- **Execution Count** — High execution counts, especially for a query that you expect to be executed very rarely, may indicate that your MySQL client application is either running a simple query to frequently, or may be running a query multiple times that could otherwise be cached. You should pay particular attention to queries where the execution count increases significantly in a short period of time compared to the normal execution rate.

**How to find:** Use the sort feature to sort the queries by execution count.

- **New queries** — new queries appearing in the Query Analyzer tab, especially if they appear after other queries have been in the display for a number of hours or days may indicate a number of issues:
- **Execution times** — long execution times, and a long max execution time compared to the average execution time may indicate a problem with a specific query and specific parameters.

**How to find:** Use the sort feature to sort the queries by execution count.

You can also use the filtering and sort options to get specific information about potential problem queries.

## 15.10.5. Troubleshooting Query Analyzer

If you are having trouble with Query Analyzer, either because the information is not being shown or the full range of queries that you expect are not appearing in the Query Analyzer page then there are a number of systems you can check.

To confirm that your system is correctly configured for Query Analysis, check the following:

- Confirm that the agent is running by checking the Agent log and the status of the server within MySQL Enterprise Service Manager
- Check the configuration of the agent. You must confirm the following:

- The **plugins** parameter within the main configuration file, `mysql-monitor-agent.ini`, must contain the **proxy** plugin:

```
plugins=proxy,agent
```

- The **agent-item-files** parameter within the main configuration file, `mysql-monitor-agent.ini`, must specify the `share/mysql-proxy/items/quan.lua` script:

```
agent-item-files = share/mysql-proxy/items/quan.lua, »
                 share/mysql-proxy/items/items-mysql-monitor.xml
```

- The proxy configuration parameters must point to the MySQL server where you want your queries to be sent. For example, if you are running your agent on the same host as your MySQL server then you might have the following lines in your `mysql-monitor-agent.ini` file:

```
proxy-address=:4040
proxy-backend-addresses = 127.0.0.1:3306
proxy-lua-script         = share/mysql-proxy/quan.lua
```

The above configuration can mean:

- The agent/proxy will listen on the current machine, using port 4040 ([proxy-address](#)).
- The agent/proxy will send all queries received on to the host 127.0.0.1 on port 3306 (the standard MySQL port), as per the [proxy-backend-addresses](#) parameter.

You can see a sample complete configuration file ([mysql-monitor-agent.ini](#)), using the 127.0.0.1 as the MySQL backend server, and reporting to a MySQL Enterprise Service Manager called [monitor](#):

```
[mysql-proxy]
plugins=proxy,agent
agent-mgmt-hostname = http://agent:password@monitor:18080/heartbeat
mysqld-instance-dir= etc/instances
agent-item-files = share/mysql-proxy/items/luan.lua,share/mysql-proxy/items/items-mysql-monitor.xml
proxy-address=:4040
proxy-backend-addresses = 127.0.0.1:3306
proxy-lua-script      = share/mysql-proxy/luan.lua
agent-uuid = a3113263-4993-4890-8235-cadef9617c4b
log-file = mysql-monitor-agent.log
pid-file=/opt/mysql/enterprise/agent/mysql-monitor-agent.pid
```

- Confirm that you can connect through the agent proxy to your backend MySQL server. You can do this by checking with the MySQL client. You must specify the same options as you would if you were connecting to the original server, including specifying the same user and password information:

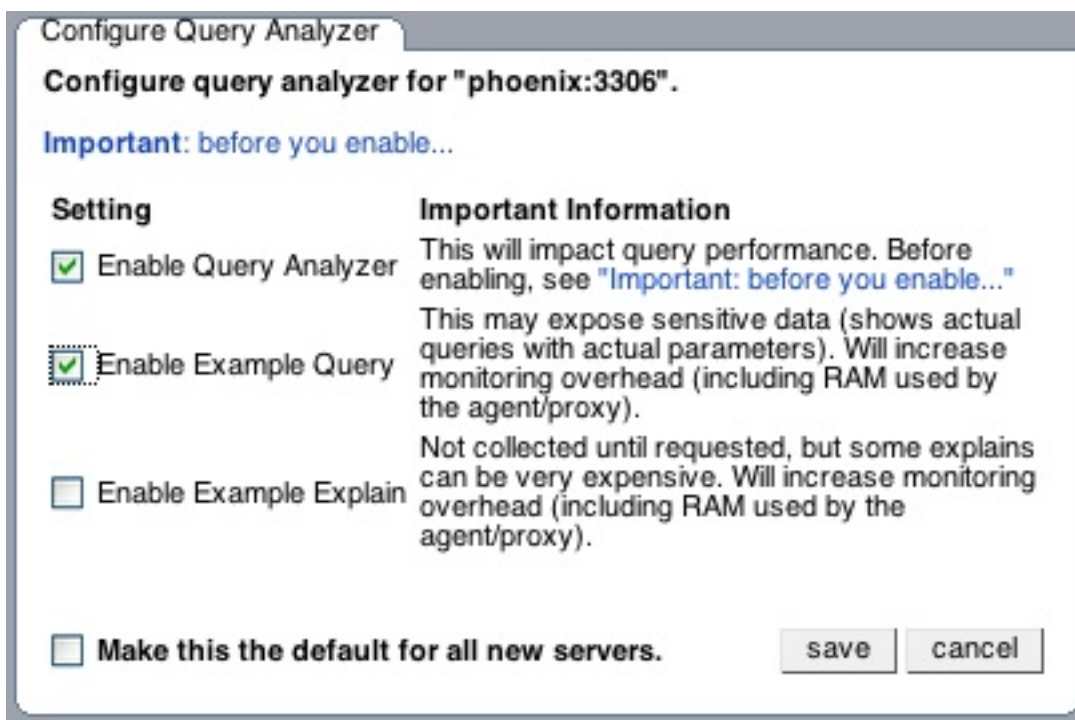

```
shell> mysql -h 127.0.0.1 --port 4040 --user=root -p
Enter password:
Welcome to the MySQL monitor.  Commands end with ; or \g.
Your MySQL connection id is 299239
Server version: 5.0.60-log Gentoo Linux mysql-5.0.60-r1
Type 'help;' or '\h' for help. Type '\c' to clear the buffer.
mysql>
```

- Check that your MySQL client application is configured to use the configured proxy port, instead of the real MySQL port when sending queries.
- Confirm that Query Analyzer enabled for your host. For more information, see [Section 15.10.6, “Query Analyzer Settings”](#).

## 15.10.6. Query Analyzer Settings

There are a number of settings related to the Query Analyzer data. You can configure the query analyzer operation by using the [CONFIGURE QUERY ANALYZER](#) link within the [QUERY ANALYZER](#) tab, or through the [CONFIGURE QUERY ANALYZER](#) button within the [MANAGE SERVERS](#) tab within the [SETTINGS](#) tab. Both methods provide you with the same dialog:

**Figure 15.51. MySQL Enterprise Dashboard: Query Analyzer Configuration**

Through either solution, the configuration options that you select are applied to the individual server or server group selected within the **SERVICES** navigation panel.

There are three configuration options available through either method:

- **ENABLE QUERY ANALYZER** configures whether query analyzer should be enabled for this server or server group. If selected, query analyzer will be enabled. To disable, select the checkbox.

If Query Analyzer has been enabled, then you can additionally configure the Example Query function by selecting the **ENABLE EXAMPLE QUERY** checkbox. Enabling this option provides an additional tab when you open the **CANONICAL QUERY** window when clicking on a query.

- **ENABLE EXAMPLE QUERY** allows the Query Analyzer to display more information about individual queries. When enabled, queries and their data items (rather than the canonical form shown by default) will be provided. Enabling this option may expose the full query statements and therefore may present a security issue.

With the **EXAMPLE QUERY** option enabled, an additional tab within the query summary details is made available. For more information, see [Section 15.10.2, "Getting Detailed Query Information"](#).

If you have enabled **EXAMPLE QUERY**, then you can additionally enable **EXAMPLE EXPLAIN**. To enable this tab, select the **ENABLE EXAMPLE EXPLAIN** checkbox.

- **ENABLE EXAMPLE EXPLAIN** provides another tab when viewing a query where you can view the output from **EXPLAIN** output from MySQL for the selected query. This will show the full query and how the query was executed within the servers.

Enabling this option may add additional overhead to the execution of your server, as the server will run an **EXPLAIN** statement each time it identifies a long running query. For more information, see [Section 15.12, "MySQL Enterprise Monitor Frequently Asked Questions"](#).

To enable or disable query analyzer for an individual server, go to the **SETTINGS** page and click on the **MANAGE SERVERS** link. To configure all the properties, click the **CONFIGURE QUERY ANALYZER** link next to server you want modify.

Alternatively, for each server, the **QUERY ANALYZER** column shows the current setting, On or Off, and whether the **EXAMPLE** and **EXPLAIN** functionality is enabled. To change any setting, click on the current status to toggle between the On/Off position.

To disable or enable Query Analyzer for the selected servers, use the **DISABLE QUERY ANALYZER** or [enable query analyzer](#) buttons within the **SETTINGS** page. You must have selected one or more servers from the list of available servers before selecting these buttons.

You can use the options that you have just selected as the default for all new servers that register with MySQL Enterprise Service

Manager by using select the **MAKE THIS THE DEFAULT FOR ALL NEW SERVERS** checkbox. By default, when a new server registers with MySQL Monitor, the server is automatically configured to supply Query Analysis data. This can have impact on the performance of your monitor and agent as it increases the amount of information supplied to the MySQL Monitor.

Configuration of Query Analyzer occurs through the **CONFIGURE DEFAULTS** button from within the **QUERY ANALYZER** page.

## 15.11. The Replication Page

### Note

MySQL Enterprise subscription, MySQL Enterprise Monitor, MySQL Replication Monitor, and MySQL Query Analyzer are only available to commercial customers. To learn more, see: <http://www.mysql.com/products/enterprise/features.html>.

Navigate to the [Replication](#) page by choosing the **REPLICATION** tab. This page provides a quick summary view of the state of your replication servers or, if you wish, you can drill down and determine specifics about any master or slave.

### Note

Servers, whether masters or slaves, must be monitored in order for them to appear on this page.

### Note

There will be no [Replication](#) page if your subscription level does not support this feature.

The [Replication](#) page groups all master servers with their slaves. Masters and their slaves are autodiscovered and a grouping is created. This grouping shows up on the replication page and also in the [Heat Chart](#) on the [Monitor](#) page. Scans run on a five minute interval, so depending upon the order of discovery, it can take as long as 2 polling intervals to create a complete group.

**Figure 15.52. MySQL Enterprise Dashboard: Replication groups**

Servers	Type	Slave IO	Slave SQL	Time Behind	Binlog
Replication 1 (5)	TREE	Running	Stopped		
local-tree-master:10001	master				master-bin.000035
local-tree-master-slave:10002	master/slave	Running	Running	00:00:00	master-slave-bin.000035
local-tree-slave3:10008	slave	Running	Running	00:00:00	
local-tree-slave2:10007	slave	Running	Running	00:00:00	
local-tree-slave:10003	slave	Running	Stopped		
Replication 4 (4)	MIXED	Running	Running		
ring1:10004	master/slave	Running	Running	00:00:00	master-bin.000030
ring2:10005	master/slave	Running	Running	00:00:00	master-bin.000030
ring2-slave:10009	slave	Running	Running	00:00:00	
ring3:10006	master/slave	Running	Running	00:00:00	master-bin.000030

Discovery events are logged to the [Replication](#) log. To view this log navigate to the [Settings](#) page and choose the **LOGS** link. View all replication-related events by clicking the **REPLICATION** link. This log can be a useful tool should you need to debug the replication topology discovery process.

### Warning

The agent must be installed on the same machine as the server you are monitoring in order for discovery to work properly. Do **not** use remote monitoring.

Replication groups can be managed from the [Manage Servers](#) page in the same way as other groups. However, any slaves removed from a server group will automatically be restored to that group. It is also possible to add non-slaves to a replication group-

ing. For more information about server groupings see [Section 15.6.3.2, “Grouping Servers”](#).

### 15.11.1. Replication Page Details

Choose a value from the **REFRESH** drop-down list box to set the rate at which information is updated. This refresh rate applies only to the information presented on this page: It is independent of the rate set for the [Monitor](#) page.

The following columns describe replication servers and their slaves:

- Servers – Displays the group name and any master servers and slaves
- Type – Indicates the topology of a server group or in the case of individual servers, whether a server is a master, a master/slave, or a slave
- Slave IO – Reports the status of the slave IO thread
- Slave SQL – Reports the status of the slave SQL thread
- Seconds Behind – The number of seconds the slave is behind the master. This column is blank if a server is a master.
- Binlog – The binlog file name
- Binlog Pos – The current position in the binlog file
- Master Binlog – The master binlog file name
- Master Binlog Pos – The current position in the master binlog file
- Last Error – The most recent error
- Unlabeled Column – Use the **RENAME GROUP** link on the server group line to edit the server group name

Levels of indentation in the [Servers](#) column show the relationship between master servers and their slaves. Most column headings are active links that allow you to change the order of display by clicking on the header. Sorting works differently for different column groupings. Click the [Seconds Behind](#) header to order servers by the number of seconds they are behind their master. However, in all cases, the server topology is respected. For example, in a [TREE](#) topology, ordering occurs within branches only.

If the agent is down, servers show in bold red in the [Servers](#) column. The [Slave IO](#) and the [Slave SQL](#) columns display **stopped** in red text if these threads are not running. If an agent is down, italics is used to display the last know status of the IO or SQL threads.

Clicking on a master server opens a dialog box that displays information about the server. The information shown includes:

- The number of slave servers
- The binlog file name
- The binlog position
- Which databases are replicated and which not

The dialog box also includes a link that allows the user to hide or show the slave servers.

Clicking on a slave server opens a dialog window showing extensive information about the slave.

## 15.12. MySQL Enterprise Monitor Frequently Asked Questions

### Note

MySQL Enterprise subscription, MySQL Enterprise Monitor, MySQL Replication Monitor, and MySQL Query Analyzer are only available to commercial customers. To learn more, see: <http://www.mysql.com/products/enterprise/features.html>.

## General Usage

### Questions

- **15.12.1:** While monitoring my network traffic I have noticed that the agents communicate information at irregular intervals to the MySQL Enterprise Service Manager. I cannot see anything in my configuration that would explain this behaviour. What is going on?
- **15.12.2:** How frequently is the data purge process executed?
- **15.12.3:** Does Query Analyzer work with all versions of MySQL and the MySQL Client Libraries?
- **15.12.4:** My MySQL Enterprise Service Manager is behind a firewall but it cannot communicate with the MySQL Enterprise website to register and download my license key and advisor bundle. I normally use a proxy service to access external websites. How do I configure the proxy settings for MySQL Enterprise Dashboard?
- **15.12.5:** What is the relationship between the advisor JAR file and the key?
- **15.12.6:** I have set the graphs to update every 5 minutes, and the page refresh to occur every minute. The page is refreshing correctly, but the graphs do not seem to update.
- **15.12.7:** Can the Trial-level key work with the Gold-level advisors JAR file?
- **15.12.8:** During query analysis, I am unable to obtain an [EXAMPLE](#) or [EXPLAIN](#) information when examining the detail of the analyzed query within the **QUERY ANALYZER** panel.
- **15.12.9:** Does the Gold-level key support Silver-level advisors?
- **15.12.10:** I have enabled [EXPLAIN](#) queries for Query Analyzer, but no queries with the [EXPLAIN](#) data are showing up in the display.
- **15.12.11:** Can I run MySQL Enterprise Service Manager on machine with other applications running?
- **15.12.12:** Why do some rules appear to have a **SEVERITY** of **UNKNOWN**?
- **15.12.13:** How do I change the name of a server?
- **15.12.14:** I have started a Data Migration of my old data for a server to MySQL Enterprise Service Manager 2.0, but I have noticed that the performance of the monitor server has degraded significantly. Can I stop the migration?

### Questions and Answers

**15.12.1: While monitoring my network traffic I have noticed that the agents communicate information at irregular intervals to the MySQL Enterprise Service Manager. I cannot see anything in my configuration that would explain this behaviour. What is going on?**

Each MySQL Enterprise Monitor Agent periodically sends information to the server about a range of different information, including the core rule and statistical data, Query Analyzer information and other data used to monitor the status of your MySQL server.

One element of this is called the MySQL Enterprise Monitor Agent Heartbeat, which is core information exchange that indicates that the monitored server is still up and running. The heartbeat information is vital because it tells the MySQL Enterprise Service Manager that the agent and server are still communicating. This information is sent regularly to the MySQL Enterprise Service Manager, but to prevent multiple agents from sending the information at the same time, and creating a large network load (or storm), the interval is randomized with each heartbeat. The randomization ensures that the information is still uploaded periodically, but without the potential to overload the network with this data.

**15.12.2: How frequently is the data purge process executed?**

A data purge process is started approximately once a minute. If you have changed the purge period then the data will start to be purged within the next minute.

**15.12.3: Does Query Analyzer work with all versions of MySQL and the MySQL Client Libraries?**

The MySQL Proxy component, and Query Analyzer, require that clients connecting through MySQL Enterprise Monitor Agent are using MySQL 5.0 or later. Clients that use the library provided with MySQL 4.1 or earlier will not work with MySQL Enterprise Monitor Agent.

**15.12.4: My MySQL Enterprise Service Manager is behind a firewall but it cannot communicate with the MySQL Enterprise website to register and download my license key and advisor bundle. I normally use a proxy service to access external websites. How do I configure the proxy settings for MySQL Enterprise Dashboard?**

To configure a proxy service, you need to edit the `apache-tomcat/conf/catalina.properties` file within the MySQL Enterprise Service Manager installation directory. To make the changes, the proxy configuration information to the end of the file by setting the `http.proxyHost` and `http.proxyPort` properties:

```
http.proxyHost=proxy.example.com
http.proxyPort=8080
```

You will need to restart the MySQL Enterprise Service Manager for the change to take effect:

```
shell> mysqlmonitorctl.sh restart
```

**15.12.5: What is the relationship between the advisor JAR file and the key?**

The JAR file contains graph and advisor definitions. The key file contains typical customer validation data such as contract information, number of servers covered, subscription level and dates.

**15.12.6: I have set the graphs to update every 5 minutes, and the page refresh to occur every minute. The page is refreshing correctly, but the graphs do not seem to update.**

The graph refresh and page refresh are two different parameters. The graphs will update according to their refresh period, regardless of the refresh period set for the main display page.

**15.12.7: Can the Trial-level key work with the Gold-level advisors JAR file?**

The Trial-level key can only be used with the Trial-level advisors JAR file.

**15.12.8: During query analysis, I am unable to obtain an `EXAMPLE` or `EXPLAIN` information when examining the detail of the analyzed query within the QUERY ANALYZER panel.**

You must explicitly enable the `EXAMPLE` and `EXPLAIN` query functionality. Make sure that you have enabled both panels. See [Section 15.10.6, “Query Analyzer Settings”](#).

**15.12.9: Does the Gold-level key support Silver-level advisors?**

The Gold-level advisor JAR file will contain Silver-level advisors plus Gold-level advisors. However, you cannot use the Gold-level key with the Silver-level advisors JAR file. The Gold-level key can only be used with the Gold-level advisors JAR file.

**15.12.10: I have enabled `EXPLAIN` queries for Query Analyzer, but no queries with the `EXPLAIN` data are showing up in the display.**

Query Analyzer only obtains `EXPLAIN` information when the MySQL Enterprise Monitor Agent identifies a long running query. If none of your queries exceed the defined threshold, then the `EXPLAIN` information is not obtained and provided to the Query Analyzer for display.

To change the query duration at which an `EXPLAIN` is triggered, you must edit the `share/mysql-proxy/quant.lua` file within the MySQL Enterprise Monitor Agent directory on each server. You need to change the value configured in the `auto_explain_min_exec_time_us`. The default is 500ms:

```
---
-- configuration
--
-- SET GLOBAL analyze_query.auto_filter = 0
if not proxy.global.config.quan then
  proxy.global.config.quan = {
    analyze_queries = true,    -- track all queries
    query_cutoff   = 160,    -- only show the first 160 chars of the query
    num_worst_queries = 5,
    auto_explain   = true,
    auto_explain_min_exec_time_us = 500 * 1000
  }
end
```

The value is expressed in microseconds, which is why the value must be multiplied by 1000. To reduce this value to 100ms you would modify the line:

```
auto_explain_min_exec_time_us = 100 * 1000
```

You do not need to restart MySQL Enterprise Monitor Agent for the changes to take effect.

#### **15.12.11: Can I run MySQL Enterprise Service Manager on machine with other applications running?**

You can, but ideally you should be running your MySQL Enterprise Service Manager on a dedicated machine, especially if you are monitoring a number of different agents. For more information, see [Section 15.4.4, “Choosing Suitable MySQL Enterprise Service Manager Hardware Configurations”](#).

#### **15.12.12: Why do some rules appear to have a SEVERITY of UNKNOWN?**

Due to timing issues, certain rules such as “32-Bit Binary Running on 64-Bit AMD Or Intel System” and “Key Buffer Size Greater Than 4 GB” do not evaluate correctly due to timing issues. This is a known issue and will be resolved in future versions of MySQL Enterprise Monitor.

#### **15.12.13: How do I change the name of a server?**

Go to the **MANAGE SERVERS** panel within **SETTINGS** and click **RENAME SERVER**.

#### **15.12.14: I have started a Data Migration of my old data for a server to MySQL Enterprise Service Manager 2.0, but I have noticed that the performance of the monitor server has degraded significantly. Can I stop the migration?**

You can stop the migration of your historical data at any time. Go to the **MANAGE SERVERS** display of the **SETTINGS** panel and click **STOP** next to each server that is being migrated. You can restart the migration at any point.

## Questions and Answers

### 15.12.1: How should I decide between MySQL Enterprise Basic, Silver, Gold and Platinum?

MySQL Enterprise subscriptions are available in 4 tiers, providing you the flexibility of choosing the capabilities and SLA that best meet your requirements. [Learn More](#) If you have questions and what to discuss your specific requirements, please [Contact MySQL Sales](#)

### 15.12.2: What is MySQL Enterprise Server?

MySQL Enterprise Server software is the most reliable, secure and up-to-date version of MySQL for cost-effectively delivering E-commerce, Online Transaction Processing (OLTP), and multi-terabyte Data Warehousing applications. It is a fully integrated transaction-safe, ACID compliant database with full commit, rollback, crash recovery and row level locking capabilities. MySQL delivers the ease of use, scalability, and performance that has made it MySQL the world's most popular open source database. [Learn More](#)

### 15.12.3: How do I get a 30-day trial on MySQL Enterprise?

You can experience the MySQL Enterprise Monitor for 30 days by registering to receive an email with login instructions. [Learn More](#)

### 15.12.4: Does MySQL Enterprise include Maintenance, Updates, and Upgrades?

Yes. As long as you have a valid contract for MySQL Enterprise, you will receive all new MySQL Enterprise Server software releases including Software Maintenance, Updates, and Upgrades. The Software Update Service will automatically notify you of the new releases.

### 15.12.5: What is a Technical Account Manager?

MySQL Enterprise, at the Platinum tier, provides the option for a Technical Account Manager (TAM). The TAM is your advocate within MySQL, who proactively works to maximize your benefits from MySQL Support Services. [Learn More](#)

### 15.12.6: Are there any Webinars available?

Yes. MySQL provides regularly scheduled Live Webinars. [Learn More](#) MySQL also provides On-Demand Webinars to fit your schedule. These are recordings of previously held Live Webinars that you can replay at any time. [Learn More](#)

### 15.12.7: What is the pricing of MySQL Enterprise?

The pricing model for MySQL Enterprise is based on two key components: per server and per year. MySQL Enterprise does not have artificial restrictions based on CPUs, Memory, Machine Size, or Named Users. MySQL Enterprise is available in 4 tiers (Basic, Silver, Gold and Platinum). Choose the tier that best meets your requirements and budget. [Learn More](#)

### 15.12.8: Does MySQL Enterprise include Emergency Hot Fix Builds?

MySQL Enterprise, at the Gold and Platinum tiers, gives you the ability to request an Emergency Hot Fix Build to fix issues not already fixed in a MySQL Rapid Update or MySQL Quarterly Service Pack.

### 15.12.9: Are there any MySQL Enterprise White Papers available?

Yes. Detailed architecture, technology, and business white papers are available. [Learn More](#)

### 15.12.10: How do I buy MySQL Enterprise?

For pricing and to buy MySQL Enterprise, visit the [Online Shop](#) For volume discounts or for more information, please [Contact MySQL Sales](#)

### 15.12.11: What is MySQL Enterprise?

The MySQL Enterprise subscription is the most comprehensive offering of MySQL database software, services and production support to ensure your business achieves the highest levels of reliability, security and uptime.

MySQL Enterprise includes:

- MySQL Enterprise Server software, the most reliable, secure and up-to date version of the world's most popular open source database
- MySQL Enterprise Monitor that continuously monitors your database and proactively advises you on how to implement MySQL best practices

- MySQL 24x7 Production Support with fast response times to assist you in the development, deployment and management of MySQL applications

MySQL Enterprise is available in 4 tiers (Basic, Silver, Gold, Platinum). [Learn More](#)

#### **15.12.12: Does MySQL provide IP (Intellectual Property) Indemnification?**

MySQL Enterprise, at the Gold and Platinum tiers, has the option of IP Indemnification, for qualifying customers at no extra cost. This provides you with legal protection that you expect from enterprise software providers. [Learn More](#)

#### **15.12.13: Can I buy MySQL Enterprise subscriptions for multiple years?**

MySQL Enterprise subscriptions have duration of at least 1 year. Customers have the flexibility of choosing terms with multi-year durations. To purchase multi-year contracts, please [Contact MySQL Sales](#)

#### **15.12.14: What is MySQL Enterprise Unlimited?**

MySQL Enterprise Unlimited is a unique offering that allows you to deploy an unlimited number of MySQL Enterprise Servers for the price of a single CPU of Oracle Enterprise Edition. [Learn More](#)

#### **15.12.15: What is MySQL Production Support?**

Production Support consists of 4 components:

- Problem Resolution Support
- Consultative Support
- Knowledge Base
- Technical Account Manager (option)

MySQL Production Support gives you priority access with guaranteed response times to assist you with the development, deployment and management of your MySQL applications. [Learn More](#)

#### **15.12.16: Can I buy MySQL Enterprise subscriptions for only some of my production MySQL database servers?**

When you choose MySQL Enterprise subscriptions, they must cover all database servers that power that specific application. To negotiate volume discounts, please [Contact MySQL Sales](#)

#### **15.12.17: Are there any Demo/Tutorials available for MySQL Enterprise?**

Yes. Multiple self-running demos are available. [Learn More](#)

#### **15.12.18: Does MySQL Enterprise include 24x7 Technical Support?**

MySQL Enterprise, at the Gold and Platinum tiers, includes 24x7 phone and email access to the MySQL Support Team. [Learn More](#)

#### **15.12.19: What if I plan to add more MySQL servers to my MySQL Enterprise subscription?**

A great option is the MySQL Enterprise Unlimited offering that allows you cover an unlimited number of MySQL servers for a fixed, low price. [Learn More](#)

#### **15.12.20: What is the list of Supported Platforms?**

MySQL Enterprise provides broad coverage in its list of Supported Platforms. [Learn More](#)

#### **15.12.21: Do all my MySQL Enterprise subscriptions need to be at the same tier?**

MySQL Enterprise subscriptions must be at the same tier (Basic, Silver, Gold, Platinum) for all database servers that power that specific application.

