blocks include:
  - SimEvents blocks from before R2016a

- MATLAB function blocks that contain system objects
- S-functions that do not implement the model operating point `get` and `set` methods but have `Pwork` vectors declared
- From Multimedia File
- To Multimedia File
- Multipath Rician Fading Channel
- Multipath Rayleigh Fading Channel
- Derepeat
- DC Blocker
- Stack
- Queue
- Read Binary File
- Write Binary File
- Video Viewer
- Frame Rate Display
- Video From Workspace
- Video To Workspace
- You cannot turn on fast restart in a model if it directly or indirectly references a model that simulates in accelerator mode and contains Simscape blocks.
- Between simulations, fast restart does not handle changes to design data, such as bus properties.
- Parameter tunability limitations apply. See “Tunability Considerations and Limitations for Other Modeling Goals” on page 40-36.
- The Fixed-Point Tool provides limited support when a model is simulated in fast restart. You must exit fast restart to collect simulation and derived ranges, and propose data types.
- When there are multiple model references to the same referenced model, you cannot change the model visibility when the model is in the reinitialized state.
- Fast restart is not compatible with the Simulink Profiler.
- When simulating a model in fast restart, you cannot run checks using Model Advisor.
- When you enable fast restart, the `sim` function supports only the single output `Simulink.SimulationOutput` form, regardless of the syntax you use.
- When you enable fast restart, you cannot pass non-tunable parameters as arguments to the `sim` function.

- “Choosing a Simulation Mode” on page 38-10
- “Save and Restore Operating Points for Stateflow Charts” (Stateflow)

- “Use Model Operating Point for Faster Simulation Workflow” on page 27-44

## Get Started with Fast Restart

### In this section...

“Prepare a Model to Use Fast Restart” on page 86-6

“Fast Restart Methodology” on page 86-8

When you need to simulate a model iteratively to tune parameters, achieve a desired response, or automate testing, use fast restart to avoid compiling again. Fast restart allows you to perform iterative simulations without compiling a model or terminating the simulation each time. A generic workflow using fast restart involves the following steps.

- 1 Enable fast restart using the **Fast Restart** button on the Simulink Toolstrip.
- 2 Simulate the model.

The first simulation requires the model to compile, initialize and capture a snapshot of the model operating point. Once the simulation is complete, it does not terminate. Instead, the model is initialized again in fast restart.

- 3 Perform any of these actions:
  - Change tunable parameters.
  - Switch between variable-step solvers.
  - Tune root-level inputs.
  - Modify variables in the base workspace or model workspace and data dictionary entries that are referenced by tunable parameters.
  - Change inputs to From File and From Workspace blocks.
  - Change the **Initial state** parameter for the next simulation.
  - Using the Signal Editor block, change data, rename signals and scenarios, and add new scenarios.
  - Change the signal logging override values for the model programmatically by using the `set_param` function and the `DataLoggingOverride` parameter. See “Override Signal Logging Settings from MATLAB” on page 77-57.

Once you have initialized a model in fast restart, you cannot

- Change the dimension, type, or complexity of a signal or variable.
- Make changes to a nontunable parameter such as sample time.
- Make structural changes such as adding or deleting blocks or connections.

These changes require you to compile the model again. To make changes like these, turn off fast restart, make your changes, and repeat this procedure.

- 4 Simulate the model. The model uses the new values of parameters and inputs that you provided but does not compile again.
- 5 Once you have achieved the desired response, turn off fast restart.

---

**Note** When you disable fast restart, the software does not retain any compilation information for the model. The model compiles when you next simulate the model.

---

## Prepare a Model to Use Fast Restart

Before you simulate a model in fast restart, ensure that the model meets these requirements:

- If you have enabled callbacks in the model, make sure they do not attempt to make structural changes when the model is reinitialized. For example, callbacks such as mask initialization commands get called at the beginning of each simulation. Therefore, avoid using mask initialization code that makes structural changes to the model.
- All blocks in the model must support `ModelOperatingPoint` object.
- The simulation mode is Normal or Accelerator mode.

---

**Note** When fast restart is on, you cannot save changes to the model after it compiles. To save changes, the software must discard information about the compiled state. To save changes to the model, disable fast restart.

---

### Enable Fast Restart

Use one of these methods to enable fast restart:

- Click the **Fast restart** button  on the Simulink Editor toolbar.
- In the MATLAB Command Window, use the `set_param` function to enable fast restart.

```
set_param(model, "FastRestart", "on")
```

### Simulate a Model using Fast Restart

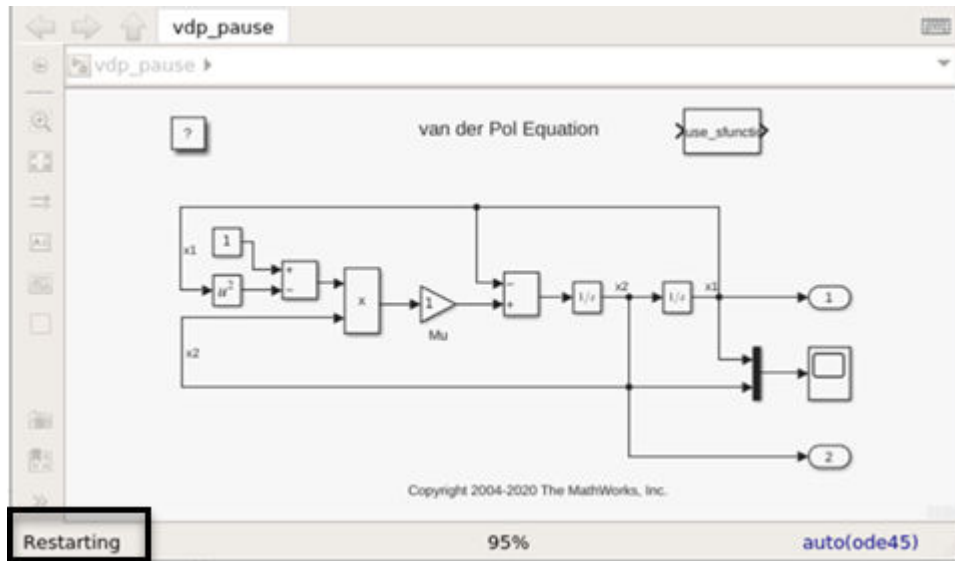

After you load your model and turn on fast restart, simulate the model.

- 1 Simulate the model by calling `sim` or clicking the **Run** button  in the Simulink Toolstrip. The first simulation in fast restart requires the model to compile and capture a snapshot of the model operating point.

Once the simulation is complete, the status bar shows that the model is compiled in fast restart.

While fast restart is in progress, the simulation status becomes **Restarting**, and the Simulink Editor becomes frozen like it is during model compilation and initialization.

- 2 Adjust tunable parameters in the model, such as the gain value of a Gain block, or tune root-level input values. You can also make changes to base workspace variables. You cannot adjust nontunable parameters such as sample time, because doing so requires the model to compile once more.
- 3 Simulate the model again. This time, the model does not compile. When you click the **Play** button or step forward, Simulink updates blocks that have new values as well as blocks that reference workspace variables.
- 4 When you are satisfied with your results, turn off fast restart by clicking the **Fast restart** button off.
- 5 To keep your changes, save the model.

---

**Note** After a model is initialized in fast restart, the software issues a warning if you attempt to make a structural change to the model. To make such changes, disable fast restart.

---

### Stop a Simulation

When you click **Stop** in the middle of a fast restart simulation:

- Simulation does not terminate.
- The model is in the initialized state.
- You can change tunable parameters in the model
- You can terminate the simulation and exit fast restart by disabling fast restart.

### Exit Fast Restart

You can exit fast restart only when the model is in the initialized state. After simulating, click the **Fast restart** button. To do this programmatically, use the `set_param` function.

```
set_param(model, "FastRestart", "off")
```

- The software terminates simulation.

- The software discards compilation information about the model.
- The model must compile again the next time you simulate.

## Fast Restart Methodology

### Tuning Parameters Between Simulations

- When a model is initialized in fast restart, in addition to block values and base workspace variables, you can tune parameters in the **Data Import/Export** and **Solver** panes in the Configuration Parameters dialog box (on the **Simulation** tab, under **Prepare**, click **Model Settings**).
- Certain parameters are tunable between simulations only when the model is initialized in fast restart. They include:
  - **Initial Value** parameter of the IC block
  - **Initial Output** parameter of the Merge block
  - **Data** parameter of the From Workspace block
  - **Active scenario** parameter of the Signal Editor block. You can also open the Signal Editor tool and edit the signal data, create and remove scenarios and signals, and so forth. You can change the **Active signal** and view the signal properties, but cannot edit the Signal Editor signal properties in fast restart.

### Switching Solvers Between Simulations

When fast restart is on, you can switch solvers between simulations. Only valid solvers that can be switched to are listed in the Solver list in the Configuration Parameters dialog box. If you switch solvers using `set_param` command between simulations and set to an invalid solver, you will see a warning and the invalid solver will be ignored.

### Model Methods and Callbacks in Fast Restart

When fast restart is on, Simulink calls model and block methods and callbacks as follows:

- 1 Call model `InitFcn` callback.
- 2 Call model `SetupRuntimeResources` method.
  - a Call `mdlSetupRuntimeResources` S-function method.
- 3 Call model `Start` method.
  - a Call `mdlStart` S-function method.
- 4 Call model `Initialize` method.
  - a Call `mdlInitializeConditions` S-function method.

---

**Note** Use the `ssIsFirstInitCond` flag to guard code that should run only during the initialization phase of any simulation, including the first and subsequent initializations in fast restart.

---

- 5 Call model and block `StartFcn` callbacks.

---

**Note** Steps 1-5 apply to all simulations in Simulink (with or without fast restart).

---

- 6 For the first simulation in fast restart, capture a simulation snapshot. A simulation snapshot contains simulation state (`ModelOperatingPoint`) and information related to logged data and visualization blocks. As part of the snapshot capture, call `ModelOperatingPoint` S-function method.
- 7 This is a standard execution phase of any simulation, with or without fast restart.
  - Call `model Outputs`.
  - Call `model Update`.
  - Call `model Derivatives`.
  - Repeat these steps in a loop until stop time or a stop is requested.
- 8 Call `model Terminate` method.
  - a Call `mdlTerminate` S-function method.
- 9 After simulation ends, call `model` and `block StopFcn` callbacks. This is a standard phase of any simulation, with or without fast restart.
- 10 Restore the simulation snapshot taken for fast restart. As part of the restore, call `set` S-function method.
- 11 Wait in a reinitialized state until one of these actions:
  - To run another simulation (programmatically or using the Simulink Editor) in fast restart, return to step 3.
  - To end Fast Restart mode and uncompile the model:
    - a Call the `model` method `CleanupRuntimeResources` and the `mdlCleanupRuntimeResources` S-function method.
    - b Do not call `StopFcn` callbacks again at this point.

In some cases, the `Start` and `Terminate` methods are only called once and not for each successive Fast Restart simulation. In these cases, these method calls are combined with calls to `SetupRuntimeResources` and `CleanupRuntimeResources`, respectively. These cases are as follows:

- When an S-function contains custom `ModelOperatingPoint` save and restore methods.
- When an S-function sets the flag `SS_OPTION_CALL_TERMINATE_ON_EXIT`.
- When an S-function is placed inside the accelerated mode of a referenced model.

For more information on model callbacks, see “Customize Model Behavior with Callbacks” on page 4-52.

### Operating Point and Initial State Values

You can change initial state values, including `ModelOperatingPoint`, in between fast restart simulations.

When a `ModelOperatingPoint` object for initial state is used in fast restart, every new simulation resets to the start time of the model and not the snapshot time of each `ModelOperatingPoint` object. Thereafter, on the first step forward, Simulink checks to see if a `ModelOperatingPoint` has been specified. If yes, Simulink restores it before computing the next step. Thus, the first simulation step effectively fast forwards to the snapshot time of the specified `ModelOperatingPoint` object.

### **Analyze Data Using the Simulation Data Inspector**

Fast restart supports data logging using the Simulation Data Inspector. Every simulation in fast restart creates an SDI object with the name **<modelname> fast restart run <number>**. The value of **number** increments for each simulation.

### **Custom Code in the Initialize Function**

When you place custom code in the **Configuration Parameters > Simulation Target > Custom Code > Initialize function** pane in the **Model Configuration Parameters** dialog box, this gets called only during the first simulation in fast restart.

# Model Component Testing

# Component Verification

---

- “Component Verification” on page 87-2
- “Run Polyspace Analysis on Generated Code by Using Packaged Options Files” on page 87-5
- “Analyze Code Generated as Standalone Code in a Distributed Workflow” on page 87-8

## Component Verification

### In this section...

“Use Foundational Blocks” on page 87-2

“Perform Rigorous Component Verification” on page 87-2

When testing models, you may find that your models do not meet design requirements. Resolving these problems requires additional component verification. Depending on your needs, you can use the Signal Editor block, blocks in the Model Verification library, or products such as Simulink Test, Simulink Design Verifier, and Simulink Coverage to test model components.

### Use Foundational Blocks

You can use the “Model Verification” library to verify the behavior of your model components. These blocks check if model signals meet specified requirements. If those requirements are not met during simulation, the blocks can stop the simulation or display a warning. For more information, see “Test Model Components”.

You can also create test cases by using the Signal Editor block to configure your input signals and then log the system outputs. For more information, see “Create and Edit Signal Data” on page 74-2. After creating the signal data, you can log the outputs and save the test cases for later use. For more information, see “Mark Signals for Logging” on page 77-43.

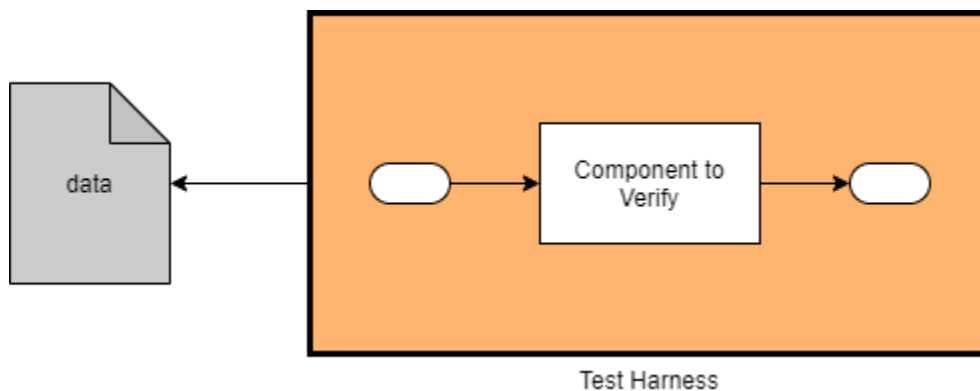

### Perform Rigorous Component Verification

Some components require a large number of tests that are difficult to manage using only the Model Verification library and the Signal Editor block. If you require more rigorous component verification, use “Simulink Test”.

You can generate test case data for either a component in isolation or for a component that is part of a model.

#### Create Test Cases for an Isolated Component

To verify how a component behaves in absence of other components, you can test isolated components.

To create test case data for an isolated component:

- 1 Create a test harness for the component with Simulink Test and add the appropriate test cases. For more information on how to create a test harness, see “Create a Test Harness” (Simulink Test).
- 2 Log the test signals.
- 3 Repeat steps 1-2 until you configure the test cases to meet your design goals.

### Create Test Cases for a Component in a Model

You can also create test case data for a component in a larger model, such as when the component is in a closed-loop controller or part of a broader container model.

To create test case data for a component in a model:

- 1 Use Simulink Test to add the appropriate test cases to the model.
- 2 Add the component to a test harness and generate the component test cases directly from the model. For more information, see “Generate Tests and Test Harnesses for a Model or Components” (Simulink Test).
- 3 If the test cases are not comprehensive, create a harness for the component and add or modify test cases.
- 4 Repeat steps 1-3 until you configure the test cases to meet your design goals.

### Run the Test Suite on the Component

If you create test cases for both isolated components and components in a model by using Simulink Test, the resulting test suite contains all of the test cases. The **Test Manager** in Simulink Test allows you to manage and execute the test cases you created. For more information, see “Create a Simple Baseline Test” (Simulink Test). The **Test Manager** also allows you to perform additional verification activities, such as analyzing coverage. For more information, see “Collect Coverage in Tests” (Simulink Test). Once the results meet your design goals, you can prepare the component for additional testing.

### Use Other Products for Additional Test Case Management

If the component coverage is incomplete, you can use Simulink Design Verifier to automatically create test cases that can supplement missing test coverage. For more information, see “What Is Test Case Generation?” (Simulink Design Verifier). You can then rerun the analysis in Simulink Test. If you are satisfied with the results, you can use the test case data to verify additional design objectives by using Simulink Coverage and Simulink Check.

You can also perform some of the activities available in Simulink Test with other products, although these options have more limited functionality. For example, you can create a test harness with the

`slvnmakeharness` function. If you are only interested in the simulation outputs, you can run the test case input signals by creating a `Simulink.SimulationInput` object and running multiple simulations. For more information, see “Running Multiple Simulations” on page 29-2.

## Run Polyspace Analysis on Generated Code by Using Packaged Options Files

When you start a Polyspace analysis directly from the Simulink toolstrip, the analysis takes the model-specific context, such as design ranges, into consideration. When running a Polyspace analysis from outside Simulink, you must specify the model-specific information by using options files. Instead of authoring these options files, use the options files generated and packaged by the function `polyspacePackNGo`.

Preserving the Simulink model context information when running a Polyspace analysis from outside Simulink can be useful in various situations. For instance:

- **Distributed workflow:** A Simulink user generates code from a model and sends the code to another development environment. In this environment, a Polyspace user, who might not have Simulink, runs a separate analysis of the generated code. By using the packaged options files, the design ranges and other model-specific information is preserved in the Polyspace analysis.
- **Analysis options not available in Simulink:** Some Polyspace analysis options are available only when the Polyspace analysis is run separately from Simulink. Use packaged options files to run a separate Polyspace analysis while preserving the model-specific information. For instance, analyze concurrent threads in generated code by running a Polyspace analysis in the generated code by using the packaged options files.

You must have Simulink to run the function `polyspacePackNGo`. You do not need Polyspace to generate the options files from a Simulink model. The `polyspacePackNGo` function supports code generated by Embedded Coder and TargetLink®. For a tutorial on using `polyspacePackNGo`, see “Analyze Code Generated as Standalone Code in a Distributed Workflow” on page 87-8.

### Generate and Package Polyspace Options Files

To generate and package Polyspace options file for analyzing code generated from a Simulink model, use `polyspacePackNGo`.

- 1 In the Simulink Editor, open the Configuration Parameters dialog box and configure the model for code generation.
- 2 To configure the model for compatibility with Polyspace, select `ert.tlc` as the **System target file**
- 3 To enable generating a code archive, select the option **Package code and artifacts**. Optionally, provide a name for the options package in the field **Zip file name**. If your code contains a custom code block, select **Use the same custom code settings as Simulation target** in the **Code Generation> Custom Code** pane.

Alternatively, in the MATLAB Command Window, enter:

```
% Configure the Simulink model mdlName for code generation
configSet = getActiveConfigSet(mdlName);
set_param(configSet, 'PackageGeneratedCodeAndArtifacts', true);
set_param(configSet, 'PackageName', 'CodeArchive.zip');
set_param(configSet, 'SystemTargetFile', 'ert.tlc');
set_param(configSet, 'RTWUseSimCustomCode', 'on');
```

- 4 Generate the code archive.

- To generate an archive of standalone generated code from the top model, use the function `slbuild`.
  - To generate code as a model reference, use the function `slbuild`. After generating code as model reference, create the code archive by using the function `packNGo`.
  - Alternatively, you can use `TargetLink` to generate the code. Create the code archive by archiving the generated code into a zip file.
- 5 To generate and package the Polyspace option files, in the MATLAB Command Window ,use the `polyspacePackNGo` function :

```
zipFile = polyspacePackNGo mdlName);
```

See “Generate and Package Polyspace Options Files”.

If you use `TargetLink` to generate code, then use the `TargetLink` subsystem name as the input argument to `polyspacepacknGo`.

- 6 Optionally, you can use a `pslinkoptions` object as a second argument to modify the default model configuration for the Polyspace analysis. Create a `pslinkoptions` object, modify model configurations and specify the object when creating the archive:

```
psOpt = pslinkoptions(mdlName);
psOpt.InputRangeMode = 'FullRange';
psOpt.ParamRangeMode = 'DesignMinMax';
zipFile = polyspacePackNGo(mdlName,psOpt);
```

See “Package Polyspace Options Files That Have Specific Polyspace Analysis Options”.

- 7 Use the optional third argument to specify whether to generate and package Polyspace options files for code generated as a model reference. Suppose you generated code as a model reference by using the `slbuild` function. To generate and package Polyspace options for the code, at the MATLAB Command Window, enter:

```
zipFile = polyspacePackNGo(mdlName,[],true);
```

See “Package Polyspace Options Files for Code Generated as a Model Reference”.

The function `polyspacepackNGo` returns the full path to the archive containing the options files. The files are located in the `polyspace` folder within the archived folder hierarchy. The content of the `polyspace` folder depends on the inputs of `polyspacePackNGo` function.

- If you do not specify the optional second and third arguments, then the folder `polyspace` contains these options files in a flat hierarchy:
  - `optionsFile.txt`: This file specifies the source files, the include files, data range specifications, and analysis options required for analyzing the generated code by using Polyspace. If your code contains custom C code, then this file specifies the relative paths of the custom source and header files.
  - `modelName_drs.xml`: This file specifies the design range specification of the model.
  - `linksData.xml`: This file links the generated code to the components of the model.
- If you specify `psOpts.ModelbyModelRef = true`, then corresponding options files are generated for all referenced models. These options files are stored in separate folders named `polyspace_<referenced model name>` within the code archive. The folder `polyspace` contains the options files for the top model.

## Run Polyspace Analysis by Using the Packaged Options Files

Once the code archive and the Polyspace option files are generated, you can use the archive to run a Polyspace analysis on the generated code in a different development environment without Simulink.

- 1 Unzip the code archive and locate the `polyspace` folder.
- 2 On a Windows or Linux command line, run: `productname -options-file optionsFile.txt -results-dir resultdir`.
  - `productname` corresponds to one of: `polyspace-bug-finder`, `polyspace-code-prover`, `polyspace-bug-finder-server`, or `polyspace-code-prover-server`.
  - `resultdir` corresponds to the location of the Polyspace results. This argument is optional.

To link the generated code with the Simulink model, the file `linksData.xml` is required. In case the file `linksData.xml` is not generated in the options file archive, use the option **Code Generator Support** in Polyspace desktop User Interface to specify which comments in the code act as links to the Simulink model. In the Polyspace desktop User Interface, select **Tools > Preferences** and locate the **Miscellaneous** tab. From the context menu **Code comments that act as code-to-model-link**, select the code generator that you used. If you select **User defined**, then specify the comments that act as a code-to-model link by specifying their prefix in the field **Comments beginning with**. For instance, if you specify the prefix as `//Link_to_model`, then Polyspace interprets comments starting with `//Link_to_model` as links to model.

If you are using Polyspace Access to view the results, upload the file `linksData.xml` in the same folder as your Polyspace results. You cannot link the code with Simulink model if you do not have the file `linksData.xml` or if you upload it outside the Polyspace result folder.

- 3 To review the result, upload it to Polyspace Access and view the results in a web browser. Alternatively, view the result by using the user interface of the Polyspace desktop products.

### See Also

`polyspacePackNGo` | `slbuild` | `packNGo`

### More About

- “Analyze Code Generated as Standalone Code in a Distributed Workflow” on page 87-8

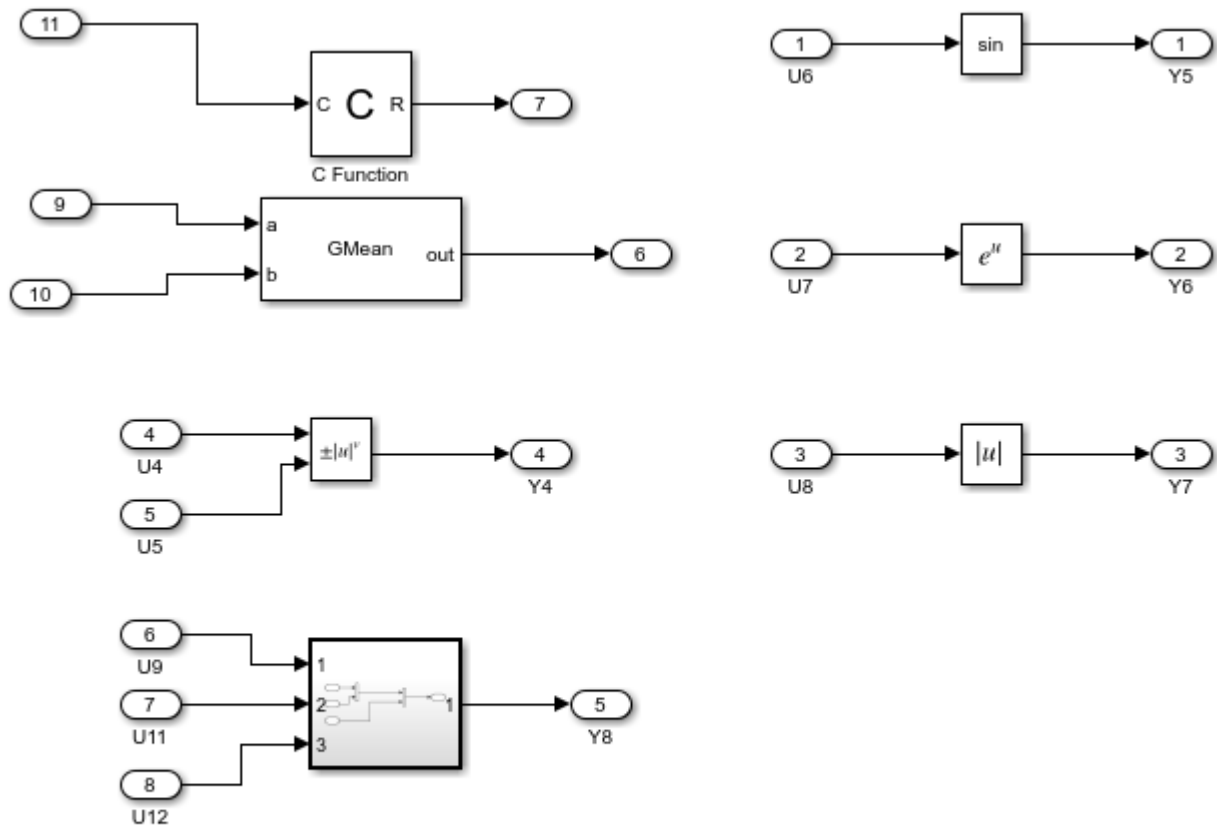

## Analyze Code Generated as Standalone Code in a Distributed Workflow

Generate and package Polyspace options files from a Simulink model by using the function `polyspacepackNGo`. Use these options files to run a Polyspace analysis on the generated code that uses model-specific information, such as design range specifications, without requiring Simulink.

### Open Model for Distributed Analysis

The model `demo_math_operations` performs various mathematical operations on the model inputs. The model has a C Function block that executes a custom C code. The model also has a C Caller block that calls the C function `GMean`, which is implemented in the source file `GMean.c`. To open the model for code generation and packaging Polyspace options file, search for the current topic and click the **Open Model** button. Alternatively, in the MATLAB Command Window, paste and run the following code.

```
openExample('sl_poly_bf_poly_code_prover/OpenModelForPolyspacePackNGoExample');  
open_system('demo_math_operations');
```

Copyright 1990-2020 The MathWorks, Inc.

## Configure Model

To configure the model for generating code and packaging Polyspace options files, specify these configuration parameters:

- To create an archive containing the generated code, set 'PackageGeneratedCodeAndArtifacts' to true.
- Specify a name for the code archive. For instance, set the name to `genCodeArchive.zip`.
- To use the custom code setting specified in **Simulation Target** during code generation, set 'RTWUseSimCustomCode' to 'on'.
- To make the model and the generated code compatible with Polyspace, set `ert.tlc` as the system target file. See "Recommended Model Configuration Parameters for Polyspace Analysis" (Polyspace Bug Finder).

In Command Window or Editor, enter these parameter configurations:

```
configSet = getActiveConfigSet('demo_math_operations');
set_param(configSet, 'PackageGeneratedCodeAndArtifacts', true);
set_param(configSet, 'PackageName', 'genCodeArchive.zip');
```

```
set_param(configSet, 'SystemTargetFile', 'ert.tlc');  
set_param(configSet, 'RTWUseSimCustomCode', 'on')
```

## Generate Code Archive

Specify a folder for storing the generated code. To start code generation, in the Command Window or in the Editor, enter:

```
codegenFolder = 'demo_math_operations_ert_rtw';  
if exist(fullfile(pwd,codegenFolder), 'dir') == 0  
    slbuild('demo_math_operations')  
end
```

Because `PackageGeneratedCodeAndArtifacts` is set to `true`, the generated code is packed into the archive `genCodeArchive.zip`.

## Generate and Package Polyspace Options File

To generate Polyspace options files for the generated code, in the Command Window or in the Editor, enter:

```
zipFile = polyspacePackNGo('demo_math_operations');
```

In the archive `genCodeArchive.zip`, find the options files in the folder `<current folder>/polyspace`.

## Run Polyspace Analysis by Using the Packaged Options Files

- 1 Unzip the code archive `genCodeArchive.zip` and locate the `<current folder>/polyspace` folder.
- 2 Open a command-line terminal and change your working folder to the `polyspace` subfolder of the unzipped folder by using the `cd` command.
- 3 Start a Polyspace analysis.
  - To run a desktop Polyspace analysis, use either `polyspace-code-prover` or `polyspace-bug-finder`. To run the Polyspace analysis in a server, use either `polyspace-bug-finder-server` or `polyspace-code-prover-server`. Polyspace Bug Finder and Code Prover analyze the code differently. See “Differences Between Polyspace Bug Finder and Polyspace Code Prover” (Polyspace Bug Finder).
  - Specify the file `optionsFile.txt` as the argument to `-options-file`.

To run a Code prover analysis, run this command: `polyspace-code-prover -options-file optionsFile.txt -results-dir Results`.

- 4 Follow the progress of the analysis in the log file that is generated in the `Results` folder.
- 5 To view the results in the desktop user interface, in the command-line interface, enter: `polyspace Results\ps_results.pscp`. The extension of the `ps_results` file changes depending on whether you run a Code Prover analysis or a Bug Finder analysis. The result contains several orange checks.

Family	Information	File
-Run-time Check		3 15 118
-Gray Check		3
-Orange Check		15
-Green Check		118
-Global Variable		2
-Not shared		2

Alternatively, upload the result to Polyspace Access. See “Upload Results to Polyspace Access” (Polyspace Bug Finder).

- 6 Address the results. For more information, see “Address Results Through Bug Fix or Comments” (Polyspace Bug Finder).

# Manage a Variant Model Using Variant Manager

---

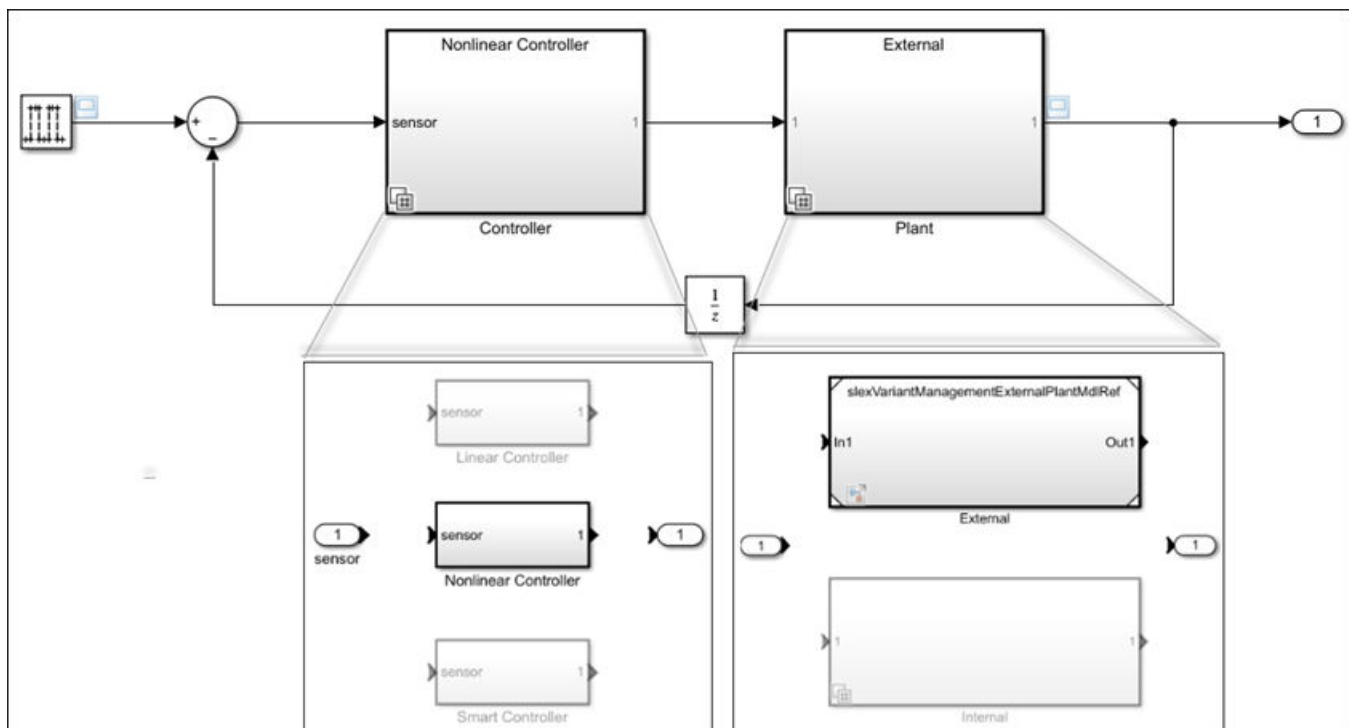

## Variant Configurations

**Note** This functionality requires Variant Manager for Simulink.

### What is a Variant Configuration?

Using variant elements in Simulink, you can represent all design alternatives of a system component in a single model. Each variant of a system component is depicted as a variant choice in the model. A variant control associated with each variant choice allows you to activate or deactivate the choice in the model.

For example, consider a model for a system with a plant and a controller. The controller component has three variant choices, `Linear`, `NonLinear`, and `Smart`. The plant component has two choices, `External` and `Internal`. This model uses Variant Subsystem blocks to represent these components and their choices. Combinations of these variant choices represents different modes or different configurations of the system, for example, a *linear controller with an internal plant with no noise* or a *nonlinear controller with an external low fidelity plant*. The latter configuration is shown in this figure.

A variant configuration represents a combination of variant choices across the model hierarchy. It contains a set of variant control variables and their values, which you can use to activate a specific variant in the model hierarchy. It helps you to easily define and manage variation points in a model.

The number of variant configurations for a model can be high depending on the number of variant choices. Configuring the choices and switching between them manually can be complicated and can introduce errors. You can use Variant Manager to define, apply, and manage variant configurations for the model.

Variant Manager enables you to:

- Create variant configurations and define constraints.
- Automatically generate and validate all possible variant configurations for a model.
- Validate and activate a configuration on the model.
- Use Variant Reducer to generate a reduced model that contains only selected configurations.
- Use Variant Analyzer to compare multiple variant configurations in a tabular form, verify that all variant choices have been activated at least once, and identify any inconsistencies in the configurations.

## Types of Variant Configurations

- The global workspace configuration:

The variant control variables and their values currently present in the base workspace or data dictionary of the model function as a temporary variant configuration for the model.

---

**Note** This configuration is temporary because it is not saved to the variant configuration object associated with the model.

---

- A named variant configuration:

You can create multiple named variant configurations that contain a set of control variables, their values, a set of constraints, and a description. You can set one of these named configurations as a preferred configuration for the model.

You can automatically generate all possible variant configurations for a model using Variant Manager. See “Generate Variant Configurations Automatically” on page 88-23.

## Constraints on Variant Configurations

A constraint is a user defined check that you can use to prevent invalid variant combinations in a model. The constraint must be satisfied by all variant configurations created for the model. It is represented as a condition expression created using variant control variables. The expression must evaluate to `true` to satisfy the constraint.

For example, this constraint checks that a `Linear` controller in a system does not have an `External` plant.

```
~((Ctrl == ControllerType.Linear) && (PlantLoc == PlantLocation.External))
```

When a model is associated with a `VariantConfigurationObject` that has constraints, Simulink validates the variant configurations against these constraints during Variant Manager activation, update diagram, simulation, and code generation workflows.

## Variant Configuration Data Object

You can use a variant configuration data object of type `Simulink.VariantConfigurationData` to manage and reuse variant configurations for a model. The object stores all the variant configurations and constraints created for a model. If the model is not associated with a variant configuration data object, Variant Manager helps you to setup a new variant configuration data object.

From the **Manage** tab in Variant Manager, you can:

- Specify a name for the variant configuration data object for the model.
- Apply the changes made to the variant configuration data object from Variant Manager to the base workspace or data dictionary used by the model.
- Export the variant configuration data object to a MAT-file or MATLAB script file.
- Import a variant configuration data object from a MAT-file or MATLAB script file into Variant Manager.
- Reload the object from the base workspace or data dictionary used by the model. This allows you to revert the changes that are not yet exported to the base workspace or data dictionary.

When you export the variant control variables in a variant configuration to the base workspace or data dictionary used by the model or when you activate a variant configuration, the corresponding variant control variables are pushed to the base workspace or data dictionary. Reloading the variant configuration object from Variant Manager does not revert these changes.

The `Simulink.VariantConfigurationData` class has methods that enable you to add or remove variant configurations, constraints, and control variables.

For an example that shows how to save and reload a variant configuration data object from Variant Manager, see “Save and Reuse Variant Configurations Using Variant Configuration Data Object” on page 88-20.

### Get Variant Configuration Data Object for Model

To get the variant configuration data object associated with a model, execute this command from the MATLAB Command-Line window.

```
vcdo = Simulink.VariantManager.getConfigurationData(model);
```

To get only the name of the variant configuration data object associated with the model, use this command:

```
get_param(model, 'VariantConfigurationObject');
```

### Edit Variant Configuration Data Object from Workspace

You can edit a variant configuration object from the base workspace or data dictionary without launching Variant Manager. Double-click the object that is present in the base workspace or in the **Configurations** section of the data dictionary in the Model Explorer. This action opens the `Simulink.VariantConfigurationData` property dialog box. This dialog box functions as a stand-alone variant manager and allows you to modify variant configurations, control variables, and constraints in the variant configuration object.

**Simulink.VariantConfigurationData: vcd**

Simulink.VariantConfigurationData object is used to define variant configuration for models.

It contains variant configurations, constraints and an optionally specified preferred configuration. The variant configurations consist of a set of control variables.

## Activate a Variant Configuration

Activating a variant configuration using Variant Manager validates that the variant elements in the model and the variant configuration are set up correctly and applies the configuration to the model. It also validates the configuration against applicable constraints. You can then compile, simulate, or generate code from the model for this configuration.

You can activate these configurations from Variant Manager:

- The global workspace configuration:

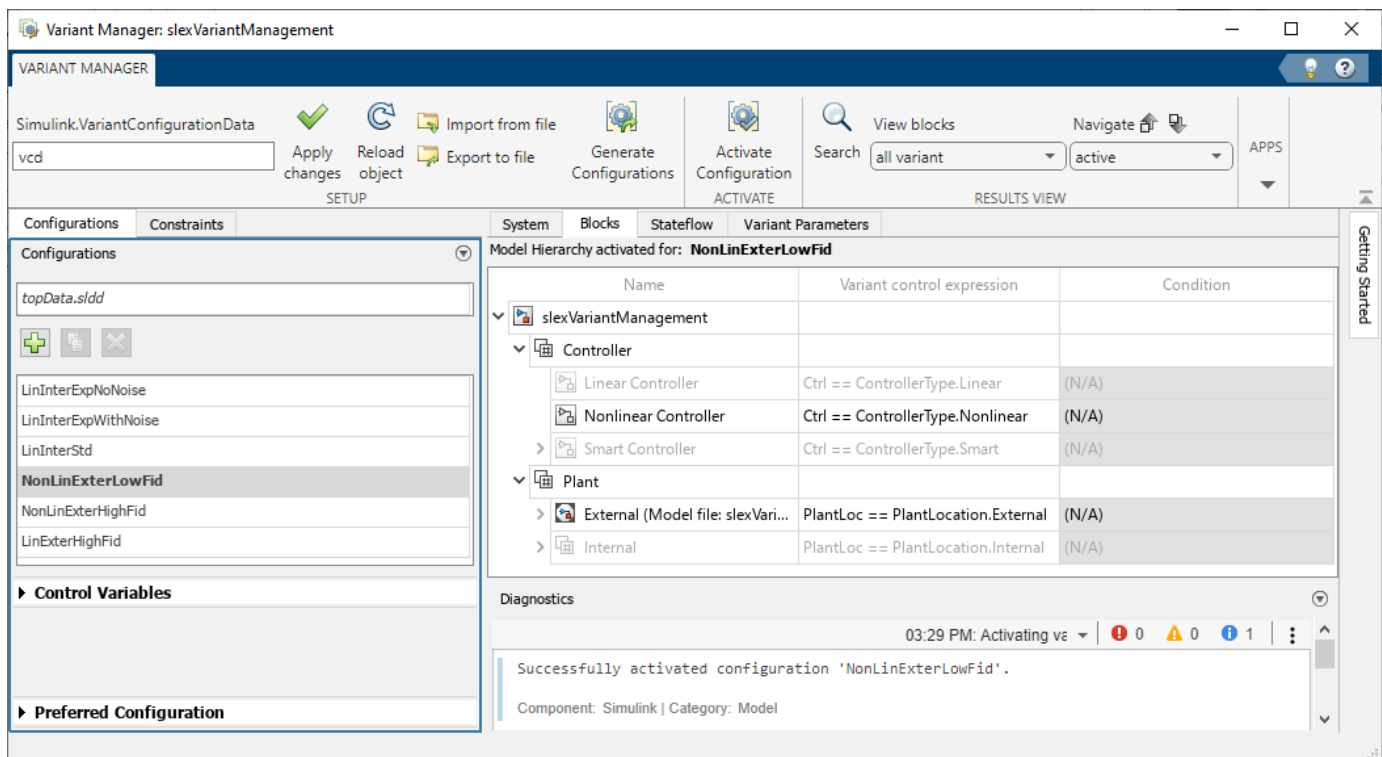

Activation is based on the control variables that are currently in the base workspace or data dictionary used by the model. You can also add new control variables to this configuration using the table in the **Control Variables** section. Activation pushes these variables to the base workspace or data dictionary.

- A named variant configuration:

Activation is only based on the values of control variables defined in the configuration. This operation also pushes the control variables to the base workspace or data dictionary used by the model.

For detailed steps to create and activate a variant configuration, see “Create and Activate Variant Configurations” on page 88-10. To activate a variant configuration programmatically, use the `Simulink.VariantManager.activateModel` method.

**Tip** On successful activation, the model hierarchy reflects the active configuration.

## Differences Between Variant Manager Activation and Update Diagram Process

Activation of a variant configuration using Variant Manager or using the `Simulink.VariantManager.activateModel` method differs from the update diagram process that Simulink performs before simulation or when you update the diagram while editing the model (**Ctrl+D**).

Activation using Variant Manager analyzes variant elements such as variant blocks or variant transitions in the model individually. The process validates that the variant elements and the variant configuration are set up correctly and then activates the configuration for the model. For example, for a variant block with **Variant control mode** set to **expression**, the process evaluates the variant controls on the block and checks if the control variables used by the block are present in the variant configuration. Variant Manager does not analyze activeness information based on block connectivity and variant condition propagation. The process does not activate variant parameters that appear in the **Variant Parameters** tab of Variant Manager.

## Referenced Component Configurations

The variant configurations for a top-level model must also define the variant control variables used by any referenced components in the model hierarchy, such as referenced models. This approach helps to maintain a single consistent definition for a variant control across the hierarchy.

If the referenced component has existing named variant configurations of its own, you can use them to set up the corresponding variant control variables in the top-level model configuration. For more information, see “Compose Variant Configurations for Top Model Using Referenced Model Configurations” on page 88-78.

## Preferred Configuration

You can set any of the named configurations defined for a model as the preferred variant configuration. You can use this property to indicate the configuration that is suited for the model for common workflows.

---

**Note** The preferred configuration does not function as the default configuration for a model. You must activate the preferred configuration explicitly on the model, if required.

---

To programmatically apply the PreferredConfiguration on your model before compiling or simulating the model, use the applyConfiguration method:

```
% Get the variant configuration data object for your model
vcd = Simulink.VariantManager.getConfigurationData(model);
% Apply the preferred configuration on the model
Simulink.VariantManager.applyConfiguration ...
(model, 'Configuration', vcd.getPreferredConfigurationName());
```

Alternatively, use this command:

```
Simulink.VariantManager.applyConfiguration ...
(model, 'Configuration', Simulink.VariantManager.getPreferredConfigurationName(model));
```

## Variant Manager View of Variant Configurations

Open the slexVariantManagement model using the following command.

```
openExample('simulink_variants/VariantConfigurationObjectForAModelRefPageExample');
open_system('slexVariantManagement');
```

On the **Modeling** tab, open the **Design** section and click **Variant Manager**.

View the **Configurations** tab in Variant Manager.

► Description

▼ **Preferred Configuration**

LinInterExpWithNoise

- The first entry indicates the base workspace or data dictionary used by the model, for example, topdata.sldd. The variant control variables and their values currently present in this workspace of the model act as a temporary variant configuration for the model.
- The table lists the named variant configurations created for the model. These configurations are stored in the variant configuration data object (of type Simulink.VariantConfigurationData) associated with the model.
- The table in the **Control Variables** section shows the variant control variables and their values defined in a selected configuration. All control variables are listed in the table, either when the

variant configuration object for the model is loaded, or when you import them from the global workspace.

In the **Control Variables** table of a top-level variant configuration, the control variables that are populated using a referenced component configuration are read-only and appear with a grey background color.

- The **Preferred Configuration** section allows you to select a named configuration that is suitable for the model for common workflows.

## Limitations

- Variant configurations can be created only for variant blocks that have **Variant control mode** set to **expression**.

- “Variant Manager for Simulink”
- “Variant Manager Workflow to Set Up Variant Configurations for Models” on page 88-59
- “Variant Manager Workflow to Manage Existing Variant Configurations in Models” on page 88-62
- “Reduce Variant Models Using Variant Reducer” on page 88-32
- “Analyze Variant Configurations in Models Containing Variant Blocks” on page 88-44

## Create and Activate Variant Configurations

**Note** This functionality requires Variant Manager for Simulink.

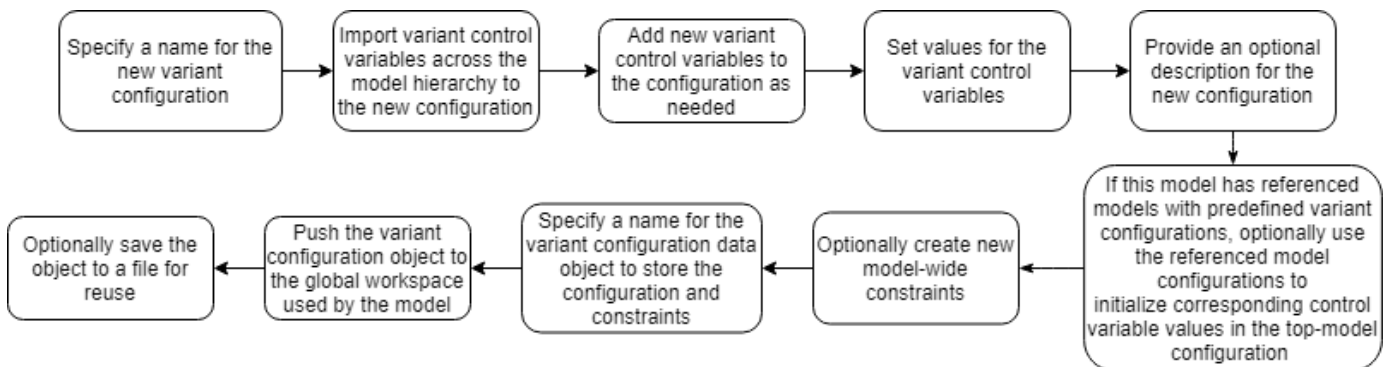

A model might contain several variant blocks, each with many variant choices. A variant configuration is used to represent a combination of such variant choices across the model hierarchy. For example, in a system with a plant and a controller, a *linear controller with an internal plant with no noise* and a *nonlinear controller with an external low fidelity plant* represent two different configurations of the system.

You can use Variant Manager to create and manage variant configurations for a model. Variant Manager defines a variant configuration as a set of variant control variables and their values that can activate a specific variation in the model hierarchy. For more information on variant configurations, see “Variant Configurations” on page 88-2. For an overview of Variant Manager, see “Variant Manager for Simulink”.

### Steps to Create Variant Configurations

You can create multiple named variant configurations for a model or you can create variant control variables in the workspace used by the model to use as a temporary variant configuration for the model.

This image shows the high-level workflow to create and save a new named variant configuration for a model.

### Open Variant Manager

Open the model for which you want to create new variant configurations. Here, open the `slexVariantManagement` model using the following command.

```
openExample('simulink_variants/VariantConfigurationObjectForAModelRefPageExample');
open_system('slexVariantManagement');
```

On the **Modeling** tab, open the **Design** section and click **Variant Manager**.

### Configurations Tab in Variant Manager

View the **Configurations** tab in Variant Manager.

► Description

▼ **Preferred Configuration**

LinInterExpWithNoise

- The first entry indicates the base workspace or data dictionary used by the model, for example, topdata.sldd. The variant control variables and their values currently present in this workspace of the model act as a temporary variant configuration for the model.
- The table lists the named variant configurations created for the model. These configurations are stored in the variant configuration data object (of type Simulink.VariantConfigurationData) associated with the model.
- The table in the **Control Variables** section shows the variant control variables and their values defined in a selected configuration. All control variables are listed in the table, either when the

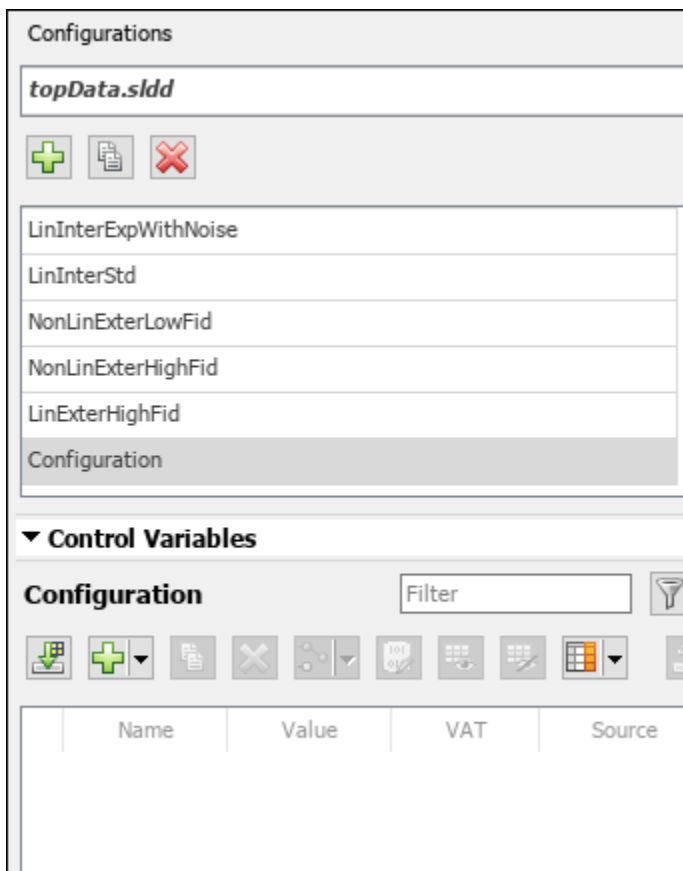

variant configuration object for the model is loaded, or when you import them from the global workspace.

In the **Control Variables** table of a top-level variant configuration, the control variables that are populated using a referenced component configuration are read-only and appear with a grey background color.

- The **Preferred Configuration** section allows you to select a named configuration that is suitable for the model for common workflows.

## Add New Variant Configuration

- 1 To create a temporary variant configuration in the base workspace or data dictionary used by the model, click the entry corresponding to the storage location used by the model in the **Configurations** tab, for example, `topdata.sldd`.
- 2 To add a new named variant configuration, click the Add variant configuration button . A new row is added to the table of named configurations. Type a name for this configuration in the box.

## Add, Import, or Export Control Variables in Variant Configuration

- 1 In the **Configurations** tab, scroll down to see the **Control Variables** section. The section shows the name of the currently selected variant configuration.

- 2 In this section, click the Import control variables across model hierarchy button  to import any existing control variables from the base workspace or data dictionary used by the model to the variant configuration.
- 3 To add a new control variable to the variant configuration, click the Add control variable button . By default, this operation adds a new control variable of type `Simulink.VariantControl` with a normal MATLAB variable as its value to the control variables table. To add other types of control variables, click the down arrow on the button. You can update the values in this table.

---

**Note** You can create variant control variables in the MATLAB base workspace or a data dictionary.

For a list of actions that you can perform from the control variables table, see “Edit Control Variables in Variant Configuration” on page 88-14.

---

- 4 To export the control variables to the base workspace or data dictionary used by the model, click the Export control variables to global workspace(s) button .
- 5 You can use the **Description** section to provide an optional description for the configuration.

Configurations

▼ Description

## Edit Control Variables in Variant Configuration

You can perform these operations from the **Control Variables** section.

Operation	Action
Add new control variables to a configuration	<p>Click the Add control variable button .</p> <p>The default type of a new control variable is <code>Simulink.VariantControl</code>, with a normal MATLAB variable as its value.</p> <p>You can also add these types of variables. To see all the options, click the down arrow on the button.</p> <ul style="list-style-type: none"> <li>• Normal MATLAB variable</li> <li>• <code>Simulink.Parameter</code></li> <li>• <code>AUTOSAR.Parameter</code></li> </ul>
Import existing the control variables from the base workspace or data dictionary used by the model to a configuration	<p>Click the Import control variables across model hierarchy button .</p> <p><b>Note</b> Control variables from blocks in Label mode are not imported as they are not variant control variables.</p>
Export control variables to the base workspace or data dictionary used by the model	<p>Click the Export control variables to global workspace(s) button .</p>
Sort the rows based on each column	<p>Click the column names, such as <b>Name</b>, <b>Value</b>, <b>VAT</b>, or <b>Source</b>, in the header row to sort the table based on the values in that column.</p>
Show or hide the usage of control variables in a configuration	<ul style="list-style-type: none"> <li>• To find the usage of a particular variant control variable in a variant configuration, select the variable in the control variables table and click the Show usage of selected control variables button . The rows that contain the variable appear highlighted in the model hierarchy table.</li> <li>• To hide the usage of a variant control variable, click the Hide usage of selected control variables button .</li> </ul> <p>Alternatively, right-click the variable in the control variables table and select <b>Show usage</b> or <b>Hide usage</b>.</p> <p><b>Tip</b> You can navigate the model hierarchy to understand the usage of control variables in a configuration. After you activate a variant configuration, enable <b>Show usage</b> for the required variant control variables. Now select the <b>variable usage</b> option in the <b>Navigate</b> filter in the toolstrip. Use the arrow key to step through the model hierarchy rows that use those variables.</p>

Operation	Action
Change the data type of control variables in a configuration	<p>Click the down arrow in the Convert to <code>Simulink.VariantControl</code> button  to see the options for conversion.</p> <p>You can convert the control variables to any of these types:</p> <ul style="list-style-type: none"> <li>• <code>Simulink.VariantControl</code>, with a <code>Simulink.Parameter</code> object as its value</li> <li>• <code>Simulink.VariantControl</code>, with a normal MATLAB variable as its value</li> <li>• <code>Simulink.Parameter</code></li> <li>• <code>AUTOSAR.Parameter</code></li> <li>• Normal MATLAB variable</li> </ul> <p>For an example that shows the use of different types of variant control variables and their purpose, see “Use Variant Control Variables in Variant Blocks” on page 12-53.</p>
Edit <code>Simulink.Parameter</code> or <code>AUTOSAR.Parameter</code> control variables	<p>Use the Edit <code>Simulink.Parameter</code> or <code>AUTOSAR.Parameter</code> control variable button .</p> <p>To specify <code>Simulink.Parameter</code> control variable as an expression, set the Value property of the parameter object by using an equals sign (=) followed by a mathematical expression. For example, enter = A + B.</p>
Filter the table based on type of control variables	Use the Filter based on variable types button  .
Filter content in the table	Enter the search term in the Filter text box. Press <b>Esc</b> to clear the text box.

## Set Up Variant Configurations for Referenced Components

Your model may consist of referenced models that have predefined variant configurations. The variant configurations for a top-level model must also define the variant control variables used by any referenced components in the model hierarchy, such as referenced models. This approach helps to maintain a single consistent definition for a variant control across the hierarchy.

If the referenced component has existing named variant configurations of its own, you can use them to set up the corresponding variant control variables in the top-level model configuration. You can use the Component Configurations view in Variant Manager to select the referenced component configurations to be used for the initialization. For steps to use the **Component Configurations** view, see “Compose Variant Configurations for Top Model Using Referenced Model Configurations” on page 88-78.

## Define Constraints for Variant Configurations

A constraint is a user defined check that you can use to prevent invalid variant combinations in a model. You can define model-wide constraints that must be satisfied by all variant configurations

created for the model. It is represented as a condition expression created using variant control variables. The expression must evaluate to true to satisfy the constraint. When you activate a variant configuration, Variant Manager validates the configuration against the applicable constraints.

---

**Note** Variant Manager constraints are also validated when you compile the model for an active configuration. However, these constraints are not validated post compilation, for example, at startup variant activation time.

---

- 1 Click the **Constraints** tab in the Variant Manager window. The **Constraints** table lists any existing constraints created for the model.
- 2 To add a new constraint, click the Add constraint button . A new row gets added.
- 3 Enter a name for the constraint in the box.
- 4 In the **Constraint Definition** section, in the **Condition** box, enter the boolean condition expression defined in terms of variant control variables. The condition must evaluate to true to satisfy the constraint.
- 5 In the **Description** box, enter an optional description for the constraint.

### Constraints

LinNotExtern  
Constraint\_new

**▼ Constraint Definition**

**Constraint\_new**

 Specify model-wide constraints as logical expressions using variant control variables that must evaluate to true.   
Example: "Ctrl ~= Controller.Experimental" constraint ensures that an experimental controller is not used by this model.

**Condition**

Ctrl~=ControllerType.Experimental

**Description**

**Tip** You can change the layout of the Variant Manager window to keep the **Configurations** and **Constraints** panes next to each other. This layout allows you to refer the **Control Variables** section when defining constraints. To move a pane, click at the top of the pane and drag.

## Save Variant Configurations

You can use a variant configuration object of type `Simulink.VariantConfigurationData` to store all named variant configurations and constraints for a model. If the model is not yet associated with a variant configuration object, Variant Manager helps you to setup a new variant configuration data object.

- 1 Type a name for the variant configuration data object in the **Simulink.VariantConfigurationData** text box in the Variant Manager toolstrip.
- 2 To export the variant configuration data object to the base workspace or Simulink data dictionary used by the model, click **Apply changes**. This action also associates the object with the model.
- 3 To reload the object from the base workspace or data dictionary used by the model, click **Reload object**. This allows you to revert the changes that are not yet exported to these storage locations.

When you export the variant control variables in a variant configuration or when you activate a variant configuration, the corresponding variant control variables are pushed to the base workspace or data dictionary used by the model. Reloading the variant configuration object from Variant Manager does not revert these changes.

- 4 To disassociate the variant configuration data object from the model, set the **Simulink.VariantConfigurationData** box to empty and click **Apply changes**.
- 5 To export the variant configuration data object to a MAT-file or MATLAB script file, click **Export to file**.

If the model uses base workspace, this option allows you to save the object for reuse.

- 6 To load the variant configuration data object saved in a file into Variant Manager, click **Import from file**.

## Validate and Activate Variant Configuration

- To activate either a named variant configuration or the temporary configuration present in the base workspace or data dictionary, select the corresponding entry from the **Configurations** tab and click **Activate Configuration**.

The operation validates the configuration and applies the selected configuration to the model. Activation also pushes control variables in the configuration to the base workspace or data dictionary used by the model.

- Any errors related to the process are reported in the **Diagnostics** pane.
- On successful activation, the model hierarchy table reflects the changes. You can:
  - Explore the active variant choices in the **Blocks** or **System** tab of the model hierarchy. You can also navigate the hierarchy using the **Navigate** filter to understand control variable usage, active choices, and invalid choices.
  - Compile or simulate the model for the active configuration.

To activate a model programmatically, see `Simulink.VariantManager.activateModel`.

For information on how the activation process differs from model compilation (update diagram), see “Differences Between Variant Manager Activation and Update Diagram Process” on page 88-6.

## Save and Reuse Variant Configurations Using Variant Configuration Data Object

This example shows how to use Variant Manager to save and reuse variant configurations for a Simulink® model using a variant configuration data object.

Learn how to use Variant Manager to:

- Export a variant configuration data object to the base workspace or data dictionary used by the model.
- Export the variant configuration data object to a file for reuse.
- Import the variant configuration data object from a file.
- Reload the variant configuration data object from the base workspace or data dictionary used by the model.

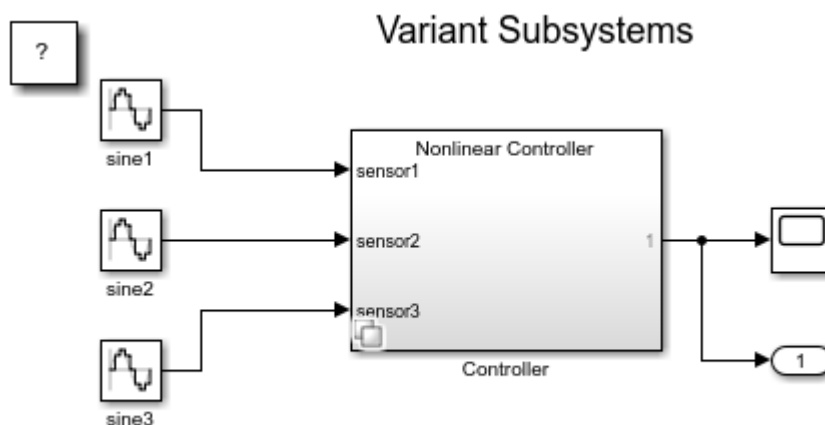

### Overview of Variant Configurations

A *variant configuration* allows you to define a named set of variant control variables and their values, which can be used to activate a specific variation of a Simulink model. A *variant configuration data object* (instance of the `Simulink.VariantConfigurationData` class) stores the collection of all variant configurations and constraints defined for a model. For more information, see “Variant Configurations” on page 88-2.

### Open Variant Manager

1. Open the model for which you want to create a variant configuration data object. Consider the model `slexVariantSubsystems`.

```
open_system('slexVariantSubsystems');
```

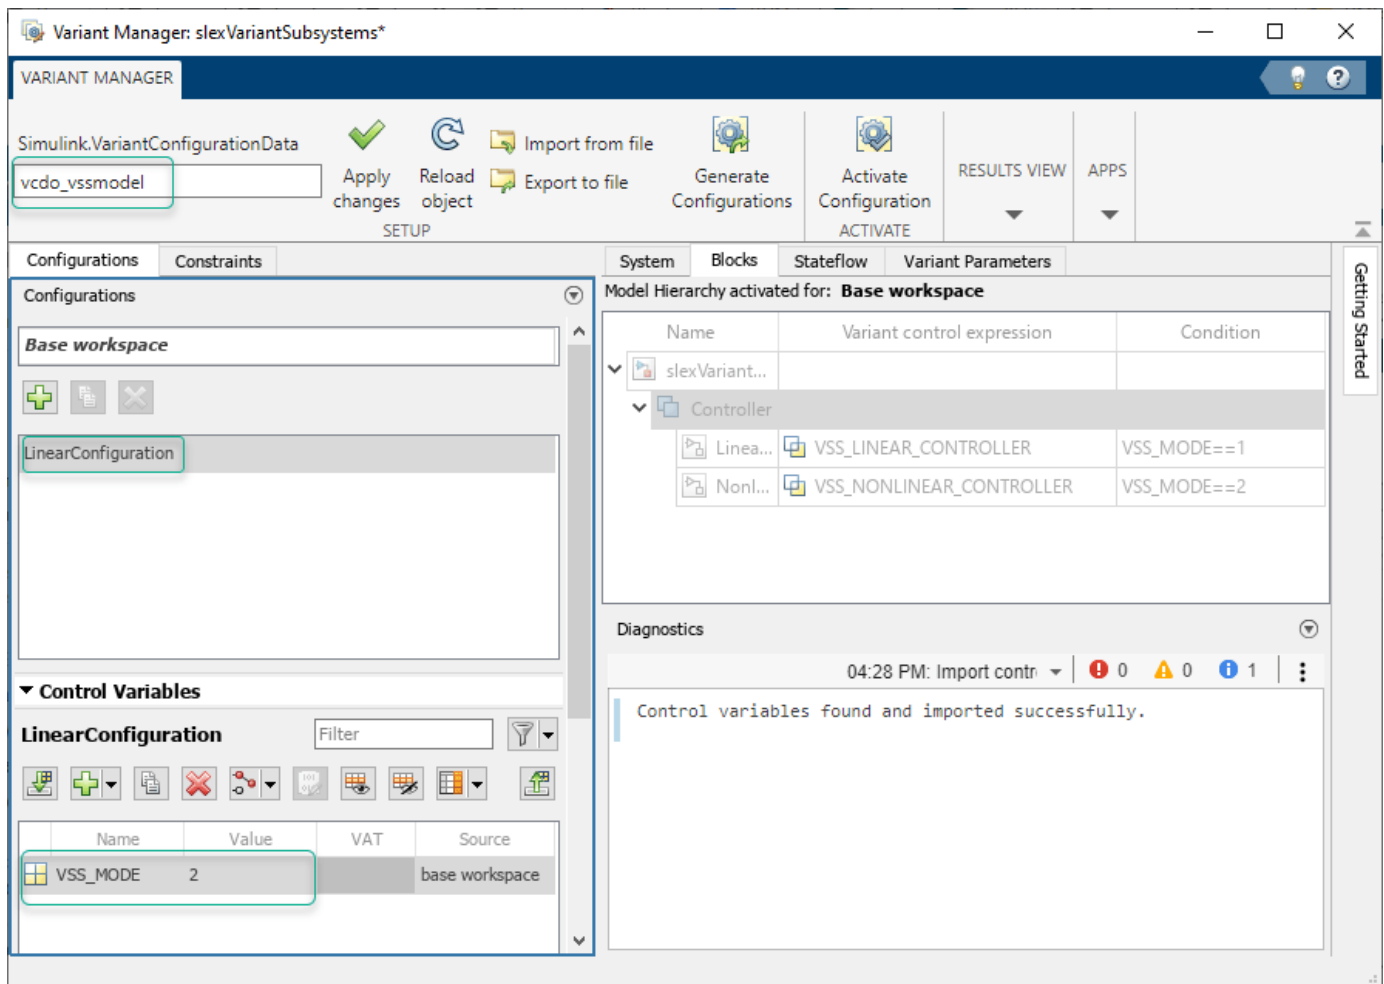

Copyright 2010-2013 The MathWorks, Inc.

2. On the **Modeling** tab, in the **Design** section, click **Variant Manager**. The Variant Manager window opens and shows the **Manage** tab.

## Define New Variant Configuration

1. In Variant Manager, in the **Configurations** tab, click the Add variant configuration button. A new row is added. In the box, enter the name `LinearConfiguration`.
2. In the **Configurations** tab, scroll down to see the **Control Variables** section.
3. To import the control variables for the variant configuration from the base workspace or data dictionary used by the model, click the Import control variables across model hierarchy button in the **Control Variables** section.
4. Click the Add control variable button in the control variables table to add new control variables to this configuration.
5. In the **Simulink.VariantConfigurationData** text box in the toolstrip, type a name for the variant configuration data object, for example, `vcdo_vssmodel`.

## Export Variant Configuration Data Object

- To export the variant configuration data object to the base workspace or data dictionary used by the model, click **Apply changes** in the Variant Manager toolstrip. This step also associates the data object with the model.

- You can retrieve the variant configuration data object associated with a model using the parameter `VariantConfigurationObject`. Run this command in the MATLAB® Command Window.

```
get_param('slexVariantSubsystems','VariantConfigurationObject')
```

```
ans =
```

```
'vcdo_vssmodel'
```

- To disassociate the variant configuration data object from the model, set the **Simulink.VariantConfigurationData** box to empty and click **Apply changes**.

### Save Variant Configuration Data Object to File for Reuse

When you export the variant configuration data object to the base workspace, it is available only for the current MATLAB session. To store the variant configurations for reuse, save it in a MAT-file or MATLAB script.

1. Click **Export to file** in the toolbar.
2. In the **Save to file** dialog box, enter the name and type of the file to store the object. Click **Save**.

### Load Variant Configuration Data Object from File

You can import a variant configuration data object that is stored in a MAT-file or MATLAB script into Variant Manager.

1. Click **Import from file** in the Variant Manager toolbar.
2. In the **Import from file** dialog box, select the file and click **Open**.

### Reload Variant Configuration Data Object

To reload the variant configuration object from the base workspace or data dictionary used by the model, click **Reload object** in the Variant Manager toolbar. This allows you to revert the changes that are not yet exported to these storage locations.

When you export the variant control variables in a variant configuration or when you activate a variant configuration, the corresponding variant control variables are pushed to the base workspace or data dictionary used by the model. Reloading the variant configuration object from Variant Manager does not revert these changes.

# Generate Variant Configurations Automatically

---

**Note** This functionality requires Variant Manager for Simulink.

---

A model might contain several variant blocks, each with many variant choices. A variant configuration is used to represent a combination of such variant choices across the model hierarchy. For example, in a system with a plant and a controller, a *linear controller with an internal plant with no noise* and a *nonlinear controller with an external low fidelity plant* represent two different configurations of the system.

You can use Variant Manager to create and manage variant configurations for a model. Variant Manager defines a variant configuration as a set of variant control variables and their values that can activate a specific variation in the model hierarchy. For more information on variant configurations, see “Variant Configurations” on page 88-2. For an overview of Variant Manager, see “Variant Manager for Simulink”.

## Generate Variant Configurations Using Variant Manager

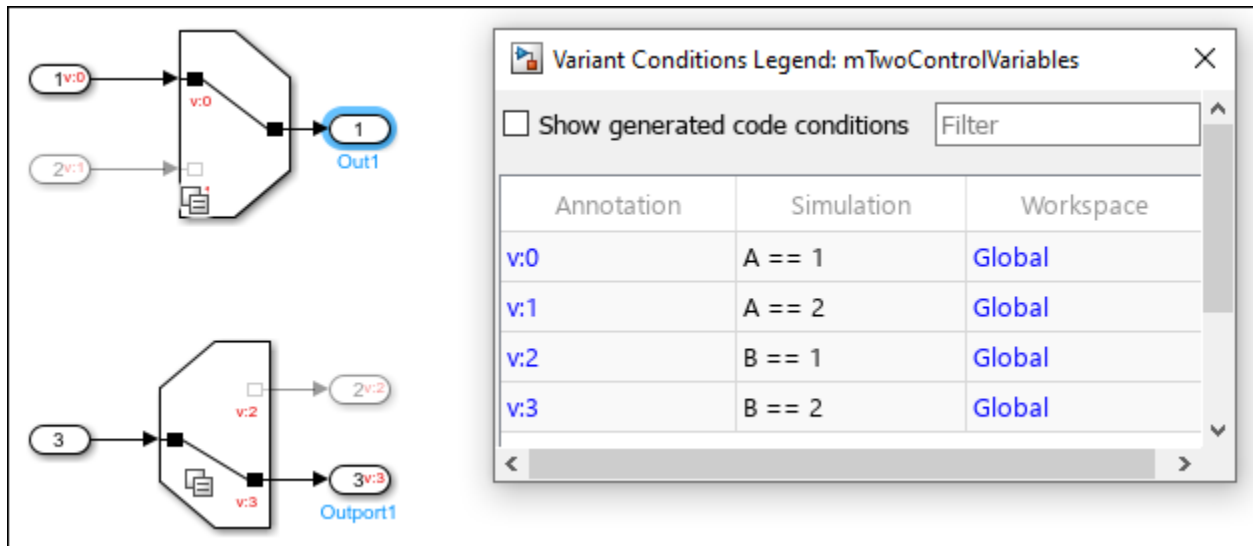

Creating all possible variant configurations for a model manually can be time consuming. You must activate them individually to check if they are valid and if they satisfy necessary constraints. You can automatically generate variant configurations for a model using Variant Manager, which allows you to:

- Consider all possible combinations of variant control variables while creating configurations.
- Specify the value range that must be considered for each control variable. This specification allows you to control the process and generate only the required subset of configurations.
- Create configurations that satisfy some preconditions.
- Automatically validate generated configurations to identify invalid cases.
- Generate valid configurations for which model compiles successfully or all configurations including invalid ones.
- Export selected configurations to the variant configuration data object associated with the model.
- Export the preconditions as global constraints in the variant configuration data object.

To generate variant configurations programmatically, use the `Simulink.VariantManager.generateConfigurations` method.

### Example for Generated Configurations for a Simple Variant Model

Consider a simple model with two inline variant blocks. The blocks use two control variables, A and B, each with two possible values, 1 and 2.

The total number of possible variant configurations for this model is four ( $2 \times 2$ ). Here is the list of configurations generated for this model from Variant Manager.

**Configure Control Variables**

↑ ↓

Name	Data Type	Values
A	double	[1, 2]
B	double	[1, 2]

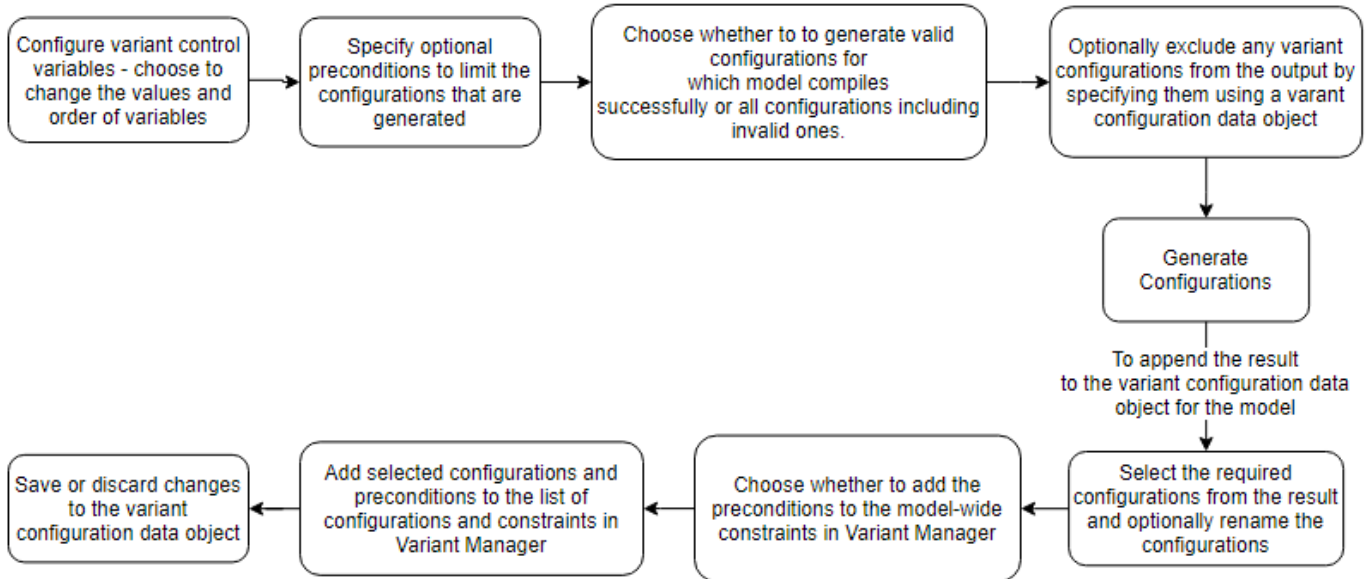

**Generated Configurations**

Validity : valid-unique

	Name	A	B
<input checked="" type="checkbox"/>	VarConf_1_E1	1	1
<input checked="" type="checkbox"/>	VarConf_2_E2	1	2
<input checked="" type="checkbox"/>	VarConf_3_E3	2	1
<input checked="" type="checkbox"/>	VarConf_4_E4	2	2

## Steps to Generate Configurations

This image shows the steps to generate variant configurations from Variant Manager.

- 1 Open the model for which you want to generate variant configurations.
- 2 Open Variant Manager.

On the **Modeling** tab, open the **Design** section and click **Variant Manager**. Alternatively, right-click the variant badge on any variant block in the model and select **Open in Variant Manager**.

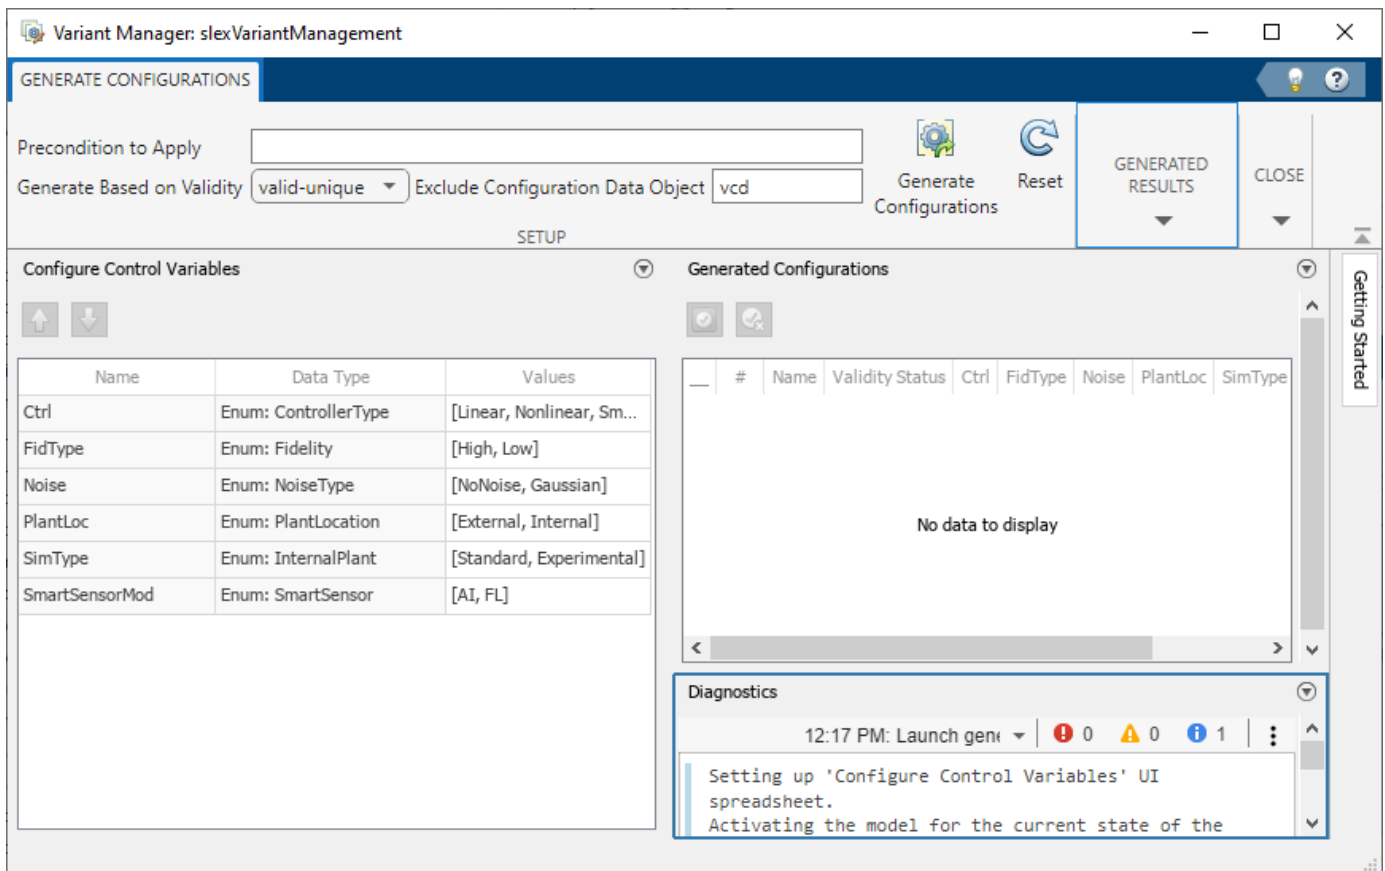

- 3 Open the **Generate Configurations** tab.

In the Variant Manager toolstrip, in the **Setup** section, click **Generate Configurations**.

This image shows the Generate Configurations window for the `slexVariantManagement` model. To open the model, run the below command from the MATLAB Command-Line.

```
openExample('simulink_variants/AutomaticallyGenerateVariantConfigurationsRefPageExample');
open_system('slexVariantManagement');
```

- 4 Configure variant control variables for the operation.

The **Configure Control Variables** tab lists the variant control variables used by the model.

To change the order of control variables in the table, use  and . This change affects only the order in which control variable combinations are considered for the generation process and has no impact on the effective configurations generated.

The **Values** column is filled with the possible values for the control variables, as specified in the model. You can edit the values as needed. You can also specify only a required subset of values, which allows you to restrict the configurations that gets generated. For example, provide the value `Linear` for the variable `Ctrl` to generate configurations for the linear controller alone.

- 5 Specify optional preconditions.

In the **Precondition to Apply** text box, specify conditions to limit the configurations to generate. The value must be a character vector or cell array of character vectors containing valid boolean expressions defined on the variant control variables. For example, the condition `{ 'Ctrl == ControllerType.Linear', 'PlantLoc == PlantLocation.Internal' }` generates only configurations corresponding to the specified values for `Ctrl` and `PlantLoc` variables.

- 6 Specify the type of configurations to generate, based on validity.

In the **Generate Based on Validity** list, select one of these values:

- **valid** — Include only valid configurations. These include duplicate configurations that are functionally equivalent.
- **valid-unique** — Include only valid configurations without duplicates that are functionally equivalent (default).

If a configuration has functional equivalents, this option lists one of those equivalent configurations in the result.

- **all** — Include valid, invalid, and duplicate configurations.

---

**Note** Two variant configurations are functionally equivalent if they result in the same set of active blocks in the model. You can identify a group of functionally equivalent configurations in the generated results by the **Validity Status** value `EquivalentK`, where  $K$  is an annotation used to group equivalent configurations, for example, `Equivalent1`.

An invalid variant configuration violates variant semantics and causes an error during the update diagram process. For example, you have a configuration that deactivates all choices in an inline variant block. However, this block has the **Allow zero variant control** set to `off`, which contradicts the deactivation and causes an error.

For any validity option, the process generates only those configurations that satisfy the specified preconditions.

---

## 7 Optionally exclude specific configurations from the result.

In the **Exclude Configuration Data Object** text box, you can specify the name of a `Simulink.VariantConfigurationData` object that contains the variant configurations that must not be generated. By default, the name of the current variant configuration data object associated with the model is populated in this box, and configurations present in this object are ignored.

## 8 Click **Generate Configurations**.

The **Generated Configurations** pane shows the result in a tabular form. Valid configurations appear highlighted in green and invalid ones in red.

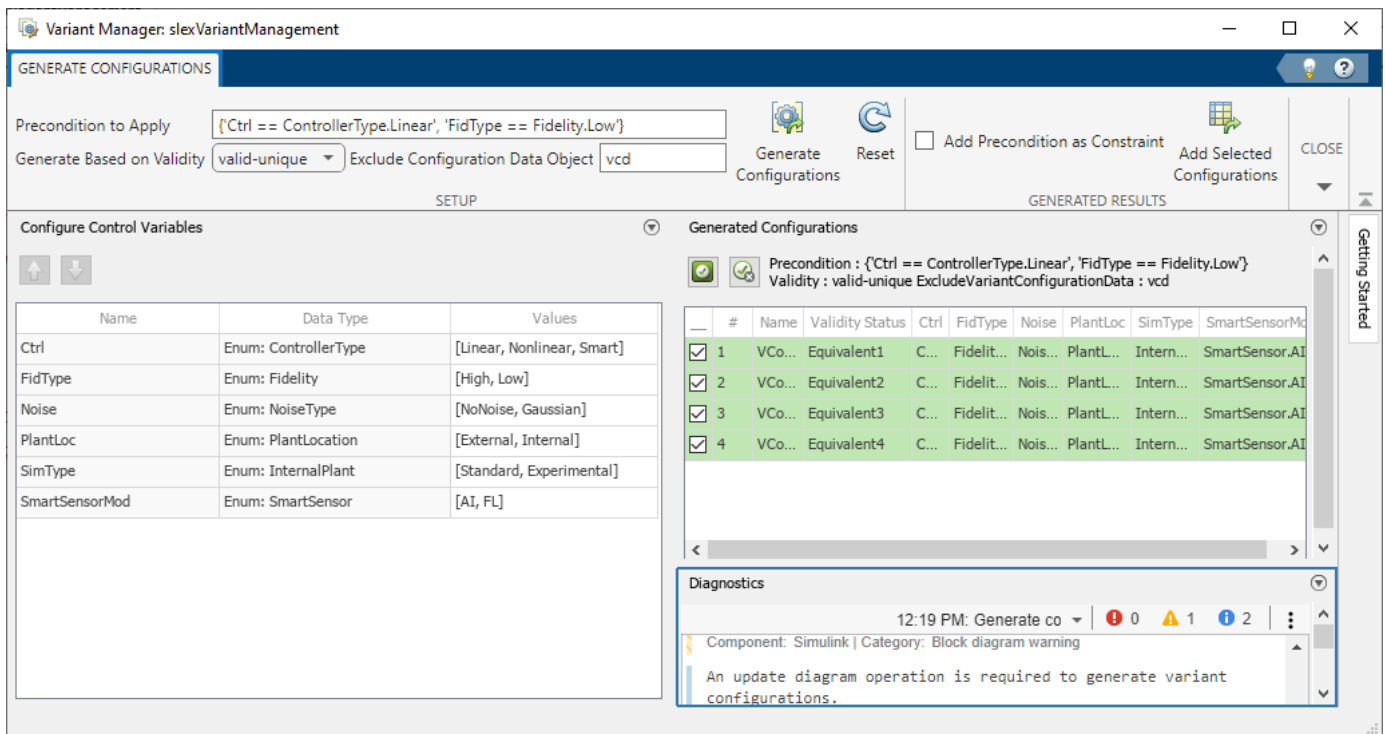

The **Validity Status** column in the result indicates whether a configuration is unique, a functional equivalent, or an invalid one. The field has one of these values:

- **Unique** — Configuration is valid and unique without any functional equivalents.
- **EquivalentK** — Configuration is valid and is a functional equivalent of another configuration.  $K$  is an annotation to identify a group of equivalent configurations, for example, `Equivalent1`.

If you had set the **Generate Based on Validity** option to `valid-unique` and a generated configuration has functional equivalents, the result shows one of those configurations with **Validity Status** set to `EquivalentK`.

- **Invalid** — Configuration is not valid.

You can edit the configuration names in the **Name** column. You can use  and  buttons to toggle the selection of the table rows.

- 9 Export the generated configurations to the variant configuration data object associated with the model. Perform this step if you would like to save the generated configurations.
  - Select the configurations that you want to export from the table in the **Generated Configurations** pane.
  - To export the specified precondition as constraint in the variant configuration data object, select **Add Precondition as Constraint**.
  - Click **Add Selected Configurations**. This operation adds the selected configurations to the list of named configurations in the **Configurations** tab. If you selected **Add Precondition as Constraint**, the operation also adds the preconditions as constraints to the **Constraints** tab.
  - Click **Close Generate Configurations** to return to the **Manage** tab of Variant Manager.
- 10 Save or revert the changes to the variant configuration data object. After exporting the generated configurations, you can use any of these options in the **Manage** tab to save or revert your changes:
  - To apply the changes to the base workspace or data dictionary used by the model, click **Apply changes**.
  - To reload the variant configuration object from the base workspace or data dictionary used by the model, click **Reload object**. This allows you to revert the changes that are not yet exported to these storage locations.
  - To permanently save the new configurations and constraints in the variant configuration data object to a file, click **Export to file**.

### Snapshot of Generation Process

When you generate variant configurations automatically using Variant Manager or using the `Simulink.VariantManager.generateConfigurations` method, Simulink captures a snapshot of the auto-generation process. A sub-folder named based on the timestamp of the operation is created

each time you generate configurations and is saved inside the `<modelName>_vmgrsnap` folder within the model folder. Using the snapshot, you can get an overview of the input and output of the auto-generation process and manually compare the results between snapshots to understand the impact of model edits on the generated configurations. The snapshot contains different files that stores the following information. These contents are subject to change across future releases.

- Blocks considered
- Variant control variables used
- Command used for generating the configurations
- Generated configurations

## Limitations

- The auto-generation process supports only `==`, `~=`, `&&`, `||`, and `~` operators in the variant control expressions of variant blocks and in the preconditions. If the variant control expressions use other operators such as arithmetic or relational operators, the configurations that can activate those variant choices might not get generated.
- The process does not support generating variant configurations for these modeling elements:
  - Variant blocks with a **Variant control expression** that contains noninteger double values, structure fields, or `Simulink.Parameter` objects with value set to an expression of type `slexpr`
  - Variant parameter objects of type `Simulink.VariantVariable`
  - Model that represents a library or subsystem
- For variant blocks with the **Variant control mode** parameter set to `label`, the variant control labels are strings, not variables. Hence they are not present in the generated configurations.

## Variant Subsystem Blocks

For Variant Subsystem blocks, these conditions also apply:

- If the **Variant control mode** parameter is set to `label`, only the variations present in the active label path are considered when you generate configurations.

Consider this model hierarchy for a model with a Variant Subsystem block in `label` mode. The active choice for the variant subsystem is the Subsystem block, which has its variant control set to a label, `SUB1`. The variant control variable `A` is used by the active choice and is considered when you generate configurations. The process does not consider the control variable `B` because it is in the inactive choice of the variant subsystem.

Name	Variant Control	Condition
mLabelMode		
Variant Subsystem		
Subsystem	SUB1	(N/A)
Variant Source		
Input 1	PORT_1	(N/A)
Input 2	PORT_2	(N/A)
Variant Source1		
Input 1	A==1	(N/A)
Input 2	A==2	(N/A)
Subsystem1	SUB2	(N/A)
Variant Sink		
Output 1	B==1	(N/A)
Output 2	B==2	(N/A)

Here is the list of all generated configurations.

Name	Data Type	Values
A	double	[1, 2]

	Name	A
<input checked="" type="checkbox"/>	VarConf_1_E1	1
<input checked="" type="checkbox"/>	VarConf_2_E1	2

- If the **Variant control mode** parameter is set to `sim codegen switching`, only the variations present in the `sim choice` are considered when you generate configurations. For the variant controls present in the `codegen hierarchy`, only the default values are included in the generated configurations.

Consider this model hierarchy for a model with a Variant Subsystem block in `sim codegen switching` mode. The `sim choice` for the variant subsystem is the Subsystem block. The variant control variable B present in this choice is considered when you generate configurations. The process only considers the default value for the control variable C because it is in the `codegen choice` of the variant subsystem.

Name	Variant Control	Condition
<ul style="list-style-type: none"> <li>mSimCodegenWithUDAAC <ul style="list-style-type: none"> <li>Variant Subsystem <ul style="list-style-type: none"> <li>Subsystem (sim) (N/A) <ul style="list-style-type: none"> <li>Variant Sink <ul style="list-style-type: none"> <li>Output 1 (B==1) <span style="border: 1px solid black; padding: 2px;">B is in sim choice</span></li> <li>Output 2 (B==2) (N/A)</li> </ul> </li> <li>Subsystem1 (codegen) (N/A) <ul style="list-style-type: none"> <li>Variant Source <ul style="list-style-type: none"> <li>Input 1 (C==1) <span style="border: 1px solid black; padding: 2px;">C is in codegen choice</span></li> <li>Input 2 (C==2) (N/A)</li> </ul> </li> </ul> </li> </ul> </li> </ul> </li> </ul> </li></ul>		

Here is the list of all generated configurations.

Configure Control Variables			Validity : all	
Name	Data Type	Values	B	C
B	double	[1, 2]		
C	double	[1]		
<input checked="" type="checkbox"/>	VarConf_1_E1		1	1
<input checked="" type="checkbox"/>	VarConf_2_E2		2	1

- If the **Variant activation time** is set to update diagram, only the variations in the active choice are considered for generating configurations.

## Reduce Variant Models Using Variant Reducer

---

**Note** This functionality requires Variant Manager for Simulink.

---

A model might contain several variant blocks, each with many variant choices. A variant configuration is used to represent a combination of such variant choices across the model hierarchy. For example, in a system with a plant and a controller, a *linear controller with an internal plant with no noise* and a *nonlinear controller with an external low fidelity plant* represent two different configurations of the system.