#### **15.12.22: What is MySQL Consultative Support?**

MySQL Enterprise, at the Gold and Platinum tiers, includes Consultative Support. This is a proactive approach to support that is designed to help you avoid critical outages. MySQL Support Engineers advise you on how to properly design and tune your MySQL servers, schema, queries, and replication set-up to maximize performance and availability. Also, by taking the initiative to properly design and tune your MySQL database applications you can avoid having to purchase expensive hardware for your IT infrastructure. [Learn More](#)

## MySQL Monitor

- [15.12.15](#): Which Advisors and features are included under different MySQL Enterprise subscription levels?

### Questions and Answers

#### **15.12.1: What is MySQL Enterprise Monitor?**

Included as part of a MySQL Enterprise subscription, the MySQL Enterprise Monitor is a distributed, web-based application that helps customers reduce downtime, tighten security and increase throughput of their MySQL servers by telling them about problems in their database applications before they occur. It is downloadable from the Enterprise Customer web site and is deployed within the safety of the customer datacenter. [Learn More](#)

#### **15.12.2: What versions of MySQL are supported by the MySQL Enterprise Monitor?**

The MySQL Enterprise Monitor can be used to monitor MySQL versions 4.0 – 5.x.

#### **15.12.3: What MySQL Enterprise subscription levels include the MySQL Enterprise Monitor?**

The Enterprise Monitor is available under MySQL Enterprise subscription levels Silver, Gold and Platinum. [Learn More](#)

#### **15.12.4: What are the features and related benefits of the MySQL Enterprise Monitor?**

The MySQL Enterprise Monitor is like having a "Virtual DBA Assistant" at your side to recommend best practices to eliminate security vulnerabilities, improve replication, and optimize performance. For the complete features and benefits, visit the [MySQL Enterprise Monitor Features and Benefits page](#).

#### **15.12.5: What are the MySQL Enterprise Advisors and Advisor Rules?**

The MySQL Enterprise Advisors are a set of best practice guidelines for the optimal use of MySQL. Advisors are spread across database specific disciplines and are comprised of a set of MySQL Advisor Rules that proactively monitor all MySQL servers and report on database application problems before they occur. Each Advisor Rule provides a detailed overview of the problem it is designed to identify, advices on how to correct the problem, specifies commands to implement the recommended fix and links to additional resources for additional research into the issue at hand. [Learn More](#)

#### **15.12.6: How is the Enterprise Monitor web application architected?**

The Enterprise Monitor web application is comprised of 3 components:

- **Service Agent:** A lightweight C program that is installed on each of the monitored MySQL servers. Its purpose is to collect MySQL SQL and operating system metrics that allow the DBA to monitor the overall health, availability and performance of the MySQL server. The Service Agent is the only component within the application that touches or connects to the MySQL Server. It reports the data it collects via XML over HTTP to the centralized Service Manager.
- **Service Manager:** The main server of the application. The Service Manager manages and stores the data collections that come in from each service agent. It analyzes these collections using MySQL provided best practice Advisor rules to determine the health, security, availability and performance of each of the monitored MySQL Servers. The Service Manager also provides the content for the Enterprise Dashboard which serves as the client user interface for the distributed web application.
- **Repository:** A MySQL database that is used to stored data collections and application-level configuration data.

#### **15.12.7: What operating system platforms are supported by the MySQL Enterprise Monitor?**

The Enterprise Monitor Service Manager is fully supported on most current versions of Linux, Windows XP and Server Editions, Solaris and Mac OSX. The Service Agent supports any platform supported by the MySQL Enterprise server. For the complete list of MySQL Enterprise supported operating systems and CPUs, visit the [Supported Platforms page](#).

#### **15.12.8: How do I get the MySQL Enterprise Monitor?**

The MySQL Enterprise Monitor is available for download to MySQL Enterprise customers at the Silver, Gold and Platinum subscription levels.

- To experience the MySQL Enterprise Monitor for 30 days, visit the [Trial Subscription page](#)
- To buy MySQL Enterprise, visit the [Online Shop](#)

#### **15.12.9: What makes MySQL Enterprise unique?**

Of the products on the market that monitor MySQL, SQL code and OS specific metrics, the MySQL Enterprise Monitor is the only solution that is built and supported by the engineers at MySQL. Unlike other solutions that report on raw MySQL and OS level metrics, the MySQL Enterprise Monitor is designed to optimize the use of MySQL by proactively monitoring MySQL instances and providing notifications and “MySQL DBA expertise in a box” advice on corrective measures DBAs can take before problems occur.

#### **15.12.10: What are the long-term benefits of the MySQL Enterprise Monitor?**

Over time, the task of managing even medium-scale MySQL server farms becomes exponentially more complicated, especially as the load of users, connections, application queries, and objects on each MySQL server increases. The Enterprise Monitor continually monitors the dynamic security, performance, replication and schema relevant metrics of all MySQL servers, so as the number of MySQL continues to grow, DBAs are kept up to date on potential problems and proactive measures that can be implemented to ensure each server continues to operate at the highest levels of security, performance and reliability.

#### **15.12.11: Which set of Enterprise Advisors, Advisor Rules and features are best for my use of MySQL?**

The Enterprise Monitor Advisors and Advisor Rules are available at 3 MySQL Enterprise subscription tiers: Choose MySQL Enterprise Silver if you need:

- Assurance you are running the most current, bug-free version of MySQL across all of your servers.
- Recoverability of your MySQL servers.
- The highest level of security for your MySQL servers.
- Monitoring of maximum or disallowed MySQL connections.
- Optimized startup configuration settings.

Choose MySQL Enterprise Gold, when you need everything in Silver, PLUS:

- Easy collection and detection of problematic SQL code running on your production or development systems.
- Insight and corrective advice on MySQL replication status, sync, and performance related issues.
- Auto detection and documenting of your Replication topologies.

- Advanced monitoring of your Replication and Scale-out environment.

Choose MySQL Enterprise Platinum, when you need everything in Gold, PLUS:

- Identification and advice on unplanned database and object level schema changes (Create, Alter, and Drop) across your MySQL servers.
- Proactive monitoring and advice on tuning the performance of your MySQL servers.

#### **15.12.12: How is the MySQL Enterprise Monitor installed and deployed?**

The Enterprise Monitor is powered by a distributed web application that is installed and deployed within the confines of the corporate firewall.

#### **15.12.13: What are the immediate benefits of implementing the MySQL Enterprise Monitor?**

Often MySQL installations are implemented with default settings that may not be best suited for specific applications or usage patterns. The MySQL Advisors go to work immediately in these environments to identify potential problems and proactively notify and advise DBAs on key MySQL settings that can be tuned to improve availability, tighten security, and increase the throughput of their existing MySQL servers

#### **15.12.14: How are subscribers notified about the availability of new or updated MySQL Enterprise Monitor, MySQL Enterprise Advisors and Advisor Rules?**

Customers will receive notifications of new and updated MySQL Enterprise Monitor and Advisors as they become available via the MySQL Enterprise Software Update Service. Notifications will be generated and sent based on the customer profile and the MySQL Enterprise subscription level.

#### **15.12.15: Which Advisors and features are included under different MySQL Enterprise subscription levels?**

For the complete list of the MySQL Enterprise Advisors that are available under each MySQL Enterprise subscription level, visit the [Features page](#).

### **MySQL Query Analyzer**

#### **Questions**

- [15.12.1](#): Can I leave the MySQL Query Analyzer enabled at all times?
- [15.12.2](#): What are the typical use cases of the MySQL Query Analyzer?
- [15.12.3](#): What is the MySQL Query Analyzer?
- [15.12.4](#): What are the main features and benefits of the MySQL Query Analyzer?
- [15.12.5](#): What makes the MySQL Query Analyzer unique?
- [15.12.6](#): How are subscribers notified about updates to the MySQL Query Analyzer application components?
- [15.12.7](#): How can I get the MySQL Query Analyzer?
- [15.12.8](#): How is the MySQL Query Analyzer installed and enabled?
- [15.12.9](#): What overhead can I expect when the MySQL Query Analyzer is installed and enabled?

#### **Questions and Answers**

##### **15.12.1: Can I leave the MySQL Query Analyzer enabled at all times?**

We have customers who have the Query Analyzer enabled and collecting queries on their development and QA servers so they can tune their code and monitor the fixes as part of the development process. For production systems, Query collection and analysis can easily be toggled on when a slowdown occurs. To avoid collection mode overhead many users are using simple scripts to enable the Query Analyzer to sample queries during non-peak hours, typically during 30 minute windows. They can then view the collected queries using the date/time or interval filter options.

##### **15.12.2: What are the typical use cases of the MySQL Query Analyzer?**

The typical use cases for developers, DBAs and system administrators are:

- Developers – Monitor and tune application queries during development before they are promoted to production.
- DBAs and System Administrators – Identify problem SQL code as it runs in production and advise development teams on how to tune. This use case benefits the most from regular sampling of queries as they are running, most often during non-peak hours.

### **15.12.3: What is the MySQL Query Analyzer?**

The MySQL Query Analyzer allows DBAs, developers and system administrators to improve application performance by collecting, monitoring, and analyzing queries as they run on their MySQL servers. [Learn More](#)

### **15.12.4: What are the main features and benefits of the MySQL Query Analyzer?**

For the complete features and benefits, visit the [MySQL Enterprise Monitor Features and Benefits page](#).

### **15.12.5: What makes the MySQL Query Analyzer unique?**

Other products (free, open source and commercial) that provide MySQL query monitoring are dependent on the MySQL Slow Query Log being enabled and available for sampling. While this provides some time savings over the DBA collecting and parsing the Log, the Slow Query Log comes with overhead and does not capture sub millisecond executions. The log data also grows very large very quickly.

The MySQL Query Analyzer collects queries and execution statistics with no dependence on the SQL Query Log, it captures all SQL statements sent to the MySQL server and provides an aggregated view into the most expensive queries in number of executions and total execution time. It is also fully supported as part of the MySQL Enterprise subscription.

### **15.12.6: How are subscribers notified about updates to the MySQL Query Analyzer application components?**

Customers will receive notifications of the MySQL Query Analyzer updates as they become available via the MySQL Enterprise Software Update and Alert Service. Notifications will be generated and sent based on the customer profile and the MySQL Enterprise subscription level.

### **15.12.7: How can I get the MySQL Query Analyzer?**

The MySQL Query Analyzer is available for download to MySQL Enterprise customers at the Gold and Platinum subscription levels.

- To experience the MySQL Enterprise Monitor for 30 days, visit the [Trial Subscription page](#)
- To buy MySQL Enterprise, visit the [Online Shop](#)

### **15.12.8: How is the MySQL Query Analyzer installed and enabled?**

The Query Analyzer feature is installed with the Service Agent. It is enabled during agent installation and can be toggled between collection and pass-thru modes from the Query Analysis page of the Enterprise Monitor.

### **15.12.9: What overhead can I expect when the MySQL Query Analyzer is installed and enabled?**

The average overhead when in active collection mode is in the 15-20% range. In pass-thru mode the overhead is minimal, weighing in at 1-5% on most MySQL systems of average load.

---

# Chapter 16. Replication

Replication enables data from one MySQL database server (called the master) to be replicated to one or more MySQL database servers (slaves). Replication is asynchronous - your replication slaves do not need to be connected permanently to receive updates from the master, which means that updates can occur over long-distance connections and even temporary solutions such as a dial-up service. Depending on the configuration, you can replicate all databases, selected databases, or even selected tables within a database.

The target uses for replication in MySQL include:

- Scale-out solutions - spreading the load among multiple slaves to improve performance. In this environment, all writes and updates must take place on the master server. Reads, however, may take place on one or more slaves. This model can improve the performance of writes (since the master is dedicated to updates), while dramatically increasing read speed across an increasing number of slaves.
- Data security - because data is replicated to the slave, and the slave can pause the replication process, it is possible to run backup services on the slave without corrupting the corresponding master data.
- Analytics - live data can be created on the master, while the analysis of the information can take place on the slave without affecting the performance of the master.
- Long-distance data distribution - if a branch office would like to work with a copy of your main data, you can use replication to create a local copy of the data for their use without requiring permanent access to the master.

Replication in MySQL features support for one-way, asynchronous replication, in which one server acts as the master, while one or more other servers act as slaves. This is in contrast to the *synchronous* replication which is a characteristic of MySQL Cluster (see [Chapter 17, MySQL Cluster](#)).

There are a number of solutions available for setting up replication between two servers, but the best method to use depends on the presence of data and the engine types you are using. For more information on the available options, see [Section 16.1.1, “How to Set Up Replication”](#).

Replication is controlled through a number of different options and variables. These control the core operation of the replication, timeouts and the databases and filters that can be applied on databases and tables. For more information on the available options, see [Section 16.1.2, “Replication and Binary Logging Options and Variables”](#).

You can use replication to solve a number of different problems, including problems with performance, supporting the backup of different databases and for use as part of a larger solution to alleviate system failures. For information on how to address these issues, see [Section 16.2, “Replication Solutions”](#).

For notes and tips on how different data types and statements are treated during replication, including details of replication features, version compatibility, upgrades, and problems and their resolution, including an FAQ, see [Section 16.3, “Replication Notes and Tips”](#).

Detailed information on the implementation of replication, how replication works, the process and contents of the binary log, background threads and the rules used to decide how statements are recorded and replication, see [Section 16.4, “Replication Implementation Overview”](#).

## MySQL Enterprise

The MySQL Enterprise Monitor provides numerous advisors that give immediate feedback about replication-related problems. For more information, see <http://www.mysql.com/products/enterprise/advisors.html>.

## 16.1. Replication Configuration

Replication between servers in MySQL works through the use of the binary logging mechanism. The MySQL instance operating as the master (the source of the database changes) writes updates and changes as “events” to the binary log. The information in the binary log is stored in different logging formats according to the database changes being recorded. Slaves are configured to read the binary log from the master and to execute the events in the binary log on the slave's local database.

The master is dumb in this scenario. Once binary logging has been enabled, all statements are recorded in the binary log. Each slave will receive a copy of the entire contents of the binary log. It is the responsibility of the slave to decide which statements in the binary log should be executed; you cannot configure the master to log only certain events. If you do not specify otherwise, all events in the master binary log are executed on the slave. If required, you can configure the slave to process only events that apply to particular databases or tables.

Slaves keep a record of the binary log file and position within the log file that they have read and processed from the master. This means that multiple slaves can be connected to the master and executing different parts of the same binary log. Because the slaves

control this process, individual slaves can be connected and disconnected from the server without affecting the master's operation. Also, because each slave remembers the position within the binary log, it is possible for slaves to be disconnected, reconnect and then “catch up” by continuing from the recorded position.

Both the master and each slave must be configured with a unique ID (using the `server-id` option). In addition, the slave must be configured with information about the master host name, log file name and position within that file. These details can be controlled from within a MySQL session using the `CHANGE MASTER TO` statement. The details are stored within the `master.info` file.

In this section the setup and configuration required for a replication environment is described, including step-by-step instructions for creating a new replication environment. The major components of this section are:

- For a guide to setting up two or more servers for replication see [Section 16.1.1, “How to Set Up Replication”](#). This section deals with the setup of the systems and provides methods for copying data between the master and slaves.
- Detailed information on the different configuration options and variables that apply to replication is provided in [Section 16.1.2, “Replication and Binary Logging Options and Variables”](#).
- Once started, the replication process should require little administration or monitoring. However, for advice on common tasks that you may want to execute, see [Section 16.1.3, “Common Replication Administration Tasks”](#).

## 16.1.1. How to Set Up Replication

This section describes how to set up complete replication of a MySQL server. There are a number of different methods for setting up replication, and the exact method that you use will depend on how you are setting up replication, and whether you already have data within your master database.

There are some generic tasks which may be required for all replication setups:

- You may want to create a separate user that will be used by your slaves to authenticate with the master to read the binary log for replication. The step is optional. See [Section 16.1.1.1, “Creating a User for Replication”](#).
- You must configure the master to support the binary log and configure a unique ID. See [Section 16.1.1.2, “Setting the Replication Master Configuration”](#).
- You must configure a unique ID for each slave that you want to connect to the master. See [Section 16.1.1.3, “Setting the Replication Slave Configuration”](#).
- Before starting a data snapshot or the replication process, you should record the position of the binary log on the master. You will need this information when configuring the slave so that the slave knows where within the binary log to start executing events. See [Section 16.1.1.4, “Obtaining the Master Replication Information”](#).
- If you already have data on your master and you want to synchronize your slave with this base data, then you will need to create a data snapshot of your database. You can create a snapshot using `mysqldump` (see [Section 16.1.1.5, “Creating a Data Snapshot Using `mysqldump`”](#)) or by copying the data files directly (see [Section 16.1.1.6, “Creating a Data Snapshot Using Raw Data Files”](#)).
- You will need to configure the slave with the master settings, such as the host name, login credentials and binary log name and positions. See [Section 16.1.1.10, “Setting the Master Configuration on the Slave”](#).

Once you have configured the basic options, you will need to follow the instructions for your replication setup. A number of alternatives are provided:

- If you are establishing a new MySQL master and one or more slaves, then you need only set up the configuration, as you have no data to exchange. For guidance on setting up replication in this situation, see [Section 16.1.1.7, “Setting Up Replication with New Master and Slaves”](#).
- If you are already running a MySQL server, and therefore already have data that will need to be transferred to your slaves before replication starts, have not previously configured the binary log and are able to shut down your MySQL server for a short period during the process, see [Section 16.1.1.8, “Setting Up Replication with Existing Data”](#).
- If you are setting up additional slaves to an existing replication environment then you can set up the slaves without affecting the master. See [Section 16.1.1.9, “Introducing Additional Slaves to an Existing Replication Environment”](#).

If you want to administer a MySQL replication setup, we suggest that you read this entire chapter through and try all statements mentioned in [Section 12.6.1, “SQL Statements for Controlling Master Servers”](#), and [Section 12.6.2, “SQL Statements for Con-](#)

trolling Slave Servers”. You should also familiarize yourself with the replication startup options described in [Section 16.1.2, “Replication and Binary Logging Options and Variables”](#).

### Note

Note that certain steps within the setup process require the `SUPER` privilege. If you do not have this privilege then enabling replication may not be possible.

#### 16.1.1.1. Creating a User for Replication

Each slave must connect to the master using a standard MySQL user name and password, so there must be a user account on the master that the slave can use to connect. Any account can be used for this operation, providing it has been granted the `REPLICATION SLAVE` privilege.

You do not need to create a specific user for replication. However, you should be aware that the user name and password will be stored in plain text within the `master.info` file. Therefore, you may want to create a user that only has privileges for the replication process.

To create a user or grant an existing user the privileges required for replication, use the `GRANT` statement. If you create a user solely for the purposes of replication then that user needs only the `REPLICATION SLAVE` privilege. For example, to create a user, `repl`, that can connect for replication from any host within the `mydomain.com` domain, issue this statement on the master:

```
mysql> GRANT REPLICATION SLAVE ON *.*
-> TO 'repl'@'%mydomain.com' IDENTIFIED BY 'slavepass';
```

See [Section 12.5.1.3, “GRANT Syntax”](#), for more information on the `GRANT` statement.

You may wish to create a different user for each slave, or use the same user for each slave that needs to connect. As long as each user that you want to use for the replication process has the `REPLICATION SLAVE` privilege you can create as many users as you require.

#### 16.1.1.2. Setting the Replication Master Configuration

For replication to work you *must* enable binary logging on the master. If binary logging is not enabled, replication will not be possible as it is the binary log that is used to exchange data between the master and slaves.

Each server within a replication group must be configured with a unique `server-id` value. The server ID is used to identify individual servers within the group, and must be positive integer between 1 and  $(2^{32})-1$ . How you organize and select the numbers is entirely up to you.

To configure the binary log and server ID options, you will need to shut down your MySQL server and edit the configuration of the `my.cnf` or `my.ini` file.

You will need to add the following options to the configuration file within the `[mysqld]` section. If these options already exist, but are commented out, uncomment the options and alter them according to your needs. For example, to enable binary logging, using a log file name prefix of `mysql-bin`, and setting a server ID of 1:

```
[mysqld]
log-bin=mysql-bin
server-id=1
```

### Note

For the greatest possible durability and consistency in a replication setup using `InnoDB` with transactions, you should use `innodb_flush_log_at_trx_commit=1` and `sync_binlog=1` in the master `my.cnf` file.

### Note

Ensure that the `skip-networking` option has not been enabled on your replication master. If networking has been disabled, then your slave will not be able to communicate with the master and replication will fail.

#### 16.1.1.3. Setting the Replication Slave Configuration

The only option you must configure on the slave is to set the unique server ID. If this option is not already set, or the current value conflicts with the value that you have chosen for the master server, then you should shut down your slave server, and edit the configuration to specify the server ID. For example:

```
[mysqld]
server-id=2
```

If you are setting up multiple slaves, each one must have a unique `server-id` value that differs from that of the master and from each of the other slaves. Think of `server-id` values as something similar to IP addresses: These IDs uniquely identify each server instance in the community of replication partners.

If you do not specify a `server-id` value, it defaults to 0.

### Note

If you omit `server-id` (or set it explicitly to 0), a master refuses connections from all slaves, and a slave refuses to connect to a master. Thus, omitting `server-id` is good only for backup with a binary log.

You do not have to enable binary logging on the slave for replication to be enabled. However, if you enable binary logging on the slave then you can use the binary log for data backups and crash recovery on the slave, and also use the slave as part of a more complex replication topology (for example, where the slave acts as a master to other slaves).

## 16.1.1.4. Obtaining the Master Replication Information

To configure replication on the slave you must determine the master's current point within the master binary log. You will need this information so that when the slave starts the replication process, it is able to start processing events from the binary log at the correct point.

If you have existing data on your master that you want to synchronize on your slaves before starting the replication process, then you must stop processing statements on the master, obtain the current position, and then dump the data, before allowing the master to continue executing statements. If you do not stop the execution of statements, the data dump and the master status information that you use will not match and you will end up with inconsistent or corrupted databases on the slaves.

To get the master status information, follow these steps:

1. Start the command-line client and flush all tables and block write statements by executing the `FLUSH TABLES WITH READ LOCK` statement:

```
mysql> FLUSH TABLES WITH READ LOCK;
```

For `InnoDB` tables, note that `FLUSH TABLES WITH READ LOCK` also blocks `COMMIT` operations.

### Warning

Leave the client from which you issued the `FLUSH TABLES` statement running so that the read lock remains in effect. If you exit the client, the lock is released.

2. Use the `SHOW MASTER STATUS` statement to determine the current binary log file name and offset on the master:

```
mysql > SHOW MASTER STATUS;
+-----+-----+-----+-----+
| File           | Position | Binlog_Do_DB | Binlog_Ignore_DB |
+-----+-----+-----+-----+
| mysql-bin.003 | 73       | test         | manual,mysql      |
+-----+-----+-----+-----+
```

The `File` column shows the name of the log file and `Position` shows the offset within the file. In this example, the binary log file is `mysql-bin.003` and the offset is 73. Record these values. You need them later when you are setting up the slave. They represent the replication coordinates at which the slave should begin processing new updates from the master.

If the master has been running previously without binary logging enabled, the log name and position values displayed by `SHOW MASTER STATUS` or `mysqldump --master-data` will be empty. In that case, the values that you need to use later when specifying the slave's log file and position are the empty string (') and 4.

You now have the information you need to enable the slave to start reading from the binary log in the correct place to start replication.

If you have existing data that needs be to synchronized with the slave before you start replication, leave the client running so that the lock remains in place and then proceed to [Section 16.1.1.5, “Creating a Data Snapshot Using `mysqldump`”](#), or [Section 16.1.1.6, “Creating a Data Snapshot Using Raw Data Files”](#).

If you are setting up a brand new master and slave replication group, then you can exit the client and release the locks.

## 16.1.1.5. Creating a Data Snapshot Using `mysqldump`

One way to create a snapshot of the data in an existing master database is to use the `mysqldump` tool. Once the data dump has

been completed, you then import this data into the slave before starting the replication process.

To obtain a snapshot of the data using `mysqldump`:

- If you haven't already locked the tables on the server to prevent statements that update data from executing:

Start the command-line client and flush all tables and block write statements by executing the `FLUSH TABLES WITH READ LOCK` statement:

```
mysql> FLUSH TABLES WITH READ LOCK;
```

Remember to use `SHOW MASTER STATUS` and record the binary log details for use when starting up the slave. The point in time of your snapshot and the binary log position must match. See [Section 16.1.1.4, “Obtaining the Master Replication Information”](#).

- In another session, use `mysqldump` to create a dump either of all the databases you want to replicate, or of selected individual databases. For example:

```
shell> mysqldump --all-databases --lock-all-tables >dbdump.db
```

- An alternative to using a bare dump, is to use the `--master-data` option, which automatically appends the `CHANGE MASTER TO` statement required on the slave to start the replication process.

```
shell> mysqldump --all-databases --master-data >dbdump.db
```

- In the client where you acquired the read lock, release the lock:

```
mysql> UNLOCK TABLES;
```

When choosing databases to include in the dump, remember that you will need to filter out databases on each slave that you do not want to include in the replication process.

You will need either to copy the dump file to the slave, or to use the file from the master when connecting remotely to the slave to import the data.

### 16.1.1.6. Creating a Data Snapshot Using Raw Data Files

If your database is particularly large, copying the raw data files may be more efficient than using `mysqldump` and importing the file on each slave.

However, using this method with tables in storage engines with complex caching or logging algorithms may not give you a perfect “in time” snapshot as cache information and logging updates may not have been applied, even if you have acquired a global read lock. How the storage engine responds to this depends on its crash recovery abilities.

In addition, this method does not work reliably if the master and slave have different values for `ft_stopword_file`, `ft_min_word_len`, or `ft_max_word_len` and you are copying tables having fulltext indexes.

If you are using `InnoDB` tables, you should use the `InnoDB Hot Backup` tool to obtain a consistent snapshot. This tool records the log name and offset corresponding to the snapshot to be later used on the slave. `Hot Backup` is a non-free (commercial) tool that is not included in the standard MySQL distribution. See the `InnoDB Hot Backup` home page at <http://www.innodb.com/hot-backup> for detailed information.

Otherwise, you can obtain a reliable binary snapshot of `InnoDB` tables only after shutting down the MySQL Server.

To create a raw data snapshot of `MyISAM` tables you can use standard copy tools such as `cp` or `copy`, a remote copy tool such as `scp` or `rsync`, an archiving tool such as `zip` or `tar`, or a file system snapshot tool such as `dump`, providing that your MySQL data files exist on a single file system. If you are replicating only certain databases then make sure you copy only those files that related to those tables. (For `InnoDB`, all tables in all databases are stored in a single file unless you have the `innodb_file_per_table` option enabled.)

You may want to specifically exclude the following files from your archive:

- Files relating to the `mysql` database.
- The `master.info` file.
- The master's binary log files.

- Any relay log files.