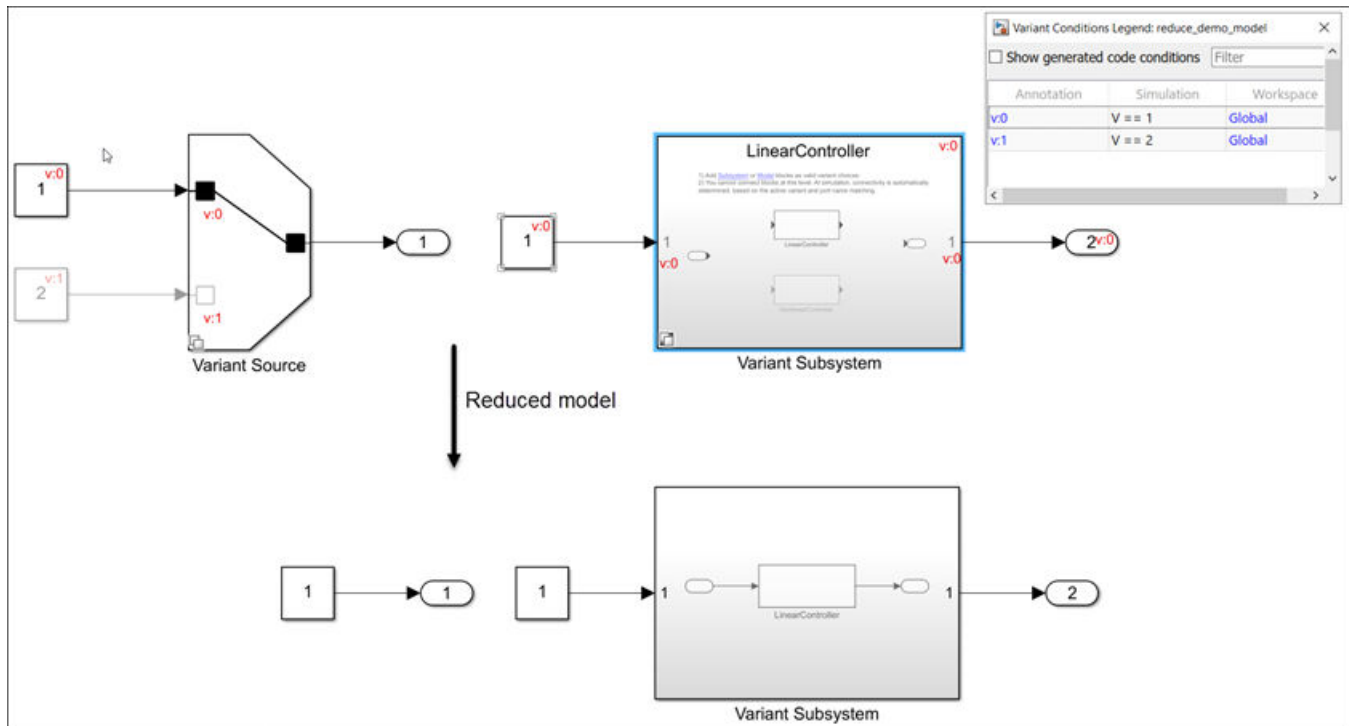

You can use Variant Manager to create and manage variant configurations for a model. Variant Manager defines a variant configuration as a set of variant control variables and their values that can activate a specific variation in the model hierarchy. For more information on variant configurations, see “Variant Configurations” on page 88-2. For an overview of Variant Manager, see “Variant Manager for Simulink”.

### Variant Reducer

You can use the Variant Reducer tool in Variant Manager to automatically generate a simplified, standalone model that contains only a subset of variant configurations from the input model. The generated model is called a reduced model. The reduced model retains the variant configurations that you choose from the parent variant model. For example, you can generate a reduced model that represents a specific product from a product line (single configuration reduction) or one that corresponds to a product line from a product line family (multi-configuration reduction).

#### Example of Reducing a Simple Variant Model

Consider a simple variant model with a Variant Source and a Variant Subsystem block. The blocks have two variant choices activated by the conditions  $V == 1$  and  $V == 2$ . If you reduce this model for the variant configuration  $V = 1$ , Variant Reducer retains only this configuration and removes the inactive choice corresponding to  $V = 2$  in the reduced model.

### Steps in Reduction Process

Variant Reducer performs these high-level operations during the reduction process:

- Removes inactive model components based on the variant configurations that you choose to retain in the reduced model.
- Removes or modifies model components such as blocks, variant parameter objects, masks, model references, subsystem references, libraries, dependent files such as MAT or SLDD files, and variables in the input model. For information on model components that are modified or not reduced, see “Considerations and Limitations for Variant Reduction” on page 88-41.
- Packages the reduced artifacts into a user-specified output folder.
- Generates a detailed summary of the reduction process that helps you to analyze these changes.

### Modes and Options for Reduction

Variant Reducer provides different modes and options that you can set before reducing the model.

Mode	Purpose
<b>Reduction mode</b>	<p>Provides multiple ways to specify the configurations to be retained in the reduced model.</p> <p>You can choose configurations based on:</p> <ul style="list-style-type: none"> <li>• Current values of variant control variables in the base workspace or data dictionary used by the model</li> <li>• Named variant configurations created for the model</li> <li>• Specified values of variant control variables</li> </ul>

Mode	Purpose
<b>Compile mode</b>	Compile the input model in simulation or code generation mode as part of the reduction process.
Option	Purpose
<b>Files to exclude</b>	Exclude Simulink data dictionary files (*.sldd) and MAT-files (*.mat) outside the matlabroot folder during reduction.
<b>Output folder</b>	Folder to place the reduced model and artifacts
<b>Model suffix</b>	Suffix to append to the name of reduced model and artifacts
<b>Preserve signal attributes</b>	Try to preserve compiled signal attributes between the original and the reduced model by adding signal specification blocks in the reduced model.
<b>Open reduced model</b>	Change the current working folder to the output folder specified for reduction and open the reduced model.
<b>Generate detailed summary</b>	Generate a detailed summary for the reduced model. This requires a Simulink Report Generator license.

## Reduce Variant Model Using Variant Manager

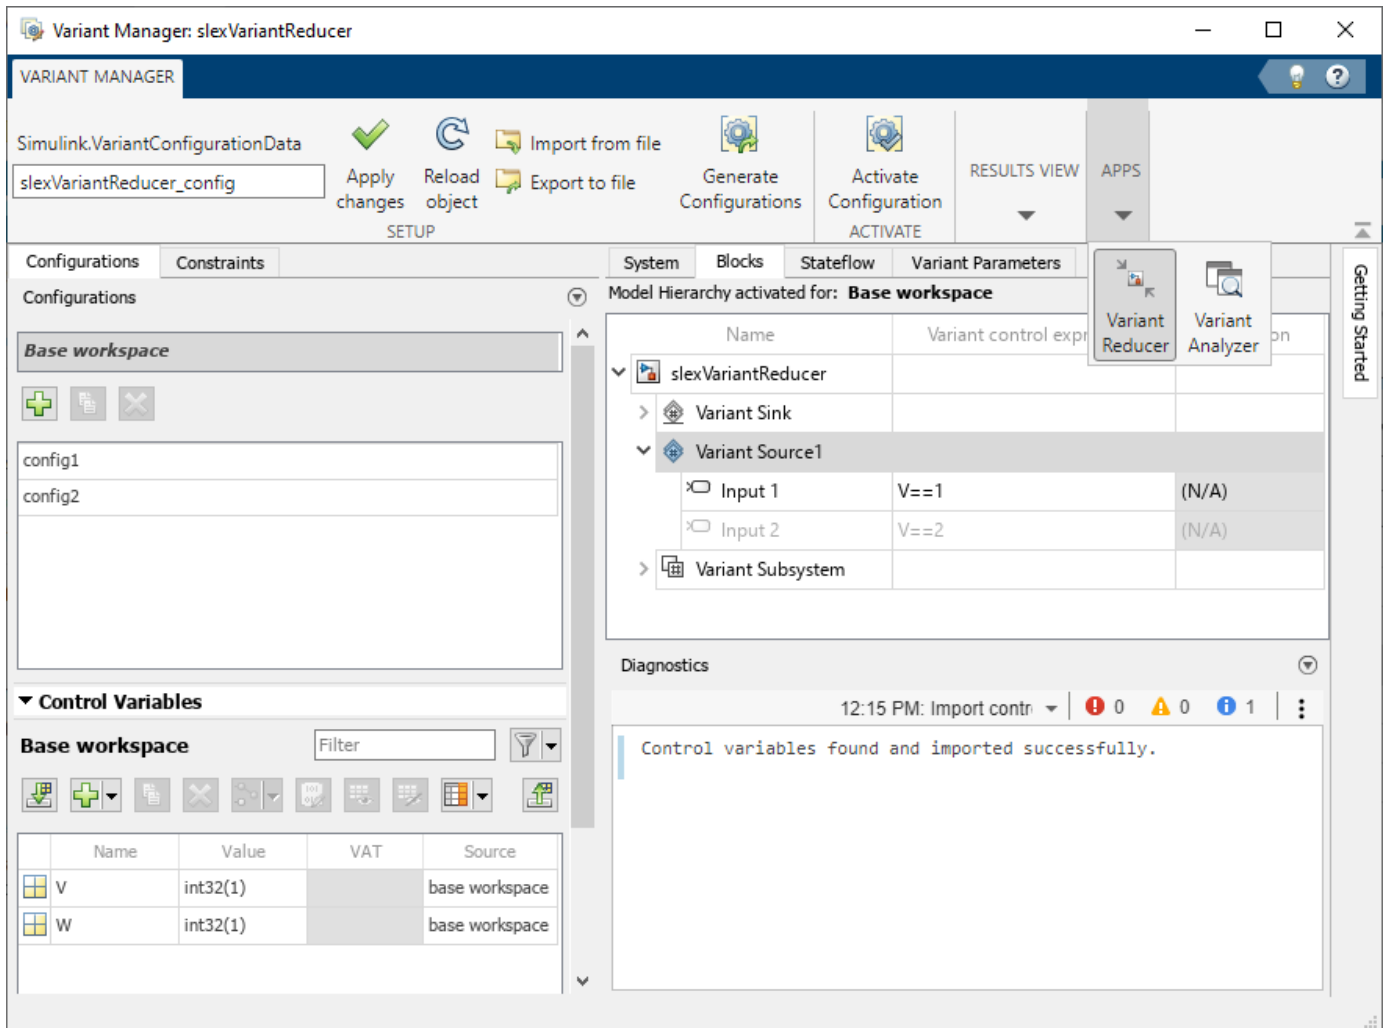

- 1 Open Variant Manager for the model that must be reduced. Here, open the `slexVariantReducer` model using the following command.

```
openExample('simulink_variants/ReduceAVariantModelForSelectedVariantConfigurationExample');
```

On the **Modeling** tab, open the **Design** section and click **Variant Manager**. Alternatively, right-click the variant badge on any variant block in the model and select **Open in Variant Manager**.

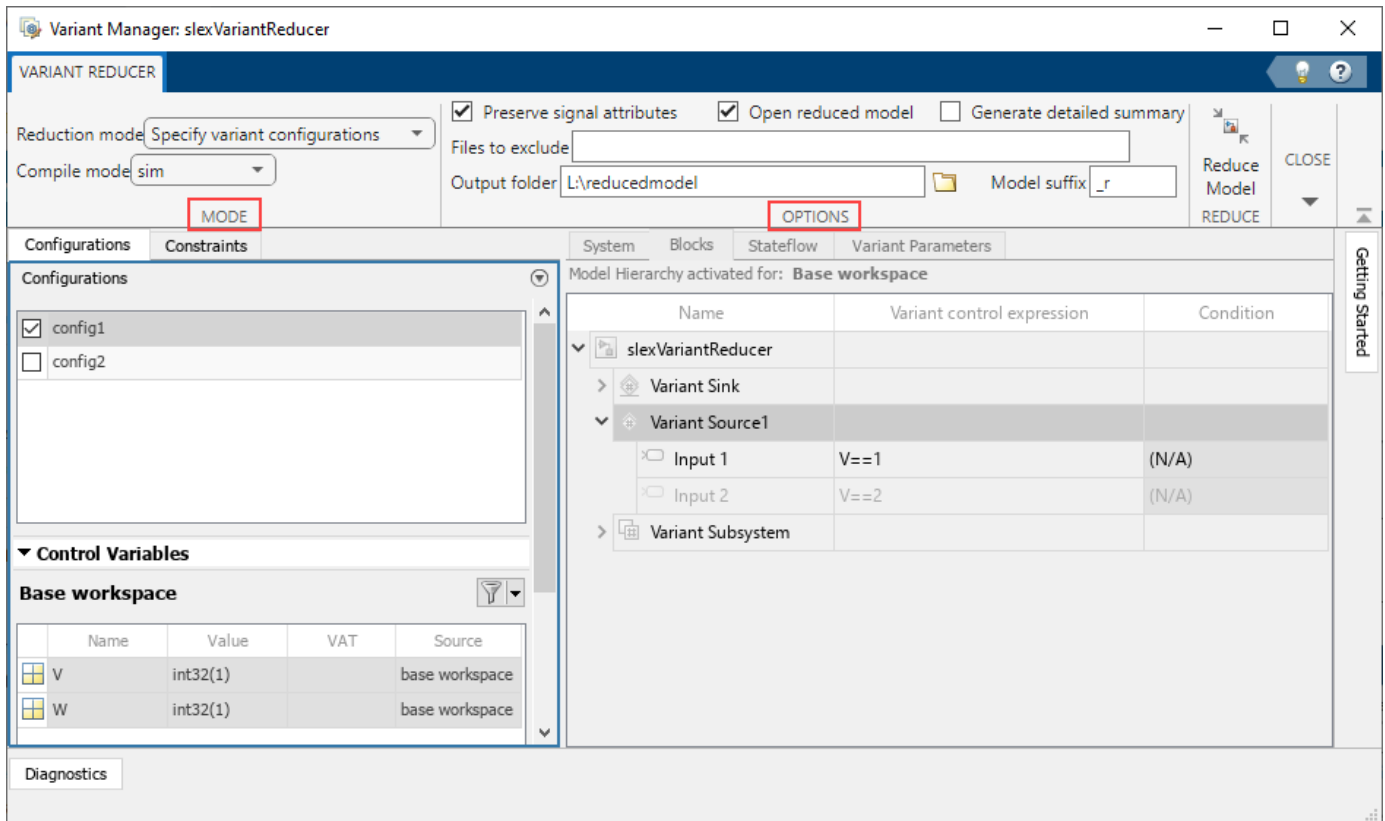

This image shows the Variant Manager window for the `slexVariantReducer` model. The model has two predefined variant configurations named `config1` (`V == 1 && W == 2`) and `config2` (`V == 2 && W == 2`).

- 2 Open Variant Reducer. In the Variant Manager toolstrip, in the Apps section, click **Variant Reducer**.

This image shows the Variant Reducer window.

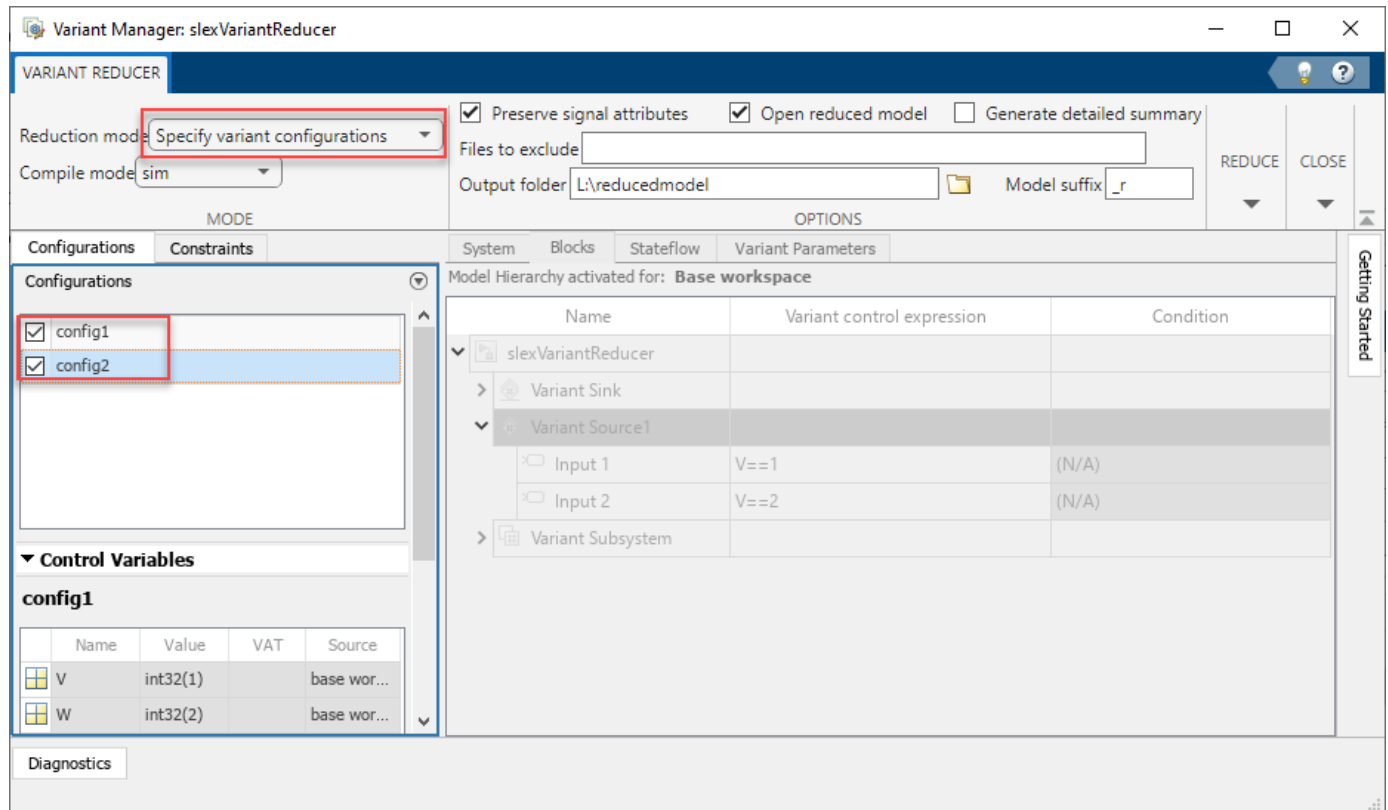

- 3 Specify the different settings for reduction in the **Mode** and **Options** sections of the Variant Reducer toolstrip. If you do not modify the settings, Variant Reducer uses default values for reduction. The purpose of each setting is detailed in the following steps.
- 4 Select a **Reduction mode** option:
  - **Current variant control values:** Reduce the model based on the variant control variable values in the base workspace or data dictionary used by the model.
  - **Specify variant configurations:** Reduce the model for the named configurations defined in a variant configuration data object associated with the model.

---

**Note** In this mode, Variant Reducer stores the variant control variable values from the last selected configuration in the base workspace or data dictionary used by the model.

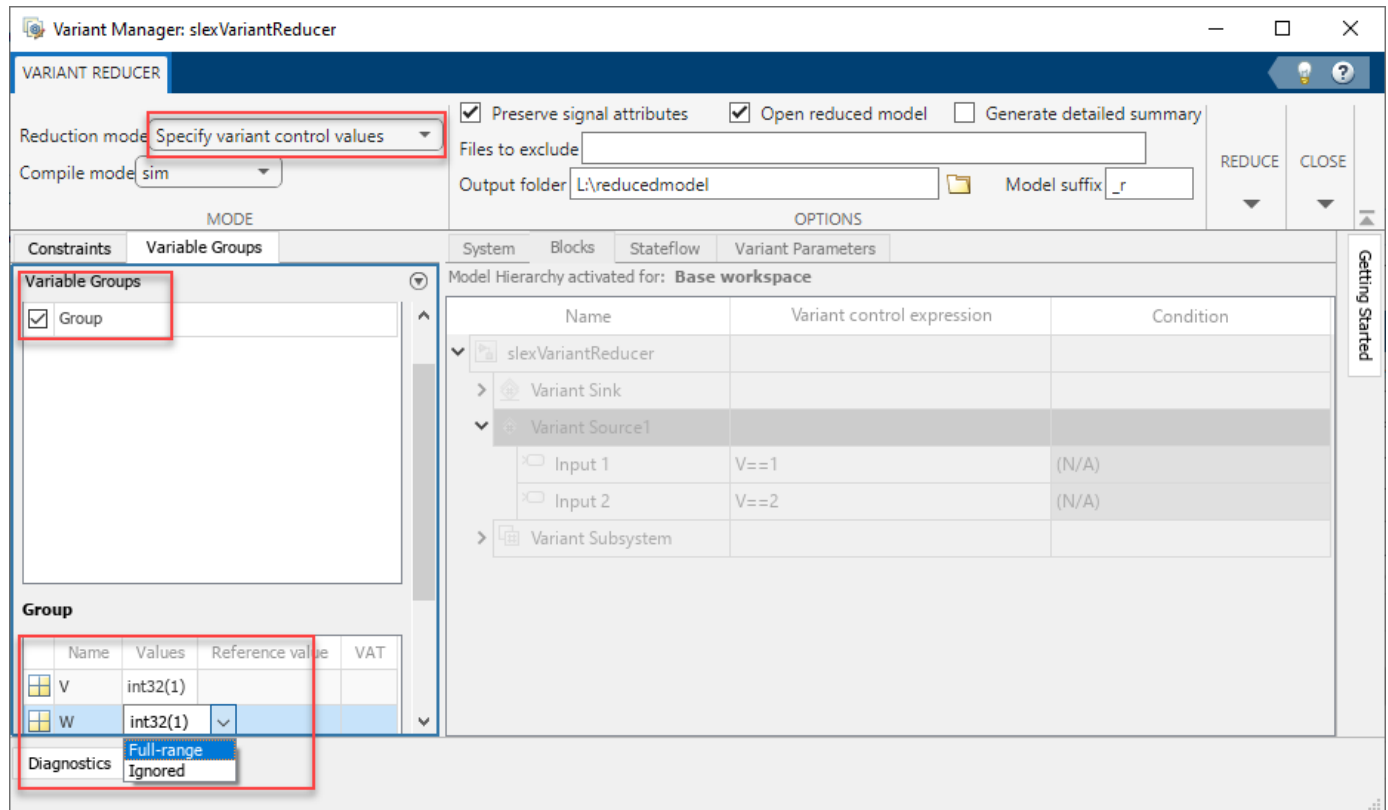

---

Select the required configurations from the **Configurations** tab.

- Specify variant control values:** Reduce the model by specifying values for the variant control variables. If the model does not have any predefined named configurations, Variant Reducer uses this mode by default. You can create multiple variable groups that correspond to different variant configurations to be retained in the reduced model. In each variable group, you must specify the variant control variables and the values to be considered for each variable.

**Note** In this mode, the reduced model has a new variant configuration data object that contains the specified variable groups.

To add a new variable group, click  in the **Variable Groups** table.

In the **Group** table, in the **Values** column, you can either specify a value for the variant control variable or select **Full - range** or **Ignored** from the list.

- Variant control value as a vector — Reduce the model for all combinations of the specified values. For example, if you specify values  $V = 1$  and  $W = [1, 2]$ , then the model is reduced for the configurations  $\{V == 1, W == 1\}$  and  $\{V == 1, W == 2\}$ .
- **Full - range** — Reduce the model for all valid values of the specified variant control variable. In the **Reference value** column, you must enter a reference value for the variable for which the model compiles successfully.
- **Ignored** — The variant control variable is not considered while reducing the model.

### Note

- To use a full-range variant control variable, you must set the **Variant activation time** in the block parameters dialog of the block that uses that variant control variable to code compile.
- You can specify at most one full-range variant control variable in a variant block.
- Specifying the value of a variant control variable as **full - range** during reduction is not supported if the variable is used by variant parameters visible to the model, even if the parameter is not used in the model hierarchy.

- 5 For **Compile mode**, select `sim` to compile the model for simulation or `codegen` to compile the model in code generation mode as part of reducing the model. If the model contains variant blocks with the **Variant control mode** parameter set to `sim` or `codegen` switching, you can select `codegen` to retain the code generation branches of the blocks in the reduced model. For the default value `sim`, Variant Reducer compiles and retains the simulation branches in the top-level model.
- 6 Select **Preserve signal attributes** to preserve the compiled signal attributes between the original and reduced model. When this option is selected, the Variant Reducer tries to preserve the compiled signal attributes between the original and reduced models by adding signal specification blocks at appropriate block ports in the reduced model. Compiled signal attributes include signal data types, signal dimensions, and compiled sample times.
- 7 Select **Generate detailed summary** to generate the Variant Reducer summary report in the output folder. The Variant Reducer summary contains a summary of Variant Reducer Options, Original and Reduced Model Differences, Dependent Artifacts, Callbacks, and Warnings. For more information, see “Explore Variant Reducer Summary” on page 88-40.

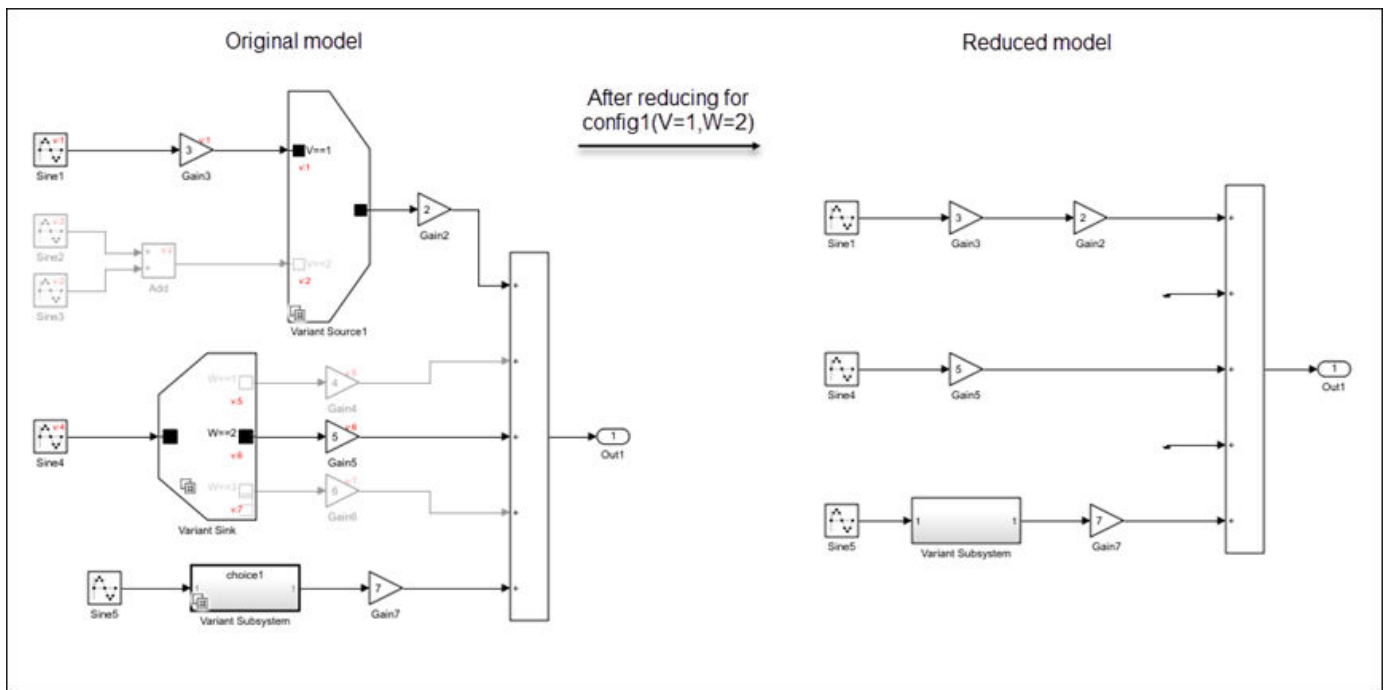

---

**Note** To generate a detailed summary, you must have a Simulink Report Generator license.

---

- 8 Use the **Files to exclude** box to specify any dependent Simulink data dictionary files (`*.sldd`) and MAT-files (`*.mat`) outside the MATLAB root folder to exclude during reduction. Value must be a cell array of character vectors.  
  
You can specify the full path of the directory or the specific files that must be skipped. You can also provide wildcard characters, for example, `{'*.*.sldd'}` or `{'topData.sldd'}`.
- 9 Specify a value for **Model suffix**. The model suffix value is appended to the names of the reduced models, data dictionaries, and related artifacts. By default, the suffix is `_r`.
- 10 In the **Output folder** box, browse for or enter the output folder in which to store the reduced model and related artifacts. The output folder must not be under `matlabroot`. By default, the reduced artifacts are generated in a folder named `reducedModel` within the original model folder.  
  
If the output folder contains the `variant_reducer.log` file from a previous model reduction, then Variant Reducer overwrites all the files available in that folder during any subsequent reduction.
- 11 Select **Open reduced model** to change the current working folder to the output folder and open the reduced model.
- 12 Click **Reduce Model**.

This image shows the result of reducing the model for the configuration `config1` with values  $V = 1$  and  $W = 2$ .

**13** To return to the **Manage** tab of Variant Manager, click **Close Reducer**.

## Explore Variant Reducer Summary

If you set the **Generate detailed summary** option for a reduction, Variant Reducer generates a detailed report of the reduction process as an HTML file. The report is saved in the output folder where reduced artifacts are saved.

---

**Note** A Simulink Report Generator license is required to generate a Variant Reducer summary.

---

Use the Variant Reducer summary to:

- Verify the input and output options used for reduction, for example, the input variant configuration and the output folder location.
- Analyze the differences between the original model and the reduced model, for example:
  - Blocks that have been inserted, deleted, or modified
  - Masks that have been modified
  - Dependent data files or Simulink cache files that have been modified
- Identify any warnings.
- Identify components that are not reduced and determine the manual updates that might be required, for example, callback code and Stateflow variant transitions.
- Navigate the interactive views of the original and reduced models.

The screenshot displays the Simulink Web View interface for a variant reducer. The main content area is titled "Variant Reducer Detailed Summary for 'slexVariantReducer\_r'". It includes a table of contents on the left and a right-hand panel with "Variant Source1" and "Variant Subsystem" details.

**Variant Reducer Options**

**Variant Configurations**

The following input variant configurations were specified.

**config1**

**Variant Control Variables**

## Reduce a Model Programmatically

To reduce a model programmatically, see `Simulink.VariantManager.reduceModel`.

## Considerations and Limitations for Variant Reduction

### Limitations

- Reduction of models that contain the Variant Connector block is not supported.
- Specifying the value of a variant control variable as `full-range` during reduction is not supported if the variable is used by variant parameters visible to the model, even if the parameter is not used in the model hierarchy.

### Variant Conditions on Simulink Function Blocks After Reduction

If a model that contains a Simulink Function block is reduced for any or a combination of the available variant conditions on the block, then the Simulink Function block in the reduced model becomes unconditional.

Consider a model that contains a Simulink Function block with the value of the **Variant control** parameter set to `V == 1 || V == 2 || V == 3 || V == 4`.

- If the model is reduced for the variant control values `V = 1`, `V = 2`, and `V = 3`, then the Simulink Function block in the reduced model is unconditional.

- If the model is reduced for the variant control values  $V = 1$ ,  $V = 2$ , and  $V = 5$ , then the Simulink Function block in the reduced model remains conditional with the value of the **Variant control** parameter set to  $V == 1 \ || \ V == 2$ .

### Modifications to Model Components

- Additional blocks are added automatically to the reduced model to ensure consistent simulation semantics. Additional blocks include Signal Specification blocks for consistent signal attributes (data type, dimensions, complexity) or the Ground and the Terminator blocks for unconnected signals.
- Variant parameter objects (instance of the `Simulink.VariantVariable` class) are reduced.
- Referenced models and library blocks present in the model hierarchy are reduced.
- If the model contains resolved library links, the corresponding parent is reduced for the specified configuration and is referenced in the model.
- Reduced models are saved with a MAT-file that contains saved variant configurations. The file loads during the `PostLoadFcn` callback of the reduced model.
- Variant subsystem and Model Variant blocks with only one choice are converted to normal Subsystem or Model blocks.
- Single-input, single-output Variant Source and Variant Sink blocks are removed if they are active across all specified configurations.
- During model reduction, commented blocks present on the active path are retained. Commented blocks present on an inactive path are removed.
- Signal attributes such as data type, complexity, or dimensions that come from the inactive elements in Stateflow charts might not be retained in the reduced model.

### Model Components That Are Not Reduced

These model components are not reduced automatically and might require manual intervention. To identify such artifacts, use the Variant Reducer summary report.

- Callback code:
  - Callbacks such as `InitFcn`, `PreLoad`, `PostLoad`, mask initialization code, and mask parameter callback code must be modified manually.
  - Callback code in the inactive variant components is removed. This action can cause unexpected behavior in the reduced model.
- During model reduction, elements in the Stateflow canvas, including variant transitions, are not modified.
- If a model has dependencies on files that are located under `matlabroot` (Simulink libraries, `.m` files, `.mat` files, or `.sldd` files), the files are not modified or copied to the output folder during model reduction.
- Library blocks under the MATLAB root are not reduced.
- Variant blocks with `startup` activation time and any blocks connected to it are not reduced.

- “Reduce Model Containing Variant Parameters” on page 88-69

## Analyze Variant Configurations in Models Containing Variant Blocks

---

**Note** This functionality requires Variant Manager for Simulink.

---

A model might contain several variant blocks, each with many variant choices. A variant configuration is used to represent a combination of such variant choices across the model hierarchy. For example, in a system with a plant and a controller, a *linear controller with an internal plant with no noise* and a *nonlinear controller with an external low fidelity plant* represent two different configurations of the system.

You can use Variant Manager to create and manage variant configurations for a model. Variant Manager defines a variant configuration as a set of variant control variables and their values that can activate a specific variation in the model hierarchy. For more information on variant configurations, see “Variant Configurations” on page 88-2. For an overview of Variant Manager, see “Variant Manager for Simulink”.

### Analyze Variant Configurations Using Variant Analyzer

Use Variant Analyzer to:

- Compare different variant configurations for a model to understand the model elements used in each.
- Check if all variant choices have been activated at least once and whether the model is covered completely for simulation and code generation.
- Verify if the active, implemented model is different between different variant configurations.
- Find dependent model artifacts such as referenced models and libraries used by a particular variant configuration.

You can analyze the named variant configurations created for the model or perform an analysis after setting values for the variant control variables. The report generated by the tool displays:

- Variant configurations analyzed
- A model hierarchy with all the blocks
- Variant activeness of each block in each variant configuration
- Propagated variant conditions on a block for each variant configuration

The analysis results help you to determine which blocks are used in different variant configurations. The unused blocks are highlighted in red, which represents untested and uncovered parts of the model. The heatmap view helps you determine the similarities and differences in the active, implemented model between different variant configurations. This information can be used to refine the variant configurations and to update the model to provide full simulation coverage across all variant configurations.

## Run Variant Analyzer

- 1 Open the variant model that must be analyzed. Here, open the `slexVariantConfigurationAnalysis` model using the following command.

```
openExample('simulink_variants/AnalyzeVariantConfigurationsInModelRefPageExample');
open_system('slexVariantConfigurationAnalysis');
```

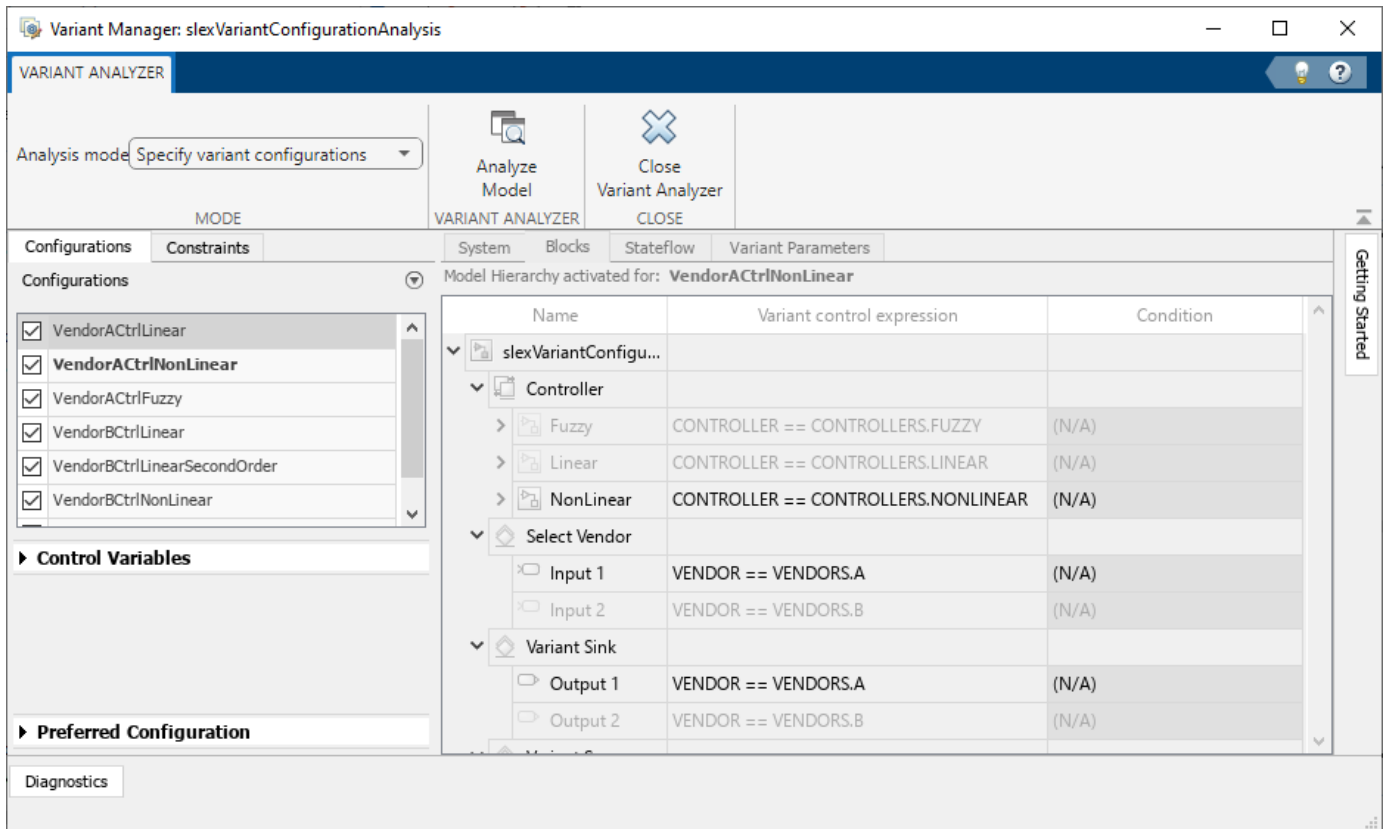

This model contains multiple vendor choices for the sensors and different controller implementations based on the sensor input. The choice of vendor sensors is modeled with Variant Source and Variant Sink blocks. The different controller choices is modeled using Variant Subsystem block.

- 2 Open Variant Manager. On the **Modeling** tab, open the **Design** section and click **Variant Manager**. Alternatively, right-click the variant badge on any variant block and select **Open in Variant Manager**.

The Variant Manager opens and displays the predefined configurations. To open Variant Analyzer, in the Variant Manager toolstrip, in the **Apps** section, click **Variant Analyzer**.

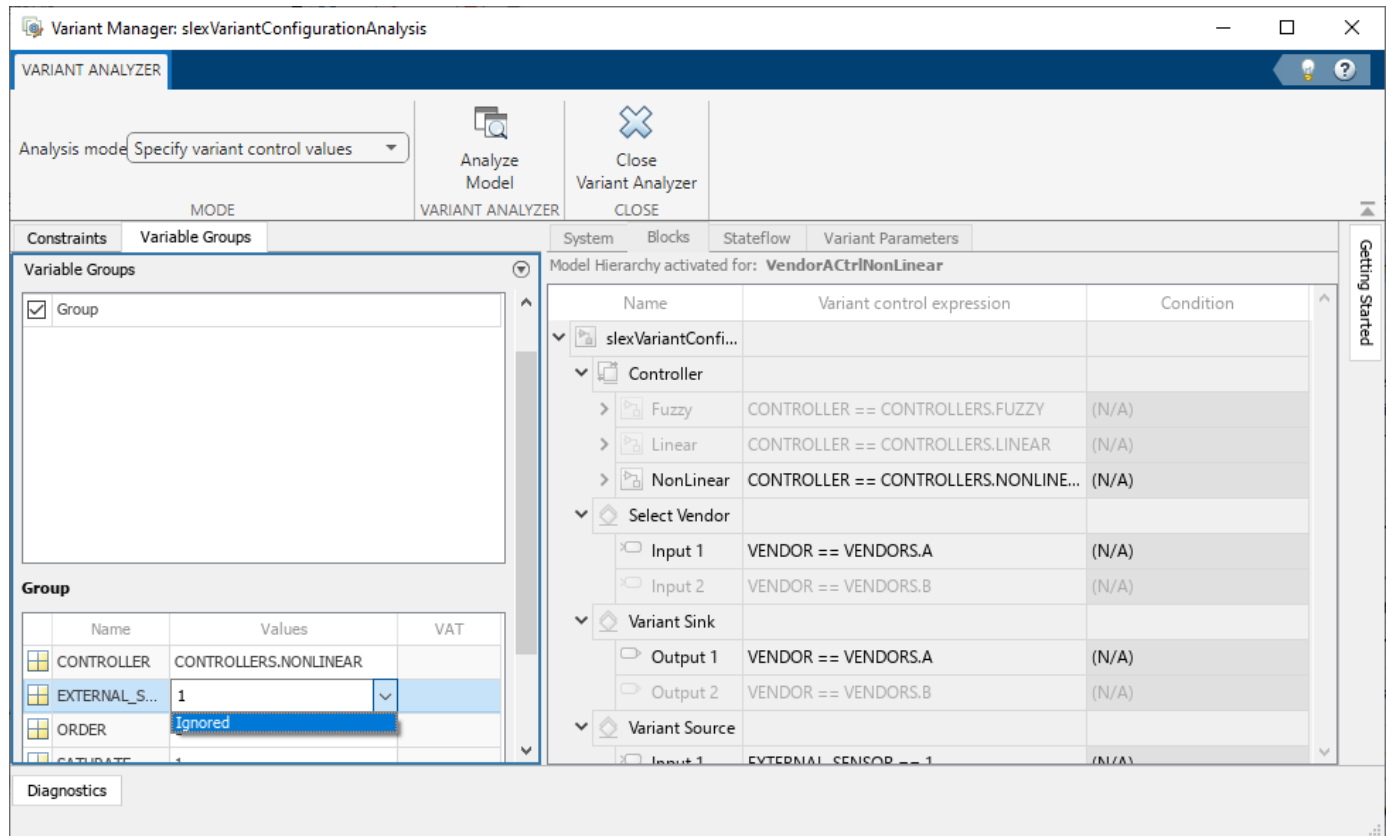

- 3 For **Analysis mode**, choose whether to analyze the predefined named configurations for the model or if you need to specify values for the variant control variables.
  - **Specify variant configurations** — Select from the list of named variant configurations in the **Configurations** tab.
  - **Specify variant control values** — Analyze the model by specifying values for the variant control variables. You can create multiple variable groups that correspond to different variant configurations to be analyzed. In each variable group, you must specify the variant control variables and the values to be considered for each variable.

To add a new variable group, click the Add variable group button  in the **Variable Groups** table and set the values for variant control variables. You can either specify a variant control value or select **Ignored** from the **Values** list.

- Variant control value as a vector — Analyze for all combinations of the specified values. For example, if you specify values  $V = 1$  and  $W = [1, 2]$ , then the model is analyzed for the configurations  $\{V == 1, W == 1\}$  and  $\{V == 1, W == 2\}$ .
- Ignored — The variant control variable is not considered while analyzing the model.

- 4 Click **Analyze Model**. The variant analysis report opens in a new window.
- 5 Click **Close Analyzer** to return to the **Manage** tab in Variant Manager.

## Explore Variant Analysis Report

The variant analysis report displays a tree-table view of the model hierarchy and all of the analyzed variant configurations.

This image shows the analysis report for four named variant configurations.

c:1	CONTROLLER == CONTROLLERS.LINEAR && EXTERNAL_SENSOR == 1 && VENDOR == VENDORS.B
c:10	(CONTROLLER == CONTROLLERS.LINEAR && EXTERNAL_SENSOR == 0 && VENDOR == VENDORS.A)    (CONTROLLER
c:11	CONTROLLER == CONTROLLERS.LINEAR && VENDOR == VENDORS.A
c:12	CONTROLLER == CONTROLLERS.LINEAR && VENDOR == VENDORS.B

**Callouts:**

- Block activeness icon (Always Active / Partially Active / Never Active in any configuration)
- Block that is not active in any configuration highlighted in red
- Variant condition annotation (c:#) for each block in a configuration
- The propagated variant condition corresponding to each annotation

### Icons and Formatting

This table explains the icons and formatting used in the report.

Formatting	Meaning
Rows and Columns	Each row in the table corresponds to a block in the model. Each column represents a variant configuration.
Check mark	The ✓ symbol is for a visual aid and indicates that the block is active in the corresponding variant configuration.
Background color	<p>An entire row including the block name appears with a red background color if it is not active in any of the variant configurations. Such a block indicates an untested path in the model.</p> <p>A table field with red background color indicates that a particular block is not active in a specific configuration.</p> <p>For example, in this model, the Vendor A block is active in the variant configurations VendorACtrlLinear and VendorACtrlNonLinear and inactive in the variant configurations VendorBCtrlLinear and VendorBCtrlNonLinear.</p>

Formatting	Meaning
Block activeness icons	The  ,  , and  icons in the <b>Activeness</b> column indicate if a block is active in all the configurations, active in some configurations, or inactive in all configurations, respectively.
Variant condition annotations (c:#)	<p>The annotations in the table fields represent a variant condition that the block receives for a particular configuration. The propagated variant condition on a block changes according to the active variant configuration.</p> <p>You can refer the table in the <b>Annotation</b> pane for mapping between the annotations (c:#) and the propagated variant conditions that each of them represent. The propagated variant conditions help you understand why a block is active for a given variant configuration (the variant condition is evaluated based on the values of the control variables defined in the configuration). Click on an annotation in the table. All the blocks that have that annotation appear highlighted in the configurations table.</p>

### Filter the Report

Filter the report based on your desired type of filter.

Desired Filter	Filtering Method
Name of block	Enter the block name in the <b>Search Blocks</b> box and press <b>Enter</b> .
Type of block	<p>Select an option from the <b>View Blocks</b> list:</p> <ul style="list-style-type: none"> <li>• <b>Variant</b> to display only variant blocks in the model.</li> <li>• <b>Hierarchical</b> to display all hierarchical blocks in the model, for example, Subsystem or Model blocks. This view allows you to explore subsystems or model references one by one instead of looking through the complete model.</li> <li>• <b>All blocks</b> to display all blocks in the model.</li> </ul>
Block activeness	<div data-bbox="565 1392 829 1575" style="border: 1px solid gray; padding: 5px; margin-bottom: 10px;"> <input checked="" type="checkbox"/>  Always Active  <input checked="" type="checkbox"/>  Partially Active  <input checked="" type="checkbox"/>  Never Active </div> <ul style="list-style-type: none"> <li>• <b>Always Active</b> displays blocks that are always active in the model.</li> <li>• <b>Partially Active</b> displays blocks that are active in some configurations and inactive in others among the selected configurations.</li> <li>• <b>Never Active</b> displays blocks that are never active in the model. These blocks appear highlighted in red, which indicates they are untested and uncovered parts of the model and require updates to provide full simulation coverage.</li> </ul>

## Example Variant Analysis Reports

Consider this report for a model with several unused blocks. The **Never Active** option is selected to view the unused blocks.