To get the most consistent results with a raw data snapshot you should shut down the server during the process, as below:

1. Acquire a read lock and get the master's status. See [Section 16.1.1.4, “Obtaining the Master Replication Information”](#).
2. In a separate session, shut down the MySQL server:

```
shell> mysqladmin shutdown
```

3. Take a copy of the MySQL data files. Examples are shown below for common solutions - you need to choose only one of these solutions:

```
shell> tar cf /tmp/db.tar ./data
shell> zip -r /tmp/db.zip ./data
shell> rsync --recursive ./data /tmp/dbdata
```

4. Start up the MySQL instance on the master.

If you are not using [InnoDB](#) tables, you can get a snapshot of the system from a master without shutting down the server as described in the following steps:

1. Acquire a read lock and get the master's status. See [Section 16.1.1.4, “Obtaining the Master Replication Information”](#).
2. Take a copy of the MySQL data files. Examples are shown below for common solutions - you need to choose only one of these solutions:

```
shell> tar cf /tmp/db.tar ./data
shell> zip -r /tmp/db.zip ./data
shell> rsync --recursive ./data /tmp/dbdata
```

3. In the client where you acquired the read lock, release the lock:

```
mysql> UNLOCK TABLES;
```

Once you have created the archive or copy of the database, you will need to copy the files to each slave before starting the slave replication process.

### 16.1.1.7. Setting Up Replication with New Master and Slaves

Setting up replication with a new master and slaves (that is, with no existing data) is the easiest and most straightforward method for setting up replication.

You can also use this method if you are setting up new servers but have an existing dump of the databases from a different server that you want to load into your replication configuration. By loading the data into a new master, the data will be automatically replicated to the slaves.

To set up replication between a new master and slave:

1. Configure the MySQL master with the necessary configuration properties. See [Section 16.1.1.2, “Setting the Replication Master Configuration”](#).
2. Start up the MySQL master.
3. Set up a user. See [Section 16.1.1.1, “Creating a User for Replication”](#).
4. Obtain the master status information. See [Section 16.1.1.4, “Obtaining the Master Replication Information”](#).
5. On the master, release the read lock:

```
mysql> UNLOCK TABLES;
```

6. On the slave, edit the MySQL configuration. See [Section 16.1.1.3, “Setting the Replication Slave Configuration”](#).

7. Start up the MySQL slave.
8. Execute the `CHANGE MASTER TO` statement to set the master replication server configuration.

Perform the slave setup steps on each slave.

Because there is no data to load or exchange on a new server configuration you do not need to copy or import any information.

If you are setting up a new replication environment using the data from a different existing database server, you will now need to run the dump file generated from that server on the new master. The database updates will automatically be propagated to the slaves:

```
shell> mysql -h master < fulldb.dump
```

### 16.1.1.8. Setting Up Replication with Existing Data

When setting up replication with existing data, you will need to decide how best to get the data from the master to the slave before starting the replication service.

The basic process for setting up replication with existing data is as follows:

1. If you have not already configured the `server-id` and binary logging, you will need to shut down your master to configure these options. See [Section 16.1.1.2, “Setting the Replication Master Configuration”](#).

If you have to shut down your master server, this is a good opportunity to take a snapshot of its databases. You should obtain the master status (see [Section 16.1.1.4, “Obtaining the Master Replication Information”](#)) before taking down the master, updating the configuration and taking a snapshot. For information on how to create a snapshot using raw data files, see [Section 16.1.1.6, “Creating a Data Snapshot Using Raw Data Files”](#).

2. If your server is already correctly configured, obtain the master status (see [Section 16.1.1.4, “Obtaining the Master Replication Information”](#)) and then use `mysqldump` to take a snapshot (see [Section 16.1.1.5, “Creating a Data Snapshot Using `mysqldump`”](#)) or take a raw snapshot of the live server using the guide in [Section 16.1.1.6, “Creating a Data Snapshot Using Raw Data Files”](#).
3. With the MySQL master running, create a user to be used by the slave when connecting to the master during replication. See [Section 16.1.1.1, “Creating a User for Replication”](#).
4. Update the configuration of the slave. See [Section 16.1.1.3, “Setting the Replication Slave Configuration”](#).
5. The next step depends on how you created the snapshot of data on the master.

If you used `mysqldump`:

- a. Start the slave, skipping replication by using the `--skip-slave` option.
- b. Import the dump file:

```
shell> mysql < fulldb.dump
```

If you created a snapshot using the raw data files:

- a. Extract the data files into your slave data directory. For example:

```
shell> tar xvf dbdump.tar
```

You may need to set permissions and ownership on the files to match the configuration of your slave.

- b. Start the slave, skipping replication by using the `--skip-slave` option.
6. Configure the slave with the master status information. This will tell the slave the binary log file and position within the file where replication needs to start, and configure the login credentials and host name of the master. For more information on the statement required, see [Section 16.1.1.10, “Setting the Master Configuration on the Slave”](#).
7. Start the slave threads:

```
mysql> START SLAVE;
```

After you have performed this procedure, the slave should connect to the master and catch up on any updates that have occurred since the snapshot was taken.

If you have forgotten to set the `server-id` option for the master, slaves cannot connect to it.

If you have forgotten to set the `server-id` option for the slave, you get the following error in the slave's error log:

```
Warning: You should set server-id to a non-0 value if master_host
is set; we will force server id to 2, but this MySQL server will
not act as a slave.
```

You also find error messages in the slave's error log if it is not able to replicate for any other reason.

Once a slave is replicating, you can find in its data directory one file named `master.info` and another named `relay-log.info`. The slave uses these two files to keep track of how much of the master's binary log it has processed. Do *not* remove or edit these files unless you know exactly what you are doing and fully understand the implications. Even in that case, it is preferred that you use the `CHANGE MASTER TO` statement to change replication parameters. The slave will use the values specified in the statement to update the status files automatically.

### Note

The content of `master.info` overrides some of the server options specified on the command line or in `my.cnf`. See Section 16.1.2, “Replication and Binary Logging Options and Variables”, for more details.

Once you have a snapshot of the master, you can use it to set up other slaves by following the slave portion of the procedure just described. You do not need to take another snapshot of the master; you can use the same one for each slave.

## 16.1.1.9. Introducing Additional Slaves to an Existing Replication Environment

If you want to add another slave to the existing replication configuration then you can do so without stopping the master. Instead, you duplicate the settings on the slaves by making a copy of one of the slaves.

To duplicate the slave:

1. Shut down the existing slave:

```
shell> mysqladmin shutdown
```

2. Copy the data directory from the existing slave to the new slave. You can do this by creating an archive using `tar` or `Win-Zip`, or by performing a direct copy using a tool such as `cp` or `rsync`. Ensure that you also copy the log files and relay log files.

### Note

A common problem that is encountered when adding new replication slaves is that the new slave fails with a series of warning and error messages like these:

```
071118 16:44:10 [Warning] Neither --relay-log nor --relay-log-index were used; so
replication may break when this MySQL server acts as a slave and has his hostname
changed!! Please use '--relay-log=new_slave_hostname-relay-bin' to avoid this problem.
071118 16:44:10 [ERROR] FAILED TO OPEN THE RELAY LOG './OLD_SLAVE_HOSTNAME-RELAY-BIN.003525'
(RELAY_LOG_POS 22940879)
071118 16:44:10 [ERROR] COULD NOT FIND TARGET LOG DURING RELAY LOG INITIALIZATION
071118 16:44:10 [ERROR] FAILED TO INITIALIZE THE MASTER INFO STRUCTURE
```

This is due to the fact that, if the `--relay-log` option is not specified, the relay log files contain the host name as part of their file names. (This is also true of the relay log index file if the `--relay-log-index` option is not used. See Section 16.1.2, “Replication and Binary Logging Options and Variables”, for more information about these options.)

To avoid this problem, use the same value for `--relay-log` on the new slave that was used on the existing slave. (If this option was not set explicitly on the existing slave, use `existing_slave_hostname-relay-bin`.) If this is not feasible, then copy the existing slave's relay log index file to the new slave and set the `--relay-log-index` option on the new slave to match what was used on the existing slave. (If this option was not set explicitly on the existing slave, use `existing_slave_hostname-relay-bin.index`.) Alternatively — if you have already tried to start the new slave (after following the remaining steps in this section) and have encountered errors like those described previously — then perform the following steps:

- a. If you have not already done so, issue a `STOP SLAVE` on the new slave.

If you have already started the existing slave again, issue a `STOP SLAVE` on the existing slave as well.

- b. Copy the contents of the existing slave's relay log index file into the new slave's relay log index file, making sure to overwrite any content already in the file.
  - c. Proceed with the remaining steps in this section.
3. Copy the `master.info` and `relay-log.info` files from the existing slave to the new slave. These files hold the current log positions.
4. Start the existing slave.
5. On the new slave, edit the configuration and give the new slave a new unique `server-id`.
6. Start the new slave; the `master.info` file options will be used to start the replication process.

### 16.1.1.10. Setting the Master Configuration on the Slave

To set up the slave to communicate with the master for replication, you must tell the slave the necessary connection information. To do this, execute the following statement on the slave, replacing the option values with the actual values relevant to your system:

```
mysql> CHANGE MASTER TO
->     MASTER_HOST='master_host_name',
->     MASTER_USER='replication_user_name',
->     MASTER_PASSWORD='replication_password',
->     MASTER_LOG_FILE='recorded_log_file_name',
->     MASTER_LOG_POS=recorded_log_position;
```

#### Note

Replication cannot use Unix socket files. You must be able to connect to the master MySQL server using TCP/IP.

The following table shows the maximum allowable length for the string-valued options.

Option	Maximum Length
<code>MASTER_HOST</code>	60
<code>MASTER_USER</code>	16
<code>MASTER_PASSWORD</code>	32
<code>MASTER_LOG_FILE</code>	255

## 16.1.2. Replication and Binary Logging Options and Variables

The next few sections contain information about `mysqld` options and server variables that are used in replication and for controlling the binary log. Options and variables for use on replication masters and replication slaves are covered separately, as are options and variables relating to binary logging. A set of quick-reference tables providing basic information about these options and variables is also included (in the next section following this one).

Of particular importance is the `--server-id` option.

<b>Command Line Format</b>	<code>--server-id=#</code>	
<b>Config File Format</b>	<code>server-id</code>	
<b>Option Sets Variable</b>	Yes, <code>server_id</code>	
<b>Variable Name</b>	<code>server_id</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	Yes	
<b>Value Set</b>	<b>Type</b>	<code>numeric</code>
	<b>Default</b>	<code>0</code>
	<b>Range</b>	<code>0-4294967295</code>

This option is common to both master and slave replication servers, and is used in replication to enable master and slave servers to identify themselves uniquely. For additional information, see [Section 16.1.2.2, “Replication Master Options and Variables”](#), and [Section 16.1.2.3, “Replication Slave Options and Variables”](#).

On the master and each slave, you *must* use the `--server-id` option to establish a unique replication ID in the range from 1 to 232 – 1; by “unique”, we mean that each ID must be different from every other ID in use by any other replication master or slave. Example: `server-id=3`.

If you omit `--server-id`, it assumes the default value 0, in which case a master refuses connections from all slaves, and a slave refuses to connect to a master. See [Section 16.1.1.3, “Setting the Replication Slave Configuration”](#), for more information.

### 16.1.2.1. Replication and Binary Logging Option and Variable Reference

The following tables list basic information about the MySQL command-line options and system variables applicable to replication and the binary log.

**Table 16.1. `mysqld` Replication Option/Variable Summary**

Name	Cmd-Line	Option file	System Var	Status Var	Var Scope	Dynamic
<a href="#">abort-slave-event-count</a>	Yes	Yes				
<a href="#">Com_change_master</a>				Yes	Both	No

Section 16.1.2.4, “Binary Log Options and Variables”, provides more detailed information about options and variables relating to binary logging. For additional general information about the binary log, see [Section 5.2.3](#), “The Binary Log”.

For a table showing *all* command-line options, system and status variables used with `mysqld`, see [Section 5.1.1](#), “Server Option and Variable Reference”.

## 16.1.2.2. Replication Master Options and Variables

This section describes the server options and system variables that you can use on replication master servers. You can specify the options either on the [command line](#) or in an [option file](#). You can specify system variable values using [SET](#).

On the master and each slave, you must use the `server-id` option to establish a unique replication ID. For each server, you should pick a unique positive integer in the range from 1 to  $2^{32} - 1$ , and each ID must be different from every other ID in use by any other replication master or slave. Example: `server-id=3`.

For options used on the master for controlling binary logging, see [Section 16.1.2.4, “Binary Log Options and Variables”](#).

- `auto_increment_increment`

<b>Version Introduced</b>	5.0.2	
<b>Command Line Format</b>	<code>--auto_increment_increment[=#]</code>	
<b>Config File Format</b>	<code>auto_increment_increment</code>	
<b>Option Sets Variable</b>	Yes, <code>auto_increment_increment</code>	
<b>Variable Name</b>	<code>auto_increment_increment</code>	
<b>Variable Scope</b>	Both	
<b>Dynamic Variable</b>	Yes	
<b>Value Set</b>	<b>Type</b>	numeric
	<b>Default</b>	1
	<b>Range</b>	1-65535

`auto_increment_increment` and `auto_increment_offset` are intended for use with master-to-master replication, and can be used to control the operation of `AUTO_INCREMENT` columns. Both variables have global and session values, and each can assume an integer value between 1 and 65,535 inclusive. Setting the value of either of these two variables to 0 causes its value to be set to 1 instead. Attempting to set the value of either of these two variables to an integer greater than 65,535 or less than 0 causes its value to be set to 65,535 instead. Attempting to set the value of `auto_increment_increment` or `auto_increment_offset` to a non-integer value gives rise to an error, and the actual value of the variable remains unchanged.

These two variables affect `AUTO_INCREMENT` column behavior as follows:

- `auto_increment_increment` controls the interval between successive column values. For example:

```
mysql> SHOW VARIABLES LIKE 'auto_inc%';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| auto_increment_increment | 1 |
| auto_increment_offset | 1 |
+-----+-----+
2 rows in set (0.00 sec)

mysql> CREATE TABLE autoinc1
-> (col INT NOT NULL AUTO_INCREMENT PRIMARY KEY);
Query OK, 0 rows affected (0.04 sec)

mysql> SET @@auto_increment_increment=10;
Query OK, 0 rows affected (0.00 sec)

mysql> SHOW VARIABLES LIKE 'auto_inc%';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| auto_increment_increment | 10 |
| auto_increment_offset | 1 |
+-----+-----+
2 rows in set (0.01 sec)

mysql> INSERT INTO autoinc1 VALUES (NULL), (NULL), (NULL), (NULL);
Query OK, 4 rows affected (0.00 sec)
Records: 4 Duplicates: 0 Warnings: 0

mysql> SELECT col FROM autoinc1;
+----+
| col |
+----+
| 1 |
| 11 |
| 21 |
| 31 |
+----+
```

```
4 rows in set (0.00 sec)
```

(Note how `SHOW VARIABLES` is used here to obtain the current values for these variables.)

- `auto_increment_offset` determines the starting point for the `AUTO_INCREMENT` column value. Consider the following, assuming that these statements are executed during the same session as the example given in the description for `auto_increment_increment`:

```
mysql> SET @@auto_increment_offset=5;
Query OK, 0 rows affected (0.00 sec)

mysql> SHOW VARIABLES LIKE 'auto_inc%';
+-----+
| Variable_name          | Value |
+-----+
| auto_increment_increment | 10    |
| auto_increment_offset   | 5     |
+-----+
2 rows in set (0.00 sec)

mysql> CREATE TABLE autoinc2
  -> (col INT NOT NULL AUTO_INCREMENT PRIMARY KEY);
Query OK, 0 rows affected (0.06 sec)

mysql> INSERT INTO autoinc2 VALUES (NULL), (NULL), (NULL), (NULL);
Query OK, 4 rows affected (0.00 sec)
Records: 4 Duplicates: 0 Warnings: 0

mysql> SELECT col FROM autoinc2;
+-----+
| col |
+-----+
| 5   |
| 15  |
| 25  |
| 35  |
+-----+
4 rows in set (0.02 sec)
```

If the value of `auto_increment_offset` is greater than that of `auto_increment_increment`, the value of `auto_increment_offset` is ignored.

Should one or both of these variables be changed and then new rows inserted into a table containing an `AUTO_INCREMENT` column, the results may seem counterintuitive because the series of `AUTO_INCREMENT` values is calculated without regard to any values already present in the column, and the next value inserted is the least value in the series that is greater than the maximum existing value in the `AUTO_INCREMENT` column. In other words, the series is calculated like so:

$$\text{auto\_increment\_offset} + N \times \text{auto\_increment\_increment}$$

where  $N$  is a positive integer value in the series [1, 2, 3, ...]. For example:

```
mysql> SHOW VARIABLES LIKE 'auto_inc%';
+-----+
| Variable_name          | Value |
+-----+
| auto_increment_increment | 10    |
| auto_increment_offset   | 5     |
+-----+
2 rows in set (0.00 sec)

mysql> SELECT col FROM autoinc1;
+-----+
| col |
+-----+
| 1   |
| 11  |
| 21  |
| 31  |
+-----+
4 rows in set (0.00 sec)

mysql> INSERT INTO autoinc1 VALUES (NULL), (NULL), (NULL), (NULL);
Query OK, 4 rows affected (0.00 sec)
Records: 4 Duplicates: 0 Warnings: 0

mysql> SELECT col FROM autoinc1;
+-----+
| col |
+-----+
| 1   |
| 11  |
| 21  |
| 31  |
| 35  |
| 45  |
| 55  |
+-----+
```

```
| 65 |
+-----+
8 rows in set (0.00 sec)
```

The values shown for `auto_increment_increment` and `auto_increment_offset` generate the series  $5 + N \times 10$ , that is, [5, 15, 25, 35, 45, ...]. The greatest value present in the `col` column prior to the `INSERT` is 31, and the next available value in the `AUTO_INCREMENT` series is 35, so the inserted values for `col` begin at that point and the results are as shown for the `SELECT` query.

It is not possible to confine the effects of these two variables to a single table, and thus they do not take the place of the sequences offered by some other database management systems; these variables control the behavior of all `AUTO_INCREMENT` columns in *all* tables on the MySQL server. If the global value of either variable is set, its effects persist until the global value is changed or overridden by setting the session value, or until `mysqld` is restarted. If the local value is set, the new value affects `AUTO_INCREMENT` columns for all tables into which new rows are inserted by the current user for the duration of the session, unless the values are changed during that session.

The `auto_increment_increment` variable was added in MySQL 5.0.2. Its default value is 1. See [Section 16.3.1.1, “Replication and AUTO\\_INCREMENT”](#).

`auto_increment_increment` is supported for use with `NDB` tables beginning with MySQL 5.0.46. Previously, setting it when using MySQL Cluster tables produced unpredictable results.

- `auto_increment_offset`

<b>Version Introduced</b>	5.0.2	
<b>Command Line Format</b>	<code>--auto_increment_offset[=#]</code>	
<b>Config File Format</b>	<code>auto_increment_offset</code>	
<b>Option Sets Variable</b>	Yes, <code>auto_increment_offset</code>	
<b>Variable Name</b>	<code>auto_increment_offset</code>	
<b>Variable Scope</b>	Both	
<b>Dynamic Variable</b>	Yes	
<b>Value Set</b>	<b>Type</b>	numeric
	<b>Default</b>	1
	<b>Range</b>	1-65535

This variable was introduced in MySQL 5.0.2. Its default value is 1. For particulars, see the description for `auto_increment_increment`.

`auto_increment_offset` is supported for use with `NDB` tables beginning with MySQL 5.0.46. Previously, setting it when using MySQL Cluster tables produced unpredictable results.

### 16.1.2.3. Replication Slave Options and Variables

This section describes the server options and system variables that you can use on slave replication servers. You can specify the options either on the [command line](#) or in an [option file](#). Many of the options can be reset while the server is running by using the `CHANGE MASTER TO` statement. You can specify system variable values using `SET`.

**Server ID.** On the master and each slave, you must use the `server-id` option to establish a unique replication ID. For each server, you should pick a unique positive integer in the range from 1 to  $2^{32} - 1$ , and each ID must be different from every other ID. Example: `server-id=3`.

Some slave server replication options are handled in a special way, in the sense that each is ignored if a `master.info` file exists when the slave starts and contains a value for the option. The following options are handled this way:

- `--master-host`
- `--master-user`
- `--master-password`
- `--master-port`
- `--master-connect-retry`

- `--master-ssl`
- `--master-ssl-ca`
- `--master-ssl-capath`
- `--master-ssl-cert`
- `--master-ssl-cipher`
- `--master-ssl-key`

The `master.info` file format included values corresponding to the SSL options, and includes as its first line the number of lines in the file. (See [Section 16.4.2, “Replication Relay and Status Files”](#).) If you upgrade an older server (that is, a server running a MySQL version prior to 4.1.1), the new server upgrades the `master.info` file to the new format automatically when it starts. However, if you downgrade a newer server to a version older than 4.1.1, you should manually remove the first line before starting the older server for the first time. Note that, in this case, the downgraded server can no longer use an SSL connection to communicate with the master.

If no `master.info` file exists when the slave server starts, it uses the values for those options that are specified in option files or on the command line. This occurs when you start the server as a replication slave for the very first time, or when you have run `RESET SLAVE` and then have shut down and restarted the slave.

If the `master.info` file exists when the slave server starts, the server uses its contents and ignores any options that correspond to the values listed in the file. Thus, if you start the slave server with different values of the startup options that correspond to values in the `master.info` file, the different values have no effect, because the server continues to use the `master.info` file. To use different values, you must either restart after removing the `master.info` file or (preferably) use the `CHANGE MASTER TO` statement to reset the values while the slave is running.

Suppose that you specify this option in your `my.cnf` file:

```
[mysqld]
master-host=some_host
```

The first time you start the server as a replication slave, it reads and uses that option from the `my.cnf` file. The server then records the value in the `master.info` file. The next time you start the server, it reads the master host value from the `master.info` file only and ignores the value in the option file. If you modify the `my.cnf` file to specify a different master host of `some_other_host`, the change still has no effect. You should use `CHANGE MASTER TO` instead.

#### MySQL Enterprise

For expert advice regarding slave startup options subscribe to the MySQL Enterprise Monitor. For more information, see <http://www.mysql.com/products/enterprise/advisors.html>.

Because the server gives an existing `master.info` file precedence over the startup options just described, you might prefer not to use startup options for these values at all, and instead specify them by using the `CHANGE MASTER TO` statement. See [Section 12.6.2.1, “CHANGE MASTER TO Syntax”](#).

This example shows a more extensive use of startup options to configure a slave server:

```
[mysqld]
server-id=2
master-host=db-master.mycompany.com
master-port=3306
master-user=pertinax
master-password=freitag
master-connect-retry=60
report-host=db-slave.mycompany.com
```

**Startup options for replication slaves.** The following list describes startup options for controlling replication slaves. Many of these options can be reset while the server is running by using the `CHANGE MASTER TO` statement. Others, such as the `--replicate-*` options, can be set only when the slave server starts. Replication-related system variables are discussed later in this section.

- `--log-slave-updates`

Normally, a slave does not log to its own binary log any updates that are received from a master server. This option tells the slave to log the updates performed by its SQL thread to its own binary log. For this option to have any effect, the slave must also be started with the `--log-bin` option to enable binary logging. `--log-slave-updates` is used when you want to chain replication servers. For example, you might want to set up replication servers using this arrangement:

---

```
A -> B -> C
```

Here, **A** serves as the master for the slave **B**, and **B** serves as the master for the slave **C**. For this to work, **B** must be both a master *and* a slave. You must start both **A** and **B** with `--log-bin` to enable binary logging, and **B** with the `--log-slave-updates` option so that updates received from **A** are logged by **B** to its binary log.

- `--log-warnings[=level]`

This option causes a server to print more messages to the error log about what it is doing. With respect to replication, the server generates warnings that it succeeded in reconnecting after a network/connection failure, and informs you as to how each slave thread started. This option is enabled by default; to disable it, use `--skip-log-warnings`. Aborted connections are not logged to the error log unless the value is greater than 1.

Note that the effects of this option are not limited to replication. It produces warnings across a spectrum of server activities.

- `--master-connect-retry=seconds`

The number of seconds that the slave thread sleeps before trying to reconnect to the master in case the master goes down or the connection is lost. The value in the `master.info` file takes precedence if it can be read. If not set, the default is 60. Connection retries are not invoked until the slave times out reading data from the master according to the value of `--slave-net-timeout`. The number of reconnection attempts is limited by the `--master-retry-count` option.

- `--master-host=host_name`

The host name or IP number of the master replication server. The value in `master.info` takes precedence if it can be read. If no master host is specified, the slave thread does not start.

- `--master-info-file=file_name`

The name to use for the file in which the slave records information about the master. The default name is `master.info` in the data directory.

- `--master-password=password`

The password of the account that the slave thread uses for authentication when it connects to the master. The value in the `master.info` file takes precedence if it can be read. If not set, an empty password is assumed.

- `--master-port=port_number`

The TCP/IP port number that the master is listening on. The value in the `master.info` file takes precedence if it can be read. If not set, the compiled-in setting is assumed (normally 3306).

- `--master-retry-count=count`

The number of times that the slave tries to connect to the master before giving up. Reconnects are attempted at intervals set by the `CHANGE MASTER TO` statement or `--master-connect-retry` option and reconnects are triggered when data reads by the slave time out according to the `--slave-net-timeout` option. The default value is 86400.

- `--master-ssl, --master-ssl-ca=file_name, --master-ssl-capath=directory_name, --master-ssl-cert=file_name, --master-ssl-cipher=cipher_list, --master-ssl-key=file_name`

These options are used for setting up a secure replication connection to the master server using SSL. Their meanings are the same as the corresponding `--ssl, --ssl-ca, --ssl-capath, --ssl-cert, --ssl-cipher, --ssl-key` options that are described in [Section 5.5.7.3, "SSL Command Options"](#). The values in the `master.info` file take precedence if they can be read.

- `--master-user=user_name`

The user name of the account that the slave thread uses for authentication when it connects to the master. This account must have the `REPLICATION SLAVE` privilege. `FILE` privilege instead.) The value in the `master.info` file takes precedence if it can be read. If the master user name is not set, the name `test` is assumed.

- `--read-only`

Cause the slave to allow no updates except from slave threads or from users having the `SUPER` privilege. On a slave server, this can be useful to ensure that the slave accepts updates only from its master server and not from clients. This variable does not apply to `TEMPORARY` tables.

- `--relay-log=file_name`

The basename for the relay log. The default basename is `host_name-relay-bin`. The server creates relay log files in sequence by adding a numeric suffix to the basename.

Due to the manner in which MySQL parses server options, if you specify this option, you must supply a value; *the default basename is used only if the option is not actually specified*. If you use the `--relay-log` option without specifying a value, unexpected behavior is likely to result; this behavior depends on the other options used, the order in which they are specified, and whether they are specified on the command line or in an option file. For more information about how MySQL handles server options, see [Section 4.2.3, “Specifying Program Options”](#).

If you specify this option, the value specified is also used as the basename for the relay log index file. You can override this behavior by specifying a different relay log index file basename using the `--relay-log-index` option.

You may find the `--relay-log` option useful in performing the following tasks:

- Creating relay logs whose names are independent of host names.
- If you need to put the relay logs in some area other than the data directory, because your relay logs tend to be very large and you do not want to decrease `max_relay_log_size`.
- To increase speed by using load-balancing between disks.
- `--relay-log-index=file_name`

The name to use for the relay log index file. The default name is `host_name-relay-bin.index` in the data directory, where `host_name` is the name of the slave server.

Due to the manner in which MySQL parses server options, if you specify this option, you must supply a value; *the default basename is used only if the option is not actually specified*. If you use the `--relay-log-index` option without specifying a value, unexpected behavior is likely to result; this behavior depends on the other options used, the order in which they are specified, and whether they are specified on the command line or in an option file. For more information about how MySQL handles server options, see [Section 4.2.3, “Specifying Program Options”](#).

If you specify this option, the value specified is also used as the basename for the relay logs. You can override this behavior by specifying a different relay log file basename using the `--relay-log` option.

- `--relay-log-info-file=file_name`

The name to use for the file in which the slave records information about the relay logs. The default name is `relay-log.info` in the data directory.

- `--relay-log-purge={0|1}`

Disable or enable automatic purging of relay logs as soon as they are no longer needed. The default value is 1 (enabled). This is a global variable that can be changed dynamically with `SET GLOBAL relay_log_purge = N`.

- `--max-relay-log-size=size`

The size at which the server rotates relay log files automatically. For more information, see [Section 16.4.2, “Replication Relay and Status Files”](#). Default is 1GB.

- `--relay-log-space-limit=size`

This option places an upper limit on the total size in bytes of all relay logs on the slave. A value of 0 means “no limit.” This is useful for a slave server host that has limited disk space. When the limit is reached, the I/O thread stops reading binary log events from the master server until the SQL thread has caught up and deleted some unused relay logs. Note that this limit is not absolute: There are cases where the SQL thread needs more events before it can delete relay logs. In that case, the I/O thread exceeds the limit until it becomes possible for the SQL thread to delete some relay logs, because not doing so would cause a deadlock. You should not set `--relay-log-space-limit` to less than twice the value of `--max-relay-log-size` (or `--max-binlog-size` if `--max-relay-log-size` is 0). In that case, there is a chance that the I/O thread waits for free space because `--relay-log-space-limit` is exceeded, but the SQL thread has no relay log to purge and is unable to satisfy the I/O thread. This forces the I/O thread to ignore `--relay-log-space-limit` temporarily.

- `--replicate-do-db=db_name`

Tell the slave to restrict replication to statements where the default database (that is, the one selected by `USE`) is `db_name`. To specify more than one database, use this option multiple times, once for each database. Note that this does not replicate cross-database statements such as `UPDATE some_db.some_table SET foo='bar'` while having selected a different database or no database.

## ■ Warning

To specify multiple databases you *must* use multiple instances of this option. Because database names can contain commas, if you supply a comma separated list then the list will be treated as the name of a single database.

An example of what does not work as you might expect: If the slave is started with `--replicate-do-db=sales` and you issue the following statements on the master, the `UPDATE` statement is *not* replicated:

```
USE prices;
UPDATE sales.january SET amount=amount+1000;
```

The main reason for this “check just the default database” behavior is that it is difficult from the statement alone to know whether it should be replicated (for example, if you are using multiple-table `DELETE` or multiple-table `UPDATE` statements that go across multiple databases). It is also faster to check only the default database rather than all databases if there is no need.

If you need cross-database updates to work, use `--replicate-wild-do-table=db_name.%` instead. See [Section 16.4.3, “How Servers Evaluate Replication Rules”](#).

- `--replicate-ignore-db=db_name`

Tells the slave to not replicate any statement where the default database (that is, the one selected by `USE`) is `db_name`. To specify more than one database to ignore, use this option multiple times, once for each database. You should not use this option if you are using cross-database updates and you do not want these updates to be replicated. See [Section 16.4.3, “How Servers Evaluate Replication Rules”](#).

An example of what does not work as you might expect: If the slave is started with `--replicate-ignore-db=sales` and you issue the following statements on the master, the `UPDATE` statement *is* replicated:

```
USE prices;
UPDATE sales.january SET amount=amount+1000;
```

### Note

In the preceding example the statement is replicated because `--replicate-ignore-db` only applies to the default database (set through the `USE` statement). Because the `sales` database was specified explicitly in the statement, the statement has not been filtered.

If you need cross-database updates to work, use `--replicate-wild-ignore-table=db_name.%` instead. See [Section 16.4.3, “How Servers Evaluate Replication Rules”](#).

- `--replicate-do-table=db_name.tbl_name`

Tells the slave thread to restrict replication to the specified table. To specify more than one table, use this option multiple times, once for each table. This works for cross-database updates, in contrast to `--replicate-do-db`. See [Section 16.4.3, “How Servers Evaluate Replication Rules”](#).

- `--replicate-ignore-table=db_name.tbl_name`

Tells the slave thread to not replicate any statement that updates the specified table, even if any other tables might be updated by the same statement. To specify more than one table to ignore, use this option multiple times, once for each table. This works for cross-database updates, in contrast to `--replicate-ignore-db`. See [Section 16.4.3, “How Servers Evaluate Replication Rules”](#).

- `--replicate-rewrite-db=from_name->to_name`

Tells the slave to translate the default database (that is, the one selected by `USE`) to `to_name` if it was `from_name` on the master. Only statements involving tables are affected (not statements such as `CREATE DATABASE`, `DROP DATABASE`, and `ALTER DATABASE`), and only if `from_name` is the default database on the master. This does not work for cross-database updates. To specify multiple rewrites, use this option multiple times. The server uses the first one with a `from_name` value that matches. The database name translation is done *before* the `--replicate-*` rules are tested.

If you use this option on the command line and the “>” character is special to your command interpreter, quote the option value. For example:

```
shell> mysqld --replicate-rewrite-db="olddb->newdb"
```

- `--replicate-same-server-id`

To be used on slave servers. Usually you should use the default setting of 0, to prevent infinite loops caused by circular replication. If set to 1, the slave does not skip events having its own server ID. Normally, this is useful only in rare configurations. Cannot be set to 1 if `--log-slave-updates` is used. By default, the slave I/O thread does not write binary log events to

the relay log if they have the slave's server ID (this optimization helps save disk usage). If you want to use `--replicate-same-server-id`, be sure to start the slave with this option before you make the slave read its own events that you want the slave SQL thread to execute.

- `--replicate-wild-do-table=db_name.tbl_name`

Tells the slave thread to restrict replication to statements where any of the updated tables match the specified database and table name patterns. Patterns can contain the “%” and “\_” wildcard characters, which have the same meaning as for the `LIKE` pattern-matching operator. To specify more than one table, use this option multiple times, once for each table. This works for cross-database updates. See [Section 16.4.3, “How Servers Evaluate Replication Rules”](#).

Example: `--replicate-wild-do-table=foo%.bar%` replicates only updates that use a table where the database name starts with `foo` and the table name starts with `bar`.

If the table name pattern is `%`, it matches any table name and the option also applies to database-level statements (`CREATE DATABASE`, `DROP DATABASE`, and `ALTER DATABASE`). For example, if you use `--replicate-wild-do-table=foo%.%`, database-level statements are replicated if the database name matches the pattern `foo%`.

To include literal wildcard characters in the database or table name patterns, escape them with a backslash. For example, to replicate all tables of a database that is named `my_own%db`, but not replicate tables from the `my1ownAABCdb` database, you should escape the “\_” and “%” characters like this: `--replicate-wild-do-table=my\_own\%db`. If you're using the option on the command line, you might need to double the backslashes or quote the option value, depending on your command interpreter. For example, with the `bash` shell, you would need to type `--replicate-wild-do-table=my\\\_own\\%db`.

- `--replicate-wild-ignore-table=db_name.tbl_name`

Tells the slave thread not to replicate a statement where any table matches the given wildcard pattern. To specify more than one table to ignore, use this option multiple times, once for each table. This works for cross-database updates. See [Section 16.4.3, “How Servers Evaluate Replication Rules”](#).

Example: `--replicate-wild-ignore-table=foo%.bar%` does not replicate updates that use a table where the database name starts with `foo` and the table name starts with `bar`.

For information about how matching works, see the description of the `--replicate-wild-do-table` option. The rules for including literal wildcard characters in the option value are the same as for `--replicate-wild-ignore-table` as well.

- `--report-host=host_name`

The host name or IP number of the slave to be reported to the master during slave registration. This value appears in the output of `SHOW SLAVE HOSTS` on the master server. Leave the value unset if you do not want the slave to register itself with the master. Note that it is not sufficient for the master to simply read the IP number of the slave from the TCP/IP socket after the slave connects. Due to NAT and other routing issues, that IP may not be valid for connecting to the slave from the master or other hosts.

- `--report-password=password`

The account password of the slave to be reported to the master during slave registration. This value appears in the output of `SHOW SLAVE HOSTS` on the master server if the `--show-slave-auth-info` option is given.

- `--report-port=slave_port_num`

The TCP/IP port number for connecting to the slave, to be reported to the master during slave registration. Set this only if the slave is listening on a non-default port or if you have a special tunnel from the master or other clients to the slave. If you are not sure, do not use this option.

- `--report-user=user_name`

The account user name of the slave to be reported to the master during slave registration. This value appears in the output of `SHOW SLAVE HOSTS` on the master server if the `--show-slave-auth-info` option is given.

- `--show-slave-auth-info`

Display slave user names and passwords in the output of `SHOW SLAVE HOSTS` on the master server for slaves started with the `--report-user` and `--report-password` options.

- `--skip-slave-start`

Tells the slave server not to start the slave threads when the server starts. To start the threads later, use a `START SLAVE` state-

ment.

- `--slave_compressed_protocol={0|1}`

If this option is set to 1, use compression for the slave/master protocol if both the slave and the master support it. The default is 0 (no compression).

- `--slave-load-tmpdir=file_name`

The name of the directory where the slave creates temporary files. This option is by default equal to the value of the `tmpdir` system variable. When the slave SQL thread replicates a `LOAD DATA INFILE` statement, it extracts the file to be loaded from the relay log into temporary files, and then loads these into the table. If the file loaded on the master is huge, the temporary files on the slave are huge, too. Therefore, it might be advisable to use this option to tell the slave to put temporary files in a directory located in some file system that has a lot of available space. In that case, the relay logs are huge as well, so you might also want to use the `--relay-log` option to place the relay logs in that file system.

The directory specified by this option should be located in a disk-based file system (not a memory-based file system) because the temporary files used to replicate `LOAD DATA INFILE` must survive machine restarts. The directory also should not be one that is cleared by the operating system during the system startup process.

- `--slave-net-timeout=seconds`

The number of seconds to wait for more data from the master before the slave considers the connection broken, aborts the read, and tries to reconnect. The first retry occurs immediately after the timeout. The interval between retries is controlled by the `CHANGE MASTER TO` statement or `--master-connect-retry` option and the number of reconnection attempts is limited by the `--master-retry-count` option. The default is 3600 seconds (one hour).

- `--slave-skip-errors=[err_code1,err_code2,...|all]`

Normally, replication stops when an error occurs on the slave. This gives you the opportunity to resolve the inconsistency in the data manually. This option tells the slave SQL thread to continue replication when a statement returns any of the errors listed in the option value.

Do not use this option unless you fully understand why you are getting errors. If there are no bugs in your replication setup and client programs, and no bugs in MySQL itself, an error that stops replication should never occur. Indiscriminate use of this option results in slaves becoming hopelessly out of synchrony with the master, with you having no idea why this has occurred.

For error codes, you should use the numbers provided by the error message in your slave error log and in the output of `SHOW SLAVE STATUS`. [Appendix B, Errors, Error Codes, and Common Problems](#), lists server error codes.

You can also (but should not) use the very non-recommended value of `all` to cause the slave to ignore all error messages and keeps going regardless of what happens. Needless to say, if you use `all`, there are no guarantees regarding the integrity of your data. Please do not complain (or file bug reports) in this case if the slave's data is not anywhere close to what it is on the master. *You have been warned.*

Examples:

```
--slave-skip-errors=1062,1053
--slave-skip-errors=all
```

- `--abort-slave-event-count`

<b>Command Line Format</b>	<code>--abort-slave-event-count=#</code>	
<b>Config File Format</b>	<code>abort-slave-event-count</code>	
<b>Value Set</b>	<b>Type</b>	numeric
	<b>Default</b>	0
	<b>Min Value</b>	0

When this option is set to some positive integer *value* other than 0 (the default) it affects replication behavior as follows: After the slave SQL thread has started, *value* log events are allowed to be executed; after that, the slave SQL thread does not receive any more events, just as if the network connection from the master were cut. The slave thread continues to run, and the output from `SHOW SLAVE STATUS` displays `Yes` in both the `Slave_IO_Running` and the `Slave_SQL_Running` columns, but no further events are read from the relay log.

This option is used internally by the MySQL test suite for replication testing and debugging. It is not intended for use in a production setting.

- `--disconnect-slave-event-count`

<b>Command Line Format</b>	<code>--disconnect-slave-event-count=#</code>	
<b>Config File Format</b>	<code>disconnect-slave-event-count</code>	
<b>Value Set</b>	<b>Type</b>	numeric
	<b>Default</b>	0

This option is used internally by the MySQL test suite for replication testing and debugging.

**System variables used on replication slaves.** The following system variables are used for controlling replication slave servers. Those that can be set are specified using `SET`. Server options used with replication slaves are listed earlier in this section.

- `init_slave`

<b>Command Line Format</b>	<code>--init-slave=name</code>	
<b>Config File Format</b>	<code>init_slave</code>	
<b>Option Sets Variable</b>	Yes, <code>init_slave</code>	
<b>Variable Name</b>	<code>init_slave</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	Yes	
<b>Value Set</b>	<b>Type</b>	string

This variable is similar to `init_connect`, but is a string to be executed by a slave server each time the SQL thread starts. The format of the string is the same as for the `init_connect` variable.

#### Note

The SQL thread sends an acknowledgement to the client before `init_slave` is executed. Therefore, it is not guaranteed that `init_slave` has been executed when `START SLAVE` returns. See [Section 12.6.2.7, “START SLAVE Syntax”](#), for more information.

- `rpl_recovery_rank`

This variable is unused.

- `slave_compressed_protocol`

<b>Command Line Format</b>	<code>--slave_compressed_protocol</code>	
<b>Config File Format</b>	<code>slave_compressed_protocol</code>	
<b>Option Sets Variable</b>	Yes, <code>slave_compressed_protocol</code>	
<b>Variable Name</b>	<code>slave_compressed_protocol</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	Yes	
<b>Value Set</b>	<b>Type</b>	boolean
	<b>Default</b>	FALSE

Whether to use compression of the slave/master protocol if both the slave and the master support it.

- `slave_load_tmpdir`

<b>Command Line Format</b>	<code>--slave-load-tmpdir=name</code>	
<b>Config File Format</b>	<code>slave-load-tmpdir</code>	
<b>Option Sets Variable</b>	Yes, <code>slave_load_tmpdir</code>	
<b>Variable Name</b>	<code>slave_load_tmpdir</code>	

<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	No	
<b>Value Set</b>	<b>Type</b>	filename
	<b>Default</b>	/tmp

The name of the directory where the slave creates temporary files for replicating `LOAD DATA INFILE` statements.

- `slave_net_timeout`

<b>Command Line Format</b>	<code>--slave-net-timeout=#</code>	
<b>Config File Format</b>	<code>slave-net-timeout</code>	
<b>Option Sets Variable</b>	Yes, <code>slave_net_timeout</code>	
<b>Variable Name</b>	<code>slave_net_timeout</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	Yes	
<b>Value Set</b>	<b>Type</b>	numeric
	<b>Default</b>	3600
	<b>Min Value</b>	1

The number of seconds to wait for more data from a master/slave connection before aborting the read. This timeout applies only to TCP/IP connections, not to connections made via Unix socket files, named pipes, or shared memory.

- `slave_skip_errors`

<b>Command Line Format</b>	<code>--slave-skip-errors=name</code>	
<b>Config File Format</b>	<code>slave-skip-errors</code>	
<b>Option Sets Variable</b>	Yes, <code>slave_skip_errors</code>	
<b>Variable Name</b>	<code>slave_skip_errors</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	No	

Normally, replication stops when an error occurs on the slave. This gives you the opportunity to resolve the inconsistency in the data manually. This variable tells the slave SQL thread to continue replication when a statement returns any of the errors listed in the variable value.

- `sql_slave_skip_counter`

<b>Variable Name</b>	<code>sql_slave_skip_counter</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	Yes	
<b>Value Set</b>	<b>Type</b>	numeric

The number of events from the master that a slave server should skip.

### Important

If skipping the number of events specified by setting this variable would cause the slave to begin in the middle of an event group, the slave continues to skip until it finds the beginning of the next event group and begins from that point. See [Section 12.6.2.6, “SET GLOBAL SQL\\_SLAVE\\_SKIP\\_COUNTER Syntax”](#), for more information.

- `slave_transaction_retries`

<b>Version Introduced</b>	5.0.3
<b>Command Line Format</b>	<code>--slave_transaction_retries=#</code>

<b>Config File Format</b>	<a href="#">slave_transaction_retries</a>	
<b>Option Sets Variable</b>	Yes, <a href="#">slave_transaction_retries</a>	
<b>Variable Name</b>	<a href="#">slave_transaction_retries</a>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	Yes	
<b>Value Set</b>	<b>Platform Bit Size</b>	32
	<b>Type</b>	numeric
	<b>Default</b>	10
	<b>Range</b>	0-4294967295
<b>Value Set</b>	<b>Platform Bit Size</b>	64
	<b>Type</b>	numeric
	<b>Default</b>	10
	<b>Range</b>	0-18446744073709547520

If a replication slave SQL thread fails to execute a transaction because of an InnoDB deadlock or because the transaction's execution time exceeded InnoDB's `innodb_lock_wait_timeout` or NDBCLUSTER's `TransactionDeadlockDetectionTimeout` or `TransactionInactiveTimeout`, it automatically retries `slave_transaction_retries` times before stopping with an error. Prior to MySQL 5.0.3, the default is 0, and you must explicitly set the value greater than 0 to enable the “retry” behavior. In MySQL 5.0.3 or newer, the default is 10.

#### 16.1.2.4. Binary Log Options and Variables

You can use the `mysqld` options and system variables that are described in this section to affect the operation of the binary log as well as to control which statements are written to the binary log. For additional information about the binary log, see [Section 5.2.3, “The Binary Log”](#). For additional information about using MySQL server options and system variables, see [Section 5.1.2, “Server Command Options”](#), and [Section 5.1.3, “Server System Variables”](#).

**Startup options used with binary logging.** The following list describes startup options for enabling and configuring the binary log. Many of these options can be reset while the server is running by using the `CHANGE MASTER TO` statement. Others, can be set only when the slave server starts. System variables used with binary logging are discussed later in this section.

- `--log-bin[=base_name]`

<b>Command Line Format</b>	<code>--log-bin</code>	
<b>Config File Format</b>	<code>log-bin</code>	
<b>Variable Name</b>	<code>log_bin</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	No	
<b>Value Set</b>	<b>Type</b>	<code>filename</code>
	<b>Default</b>	<code>OFF</code>

Enable binary logging. The server logs all statements that change data to the binary log, which is used for backup and replication. See [Section 5.2.3, “The Binary Log”](#).

The option value, if given, is the basename for the log sequence. The server creates binary log files in sequence by adding a numeric suffix to the basename. It is recommended that you specify a basename (see [Additional Known Issues](#), for the reason). Otherwise, MySQL uses `host_name-bin` as the basename.

- `--log-bin-index[=file_name]`

<b>Command Line Format</b>	<code>--log-bin-index=name</code>	
<b>Config File Format</b>	<code>log-bin-index</code>	
<b>Value Set</b>	<b>Type</b>	<code>filename</code>
	<b>Default</b>	<code>OFF</code>

The index file for binary log file names. See [Section 5.2.3, “The Binary Log”](#). If you omit the file name, and if you didn't specify one with `--log-bin`, MySQL uses `host_name-bin.index` as the file name.

- **Statement selection options.** The options in the following list affect which statements are written to the binary log, and thus sent by a replication master server to its slaves.

- `--binlog-do-db=db_name`

Tell the server to restrict binary logging to updates for which the default database is `db_name` (that is, the database selected by `USE`). All other databases that are not explicitly mentioned are ignored. If you use this option, you should ensure that you do updates only in the default database.

There is an exception to this for `CREATE DATABASE`, `ALTER DATABASE`, and `DROP DATABASE` statements. The server uses the database named in the statement (not the default database) to decide whether it should log the statement.

An example of what does not work as you might expect: If the server is started with `binlog-do-db=sales`, and you run `USE prices; UPDATE sales.january SET amount=amount+1000;`, this statement is *not* written into the binary log.

### Important

To log multiple databases, use this option multiple times, specifying the option once for each database to be logged.

- `--binlog-ignore-db=db_name`

Tell the server to suppress binary logging of updates for which the default database is `db_name` (that is, the database selected by `USE`). If you use this option, you should ensure that you do updates only in the default database.

As with the `--binlog-do-db` option, there is an exception for the `CREATE DATABASE`, `ALTER DATABASE`, and `DROP DATABASE` statements. The server uses the database named in the statement (not the default database) to decide whether it should log the statement.

An example of what does not work as you might expect: If the server is started with `binlog-ignore-db=sales`, and you run `USE prices; UPDATE sales.january SET amount = amount + 1000;`, this statement *is* written into the binary log.

### Important

To ignore multiple databases, use this option multiple times, specifying the option once for each database to be ignored.

Additional server options that can be used to control logging also affect the binary log. For more information about these, see [Section 5.1.2, “Server Command Options”](#). For more information about how the options in the previous list are applied, see [Section 5.2.3, “The Binary Log”](#).

There are also options for slave servers that control which statements received from the master should be executed or ignored. For details, see [Section 16.1.2.3, “Replication Slave Options and Variables”](#).

- `--log-bin-trust-function-creators[={0|1}]`

<b>Version Introduced</b>	5.0.16	
<b>Command Line Format</b>	<code>--log-bin-trust-function-creators</code>	
<b>Config File Format</b>	<code>log-bin-trust-function-creators</code>	
<b>Option Sets Variable</b>	Yes, <code>log_bin_trust_function_creators</code>	
<b>Variable Name</b>	<code>log_bin_trust_function_creators</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	Yes	
<b>Value Set</b>	<b>Type</b>	boolean
	<b>Default</b>	FALSE

With no argument or an argument of 1, this option sets the `log_bin_trust_function_creators` system variable to 1. With an argument of 0, this option sets the system variable to 0. `log_bin_trust_function_creators` affects how MySQL enforces restrictions on stored function and trigger creation. See [Section 18.5, “Binary Logging of Stored Programs”](#).

This option was added in MySQL 5.0.16.

- `--log-bin-trust-routine-creators[={0|1}]`

<b>Version Introduced</b>	5.0.6	
<b>Version Deprecated</b>	5.0.16	
<b>Command Line Format</b>	<code>--log-bin-trust-routine-creators</code>	
<b>Config File Format</b>	<code>log-bin-trust-routine-creators</code>	
<b>Option Sets Variable</b>	Yes, <code>log_bin_trust_routine_creators</code>	
<b>Variable Name</b>	<code>log-bin-trust-routine-creators</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	Yes	
<b>Deprecated</b>	5.0.16, by <code>log-bin-trust-function-creators</code>	
<b>Value Set</b>	<b>Type</b>	boolean
	<b>Default</b>	FALSE

This is the old name for `--log-bin-trust-function-creators`. Before MySQL 5.0.16, it also applies to stored procedures, not just stored functions and sets the `log_bin_trust_routine_creators` system variable. As of 5.0.16, this option is deprecated. It is recognized for backward compatibility but its use results in a warning.

This option was added in MySQL 5.0.6.

**Testing and debugging options.** The following binary log options are used in replication testing and debugging. They are not intended for use in normal operations.

- `--max-binlog-dump-events`

<b>Command Line Format</b>	<code>--max-binlog-dump-events=#</code>	
<b>Config File Format</b>	<code>max-binlog-dump-events</code>	
<b>Value Set</b>	<b>Type</b>	numeric
	<b>Default</b>	0

This option is used internally by the MySQL test suite for replication testing and debugging.

- `--sporadic-binlog-dump-fail`

<b>Command Line Format</b>	<code>--sporadic-binlog-dump-fail</code>	
<b>Config File Format</b>	<code>sporadic-binlog-dump-fail</code>	
<b>Value Set</b>	<b>Type</b>	boolean
	<b>Default</b>	FALSE

This option is used internally by the MySQL test suite for replication testing and debugging.

**System variables used with the binary log.** The following system variables are used for controlling replication slave servers. Those that can be set are specified using `SET`. Server options used with replication slaves are listed earlier in this section.

- `log_slave_updates`

Whether updates received by a slave server from a master server should be logged to the slave's own binary log. Binary logging must be enabled on the slave for this variable to have any effect. See [Section 16.1.2.3, “Replication Slave Options and Variables”](#).

- `max_binlog_cache_size`

<b>Command Line Format</b>	<code>--max_binlog_cache_size=#</code>	
<b>Config File Format</b>	<code>max_binlog_cache_size</code>	
<b>Option Sets Variable</b>	Yes, <code>max_binlog_cache_size</code>	
<b>Variable Name</b>	<code>max_binlog_cache_size</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	Yes	
<b>Value Set</b>	<b>Platform Bit Size</b>	32
	<b>Type</b>	numeric
	<b>Default</b>	4294967295
	<b>Range</b>	4096-4294967295
<b>Value Set</b>	<b>Platform Bit Size</b>	64
	<b>Type</b>	numeric
	<b>Default</b>	18446744073709547520
	<b>Range</b>	4096-18446744073709547520

If a multiple-statement transaction requires more than this many bytes of memory, the server generates a `MULTI-STATEMENT TRANSACTION REQUIRED MORE THAN 'MAX_BINLOG_CACHE_SIZE' BYTES OF STORAGE` error. The minimum value is 4096; the maximum and default values are 4GB on 32-bit platforms and 16 PB (petabytes) on 64-bit platforms.

- `max_binlog_size`

<b>Command Line Format</b>	<code>--max_binlog_size=#</code>	
<b>Config File Format</b>	<code>max_binlog_size</code>	
<b>Option Sets Variable</b>	Yes, <code>max_binlog_size</code>	
<b>Variable Name</b>	<code>max_binlog_size</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	Yes	
<b>Value Set</b>	<b>Type</b>	numeric
	<b>Default</b>	1073741824
	<b>Min Value</b>	4096

If a write to the binary log causes the current log file size to exceed the value of this variable, the server rotates the binary logs (closes the current file and opens the next one). You cannot set this variable to more than 1GB or to less than 4096 bytes. The default value is 1GB.

A transaction is written in one chunk to the binary log, so it is never split between several binary logs. Therefore, if you have big transactions, you might see binary logs larger than `max_binlog_size`.

If `max_relay_log_size` is 0, the value of `max_binlog_size` applies to relay logs as well.

- `sync_binlog`

<b>Version Introduced</b>	5.0.1	
<b>Command Line Format</b>	<code>--sync-binlog=#</code>	
<b>Config File Format</b>	<code>sync_binlog</code>	
<b>Option Sets Variable</b>	Yes, <code>sync_binlog</code>	
<b>Variable Name</b>	<code>sync_binlog</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	Yes	
<b>Value Set</b>	<b>Platform Bit Size</b>	32
	<b>Type</b>	numeric
	<b>Default</b>	0

	<b>Range</b>	0-4294967295
<b>Value Set</b>	<b>Platform Bit Size</b>	64
	<b>Type</b>	numeric
	<b>Default</b>	0
	<b>Range</b>	0-18446744073709547520

If the value of this variable is greater than 0, the MySQL server synchronizes its binary log to disk (using `fdatasync()`) after every `sync_binlog` writes to the binary log. There is one write to the binary log per statement if autocommit is enabled, and one write per transaction otherwise. The default value of `sync_binlog` is 0, which does no synchronizing to disk. A value of 1 is the safest choice, because in the event of a crash you lose at most one statement or transaction from the binary log. However, it is also the slowest choice (unless the disk has a battery-backed cache, which makes synchronization very fast).