The screenshot shows the 'VARIANT ANALYSIS' window with the following controls:

- Search Blocks: Search Block (text input)
- View Blocks: All Blocks (dropdown menu)
- Filter: Always Active (radio), Partially Active (radio), Never Active (radio, checked)

...	Model Hierarchy	VendorA...	VendorA...	VendorA...	VendorB...	VendorB...	VendorB...	VendorB...
	▼ sensor_vendors							
●	▼ Controller	c:3 ✓	c:13 ✓	c:24 ✓	c:3 ✓	c:13 ✓	c:13 ✓	c:24 ✓
○	▼ Linear	c:5	c:14 ✓	c:5	c:5	c:14 ✓	c:14 ✓	c:5
○	▼ Linear_Control		✓			✓	✓	
○	▼ Second order		c:16			c:16	c:16	
○	In1							
○	Discrete Tran							
○	Discrete Tran							
○	Out1							
○	▼ NonLinear	c:5	c:5	c:25 ✓	c:5	c:5	c:5	c:25 ✓
○	F1_Unsat			c:28				c:28
○	InternalData	c:6	c:17	c:29	c:6	c:17	c:17	c:29

Annotation	Condition
c:6	(CONTROLLER == CONTROLLERS.FUZZY && EXTERNAL_SENSOR == 0 && VENDOR == VENDORS.A)    (CON
c:8	(CONTROLLER == CONTROLLERS.FUZZY && EXTERNAL_SENSOR == 0 && VENDOR == VENDORS.A)    (CON
c:7	(CONTROLLER == CONTROLLERS.FUZZY && EXTERNAL_SENSOR == 1 && VENDOR == VENDORS.A)    (CON
c:3	(CONTROLLER == CONTROLLERS.FUZZY && VENDOR == VENDORS.A)    (CONTROLLER == CONTROLLERS.
c:17	(CONTROLLER == CONTROLLERS.LINEAR && EXTERNAL_SENSOR == 0 && VENDOR == VENDORS.A)    (COI
c:19	(CONTROLLER == CONTROLLERS.LINEAR && EXTERNAL_SENSOR == 0 && VENDOR == VENDORS.A)    (COI
c:18	(CONTROLLER == CONTROLLERS.LINEAR && EXTERNAL_SENSOR == 1 && VENDOR == VENDORS.A)    (COI

The blocks in the **Second order** controller inside the **Linear\_Control** and **F1\_Unsat** filter are unused. To make these unused blocks part of the active model in at least one of the variant configurations, modify the model or update the variant configurations.

This image shows the report for a model with two identical variant configurations. The **Partially Active** option is selected to get this result.

The variant configurations VendorBCtrlLinear and VendorBCtrlSecondOrder have no differences between them. The resulting active model for both these configurations will be the same. To resolve this result, update the variant configurations or update the model appropriately.

## Analyze Variant Configurations Programmatically

Use an instance of the `Simulink.VariantConfigurationAnalysis` class to analyze variant configurations programmatically.

## Limitations

The Variant Analyzer tool does not support variant blocks with the **Variant activation time** parameter set to `startup`.

## See Also

[Simulink.VariantConfigurationData](#) | [Simulink.VariantManager](#) | [Simulink.VariantConfigurationAnalysis](#)

## More About

- “Variant Manager for Simulink”

- “Create and Activate Variant Configurations” on page 88-10

## Reduce Model Containing Variant Blocks

This example shows how to reduce a Simulink® model that contains variant blocks both programmatically and by using Variant Reducer in Variant Manager.

A variant model can have multiple variant configurations associated with it. Each variant configuration represents a combination of variant control values that activates a specific variant choice. You can generate a reduced version of a variant model that contains only a subset of variant configurations from the original model using Variant Reducer.

### Explore Model

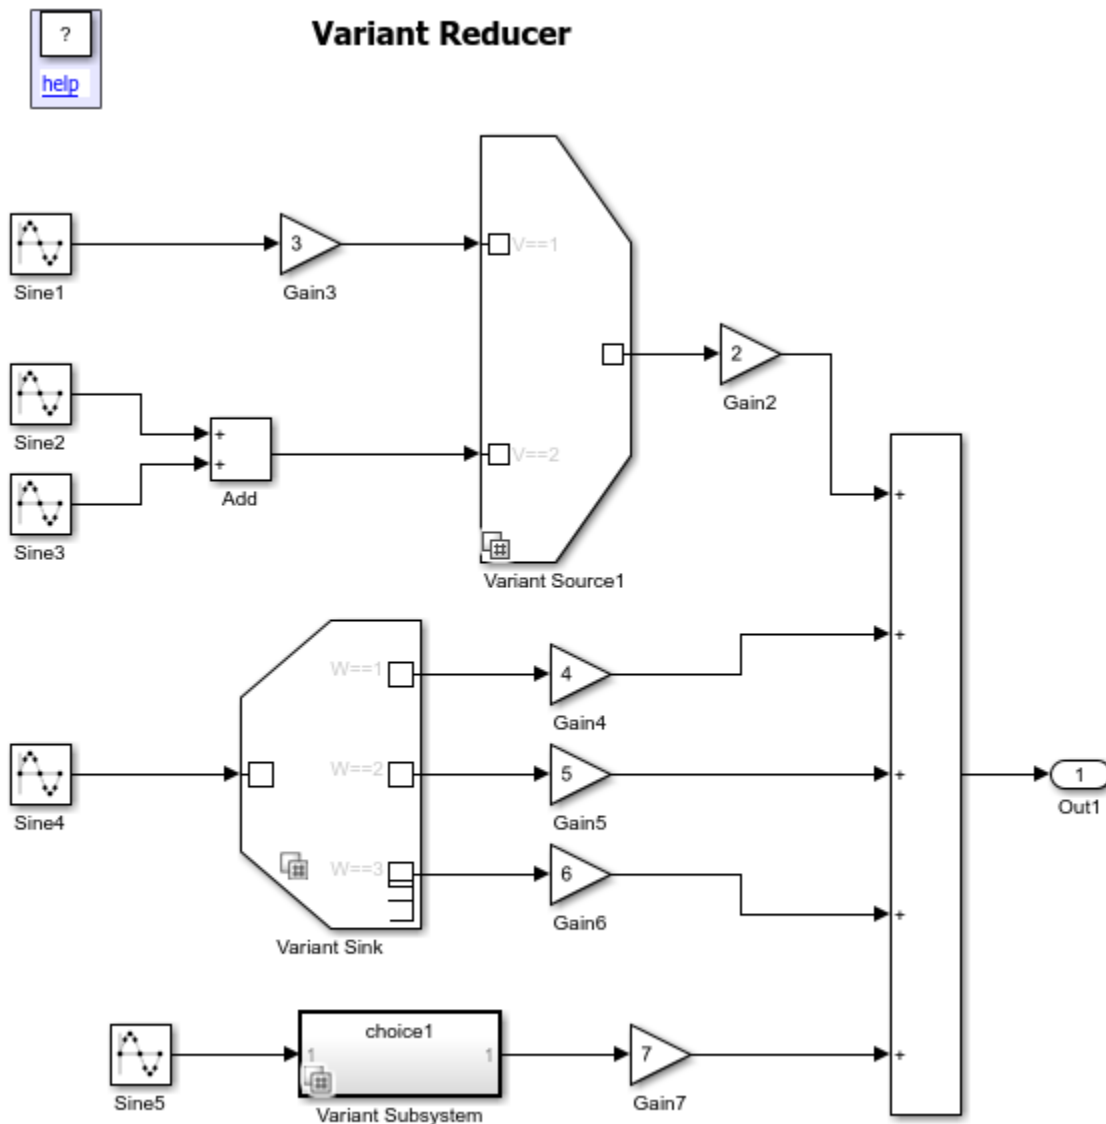

Open the model `slexVariantReducer`. The model contains a Variant Source block, a Variant Sink block, and a Variant Subsystem block with these variant choices:

- Variant Source:  $V == 1$  and  $V == 2$
- Variant Sink:  $W == 1$ ,  $W == 2$ , and  $W == 3$
- Variant Subsystem:  $V == 1$  and  $V == 2$

On the **Modeling** tab of the Simulink toolstrip, select **Model Explorer > Model Properties > Callbacks**. The `PostLoadfn` callback function of the model defines the variant control variables  $V$  and  $W$  and loads the `slexVariantReducer_config.mat` file.

The model has two predefined variant configurations named `config1` ( $V == 1 \ \&\& \ W == 2$ ) and `config2` ( $V == 2 \ \&\& \ W == 2$ ). These configurations are saved in a variant configuration data object, `slexVariantReducer_config`, which is in turn saved in the `slexVariantReducer_config.mat` file.

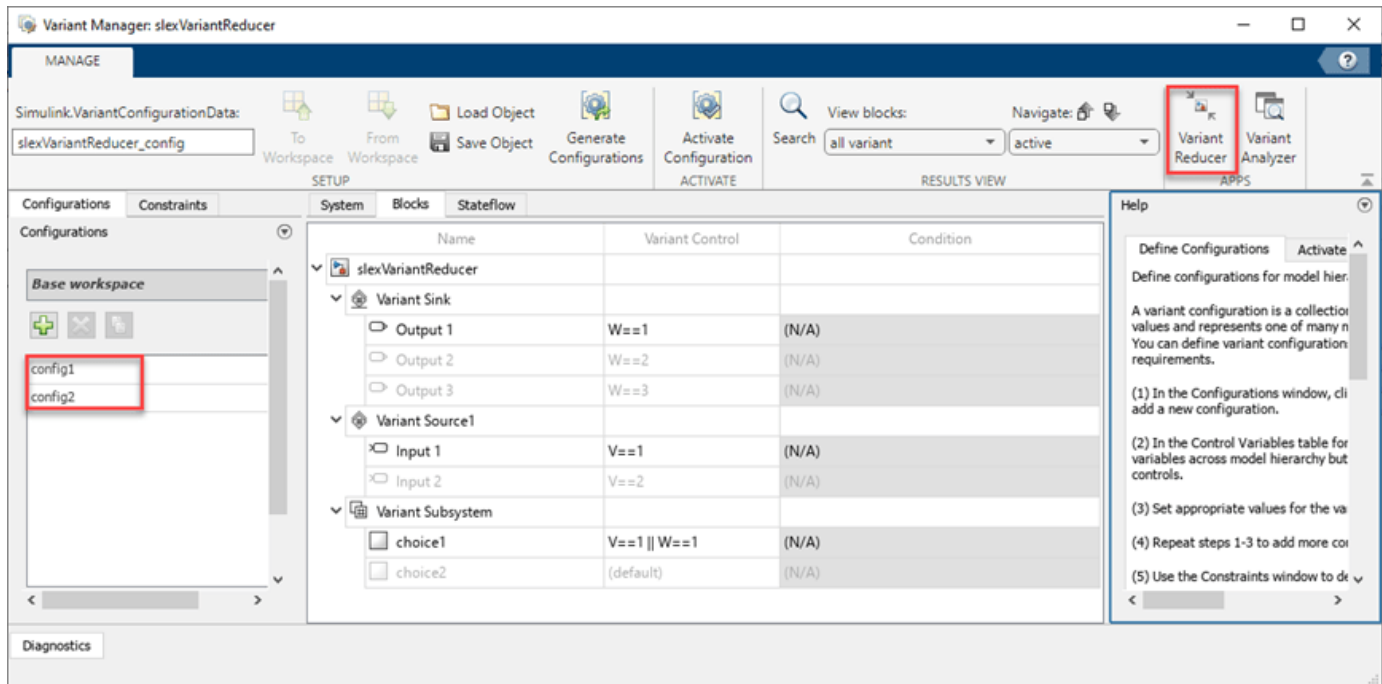

```
open_system('slexVariantReducer');
```

## Reduce Model from Variant Manager

### Open Variant Manager

1. To open Variant Manager, right-click the variant badge on any of the variant blocks and select **Open in Variant Manager**. The Variant Manager window opens and shows the predefined variant configurations.

2. To open Variant Reducer, in the Variant Manager toolbar, in the **Apps** section, click **Variant Reducer**. The Variant Reducer window opens.

### Choose Reduction Mode

Using the **Reduction mode** option in Variant Reducer, you can specify the configurations that you want to retain in the reduced model.

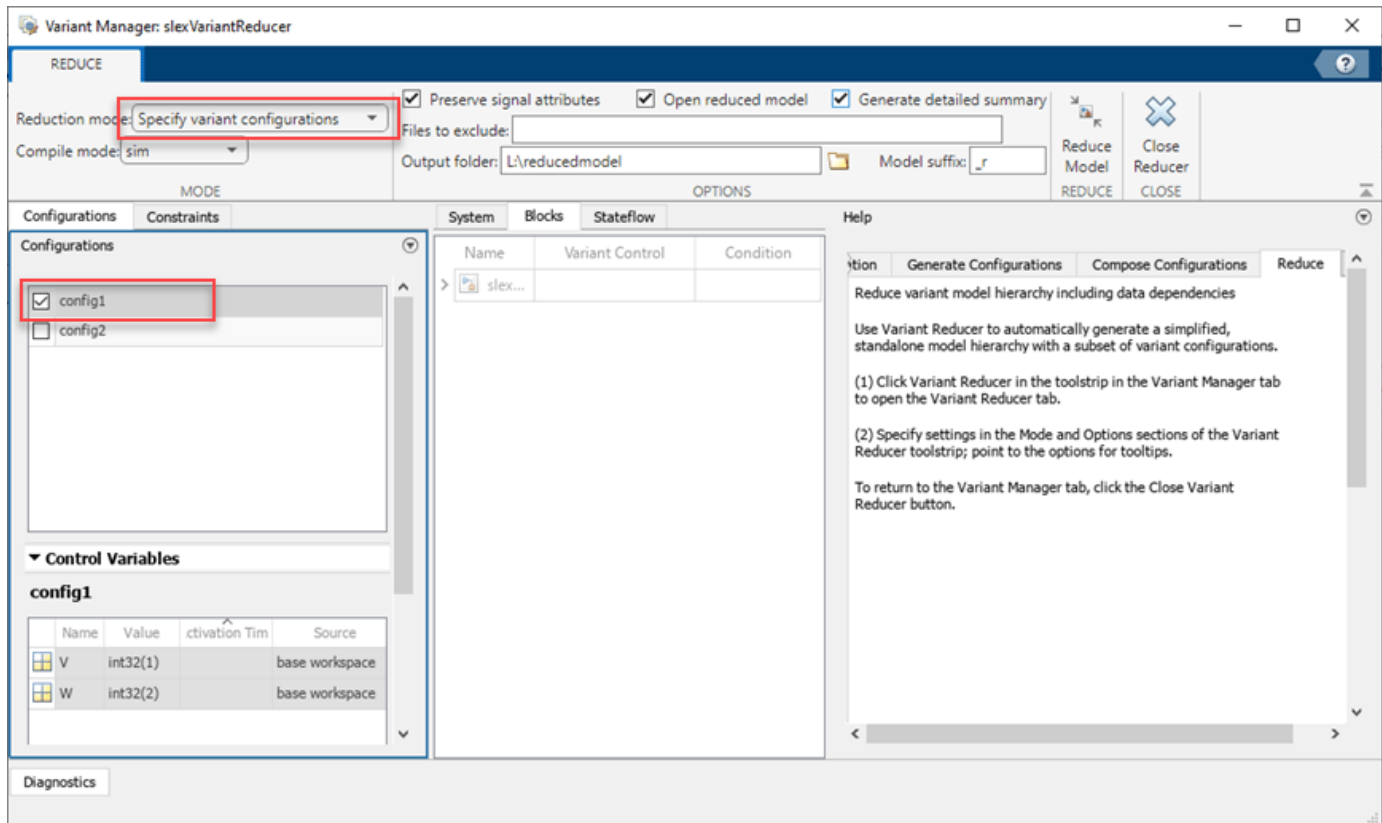

- Current values of variant control variables in the base workspace or data dictionary used by the model
- Named variant configurations created for the model
- Variable groups that contain variant control variables and their values

Select either a named configuration or a variable group as detailed in the following sections.

### Specify Named Variant Configuration

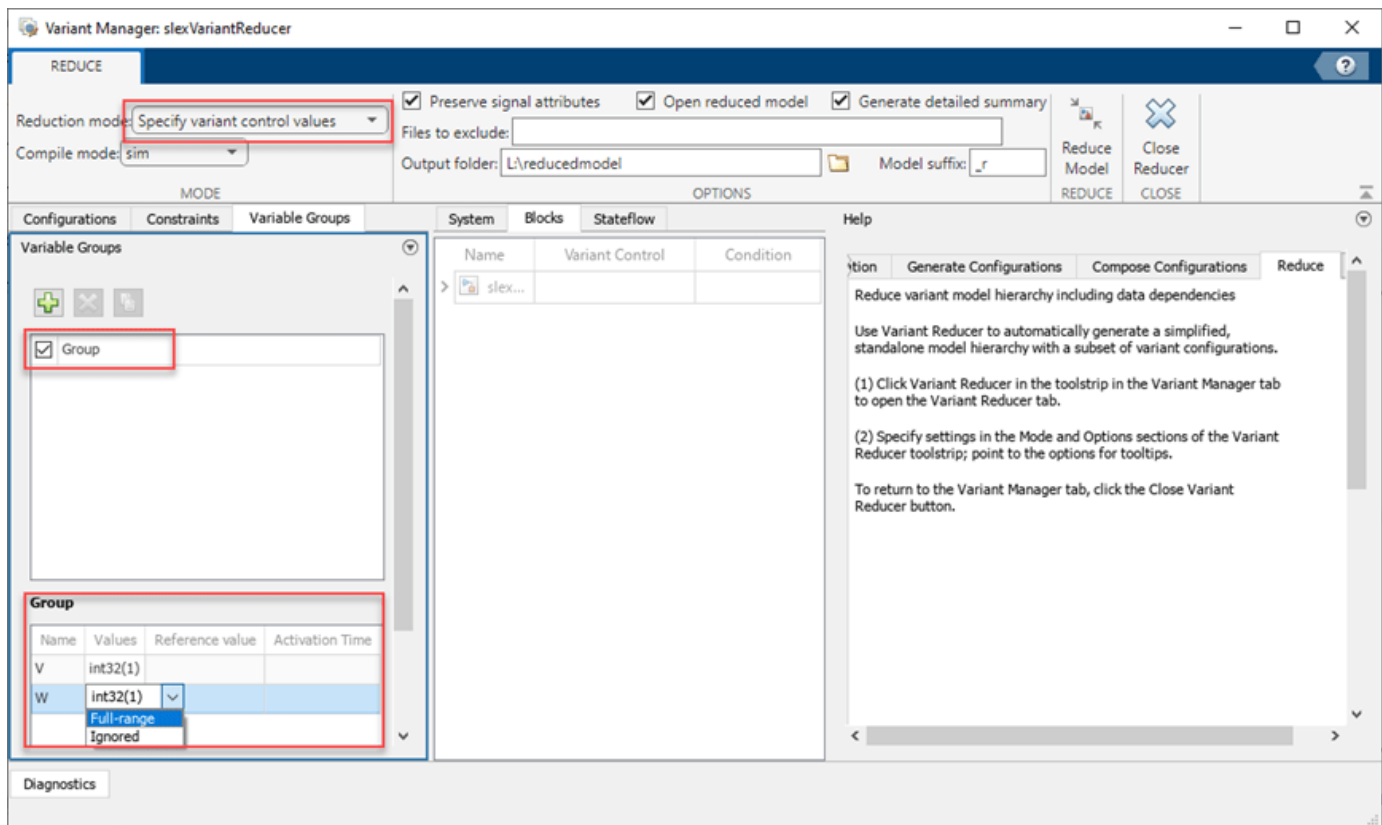

1. In the Variant Reducer toolbar, from the **Reduction mode** list, select the **Specify variant configurations** option.
2. Select the configuration to be retained in the reduced model from the **Configurations** tab.

### Specify Named Variable Group

1. In the Variant Reducer toolstrip, from the **Reduction mode** list, select the **Specify variant control values** option.
2. Select the group of variables to be retained in the reduced model from the **Variable Groups** tab. To create a new named variable group, click the **Add variable group** button.
3. In the **Group** table, in the **Values** column, you can either specify a value for the variant control variable or select Full - range or Ignored from the list.

## Reduce

1. You can modify the other reduction settings in the **Mode** and **Options** section of the Variant Reducer toolstrip as needed. If you do not modify the settings, Variant Reducer uses default values for reduction.
2. Click **Reduce Model**. The reduced model for the selected configurations is created.

If the model contains resolved library links or referenced models, the corresponding parent is reduced for the specified configuration and is referenced in the model. The reduced model, reduced referenced model, and reduced library get their names from the corresponding model, referenced model, or library with `_r` (model suffix) appended to it.

## Reduce Model Programmatically

To reduce the model programmatically, run either of these commands in the MATLAB® Command Window:

- Generate a reduced model by specifying a variable group and place reduced artifacts in the specified output folder.

```
Simulink.VariantManager.reduceModel('slxVariantReducer', 'VariableGroups', {'V', 1, 'W', 1}, 'Outp
```

- Generate a reduced model for the named variant configuration `config1` to the default output folder `reducedModel` and open the reduced model.

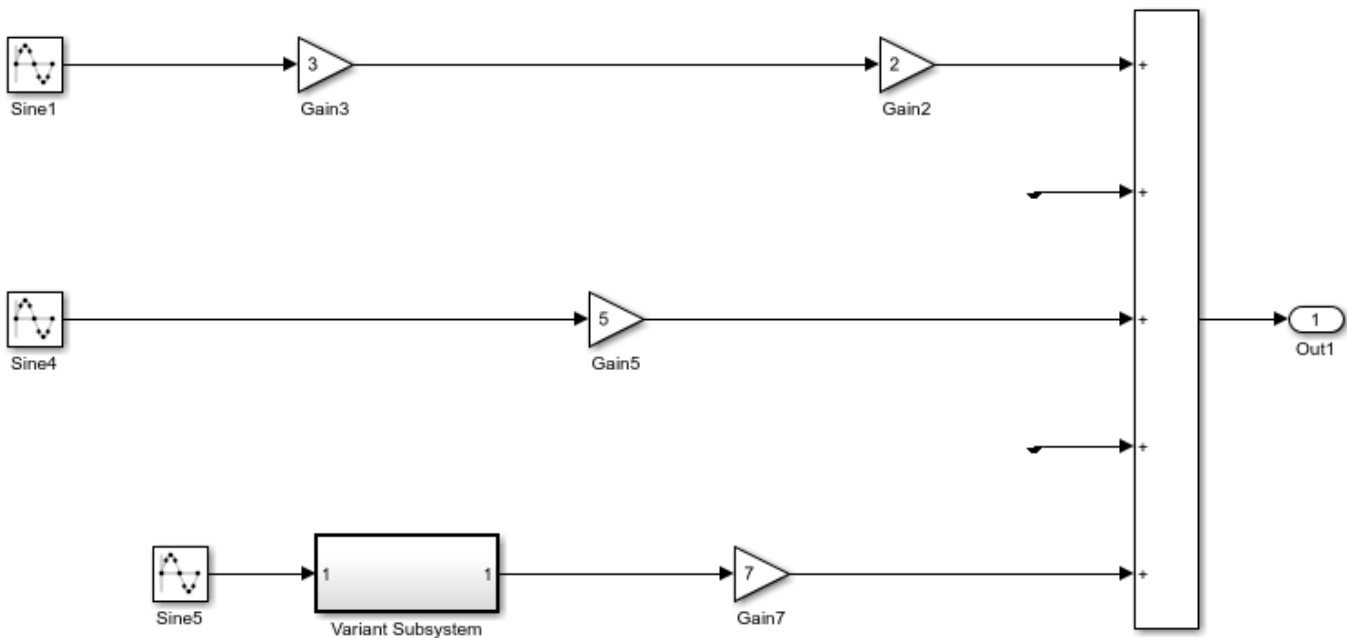

```
Simulink.VariantManager.reduceModel...
('slxVariantReducer', 'NamedConfigurations', {'config1'});
```

```
cd ./reducedModel;
open_system('slexVariantReducer_r');
```

Successfully created reduced model

## Variant Manager Workflow to Set Up Variant Configurations for Models

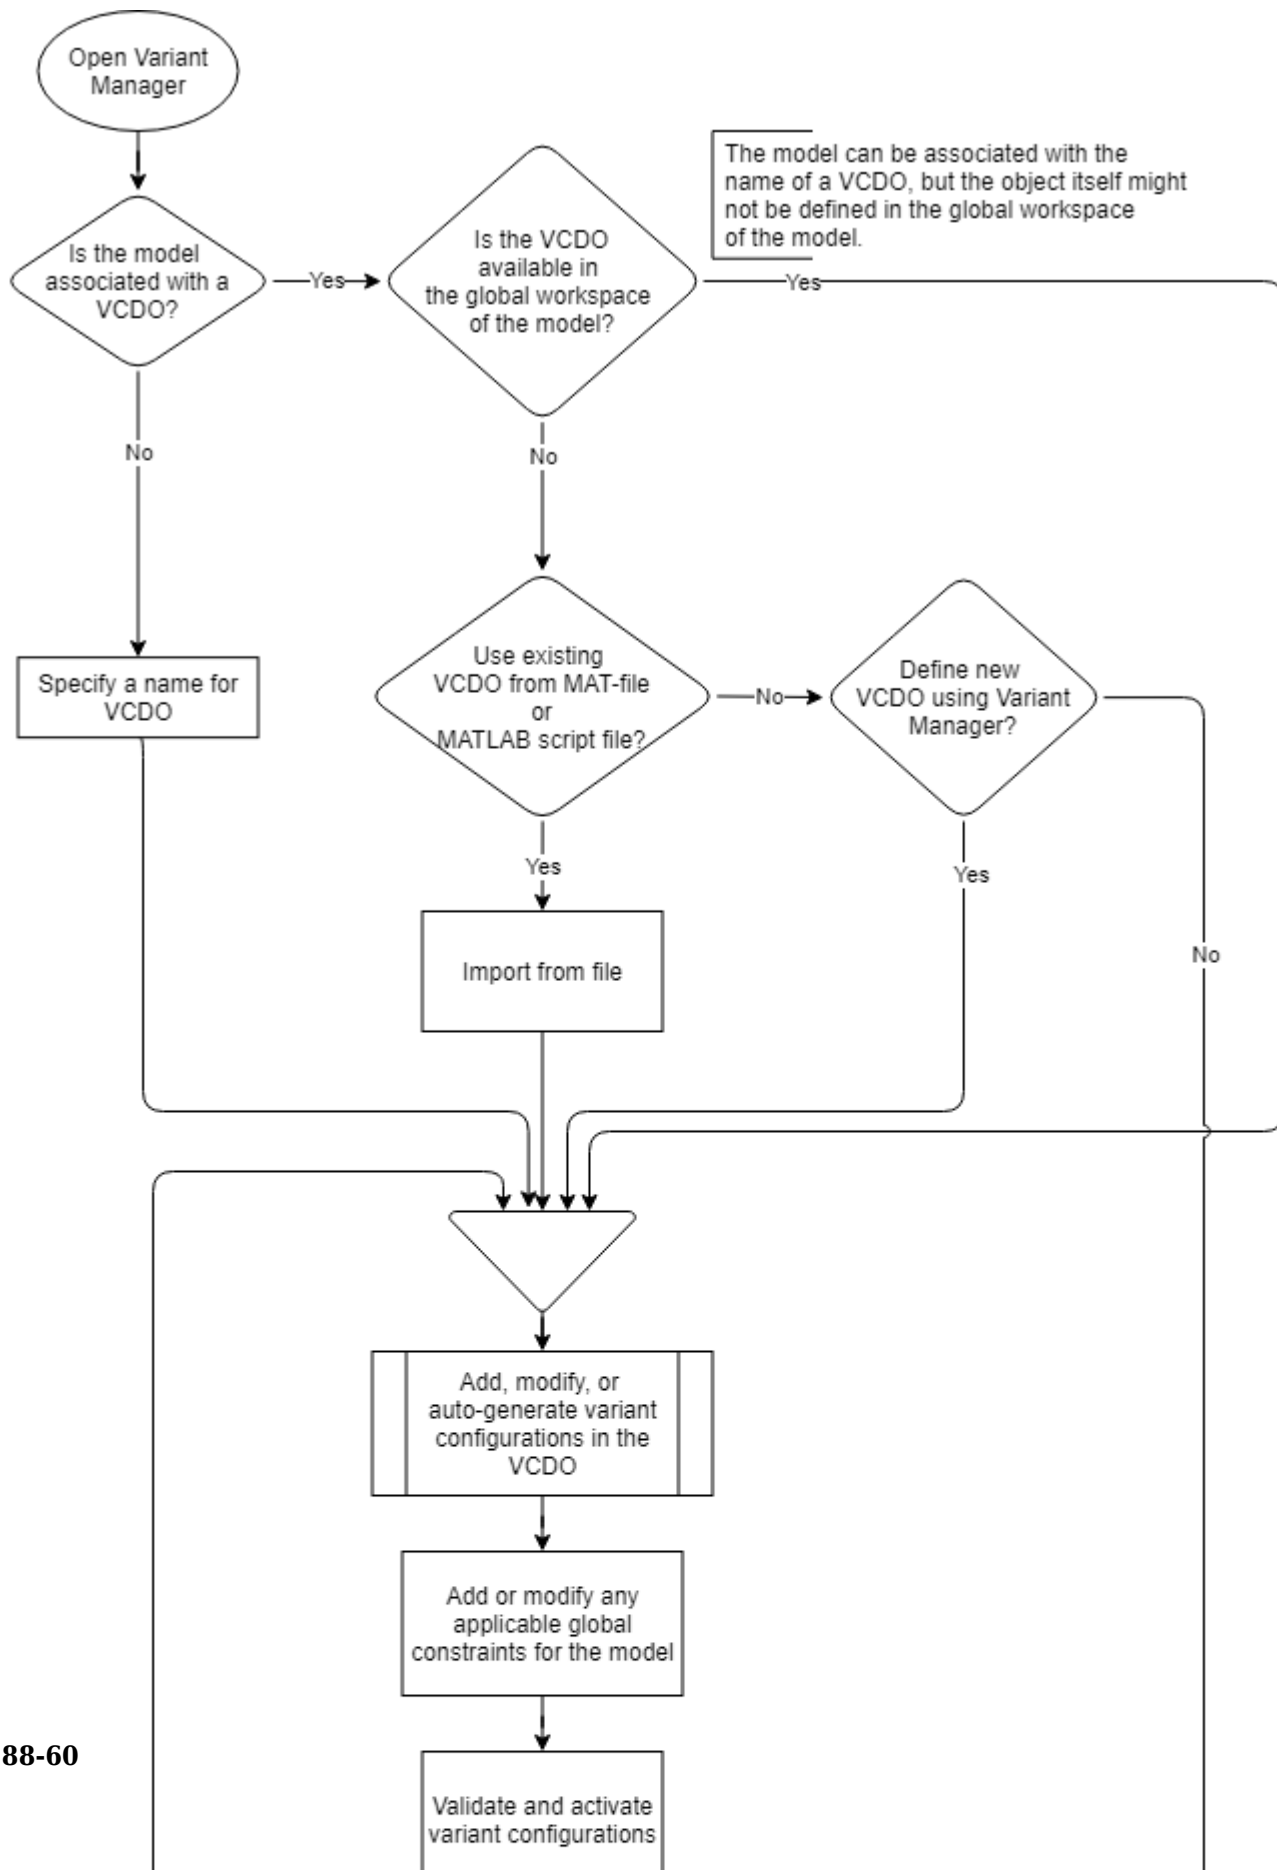

---

**Note** This functionality requires Variant Manager for Simulink.

---

This flowchart shows the high-level workflow to set up variant configurations for a model using Variant Manager.

A variant configuration data object (VCDO) is an instance of the `Simulink.VariantConfigurationData` class. The object stores all the variant configurations and constraints created for a model. The `VariantConfigurationObject` model parameter indicates the name of the VCDO that is associated with a model. You can view and set this value using the **`Simulink.VariantConfigurationData`** field in the Variant Manager.

For more information about variant configurations, see “Variant Configurations” on page 88-2.

For more information about creating and activating variant configurations in Variant Manager, see “Create and Activate Variant Configurations” on page 88-10.

## Variant Manager Workflow to Manage Existing Variant Configurations in Models

---

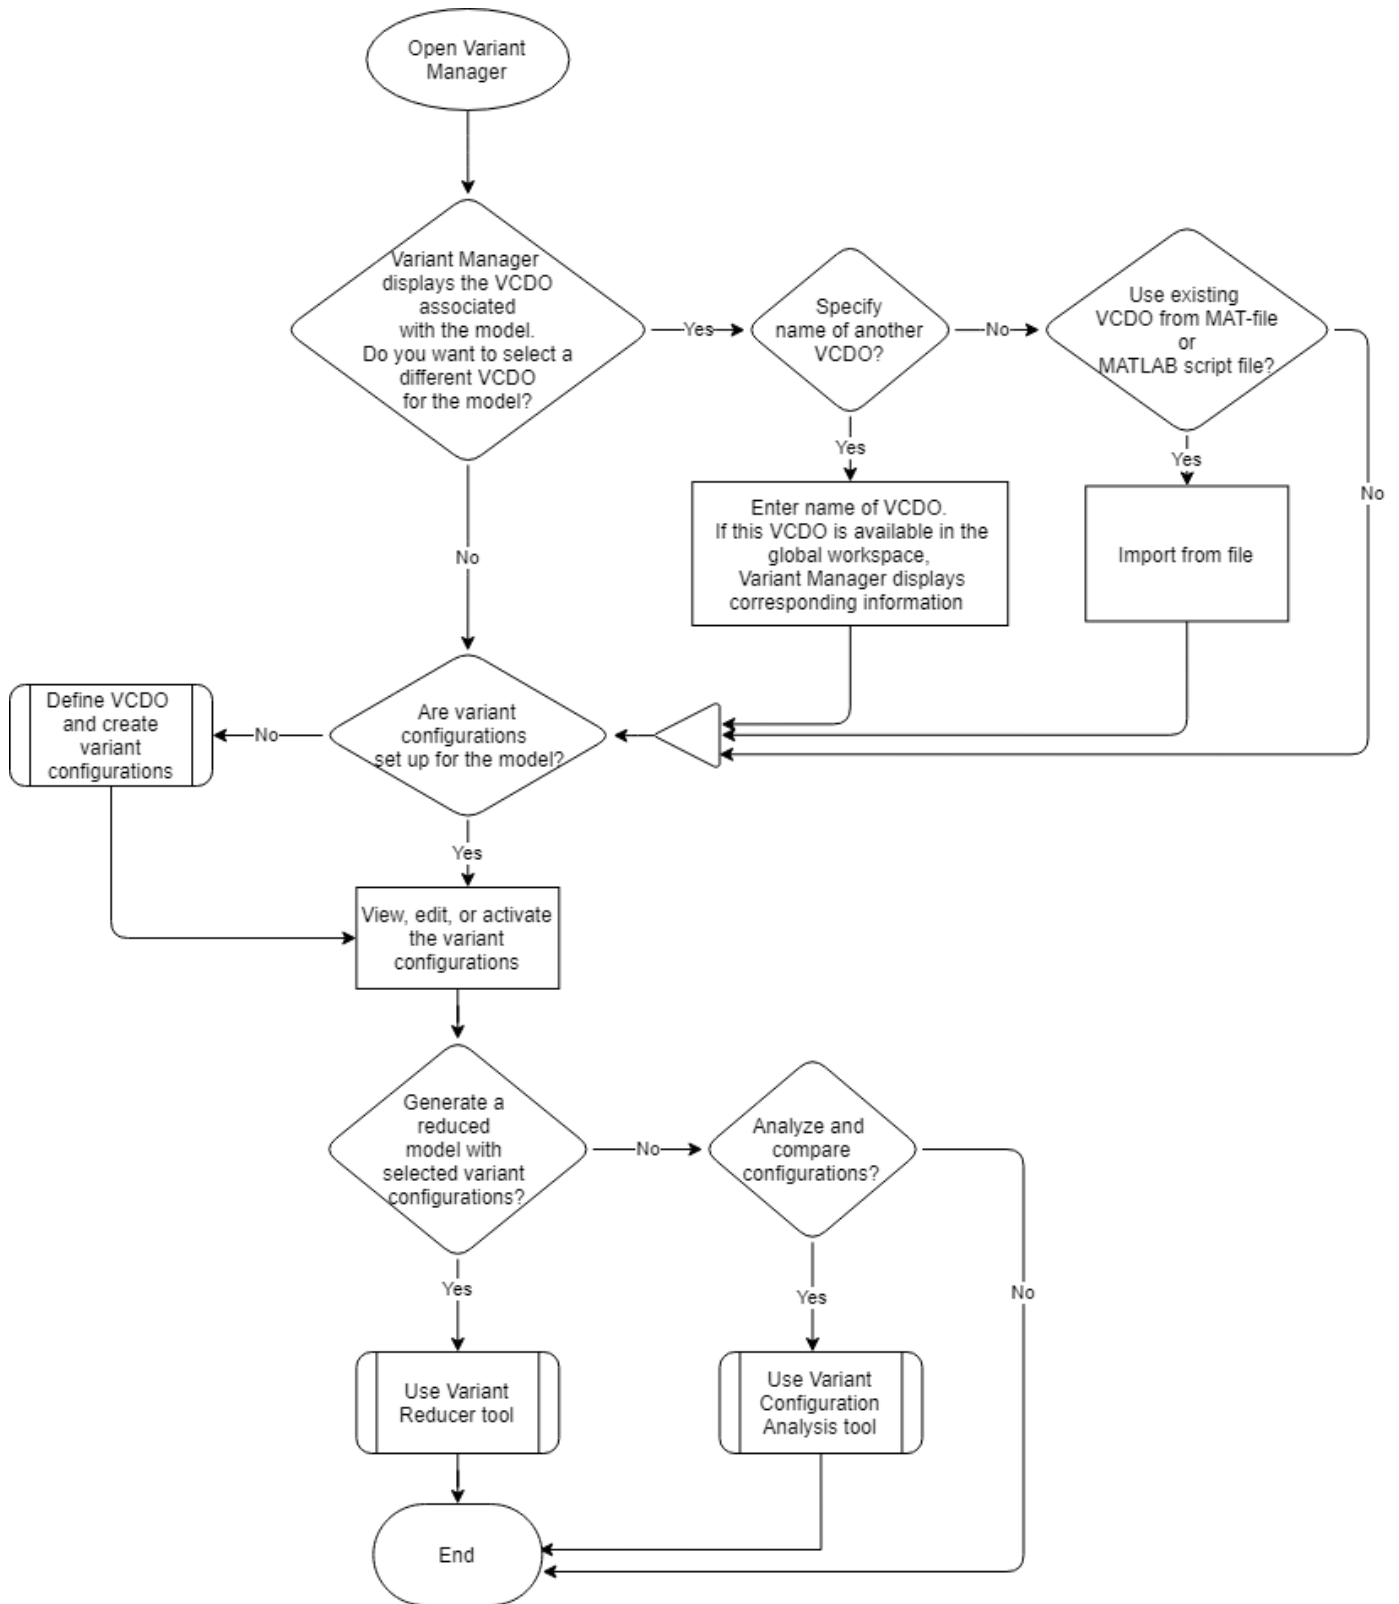

**Note** This functionality requires Variant Manager for Simulink.

---

This flowchart shows the operations that can be performed from Variant Manager after variant configurations are created for a model.

A variant configuration data object (VCDO) is an instance of the `Simulink.VariantConfigurationData` class. The object stores all the variant configurations and constraints created for a model. The `VariantConfigurationObject` model parameter indicates the name of the VCDO that is associated with a model. You can view and set this value using the **`Simulink.VariantConfigurationData`** field in the Variant Manager.

For more information about saving and reusing variant configurations in Variant Manager, see “Save and Reuse Variant Configurations Using Variant Configuration Data Object” on page 88-20.

For more information about reducing a model, see “Reduce Variant Models Using Variant Reducer” on page 88-32.

For more information about analyzing a model, see “Analyze Variant Configurations in Models Containing Variant Blocks” on page 88-44.

## Compatibility Considerations When Using Variant Manager for Simulink Support Package

Starting in R2022b, the variant manager functionality in Simulink is available as a support package named Variant Manager for Simulink.

The next sections describe compatibility considerations when using the new Variant Manager functionality.

### Changes to the `Simulink.VariantConfigurationData` class

These class members will be removed in a future release. Scripts that use these class members continue to work with a warning.

To be Removed	Recommended Replacement
DefaultConfiguration property	PreferredConfiguration property
SubModelConfigurations property	The variant configurations for a top-level model must also define the variant control variables used by any referenced components in the model hierarchy.
validateModel method	<code>Simulink.VariantManager.activateModel</code> method
getFor method	<code>Simulink.VariantManager.getConfigurationData</code> method
addSubModelConfigurations method	<code>Simulink.VariantConfigurationData.addComponentConfigurations</code> method
removeSubModelConfiguration method	<code>Simulink.VariantConfigurationData.removeComponentConfiguration</code> method
getDefaultConfiguration method	<code>Simulink.VariantConfigurationData.getPreferredConfiguration</code> method
setDefaultConfigurationName method	<code>Simulink.VariantConfigurationData.setPreferredConfiguration</code> method

- DefaultConfiguration property will be removed. Use the PreferredConfiguration property instead.

Setting a default variant configuration for a variant configuration data object is not recommended. Previously, if you had set a default configuration, compiling or simulating the model automatically activated the default configuration irrespective of the variant control variable values in the base workspace or data dictionary used by the model. Now, this behavior is not applicable and setting the DefaultConfiguration property has no effect.

You can set any of the named configurations defined for a model as the PreferredConfiguration. You can use this property to indicate the configuration that is suited for the model for common workflows. This configuration is not applied automatically when compiling or simulating a model. You must apply the preferred configuration explicitly on the model, if required.

If the variant configuration data object (vcd) for your model has an existing DefaultConfiguration, you can convert it to PreferredConfiguration using this command:

```
vcd.convertDefaultToPreferred(model);
```

You can use this syntax to additionally update the `PostLoadFcn` or `InitFcn` callbacks of the model or both, to activate the preferred configuration on the model:

```
vcd.convertDefaultToPreferred(model, ...
    AddActivateToPostLoadFcn=true,AddActivateToInitFcn=true);
```

To apply the `PreferredConfiguration` on your model before compiling or simulating the model, use this command:

```
Simulink.VariantManager.applyConfiguration ...
(model, 'Configuration',vcd.getPreferredConfigurationName());
```

- `SubModelConfigurations` property will be removed.

The variant configurations for a top-level model must also define the variant control variables used by any referenced components in the model hierarchy, such as referenced models. This approach helps to maintain a single consistent definition for a variant control across the hierarchy.

If the referenced component has named variant configurations of its own, you can use them to set up the corresponding variant control variables in the top-level model configuration. For more information, see “Compose Variant Configurations for Top Model Using Referenced Model Configurations” on page 88-78.

---

**Note** For existing models with an associated variant configuration object, variant control variables in the referenced model configuration will be automatically migrated to the variant configuration of the top-level model. You must save the variant configuration object using `Variant Manager` to fix related warnings.

---

- `validateModel` method will be removed. Use the `Simulink.VariantManager.activateModel` method instead to validate and activate a variant configuration on the model.

Calling the `validateModel` method is equivalent to calling the `activateModel` method, but the `validateModel` method returns a logical value that indicates success or failure, whereas the `activateModel` method throws an error if the activation fails.

- Change in the format of `errors` output argument of `validateModel` method — The fields `Type`, `Source`, `PathInModel`, and `PathInHierarchy` have been removed from the structure named `Errors` within the second output argument, `errors`.

This example shows the fields available in the structure `Errors` for a model named `myModel` with activation errors.

```
[success,errors] = Simulink.VariantConfigurationData.validateModel('myModel')
```

```
success =
```

```
    logical
```

```
    0
```

```
errors =
```

```
    1×2 cell array
```

```

    {1x1 struct}    {1x1 struct}
errors{1}
ans =
    struct with fields:
        Model: 'myModel'
        Errors: {1x16 cell}
errors{1}.Errors{1}
ans =
    struct with fields:
        Message: 'Variant control 'V'=1' used by block 'myModel/Variant Source'
        must return a logical value.
        Caused by: Unrecognized function or variable 'V'.'
        MessageID: 'Simulink:Variants:ErrorInEvalOfVarControl'

```

## Changes to the Simulink.VariantManager class

New Methods	Purpose
Simulink.VariantManager.activateModel	Validate and activate a variant configuration on a model.
Simulink.VariantManager.applyConfiguration	Apply a variant configuration on a model.
Simulink.VariantManager.generateConfigurations	Generate variant configurations for a model automatically
Simulink.VariantManager.getPreferredConfigurationName	Get the name of the preferred variant configuration for a model.
Simulink.VariantManager.getConfigurationData	Get the variant configuration data object for a model.

## Variant Reducer and Variant Analyzer

Variant Reducer and Variant Analyzer no longer require a Simulink Design Verifier license.

## Reduce Model Containing Variant Parameters

This example shows how to reduce a Simulink® model that contains variant parameters using Variant Reducer in Variant Manager. The example explains the reduction process for these scenarios:

a. Reduction of these types of variant parameter objects for a single variant configuration:

- With numeric values
- With values of type `Simulink.Parameter`
- With the **Specification** property set

b. Reduction of variant parameters for multiple variant configurations

Variant parameters enable you to vary the values of block parameters in a Simulink model conditionally. You create a variant parameter as an object of type `Simulink.VariantVariable`. This object defines the set of possible values for a parameter and a variant condition expression associated with each value. After creating the object, you can use it to set the value of block parameters in a model, such as the **Gain** parameter of a **Gain** block. During simulation, the value associated with the variant condition that evaluates to `true` becomes the active value of that parameter. The values associated with the conditions that evaluate to `false` become inactive. For more information, see “Use Variant Parameters to Reuse Block Parameters with Different Values” on page 90-2.

Using Variant Reducer, you can generate a reduced model that retains only the selected variant configurations that you choose from the parent variant model. The tool removes the model components that are inactive in the specified variant configurations and packages the reduced artifacts into a user-specified output folder. In the case of variant parameters, the reduction process retains only the specified values from the `Simulink.VariantVariable` objects and removes the remaining inactive choices based on the input configurations that you specify.

For more information on Variant Reducer, see “Reduce Variant Models Using Variant Reducer” on page 88-32.