If the value of `sync_binlog` is 0 (the default), no extra flushing is done. The server relies on the operating system to flush the file contents occasionally as for any other file.

### 16.1.3. Common Replication Administration Tasks

Once replication has been started it should execute without requiring much regular administration. Depending on your replication environment, you will want to check the replication status of each slave either periodically, daily, or even more frequently.

#### MySQL Enterprise

For regular reports regarding the status of your slaves, subscribe to the MySQL Network Monitoring and Advisory Service. For more information, see <http://www.mysql.com/products/enterprise/advisors.html>.

#### 16.1.3.1. Checking Replication Status

The most common task when managing a replication process is to ensure that replication is taking place and that there have been no errors between the slave and the master.

The primary statement for this is `SHOW SLAVE STATUS` which you must execute on each slave:

```
mysql> SHOW SLAVE STATUS\G
***** 1. row *****
      Slave_IO_State: Waiting for master to send event
      Master_Host: master1
      Master_User: root
      Master_Port: 3306
      Connect_Retry: 60
      Master_Log_File: mysql-bin.000004
      Read_Master_Log_Pos: 931
      Relay_Log_File: slavel-relay-bin.000056
      Relay_Log_Pos: 950
      Relay_Master_Log_File: mysql-bin.000004
      Slave_IO_Running: Yes
      Slave_SQL_Running: Yes
      Replicate_Do_DB:
      Replicate_Ignore_DB:
      Replicate_Do_Table:
      Replicate_Ignore_Table:
      Replicate_Wild_Do_Table:
      Replicate_Wild_Ignore_Table:
      Last_Errno: 0
      Last_Error:
      Skip_Counter: 0
      Exec_Master_Log_Pos: 931
      Relay_Log_Space: 1365
      Until_Condition: None
      Until_Log_File:
      Until_Log_Pos: 0
      Master_SSL_Allowed: No
      Master_SSL_CA_File:
      Master_SSL_CA_Path:
      Master_SSL_Cert:
      Master_SSL_Cipher:
      Master_SSL_Key:
      Seconds_Behind_Master: 0
1 row in set (0.01 sec)
```

The key fields from the status report to examine are:

- `Slave_IO_State` — indicates the current status of the slave. See [Section 7.5.6.5, “Replication Slave I/O Thread States”](#), and [Section 7.5.6.6, “Replication Slave SQL Thread States”](#), for more information.

- `Slave_IO_Running` — shows whether the IO thread for the reading the master's binary log is running.
- `Slave_SQL_Running` — shows whether the SQL thread for the executing events in the relay log is running.
- `Last_Error` — shows the last error registered when processing the relay log. Ideally this should be blank, indicating no errors.
- `Seconds_Behind_Master` — shows the number of seconds that the slave SQL thread is behind processing the master binary log. A high number (or an increasing one) can indicate that the slave is unable to cope with the large number of statements from the master.

A value of 0 for `Seconds_Behind_Master` can usually be interpreted as meaning that the slave has caught up with the master, but there are some cases where this is not strictly true. For example, this can occur if the network connection between master and slave is broken but the slave I/O thread has not yet noticed this — that is, `slave_net_timeout` has not yet elapsed.

It is also possible that transient values for `Seconds_Behind_Master` may not reflect the situation accurately. When the slave SQL thread has caught up on I/O, `Seconds_Behind_Master` displays 0; but when the slave I/O thread is still queuing up a new event, `Seconds_Behind_Master` may show a large value until the SQL thread finishes executing the new event. This is especially likely when the events have old timestamps; in such cases, if you execute `SHOW SLAVE STATUS` several times in a relatively short period, you may see this value change back and forth repeatedly between 0 and a relatively large value.

On the master, you can check the status of slaves by examining the list of running processes. Slaves execute the `Binlog Dump` command:

```
mysql> SHOW PROCESSLIST \G;
***** 4. row *****
   Id: 10
  User: root
   Host: slave1:58371
    db: NULL
Command: Binlog Dump
   Time: 777
   State: Has sent all binlog to slave; waiting for binlog to be updated
   Info: NULL
```

Because it is the slave that drives the core of the replication process, very little information is available in this report.

If you have used the `--report-host` option, then the `SHOW SLAVE HOSTS` statement will show basic information about connected slaves:

```
mysql> SHOW SLAVE HOSTS;
+-----+-----+-----+-----+-----+
| Server_id | Host   | Port | Rpl_recovery_rank | Master_id |
+-----+-----+-----+-----+-----+
|         10 | slave1 | 3306 |                 0 |          1 |
+-----+-----+-----+-----+-----+
1 row in set (0.00 sec)
```

The output includes the ID of the slave server, the value of the `--report-host` option, the connecting port, master ID and the priority of the slave for receiving binary log updates.

### 16.1.3.2. Pausing Replication on the Slave

You can stop and start the replication of statements on the slave using the `STOP SLAVE` and `START SLAVE` statements.

To stop execution of the binary log from the master, use `STOP SLAVE`:

```
mysql> STOP SLAVE;
```

When execution is stopped, the slave does not read the binary log from the master (the `IO_THREAD`) and stops processing events from the relay log that have not yet been executed (the `SQL_THREAD`). You can pause either the IO or SQL threads individually by specifying the thread type. For example:

```
mysql> STOP SLAVE IO_THREAD;
```

Stopping the SQL thread can be useful if you want to perform a backup or other task on a slave that only processes events from the master. The IO thread will continue to be read from the master, but not executed, which will make it easier for the slave to catch up when you start slave operations again.

Stopping the IO thread will allow the statements in the relay log to be executed up until the point where the relay log has ceased to

receive new events. Using this option can be useful when you want to pause execution to allow the slave to catch up with events from the master, when you want to perform administration on the slave but also ensure you have the latest updates to a specific point. This method can also be used to pause execution on the slave while you conduct administration on the master while ensuring that there is not a massive backlog of events to be executed when replication is started again.

To start execution again, use the `START SLAVE` statement:

```
mysql> START SLAVE;
```

If necessary, you can start either the `IO_THREAD` or `SQL_THREAD` threads individually.

## 16.2. Replication Solutions

Replication can be used in many different environments for a range of purposes. In this section you will find general notes and advice on using replication for specific solution types.

For information on using replication in a backup environment, including notes on the setup, backup procedure, and files to back up, see [Section 16.2.1, “Using Replication for Backups”](#).

For advice and tips on using different storage engines on the master and slaves, see [Section 16.2.2, “Using Replication with Different Master and Slave Storage Engines”](#).

Using replication as a scale-out solution requires some changes in the logic and operation of applications that use the solution. See [Section 16.2.3, “Using Replication for Scale-Out”](#).

For performance or data distribution reasons you may want to replicate different databases to different replication slaves. See [Section 16.2.4, “Replicating Different Databases to Different Slaves”](#)

As the number of replication slaves increases, the load on the master can increase (because of the need to replicate the binary log to each slave) and lead to a reduction in performance of the master. For tips on improving your replication performance, including using a single secondary server as an replication master, see [Section 16.2.5, “Improving Replication Performance”](#).

For guidance on switching masters, or converting slaves into masters as part of an emergency failover solution, see [Section 16.2.6, “Switching Masters During Failover”](#).

To secure your replication communication you can encrypt the communication channel by using SSL to exchange data. Step-by-step instructions can be found in [Section 16.2.7, “Setting Up Replication Using SSL”](#).

### 16.2.1. Using Replication for Backups

You can use replication as a backup solution by replicating data from the master to a slave, and then backing up the data slave. Because the slave can be paused and shut down without affecting the running operation of the master you can produce an effective snapshot of 'live' data that would otherwise require a shutdown of the master database.

How you back up the database will depend on the size of the database and whether you are backing up only the data, or the data and the replication slave state so that you can rebuild the slave in the event of failure. There are therefore two choices:

If you are using replication as a solution to enable you to back up the data on the master, and the size of your database is not too large, then the `mysqldump` tool may be suitable. See [Section 16.2.1.1, “Backing Up a Slave Using `mysqldump`”](#).

For larger databases, where `mysqldump` would be impractical or inefficient, you can back up the raw data files instead. Using the raw data files option also means that you can back up the binary and relay logs that will enable you to recreate the slave in the event of a slave failure. For more information, see [Section 16.2.1.2, “Backing Up Raw Data from a Slave”](#).

#### 16.2.1.1. Backing Up a Slave Using `mysqldump`

Using `mysqldump` to create a copy of the database enables you to capture all of the data in the database in a format that allows the information to be imported into another instance of MySQL. Because the format of the information is SQL statements the file can easily be distributed and applied to running servers in the event that you need access to the data in an emergency. However, if the size of your data set is very large then `mysqldump` may be impractical.

When using `mysqldump` you should stop the slave before starting the dump process to ensure that the dump contains a consistent set of data:

1. Stop the slave from processing requests. You can either stop the slave completely using `mysqladmin`:

```
shell> mysqladmin stop-slave
```

Alternatively, you can stop processing the relay log files by stopping the replication SQL thread. Using this method will allow the binary log data to be transferred. Within busy replication environments this may speed up the catch-up process when you start the slave processing again:

```
shell> mysql -e 'STOP SLAVE SQL_THREAD;'
```

2. Run `mysqldump` to dump your databases. You may either select databases to be dumped, or dump all databases. For more information, see [Section 4.5.4, “mysqldump — A Database Backup Program”](#). For example, to dump all databases:

```
shell> mysqldump --all-databases >fulldb.dump
```

3. Once the dump has completed, start slave operations again:

```
shell> mysqladmin start-slave
```

In the preceding example you may want to add login credentials (user name, password) to the commands, and bundle the process up into a script that you can run automatically each day.

If you use this approach, make sure you monitor the slave replication process to ensure that the time taken to run the backup in this way is not affecting the slave's ability to keep up with events from the master. See [Section 16.1.3.1, “Checking Replication Status”](#). If the slave is unable to keep up you may want to add another server and distribute the backup process. For an example of how to configure this scenario, see [Section 16.2.4, “Replicating Different Databases to Different Slaves”](#).

### 16.2.1.2. Backing Up Raw Data from a Slave

To guarantee the integrity of the files that are copied, backing up the raw data files on your MySQL replication slave should take place while your slave server is shut down. If the MySQL server is still running then background tasks, particularly with storage engines with background processes such as InnoDB, may still be updating the database files. With InnoDB, these problems should be resolved during crash recovery, but since the slave server can be shut down during the backup process without affecting the execution of the master it makes sense to take advantage of this facility.

To shut down the server and back up the files:

1. Shut down the slave MySQL server:

```
shell> mysqladmin shutdown
```

2. Copy the data files. You can use any suitable copying or archive utility, including `cp`, `tar` or `WinZip`:

```
shell> tar cf /tmp/dbbackup.tar ./data
```

3. Start up the `mysqld` process again:

```
shell> mysqld_safe &
```

Under Windows:

```
C:\> "C:\Program Files\MySQL\MySQL Server 5.0\bin\mysqld"
```

Normally you should back up the entire data folder for the slave MySQL server. If you want to be able to restore the data and operate as a slave (for example, in the event of failure of the slave), then when you back up the slave's data, you should back up the slave status files, `master.info` and `relay-log.info`, along with the relay log files. These files are needed to resume replication after you restore the slave's data.

If you lose the relay logs but still have the `relay-log.info` file, you can check it to determine how far the SQL thread has executed in the master binary logs. Then you can use `CHANGE MASTER TO` with the `MASTER_LOG_FILE` and `MASTER_LOG_POS` options to tell the slave to re-read the binary logs from that point. Of course, this requires that the binary logs still exist on the master server.

If your slave is subject to replicating `LOAD DATA INFILE` statements, you should also back up any `SQL_LOAD-*` files that exist in the directory that the slave uses for this purpose. The slave needs these files to resume replication of any interrupted `LOAD DATA INFILE` operations. The directory location is specified using the `--slave-load-tmpdir` option. If this option is not specified, the directory location is the value of the `tmpdir` system variable.

## 16.2.2. Using Replication with Different Master and Slave Storage Engines

The replication process does not care if the source table on the master and the replicated table on the slave use different engine types. In fact, the system variables `storage_engine` and `table_type` are not replicated.

This provides a number of advantages in the replication process in that you can take advantage of different engine types for different replication scenarios. For example, in a typical scaleout scenario (see [Section 16.2.3, “Using Replication for Scale-Out”](#)), you want to use `InnoDB` tables on the master to take advantage of the transactional functionality, but use `MyISAM` on the slaves where transaction support is not required because the data is only read. When using replication in a data logging environment you may want to use the `Archive` storage engine on the slave.

Setting up different engines on the master and slave depends on how you set up the initial replication process:

- If you used `mysqldump` to create the database snapshot on your master then you could edit the dump text to change the engine type used on each table.

Another alternative for `mysqldump` is to disable engine types that you do not want to use on the slave before using the dump to build the data on the slave. For example, you can add the `--skip-innodb` option on your slave to disable the `InnoDB` engine. If a specific engine does not exist, MySQL will use the default engine type, usually `MyISAM`. If you want to disable further engines in this way, you may want to consider building a special binary to be used on the slave that only supports the engines you want.

- If you are using raw data files for the population of the slave, you will be unable to change the initial table format. Instead, use `ALTER TABLE` to change the table types after the slave has been started.
- For new master/slave replication setups where there are currently no tables on the master, avoid specifying the engine type when creating new tables.

If you are already running a replication solution and want to convert your existing tables to another engine type, follow these steps:

1. Stop the slave from running replication updates:

```
mysql> STOP SLAVE;
```

This will enable you to change engine types without interruptions.

2. Execute an `ALTER TABLE ... Engine='enginetype'` for each table where you want to change the engine type.
3. Start the slave replication process again:

```
mysql> START SLAVE;
```

Although the `storage_engine` and `table_type` variables are not replicated, be aware that `CREATE TABLE` and `ALTER TABLE` statements that include the engine specification will be correctly replicated to the slave. For example, if you have a CSV table and you execute:

```
mysql> ALTER TABLE csvtable Engine='MyISAM';
```

The above statement will be replicated to the slave and the engine type on the slave will be converted to `MyISAM`, even if you have previously changed the table type on the slave to an engine other than CSV. If you want to retain engine differences on the master and slave, you should be careful to use the `storage_engine` variable on the master when creating a new table. For example, instead of:

```
mysql> CREATE TABLE tablea (columna int) Engine=MyISAM;
```

Use this format:

```
mysql> SET storage_engine=MyISAM;
mysql> CREATE TABLE tablea (columna int);
```

When replicated, the `storage_engine` variable will be ignored, and the `CREATE TABLE` statement will be executed with the slave's default engine type.

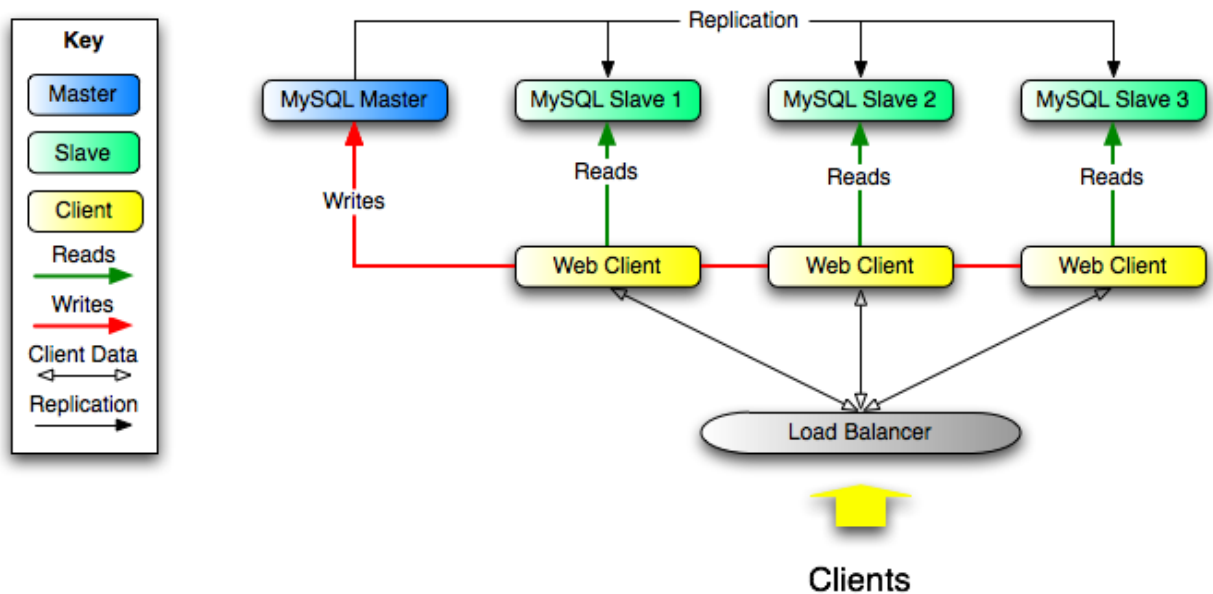

## 16.2.3. Using Replication for Scale-Out

You can use replication as a scale-out solution, i.e. where you want to split up the load of database queries across multiple database servers, within some reasonable limitations.

Because replication works from the distribution of one master to one or more slaves, using replication for scaleout works best in an environment where you have a high number of reads and low number of writes/updates. Most websites fit into this category, where users are browsing the website, reading articles, posts, or viewing products. Updates only occur during session management, or when making a purchase or adding a comment/message to a forum.

Replication in this situation enables you to distribute the reads over the replication slaves, while still allowing your web servers to communicate with the replication master when a write is required. You can see a sample replication layout for this scenario in [Figure 16.1, “Using replication to improve the performance during scaleout”](#).

**Figure 16.1. Using replication to improve the performance during scaleout**

If the part of your code that is responsible for database access has been properly abstracted/modularized, converting it to run with a replicated setup should be very smooth and easy. Change the implementation of your database access to send all writes to the master, and to send reads to either the master or a slave. If your code does not have this level of abstraction, setting up a replicated system gives you the opportunity and motivation to clean it up. Start by creating a wrapper library or module that implements the following functions:

- `safe_writer_connect()`
- `safe_reader_connect()`
- `safe_reader_statement()`
- `safe_writer_statement()`

`safe_` in each function name means that the function takes care of handling all error conditions. You can use different names for the functions. The important thing is to have a unified interface for connecting for reads, connecting for writes, doing a read, and doing a write.

Then convert your client code to use the wrapper library. This may be a painful and scary process at first, but it pays off in the long run. All applications that use the approach just described are able to take advantage of a master/slave configuration, even one involving multiple slaves. The code is much easier to maintain, and adding troubleshooting options is trivial. You need modify only one or two functions; for example, to log how long each statement took, or which statement among those issued gave you an error.

If you have written a lot of code, you may want to automate the conversion task by using the `replace` utility that comes with standard MySQL distributions, or write your own conversion script. Ideally, your code uses consistent programming style conventions. If not, then you are probably better off rewriting it anyway, or at least going through and manually regularizing it to use a consistent style.

## 16.2.4. Replicating Different Databases to Different Slaves

There may be situations where you have a single master and want to replicate different databases to different slaves. For example, you may want to distribute different sales data to different departments to help spread the load during data analysis. A sample of this layout is shown in [Figure 16.2, “Using replication to replicate databases to separate replication slaves”](#).

**Figure 16.2. Using replication to replicate databases to separate replication slaves**

You can achieve this separation by configuring the master and slaves as normal, and then limiting the binary log statements that each slave processes by using the `--replicate-wild-do-table` configuration option on each slave.

### Important

You should *not* use `--replicate-do-db` for this purpose, since its affects vary according to the database that is currently selected.

For example, to support the separation as shown in [Figure 16.2, “Using replication to replicate databases to separate replication slaves”](#), you should configure each replication slave as follows, before executing `START SLAVE`:

- Replication slave 1 should use `--replicate-wild-do-table=databaseA.%`.
- Replication slave 2 should use `--replicate-wild-do-table=databaseB.%`.
- Replication slave 3 should use `--replicate-wild-do-table=databaseC.%`.

If you have data that needs to be synchronized to the slaves before replication starts, you have a number of choices:

- Synchronize all the data to each slave, and delete the databases, tables, or both that you do not want to keep.
- Use `mysqldump` to create a separate dump file for each database and load the appropriate dump file on each slave.
- Use a raw data file dump and include only the specific files and databases that you need for each slave.

### Note

This does not work with `InnoDB` databases unless you use `innodb_file_per_table`.

Each slave in this configuration receives the entire binary log from the master, but executes only those events from the binary log that apply to the databases and tables included by the `--replicate-wild-do-table` option in effect on that slave.

## 16.2.5. Improving Replication Performance

As the number of slaves connecting to a master increases, the load, although minimal, also increases, as each slave uses up a client connection to the master. Also, as each slave must receive a full copy of the master binary log, the network load on the master may also increase and start to create a bottleneck.

If you are using a large number of slaves connected to one master, and that master is also busy processing requests (for example, as part of a scaleout solution), then you may want to improve the performance of the replication process.

One way to improve the performance of the replication process is to create a deeper replication structure that enables the master to replicate to only one slave, and for the remaining slaves to connect to this primary slave for their individual replication requirements. A sample of this structure is shown in [Figure 16.3, “Using an additional replication host to improve performance”](#).

**Figure 16.3. Using an additional replication host to improve performance**

For this to work, you must configure the MySQL instances as follows:

- Master 1 is the primary master where all changes and updates are written to the database. Binary logging should be enabled on this machine.
- Master 2 is the slave to the Master 1 that provides the replication functionality to the remainder of the slaves in the replication structure. Master 2 is the only machine allowed to connect to Master 1. Master 2 also has binary logging enabled, and the `--log-slave-updates` option so that replication instructions from Master 1 are also written to Master 2's binary log so that they can then be replicated to the true slaves.
- Slave 1, Slave 2, and Slave 3 act as slaves to Master 2, and replicate the information from Master 2, which is really the data logged on Master 1.

The above solution reduces the client load and the network interface load on the primary master, which should improve the overall performance of the primary master when used as a direct database solution.

If your slaves are having trouble keeping up with the replication process on the master then there are a number of options available:

- If possible, you should put the relay logs and the data files on different physical drives. To do this, use the `--relay-log` option to specify the location of the relay log.
- If the slaves are significantly slower than the master, then you may want to divide up the responsibility for replicating different databases to different slaves. See [Section 16.2.4, “Replicating Different Databases to Different Slaves”](#).
- If your master makes use of transactions and you are not concerned about transaction support on your slaves, then use [MyISAM](#) or another non-transactional engine. See [Section 16.2.2, “Using Replication with Different Master and Slave Storage Engines”](#).
- If your slaves are not acting as masters, and you have a potential solution in place to ensure that you can bring up a master in the event of failure, then you can switch off `--log-slave-updates`. This prevents 'dumb' slaves from also logging events they have executed into their own binary log.

## 16.2.6. Switching Masters During Failover

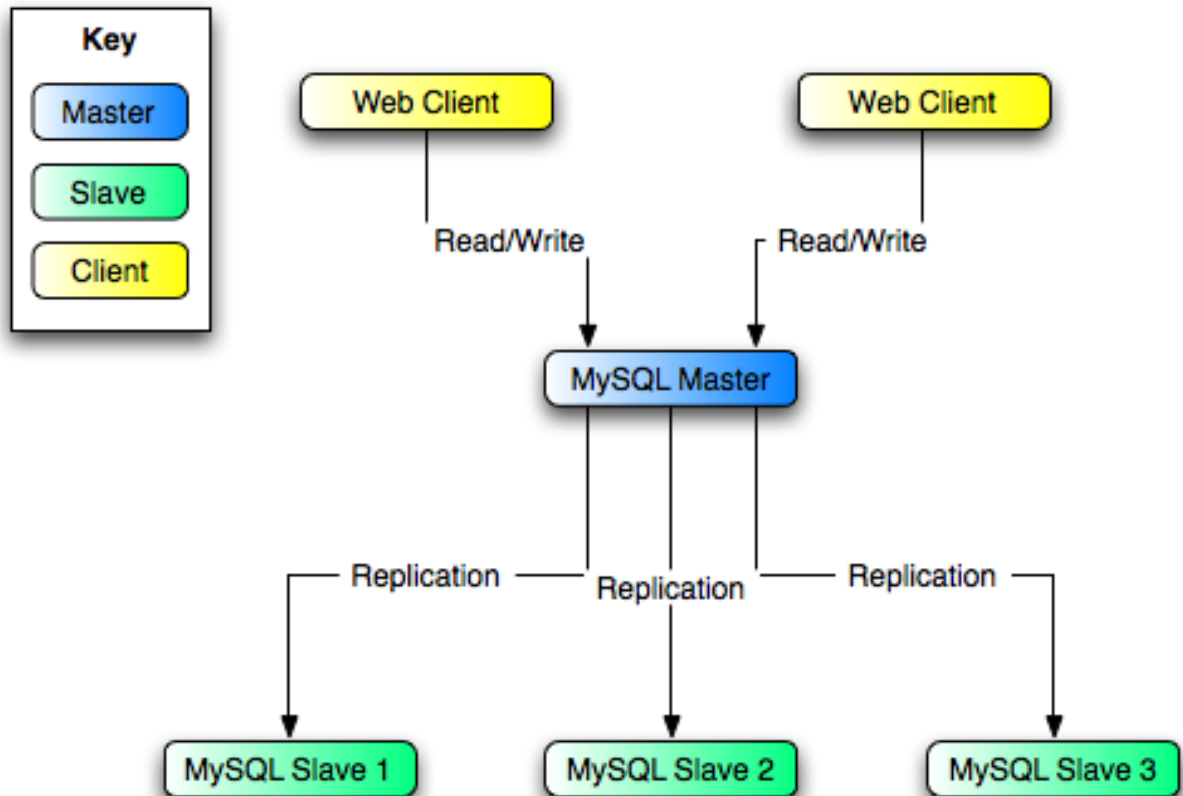

There is currently no official solution for providing failover between master and slaves in the event of a failure. With the currently available features, you would have to set up a master and a slave (or several slaves), and to write a script that monitors the master to check whether it is up. Then instruct your applications and the slaves to change master in case of failure.

Remember that you can tell a slave to change its master at any time, using the `CHANGE MASTER TO` statement. The slave will not check whether the databases on the master are compatible with the slave, it will just start executing events from the specified log

and position on the new master. In a failover situation all the servers in the group are probably executing the same events from the same binary log, so changing the source of the events should not affect the database structure or integrity providing you are careful.

Run your slaves with the `--log-bin` option and without `--log-slave-updates`. In this way, the slave is ready to become a master as soon as you issue `STOP SLAVE; RESET MASTER`, and `CHANGE MASTER TO` statement on the other slaves. For example, assume that you have the structure shown in Figure 16.4, “Redundancy using replication, initial structure”.

**Figure 16.4. Redundancy using replication, initial structure**

In this diagram, the `MySQL Master` holds the master database, the `MySQL Slave` computers are replication slaves, and the `Web Client` machines are issuing database reads and writes. Web clients that issue only reads (and would normally be connected to the slaves) are not shown, as they do not need to switch to a new server in the event of failure. For a more detailed example of a read/write scaleout replication structure, see Section 16.2.3, “Using Replication for Scale-Out”.

Each `MySQL Slave` (`Slave 1`, `Slave 2`, and `Slave 3`) are slaves running with `--log-bin` and without `--log-slave-updates`. Because updates received by a slave from the master are not logged in the binary log unless `--log-slave-updates` is specified, the binary log on each slave is empty initially. If for some reason `MySQL Master` becomes unavailable, you can pick one of the slaves to become the new master. For example, if you pick `Slave 1`, all `Web Clients` should be redirected to `Slave 1`, which will log updates to its binary log. `Slave 2` and `Slave 3` should then replicate from `Slave 1`.

The reason for running the slave without `--log-slave-updates` is to prevent slaves from receiving updates twice in case you cause one of the slaves to become the new master. Suppose that `Slave 1` has `--log-slave-updates` enabled. Then it will write updates that it receives from `Master` to its own binary log. When `Slave 2` changes from `Master` to `Slave 1` as its master, it may receive updates from `Slave 1` that it has already received from `Master`.

Make sure that all slaves have processed any statements in their relay log. On each slave, issue `STOP SLAVE IO_THREAD`, then check the output of `SHOW PROCESSLIST` until you see `Has read all relay log`. When this is true for all slaves, they can be reconfigured to the new setup. On the slave `Slave 1` being promoted to become the master, issue `STOP SLAVE` and `RESET MASTER`.

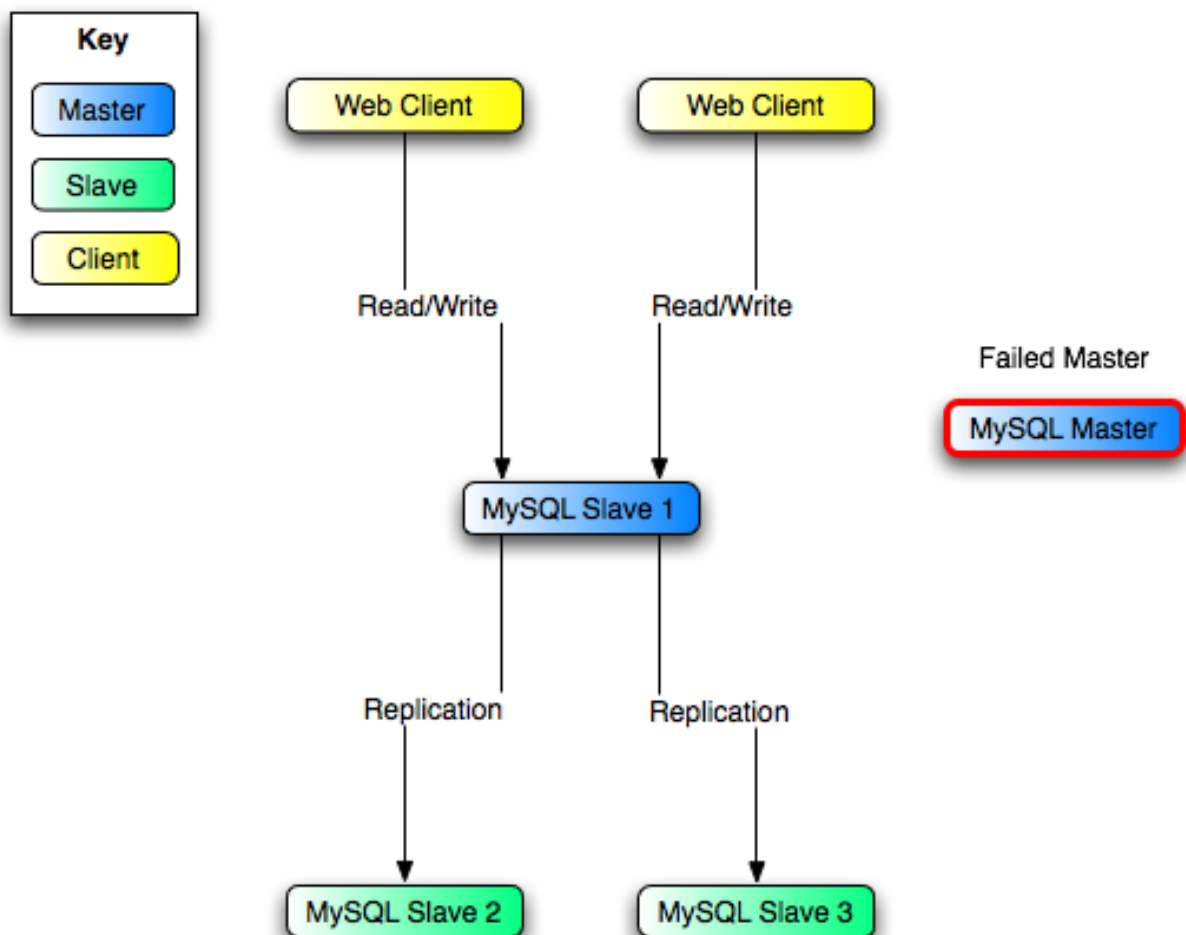

On the other slaves `Slave 2` and `Slave 3`, use `STOP SLAVE` and `CHANGE MASTER TO MASTER_HOST='Slave1'` (where `'Slave1'` represents the real host name of `Slave 1`). To use `CHANGE MASTER TO`, add all information about how to connect to `Slave 1` from `Slave 2` or `Slave 3` (`user, password, port`). In `CHANGE MASTER TO`, there is no need to

specify the name of `Slave 1`'s binary log or binary log position to read from: We know it is the first binary log and position 4, which are the defaults for `CHANGE MASTER TO`. Finally, use `START SLAVE` on `Slave 2` and `Slave 3`.

Once the new replication is in place, you will then need to instruct each `Web Client` to direct their statements to `Slave 1`. From that point on, all updates statements sent by `Web Client` to `Slave 1` are written to the binary log of `Slave 1`, which then contains every update statement sent to `Slave 1` since `Master` died.

The resulting server structure is shown in [Figure 16.5, “Redundancy using replication, after master failure”](#).

**Figure 16.5. Redundancy using replication, after master failure**

When `Master` is up again, you must issue on it the same `CHANGE MASTER TO` as that issued on `Slave 2` and `Slave 3`, so that `Master` becomes a slave of `S1` and picks up each `Web Client` writes that it missed while it was down.

To make `Master` a master again (because it is the most powerful machine, for example), use the preceding procedure as if `Slave 1` was unavailable and `Master` was to be the new master. During this procedure, do not forget to run `RESET MASTER` on `Master` before making `Slave 1`, `Slave 2`, and `Slave 3` slaves of `Master`. Otherwise, they may pick up old `Web Client` writes from before the point at which `Master` became unavailable.

Note that there is no synchronization between the different slaves to a master. Some slaves might be ahead of others. This means that the concept outlined in the previous example might not work. In practice, however, the relay logs of different slaves will most likely not be far behind the master, so it would work, anyway (but there is no guarantee).

A good way to keep your applications informed as to the location of the master is by having a dynamic DNS entry for the master. With `bind` you can use `nsupdate` to dynamically update your DNS.

## 16.2.7. Setting Up Replication Using SSL

Setting up replication using an SSL connection is similar to setting up a server and client using SSL. You will need to obtain (or

create) a suitable security certificate that you can use on the master, and a similar certificate (from the same certificate authority) on each slave.

To use SSL for encrypting the transfer of the binary log required during replication you must first set up the master to support SSL network connections. If the master does not support SSL connections (because it has not been compiled or configured for SSL), then replication through an SSL connection will not be possible.

For more information on setting up a server and client for SSL connectivity, see [Section 5.5.7.2, “Using SSL Connections”](#).

To enable SSL on the master you will need to create or obtain suitable certificates and then add the following configuration options to the master's configuration within the `mysqld` section:

```
ssl-ca=cacert.pem
ssl-cert=server-cert.pem
ssl-key=server-key.pem
```

### Note

You should use full path to specify the location of your certificate files.

The options are as follows:

- `ssl-ca` identifies the Certificate Authority (CA) certificate.
- `ssl-cert` identifies the server public key. This can be sent to the client and authenticated against the CA certificate that it has.
- `ssl-key` identifies the server private key.

On the slave, you have two options available for setting the SSL information. You can either add the slaves certificates to the `client` section of the slave configuration file, or you can explicitly specify the SSL information using the `CHANGE MASTER TO` statement.

Using the former option, add the following lines to the `client` section of the slave configuration file:

```
[client]
ssl-ca=cacert.pem
ssl-cert=server-cert.pem
ssl-key=server-key.pem
```

Restart the slave server, using the `--skip-slave` to prevent the slave from connecting to the master. Use `CHANGE MASTER TO` to specify the master configuration, using the `master_ssl` option to enable SSL connectivity:

```
mysql> CHANGE MASTER TO \
  MASTER_HOST='master_hostname', \
  MASTER_USER='replicate', \
  MASTER_PASSWORD='password', \
  MASTER_SSL=1;
```

To specify the SSL certificate options during the `CHANGE MASTER TO` command, append the SSL options:

```
CHANGE MASTER TO \
  MASTER_HOST='master_hostname', \
  MASTER_USER='replicate', \
  MASTER_PASSWORD='password', \
  MASTER_SSL=1, \
  MASTER_SSL_CA = 'ca_file_name', \
  MASTER_SSL_CAPATH = 'ca_directory_name', \
  MASTER_SSL_CERT = 'cert_file_name', \
  MASTER_SSL_KEY = 'key_file_name';
```

Once the master information has been updated, start the slave replication process:

```
mysql> START SLAVE;
```

You can use the `SHOW SLAVE STATUS` to confirm that SSL connection has been completed.

For more information on the `CHANGE MASTER TO` syntax, see [Section 12.6.2.1, “CHANGE MASTER TO Syntax”](#).

If you want to enforce SSL connections to be used during replication, then create a user with the `REPLICATION SLAVE` privilege and use the `REQUIRE_SSL` option for that user. For example:

```
mysql> GRANT REPLICATION SLAVE ON *.*
-> TO 'repl'@'%mydomain.com' IDENTIFIED BY 'slavepass' REQUIRE SSL;
```

## 16.3. Replication Notes and Tips

### 16.3.1. Replication Features and Issues

The following sections provide information about what is supported and what is not in MySQL replication, and about specific issues and situations that may occur when replicating certain statements.

Statement-based replication depends on compatibility at the SQL level between the master and slave. In others, successful SBR requires that any SQL features used be supported by both the master and the slave servers. For example, if you use a feature on the master server that is available only in MySQL 5.0 (or later), you cannot replicate to a slave that uses MySQL 4.1 (or earlier).

Such incompatibilities also can occur within a release series when using pre-production releases of MySQL. For example, the `SLEEP()` function is available beginning with MySQL 5.0.12. If you use this function on the master, you cannot replicate to a slave that uses MySQL 5.0.11 or earlier.

For this reason, we recommend that you use Generally Available (GA) releases of MySQL for statement-based replication in a production setting, since we do not introduce new SQL statements or change their behavior within a given release series once that series reaches GA release status.

If you are planning to use replication between MySQL 5.0 and a previous MySQL release series, it is also a good idea to consult the edition of the *MySQL Reference Manual* corresponding to the earlier release series for information regarding the replication characteristics of that series.

For additional information specific to replication and InnoDB, see [Section 13.2.4.5, “InnoDB and MySQL Replication”](#).

#### 16.3.1.1. Replication and `AUTO_INCREMENT`

Replication of `AUTO_INCREMENT`, `LAST_INSERT_ID()`, and `TIMESTAMP` values is done correctly, subject to the following exceptions.

- `INSERT DELAYED ... VALUES(LAST_INSERT_ID())` inserts a different value on the master and the slave. ([Bug#20819](#)) This is fixed in MySQL 5.1 when using row-based or mixed-format binary logging. For more information, see [Replication Formats](#).
- Before MySQL 5.0.26, a stored procedure that uses `LAST_INSERT_ID()` does not replicate properly.
- When a statement uses a stored function that inserts into an `AUTO_INCREMENT` column, the generated `AUTO_INCREMENT` value is not written into the binary log, so a different value can in some cases be inserted on the slave. This is also true of a trigger that causes an `INSERT` into an `AUTO_INCREMENT` column.
- An insert into an `AUTO_INCREMENT` column caused by a stored routine or trigger running on a master that uses MySQL 5.0.60 or earlier does not replicate correctly to a slave running MySQL 5.1.12 through 5.1.23 (inclusive) or MySQL 6.0.0 through 6.0.4 (inclusive). ([Bug#33029](#))
- Adding an `AUTO_INCREMENT` column to a table with `ALTER TABLE` might not produce the same ordering of the rows on the slave and the master. This occurs because the order in which the rows are numbered depends on the specific storage engine used for the table and the order in which the rows were inserted. If it is important to have the same order on the master and slave, the rows must be ordered before assigning an `AUTO_INCREMENT` number. Assuming that you want to add an `AUTO_INCREMENT` column to the table `t1`, the following statements produce a new table `t2` identical to `t1` but with an `AUTO_INCREMENT` column:

```
CREATE TABLE t2 LIKE t1;
ALTER TABLE t2 ADD id INT AUTO_INCREMENT PRIMARY KEY;
INSERT INTO t2 SELECT * FROM t1 ORDER BY col1, col2;
```

This assumes that the table `t1` has columns `col1` and `col2`.

#### Important

To guarantee the same ordering on both master and slave, *all* columns of `t1` must be referenced in the `ORDER BY` clause.

- The instructions just given are subject to the limitations of `CREATE TABLE ... LIKE`: Foreign key definitions are ignored, as are the `DATA DIRECTORY` and `INDEX DIRECTORY` table options. If a table definition includes any of those characteristics, create `t2` using a `CREATE TABLE` statement that is identical to the one used to create `t1`, but with the addition of the

`AUTO_INCREMENT` column.

- Regardless of the method used to create and populate the copy having the `AUTO_INCREMENT` column, the final step is to drop the original table and then rename the copy:

```
DROP t1;
ALTER TABLE t2 RENAME t1;
```

See also [Section B.1.7.1, “Problems with ALTER TABLE”](#).

### 16.3.1.2. Replication and Character Sets

The following applies to replication between MySQL servers that use different character sets:

1. If the master uses MySQL 4.1, you must *always* use the same *global* character set and collation on the master and the slave, regardless of the MySQL version running on the slave. (These are controlled by the `--character-set-server` and `--collation-server` options.) Otherwise, you may get duplicate-key errors on the slave, because a key that is unique in the master character set might not be unique in the slave character set. Note that this is not a cause for concern when master and slave are both MySQL 5.0 or later.
2. If the master is older than MySQL 4.1.3, the character set of any client should never be made different from its global value because this character set change is not known to the slave. In other words, clients should not use `SET NAMES`, `SET CHARACTER SET`, and so forth. If both the master and the slave are 4.1.3 or newer, clients can freely set session values for character set variables because these settings are written to the binary log and so are known to the slave. That is, clients can use `SET NAMES` or `SET CHARACTER SET` or can set variables such as `collation_client` or `collation_server`. However, clients are prevented from changing the *global* value of these variables; as stated previously, the master and slave must always have identical global character set values.
3. If you have databases on the master with character sets that differ from the global `character_set_server` value, you should design your `CREATE TABLE` statements so that tables in those databases do not implicitly rely on the database default character set. A good workaround is to state the character set and collation explicitly in `CREATE TABLE` statements.

### 16.3.1.3. Replication of CREATE TABLE ... SELECT Statements

This section discusses the rules that are applied when a `CREATE TABLE ... SELECT` statement is replicated.

#### Note

`CREATE TABLE ... SELECT` always performs an implicit commit ([Section 12.4.3, “Statements That Cause an Implicit Commit”](#)).

**Statement succeeds.** If the `CREATE TABLE ... SELECT` statement succeeds on the master, then the `CREATE TABLE ... SELECT` statement is itself replicated.

**Statement fails.** The failure of a `CREATE TABLE ... SELECT` is handled according to the following criteria:

- **No IF NOT EXISTS option.** If the `CREATE TABLE ... SELECT` does not contain an `IF NOT EXISTS` option, then the statement has no effect. However, the implicit commit caused by the statement is logged. This is true regardless of the storage engine used and the reason for which the statement failed.
- **Statement uses IF NOT EXISTS.** If the `CREATE TABLE ... SELECT` statement includes the `IF NOT EXISTS` option and fails, the `CREATE TABLE IF NOT EXISTS ... SELECT` is logged with an error.

### 16.3.1.4. Replication and DIRECTORY Table Options

If a `DATA DIRECTORY` or `INDEX DIRECTORY` table option is used in a `CREATE TABLE` statement on the master server, the table option is also used on the slave. This can cause problems if no corresponding directory exists in the slave host file system or if it exists but is not accessible to the slave server. This can be overridden by using the `NO_DIR_IN_CREATE` server SQL mode on the slave, which causes the slave to ignore the `DATA DIRECTORY` and `INDEX DIRECTORY` table options when replicating `CREATE TABLE` statements. The result is that `MyISAM` data and index files are created in the table's database directory.

For more information, see [Section 5.1.7, “Server SQL Modes”](#).

### 16.3.1.5. Replication of DROP ... IF EXISTS Statements

The statements `DROP DATABASE IF EXISTS`, `DROP TABLE IF EXISTS`, and `DROP VIEW IF EXISTS` are always replicated, even if the database, table, or view to be dropped does not exist on the master. This is to ensure that the object to be dropped no longer exists on either the master or the slave, once the slave has caught up with the master.

Beginning with MySQL 5.0.82, the statements `DROP PROCEDURE IF EXISTS` and `DROP FUNCTION IF EXISTS` are also replicated, even if the procedure or function to be dropped does not exist on the master. ([Bug#13684](#))

### 16.3.1.6. Replication with Floating-Point Values

With statement-based replication, values are converted from decimal to binary. Because conversions between decimal and binary representations of them may be approximate, comparisons involving floating-point values are inexact. This is true for operations that use floating-point values explicitly, or that use values that are converted to floating-point implicitly. Comparisons of floating-point values might yield different results on master and slave servers due to differences in computer architecture, the compiler used to build MySQL, and so forth. See [Section 11.2.2, “Type Conversion in Expression Evaluation”](#), and [Section B.1.5.8, “Problems with Floating-Point Comparisons”](#).

#### MySQL Enterprise

For expert advice regarding replication subscribe to the MySQL Enterprise Monitor. For more information, see <http://www.mysql.com/products/enterprise/advisors.html>.

### 16.3.1.7. Replication and `FLUSH`

Some forms of the `FLUSH` statement are not logged because they could cause problems if replicated to a slave: `FLUSH LOGS`, `FLUSH MASTER`, `FLUSH SLAVE`, and `FLUSH TABLES WITH READ LOCK`. For a syntax example, see [Section 12.5.6.2, “FLUSH Syntax”](#). The `FLUSH TABLES`, `ANALYZE TABLE`, `OPTIMIZE TABLE`, and `REPAIR TABLE` statements are written to the binary log and thus replicated to slaves. This is not normally a problem because these statements do not modify table data.

However, this behavior can cause difficulties under certain circumstances. If you replicate the privilege tables in the `mysql` database and update those tables directly without using `GRANT`, you must issue a `FLUSH PRIVILEGES` on the slaves to put the new privileges into effect. In addition, if you use `FLUSH TABLES` when renaming a `MyISAM` table that is part of a `MERGE` table, you must issue `FLUSH TABLES` manually on the slaves. These statements are written to the binary log unless you specify `NO_WRITE_TO_BINLOG` or its alias `LOCAL`.

### 16.3.1.8. Replication and System Functions

Certain functions do not replicate well under some conditions:

- The `USER()`, `CURRENT_USER()`, `UUID()`, `VERSION()`, and `LOAD_FILE()` functions are replicated without change and thus do not work reliably on the slave.
- For `NOW()`, the binary log includes the timestamp and replicates correctly.

As of MySQL 5.0.13, the `SYSDATE()` function is no longer equivalent to `NOW()`. Implications are that `SYSDATE()` is not replication-safe because it is not affected by `SET TIMESTAMP` statements in the binary log and is non-deterministic. To avoid this, you can start the server with the `--sysdate-is-now` option to cause `SYSDATE()` to be an alias for `NOW()`.

- The `GET_LOCK()`, `RELEASE_LOCK()`, `IS_FREE_LOCK()`, and `IS_USED_LOCK()` functions that handle user-level locks are replicated without the slave knowing the concurrency context on master. Therefore, these functions should not be used to insert into a master's table because the content on the slave would differ. (For example, do not issue a statement such as `INSERT INTO mytable VALUES(GET_LOCK(...))`.)

As a workaround for the preceding limitations, you can use the strategy of saving the problematic function result in a user variable and referring to the variable in a later statement. For example, the following single-row `INSERT` is problematic due to the reference to the `UUID()` function:

```
INSERT INTO t VALUES(UUID());
```

To work around the problem, do this instead:

```
SET @my_uuid = UUID();
INSERT INTO t VALUES(@my_uuid);
```

That sequence of statements replicates because the value of `@my_uuid` is stored in the binary log as a user-variable event prior to the `INSERT` statement and is available for use in the `INSERT`.

The same idea applies to multiple-row inserts, but is more cumbersome to use. For a two-row insert, you can do this:

```
SET @my_uuid1 = UUID(); @my_uuid2 = UUID();
```

```
INSERT INTO t VALUES(@my_uuid1),(@my_uuid2);
```

However, if the number of rows is large or unknown, the workaround is difficult or impracticable. For example, you cannot convert the following statement to one in which a given individual user variable is associated with each row:

```
INSERT INTO t2 SELECT UUID(), * FROM t1;
```

Non-delayed `INSERT` statements that refer to `RAND()` or user-defined variables replicate correctly. However, changing the statements to use `INSERT DELAYED` can result in different results on master and slave.

Within a stored function, `RAND()` replicates correctly as long as it is invoked only once during the execution of the function. (You can consider the function execution timestamp and random number seed as implicit inputs that are identical on the master and slave.)

The `FOUND_ROWS()` and `ROW_COUNT()` functions are also not replicated reliably. A workaround is to store the result of the function call in a user variable, and then use that in the `INSERT` statement. For example, if you wish to store the result in a table named `mytable`, you might normally do so like this:

```
SELECT SQL_CALC_FOUND_ROWS FROM mytable LIMIT 1;
INSERT INTO mytable VALUES( FOUND_ROWS() );
```

However, if you are replicating `mytable`, then you should use `SELECT INTO`, and then store the variable in the table, like this:

```
SELECT SQL_CALC_FOUND_ROWS INTO @found_rows FROM mytable LIMIT 1;
INSERT INTO mytable VALUES(@found_rows);
```

In this way, the user variable is replicated as part of the context, and applied on the slave correctly.

### 16.3.1.9. Replication and `LIMIT`

Replication of `LIMIT` clauses in `DELETE`, `UPDATE`, and `INSERT ... SELECT` statements is not guaranteed, since the order of the rows affected is not defined. Such statements can be replicated correctly only if they also contain an `ORDER BY` clause.

### 16.3.1.10. Replication and `LOAD` Operations

Using `LOAD TABLE FROM MASTER` where the master is running MySQL 4.1 and the slave is running MySQL 5.0 may corrupt the table data, and is not supported. ([Bug#16261](#))

The `LOAD DATA INFILE` statement's `CONCURRENT` option is not replicated; that is, `LOAD DATA CONCURRENT INFILE` is replicated as `LOAD DATA INFILE`, and `LOAD DATA CONCURRENT LOCAL INFILE` is replicated as `LOAD DATA LOCAL INFILE`. ([Bug#34628](#))

*The following applies only if either the master or the slave is running MySQL version 5.0.3 or older:* If on the master a `LOAD DATA INFILE` is interrupted (integrity constraint violation, killed connection, and so on), the slave skips the `LOAD DATA INFILE` entirely. This means that if this command permanently inserted or updated table records before being interrupted, these modifications are not replicated to the slave.

### 16.3.1.11. Replication and the Slow Query Log

Replication slaves do not write replicated queries to the slow query log, even if the same queries were written to the slow query log on the master.

This is a known issue which we intend to fix in a future version of MySQL. ([Bug#23300](#))

### 16.3.1.12. Replication During a Master Crash

A crash on the master side can result in the master's binary log having a final position less than the most recent position read by the slave, due to the master's binary log file not being flushed. This can cause the slave not to be able to replicate when the master comes back up. Setting `sync_binlog=1` in the master `my.cnf` file helps to minimize this problem because it causes the master to flush its binary log more frequently.

### 16.3.1.13. Replication During a Master Shutdown

It is safe to shut down a master server and restart it later. When a slave loses its connection to the master, the slave tries to reconnect immediately and retries periodically if that fails. The default is to retry every 60 seconds. This may be changed with the `CHANGE MASTER TO` statement or `--master-connect-retry` option. A slave also is able to deal with network connectivity outages. However, the slave notices the network outage only after receiving no data from the master for `slave_net_timeout` seconds. If your outages are short, you may want to decrease `slave_net_timeout`. See [Section 5.1.3, "Server System Variables"](#).

### 16.3.1.14. Replication with **MEMORY** Tables

When a server shuts down and restarts, its **MEMORY** (**HEAP**) tables become empty. The master replicates this effect to slaves as follows: The first time that the master uses each **MEMORY** table after startup, it logs an event that notifies the slaves that the table needs to be emptied by writing a **DELETE** statement for that table to the binary log. See [Section 13.4, “The \*\*MEMORY\*\* \(\*\*HEAP\*\*\) Storage Engine”](#), for more information about **MEMORY** tables.

### 16.3.1.15. Replication of the System **mysql** Database

User privileges are replicated only if the **mysql** database is replicated. That is, the **GRANT**, **REVOKE**, **SET PASSWORD**, **CREATE USER**, and **DROP USER** statements take effect on the slave only if the replication setup includes the **mysql** database.

### 16.3.1.16. Replication and the Query Optimizer

It is possible for the data on the master and slave to become different if a statement is designed in such a way that the data modification is non-deterministic; that is, left up to the query optimizer. (This is in general not a good practice, even outside of replication.) Examples of non-deterministic statements include **DELETE** or **UPDATE** statements that use **LIMIT** with no **ORDER BY** clause; see [Section 16.3.1.9, “Replication and \*\*LIMIT\*\*”](#), for a detailed discussion of these.

Also see [Additional Known Issues](#).

### 16.3.1.17. Replication and Reserved Words

You can encounter problems when you are attempting to replicate from an older master to a newer slave and you make use of identifiers on the master that are reserved words in the newer MySQL version running on the slave. An example of this is using a table column named **current\_user** on a 4.0 master that is replicating to a 4.1 or higher slave, because **CURRENT\_USER** is a reserved word beginning in MySQL 4.1. Replication can fail in such cases with Error 1064 **YOU HAVE AN ERROR IN YOUR SQL SYNTAX. . . , even if a database or table named using the reserved word or a table having a column named using the reserved word is excluded from replication**. This is due to the fact that each SQL statement must be parsed by the slave prior to execution, so that the slave knows which database object or objects would be effected by the statement; only after the statement is parsed can the slave apply any filtering rules defined by **--replicate-do-db**, **--replicate-do-table**, **--replicate-ignore-db**, and **--replicate-ignore-table**.

To work around the problem of database, table, or column names on the master which would be regarded as reserved words by the slave, do one of the following:

- Use one or more **ALTER TABLE** statements on the master to change the names of any database objects where these names would be considered reserved words on the slave, and change any SQL statements that use the old names to use the new names instead.
- In any SQL statements using these database object names, set the names off using backtick characters (```).

For listings of reserved words by MySQL version, see [Reserved Words](#), in the *MySQL Server Version Reference*.

### 16.3.1.18. Slave Errors during Replication

If a statement on a slave produces an error, the slave SQL thread terminates, and the slave writes a message to its error log. You should then connect to the slave manually and determine the cause of the problem. (**SHOW SLAVE STATUS** is useful for this.) Then fix the problem (for example, you might need to create a non-existent table) and run **START SLAVE**.