### Explore Model

1. Open the model `slexVariantParameters`.

```
open_system('slexVariantParameters');
```

## Variant Parameters with Different Activation Times

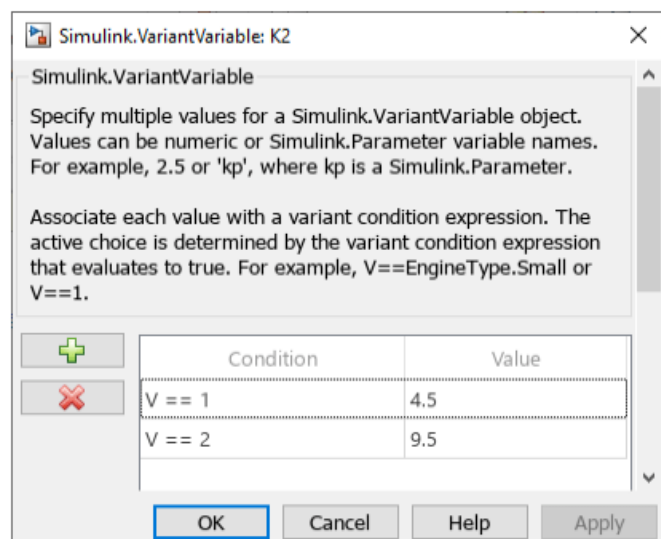

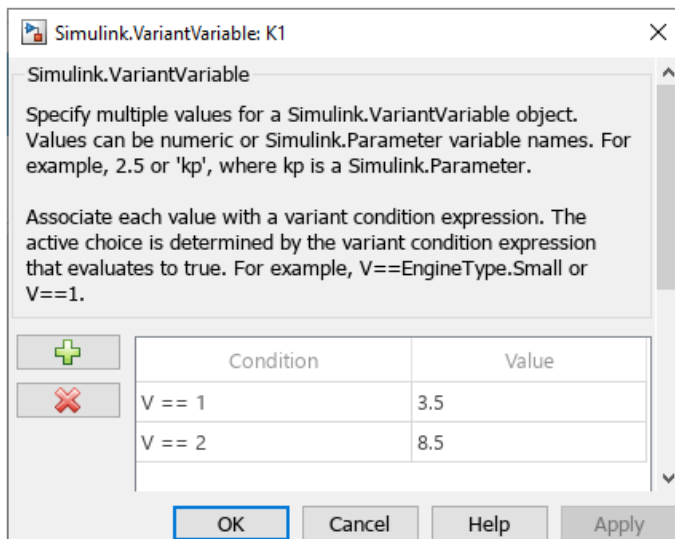

Copyright 2020-2021 The MathWorks, Inc.

The model contains two Gain blocks. The **Gain** parameters of the blocks are set to the variant parameter objects K1 and K2.

2. Open the `slexVariantParameterData.m` file to see the definitions of objects used by this model.

- K1 and K2 are defined as objects of type `Simulink.VariantVariable`. Both K1 and K2 have two choices. The choices have numeric double values and a variant condition expression associated with each value.
- The variant condition is defined using a `Simulink.VariantControl` object, V, with value set to 1. During simulation, the value of V determines the active value of the variant parameter objects K1 and K2.
- The objects get created in the base workspace of the model during model load.
- Double-click on K1 and K2 in the MATLAB® workspace to view their possible values.

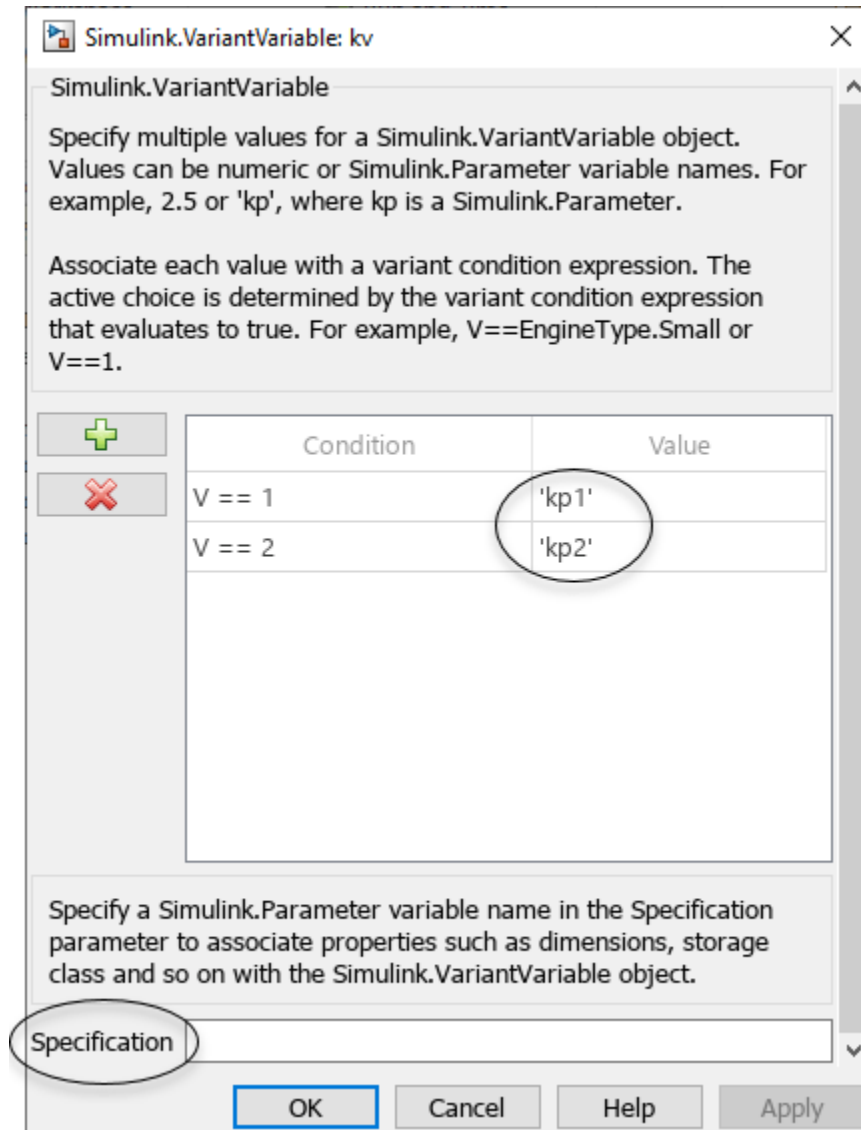

This example additionally refers to these type of variant parameters that are not present in the `slexVariantParameters` model:

- Variant parameters that have `Simulink.Parameter` objects as choice values
- Variant parameters with an associated **Specification**, which helps you to set properties of the object such as data type, dimensions and storage class.

For example, this variant parameter has the values `kp1` and `kp2`, which are names of `Simulink.Parameter` objects.

### Open Variant Reducer

1. Open Variant Manager. On the **Modeling** tab, open the **Design** section and click Variant Manager.
2. To open Variant Reducer, in the Variant Manager toolstrip, in the **Apps** section, click **Variant Reducer**.

### Choose Reduction Mode

The **Reduction mode** option in Variant Reducer provides multiple ways to specify the configurations that you want to retain in the reduced model. You can select single or multiple named variant configurations created for the model, or you can directly specify the required variant control variables and their values by defining variable groups.

- When you reduce a variant parameter object for a single configuration, you specify only a single choice of the object that must be retained in the reduced model. The reduced object will have only one value without any variant capability. So, based on the type of value the variant parameter object has, the reduction process converts it into a normal MATLAB® variable with a numeric value or into a `Simulink.Parameter` object.

Condition	Value
V == 1	3.5
V == 2	8.5

Retain only this value in the reduced model

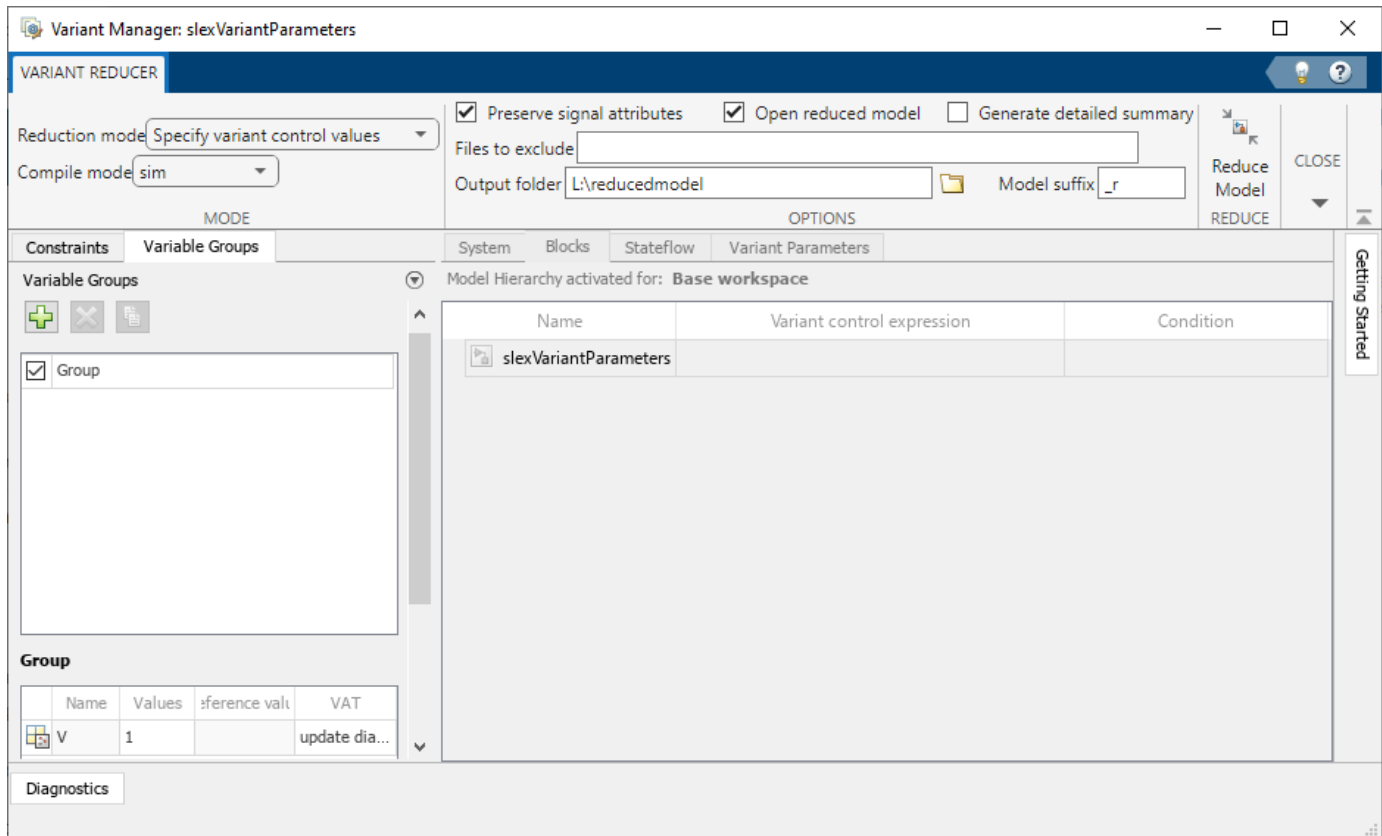

- When you reduce a variant parameter object for multiple configurations, the reduction process retains the configurations that you specify in the reduced model. The process does not convert the `Simulink.VariantVariable` object to any other type.

Condition	Value
V == 1	3.5
V == 2	8.5
V == 3	10.5

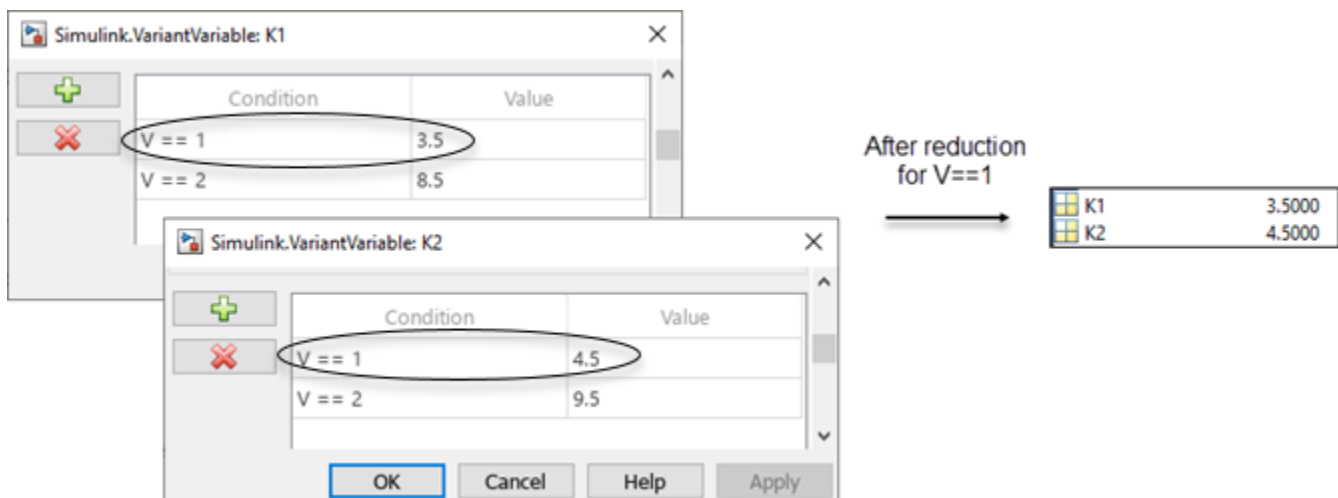

Retain both these choices in the reduced model

### Reduce Model for Single Variant Configuration

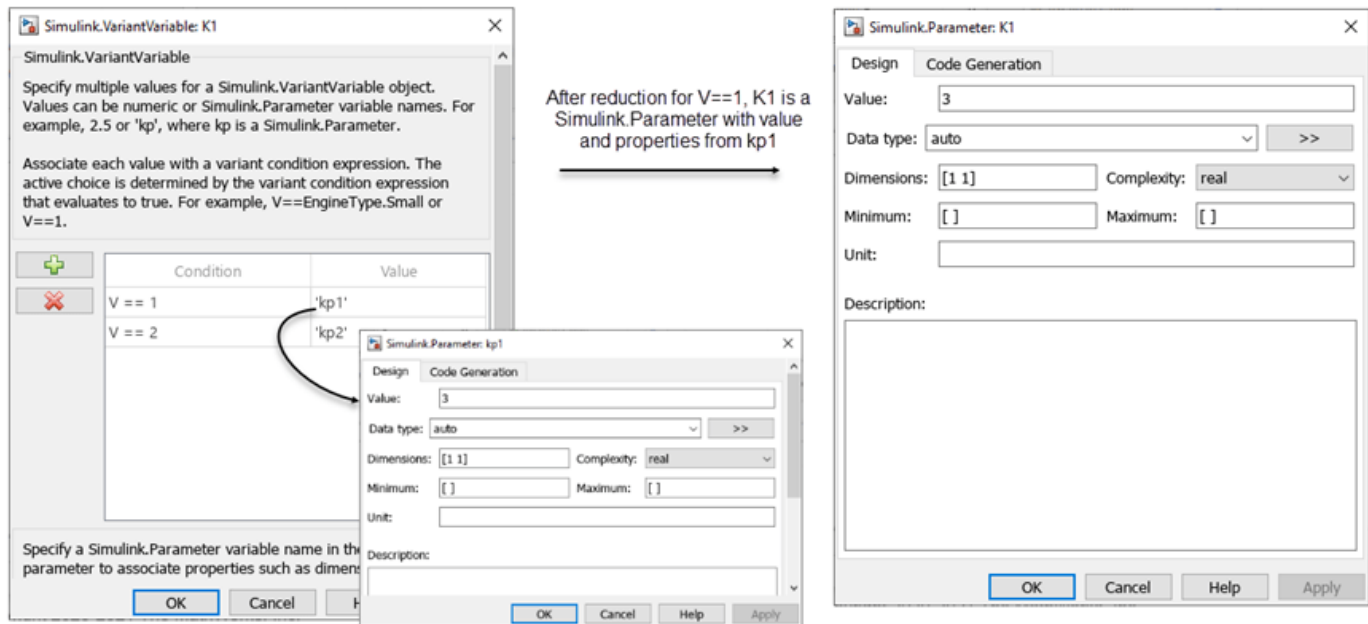

In the Variant Reducer window for the example model, the **Variable Groups** tab opens by default because there are no named configurations defined for the model. The **Group** table shows the current value of the variant control V as 1. In the example, choices of K1 and K2 have numeric double values.

1. Specify the values for different reduction options as needed in the **Options** section of the toolbar.
2. Click **Reduce Model**. Variant Reducer reduces the model for the condition  $V==1$ .
3. Observe the objects K1 and K2 in the base workspace. You can see that K1 and K2 are converted to normal MATLAB variables of type `double`, with values corresponding to the condition  $V==1$ .

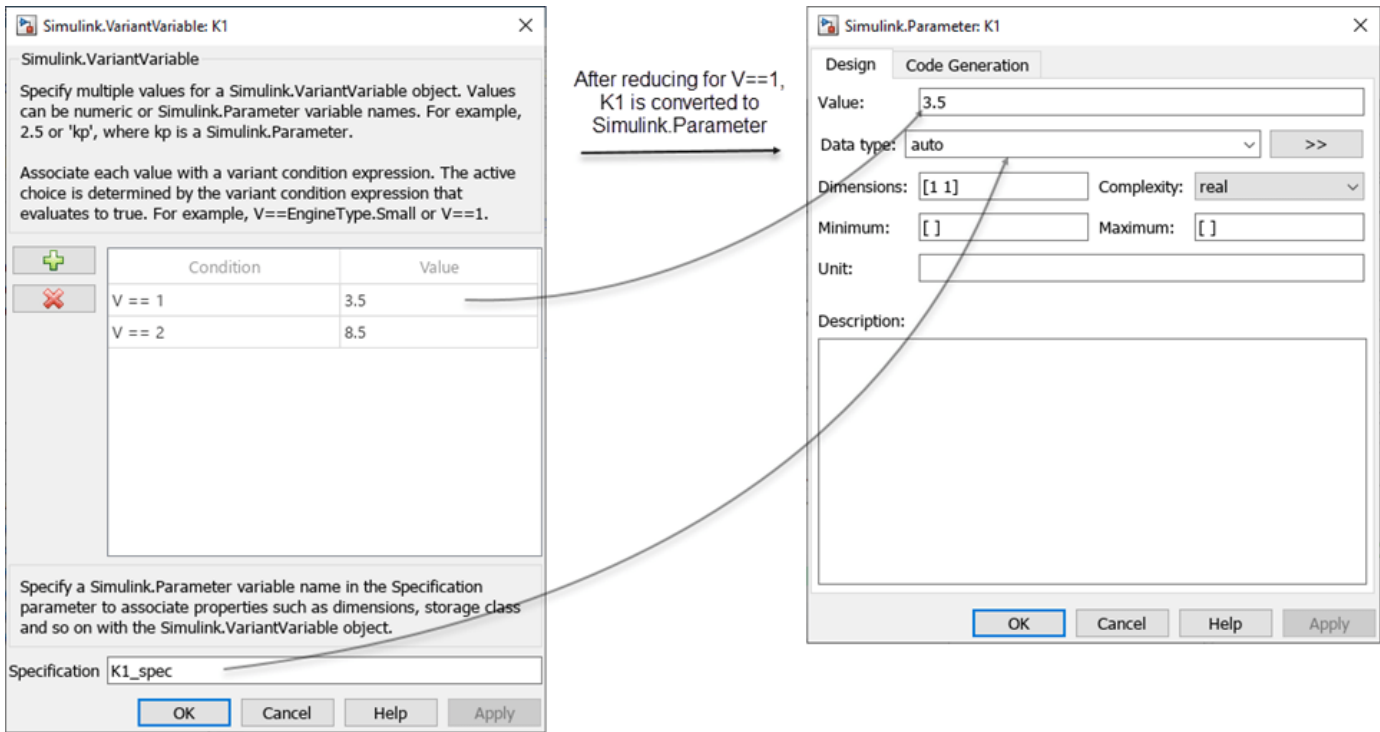

Instead, if the choice value of the variant parameter is a `Simulink.Parameter` object, then after reduction the variant parameter object is converted into a `Simulink.Parameter` object with values and properties based on the selected choice.

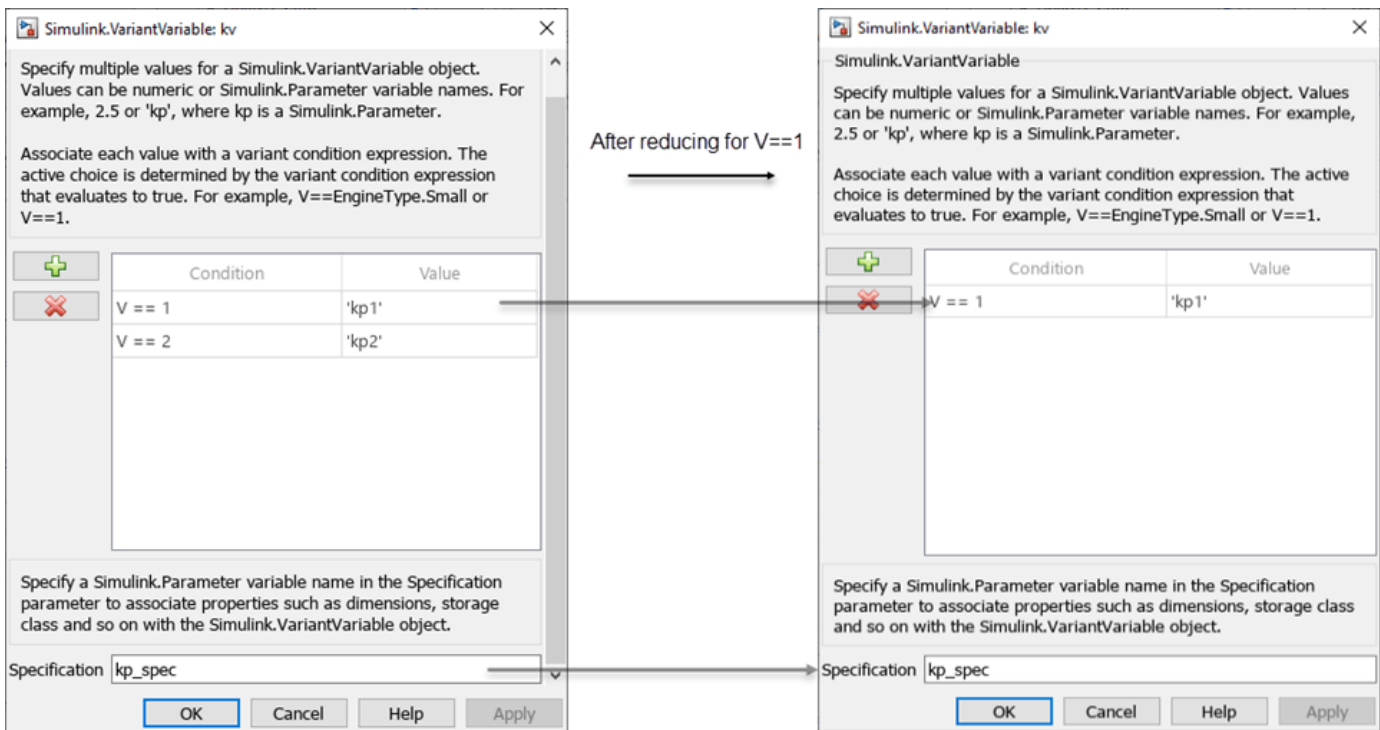

### Variant Parameter Object with Specification

If the variant parameter object has the **Specification** property set, then these changes apply for single configuration reduction:

- A variant parameter object with a numeric choice value is converted into a `Simulink.Parameter` object that has a value based on the selected configuration and remaining properties derived from the **Specification** property of the variant parameter object.

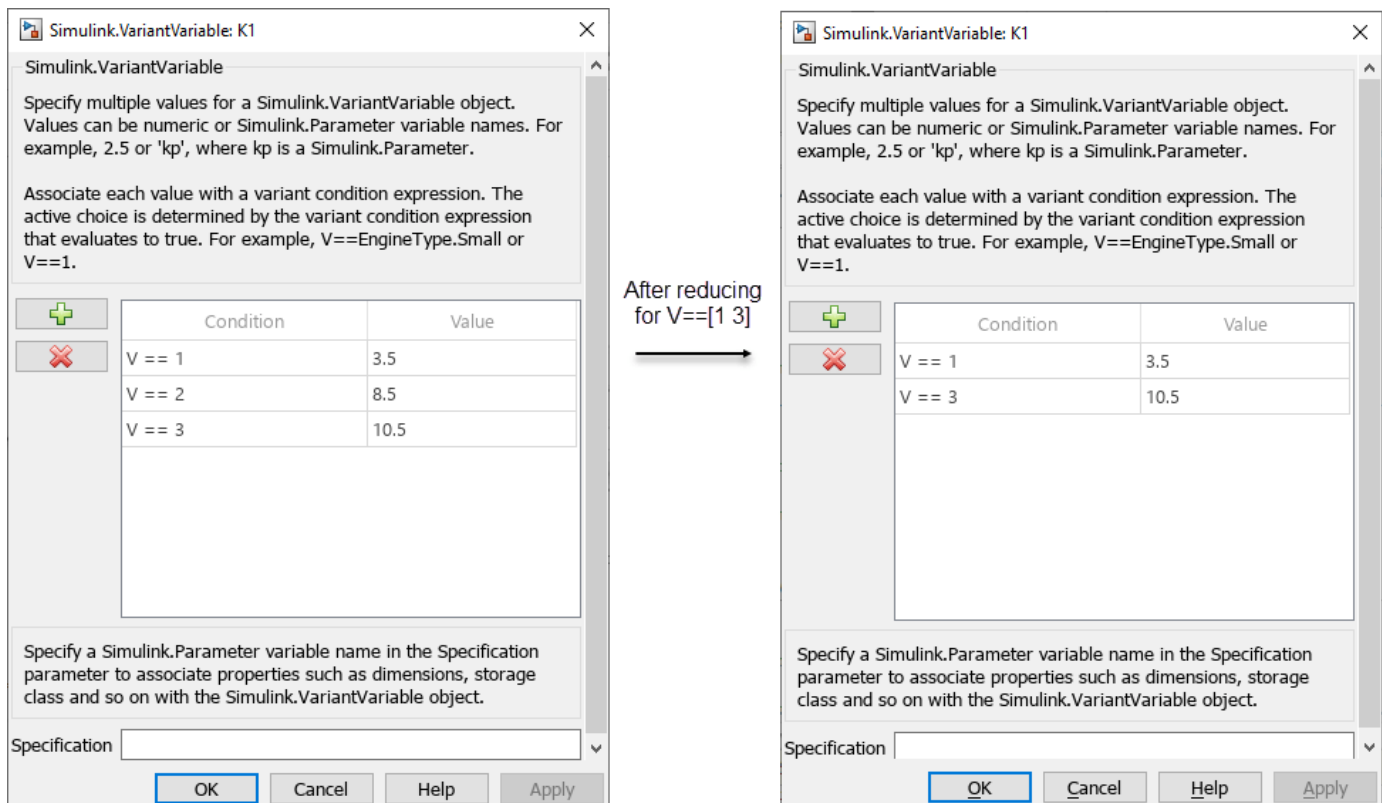

- A variant parameter object with choice value set to a Simulink.Parameter object is not converted to any other type. It remains of type Simulink.VariantVariable and retains the selected configuration and **Specification**.

## Reduce Model for Multiple Configurations

Close the reduced model and open the `slexVariantParameters` model again.

1. In the base workspace, double-click the variant parameter object K1. In the `Simulink.VariantVariable` dialog box, add one more choice to K1 with **Condition** as `V==3` and **Value** as `10.5`. Repeat this step for K2.
2. Open Variant Reducer for the model.
3. In the **Variable Groups** tab, specify the value for V as `[1 3]`.
4. Click **Reduce Model**. Variant Reducer reduces the model for the conditions `V==1` and `V==3`.
5. Observe the objects K1 and K2 in the base workspace. You can see that they are variant parameter objects with two choices corresponding to `V==1` and `V==3`.

## Reduce Model Programmatically

- Reduce the model programmatically for the single configuration specified by the condition `V==1`.

```
Simulink.VariantManager.reduceModel('slexVariantParameters', 'VariableGroups', {'V', 1});
```

- Reduce the model for multiple configurations specified by the conditions `V==1` and `V==3`.

```
Simulink.VariantManager.reduceModel('slexVariantParameters', 'VariableGroups', {'V', 1}, {'V', 3});
```

- Reduce the model by specifying a named variant configuration that is present in the variant configuration data object associated with the model.

```
Simulink.VariantManager.reduceModel('slexVariantParameters','NamedConfigurations',{'vpConfig1'},
'OutputFolder','L:\reducedModel')
```

### Summary of Variant Parameter Reduction

In a single configuration reduction, variant parameters convert as follows:

a. Without a **Specification**:

- A variant parameter with numeric choice values converts to a normal MATLAB variable of same data type.
- A variant parameter with `Simulink.Parameter` objects as choice values converts to `Simulink.Parameter` object with values and properties based on the selected configuration.

b. With a **Specification**:

- A variant parameter with numeric choice values converts to a `Simulink.Parameter` object that has values based on the selected configuration and remaining properties derived from the **Specification** property of the variant parameter object.
- A variant parameter with `Simulink.Parameter` objects as choice values remains as a variant parameter object with the same **Specification** and `Simulink.Parameter` objects as values, based on the selected configuration.

In a multiple configuration reduction, the model retains the variant parameter object with the selected configurations and **Specification**, if available.

**NOTE:** Specifying the value of a variant control variable as `full-range` during reduction is not supported if the variable is used by variant parameters visible to the model, even if the parameter is not used in the model hierarchy.

## Compose Variant Configurations for Top Model Using Referenced Model Configurations

A variant configuration represents a combination of variant choices across a Simulink model hierarchy. It contains a set of variant control variables and their values, which can be used to activate a specific variation in the model hierarchy. Variant Manager allows you to create and manage the variant configurations for a model.

In Variant Manager, a variant configuration for a top-level model must also define the variant control variables used by any referenced components in the model hierarchy, such as referenced models. This approach helps to maintain a single consistent definition for a variant control across the hierarchy.

You can either directly add the variant control variables used by a referenced component to the top-level model configuration or if the referenced component has named variant configurations of its own, you can use them to set up the control variables in the top-level configuration. This topic explains how to use the **Component Configurations** view in Variant Manager to select the referenced component configurations to be used for the initialization.

To add or remove component configurations programmatically, use the `addComponentConfiguration` and `removeComponentConfiguration` methods.

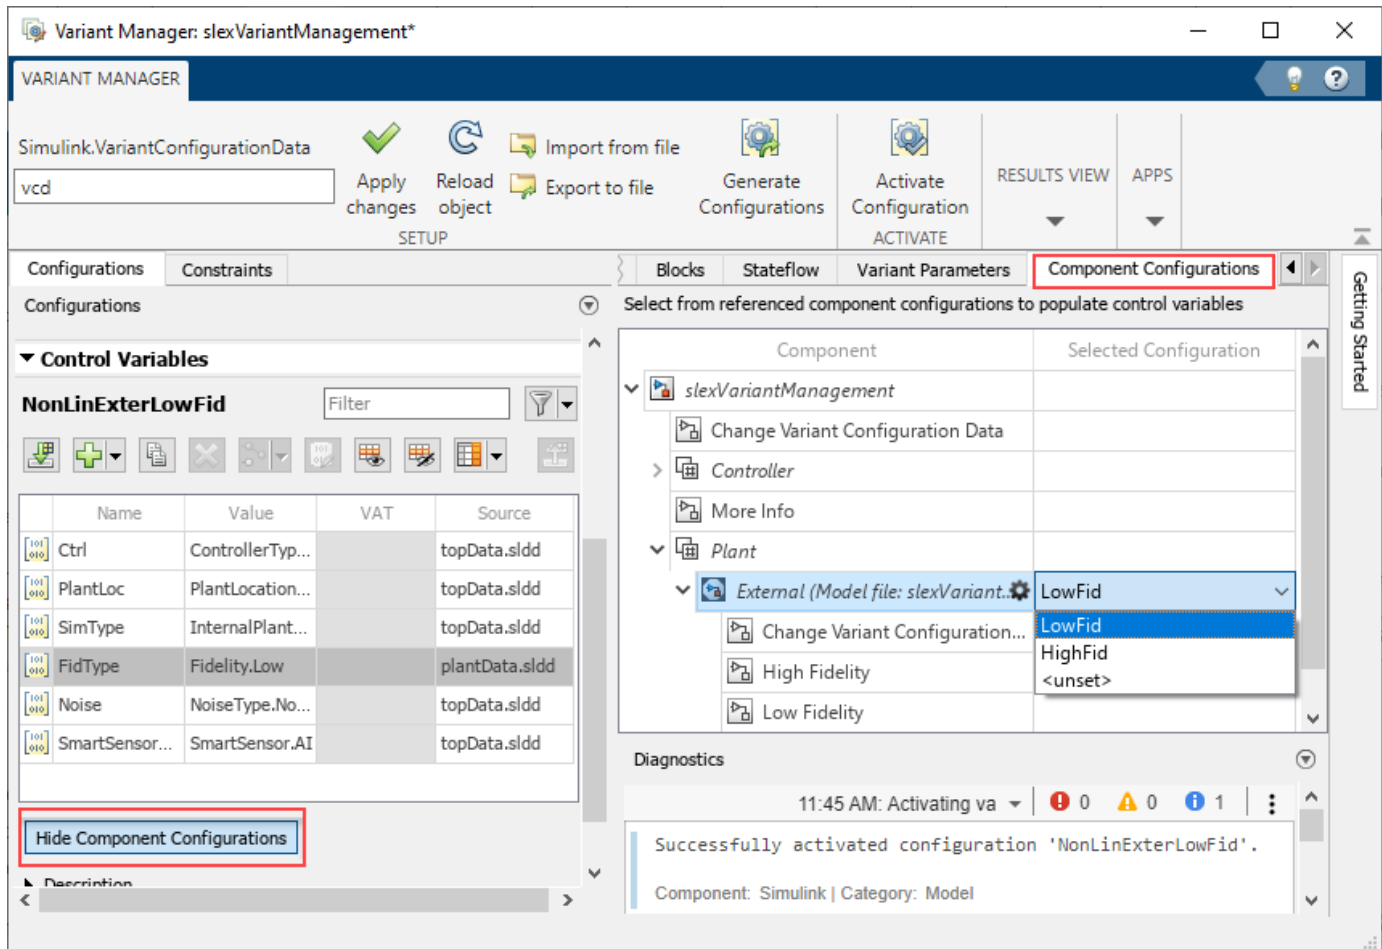

### Open Component Configurations View

To open the **Component Configurations** view for a top-level model configuration:

- 1 Open Variant Manager for the top-level model. On the **Modeling** tab, open the **Design** section and click **Variant Manager**.
- 2 Click the required configuration in the **Configurations** tab.
- 3 In the **Control Variables** section for the selected variant configuration, click **Show Component Configurations**. This action opens the **Component Configurations** view as a tab in the model hierarchy pane.

This image shows the **Component Configurations** tab for the `slexVariantManagement` model.

## Select Variant Configuration for Referenced Component

- Expand the model hierarchy in the **Component Configurations** tab.
- Locate the required referenced component in the **Component** column of the hierarchy.

The **Selected Configuration** field for the component is set to **unset** by default. With this setting, you can directly add the control variables required by the component in the **Control Variables** table of the top-level configuration and update them with any valid custom value.

- To use an existing named configuration, select it from the list in the **Selected Configuration** column. This action adds the control variables present in that configuration to the top-level model configuration.

**Note** In the **Control Variables** table of a top-level variant configuration, the control variables that are populated using a referenced component configuration are read-only and appear with a grey background color.

- To close the tab, click **Hide Component Configurations** in the **Control Variables** section.
- After selecting component configurations, you can use any of these options in the **Manage** tab to save or revert your changes:

- To apply the changes to the base workspace or data dictionary of the model, click **Apply changes**.
- To reload the variant configuration object from the base workspace or data dictionary used by the model, click **Reload object**. This allows you to revert the changes that are not yet exported to these storage locations.
- To permanently save the changes in the variant configuration data object to a file, click **Export to file**.

---

**Tip** A  icon next to a component in the **Component** column indicates that it has predefined variant configurations.

---

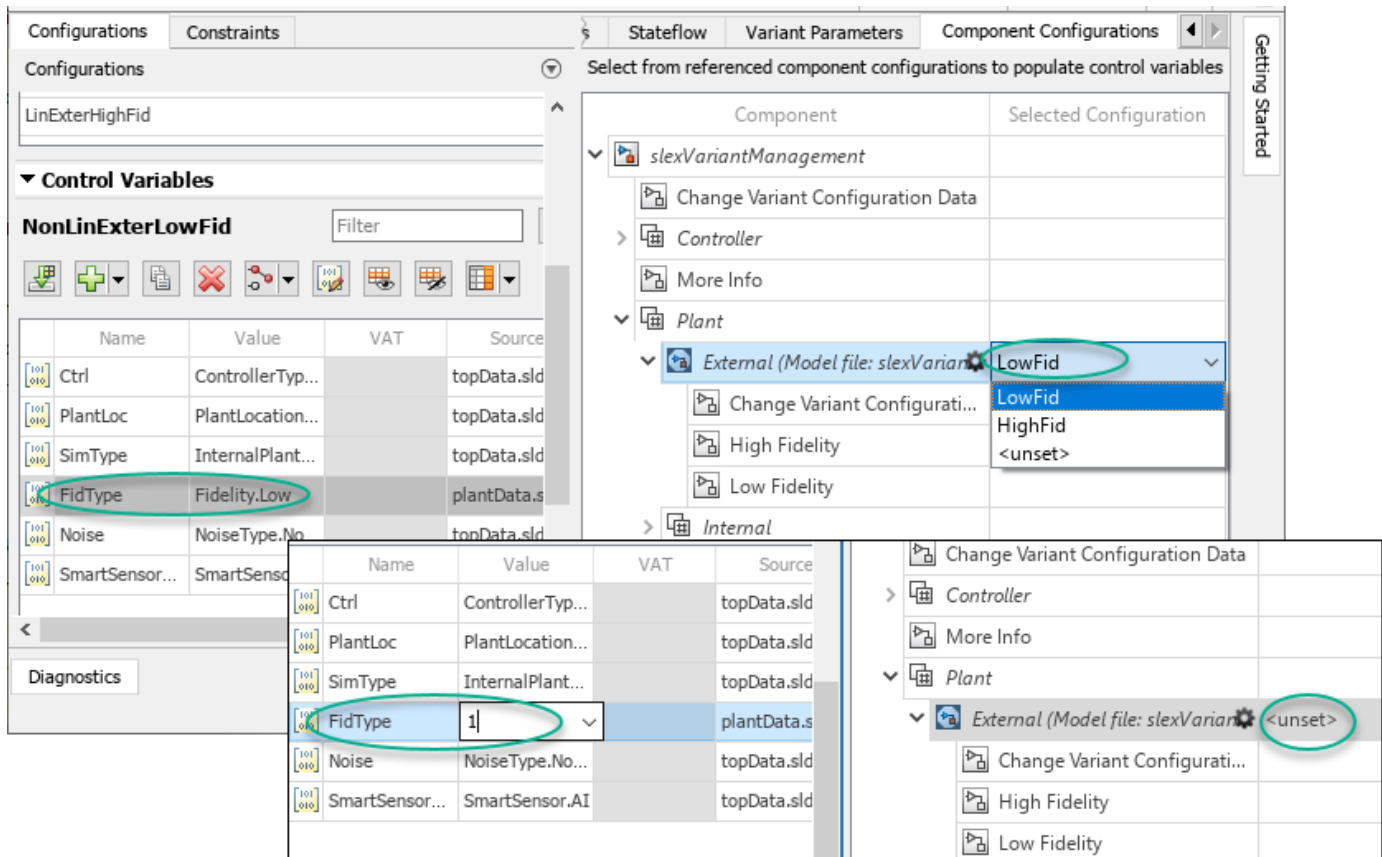

## Clear Selected Variant Configuration

You can unset the variant configuration that you specified for a referenced component from the **Component Configurations** tab. This action does not remove the control variables added to the top-level configuration previously.

To unset the variant configuration for a referenced component, in the **Component Configurations** tab, in the **Selected Configuration** column, select **unset**. In the **Control Variables** table, the control variables populated from this configuration become editable.

## Component Configurations View Example

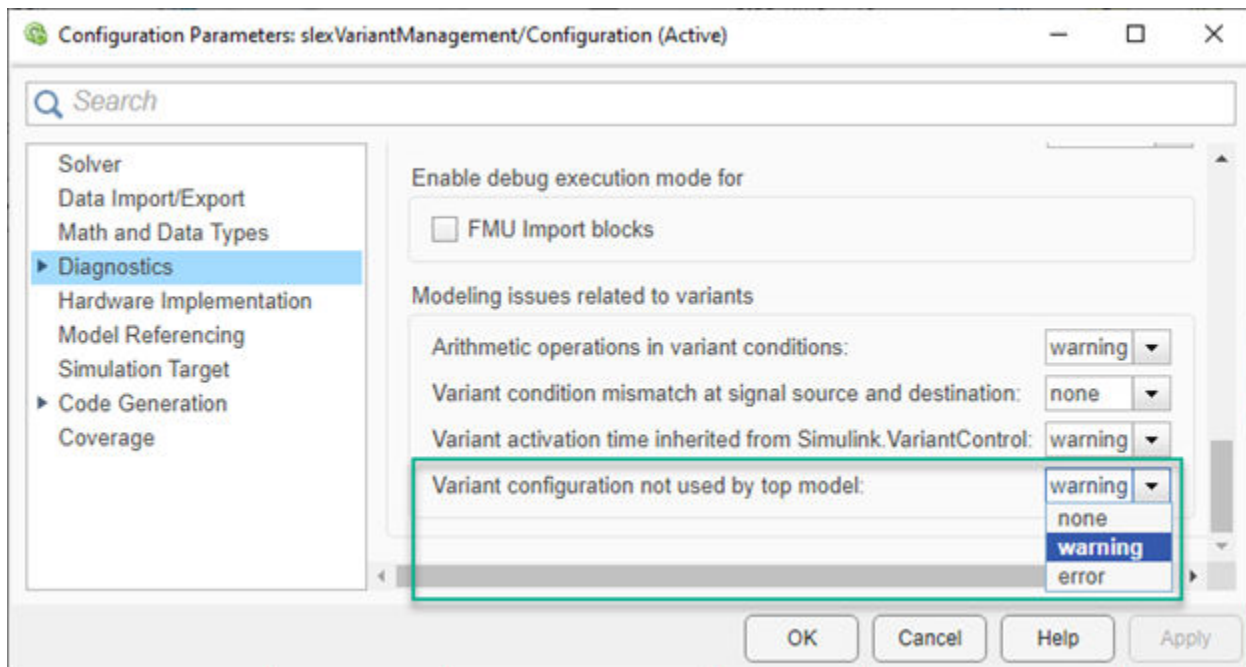

In this example, the External Plant component has two predefined configurations, HighFid and LowFid. Selecting one of them adds or updates the corresponding control variable, FidType, in the top-level model configuration, NonLinExterLowFid. Selecting **unset** allows you to provide custom values.

## Validate That Top-Level Model Uses Referenced Component Configuration

For a referenced model that has predefined variant configurations of its own, you can detect when a top-level model does not use one of these configurations to set up its own variant configurations. You can use the model configuration parameter **Variant configuration not used by top model** for a referenced model to specify the diagnostic action to take for such a scenario. This setting helps you to verify that the referenced model is used only for its tested variant configurations.

- 1 To open the Configuration Parameters dialog box, in the Simulink Editor, on the **Modeling** tab, click **Model Settings** .
- 2 Click the **Diagnostics** pane in the tree on the left side of the dialog box.
- 3 Point to the ellipsis toward the bottom of the dialog box and click **Advanced parameters**.
- 4 In the **Modeling issues related to variants** section, select the required option for the **Variant configuration not used by top model** parameter.

## See Also

### More About

- “Variant Configurations” on page 88-2
- “Create and Activate Variant Configurations” on page 88-10
- “Variant Manager for Simulink”

## Validate and Activate Variant Configurations

This example shows how to validate and activate a variant configuration programmatically.

To activate a variant configuration from Variant Manager, see “Create and Activate Variant Configurations” on page 88-10.

Open the model `slexVariantManagement`.

```
open_system('slexVariantManagement');
```

Activate and validate the model using the variant control variables and their values currently present in the base workspace or data dictionary used by the model.

```
Simulink.VariantManager.activateModel('slexVariantManagement')
```

Activate and validate the model using the variant configuration `LinInterExpNoNoise`.

```
Simulink.VariantManager.activateModel ...  
('slexVariantManagement', Configuration = "LinInterExpNoNoise")
```

## Analyze Variant Configurations Programmatically

This example shows how to use the `Simulink.VariantConfigurationAnalysis` class to analyze variant configurations programmatically.

To analyze variant configurations using Variant Manager, see “Analyze Variant Configurations in Models Containing Variant Blocks” on page 88-44.

Open the model `slexVariantConfigurationAnalysis`.

```
open_system('slexVariantConfigurationAnalysis');
```

You can provide either a list of named variant configurations or the variable groups to analyze to the `Simulink.VariantConfigurationAnalysis` class. The operation returns a variant configuration analysis object for the model.

```
varConfigObjNamedConfig = Simulink.VariantConfigurationAnalysis('slexVariantConfigurationAnalysis',  
    'NamedConfigurations', {'VendorACtrlLinear', ...  
    'VendorACtrlNonLinear', 'VendorACtrlFuzzy'})
```

```
varConfigObjNamedConfig =  
    VariantConfigurationAnalysis with properties:
```

```
    ModelName: 'slexVariantConfigurationAnalysis'  
    Configurations: {'VendorACtrlFuzzy' 'VendorACtrlLinear' 'VendorACtrlNonLinear'}
```

```
varConfigObjVarGroup = Simulink.VariantConfigurationAnalysis('slexVariantConfigurationAnalysis',  
    'VariableGroups', [struct('Name', 'VendorANonLinear', ...  
    'VariantControls', {'CONTROLLER', 1, 'EXTERNAL_SENSOR', 1, 'ORDER', 1,  
    struct('Name', 'VendorALinear', ...  
    'VariantControls', {'CONTROLLER', 0, 'EXTERNAL_SENSOR', 1, 'ORDER', 1,
```

You can use the variant configuration analysis object to analyze the variant configurations using different methods specified in the following steps.