### 16.3.1.19. Replication during a Slave Shutdown

Shutting down the slave (cleanly) is also safe because it keeps track of where it left off. Unclean shutdowns might produce problems, especially if the disk cache was not flushed to disk before the system went down. Your system fault tolerance is greatly increased if you have a good uninterruptible power supply. Unclean shutdowns of the master may cause inconsistencies between the content of tables and the binary log in master; this can be avoided by using **InnoDB** tables and the **--innodb\_safe\_binlog** option on the master. See [Section 5.2.3, “The Binary Log”](#).

#### Note

**--innodb\_safe\_binlog** is unneeded as of MySQL 5.0.3, having been made obsolete by the introduction of XA transaction support.

### 16.3.1.20. Replication and Temporary Tables

**Safe shutdown of slaves when using temporary tables.** Temporary tables are replicated except in the case where you shut down the slave server (not just the slave threads) and you have replicated temporary tables that are used in updates that have not yet been

executed on the slave. If you shut down the slave server, the temporary tables needed by those updates are no longer available when the slave is restarted. To avoid this problem, do not shut down the slave while it has temporary tables open. Instead, use the following procedure:

1. Issue a `STOP SLAVE SQL_THREAD` statement.
2. Use `SHOW STATUS` to check the value of the `Slave_open_temp_tables` variable.
3. If the value is 0, issue a `mysqladmin shutdown` command to stop the slave.
4. If the value is not 0, restart the slave SQL thread with `START SLAVE SQL_THREAD`.
5. Repeat the procedure later until the `Slave_open_temp_tables` variable is 0 and you can stop the slave.

**Temporary tables and replication options.** By default, all temporary tables are replicated; this happens whether or not there are any matching `--replicate-do-db`, `--replicate-do-table`, or `--replicate-wild-do-table` options in effect. However, the `--replicate-ignore-table` and `--replicate-wild-ignore-table` options are honored for temporary tables.

A recommended practice when using replication is to designate a prefix for exclusive use in naming temporary tables that you do not want replicated, then employ a matching `--replicate-wild-ignore-table` option. For example, you might give all such tables names beginning with `norep_` (such as `norep_tablea`, `norep_tableb`, and so on), then use `--replicate-wild-ignore-table=norep_` to prevent the replication of these tables.

### 16.3.1.21. Replication Retries and Timeouts

In MySQL 5.0 (starting from 5.0.3), there is a global system variable `slave_transaction_retries`: If the replication slave SQL thread fails to execute a transaction because of an InnoDB deadlock or because it exceeded the InnoDB `innodb_lock_wait_timeout` or the NDBCLUSTER `TransactionDeadlockDetectionTimeout` or `TransactionInactiveTimeout` value, the transaction automatically retries `slave_transaction_retries` times before stopping with an error. The default value is 10. Starting from MySQL 5.0.4, the total retry count can be seen in the output of `SHOW STATUS`; see Section 5.1.6, “Server Status Variables”.

### 16.3.1.22. Replication and Time Zones

If the master uses MySQL 4.1, the same system time zone should be set for both master and slave. Otherwise some statements will not be replicated properly, such as statements that use the `NOW()` or `FROM_UNIXTIME()` functions. You can set the time zone in which MySQL server runs by using the `--timezone=timezone_name` option of the `mysqld_safe` script or by setting the `TZ` environment variable. Both master and slave should also have the same default connection time zone setting; that is, the `--default-time-zone` parameter should have the same value for both master and slave. Note that this is not necessary when the master is MySQL 5.0 or later.

`CONVERT_TZ(..., ..., @session.time_zone)` is properly replicated only if both master and slave are running MySQL 5.0.4 or newer.

### 16.3.1.23. Replication and Transactions

It is possible to replicate transactional tables on the master using non-transactional tables on the slave. For example, you can replicate an InnoDB master table as a MyISAM slave table. However, if you do this, there are problems if the slave is stopped in the middle of a `BEGIN/COMMIT` block because the slave restarts at the beginning of the `BEGIN` block.

In situations where transactions mix updates to transactional and non-transactional tables, the order of statements in the binary log is correct, and all needed statements are written to the binary log even in case of a `ROLLBACK`. However, when a second connection updates the non-transactional table before the first connection's transaction is complete, statements can be logged out of order, because the second connection's update is written immediately after it is performed, regardless of the state of the transaction being performed by the first connection.

Due to the non-transactional nature of MyISAM tables, it is possible to have a statement that only partially updates a table and returns an error code. This can happen, for example, on a multiple-row insert that has one row violating a key constraint, or if a long update statement is killed after updating some of the rows. If that happens on the master, the slave thread exits and waits for the database administrator to decide what to do about it unless the error code is legitimate and execution of the statement results in the same error code on the slave. If this error code validation behavior is not desirable, some or all errors can be masked out (ignored) with the `--slave-skip-errors` option.

If you update transactional tables from non-transactional tables inside a `BEGIN/COMMIT` sequence, updates to the binary log may be out of synchrony with table states if the non-transactional table is updated before the transaction commits. This occurs because the transaction is written to the binary log only when it is committed.

In situations where transactions mix updates to transactional and non-transactional tables, the order of statements in the binary log

is correct, and all needed statements are written to the binary log even in case of a `ROLLBACK`. However, when a second connection updates the non-transactional table before the first connection's transaction is complete, statements can be logged out of order, because the second connection's update is written immediately after it is performed, regardless of the state of the transaction being performed by the first connection.

### Caution

You should avoid transactions that update both transactional and non-transactional tables in a replication environment.

When the storage engine type of the slave is non-transactional, transactions on the master that mix updates of transactional and non-transactional tables should be avoided because they can cause inconsistency of the data between the master's transactional table and the slave's non-transactional table. That is, such transactions can lead to master storage engine-specific behavior with the possible effect of replication going out of synchrony. MySQL does not issue a warning about this currently, so extra care should be taken when replicating transactional tables from the master to non-transactional ones on the slaves.

## 16.3.1.24. Replication and Triggers

**Known issue:** In MySQL 5.0.17, the syntax for `CREATE TRIGGER` changed to include a `DEFINER` clause for specifying which access privileges to check at trigger invocation time. (See [Section 12.1.11, “CREATE TRIGGER Syntax”](#), for more information.) However, if you attempt to replicate from a master server older than MySQL 5.0.17 to a slave running MySQL 5.0.17 through 5.0.19, replication of `CREATE TRIGGER` statements fails on the slave with a `Definer not fully qualified` error. A workaround is to create triggers on the master using a version-specific comment embedded in each `CREATE TRIGGER` statement:

```
CREATE /*!50017 DEFINER = 'root'@'localhost' */ TRIGGER ... ;
```

`CREATE TRIGGER` statements written this way will replicate to newer slaves, which pick up the `DEFINER` clause from the comment and execute successfully.

This slave problem is fixed as of MySQL 5.0.20.

## 16.3.1.25. Replication and User Privileges

User privileges are replicated only if the `mysql` database is replicated. That is, the `GRANT`, `REVOKE`, `SET PASSWORD`, `CREATE USER`, and `DROP USER` statements take effect on the slave only if the replication setup includes the `mysql` database.

If you're replicating all databases, but don't want statements that affect user privileges to be replicated, set up the slave to not replicate the `mysql` database, using the `--replicate-wild-ignore-table=mysql.%` option. The slave recognizes that issuing privilege-related SQL statements have no effect, and thus it does not execute those statements.

## 16.3.1.26. Replication and Variables

The `foreign_key_checks`, `unique_checks`, and `sql_auto_is_null` variables are all replicated.

`sql_mode` is also replicated except for the `NO_DIR_IN_CREATE` mode. However, when `mysqlbinlog` parses a `SET @@sql_mode = value` statement, the full `value`, including `NO_DIR_IN_CREATE`, is passed to the receiving server.

The `storage_engine` system variable is not replicated, which is a good thing for replication between different storage engines.

Starting from MySQL 5.0.3 (master and slave), replication works even if the master and slave have different global character set variables. Starting from MySQL 5.0.4 (master and slave), replication works even if the master and slave have different global time zone variables.

Session variables are not replicated properly when used in statements that update tables. For example, `SET MAX_JOIN_SIZE=1000` followed by `INSERT INTO mytable VALUES(@@MAX_JOIN_SIZE)` will not insert the same data on the master and the slave. This does not apply to the common sequence of `SET TIME_ZONE=...` followed by `INSERT INTO mytable VALUES(CONVERT_TZ(..., ..., @@time_zone))`, which replicates correctly as of MySQL 5.0.4.

Update statements that refer to user-defined variables (that is, variables of the form `@var_name`) are replicated correctly in MySQL 5.0. However, this is not true for versions prior to 4.1. Note that user variable names are case insensitive starting in MySQL 5.0. You should take this into account when setting up replication between MySQL 5.0 and older versions.

## 16.3.1.27. Replication and Views

Views are always replicated to slaves. Views are filtered by their own name, not by the tables they refer to. This means that a view can be replicated to the slave even if the view contains a table that would normally be filtered out by `replication-ignore-table` rules. Care should therefore be taken to ensure that views do not replicate table data that would normally be filtered for security reasons.

## 16.3.2. Replication Compatibility Between MySQL Versions

MySQL supports replication from one major version to the next higher major version. For example, you can replicate from a master running MySQL 4.1 to a slave running MySQL 5.0, from a master running MySQL 5.0 to a slave running MySQL 5.1, and so on.

In some cases, it is also possible to replicate between a master and a slave that is more than one major version newer than the master. However, there are known issues with trying to replicate from a master running MySQL 4.1 or earlier to a slave running MySQL 5.1 or later. To work around such problems, you can insert a MySQL server running an intermediate version between the two; for example, rather than replicating directly from a MySQL 4.1 master to a MySQL 5.1 slave, it is possible to replicate from a MySQL 4.1 server to a MySQL 5.0 server, and then from the MySQL 5.0 server to a MySQL 5.1 server.

### Important

We highly recommend using the most recent release available within a given MySQL major version because replication (and other) capabilities are continually being improved. We also recommend upgrading masters and slaves that use alpha or beta releases of a major version of MySQL to GA (production) releases when these become available for that major version.

Replication from newer masters to older slaves may be possible, but is generally not supported. This is due to a number of factors:

- **Binary log format changes.** The binary log format can change between major releases. While we attempt to maintain backward-compatibility, this is not always possible. Major changes were made in MySQL 5.0.3 (for improvements to handling of character sets and `LOAD DATA INFILE`) and 5.0.4 (for improvements to handling of time zones). Because of these changes, replication from a MySQL 5.0.3 or later master to a MySQL 5.0.2 or earlier slave is not supported. This also means that replication from a MySQL 5.0.3 (or later) master to any MySQL 4.1 (or earlier) slave is generally not supported.

This also has significant implications for upgrading replication servers; see [Section 16.3.3, “Upgrading a Replication Setup”](#), for more information.

- **Use of row-based replication.** You cannot replicate using row-based replication from a MySQL 5.1.5 or later master to a slave running an earlier version of MySQL, since MySQL versions prior to 5.1.5 do not support RBR.

### Note

Row-based replication is not available in MySQL 5.0. For more information about row-based replication in MySQL 5.1, see [Replication Formats](#).

- **SQL incompatibilities.** You cannot replicate from a newer master to an older slave using statement-based replication if the statements to be replicated use SQL features available on the master but not on the slave.

For more information on potential replication issues, see [Section 16.3.1, “Replication Features and Issues”](#).

## 16.3.3. Upgrading a Replication Setup

When you upgrade servers that participate in a replication setup, the procedure for upgrading depends on the current server versions and the version to which you are upgrading.

This section applies to upgrading replication from older versions of MySQL to MySQL 5.0. A 4.0 server should be 4.0.3 or newer.

When you upgrade a master to 5.0 from an earlier MySQL release series, you should first ensure that all the slaves of this master are using the same 5.0.x release. If this is not the case, you should first upgrade the slaves. To upgrade each slave, shut it down, upgrade it to the appropriate 5.0.x version, restart it, and restart replication. The 5.0 slave is able to read the old relay logs written prior to the upgrade and to execute the statements they contain. Relay logs created by the slave after the upgrade are in 5.0 format.

After the slaves have been upgraded, shut down the master, upgrade it to the same 5.0.x release as the slaves, and restart it. The 5.0 master is able to read the old binary logs written prior to the upgrade and to send them to the 5.0 slaves. The slaves recognize the old format and handle it properly. Binary logs created by the master following the upgrade are in 5.0 format. These too are recognized by the 5.0 slaves.

In other words, there are no measures to take when upgrading to MySQL 5.0, except that the slaves must be MySQL 5.0 before you can upgrade the master to 5.0. Note that downgrading from 5.0 to older versions does not work so simply: You must ensure that any 5.0 binary logs or relay logs have been fully processed, so that you can remove them before proceeding with the downgrade.

## 16.3.4. Replication FAQ

### Questions

- [16.3.4.1](#): How do I configure a slave if the master is running and I do not want to stop it?
- [16.3.4.2](#): Does the slave need to be connected to the master all the time?

## Questions and Answers

### 16.3.4.1: How do I configure a slave if the master is running and I do not want to stop it?

There are several possibilities. If you have taken a snapshot backup of the master at some point and recorded the binary log file name and offset (from the output of `SHOW MASTER STATUS`) corresponding to the snapshot, use the following procedure:

1. Make sure that the slave is assigned a unique server ID.
2. Execute the following statement on the slave, filling in appropriate values for each option:

```
mysql> CHANGE MASTER TO
->     MASTER_HOST='master_host_name',
->     MASTER_USER='master_user_name',
->     MASTER_PASSWORD='master_pass',
->     MASTER_LOG_FILE='recorded_log_file_name',
->     MASTER_LOG_POS=recorded_log_position;
```

3. Execute `START SLAVE` on the slave.

If you do not have a backup of the master server, here is a quick procedure for creating one. All steps should be performed on the master host.

1. Issue this statement to acquire a global read lock:

```
mysql> FLUSH TABLES WITH READ LOCK;
```

2. With the lock still in place, execute this command (or a variation of it):

```
shell> tar zcf /tmp/backup.tar.gz /var/lib/mysql
```

3. Issue this statement and record the output, which you will need later:

```
mysql> SHOW MASTER STATUS;
```

4. Release the lock:

```
mysql> UNLOCK TABLES;
```

An alternative to using the preceding procedure to make a binary copy is to make an SQL dump of the master. To do this, you can use `mysqldump --master-data` on your master and later load the SQL dump into your slave. However, this is slower than

making a binary copy.

Regardless of which of the two methods you use, afterward follow the instructions for the case when you have a snapshot and have recorded the log file name and offset. You can use the same snapshot to set up several slaves. Once you have the snapshot of the master, you can wait to set up a slave as long as the binary logs of the master are left intact. The two practical limitations on the length of time you can wait are the amount of disk space available to retain binary logs on the master and the length of time it takes the slave to catch up.

#### 16.3.4.2: Does the slave need to be connected to the master all the time?

No, it does not. The slave can go down or stay disconnected for hours or even days, and then reconnect and catch up on updates. For example, you can set up a master/slave relationship over a dial-up link where the link is up only sporadically and for short periods of time. The implication of this is that, at any given time, the slave is not guaranteed to be in synchrony with the master unless you take some special measures.

#### 16.3.4.3: How do I know how late a slave is compared to the master? In other words, how do I know the date of the last statement replicated by the slave?

You can read the `Seconds_Behind_Master` column in `SHOW SLAVE STATUS`. See [Section 16.4.1, “Replication Implementation Details”](#).

When the slave SQL thread executes an event read from the master, it modifies its own time to the event timestamp. (This is why `TIMESTAMP` is well replicated.) In the `Time` column in the output of `SHOW PROCESSLIST`, the number of seconds displayed for the slave SQL thread is the number of seconds between the timestamp of the last replicated event and the real time of the slave machine. You can use this to determine the date of the last replicated event. Note that if your slave has been disconnected from the master for one hour, and then reconnects, you may immediately see `Time` values like 3600 for the slave SQL thread in `SHOW PROCESSLIST`. This is because the slave is executing statements that are one hour old.

#### 16.3.4.4: How do I force the master to block updates until the slave catches up?

Use the following procedure:

1. On the master, execute these statements:

```
mysql> FLUSH TABLES WITH READ LOCK;
mysql> SHOW MASTER STATUS;
```

Record the replication coordinates (the log file name and offset) from the output of the `SHOW` statement.

2. On the slave, issue the following statement, where the arguments to the `MASTER_POS_WAIT()` function are the replication coordinate values obtained in the previous step:

```
mysql> SELECT MASTER_POS_WAIT('log_name', log_offset);
```

The `SELECT` statement blocks until the slave reaches the specified log file and offset. At that point, the slave is in synchrony with the master and the statement returns.

3. On the master, issue the following statement to allow the master to begin processing updates again:

```
mysql> UNLOCK TABLES;
```

#### 16.3.4.5: What issues should I be aware of when setting up two-way replication?

MySQL replication currently does not support any locking protocol between master and slave to guarantee the atomicity of a distributed (cross-server) update. In other words, it is possible for client A to make an update to co-master 1, and in the meantime, before it propagates to co-master 2, client B could make an update to co-master 2 that makes the update of client A work differently than it did on co-master 1. Thus, when the update of client A makes it to co-master 2, it produces tables that are different from what you have on co-master 1, even after all the updates from co-master 2 have also propagated. This means that you should not chain two servers together in a two-way replication relationship unless you are sure that your updates can safely happen in any order, or unless you take care of mis-ordered updates somehow in the client code.

You should also realize that two-way replication actually does not improve performance very much (if at all) as far as updates are concerned. Each server must do the same number of updates, just as you would have a single server do. The only difference is that there is a little less lock contention, because the updates originating on another server are serialized in one slave thread. Even this benefit might be offset by network delays.

#### 16.3.4.6: How can I use replication to improve performance of my system?

You should set up one server as the master and direct all writes to it. Then configure as many slaves as you have the budget and

rackspace for, and distribute the reads among the master and the slaves. You can also start the slaves with the `--skip-innodb`, `--skip-bdb`, `--low-priority-updates`, and `--delay-key-write=ALL` options to get speed improvements on the slave end. In this case, the slave uses non-transactional MyISAM tables instead of InnoDB and BDB tables to get more speed by eliminating transactional overhead.

#### 16.3.4.7: What should I do to prepare client code in my own applications to use performance-enhancing replication?

If the part of your code that is responsible for database access has been properly abstracted/modularized, converting it to run with a replicated setup should be very smooth and easy. Change the implementation of your database access to send all writes to the master, and to send reads to either the master or a slave. If your code does not have this level of abstraction, setting up a replicated system gives you the opportunity and motivation to clean up. Start by creating a wrapper library or module that implements the following functions:

- `safe_writer_connect()`
- `safe_reader_connect()`
- `safe_reader_statement()`
- `safe_writer_statement()`

`safe_` in each function name means that the function takes care of handling all error conditions. You can use different names for the functions. The important thing is to have a unified interface for connecting for reads, connecting for writes, doing a read, and doing a write.

Then convert your client code to use the wrapper library. This may be a painful and scary process at first, but it pays off in the long run. All applications that use the approach just described are able to take advantage of a master/slave configuration, even one involving multiple slaves. The code is much easier to maintain, and adding troubleshooting options is trivial. You need modify only one or two functions; for example, to log how long each statement took, or which statement among those issued gave you an error.

If you have written a lot of code, you may want to automate the conversion task by using the `replace` utility that comes with standard MySQL distributions, or write your own conversion script. Ideally, your code uses consistent programming style conventions. If not, then you are probably better off rewriting it anyway, or at least going through and manually regularizing it to use a consistent style.

#### 16.3.4.8: When and how much can MySQL replication improve the performance of my system?

MySQL replication is most beneficial for a system that processes frequent reads and infrequent writes. In theory, by using a single-master/multiple-slave setup, you can scale the system by adding more slaves until you either run out of network bandwidth, or your update load grows to the point that the master cannot handle it.

To determine how many slaves you can use before the added benefits begin to level out, and how much you can improve performance of your site, you need to know your query patterns, and to determine empirically by benchmarking the relationship between the throughput for reads (reads per second, or `reads`) and for writes (`writes`) on a typical master and a typical slave. The example here shows a rather simplified calculation of what you can get with replication for a hypothetical system.

Let's say that system load consists of 10% writes and 90% reads, and we have determined by benchmarking that `reads` is  $1200 - 2 \times \text{writes}$ . In other words, the system can do 1,200 reads per second with no writes, the average write is twice as slow as the average read, and the relationship is linear. Let us suppose that the master and each slave have the same capacity, and that we have one master and  $N$  slaves. Then we have for each server (master or slave):

$$\text{reads} = 1200 - 2 \times \text{writes}$$

$$\text{reads} = 9 \times \text{writes} / (N + 1) \text{ (reads are split, but writes go to all servers)}$$

$$9 \times \text{writes} / (N + 1) + 2 \times \text{writes} = 1200$$

$$\text{writes} = 1200 / (2 + 9/(N+1))$$

The last equation indicates the maximum number of writes for  $N$  slaves, given a maximum possible read rate of 1,200 per minute and a ratio of nine reads per write.

This analysis yields the following conclusions:

- If  $N = 0$  (which means we have no replication), our system can handle about  $1200/11 = 109$  writes per second.
- If  $N = 1$ , we get up to 184 writes per second.

- If  $N = 8$ , we get up to 400 writes per second.
- If  $N = 17$ , we get up to 480 writes per second.
- Eventually, as  $N$  approaches infinity (and our budget negative infinity), we can get very close to 600 writes per second, increasing system throughput about 5.5 times. However, with only eight servers, we increase it nearly four times.

Note that these computations assume infinite network bandwidth and neglect several other factors that could be significant on your system. In many cases, you may not be able to perform a computation similar to the one just shown that accurately predicts what will happen on your system if you add  $N$  replication slaves. However, answering the following questions should help you decide whether and by how much replication will improve the performance of your system:

- What is the read/write ratio on your system?
- How much more write load can one server handle if you reduce the reads?
- For how many slaves do you have bandwidth available on your network?

#### 16.3.4.9: How do I prevent GRANT and REVOKE statements from replicating to slave machines?

Start the server with the `--replicate-wild-ignore-table=mysql.%` option.

#### 16.3.4.10: Does replication work on mixed operating systems (for example, the master runs on Linux while slaves run on Mac OS X and Windows)?

Yes.

#### 16.3.4.11: Does replication work on mixed hardware architectures (for example, the master runs on a 64-bit machine while slaves run on 32-bit machines)?

Yes.

## 16.3.5. Troubleshooting Replication

If you have followed the instructions, and your replication setup is not working, the first thing to do is *check the error log for messages*. Many users have lost time by not doing this soon enough after encountering problems.

If you cannot tell from the error log what the problem was, try the following techniques:

- Verify that the master has binary logging enabled by issuing a `SHOW MASTER STATUS` statement. If logging is enabled, `Position` is nonzero. If binary logging is not enabled, verify that you are running the master with the `--log-bin` and `--server-id` options.
- Verify that the slave is running. Use `SHOW SLAVE STATUS` to check whether the `Slave_IO_Running` and `Slave_SQL_Running` values are both `Yes`. If not, verify the options that were used when starting the slave server. For example, `--skip-slave-start` prevents the slave threads from starting until you issue a `START SLAVE` statement.
- If the slave is running, check whether it established a connection to the master. Use `SHOW PROCESSLIST`, find the I/O and SQL threads and check their `State` column to see what they display. See Section 16.4.1, “Replication Implementation Details”. If the I/O thread state says `Connecting to master`, verify the privileges for the replication user on the master, the master host name, your DNS setup, whether the master is actually running, and whether it is reachable from the slave.
- If the slave was running previously but has stopped, the reason usually is that some statement that succeeded on the master failed on the slave. This should never happen if you have taken a proper snapshot of the master, and never modified the data on the slave outside of the slave thread. If the slave stops unexpectedly, it is a bug or you have encountered one of the known replication limitations described in Section 16.3.1, “Replication Features and Issues”. If it is a bug, see Section 16.3.6, “How to Report Replication Bugs or Problems”, for instructions on how to report it.

### MySQL Enterprise

For immediate notification whenever a slave stops, subscribe to the MySQL Enterprise Monitor. For more information, see <http://www.mysql.com/products/enterprise/advisors.html>.

- If a statement that succeeded on the master refuses to run on the slave, try the following procedure if it is not feasible to do a full database resynchronization by deleting the slave's databases and copying a new snapshot from the master:
  1. Determine whether the affected table on the slave is different from the master table. Try to understand how this happened. Then make the slave's table identical to the master's and run `START SLAVE`.

2. If the preceding step does not work or does not apply, try to understand whether it would be safe to make the update manually (if needed) and then ignore the next statement from the master.
3. If you decide that you can skip the next statement from the master, issue the following statements:

```
mysql> SET GLOBAL SQL_SLAVE_SKIP_COUNTER = N;
mysql> START SLAVE;
```

The value of *N* should be 1 if the next statement from the master does not use `AUTO_INCREMENT` or `LAST_INSERT_ID()`. Otherwise, the value should be 2. The reason for using a value of 2 for statements that use `AUTO_INCREMENT` or `LAST_INSERT_ID()` is that they take two events in the binary log of the master.

See also [Section 12.6.2.6, “SET GLOBAL SQL\\_SLAVE\\_SKIP\\_COUNTER Syntax”](#).

4. If you are sure that the slave started out perfectly synchronized with the master, and that no one has updated the tables involved outside of the slave thread, then presumably the discrepancy is the result of a bug. If you are running the most recent version of MySQL, please report the problem. If you are running an older version, try upgrading to the latest production release to determine whether the problem persists.

### 16.3.6. How to Report Replication Bugs or Problems

When you have determined that there is no user error involved, and replication still either does not work at all or is unstable, it is time to send us a bug report. We need to obtain as much information as possible from you to be able to track down the bug. Please spend some time and effort in preparing a good bug report.

If you have a repeatable test case that demonstrates the bug, please enter it into our bugs database using the instructions given in [Section 1.6, “How to Report Bugs or Problems”](#). If you have a “phantom” problem (one that you cannot duplicate at will), use the following procedure:

1. Verify that no user error is involved. For example, if you update the slave outside of the slave thread, the data goes out of synchrony, and you can have unique key violations on updates. In this case, the slave thread stops and waits for you to clean up the tables manually to bring them into synchrony. *This is not a replication problem. It is a problem of outside interference causing replication to fail.*
2. Run the slave with the `--log-slave-updates` and `--log-bin` options. These options cause the slave to log the updates that it receives from the master into its own binary logs.
3. Save all evidence before resetting the replication state. If we have no information or only sketchy information, it becomes difficult or impossible for us to track down the problem. The evidence you should collect is:
  - All binary logs from the master
  - All binary logs from the slave
  - The output of `SHOW MASTER STATUS` from the master at the time you discovered the problem
  - The output of `SHOW SLAVE STATUS` from the slave at the time you discovered the problem
  - Error logs from the master and the slave
4. Use `mysqlbinlog` to examine the binary logs. The following should be helpful to find the problem statement. `log_pos` and `log_file` are the `Master_Log_File` and `Read_Master_Log_Pos` values from `SHOW SLAVE STATUS`.

```
shell> mysqlbinlog --start-position=log_pos log_file | head
```

After you have collected the evidence for the problem, try to isolate it as a separate test case first. Then enter the problem with as much information as possible into our bugs database using the instructions at [Section 1.6, “How to Report Bugs or Problems”](#).