Get the list of active blocks in the variant configuration `VendorACtrlLinear`.

```
activeblocks = varConfigObjNamedConfig.getActiveBlocks('VendorACtrlLinear');
```

Get the list of blocks that are always active across all the named variant configurations that have been analyzed.

```
alwaysActiveBlocks = varConfigObjNamedConfig.getAlwaysActiveBlocks();
```

Get the list of blocks that are active in some of the analyzed variant configurations and inactive in other configurations.

```
getBlockDifferences = varConfigObjNamedConfig.getBlockDifferences();
```

Get the list of dependent libraries for a variant configuration.

```
dependentLibraries = varConfigObjNamedConfig.getDependentLibraries('VendorACtrlNonLinear');
```

Get the list of dependent models for a variant configuration.

```
dependentModels = varConfigObjNamedConfig.getDependentModels('VendorACtrlFuzzy');
```

Get the list of blocks that are inactive in all the named variant configurations that have been analyzed.

```
neverActiveBlocks = varConfigObjNamedConfig.getNeverActiveBlocks();
```

Get the variant condition on a block in a named variant configuration.

```
variantCondition = varConfigObjNamedConfig.getVariantCondition('VendorACtrlNonLinear', ...  
'slexVariantConfigurationAnalysis/Controller/NonLinear');
```

Show the variant configuration analysis report for a model after analyzing it.

```
varConfigObjNamedConfig.showUI();
```

Hide the variant configuration analysis report for a model after analyzing it.

```
varConfigObjNamedConfig.hideUI();
```

## Generate Variant Configurations Programmatically

This example shows how to generate variant configurations for a model programmatically.

To generate variant configurations from Variant Manager, see “Generate Variant Configurations Automatically” on page 88-23.

This command returns valid variant configurations for the model `slexVariantManagement` that satisfy the conditions specified on the variant control variables `Ctrl` and `PlantLoc`.

```
model = "slexVariantManagement";
open_system(model);
[vcdataobj,configsInfo] = Simulink.VariantManager.generateConfigurations ...
(model, Precondition = {'Ctrl == ControllerType.Linear', 'PlantLoc == PlantLocation.Internal'}, ...
AddPreconditionAsConstraint = true, Validity = "valid");
```

Activating the model for the current state of the model.

An update diagram operation is required to generate variant configurations.

Performing update diagram for the model.

Evaluating 96 potential combinations to generate...

Number of generated configurations: 16

Created snapshot of the model at 'C:\TEMP\Bdoc23a\_2213998\_3568\ib570499\23\tp4d276709\simulink\_v...

The variant configuration data object `vcdataobj` stores all the valid configurations. The structure array `configsInfo` provides information on the validity status of generated configurations.

To return only valid and functionally unique configurations, set `Validity` to `valid-unique`.

```
[vcdataobj,configsInfo] = Simulink.VariantManager.generateConfigurations(model,...
Precondition = {'Ctrl == ControllerType.Linear', 'PlantLoc == PlantLocation.Internal'}, ...
AddPreconditionAsConstraint = true, Validity = "valid-unique");
```

Activating the model for the current state of the model.

An update diagram operation is required to generate variant configurations.

Performing update diagram for the model.

Evaluating 96 potential combinations to generate...

Number of generated configurations: 3

Created snapshot of the model at 'C:\TEMP\Bdoc23a\_2213998\_3568\ib570499\23\tp4d276709\simulink\_v...

To return all generated configurations, including invalid configurations, set `Validity` to `all`.

```
[vcdataobj,configsInfo] = Simulink.VariantManager.generateConfigurations(model,...
Precondition = {'Ctrl == ControllerType.Linear', 'PlantLoc == PlantLocation.Internal'}, ...
AddPreconditionAsConstraint = true, Validity = "all");
```

Activating the model for the current state of the model.

An update diagram operation is required to generate variant configurations.

Performing update diagram for the model.

Evaluating 96 potential combinations to generate...

Number of generated configurations: 16

Created snapshot of the model at 'C:\TEMP\Bdoc23a\_2213998\_3568\ib570499\23\tp4d276709\simulink\_v...

## Find Variant Control Variables for Model

This example shows how to find the variant control variables used in a model.

Open the model `slexVariantManagement`.

```
model = 'slexVariantManagement';  
open_system(model);
```

Find the variant control variables.

```
vars = Simulink.VariantManager.findVariantControlVars(model)
```

```
vars=6x1 struct array with fields:
```

```
    Name  
    Value  
    Exists  
    Source  
    SourceType
```

## Reduce Models Containing Referenced Subsystems

This example shows how to reduce a Simulink® model that contains Subsystem Reference blocks.

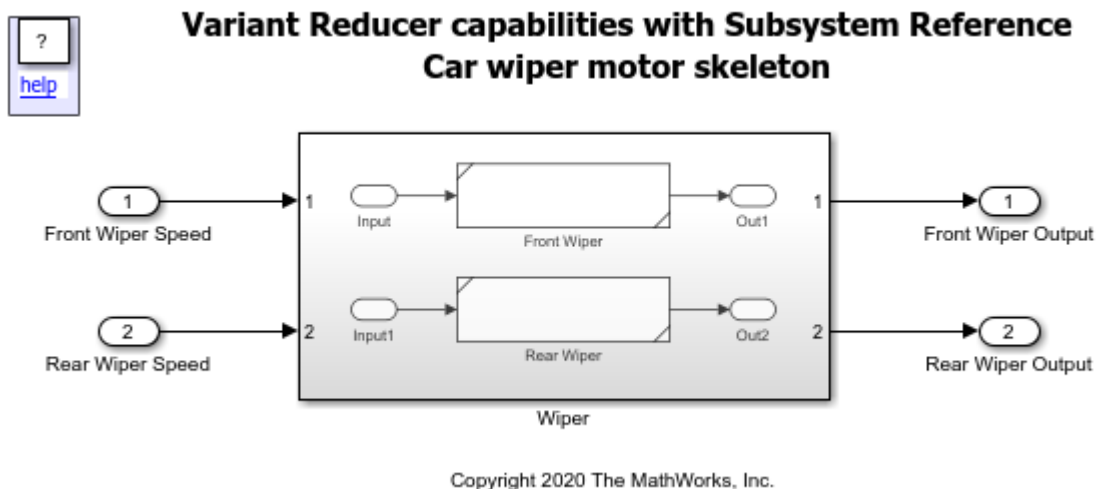

Subsystem reference allows you to save the contents of a subsystem in a separate file and reference it using a Subsystem Reference block. You can create multiple instances referencing the same subsystem file. For more information, see “Subsystem Reference” on page 4-26.

Using Variant Reducer, you can generate a reduced model that retains only the selected variant configurations that you choose from the parent variant model. For more information on Variant Reducer, see “Reduce Variant Models Using Variant Reducer” on page 88-32.

### Explore Example Model

Open the model `slexVariantReducerWiper`.

```
open_system("slexVariantReducerWiper");
```

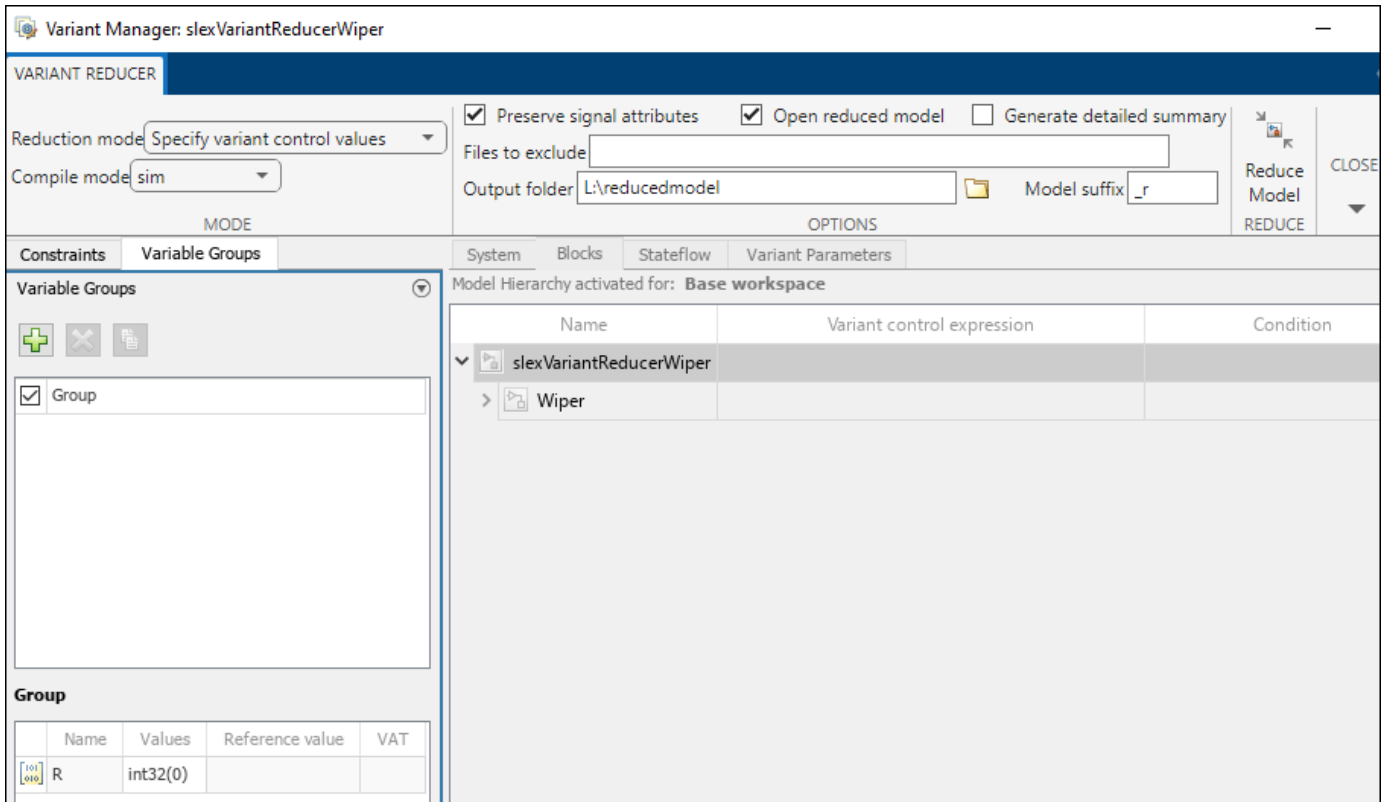

This car windshield wiper model uses subsystem reference to implement the front and rear wipers of a car. The `Wiper` subsystem contains two Subsystem Reference blocks named `Front Wiper` and `Rear Wiper`. Both of these blocks refer to the same subsystem block diagram `slexVariantWiperSubsysRef.slx`.

The referenced subsystem contains the logic to control the speed of the car's windshield wiper by using different rain sensors. The `Rain Sensor Variant Source` block in this model switches between a manual wiper and different variants of automatic rain sensors based on the variant control variable `R`. When the value of `R` is not equal to 1 or 2, the `Manual Wiper Setting` block becomes active and is used as the input to the `Controller`. When `R` is 1, the `Rain Sensor Model 1` block is the active input. When `R` is 2, `Rain Sensor Model 2` is active. To view the definition of `R`, see the `PostLoadFcn` callback of the model. For simulation workflows, the default value of `R` is set to 0, which activates the manual wiper setting.

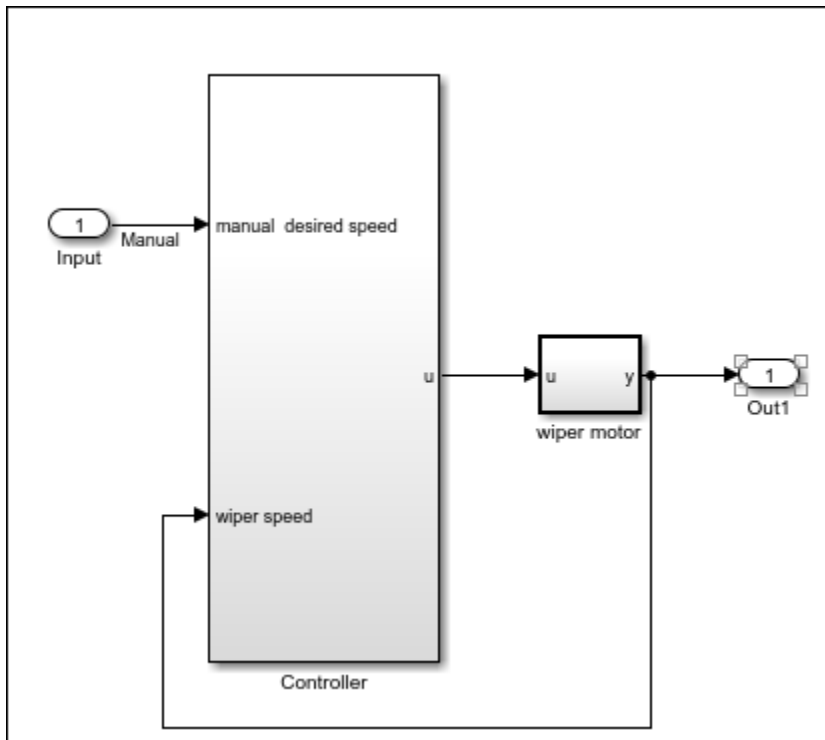

## Open Variant Reducer

1. Open Variant Manager. On the **Modeling** tab, open the **Design** section and click **Variant Manager**.
2. To open Variant Reducer, in the Variant Manager toolstrip, in the **Apps** section, click **Variant Reducer**.

## Reduce the Model

1. You can modify the reduction settings in the **Mode** and **Options** section of the Variant Reducer toolstrip as needed. If you do not modify the settings, Variant Reducer uses default values for reduction.
2. **Reduction Mode** is set to **Specify variant control values** because the model does not have any predefined variant configurations. Since the value of R is set to 0 in the **PostLoadFcn** callback function, that value is picked up for reduction. You can change the value of R to change the configuration that must be retained in the reduced model.
3. Click **Reduce Model**. Variant Reducer reduces the top-level model and the referenced subsystem for the variant configuration corresponding to  $R=0$ . The manual wiper setting is retained in the reduced models. The reduced models are named `slxVariantReducerWiper_r.slx` and `slxVariantWiperSubsysRef_r.slx` by default. This image shows the reduced referenced subsystem model.

For more information on Variant Reducer, see “Reduce Variant Models Using Variant Reducer” on page 88-32.

# Integrate Python Code With Simulink

---

- “Overview of Integrating Python Code with Simulink” on page 89-2
- “Import Python Code to Simulink Using Python Importer Wizard” on page 89-6

## Overview of Integrating Python Code with Simulink

This topic provides an overview of integrating Python® code with Simulink. You can set up your system to use Python with Simulink and use the MATLAB Function block or the MATLAB System block to integrate Python code with Simulink.

### Configure System to Use Python

To call Python modules in MATLAB, you must have a compatible version of Python installed. For more information on supported Python versions and setting up your system to use Python in MATLAB, see “Configure Your System to Use Python”.

You can access all standard Python libraries, third-party functionality, or user-created modules from MATLAB. For more information on using Python in MATLAB, see “Access Python Modules from MATLAB - Getting Started”.

### Integrate Python Code with Simulink Using MATLAB Function Block

Use the MATLAB Function block to integrate your simple Python code with Simulink. Call Python modules in the MATLAB Function block using `py.` as prefix for the Python function or class name.

This code implements a MATLAB Function that calculates the Euler formula for complex numbers for the provided input, using `py.math.cos` and `py.math.sin`.

```
function [re, img, num] = euler(x)

% Declare py.math.cos and py.math.sin as extrinsic functions
coder.extrinsic('py.math.cos', 'py.math.sin');

% Preallocate outputs
re = double(0);
img = double(0);

re = py.math.cos(x);
img = py.math.sin(x);

num = re + 1j*img;

end
```

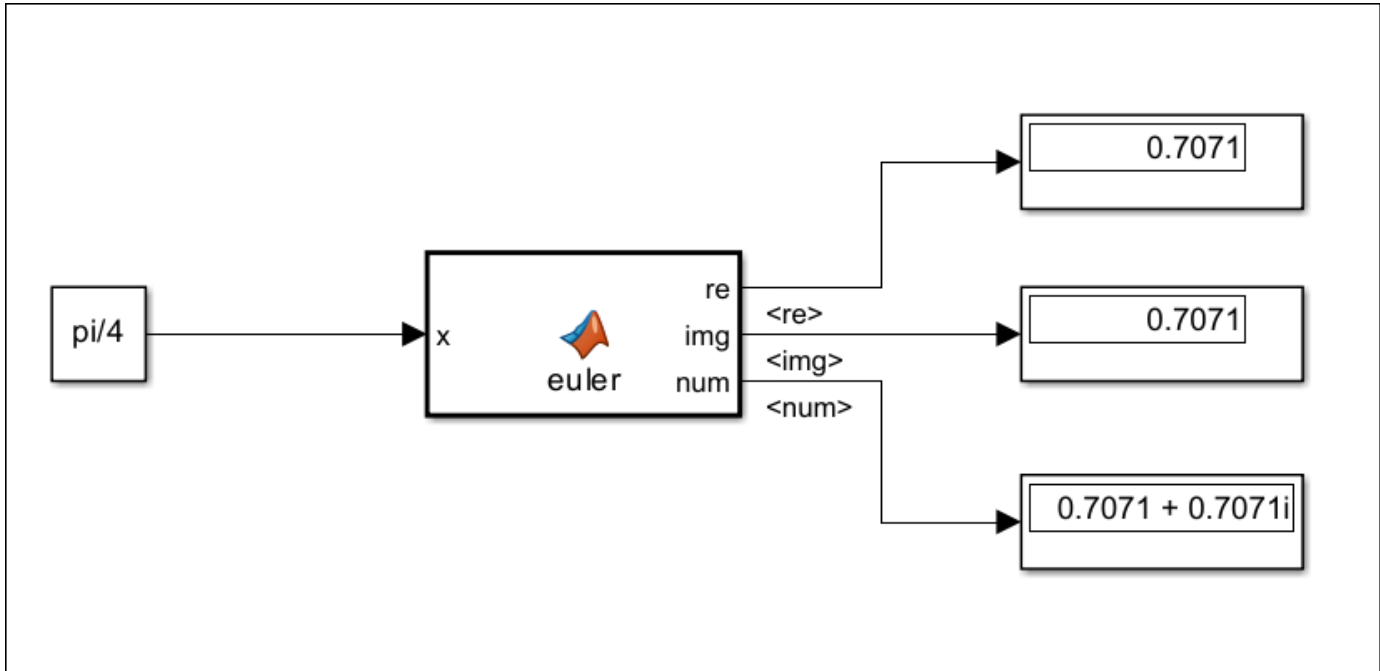

- Python modules are not supported for code generation and require the MATLAB engine for execution. You can exclude Python calls from code generation and use the MATLAB engine for execution by declaring it as an extrinsic function using `coder.extrinsic` function. This code declares `py.math.cos` and `py.math.sin` as extrinsic functions.

```
coder.extrinsic('py.math.cos', 'py.math.sin');
```

- The output that an extrinsic function returns at runtime is an `mxAarray`, also known as MATLAB array. The valid operations for a MATLAB array are limited to storing it in a variable, passing it to another extrinsic function, or returning it to MATLAB. To perform any other operation on an `mxAarray` value, such as using it in an expression in your code, you must convert the `mxAarray` to a known type at run time. To perform this action, assign the `mxAarray` to a variable whose type is already defined by a prior assignment. For more details on preallocating `mxAarray`, see “Return Output of Extrinsic Function to MATLAB at Run Time”. This code preallocates the datatype of the real and imaginary part of the number as a `double`.

```
re = double(0);
img = double(0);
```

Implement the MATLAB Function in Simulink to calculate the Euler formula for an input.

## Integrate Python Code with Simulink Using MATLAB System Block

You can use the MATLAB System block to integrate Python code with Simulink. Use this block when the algorithm requires handling of state dynamics, streaming data, or additional block customizations. You can call Python modules using `py.` as a prefix for the Python function or class name. A Python function call within the MATLAB System block does not need to be declared as an extrinsic function. Change the **Simulate Using** block parameter to **Interpreted Execution**.

This code implements a MATLAB System object that calls `py.math.cos` and `py.math.sin` to calculate the Euler formula for complex numbers.

```
classdef eulerSystem < matlab.System
    % System object to calculate Euler's formula for an input

    methods (Access = protected)

        function [re, img, num] = stepImpl(obj, u)
            % Implement algorithm

            re = py.math.cos(u);
            img = py.math.sin(u);
            num = py.math.cos(u) + 1j*py.math.sin(u);

        end

        function [c1, c2, c3] = isOutputComplexImpl(obj)
            % Implement propagator to declare complexity of outputs
```

```

    c1 = false;
    c2 = false;
    c3 = true;
end

function [flag1, flag2, flag3] = isOutputFixedSizeImpl(obj)
    % Implement propagator to declare if outputs are fixed size

    flag1 = true;
    flag2 = true;
    flag3 = true;
end

function [sz_1, sz_2, sz_3] = getOutputSizeImpl(obj)
    % Implement propagator to declare output sizes

    sz_1 = [1,1];
    sz_2 = [1,1];
    sz_3 = [1,1];
end

function [out_1, out_2, out_3] = getOutputDataTypeImpl(obj)
    % Implement propagator to declare output data types

    out_1 = "double";
    out_2 = "double";
    out_3 = "double";
end

end

end
end

```

Implement the System object in Simulink as shown below to calculate the Euler formula for an input.

You should define propagator methods when output specifications for the system block cannot be inferred directly from inputs during model compilation. The code above implements the

`isOutputComplexImpl`, `isOutputFixedSizeImpl`, `getOutputSizeImpl`, and `getOutputDataTypeImpl` propagator methods. For more information on propagation methods, see “Add and Implement Propagation Methods” on page 50-29.

## Import Python Code to Simulink Using Python Importer Wizard

This topic provides an overview of using Python Importer to implement Python modules or packages containing multiple modules in Simulink.

You can access Python Importer from Blockset Designer or as a standalone application. Python Importer lets you import Python modules or packages, select functions to import, and configure input and output ports. It generates a Simulink custom block library containing a MATLAB System block for each specified function.

Use Python Importer from Blockset Designer to:

- Add test and documentation for each block.
- Support inter-module dependencies by including a Python project folder.
- Enable packaging and sharing of the custom blockset using Blockset Designer.

The generated blocks are added to a sublibrary in Blockset Designer. For more information on creating, managing, and publishing custom blockset in Blockset Designer, see “Create a Blockset Project” on page 51-2.

Use Python Importer as a standalone application for rapid prototyping in cases where documentation and tests are not required for the generated blocks, and sharing of the blockset is not required.

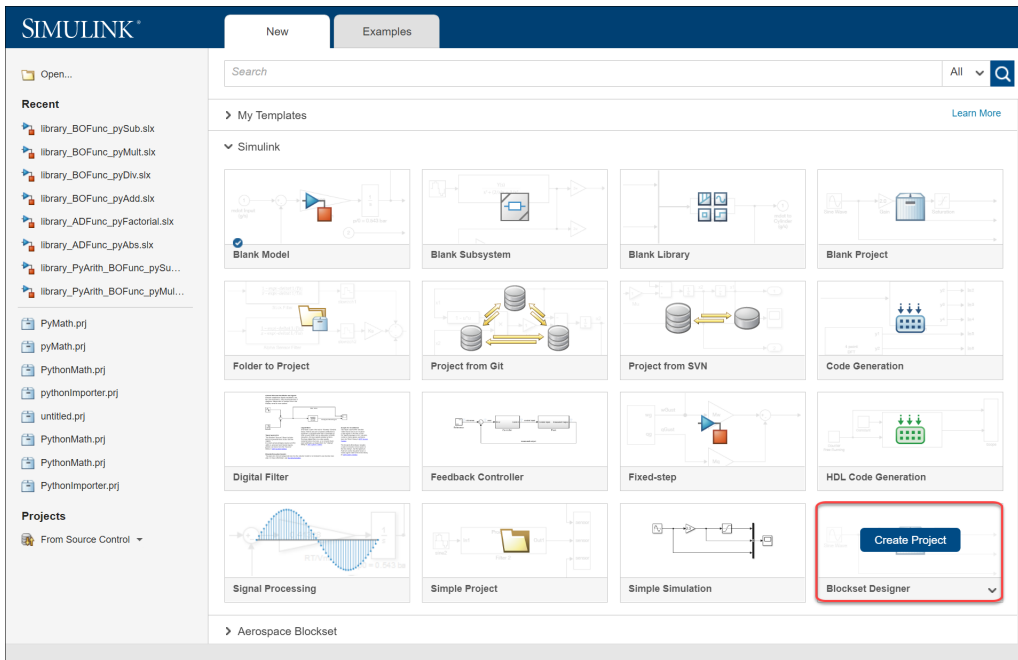

### Configure System to Use Python

To call Python modules in MATLAB, you must have a compatible version of Python installed. For more information on supported Python versions and setting up your system to use Python in MATLAB, see “Configure Your System to Use Python”.

You can access all standard Python libraries, third-party functionality, or user-created modules from MATLAB. For more information on using Python in MATLAB, see “Access Python Modules from MATLAB - Getting Started”.

### Use Python Importer with Blockset Designer

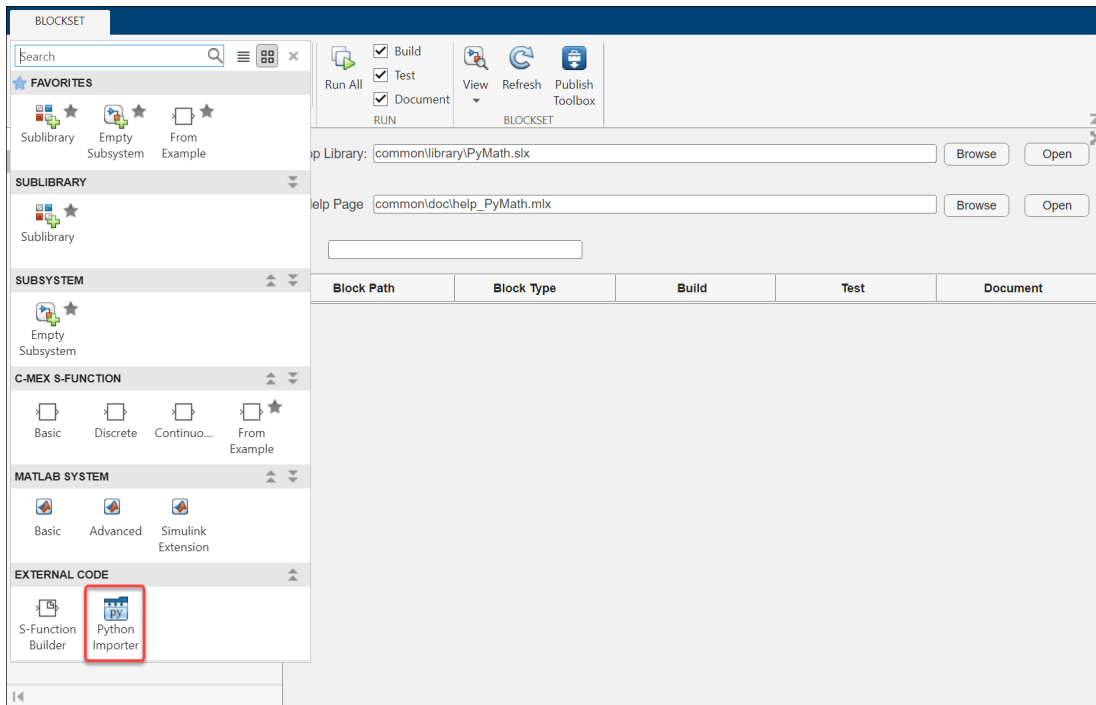

- 1 Open the Simulink start page, pause on Blockset Designer and click **Create Project**.

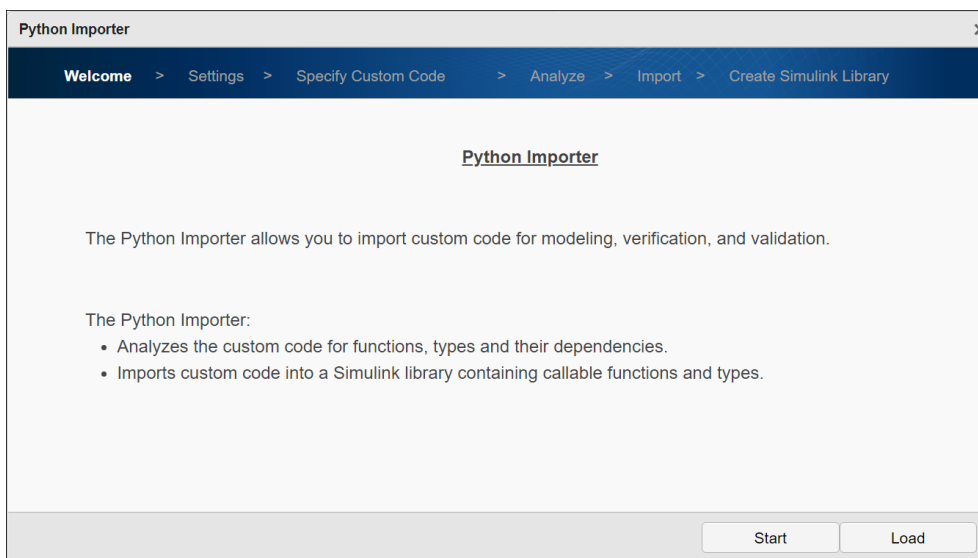

- 2 Specify a name for your project. Note that when you start typing a name for your project, a new folder is automatically created for you in the directory `username\MATLAB\Projects\<foldername>`. If you would like to specify an existing project folder, click **Browse**.

If you create a new folder, click **OK** to create a new project folder. Confirm this action by clicking **Yes**.

- 3 Now you are directed to the Blockset Designer project user interface. To open Python Importer, click the arrow on the far right of the **Add** section. Under **External Code**, click **Python Importer**.

- 4 Specify the sublibrary name. The Python Importer wizard opens.

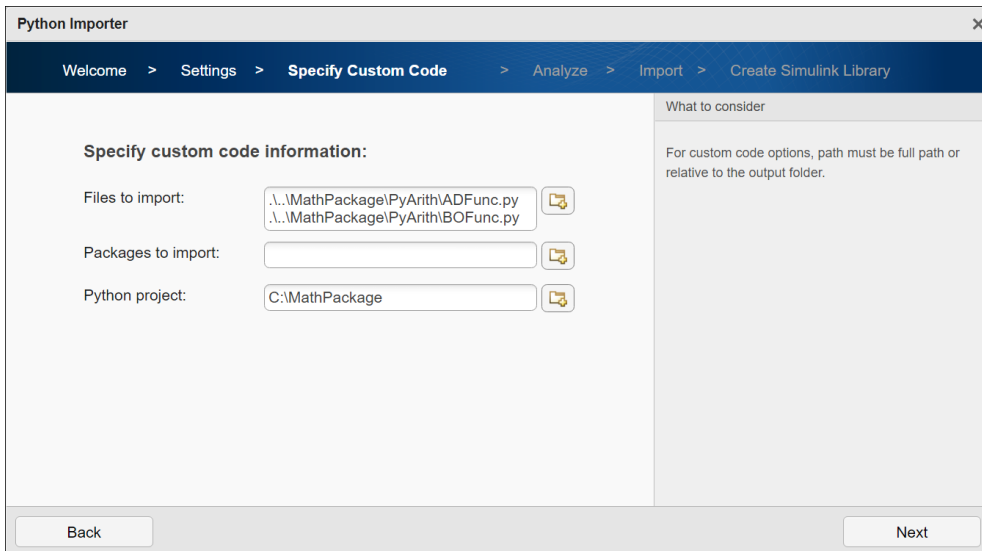

Click **Start** to begin a new session. Click **Load** to open an existing session.

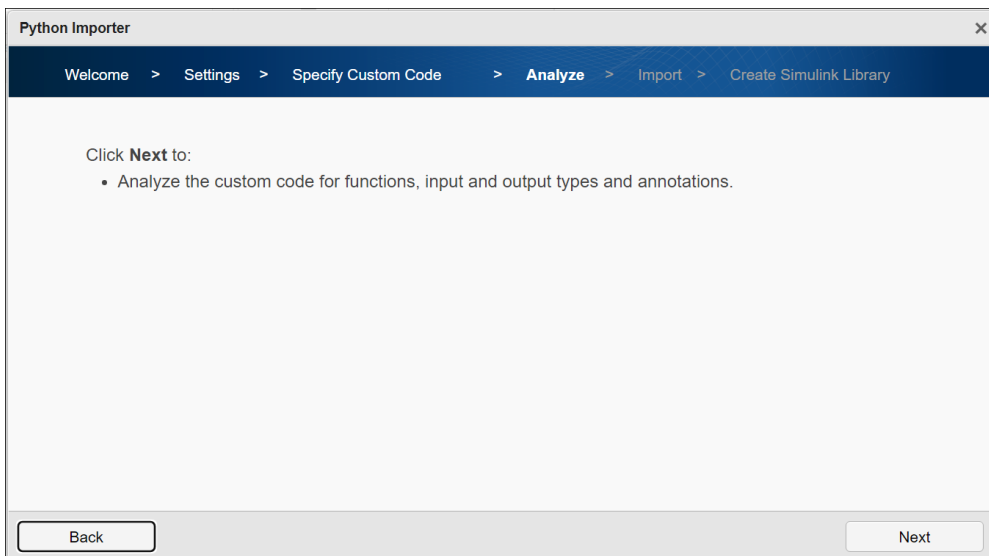

- 5 On the **Specify Custom Code** page, specify either Python module files or Python packages containing the custom code to import. For more information on Python packages, see <https://docs.python.org/3/tutorial/modules.html>. You can also specify the location of Python project containing inter-module dependencies required to execute the specified function in the modules. Python Importer does not support modules containing class definitions.

If you make a change to the source code inside a Python module or import package after starting Python Importer, you need to unload and reload the imported modules to enable Python Importer

to detect the changes. For more information on unloading and reloading python modules, see Reload Modified User-Defined Python Module section in “Call User-Defined Python Module”.

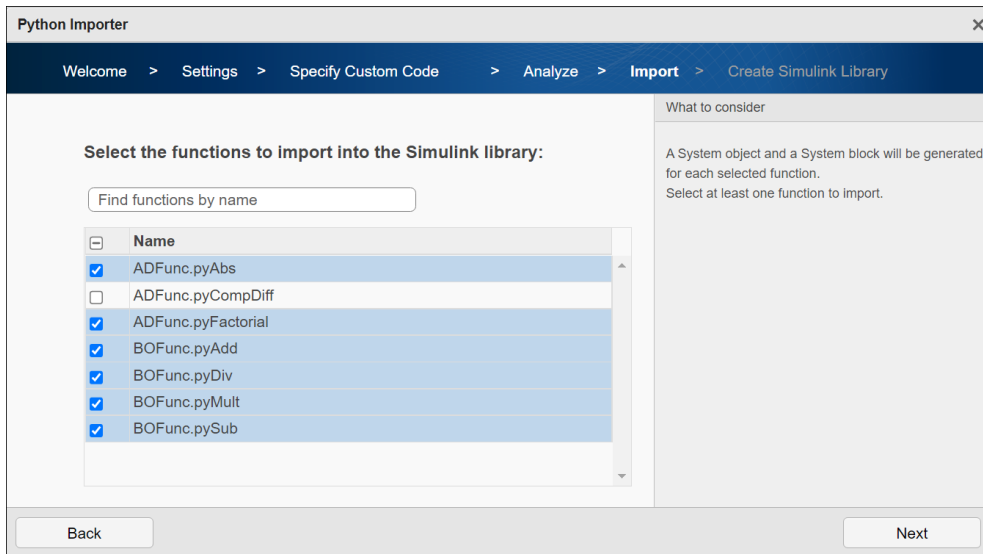

Click **Next** to proceed to the **Analyze** page.

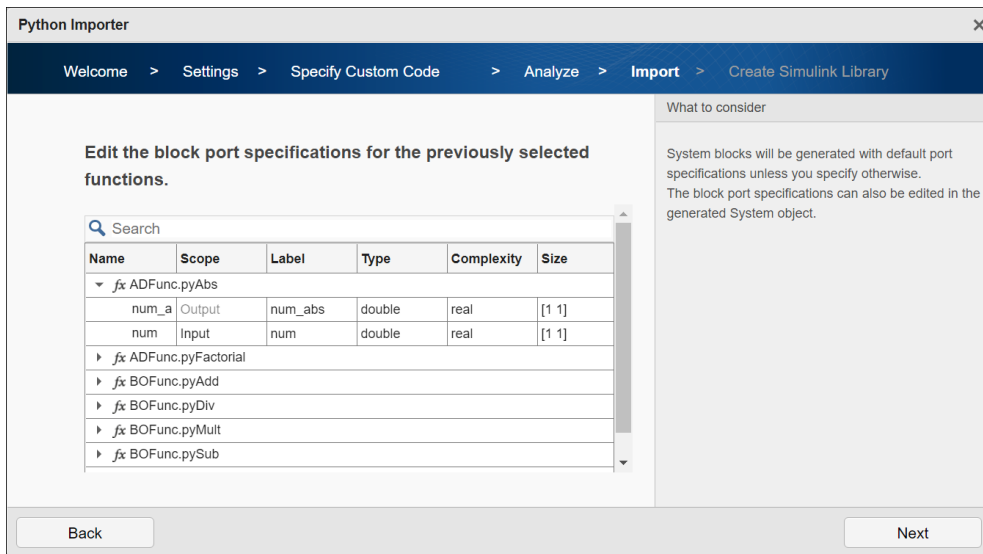

Click **Next** to configure import settings.

- 7 The Python Importer identifies functions to import from the specified custom modules or packages. On the **Import** page, select the functions that you want to import. A MATLAB System object and MATLAB System block are created for each of the selected functions.

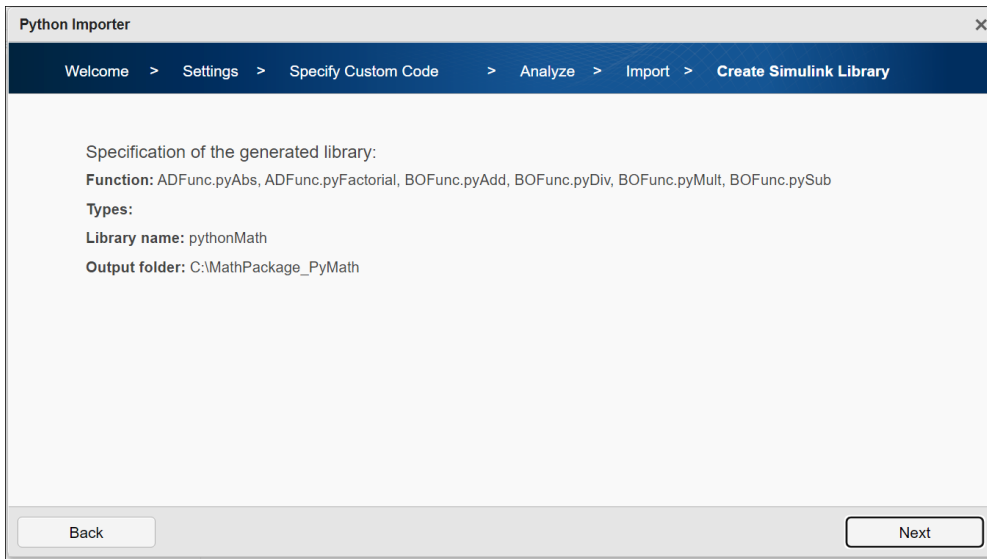

Click **Next** to continue.

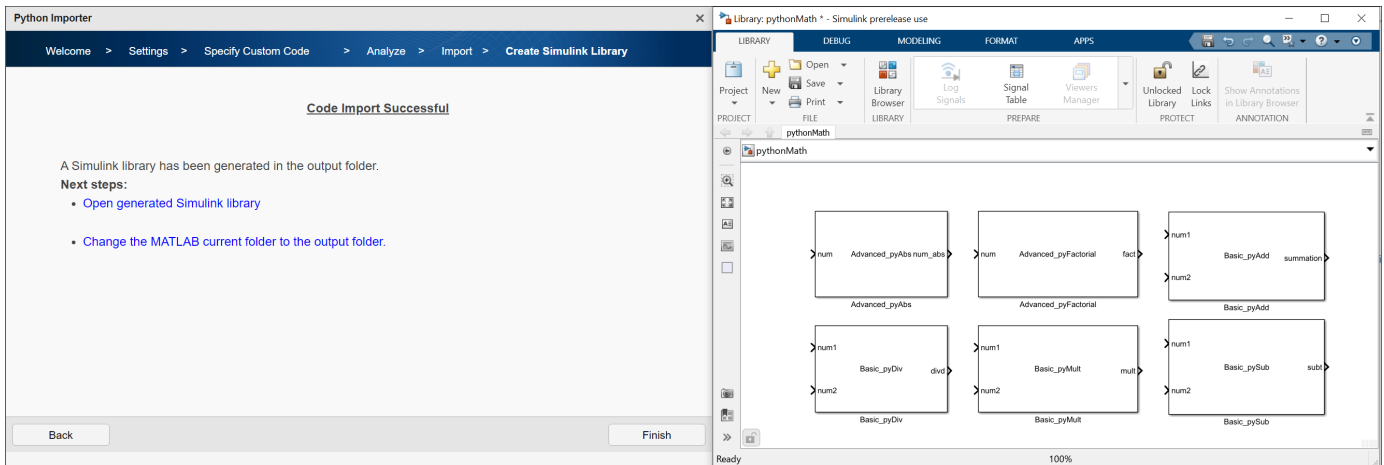

- 8 For each selected function from the previous page, the Python Importer wizard generates a default port specification for its inputs and outputs. You can change the input port into a parameter of the generated block by changing its corresponding **Scope** option. Change the input and output names using **Label** option and data type using **Type** option. Specify the size and complexity of each port using **Complexity** and **Size** options respectively.

- 9 The **Create Simulink Library** page provides specifications of the generated library. Click **Next** to confirm and generate the library.

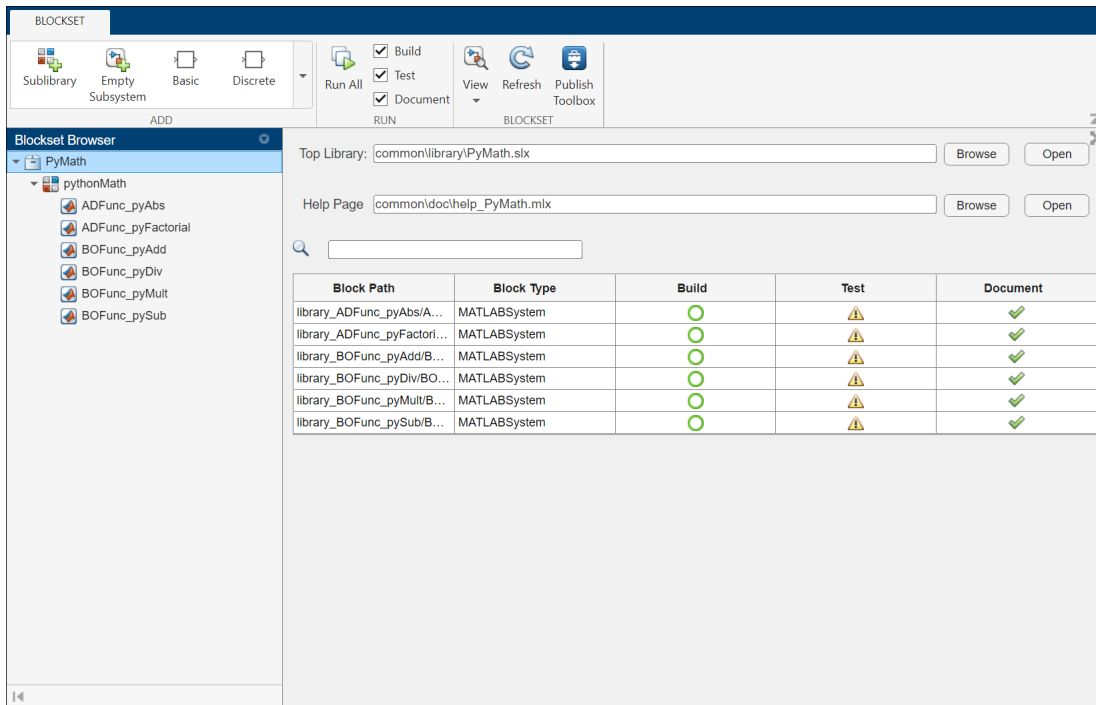

- 10** On successful completion of the import process, the block library is generated containing a MATLAB System block for each of the selected functions.

Do not close the library file. Click **Finish** to complete the import process and exit Python Importer.

- 11** Blockset Designer adds each block and its supporting files to the project. The generated blocks are added to the specified sublibrary. You can add documentation and test for the generated System blocks in Blockset Designer. For more information on Blockset Designer test and documentation, see “Create and Organize Block Artifacts” on page 51-14.

- 12 You can now publish and share the created blockset. For more information, see “Publish the Created Blockset” on page 51-18.

## Use Python Importer as a Standalone Application

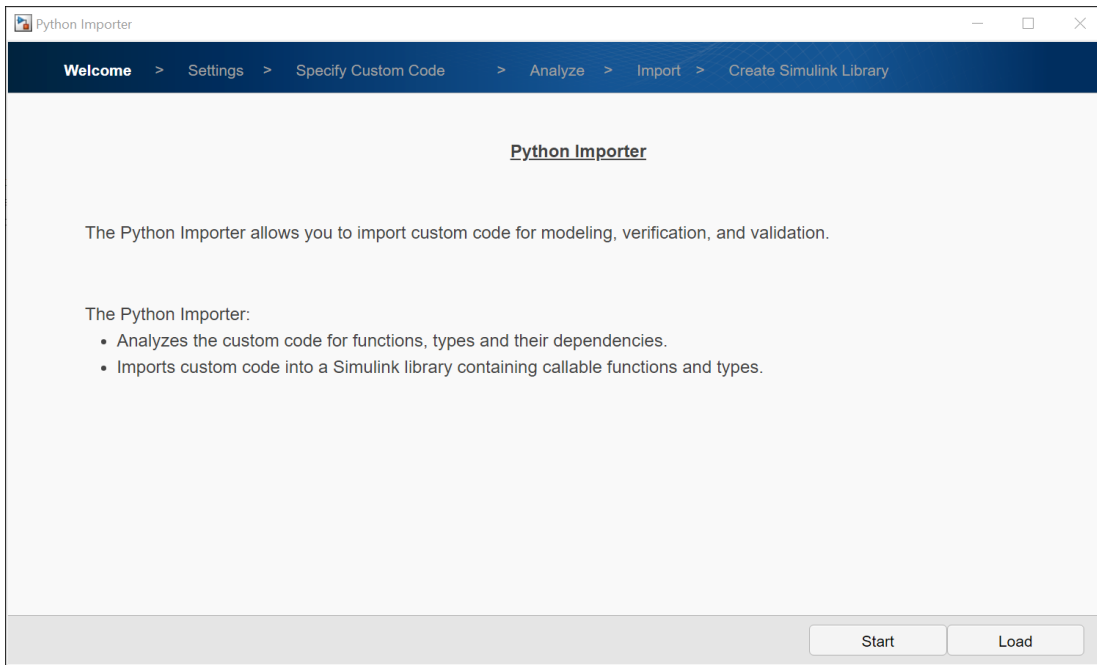

Use Python Importer as a standalone application to import Python functions and packages into Simulink for rapid prototyping.

- 1 Use these commands to launch Python Importer from the command line.

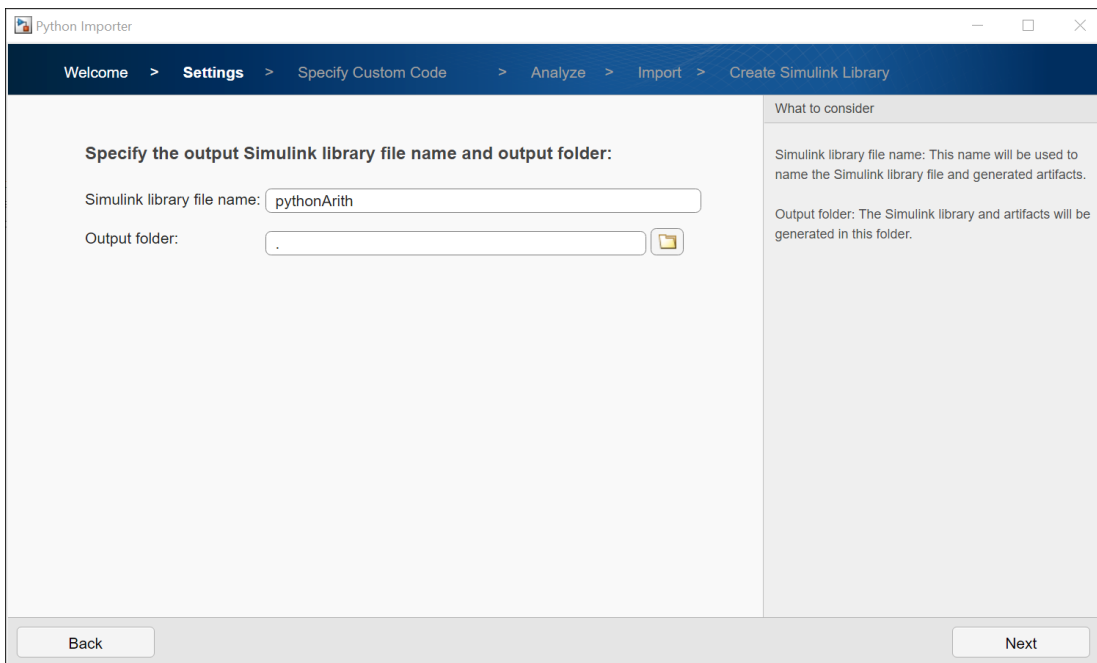

```
obj = Simulink.PythonImporter();
obj.view();
```

- 2 Once the **Welcome** page loads, click **Start** to begin the import process.

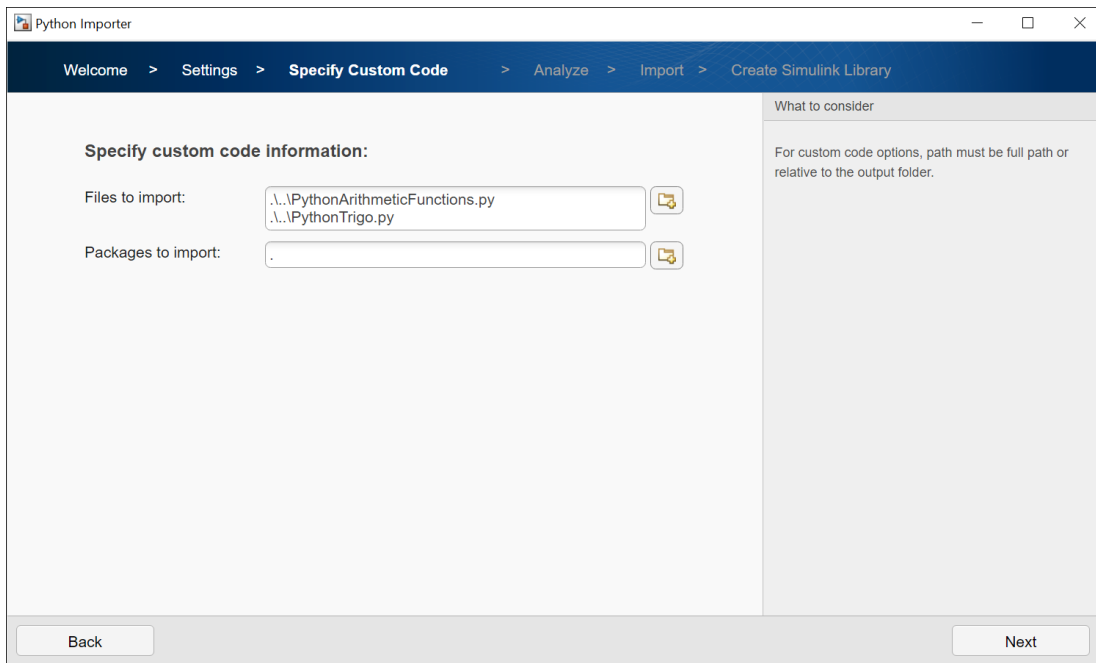

- 3 On the **Settings** page, in **Simulink library file name** box, specify the file-name for the library file in which the custom blocks will be created. In the **Output folder** box, specify the path of folder where you want the Simulink library and artifacts to be located.

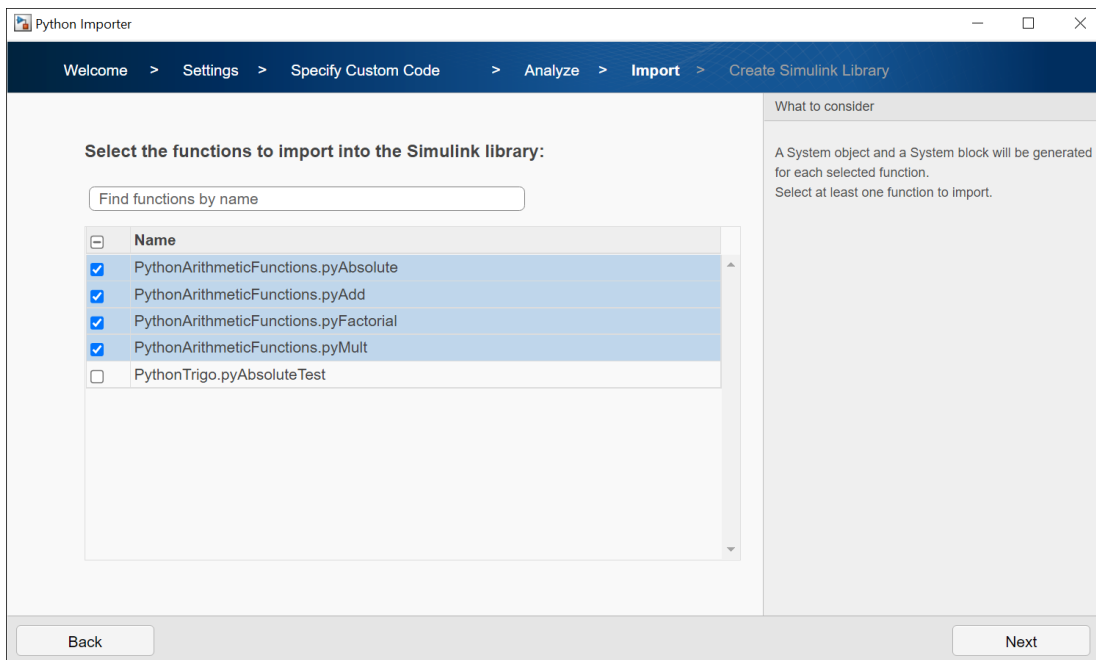

- 4 On the **Specify Custom Code** page, specify either Python Files or Python Packages containing the custom code to import. For more information on Python packages, see <https://docs.python.org/3/tutorial/modules.html>. Python Importer does not support modules containing class definitions.

If you make a change to the source code inside a Python module or import package after starting Python Importer, you need to unload and reload the imported modules to enable Python Importer to detect the changes. For more information on unloading and reloading python modules, see Reload Modified User-Defined Python Module section in “Call User-Defined Python Module”.

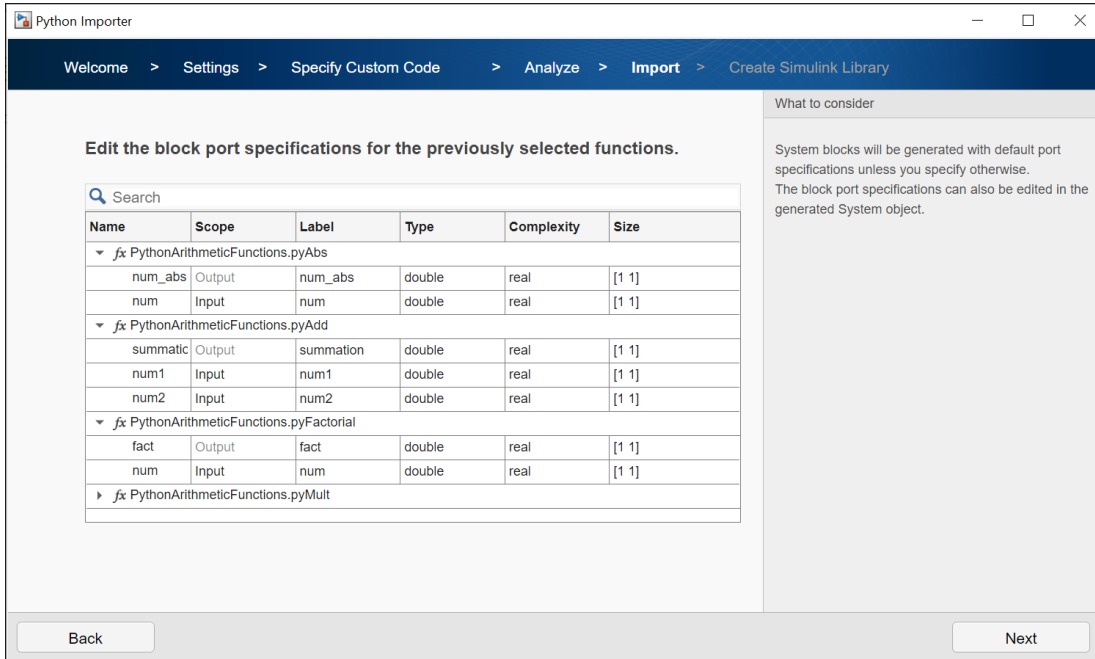

- 5 On the **Import** page, select the functions that you want to import. A MATLAB System object and MATLAB System block are created for each of the selected functions.

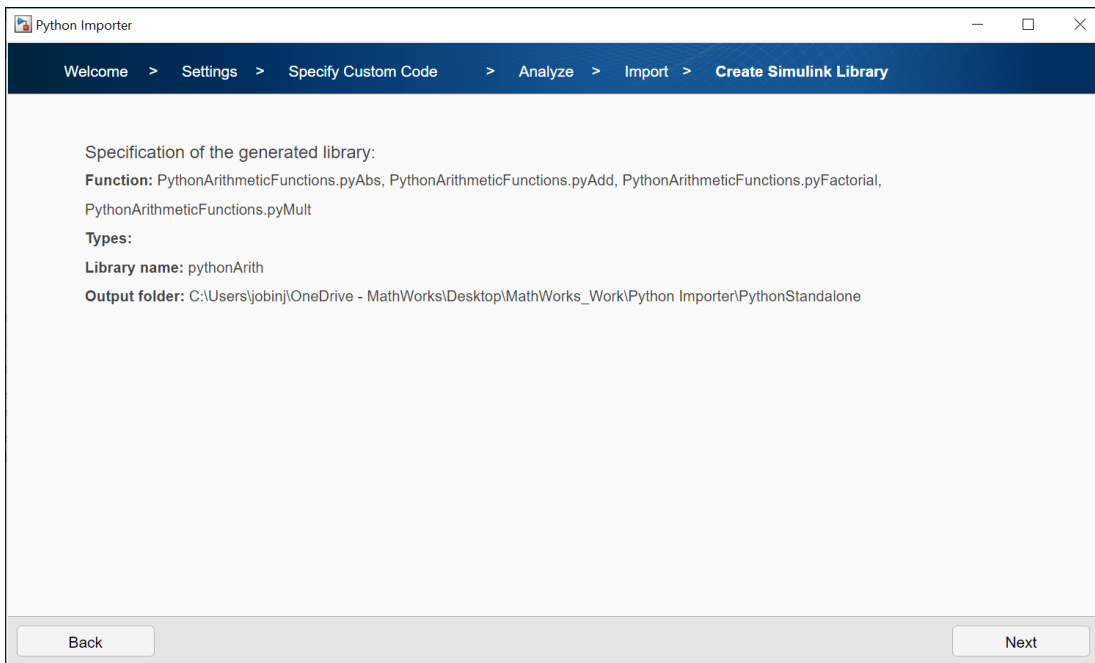

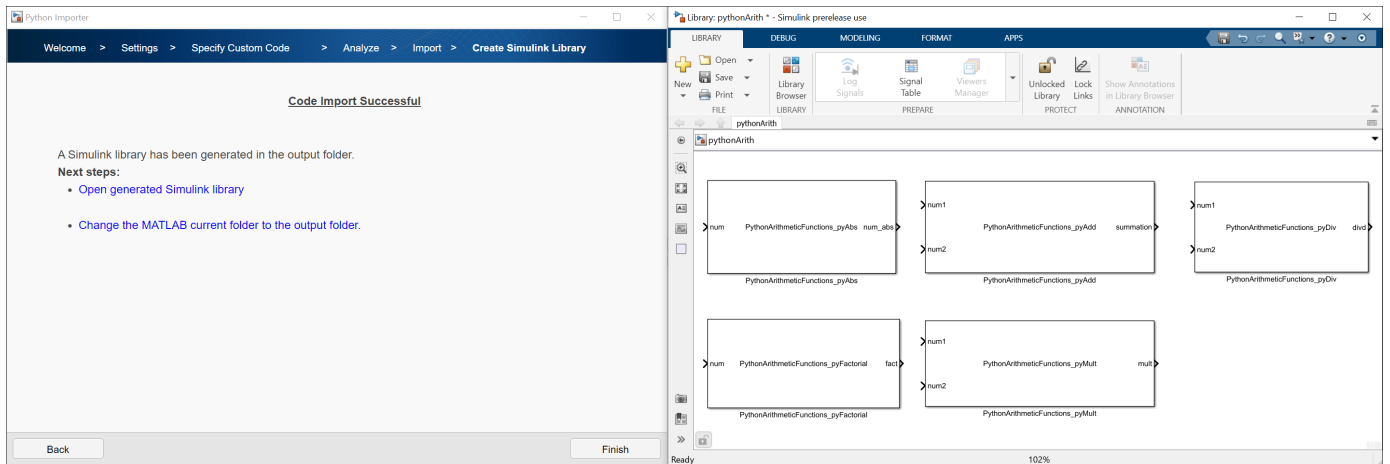

- 6 For each selected function from the previous page, the Python Importer wizard generates a default port specification for its inputs and outputs. You can change the input port into a

parameter of the generated block by changing its corresponding **Scope** option. Change the input and output names using **Label** option and data type using **Type** option. Specify the size and complexity of each port using **Complexity** and **Size** options, respectively.

7 The **Create Simulink Library** page provides specifications of the generated library. Click **Next** to confirm and generate the library.

On successful completion of the import process, the library is generated in the specified folder along with the MATLAB System object for each of the selected functions. Refresh the library browser in Simulink to find the newly generated library. For more information on adding block library to Simulink library browser, see “Add Library to Library Browser” on page 44-8.

## Use Variant Parameters to Reuse Block Parameters with Different Values

You may have a set of requirements where the structure of the model remains the same, but the values of the parameters for each requirement are different. In this scenario, you can create a single model with fixed structure and create parameters with a finite set of values where each value corresponds to different requirements. Parameters that have multiple values are called variant parameters. Variant parameters can be defined in a MATLAB base workspace or a data dictionary.

Each value of a variant parameter must be associated with a variant condition expression. You can have multiple variant parameters associated with a variant condition, provided no two values belong to the same parameter. When a condition expression evaluates to `true`, all the values associated with that condition become active and are assigned to the corresponding parameters. If you change the value of the variant control variable, a different set of values is assigned to the parameters. This way, variant parameters allow you to logically bind a set of values across different parameters to a condition expression, and the values are assigned to the parameter based on the variant condition that evaluates to `true`.

Simulink selects the active value of a variant parameter during update diagram time, during code compile time, or during the model startup time. For more information, see “Activate Variant During Different Stages of Simulation and Code Generation Workflow” on page 12-65.

Consider this model. The **Gain** parameter of the Gain block is a variant parameter with its value set to  $K$ . The variable  $K$  has two values: 3.5 and 8.5. Simulink chooses active value of  $K$  based on the value of the variant control variable  $V$ . If  $V==1$  evaluates to `true`, the value of  $K$  is set to 3.5. If  $V==2$  evaluates to `true`, the value of  $K$  is set to 8.5.

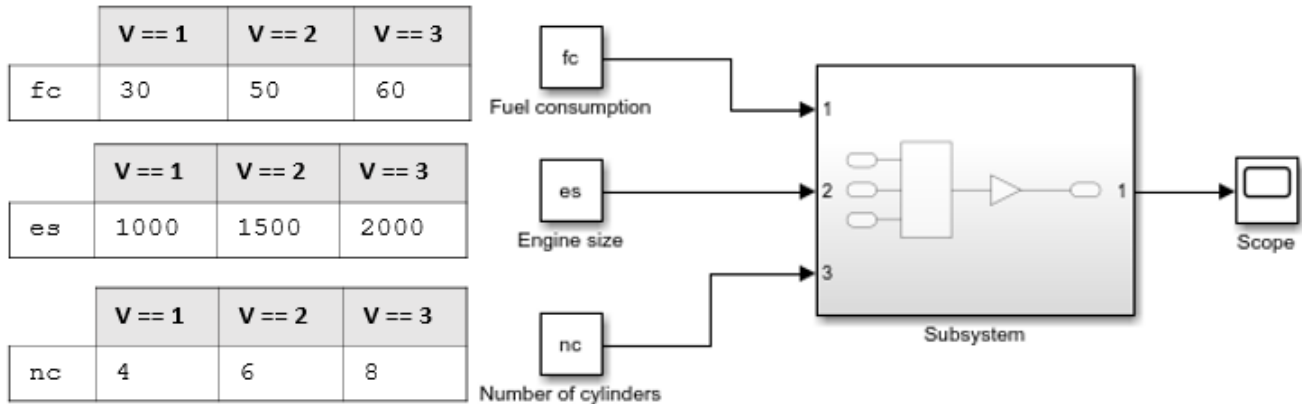

### When to Create Variant Parameters

Variant parameters provide a way to design one model for many systems that differ in block parameter values. You can group different sets of values based on the system to simulate. Each set of values is associated with a variant condition expression. During simulation, if a variant condition evaluates to `true`, then all the values associated with that condition become active. To change the set of active values, change the value of the variant control variable and run the simulation again.

Consider this model that represents an automobile system with several configurations. These configurations, although similar in several aspects, can differ in values such as fuel consumption, engine size, or number of cylinders in the engine. Instead of designing multiple blocks that together represent all possible values, you can use variant parameters to model the varying values.

## Variant Parameter with Varying Values

In this model, the Fuel consumption, Engine size, and Number of cylinders have variant parameters `fc`, `es`, and `nc`. The values of the variant parameters are based on the value of the variant control variable `V`. For example, if `V==1` evaluates to `true`, then the value of `fc` is set to 30, `es` is set to 1000, and `nc` is set to 4.

## Advantages of Using Variant Parameters

Using variant parameters in Model-Based Design provides several advantages:

- Variant parameters provide you a way to design one model for many systems.
- Variant parameters facilitate reuse of blocks. This approach improves workflow speed by reducing complexity.
- Variant parameters help you switch among different block parameter values for multiple simulation, code generation, or testing workflows.
- You are not required to regenerate the code for different values of a variant parameter because the generated code has preprocessor conditionals for each variant value of the parameter.

## Limitations of Using Variant Parameters

Using variant parameters in Model-Based Design also has limitations:

- The value of the variant control variable that determines the active value of a variant parameter must be a numeric value, an enumerated value, or a `Simulink.Parameter` object.
- Only the values of the variant parameters change based on the variant condition that evaluates to `true`. Other properties, such as storage class, data types, and so forth, remain the same irrespective of the variant condition.
- Variant parameters can only be defined in a base workspace or a data dictionary.

## **See Also**

“Create a Simple Variant Parameter Model” on page 90-5 | “Options to Represent Variant Parameters in Generated Code” (Embedded Coder)

## **Related Examples**

- “Change Active Values and Activation Time of Variant Parameters” on page 90-24
- “Compile Code Conditionally for All Values of Variant Parameters with Same and Different Dimensions” on page 90-32
- “Run Executable for Different Variant Parameter Values Without Recompiling Code” on page 90-38

## Create a Simple Variant Parameter Model

This example shows you how to create variant parameters and use them in Simulink® blocks to vary the block parameter values based on variant conditions.

Variant parameters give you a way to represent block parameters that can have multiple choice values. For example, you may implement a system where the functional behavior remains the same but some parameter values can change depending on certain conditions. You can use variant parameters to switch among different block parameter values for simulation, code generation, or testing workflows. For more information, see “Use Variant Parameters to Reuse Block Parameters with Different Values” on page 90-2.

### How to Use Variant Parameters in a Model

You create a variant parameter as a `Simulink.VariantVariable` object. This object defines the set of possible values for the parameter and a variant condition expression associated with each value. You must create a variant control variable as a `Simulink.VariantControl` object and use this variable to specify the variant condition for each value of a variant parameter.

You can create variant parameters and `Simulink.VariantControl` objects in the base workspace or in a data dictionary associated with the model. See “Storage Locations for Variant Control Variables (Operands) in Variant Parameters” on page 90-10.

After creating a variant parameter, you can use it to set the value of a block parameter, such as the **Gain** parameter of a Gain block. During simulation, the variant parameter value associated with the variant condition that evaluates to `true` becomes the active value of that block parameter. You can change the active value of a variant parameter by changing the value of the variant control variable.

### Explore Example Model

Open the model `slexVariantParameters`. The model uses the base workspace.

```
open_system('slexVariantParameters')
```

### Variant Parameters with Different Activation Times

This example uses two variant parameters, K1 and K2. Each parameter has two choice values corresponding to the variant conditions  $V==1$  and  $V==2$ . K1 specifies possible values for the **Gain** parameter of the Gain1 block, and K2 specifies possible values for the **Gain** parameter of the Gain2 block. This table shows the variant parameter values used in the model.

	V==1	V==2
K1	3.5	8.5
K2	4.5	9.5

### Create Variant Parameters and Variant Control Variable Object

To create K1 and K2 and to specify them as the **Gain** parameters of the Gain1 and Gain2 blocks:

1. Define a `Simulink.VariantControl` object V in the base workspace of the model.

```
V = Simulink.VariantControl(Value=1, ActivationTime="update diagram")
```

V =

```
VariantControl with properties:
    Value: 1
    ActivationTime: 'update diagram'
```

The `Value` property of the variant control variable object determines the active value of the variant parameter. The value of V is set to 1. The object also associates the value with a variant activation time. For more information on activation time, see “Activate Variant During Different Stages of Simulation and Code Generation Workflow” on page 12-65.

2. Create `Simulink.VariantVariable` objects to define multiple values for the **Gain** parameter of each Gain block and associate each value with a variant condition expression.

You can specify properties such as dimension, data type, and storage class for each variant parameter. For this, create a `Simulink.Parameter` object with the required properties and use the name of this object to set the `Specification` property of the variant parameter object.

```
Pspec = Simulink.Parameter(0);
Pspec.CoderInfo.StorageClass = 'ExportedGlobal';
K1 = Simulink.VariantVariable(Specification = "Pspec", Choices = {'V==1', 3.5, 'V==2', 8.5});
K2 = Simulink.VariantVariable(Specification = "Pspec", Choices = {'V==1', 4.5, 'V==2', 9.5});
```

Once you successfully create the `Simulink.VariantVariable` objects, you can modify them by using the methods described in “Public Methods” or from the `VariantVariable` dialog box. Double-click the `Simulink.VariantVariable` object created in the base workspace to open the dialog box. You can also use the Variant Parameters tab in Variant Manager to view the variant parameters present in the base workspace or data dictionaries associated with the model and to edit the variant condition and value of the choices.

3. Open the block parameter dialog box of each Gain block in the model. Specify the **Gain** parameter of the Gain1 block as K1 and the **Gain** parameter of the Gain2 block as K2.

4. To simulate the model, on the **Simulation** tab, click **Run**. During simulation, the variant condition  $V == 1$  evaluates to `true`. Simulink sets the active value of K1 and K2 to the value corresponding to

this condition. The active value is then assigned to the block parameter. The value of the **Gain** parameter of the Gain1 block is set to 3.5 and the value of the **Gain** parameter of the Gain2 block is set to 4.5.

5. To change the value of the **Gain** parameters, set the value of V to 2 and run the simulation again. You can change the value of V by performing any of these steps:

- Double-click the variant control variable created in the base workspace. In the VariantControl dialog box, specify the value of V as 2.
- In the MATLAB® Editor, execute this command:

```
V.Value = 2;
```

During simulation, because the variant condition `V == 2` evaluates to `true`, the value of the **Gain** parameter of the Gain1 block is set to 8.5, and the value of the **Gain** parameter of the Gain2 block is set to 9.5.

## Variant Control Mode in Variant Parameters

### In this section...

“Switch Between Choices Using Condition Expressions in Variant Parameters” on page 90-8

“Variant Activation Times for Different Variant Control Modes in Variant Parameters” on page 90-11

The components of a Simulink model that contain variants are activated or deactivated based on the variant choice that you select.

Each variant choice in your model is associated with a variant control. Variant controls determine which variant choice is active. By changing the value of a variant control, you can switch the active variant choice. While each variant choice is associated with a variant control, only one variant control can evaluate to `true`. When a variant control evaluates to `true`, Simulink activates the variant choice that corresponds to that variant control. For a simple example, see “Introduction to Variant Controls” on page 12-37.

### Switch Between Choices Using Condition Expressions in Variant Parameters

In `expression` mode, Simulink chooses the active variant based on the evaluation of the variant conditions. When a condition expression evaluates to `true`, the corresponding variant choice becomes active. When a condition expression evaluates to `false`, the corresponding variant choice becomes inactive. See “Switch Between Choices Using Condition Expressions in Variant Parameters” on page 90-8.

---

**Note** You can simulate and generate code from the model containing a variant parameter with **Variant control mode** set to `expression` mode. The generated code can contain active and inactive choices that are enclosed in preprocessor conditionals `#if` and `#elif`, or regular `if` conditions.

---

With `expression` type of variant control mode:

- Use “`code compile`” on page 12-68 activation time to generate a code that contains active and inactive choices of the model in C preprocessor conditionals `#if` and `#elif`. The preprocessor conditionals are conditionally compiled for the active choice that you provide as an input to the compiler. For more information, see “Compile Code Conditionally for All Values of Variant Parameters with Same and Different Dimensions” on page 90-32.
- Use “`startup`” on page 12-68 activation time to:
  - Improve the speed of iterative simulations and Simulink Test workflows using fast restart. For more information, see “Run Iterative Simulations Without Recompiling Model for Variant Systems Using Fast Restart” on page 12-211.
  - Generate a code that contains active and inactive choices of the model in regular `if` conditions. The `if` condition is evaluated and conditionally executed for the active choice that you provide as an input to the executable. For more information, see “Run Executable for Different Variant Parameter Values Without Recompiling Code” on page 90-38.

### Use expression Type of Variant Controls in Variant Parameters

To specify the variant condition expressions in variant parameters, use the `Simulink.VariantVariable` object. Once you successfully create the

`Simulink.VariantVariable` objects, you can modify them by using the methods described in “Public Methods” or from the `VariantVariable` dialog box. For more information, see “Create a Simple Variant Parameter Model” on page 90-5.

```
K1 = Simulink.VariantVariable('Choices', {'VSS_MODE == 1', 3.5, 'VSS_MODE == 2', 8.5})
```

### Types of Variant Controls in expression Mode

In variant parameters, the expression type of variant controls can be:

- Boolean condition expression for rapid prototyping. For example, `A == 1`, `A ~= B`, `A && B == 1`, and so on.
- A `Simulink.Variant` object that contains a condition expression for condition reuse. See “`Simulink.Variant` Objects for Variant Condition Reuse of Variant Parameters” on page 90-21.

Here, `A` and `B` are operands called as variant control variables. `==`, `~=`, and `&&` are operators in the condition expression. The condition expression can contain one or more such variant control variables and operators. For information on supported types and storage location of variant control variables, see “Types of Variant Control Variables (Operands) in Variant Parameters” on page 90-9 and “Storage Locations for Variant Control Variables (Operands) in Variant Parameters” on page 90-10. For information on operators, see “Types of Operators in Variant Parameters” on page 90-10.

### Types of Variant Control Variables (Operands) in Variant Parameters

In expression mode, you can specify the variant control variables as any of these types, from options to use while prototyping to options required for generating code from your model.

Specification	Purpose	Example
<code>Simulink.VariantControl</code> object	Associate a variant activation time	<code>A == 1</code> , where <code>A</code> is a <code>Simulink.VariantControl</code> object. See “Numeric Variant Control Values for Rapid Prototyping of Variant Parameters” on page 90-13.
<code>Simulink.Parameter</code> object	Generate preprocessor conditionals for code generation	<code>Vssmode == 1</code> , where <code>Vssmode</code> is a <code>Simulink.Parameter</code> object. See “ <code>Simulink.Parameter</code> Type of Variant Control Variables for Code Generation of Variant Parameters” on page 90-15.
“ <code>Simulink Enumerations</code> ” on page 73-2	Improved code readability because condition values are represented as meaningful names instead of integers	<code>LEVEL == Level.Advanced</code> , where <code>Level</code> is an integer-based enumeration class and <code>Advanced</code> is the enumerated value. See “Enumerated Types to Improve Code Readability of Variant Control Variables of Variant Parameters” on page 90-18.

Specification	Purpose	Example
Simulink.Variant object	Reuse variant conditions	LinearController == 1, where LinearController is a Simulink.Variant object that encapsulates the condition expression FUEL==2 && EMIS==1. See “Simulink.Variant Objects for Variant Condition Reuse of Variant Parameters” on page 90-21.

For list of all examples, see “Use Variant Control Variables in Variant Parameters” on page 90-13.

### Storage Locations for Variant Control Variables (Operands) in Variant Parameters

You can define the variant control variables in different storage locations based on your requirement.

**Note** All the variant control variables in a variant parameter must originate from the same storage location.

Storage Location	Use for Storage Location	Supported Types of Variant Control Variables (See “Types of Variant Control Variables (Operands) in Variant Parameters” on page 90-9)	For More Information
Base workspace	Store variables while you experiment with temporary models	Simulink.Variant, Simulink.Parameter, enumerated type, and Simulink.VariantControl	“Temporary Data: Base Workspace” on page 72-97
Data dictionary	Permanently store global data, share data between models, and track changes made to data.	Simulink.Variant, Simulink.Parameter, enumerated type, and Simulink.VariantControl	“What Is a Data Dictionary?” on page 79-2

For capabilities and advantages of each storage location, see “Determine Where to Store Variables and Objects for Simulink Models” on page 72-94

### Types of Operators in Variant Parameters

Variant condition expressions can contain MATLAB operators, provided the expression evaluates to a boolean value. In variant parameters, the operators that you can use to form a variant condition expression are:

- Parentheses for grouping

- “Relational Operators” and “Logical Operators” as listed in this table.

This table lists the supported MATLAB operators and their equivalent in the generated code. In these examples, A and B are expressions that evaluate to an integer.

Supported MATLAB Expressions	Equivalent Expression in Generated C Code
<b>Relational</b>	
A == B	A == B
A ~= B	A != B
<b>Logical</b>	
~A	!A, where A is not an integer
A && B	A && B
A    B	A    B

### Evaluate Variant Condition Expressions at Different Variant Activation Times

In expression mode, you can specify if Simulink must evaluate condition expressions during model compile, simulation-loop, code compile, or model start up stage of simulation and code generation workflow using variant activation times. For information on stages of simulation and code generation, and supported variant activation times in expression mode, see “Activate Variant During Different Stages of Simulation and Code Generation Workflow” on page 12-65.

### Variant Activation Times for Different Variant Control Modes in Variant Parameters

This table explains the variant activation time supported for different variant control modes in variant parameters. For information on variant activation times, see “Activate Variant During Different Stages of Simulation and Code Generation Workflow” on page 12-65.

Variant control mode	Variant activation time			
	update diagram	update diagram analyze all choices	code compile	startup
expression	✓	✓	✓	✓
label	not supported			
sim codegen switching	not supported

## Use Variant Control Variables in Variant Parameters

This topic explains how to use different types of variant control variables in variant parameters.

Consider the `slexVariantParameters` model.

The **Gain** parameter of the Gain blocks are variant parameters that are specified as `Simulink.VariantVariable` objects, K1 and K2. K1 and K2 have multiple values associated with variant condition expressions  $V == 1$  and  $V == 2$ . Here, the variant control variable  $V$  that determines the active value of K1 and K2 is a `Simulink.VariantControl` object. You can change  $V$  to any of these types based on your requirement.

**Note** Before you start with these examples, we recommend you complete “Create a Simple Variant Parameter Model” on page 90-5.

### In this section...

“Numeric Variant Control Values for Rapid Prototyping of Variant Parameters” on page 90-13

“Simulink.Parameter Type of Variant Control Variables for Code Generation of Variant Parameters” on page 90-15

“Enumerated Types to Improve Code Readability of Variant Control Variables of Variant Parameters” on page 90-18

“Simulink.Variant Objects for Variant Condition Reuse of Variant Parameters” on page 90-21

## Numeric Variant Control Values for Rapid Prototyping of Variant Parameters

Numeric values allow you to rapidly prototype variant values when you are still building your model. Numeric values help you focus more on building your variant values than on developing the expressions that activate those choices.

You can define numeric control values in locations listed in “Storage Locations for Variant Control Variables (Operands) in Variant Parameters” on page 90-10.

Open the `slexVariantParameters` model.

```
open_system('slexVariantParameters')
```

In the MATLAB Editor, specify variant choices in their simplest form as numeric values in `Simulink.VariantVariable` objects K1 and K2.

```
K1 = Simulink.VariantVariable('Choices',{ 'V==1', 3.5, 'V==2', 8.5})
```

```
K1 =  
VariantVariable with 2 choices:
```

Condition	Value
V == 1	3.5000
V == 2	8.5000

```
Specification: ''
```

```
Bank: ''
```

Use `getChoice`, `setChoice`, `addChoice`, `removeChoice` to access, modify, add or remove choices

```
K2 = Simulink.VariantVariable('Choices',{ 'V==1', 4.5, 'V==2', 9.5})
```

```
K2 =  
VariantVariable with 2 choices:
```

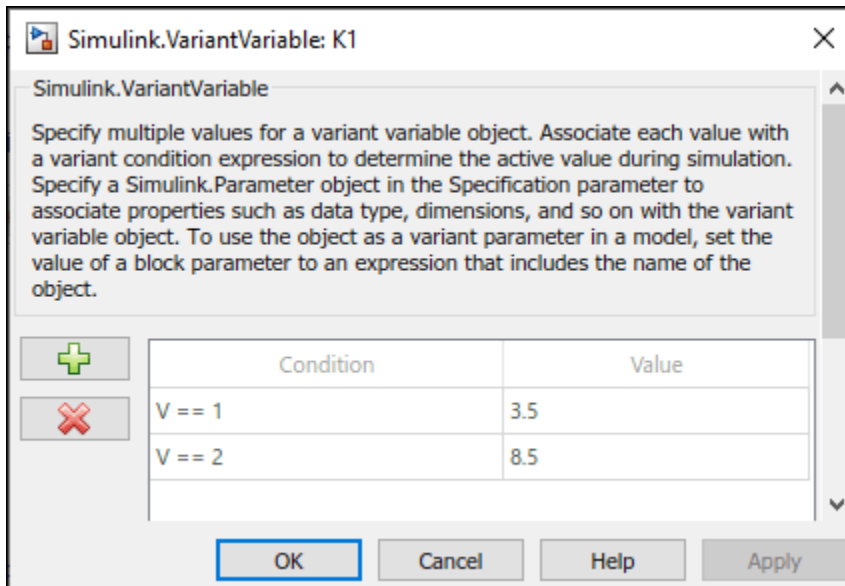

Condition	Value
V == 1	4.5000
V == 2	9.5000

```
Specification: ''
```

```
Bank: ''
```

Use `getChoice`, `setChoice`, `addChoice`, `removeChoice` to access, modify, add or remove choices

Once you successfully create the `Simulink.VariantVariable` objects, you can modify them by using the methods described in “Public Methods” or from the `VariantVariable` dialog box.

Activate one of the variant values by defining a control variable, *V*, and setting its value to 1 in a `Simulink.VariantControl` object.

```
V = Simulink.VariantControl('Value', 1, 'ActivationTime', 'update diagram')
```

```
V =
  VariantControl with properties:
      Value: 1
  ActivationTime: 'update diagram'
```

When you simulate the model, the condition `V == 1` evaluates to `true`. *K1* is assigned a value of 3.5 and *K2* is assigned a value of 8.5.

```
sim('slexVariantParameters')
```

If you change the value of *V* to 2, Simulink® sets the value of *K1* and *K2* to 4.5 and 9.5 during simulation. You can change the value of *V* using this command or from `Simulink.VariantControl` dialog box.

```
V.Value = 2;
sim('slexVariantParameters')
```

## Simulink.Parameter Type of Variant Control Variables for Code Generation of Variant Parameters

If you intend to generate code for a model containing variant parameters, specify variant control variables as `Simulink.Parameter` objects. `Simulink.Parameter` objects allow you to specify other attributes, such as data type and storage class, and control the appearance and placement of variant control variables in generated code.

- You can define a variant control variable of type `Simulink.Parameter` only in the base workspace or in a data dictionary. Defining `Simulink.Parameter` type of variant control variables in the mask or model workspace is not supported. For more information on storage locations for variant control variables, see “Storage Locations for Variant Control Variables (Operands) in Variant Parameters” on page 90-10.
- `Simulink.Parameter` objects within structures and that have data types other than `Simulink.Bus` objects are not supported.

Open the `slexVariantParameters` model.

```
open_system('slexVariantParameters')
```

In the MATLAB Editor, define a `Simulink.Parameter` object.

```
VSS_MODE = Simulink.Parameter;
VSS_MODE.Value = 1;
VSS_MODE.DataType = 'int32';
VSS_MODE.CoderInfo.StorageClass = 'Custom';
VSS_MODE.CoderInfo.CustomStorageClass = 'Define';
VSS_MODE.CoderInfo.CustomAttributes.HeaderFile = 'demo_macros.h';
```

Variant control variables defined as `Simulink.Parameter` objects can have any of the storage classes listed in “Storage Classes for Different Variant Activation Times” (Embedded Coder).

You can also convert a scalar variant control variable into a `Simulink.Parameter` object. For more information, see “Convert Variant Control Variables into Simulink.Parameter Objects” on page 12-82.

Specify the object as a variant control in `Simulink.VariantVariable` objects K1 and K2.

```
K1 = Simulink.VariantVariable('Choices',{V == 1, 3.5, 'V == 2', 8.5})
```

```
K1 =
VariantVariable with 2 choices:
```

Condition	Value
V == 1	3.5000
V == 2	8.5000

```
Specification: ''
```

```
Bank: ''
```

Use `getChoice`, `setChoice`, `addChoice`, `removeChoice` to access, modify, add or remove choices

```
K2 = Simulink.VariantVariable('Choices',{V == 1, 4.5, 'V == 2', 9.5})
```

```
K2 =
VariantVariable with 2 choices:
```

Condition	Value
V == 1	4.5000
V == 2	9.5000

```
Specification: ''
```

Bank: ''

Use `getChoice`, `setChoice`, `addChoice`, `removeChoice` to access, modify, add or remove choices

Once you successfully create the `Simulink.VariantVariable` objects, you can modify them by using the methods described in “Public Methods” or from the `VariantVariable` dialog box.

Activate one of the variant values by defining a control variable `V` and setting its value to `VSS_MODE` in a `Simulink.VariantControl` object.

```
V = Simulink.VariantControl('Value',VSS_MODE,'ActivationTime','code compile')
```

```
V =
  VariantControl with properties:
      Value: [1x1 Simulink.Parameter]
  ActivationTime: 'code compile'
```

When you simulate the model, the condition `V == 1` evaluates to `true`. `K1` is assigned a value of 3.5, and `K2` is assigned a value of 8.5.

```
sim('slexVariantParameters')
```

If you change the value of `VSS_MODE` to 2, Simulink® sets the value of `K1` and `K2` to 4.5 and 9.5 during simulation. You can change the value of `V` using this command or from `Simulink.VariantControl` dialog box.

```
VSS_MODE.Value = 2;
V.Value = VSS_MODE;
sim('slexVariantParameters')
```

Generate code from the model. For information on how to generate code, see “Generate Code Using Embedded Coder” (Embedded Coder)

The generated code contains both `Linear` and `Nonlinear` choices in preprocessor conditionals `#if` and `#elif` because of the code compile activation time. The variant control variable `V` is defined using a macro — `#define` directive — in the header file `demo_macros.h`. You can control the appearance and placement of `V` in the generated code and prevent optimizations from eliminating storage for `V` using the storage class property. For more information, see “Storage Classes for Different Variant Activation Times” (Embedded Coder).

```
% demo_macros.h
% /* Exported data define */
%
% /* Definition for custom storage class: Define */
% #define V      2      /* Referenced by:
%                       * '<Root>/Gain'
%                       * '<Root>/Gain1'
%                       */
% #endif              /* RTW_HEADER_demo_macros_h_ */
%
% /*
```

## Enumerated Types to Improve Code Readability of Variant Control Variables of Variant Parameters

Use enumerated types to give meaningful names to integers used as variant control values. For more information on enumerated type data, see “Use Enumerated Data in Simulink Models” on page 73-5.

In the MATLAB® Editor, define the classes that map enumerated values to meaningful names.

Open the `slexVariantParameters` model.

```
open_system('slexVariantParameters')
```

Specify the variant condition expressions `V == EngType.Small` and `V == EngType.Big` in Simulink.VariantVariable objects `K1` and `K2`.

```
K1 = Simulink.VariantVariable('Choices', {'V == EngType.Small',3.5,'V == EngType.Big',8.5})
```

```
K1 =
VariantVariable with 2 choices:
```

Condition	Value
<code>V == EngType.Big</code>	8.5000
<code>V == EngType.Small</code>	3.5000

```
Specification: ''
```

```
Bank: ''
```

Use `getChoice`, `setChoice`, `addChoice`, `removeChoice` to access, modify, add or remove choices

```
K2 = Simulink.VariantVariable('Choices', {'V == EngType.Small',4.5,'V == EngType.Big',9.5})
```

```
K2 =
VariantVariable with 2 choices:
```

Condition	Value
V == EngType.Big	9.5000
V == EngType.Small	4.5000

Specification: ''

Bank: ''

Use `getChoice`, `setChoice`, `addChoice`, `removeChoice` to access, modify, add or remove choices

Here, `EngType` is an integer-based enumeration class that is derived from the built-in data type, `int32`. The class has two enumeration values, `Small` and `Big`. These enumerated values have underlying integer values 1 and 2. In this example, the enumeration class is defined in the base workspace. You can choose to define the class in other storage locations as listed in “Storage Locations for Variant Control Variables (Operands) in Variant Blocks” on page 12-43.

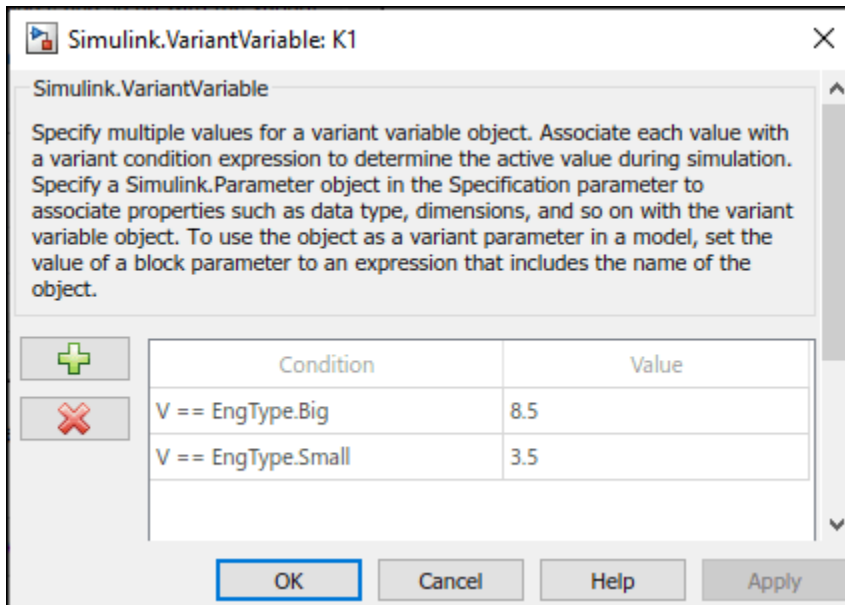

type `EngType.m`

```

classdef EngType < Simulink.IntEnumType
    enumeration
        Small (1)
        Big (2)
    end
    methods (Static)
        function retVal = addClassNameToEnumNames()
            % ADDCLASSNAMETOENUMNAMES Specifies whether to add the class name
            % as a prefix to enumeration member names in generated code.
            % Return true or false.
            % If you do not define this method, no prefix is added.
            retVal = true;
        end
    end
end
end

```

Once you successfully create the `Simulink.VariantVariable` objects, you can modify them by using the methods described in “Public Methods” or from the `VariantVariable` dialog box.

Activate one of the variant values by defining the control variable `V` and setting its value to `EngType.Small` in `Simulink.VariantControl` object `V`.

```
V = Simulink.VariantControl('Value',EngType.Small,'ActivationTime','code compile')
```

```
V =
  VariantControl with properties:
      Value: Small
  ActivationTime: 'code compile'
```

When you simulate the model, the condition `V == 1` evaluates to `true`. `K1` is assigned a value of 3.5, and `K2` is assigned a value of 8.5.

```
sim('slexVariantParameters')
```

If you change the value of `V` to 2, Simulink® sets the value of `K1` and `K2` to 4.5 and 9.5 during simulation. You can change the value of `V` using this command or from `Simulink.VariantControl` dialog box.

```
V.Value = 2
```

```
V =
  VariantControl with properties:
      Value: 2
  ActivationTime: 'code compile'
```

```
sim('slexVariantParameters')
```

The code that you generate using enumerated types contains the names of the values rather than integers.

```
% slexVariantParameters_private.h
% #if V == EngType_Big || V == EngType_Small
```

```

%      /* Variable: K1 Referenced by: '<Root>/Gain' */
%      #if V == EngType_Big
%          #define rtCP_Gain_K1                (8.5)
%      #elif V == EngType_Small
%          #define rtCP_Gain_K1                (3.5)
%      #endif
% #endif
%
% #if V == EngType_Big || V == EngType_Small
%      /* Variable: K2 Referenced by: '<Root>/Gain1' */
%      #if V == EngType_Big
%          #define rtCP_Gain1_K2              (9.5)
%      #elif V == EngType_Small
%          #define rtCP_Gain1_K2              (4.5)
%      #endif
% #endif
% #endif
% #endif                                /* RTW_HEADER_slexVariantParameters_private_h_ */

```

Note that for variant parameters with “startup” on page 12-68 activation time, only enumerations that are defined using these techniques are supported:

- Using the function `Simulink.defineIntEnumType`
- By subclassing built-in integer data types `int8`, `int16`, `int32`, `uint8`, or `uint16`, or by subclassing `Simulink.IntEnumType`

These enumerations are also supported when permanently stored in a Simulink® data dictionary. See “Enumerations in Data Dictionary” on page 79-14.

## Simulink.Variant Objects for Variant Condition Reuse of Variant Parameters

After identifying the variant values that your model requires, you can construct complex variant conditions to control the activation of your variant parameter values by defining variant conditions as `Simulink.Variant` objects. `Simulink.Variant` objects enable you to reuse common variant conditions across models and help you encapsulate complex variant condition expressions.

- You can define a variant control variable of type `Simulink.Variant` only in the base workspace or in a data dictionary. Defining `Simulink.Variant` type of variant control variables in the mask or model workspace is not supported. For more information on storage locations for variant control variables, see “Storage Locations for Variant Control Variables (Operands) in Variant Parameters” on page 90-10.
- `Simulink.Variant` within structures are not supported.

Open the `slexVariantParameters` model.

```
open_system('slexVariantParameters')
```

In the MATLAB® Editor, encapsulate variant control expressions as `Simulink.Variant` objects.

```
LinearController=Simulink.Variant('V==1');
NonLinearController=Simulink.Variant('V==2');
```

Specify the `Simulink.Variant` objects as the variant controls in a `Simulink.VariantVariable` objects K1 and K2.

```
K1 = Simulink.VariantVariable('Choices',{'LinearController',3.5,'NonLinearController',8.5})
```

```
K1 =  
VariantVariable with 2 choices:
```

Condition	Value
LinearController	3.5000
NonLinearController	8.5000

```
Specification: ''
```

```
Bank: ''
```

Use `getChoice`, `setChoice`, `addChoice`, `removeChoice` to access, modify, add or remove choices

```
K2 = Simulink.VariantVariable('Choices',{'LinearController',4.5,'NonLinearController',9.5})
```

```
K2 =  
VariantVariable with 2 choices:
```

Condition	Value
LinearController	4.5000
NonLinearController	9.5000

```
Specification: ''
```

```
Bank: ''
```

Use `getChoice`, `setChoice`, `addChoice`, `removeChoice` to access, modify, add or remove choices

Once you successfully create the `Simulink.VariantVariable` objects, you can modify them by using the methods described in “Public Methods” or from the `VariantVariable` dialog box.

Activate one of the variant values by defining a `Simulink.VariantControl` object `V` and setting its value to 1.

```
V = Simulink.VariantControl('Value',1,'ActivationTime','update diagram')
```

```
V =  
VariantControl with properties:  
    Value: 1  
    ActivationTime: 'update diagram'
```

When you simulate the model, the condition `V == 1` evaluates to `true`. `K1` is assigned a value of 3.5, and `K2` is assigned a value of 8.5.

```
sim('slexVariantParameters')
```

If you change the value of `V` to 2, Simulink® sets the value of `K1` and `K2` to 4.5 and 9.5 during simulation. You can change the value of `V` using this command or from `Simulink.VariantControl` dialog box.

```
V.Value = 2;  
sim('slexVariantParameters')
```

Using this approach, you can develop complex variant condition expressions that are reusable.

## Change Active Values and Activation Time of Variant Parameters

This example shows how to change the active values and activation time of variant parameters in a Simulink® model.

In this example, you will learn how to:

- Change active values of variant parameters using variant condition expressions.
- Change the time of determining active values using variant activation time.

### Overview of Variant Parameters

Variant parameters can have multiple values. Each value of the variant parameter is associated with a variant control expression. During simulation, the value of a variant parameter associated with the condition that evaluates to `true` is the active value of the variant parameter. The value associated with the condition that evaluates to `false` is the inactive value of the parameter. To switch between the active values, change the value of the variant control variable. For more information, see “Use Variant Parameters to Reuse Block Parameters with Different Values” on page 90-2.

### Prerequisite

Before you start with this example, we recommend you complete “Create a Simple Variant Parameter Model” on page 90-5.

### Explore the Model

1. Open the model.

```
open_system('slexVariantParameters')
```

### Variant Parameters with Different Activation Times

Copyright 2020-2021 The MathWorks, Inc.

In this model, the **Gain** parameter of the Gain blocks are variant parameters that are specified as `Simulink.VariantVariable` objects K1 and K2. The objects are defined in the `slexVariantParameterData.m` file.

2. Open the `slexVariantParameterData.m` file. The file is loaded in the **PostLoadFcn** callback of **Modeling > Model Settings > Model Properties**.

In the file, the objects K1 and K2 have multiple values associated with variant control expressions `V==1` and `V==2`. In addition to the value, you can specify attributes such as dimension, data type, and so on for each object using the “**Specification**” parameter of the object.

- **Variant control variable:** The value of the `Simulink.VariantControl` object `V` determines which values of K1 and K2 are active during simulation. If `V==1` evaluates to `true`, the values associated with `V==1` become active, and all the values associated with `V==2` become inactive. The active value of K1 is assigned to the **Gain** parameter of the Gain1 block, and the active value of K2 is assigned to the **Gain** parameter of the Gain2 block. Similarly, when `V==2` evaluates to `true`, all the values associated with `V==1` become inactive, and all the values associated with `V==2` become active. For more information on variant controls, see “Introduction to Variant Controls” on page 12-37.
- **Variant activation time:** Simulink can set active value of the variant parameter **Gain** at different stages of the simulation and code generation workflow. Based on the stage you specify as the variant activation time, Simulink determines if the generated code must contain only the active values or both active and inactive values of K1 and K2. The variant activation time also determines whether to analyze all the values of K1 and K2 for incompatibilities in signal attributes.

In this example, the value of `V` is specified as `1`, and the variant activation time is specified as `update diagram`. When you simulate this model, `V==1` evaluates to `true`. The value of K1 is set to `3.5` and the value of K2 is set to `4.5`. Simulink determines the active values during update diagram. When you generate a code from this model, the code contains only the active values of K1 and K2.

### Set Active Choice of Variant Parameters

The value of the variant control variable determines the active value of variant parameters during simulation. To switch the active values, change the value of variant control variable.

1. On the Simulink toolstrip, click **Run**. During simulation, `V==1` evaluates to `true`. As the values `3.5` and `4.5` are associated with `V==1`, these values are assigned to K1 and K2, respectively. Subsequently, the values are assigned to the **Gain** parameters of the Gain blocks.
2. To change the value of the **Gain** parameters, change the value of `V` to `2`, then simulate the model again.

```
V.Value = 2;
```

During simulation, all the values associated with `V==2` are assigned to K1 and K2. Subsequently, the values are assigned to the **Gain** parameters of the Gain blocks.

### Set Time to Determine Active Value of Variant Parameters

Simulink can set active value of the variant parameters at different stages of the simulation and code generation workflow. Based on the stage you specify as the variant activation time, Simulink determines if the generated code must contain only the active values or both active and inactive values of variant parameters. The variant activation time also determines whether to analyze all the values the variant parameters for incompatibilities in signal attributes.

For example, to specify the activation time of `V` as `update diagram`, type this command in the MATLAB® Command Window. Then, simulate the model again.

```
V.ActivationTime = 'update diagram';
```

Simulink sets the active values of K1 and K2 during update diagram before the propagation of signal attributes. The signal attributes such as dimension and data type are not analyzed for consistency across the model. The generated code contains only the active value of K1 and K2. For information on other activation times, see “Activate Variant During Different Stages of Simulation and Code Generation Workflow” on page 12-65.

## Improve Code Readability of Variant Parameters Using Enumerated Types

You can use enumerated types to improve code readability of variant control values in variant parameters. “Simulink Enumerations” on page 73-2 improve readability because enumerated types of variant controls values are represented as meaningful names instead of integers in the generated code.

You can define enumerated types of variant control values in the storage locations listed in “Storage Locations for Variant Control Variables (Operands) in Variant Parameters” on page 90-10.

For variant parameters with `startup` activation time, only enumerations that are defined using these techniques are supported:

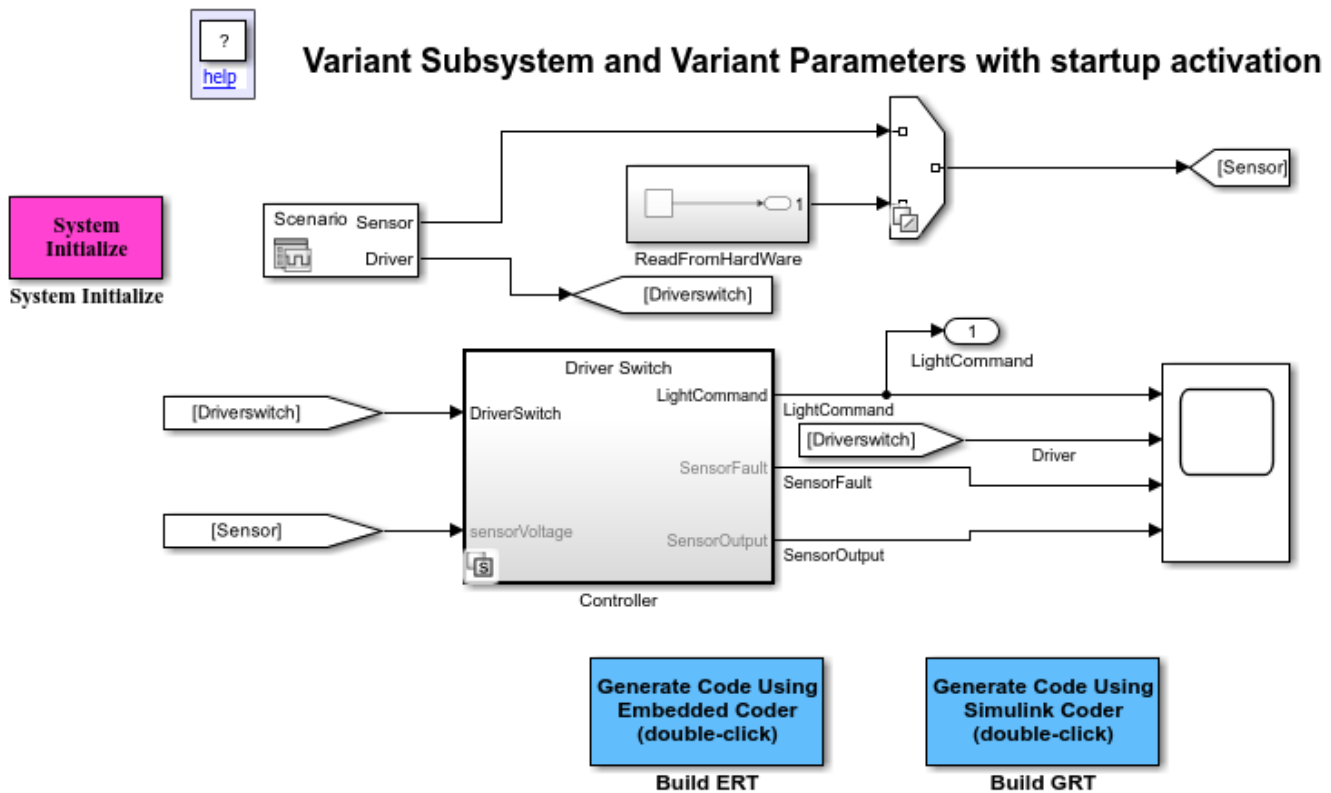

- Using the function `Simulink.defineIntEnumType`
- By subclassing built-in integer data types `int8`, `int16`, `int32`, `uint8`, or `uint16`, or by subclassing `Simulink.IntEnumType`

These enumerations are also supported when permanently stored in a Simulink® data dictionary. See “Enumerations in Data Dictionary” on page 79-14.

### Model

Open the model `slexVariantSystems`.

```
open_system('slexVariantSystems')
```

Copyright 2021-2022 The MathWorks, Inc.

This model represents a fog lamp controller system that operates in driver control mode and in sensor connected mode. In driver control mode, the intensity of the fog lamps is controlled by the driver. In sensor connected mode, the sensor adjusts the intensity of different types of fog lamps based on the intensity of ambient light in the external environment.

In this example, `lightVolt` is a variant parameter that represents fog lamp intensities. The sensor voltage from Signal Editor block is the intensity of ambient light in the external environment. The `LIGHT_TYPE` is the variant control variable that represents different types of fog lamps. `LIGHT_TYPE` enables you to switch between fog lamp intensities, `lightVolt`, for the given intensity of ambient light. `LIGHT_TYPE` can have two values, `LightType.Type1` and `LightType.Type2`.

When `LIGHT_TYPE == LightType.Type1` evaluates to `true`, a fog lamp intensity from `[0 0 0 0.7 0.7]` that corresponds to the given ambient light becomes active. When `LIGHT_TYPE == LightType.Type2` evaluates to `true`, a fog lamp intensity from `[0 0 0 1 1]` that corresponds to the given ambient light becomes active. For example, if the ambient light has an intensity 4 and the type of the fog lamp is `Type1`, the fog lamp is illuminated with intensity 0.7. Similarly, if the ambient light has an intensity 4 and the type of the fog lamp is `Type2`, the fog lamp is illuminated with intensity 1. For more information on this fog lamp controller system, see “Run Iterative Simulations Without Recompiling Model for Variant Systems Using Fast Restart” on page 12-211.

## Fog Lamp Types in a Enumeration Class

In this example, the enumeration `LightType`, saved in `LightType.m`, derives from the built-in class `Simulink.IntEnumType`. It defines two enumeration members, `Type1` and `Type2`, with underlying integer values 1 and 2.

type `LightType.m`

```
classdef LightType < Simulink.IntEnumType
% ControllerType - enumeration class used by
% slexVariantSystems

% Copyright 2021-2022 The MathWorks, Inc.

    enumeration
        Type1 (1)
        Type2 (2)
    end

    methods (Static)
        function val = getDataScope()
            val = 'Imported';
        end

        function val = getHeaderFile()
            val = 'LightType.h';
        end
    end
end
```

## Simulate Fog Lamp Controller for Different Types of Fog Lamps in Sensor Connected Mode

1. In the MATLAB® Command Window:

a. Set `CTRL_MODE` to 1 to activate the Sensors Connected.

```
CTRL_MODE.Value = int32(1)
```

```
CTRL_MODE =
```

```
Parameter with properties:
```

```
Value: 1
CoderInfo: [1x1 Simulink.CoderInfo]
Description: ''
DataType: 'int32'
Min: []
Max: []
Unit: ''
Complexity: 'real'
Dimensions: [1 1]
```

b. Set `LIGHT_TYPE` to `LightType.Type1` to represent `Type1` type of fog lamps.

```
LIGHT_TYPE.Value = LightType.Type1
```

```

LIGHT_TYPE =
  VariantControl with properties:
      Value: Type1
      ActivationTime: 'startup'

```

Check that the activation time of the LIGHT\_TYPE is set to startup.

2. Run the simulation. Use the Scope block to visualize the results. For details about the signals that the Scope block plots, see the **Model Inputs and Outputs** section of “Run Iterative Simulations Without Recompiling Model for Variant Systems Using Fast Restart” on page 12-211.

3. Change the value of LIGHT\_TYPE to LightType.Type2 and run the simulation again. Use the Scope to visualize the results.

```

LIGHT_TYPE.Value = LightType.Type2

```

```

LIGHT_TYPE =
  VariantControl with properties:
      Value: Type2
      ActivationTime: 'startup'

```

### Generate Code for Enumerated Type of fog lamps

Before you generate code from the model, make sure that you have write permission in your current folder.

To generate code using Simulink® Coder™, the configuration parameters in **Model Settings > Code Generation** are set as:

1. The **System target file** is specified as grt.
2. On the **Custom Code** pane, the header file is specified as ReadLightControllerValues.h and the source file is specified as ReadLightControllerValues.c. This setting inserts the ReadLightControllerValues() function in the model source file, slxVariantSystems.c, of the generated code.
3. In the **Apps** gallery of the model toolstrip, click **Simulink Coder**. On the **C Code** tab, click **Generate Code**. For more information, see “Generate Code Using Simulink Coder” (Simulink Coder).

```

slbuild('slxVariantSystems')

### Starting build procedure for: slxVariantSystems
### Successful completion of build procedure for: slxVariantSystems

```

### Review Generated Code

1. In the **C Code** tab, select **Open Report**.

2. From the **Generated Code** pane of the report, select the `slexVariantSystems.c` file. The `slexVariantSystems_initialize` function contains the `ReadLightControllerValues()` function to read the values of `CTRL_MODE` and `LIGHT_TYPE` for determining the mode of operation and the type of the fog lamp. The value of `LIGHT_TYPE` read using the function is compared to the enumerated names `Type1` and `Type2` that maps to the values 1 and 2 of the enumeration `LightType`. Based on the condition that evaluates to `true`, the set of fog lamp intensities to activate is determined.

```
void slexVariantSystems_initialize(void)
{
...
/* user code (Initialize function Body) */

/* System '<Root>' */
ReadValueOfVariantControls();

/* Variant Parameters startup activation time */
if (LIGHT_TYPE == Type1) {
    for (i = 0; i < 5; i++) {
        slexVariantSystems_P.lightVolt[i] = (real_T)tmp[i];
    }
} else if (LIGHT_TYPE == Type2) {
    for (i = 0; i < 5; i++) {
        slexVariantSystems_P.lightVolt[i] = tmp_0[i];
    }
}
...
}
```

## Compile Code Conditionally for All Values of Variant Parameters with Same and Different Dimensions

This example shows how to generate a C code that contains all the active and inactive values of variant parameters. The values are enclosed in preprocessor conditionals `#if` and `#elif` that enables you to compile the code conditionally based on the condition that evaluates to `true`.

In this example, you will learn how to:

- Use storage classes to control the appearance, placement, definition, and declaration of variant parameter variables in the generated code.
- Use symbolic dimensions to propagate varying dimensions of variant parameters as symbols in the generated code. Representing dimensions as symbols enables the code to flexibly switch between dimension values for the given active choice without regenerating code every time you change the value of the variant control variable.

### Overview of Variant Parameters

Variant parameters can have multiple values. Each value of the variant parameter is associated with a variant condition expression. During simulation, the value of the variant parameter associated with the condition that evaluates to `true` is the active value of that parameter. The value associated with the condition that evaluates to `false` is the inactive value of that variant parameter. For more information, see “Use Variant Parameters to Reuse Block Parameters with Different Values” on page 90-2.

In the generated code, the active and inactive values of the variant parameters are enclosed in C preprocessor conditionals `#if` and `#elif`. The preprocessor conditionals enable you to conditionally compile the code for a given active value. You generate the code only once. You can then choose the active choice of variant parameters by changing the value of the variant control variable before running the code. You do not need to regenerate the code for different variant parameter choices.

- **Representation of variant parameter variables:** The values are represented as inline or tunable variables in the generated code. The representation is determined by the storage class that you specify for the variant parameters in the model. The variant parameters with default storage class `Auto` are represented as inline variables. The variant parameters with storage class other than `Auto` are represented as tunable variables in the generated code. For more information on how different storage classes are represented in the generated code, see “Choose Storage Class for Controlling Data Representation in Generated Code” (Simulink Coder).
- **Representation of variant parameter dimensions:** If the values of a variant parameter have different dimensions, then the dimensions are represented as symbols. These symbols propagate throughout the model during simulation and then go into the generated code. To represent dimensions as symbols, you must set **Modeling > Model Settings > Diagnostics > Advanced Parameters > Allow symbolic dimension specification** to on. For more information on symbolic dimensions, see “Allow symbolic dimension specification”.

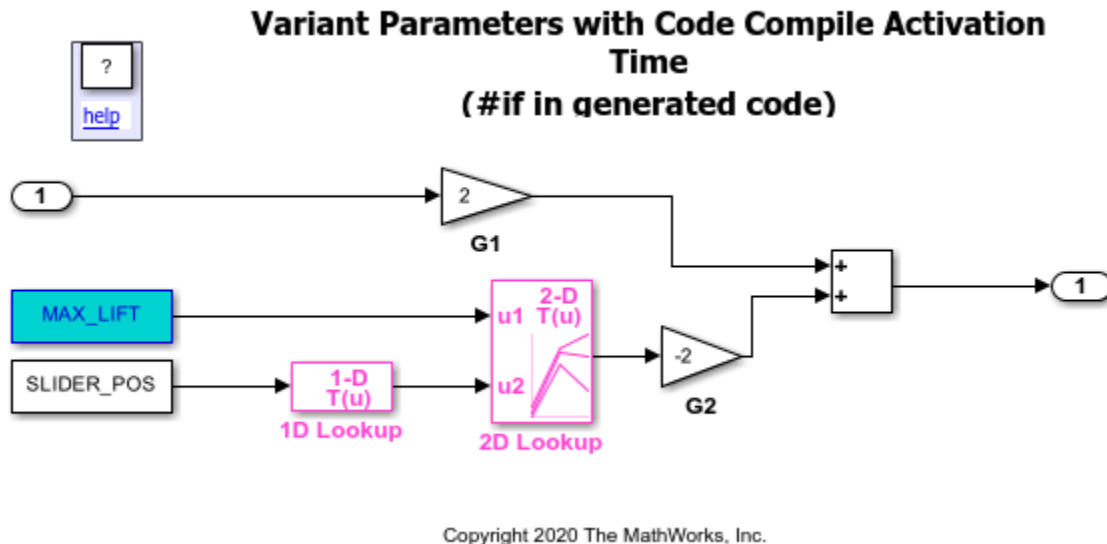

### Prerequisite

Before you start this example, we recommend you complete “Options to Represent Variant Parameters in Generated Code” (Embedded Coder).

## Explore the model

1. Open the model.

```
open_system('slexVariantParametersCC')
```

The model contains blocks that have variant parameters that are specified as `Simulink.VariantVariable` objects. The objects are defined in the `slexVariantParameterCCData.m` file.

- **Constant:** The **Constant** parameters of the Constant blocks are variant parameters. The parameters are specified as variant variable objects `MAX_LIFT` and `SLIDER_POS`.
- **Table data** and **Breakpoint sets:** The **Table data** and **Breakpoint sets** of the n-D Lookup Table blocks are variant parameters. The parameters are specified as variant variable objects `T1Break1`, `T1Data`, `T2Break`, and `T2Data`.

2. Open the `slexVariantParameterData.m`. Observe these settings in the file:

- In this file, `VCtrl` is the `Simulink.VariantControl` object that determines the active value of the variant parameter objects `MAX_LIFT`, `SLIDER_POS`, `T1Break1`, `T1Data`, `T2Break`, and `T2Data`. The value of `VCtrl` is set to 1, and its activation time is specified as `code compile`. During simulation, the condition `VCtrl==1` evaluates to true. All the values associated with `VCtrl==1` become active, and the values associated with `VCtrl==2` become inactive. When you generate a code from this model, all the active and inactive values are enclosed in preprocessor conditionals `#if` and `#elif`.
- The variant parameter objects `MAX_LIFT` and `SLIDER_POS` have scalar numeric values with a default storage class `Auto`. When you generate the code, the values of the **Constant** parameters are inlined as macros. The variant parameter objects `T1Break1`, `T1Data`, `T2Break`, and `T2Data` are of `Simulink.Parameter` type with storage class specified as `ExportedGlobal`. When you generate the code, the values are represented by symbolic names as tunable variables in the generated code.

- The variant parameter objects T1Break1 and T1Data have values with different dimensions. When you generate the code, the dimensions of these parameters are represented as symbols.

### Set Active Choice of Variant Parameters

1. On the Simulink® toolstrip, click **Run**. During simulation, `VCtrl==1` evaluates to `true`. All the values associated with `VCtrl==1` are assigned to the corresponding variant variable objects and, subsequently, to the variant parameters that use these objects. For example, when `VCtrl==1` evaluates to `true`, the value of `MAX_LIFT` is set to `10`. As the **Constant** parameter of the `Constant1` block is set to `MAX_LIFT`, the value of the **Constant** parameter is also set to `10`.

2. To change the active values, change the value of `VCtrl` to `2`, then simulate the model again.

```
VCtrl.Value = 2;
```

During simulation, all the values associated with `VCtrl==2` are assigned to the variant variable objects, and those values are then assigned to the variant parameters using those objects.

### Generate Code Using Embedded Coder

To generate code for variant parameters that have values with different dimensions, use Embedded Coder.

Before you generate code from the model, make sure that you have write permission in your current folder. To generate code, in the **Apps** gallery of the model toolstrip, click **Embedded Coder**. On the **C Code** tab, click **Build**. For more information, see “Generate Code Using Embedded Coder” (Embedded Coder).

### Review Inline and Tunable Parameters in Generated Code

1. In the **C Code** tab, select **Open Report**.

2. Select the `slexVariantParametersCC_types.h` file from the **Generated Code** pane of the report. This file defines the value of the variant control variable `VCtrl` as `1`. The variant control variable determines the active value of variant parameters.

```
#ifndef VCtrl
#define VCtrl          1
#endif
```

3. Select the `slexVariantParametersCC_private.h` file. This file includes macros (`#define`) corresponding to all the values of the variant parameters with default storage class `Auto`. The active values of variant parameters `MAX_LIFT` and `SLIDER_POS` are enclosed in the C preprocessor conditional statement (`#if`) on the macros `rtCP_Constant_MAX_LIFT` and `rtCP_Constant1_SLIDER_POS`.

```
#if VCtrl == 1 || VCtrl == 2
/* Variable: MAX_LIFT
 * Referenced by: '<Root>/Constant'
 */
#if VCtrl == 1
#define rtCP_Constant_MAX_LIFT      (10.0)
#elif VCtrl == 2
#define rtCP_Constant_MAX_LIFT      (20.0)
#endif
#endif
```

```

#if VCtrl == 1 || VCtrl == 2
/* Variable: SLIDER_POS
 * Referenced by: '<Root>/Constant1'
 */
#if VCtrl == 1
#define rtCP_Constant1_SLIDER_POS      (0.0)
#elif VCtrl == 2
#define rtCP_Constant1_SLIDER_POS      (0.5)
#endif
#endif

```

4. Select the `slexVariantParametersCC.h` file. This file includes symbolic names for all the values of the variant parameters with storage class set to `ExportGlobal`. The variables are defined as extern variables.

```

/* Exported Global Parameters
#if VCtrl == 1 || VCtrl == 2
extern real_T T1Break[T1Break_dim0]; /* Variable: T1Break
                                     * Referenced by: '<Root>/1D Lookup'
                                     */
#endif

#if VCtrl == 1 || VCtrl == 2
extern real_T T1Data[T1Data_dim0]; /* Variable: T1Data
                                     * Referenced by: '<Root>/1D Lookup'
                                     */
#endif

#if VCtrl == 1 || VCtrl == 2
extern real_T T2Break[3];          /* Variable: T2Break
                                     * Referenced by: '<Root>/2D Lookup'
                                     */
#endif

#if VCtrl == 1 || VCtrl == 2
extern real_T T2Data[9];          /* Variable: T2Data
                                     * Referenced by: '<Root>/2D Lookup'
                                     */
#endif

```

5. Select the `slexVariantParametersCC.c` file. All the values of variant parameters are enclosed in C preprocessor conditional statements `#if` and `#elif`. When you compile this code, Simulink evaluates the preprocessor conditionals and compiles the code only for the active values of variant parameters. You can then specify a different value for `VCtrl` and recompile the same code for any other active values of variant parameters.

```

/* Exported block parameters */
#if VCtrl == 1

real_T T1Break[T1Break_dim0] = { -5.0, -4.0, -3.0, -2.0, -1.0, 0.0, 1.0,
2.0, 3.0, 4.0, 5.0 }; /* Variable: T1Break
                       * Referenced by: '<Root>/1D Lookup'
                       */

real_T T1Data[T1Data_dim0] = { -0.99990920426259511, -0.999329299739067,
-0.99505475368673046, -0.9640275800758169, -0.76159415595576485, 0.0,
0.76159415595576485, 0.9640275800758169, 0.99505475368673046,
0.999329299739067, 0.99990920426259511 };

```

```

        /* Variable: T1Data
        * Referenced by: '<Root>/1D Lookup'
        */

real_T T2Break[3] = { -10.0, 0.0, 10.0 } ;
        /* Variable: T2Break
        * Referenced by: '<Root>/2D Lookup'
        */

real_T T2Data[9] = { 4.0, 16.0, 10.0, 5.0, 19.0, 18.0, 6.0,
20.0, 23.0 } ;
        /* Variable: T2Data
        * Referenced by: '<Root>/2D Lookup'
        */

#elif VCtrl == 2

real_T T1Break[T1Break_dim0] = { -10.0, -9.0, -8.0, -7.0, -6.0, -5.0,
-4.0, -3.0, -2.0, -1.0, 0.0, 1.0, 2.0, 3.0, 4.0, 5.0, 6.0, 7.0, 8.0,
9.0, 10.0 } ;
        /* Variable: T1Break
        * Referenced by: '<Root>/1D Lookup'
        */

real_T T1Data[T1Data_dim0] = { -0.99999999587769273, -0.999999969540041,
-0.99999977492967584, -0.99999833694394469, -0.99998771165079559,
-0.99990920426259511, -0.999329299739067, -0.99505475368673046,
-0.9640275800758169, -0.76159415595576485, 0.0, 0.76159415595576485,
0.9640275800758169, 0.99505475368673046, 0.999329299739067,
0.99990920426259511, 0.99998771165079559, 0.9999833694394469,
0.99999977492967584, 0.999999969540041, 0.99999999587769273 } ;
        /* Variable: T1Data
        * Referenced by: '<Root>/1D Lookup'
        */

real_T T2Break[3] = { -20.0, 0.0, 20.0 } ;
        /* Variable: T2Break
        * Referenced by: '<Root>/2D Lookup'
        */

real_T T2Data[9] = { 8.0, 32.0, 20.0, 10.0, 38.0, 36.0, 12.0,
40.0, 46.0 } ;
        /* Variable: T2Data
        * Referenced by: '<Root>/2D Lookup'
        */

#endif

```

In this file, calls to the step function of each variant are conditionally compiled. In the step function, the macros and symbol names of variant parameters are used to form the equation.

```

/* Model step function */

void slxVariantParameters_step(void)
{
    slxVariantParametersCC_Y.Out1 = look2_binlx(rtCP_Constant_MAX_LIFT,
look1_binlx(rtCP_Constant1_SLIDER_POS, T1Break, T1Data, T1Data_dim0
- 1U), T2Break, T2Break, T2Data,
slxVariantParametersCC_ConstP.udLookup_maxIndex, 3U) * -2.0 + 2.0 *
slxVariantParametersCC_U.In1;
}

```

### Review Dimension Symbol in Generated Code

Select the `slexVariantParametersCC.c` file from the **Generated Code** pane of the report. In this file, the dimensions of variant parameters `T1Break` and `T1Data` are represented as symbols `T1Break_dim0` and `T1Data_dim0` and are enclosed in C preprocessor conditional statements `#if` and `#elif`. When you compile this code, Simulink evaluates the preprocessor conditionals and preserves the code only for the active values of variant parameters. If you specify the value of `VCtrl` as 1, the condition `VCtrl == 1` evaluates to `true`, and the values enclosed in `V == 1` becomes active during code compilation. You can then specify a different value for `VCtrl` and recompile the same code for any other active values of `T1Break` and `T1Data`.

## Run Executable for Different Variant Parameter Values Without Recompiling Code

This example shows how to generate an executable that runs for different set of variant parameter values without needing to recompile the code for each set of values.

In this example, you build an executable that represents the step response of a linear system with PID controller. In the executable, the PID parameters, proportional gain and integral gain, are specified as variant parameters that have multiple values to cater to multiple requirements. Each value is associated with a variant control expression. When you run the executable, Simulink® evaluates the condition expressions. Based on the condition expression that evaluates to `true`, all the gain parameter values associated with that condition expression becomes active and the executable runs only for that set of gain values. You can then change the value of the variant control variable to run the executable for different set of gain parameter values. You are not required to recompile the code to build the executable for a different set of gain parameter values.

### Overview of Variant Parameters

Variant parameters can have multiple values. Each value of the variant parameter is associated with a variant condition expression. During simulation, the value of the variant parameter associated with the condition that evaluates to `true` is the active value of that parameter. The value associated with the condition that evaluates to `false` is the inactive value of that variant parameter. For more information, see “Use Variant Parameters to Reuse Block Parameters with Different Values” on page 90-2.

The variability and the representation of variant parameters in the generated code depends on the “ActivationTime” and the “Specification” property you specify. The activation time determines whether to include only active choice or both active and inactive choices in the code. The storage class determines whether to represent the parameters as inline or tunable variables. For more information, see “Options to Represent Variant Parameters in Generated Code” (Embedded Coder).

If you specify the activation time as `startup`, the generated code includes both active and inactive values of variant parameters. The values are enclosed in regular `if` conditions of the model initialize function of the code. When you run an executable that is built from the code, the `if` conditions are conditionally executed at the start of the execution. Based on the condition that evaluates to `true`, the executable determines the active values of the variant parameters. If you include all the values in the executable, then you do not need to recompile the code every time you change the value of the variant control variable. You build the executable only once. You can then change the value of the variant control variable and then run the executable for a different set of active values.

### Prerequisite

Before you start this example, we recommend you complete “Options to Represent Variant Parameters in Generated Code” (Embedded Coder).

### Explore the model

Open the model.

```
mdl = 'slexVariantParametersStartup';  
open_system(mdl)
```

## Variant Parameters with startup Activation Time (if in generated code)

Copyright 2021 The MathWorks, Inc.

The PID Controller block has two variant parameters, **Proportional(P)** and **Integral(I)**. The parameters are specified as `Simulink.VariantVariable` objects `Kp` and `Ki`. `Kp` and `Ki` have multiple values and are associated with a `Simulink.VariantControl` object `VCtrl`, as specified in the `slexVariantParameterGain.m` file. In this file, the activation time of `VCtrl` is specified as `startup`. So, the executable that you build from this model determines the active value of `Kp` and `Ki` at the start of its execution by reading the value of `VCtrl` from the `slexVariantParametersStartup_VCtrl.txt` file. Since, the value of `VCtrl` is specified as 1, the executable calculates the step response for the values associated with `VCtrl == 1`. To calculate the step response for a different value of `VCtrl`, change the value of `VCtrl` in the `slexVariantParametersStartup_VCtrl.txt` file and run the executable again.

### Build and Review the Generated Code With Regular `if` Conditions and `utAssert` Function

Before you generate code and build executable from the model, you first check that you have write permission in your current folder.

1. On the Simulink toolstrip, on the **Apps** tab, click **Embedded Coder**. On the **C Code** tab, click **Build**. For more information, see “Generate Code Using Embedded Coder” (Embedded Coder).

The code generator builds the executable, generates the **Code Generation Report**, and places the executable in the working folder. On Windows®, the executable is `slexVariantParametersStartup.exe`. On Linux®, the executable is `slexVariantParameterStartup`. Alternatively, enter this command in the MATLAB® Command Window to build the executable file.

```
slbuild mdl;

Build Summary

Top model targets built:

Model	Action	Rebuild Reason
slxVariantParametersStartup	Code generated and compiled.	Code generation information file does

1 of 1 models built (0 models already up to date)  
Build duration: 0h 0m 13.84s

2. On the **C Code** tab, select **Open Report**.

3. Select the `slxVariantParametersStartup.c` file. In this file, the model initialize function includes:

a. Symbolic names for all the values of `Kp` and `Ki` enclosed in regular `if` conditions. These `if` conditions are evaluated when you run the executable.

```

if (get_VCtrl() == 1)
{
    Ki = 4.5;
    Kp = 0.15;
}
else if (get_VCtrl() == 2)
{
    Ki = 4.0;
    Kp = 0.5;
}
else if (get_VCtrl() == 3)
{
    Ki = 3.5;
    Kp = 0.75;
}
else if (get_VCtrl() == 4)
{
    Ki = 3.0;
    Kp = 1.0;
}

```

b. The `utAssert` function to ensure that at least one variant condition evaluates to `true` when running the executable.

```
utAssert((get_VCtrl() == 1) || (get_VCtrl() == 2) || (get_VCtrl() == 3) || (get_VCtrl() == 4));
```

4. In the `model_step` function, the symbol names of `Kp` and `Ki` are used to form the equation.

```

void slxVariantParameters_step(void)
{
    ...
    slxVariantParametersStartup_Y.Out1 = 0.5 *
    slxVariantParametersStartup_DW.DiscreteTransferFcn_states[1];

```

```
Add = (real_T)!(slxVariantParametersStartup_M->Timing.t[0] < 1.0) -slxVariantParametersStartup
```

```
rtb_FilterCoefficient = (0.0 * Add -  
slexVariantParametersStartup_DW.Filter_DSTATE) * 100.0;  
  
slexVariantParametersStartup_B.Sum = (Kp * Add +

### Set Active Values of Variant Parameters at Model Startup Stage

Identify the version of MATLAB® software on your machine. `ispc` returns logical 1 (true) if the version of MATLAB® software is for the Microsoft® Windows® platform. Otherwise, it returns logical 0 (false). On Windows®, the executable is `slexVariantParametersStartup.exe`. On Linux®, the executable is `slexVariantParameterStartup`. To run the generated executable, enter this command in the MATLAB Command Window.

```
if ispc  
exeName = [mdl, '.exe'];  
else  
exeName = ['./', mdl];  
end  
system(exeName);  
  
** created slexVariantParametersStartup.mat **
```

At the start of the execution, the executable invokes the model initialize function. The executable reads the value of `VCtrl` from the `slexVariantParametersStartup_VCtrl.txt` file to evaluate the `if` conditions in the function. Since the value of `VCtrl` is set to 1 in the `slexVariantParametersStartup_VCtrl.txt` file, the `if` condition for `VCtrl == 1` evaluates to true. The generated executable is conditionally run for the PID gain parameter values that are associated with `VCtrl == 1` and creates a `slexVariantParametersStartup.mat` MAT-file as an output. The MAT-file contains values for the variables `rt_tout` and `rt_yout`, where `rt_yout` represents the linear step response at the output block `Out1` for each time step `rt_tout`.

You can load the variables from the MAT-file by typing this command:

```
load slexVariantParametersStartup.mat;
```

To plot the linear step response, use this function:

```
plot(rt_tout, rt_yout.signals.values, 'x-');
```

Now, change the value of `VCtrl` in the `slexVariantParametersStartup_VCtrl.txt` file to 2. Run the executable again to observe the change in the step response.

### Set Different Active Values for Variant Parameters Without Recompiling Code

The `slexVariantStartup_script.m` script implements the logic to plot the linear step response for different values of proportional gain and integral gain parameters by changing the value of the `VCtrl` using a `for` loop.

When you run the script:

In the first iteration, the executable runs and the model initialize function is invoked. The executable reads the value of `VCtrl` as 1 from the `slexVariantParametersStartup_VCtrl.txt` file to evaluate the `if` conditions in the model initialize function. The condition `VCtrl == 1` evaluates to `true`, the proportional and integral gain values that are associated with `VCtrl == 1` becomes active. The executable calculates the step response for those values and creates a `slexVariantParametersStartup.mat` MAT-file that contains the step response calculated for each time step.

In the next iteration, the value of `VCtrl` is increased to 2. The executable calculates the step response for the associated values and appends the newly calculated step response to the MAT-file.

Similarly, the executable calculates the step response for values associated with conditions `VCtrl == 3` and `VCtrl == 4`.

The script plots the linear step response as shown.

```
run slexVariantParameters_script.m;
```

```

## Reuse Variant Parameter Values from Handwritten Code Using Simulink.Parameter Variables

This example shows how to use `Simulink.Parameter` variables to generate a code that imports variant parameter values from your existing code. Importing variant parameter values allows you to reuse the values that your existing code defines. You can then integrate and compile the generated and existing code into a single executable. You can choose to generate a code that imports variant parameter values at the beginning of code compile, simulation-loop, or model startup phases of simulation and code generation workflows based on the activation time you specify. For more information, see “Activate Variant During Different Stages of Simulation and Code Generation Workflow” on page 12-65.

### Limitations

- When you use `Simulink.Parameter` variables as values in a variant parameter, corresponding properties of all the `Simulink.Parameter` variables must be the same. Only the values of `Simulink.Parameter` variables can vary.
- `Simulink.Parameter` variables as values in a variant parameter can be defined only in the base workspace and data dictionary. Defining `Simulink.Parameter` variables in the mask or model workspace is not supported.
- `Simulink.Parameter` variables as values in a variant parameter within structures and that have data types other than `Simulink.Bus` objects are not supported.
- `Simulink.Parameter` variables as values in a variant parameter must have storage classes listed in “Storage Classes for Different Variant Activation Times” (Embedded Coder).

### Prerequisite

Before you start this example, we recommend you complete “Options to Represent Variant Parameters in Generated Code” (Embedded Coder).

### Explore the Model

Open the `slexVariantParamsUsingSlParamChoices` model.

```
open_system('slexVariantParamsUsingSlParamChoices')
```

### Variant Parameters using Simulink.Parameter choice variables

Copyright 2021 The MathWorks, Inc.

In this model, the **Gain** parameter of the Gain block is set to the variant parameter `kv`.

Open the `slexVariantParameterSlParamData.m` file. This file contains the definition of `kv`. `kv` has the two values `kp1` and `kp2` of `Simulink.Parameter` type. The storage class of `kp1` and `kp2` is set to “`ImportedExtern, ImportedExternPointer`” (Embedded Coder). The value of variant control variable `V` is set to `1`, and its activation time is specified as “`startup`” on page 12-68.

During simulation, the condition `V == 1` evaluates to `true`. Since, `kp1` is associated with `V == 1`, `kp1` becomes active and `kp2` becomes inactive. The code that you generate from this model, imports values of `kp1` and `kp2` from the handwritten code that is provided in **Modeling > Model Settings > Code Generation > Custom Code > Additional Source Code > Additional Code**. You can then compile the code into a single executable that switches the active values based on the value of variant control variable `V`.

```
type slexVariantParameterSlParamData.m
```

```
% This file defines variant parameters using Simulink.Parameter variables
% as choice values for slexVariantParamsUsingSlParamChoices example. The
% variant parameter value is determined using the Simulink.Parameter values
% in simulation and code generation.

% Copyright 2021 The MathWorks, Inc.

% Variant control variable
V = Simulink.VariantControl('Value', 1, 'ActivationTime', 'startup');

% Simulink.Parameter choice variables
kp1 = Simulink.Parameter(3);
kp1.CoderInfo.StorageClass = 'ImportedExtern';

kp2 = Simulink.Parameter(6);
kp2.CoderInfo.StorageClass = 'ImportedExtern';

% Variant parameter
kv = Simulink.VariantVariable('Choices', {'V == 1', 'kp1', 'V == 2', 'kp2'});
```

### Generate Code Using Embedded Coder

Before you generate code from the model, make sure that you have write permission in your current folder.

In the **Apps** gallery of the model toolstrip, click **Embedded Coder**. On the **C Code** tab, click **Generate Code**. For more information, see “Generate Code Using Embedded Coder” (Embedded Coder).

```
slbuild('slexVariantParamsUsingSlParamChoices')

### Starting build procedure for: slexVariantParamsUsingSlParamChoices
### Successful completion of build procedure for: slexVariantParamsUsingSlParamChoices

Build Summary

Top model targets built:

Model Action Rebuild Reason
=====
slexVariantParamsUsingSlParamChoices Code generated and compiled. Code generation information

Build duration: 0h 0m 18.939s

## Review Generated Code

1. In the **C Code** tab, in the **Results** section, click **Open Report**.
2. From the **Generated Code** pane of the report, select the `slexVariantParamsUsingSlParamChoices_private.h` file. `kp1` and `kp2` are declared as extern variables to use values from your handwritten code.

```
/* Imported (extern) block parameters */
extern real_T kp1;          /* Variable: kp1
                           * Referenced by: '<Root>/Gain'
                           */
extern real_T kp2;        /* Variable: kp2
                           * Referenced by: '<Root>/Gain'
```

Your handwritten code is imported in `slexVariantParamsUsingSlParamChoices.c` file.

```
User code, define parameter choice values outside the generated code */
double kp1 = 3.0;
double kp2 = 6.0;
```

During code compile, the generated and your handwritten code is integrated into a single executable. At model startup, that is, prior to running the executable, the value of the variant parameter `kv` is determined based on the condition that evaluates to `true`.

```
/* Model initialize function */
void slexVariantParamsUsingSlParamChoices_initialize(void)
{
  /* Variant Parameters using Simulink.Parameter variables for choice values */
  if (V == 1) {
    slexVariantParamsUsingSlParam_P.kv = kp1;
  } else if (V == 2) {
    slexVariantParamsUsingSlParam_P.kv = kp2;
  }

  /* startup variant condition checks */
  utAssert((V == 1) + (V == 2) == 1);
}
```

## Group Variant Parameter Values in Code Using Variant Parameter Bank

This example shows you how to group variant parameters in the generated code by adding them to the same variant parameter bank (`Simulink.VariantBank`).

Create a variant parameter bank.

```
EngineParams = Simulink.VariantBank(Name='EngineParams', Description='Engine parameters', ...  
    VariantConditions={'V == EngType.Small', 'V == EngType.Big'}
```

Create a variant control variable `V` using the `Simulink.VariantControl` class. The `Value` property of this object allows you to select an active value for a variant parameter and the `ActivationTime` property allows you to specify a variant activation time. Use this variable to specify the variant condition expression for the choice values of a variant parameter.

Create two variant parameter objects `K1` and `K2` and associate them with the variant parameter bank `EngineParams`.

Use the name of the variant parameter bank to set the `Bank` property of a `Simulink.VariantVariable` object. The generated code groups the `Simulink.VariantVariable` objects that share the same `Bank` property in the same structure.

```
V = Simulink.VariantControl(Value=EngType.Small, ActivationTime='startup');  
K1 = Simulink.VariantVariable(Choices={'V == EngType.Small', 3, 'V == EngType.Big', 6}, Bank='Eng  
K2 = Simulink.VariantVariable(Choices={'V == EngType.Small', [3, 6, 9], 'V == EngType.Big', [5, :
```

To additionally specify code generation properties for a variant parameter bank, use the `Simulink.VariantBankCoderInfo` class.