## 16.4. Replication Implementation Overview

MySQL replication is based on the master server keeping track of all changes to your databases (updates, deletes, and so on) in its binary logs. Therefore, to use replication, you must enable binary logging on the master server. See [Section 5.2.3, “The Binary Log”](#).

Each slave server receives from the master the saved updates that the master has recorded in its binary log, so that the slave can ex-

ecute the same updates on its copy of the data.

It is *extremely* important to realize that the binary log is simply a record starting from the fixed point in time at which you enable binary logging. Any slaves that you set up need copies of the databases on your master *as they existed at the moment you enabled binary logging on the master*. If you start your slaves with databases that are not in the same state as those on the master when the binary log was started, your slaves are quite likely to fail.

After the slave has been set up with a copy of the master's data, it connects to the master and waits for updates to process. If the master fails, or the slave loses connectivity with your master, the slave keeps trying to connect periodically until it is able to resume listening for updates. The `--master-connect-retry` option controls the retry interval. The default is 60 seconds.

Each slave keeps track of where it left off when it last read from its master server. The master has no knowledge of how many slaves it has or which ones are up to date at any given time.

## 16.4.1. Replication Implementation Details

MySQL replication capabilities are implemented using three threads (one on the master server and two on the slave):

- **Slave I/O thread.** When a `START SLAVE` statement is issued on a slave server, the slave creates an *I/O thread*, which connects to the master and asks it to send the updates recorded in its binary logs.

The slave I/O thread reads the updates that the master's `Binlog Dump` thread sends (see next item) and copies them to local files — known as *relay logs* - in the slave's data directory.

The state of this thread is shown as `Slave_IO_running` in the output of `SHOW SLAVE STATUS` or as `Slave_running` in the output of `SHOW STATUS`.

- **Binlog dump thread.** The master creates a thread to send the binary log contents to the slave. This thread can be identified in the output of `SHOW PROCESSLIST` on the master as the `Binlog Dump` thread.

The binlog dump thread acquires a lock on the master's binary log for reading each event that is to be sent to the slave. As soon as the event has been read, the lock is released, even before the event is sent to the slave.

- **Slave SQL thread.** The slave creates this thread to read the relay logs that were written by the slave I/O thread. The *slave SQL thread* is also used to execute the updates contained in the relay logs.

### MySQL Enterprise

For constant monitoring of the status of slaves subscribe to the MySQL Enterprise Monitor. For more information, see <http://www.mysql.com/products/enterprise/advisors.html>.

In the preceding description, there are three threads per master/slave connection. A master that has multiple slaves creates one binlog dump thread for each currently-connected slave, and each slave has its own I/O and SQL threads.

The slave uses two threads so that reading updates from the master and executing them can be separated into two independent tasks. Thus, the task of reading statements is not slowed down if statement execution is slow. For example, if the slave server has not been running for a while, its I/O thread can quickly fetch all the binary log contents from the master when the slave starts, even if the SQL thread lags far behind. If the slave stops before the SQL thread has executed all the fetched statements, the I/O thread has at least fetched everything so that a safe copy of the statements is stored locally in the slave's relay logs, ready for execution the next time that the slave starts. This enables the master server to purge its binary logs sooner because it no longer needs to wait for the slave to fetch their contents.

The `SHOW PROCESSLIST` statement provides information that tells you what is happening on the master and on the slave regarding replication. See [Section 7.5.6, “Examining Thread Information”](#), for descriptions of all replicated-related states.

The following example illustrates how the three threads show up in the output from `SHOW PROCESSLIST`.

On the master server, the output from `SHOW PROCESSLIST` looks like this:

```
mysql> SHOW PROCESSLIST\G
***** 1. row *****
  Id: 2
  User: root
  Host: localhost:32931
  db: NULL
  Command: Binlog Dump
  Time: 94
  State: Has sent all binlog to slave; waiting for binlog to
        be updated
  Info: NULL
```

Here, thread 2 is a `Binlog Dump` replication thread for a connected slave. The `State` information indicates that all outstanding

updates have been sent to the slave and that the master is waiting for more updates to occur. If you see no `Binlog Dump` threads on a master server, this means that replication is not running — that is, that no slaves are currently connected.

On the slave server, the output from `SHOW PROCESSLIST` looks like this:

```
mysql> SHOW PROCESSLIST\G
***** 1. row *****
  Id: 10
  User: system user
  Host:
  db: NULL
  Command: Connect
  Time: 11
  State: Waiting for master to send event
  Info: NULL
***** 2. row *****
  Id: 11
  User: system user
  Host:
  db: NULL
  Command: Connect
  Time: 11
  State: Has read all relay log; waiting for the slave I/O
        thread to update it
  Info: NULL
```

This information indicates that thread 10 is the I/O thread that is communicating with the master server, and thread 11 is the SQL thread that is processing the updates stored in the relay logs. At the time that the `SHOW PROCESSLIST` was run, both threads were idle, waiting for further updates.

The value in the `Time` column can show how late the slave is compared to the master. See [Section 16.3.4, “Replication FAQ”](#). The amount of time that the slave lags behind the master that is required before the master determines that the slave is no longer connected — as with any other client connection — is dependent on the values of `net_write_timeout` and `net_retry_count`; for more information about these, see [Section 16.1.2, “Replication and Binary Logging Options and Variables”](#).

## 16.4.2. Replication Relay and Status Files

By default, relay log file names have the form `host_name-relay-bin.nnnnnn`, where `host_name` is the name of the slave server host and `nnnnnn` is a sequence number. Successive relay log files are created using successive sequence numbers, beginning with `000001`. The slave uses an index file to track the relay log files currently in use. The default relay log index file name is `host_name-relay-bin.index`. By default, the slave server creates relay log files in its data directory.

The default file names for relay logs and relay log index files can be overridden with, respectively, the `--relay-log` and `--relay-log-index` server options (see [Section 16.1.2, “Replication and Binary Logging Options and Variables”](#)). For this reason, changing a replication slave’s host name can cause replication to fail with the errors `FAILED TO OPEN THE RELAY LOG` and `COULD NOT FIND TARGET LOG DURING RELAY LOG INITIALIZATION`. This is a known issue which we intend to fix in a future MySQL release (see [Bug#2122](#)). If you anticipate that a slave’s host name may change in the future (for example, if networking is set up on the slave such that its host name can be modified via DHCP), then you can use these options to prevent this problem from occurring. However, if you encounter this issue, one way to work around it is to stop the slave server, prepend the contents of the old relay log index file to the new one, then restart the slave. On a Unix system, this can be done as shown here, where `new_host_name` is the new host name and `old_host_name` is the old one:

```
shell> cat new_host_name-relay-bin.index >> old_host_name-relay-bin.index
shell> mv old_host_name-relay-bin.index new_host_name-relay-bin.index
```

Relay logs have the same format as binary logs and can be read using `mysqlbinlog`. The SQL thread automatically deletes each relay log file as soon as it has executed all events in the file and no longer needs it. There is no explicit mechanism for deleting relay logs because the SQL thread takes care of doing so. However, `FLUSH LOGS` rotates relay logs, which influences when the SQL thread deletes them.

A slave server creates a new relay log file under the following conditions:

- Each time the I/O thread starts.
- When the logs are flushed; for example, with `FLUSH LOGS` or `mysqladmin flush-logs`.
- When the size of the current relay log file becomes too large. The meaning of “too large” is determined as follows:
  - If the value of `max_relay_log_size` is greater than 0, that is the maximum relay log file size.
  - If the value of `max_relay_log_size` is 0, `max_binlog_size` determines the maximum relay log file size.

A slave replication server creates two additional small files in the data directory. These *status files* are named `master.info` and `relay-log.info` by default. Their names can be changed by using the `--master-info-file` and `--relay-log-info-file` options. See Section 16.1.2, “Replication and Binary Logging Options and Variables”.

The two status files contain information like that shown in the output of the `SHOW SLAVE STATUS` statement, which is discussed in Section 12.6.2, “SQL Statements for Controlling Slave Servers”. Because the status files are stored on disk, they survive a slave server’s shutdown. The next time the slave starts up, it reads the two files to determine how far it has proceeded in reading binary logs from the master and in processing its own relay logs.

The I/O thread updates the `master.info` file. The following table shows the correspondence between the lines in the file and the columns displayed by `SHOW SLAVE STATUS`.

Line	Description
1	Number of lines in the file
2	Master_Log_File
3	Read_Master_Log_Pos
4	Master_Host
5	Master_User
6	Password (not shown by <code>SHOW SLAVE STATUS</code> )
7	Master_Port
8	Connect_Retry
9	Master_SSL_Allowed
10	Master_SSL_CA_File
11	Master_SSL_CA_Path
12	Master_SSL_Cert
13	Master_SSL_Cipher
14	Master_SSL_Key

The SQL thread updates the `relay-log.info` file. The following table shows the correspondence between the lines in the file and the columns displayed by `SHOW SLAVE STATUS`.

Line	Description
1	Relay_Log_File
2	Relay_Log_Pos
3	Relay_Master_Log_File
4	Exec_Master_Log_Pos

The contents of the `relay-log.info` file and the states shown by the `SHOW SLAVE STATES` command may not match if the `relay-log.info` file has not been flushed to disk. Ideally, you should only view `relay-log.info` on a slave that is offline (i.e. `mysqld` is not running). For a running system, `SHOW SLAVE STATUS` should be used.

When you back up the slave’s data, you should back up these two status files as well, along with the relay log files. They are needed to resume replication after you restore the slave’s data. If you lose the relay logs but still have the `relay-log.info` file, you can check it to determine how far the SQL thread has executed in the master binary logs. Then you can use `CHANGE MASTER TO` with the `MASTER_LOG_FILE` and `MASTER_LOG_POS` options to tell the slave to re-read the binary logs from that point. Of course, this requires that the binary logs still exist on the master server.

If your slave is subject to replicating `LOAD DATA INFILE` statements, you should also back up any `SQL_LOAD-*` files that exist in the directory that the slave uses for this purpose. The slave needs these files to resume replication of any interrupted `LOAD DATA INFILE` operations. The directory location is specified using the `--slave-load-tmpdir` option. If this option is not specified, the directory location is the value of the `tmpdir` system variable.

### 16.4.3. How Servers Evaluate Replication Rules

If a master server does not write a statement to its binary log, the statement is not replicated. If the server does log the statement, the statement is sent to all slaves and each slave determines whether to execute it or ignore it.

On the master side, decisions about which statements to log are based on the `--binlog-do-db` and `--binlog-ignore-db` options that control binary logging. For a description of the rules that servers use in evaluating these options, see Section 5.2.3,

“The Binary Log”.

On the slave side, decisions about whether to execute or ignore statements received from the master are made according to the `--replicate-*` options that the slave was started with. (See [Section 16.1.2, “Replication and Binary Logging Options and Variables”](#).) The slave evaluates these options using the following procedure, which first checks the database-level options and then the table-level options.

In the simplest case, when there are no `--replicate-*` options, the procedure yields the result that the slave executes all statements that it receives from the master. Otherwise, the result depends on the particular options given. In general, to make it easier to determine what effect an option set will have, it is recommended that you avoid mixing “do” and “ignore” options, or wildcard and non-wildcard options.

### Stage 1. Check the database options.

At this stage, the slave checks whether there are any `--replicate-do-db` or `--replicate-ignore-db` options that specify database-specific conditions:

- *No*: Permit the statement and proceed to the table-checking stage.
- *Yes*: Test the options using the same rules as for the `--binlog-do-db` and `--binlog-ignore-db` options to determine whether to permit or ignore the statement. What is the result of the test?
  - *Permit*: Do not execute the statement immediately. Defer the decision and proceed to the table-checking stage.
  - *Ignore*: Ignore the statement and exit.

This stage can permit a statement for further option-checking, or cause it to be ignored. However, statements that are permitted at this stage are not actually executed yet. Instead, they pass to the following stage that checks the table options.

### Stage 2. Check the table options.

First, as a preliminary condition, the slave checks whether the statement occurs within a stored function or (prior to MySQL 5.0.12) a stored procedure. If so, execute the statement and exit. (Stored procedures are exempt from this test as of MySQL 5.0.12 because procedure logging occurs at the level of statements that are executed within the routine rather than at the `CALL` level.)

Next, the slave checks for table options and evaluates them. If the server reaches this point, it executes all statements if there are no table options. If there are “do” table options, the statement must match one of them if it is to be executed; otherwise, it is ignored. If there are any “ignore” options, all statements are executed except those that match any `ignore` option. The following steps describe how this evaluation occurs in more detail.

1. Are there any `--replicate-**-table` options?
  - *No*: There are no table restrictions, so all statements match. Execute the statement and exit.
  - *Yes*: There are table restrictions. Evaluate the tables to be updated against them. There might be multiple tables to update, so loop through the following steps for each table looking for a matching option (first the non-wild options, and then the wild options). Only tables that are to be updated are compared to the options. For example, if the statement is `INSERT INTO sales SELECT * FROM prices`, only `sales` is compared to the options). If several tables are to be updated (multiple-table statement), the first table that matches “do” or “ignore” wins. That is, the server checks the first table against the options. If no decision could be made, it checks the second table against the options, and so on.

#### Note

In MySQL 4.1, a multiple-table update was not replicated if each table referenced by the updating statement did not have a matching `--replicate-do-table` rule. In MySQL 5.0, this is no longer true.

2. Are there any `--replicate-do-table` options?
  - *No*: Proceed to the next step.
  - *Yes*: Does the table match any of them?
    - *No*: Proceed to the next step.
    - *Yes*: Execute the statement and exit.
3. Are there any `--replicate-ignore-table` options?
  - *No*: Proceed to the next step.

- *Yes*: Does the table match any of them?
    - *No*: Proceed to the next step.
    - *Yes*: Ignore the statement and exit.
4. Are there any `--replicate-wild-do-table` options?
    - *No*: Proceed to the next step.
    - *Yes*: Does the table match any of them?
      - *No*: Proceed to the next step.
      - *Yes*: Execute the statement and exit.
  5. Are there any `--replicate-wild-ignore-table` options?
    - *No*: Proceed to the next step.
    - *Yes*: Does the table match any of them?
      - *No*: Proceed to the next step.
      - *Yes*: Ignore the statement and exit.
  6. No `--replicate-*--table` option was matched. Is there another table to test against these options?
    - *No*: We have now tested all tables to be updated and could not match any option. Are there `--replicate-do-table` or `--replicate-wild-do-table` options?
      - *No*: There were no “do” table options, so no explicit “do” match is required. Execute the statement and exit.
      - *Yes*: There were “do” table options, so the statement is executed only with an explicit match to one of them. Ignore the statement and exit.
    - *Yes*: Loop.

Examples:

- No `--replicate-*` options at all  
The slave executes all statements that it receives from the master.
- `--replicate-*--db` options, but no table options  
The slave permits or ignores statements using the database options. Then it executes all statements permitted by those options because there are no table restrictions.
- `--replicate-*--table` options, but no database options  
All statements are permitted at the database-checking stage because there are no database conditions. The slave executes or ignores statements based on the table options.
- A mix of database and table options  
The slave permits or ignores statements using the database options. Then it evaluates all statements permitted by those options according to the table options. In some cases, this process can yield what might seem a counterintuitive result. Consider the following set of options:

```
[mysqld]
replicate-do-db      = db1
replicate-do-table  = db2.mytbl2
```

Suppose that `db1` is the default database and the slave receives this statement:

```
INSERT INTO mytbl1 VALUES(1,2,3);
```

The database is `db1`, which matches the `--replicate-do-db` option at the database-checking stage. The algorithm then

proceeds to the table-checking stage. If there were no table options, the statement would be executed. However, because the options include a “do” table option, the statement must match if it is to be executed. The statement does not match, so it is ignored. (The same would happen for any table in [db1](#).)

---

## Chapter 17. MySQL Cluster

*MySQL Cluster* is a high-availability, high-redundancy version of MySQL adapted for the distributed computing environment. It uses the **NDBCLUSTER** storage engine to enable running several computers with MySQL servers and other software in a cluster. This storage engine is available in MySQL 5.0 binary releases and in RPMs compatible with most modern Linux distributions.

MySQL Cluster is currently available and supported on a number of platforms, including Linux, Solaris, Mac OS X, HP-UX, and other Unix-style operating systems on a variety of hardware. For exact levels of support available for on specific combinations of operating system versions, operating system distributions, and hardware platforms, please refer to the [Cluster Supported Platforms list](#) maintained by the MySQL Support Team on the MySQL AB Web site.

MySQL Cluster is *not* currently supported on Microsoft Windows. We are working to make Cluster available on all operating systems supported by MySQL, including Windows, and will update the information provided here as this work continues.

This chapter represents a work in progress, and its contents are subject to revision as MySQL Cluster continues to evolve. Additional information regarding MySQL Cluster can be found on the MySQL AB Web site at <http://www.mysql.com/products/cluster/>.

**Additional resources.** More information may be found in the following places:

- Answers to some commonly asked questions about Cluster may be found in the [Section A.10, “MySQL 5.0 FAQ — MySQL Cluster”](#).
- The MySQL Cluster mailing list: <http://lists.mysql.com/cluster>.
- The MySQL Cluster Forum: <http://forums.mysql.com/list.php?25>.
- Many MySQL Cluster users and some of the MySQL Cluster developers blog about their experiences with Cluster, and make feeds of these available through [PlanetMySQL](#).
- If you are new to MySQL Cluster, you may find our Developer Zone article [How to set up a MySQL Cluster for two servers](#) to be helpful.

### 17.1. MySQL Cluster Overview

*MySQL Cluster* is a technology that enables clustering of in-memory databases in a shared-nothing system. The shared-nothing architecture allows the system to work with very inexpensive hardware, and with a minimum of specific requirements for hardware or software.

MySQL Cluster is designed not to have any single point of failure. For this reason, each component is expected to have its own memory and disk, and the use of shared storage mechanisms such as network shares, network file systems, and SANs is not recommended or supported.

MySQL Cluster integrates the standard MySQL server with an in-memory clustered storage engine called **NDB**. In our documentation, the term **NDB** refers to the part of the setup that is specific to the storage engine, whereas “MySQL Cluster” refers to the combination of MySQL and the **NDB** storage engine.

A MySQL Cluster consists of a set of computers, each running one or more processes which may include a MySQL server, a data node, a management server, and (possibly) specialized data access programs. The relationship of these components in a cluster is shown here:

All these programs work together to form a MySQL Cluster. When data is stored in the `NDBCLUSTER` storage engine, the tables are stored in the data nodes. Such tables are directly accessible from all other MySQL servers in the cluster. Thus, in a payroll application storing data in a cluster, if one application updates the salary of an employee, all other MySQL servers that query this data can see this change immediately.

The data stored in the data nodes for MySQL Cluster can be mirrored; the cluster can handle failures of individual data nodes with no other impact than that a small number of transactions are aborted due to losing the transaction state. Because transactional applications are expected to handle transaction failure, this should not be a source of problems.

### 17.1.1. MySQL Cluster Core Concepts

`NDBCLUSTER` (also known as `NDB`) is an in-memory storage engine offering high-availability and data-persistence features.

The `NDBCLUSTER` storage engine can be configured with a range of failover and load-balancing options, but it is easiest to start with the storage engine at the cluster level. MySQL Cluster's `NDB` storage engine contains a complete set of data, dependent only on other data within the cluster itself.

The “Cluster” portion of MySQL Cluster is configured independently of the MySQL servers. In a MySQL Cluster, each part of the cluster is considered to be a *node*.

#### Note

In many contexts, the term “node” is used to indicate a computer, but when discussing MySQL Cluster it means a *process*. It is possible to run multiple nodes on a single computer; for a computer on which one or more cluster nodes are being run we use the term *cluster host*.

However, MySQL 5.0 does not support the use of multiple data nodes on a single computer in a production setting. See [Section 17.10.9, “Limitations Relating to Multiple MySQL Cluster Nodes”](#).

There are three types of cluster nodes, and in a minimal MySQL Cluster configuration, there will be at least three nodes, one of each of these types:

- *Management node* (MGM node): The role of this type of node is to manage the other nodes within the MySQL Cluster, performing such functions as providing configuration data, starting and stopping nodes, running backup, and so forth. Because this node type manages the configuration of the other nodes, a node of this type should be started first, before any other node. An MGM node is started with the command `ndb_mgmd`.
- *Data node*: This type of node stores cluster data. There are as many data nodes as there are replicas, times the number of frag-

ments. For example, with two replicas, each having two fragments, you need four data nodes. One replica is sufficient for data storage, but provides no redundancy; therefore, it is recommended to have 2 (or more) replicas to provide redundancy, and thus high availability. A data node is started with the command `ndbd`.

- **SQL node:** This is a node that accesses the cluster data. In the case of MySQL Cluster, an SQL node is a traditional MySQL server that uses the `NDBCLUSTER` storage engine. An SQL node is a `mysqld` process started with the `--ndbcluster` and `--ndb-connectstring` options, which are explained elsewhere in this chapter, possibly with additional MySQL server options as well.

An SQL node is actually just a specialized type of *API node*, which designates any application which accesses Cluster data. Another example of an API node is the `ndb_restore` utility that is used to restore a cluster backup. It is possible to write such applications using the NDB API. For basic information about the NDB API, see [Getting Started with the NDB API](#).

### Important

It is not realistic to expect to employ a three-node setup in a production environment. Such a configuration provides no redundancy; in order to benefit from MySQL Cluster's high-availability features, you must use multiple data and SQL nodes. The use of multiple management nodes is also highly recommended.

For a brief introduction to the relationships between nodes, node groups, replicas, and partitions in MySQL Cluster, see [Section 17.1.2, “MySQL Cluster Nodes, Node Groups, Replicas, and Partitions”](#).

Configuration of a cluster involves configuring each individual node in the cluster and setting up individual communication links between nodes. MySQL Cluster is currently designed with the intention that data nodes are homogeneous in terms of processor power, memory space, and bandwidth. In addition, to provide a single point of configuration, all configuration data for the cluster as a whole is located in one configuration file.

The management server (MGM node) manages the cluster configuration file and the cluster log. Each node in the cluster retrieves the configuration data from the management server, and so requires a way to determine where the management server resides. When interesting events occur in the data nodes, the nodes transfer information about these events to the management server, which then writes the information to the cluster log.

In addition, there can be any number of cluster client processes or applications. These are of two types:

- **Standard MySQL clients.** MySQL Cluster can be used with existing MySQL applications written in PHP, Perl, C, C++, Java, Python, Ruby, and so on. Such client applications send SQL statements to and receive responses from MySQL servers acting as MySQL Cluster SQL nodes in much the same way that they interact with standalone MySQL servers. However, MySQL clients using a MySQL Cluster as a data source can be modified to take advantage of the ability to connect with multiple MySQL servers to achieve load balancing and failover. For example, Java clients using Connector/J 5.0.6 and later can use `jdbc:mysql:loadbalance://URLs` (improved in Connector/J 5.1.7) to achieve load balancing transparently.
- **Management clients.** These clients connect to the management server and provide commands for starting and stopping nodes gracefully, starting and stopping message tracing (debug versions only), showing node versions and status, starting and stopping backups, and so on. Such clients — such as the `ndb_mgm` management client supplied with MySQL Cluster — are written using the MGM API, a C-language API that communicates directly with one or more MySQL Cluster management servers. For more information, see [The MGM API](#).

## 17.1.2. MySQL Cluster Nodes, Node Groups, Replicas, and Partitions

This section discusses the manner in which MySQL Cluster divides and duplicates data for storage.

Central to an understanding of this topic are the following concepts, listed here with brief definitions:

- **(Data) Node.** An `ndbd` process, which stores a *replica* —that is, a copy of the *partition* (see below) assigned to the node group of which the node is a member.

Each data node should be located on a separate computer. While it is also possible to host multiple `ndbd` processes on a single computer, such a configuration is not supported.

It is common for the terms “node” and “data node” to be used interchangeably when referring to an `ndbd` process; where mentioned, management (MGM) nodes (`ndb_mgmd` processes) and SQL nodes (`mysqld` processes) are specified as such in this discussion.

- **Node Group.** A node group consists of one or more nodes, and stores partitions, or sets of *replicas* (see next item).

The number of node groups in a MySQL Cluster is not directly configurable; it is function of the number of data nodes and of

the number of replicas (`NumberOfReplicas` configuration parameter), as shown here:

```
[number_of_node_groups] = number_of_data_nodes / NumberOfReplicas
```

Thus, a MySQL Cluster with 4 data nodes has 4 node groups if `NumberOfReplicas` is set to 1 in the `config.ini` file, 2 node groups if `NumberOfReplicas` is set to 2, and 1 node group if `NumberOfReplicas` is set to 4. Replicas are discussed later in this section; for more information about `NumberOfReplicas`, see [Section 17.3.4.5, “Defining MySQL Cluster Data Nodes”](#).

### Note

All node groups in a MySQL Cluster must have the same number of data nodes.

- **Partition.** This is a portion of the data stored by the cluster. There are as many cluster partitions as nodes participating in the cluster. Each node is responsible for keeping at least one copy of any partitions assigned to it (that is, at least one replica) available to the cluster.

A replica belongs entirely to a single node; a node can (and usually does) store several replicas.

- **Replica.** This is a copy of a cluster partition. Each node in a node group stores a replica. Also sometimes known as a *partition replica*. The number of replicas is equal to the number of nodes per node group.

The following diagram illustrates a MySQL Cluster with four data nodes, arranged in two node groups of two nodes each; nodes 1 and 2 belong to node group 0, and nodes 3 and 4 belong to node group 1. Note that only data (`ndbd`) nodes are shown here; although a working cluster requires an `ndb_mgm` process for cluster management and at least one SQL node to access the data stored by the cluster, these have been omitted in the figure for clarity.

The data stored by the cluster is divided into four partitions, numbered 0, 1, 2, and 3. Each partition is stored — in multiple copies — on the same node group. Partitions are stored on alternate node groups:

- Partition 0 is stored on node group 0; a *primary replica* (primary copy) is stored on node 1, and a *backup replica* (backup copy of the partition) is stored on node 2.
- Partition 1 is stored on the other node group (node group 1); this partition's primary replica is on node 3, and its backup replica is on node 4.
- Partition 2 is stored on node group 0. However, the placing of its two replicas is reversed from that of Partition 0; for Partition 2, the primary replica is stored on node 2, and the backup on node 1.
- Partition 3 is stored on node group 1, and the placement of its two replicas are reversed from those of partition 1. That is, its primary replica is located on node 4, with the backup on node 3.

What this means regarding the continued operation of a MySQL Cluster is this: so long as each node group participating in the cluster has at least one node operating, the cluster has a complete copy of all data and remains viable. This is illustrated in the next diagram.

In this example, where the cluster consists of two node groups of two nodes each, any combination of at least one node in node group 0 and at least one node in node group 1 is sufficient to keep the cluster “alive” (indicated by arrows in the diagram). However, if *both* nodes from *either* node group fail, the remaining two nodes are not sufficient (shown by the arrows marked out with an X); in either case, the cluster has lost an entire partition and so can no longer provide access to a complete set of all cluster data.

## 17.2. MySQL Cluster Multi-Computer How-To

This section is a “How-To” that describes the basics for how to plan, install, configure, and run a MySQL Cluster. Whereas the examples in [Section 17.3, “MySQL Cluster Configuration”](#) provide more in-depth information on a variety of clustering options and configuration, the result of following the guidelines and procedures outlined here should be a usable MySQL Cluster which meets the *minimum* requirements for availability and safeguarding of data.

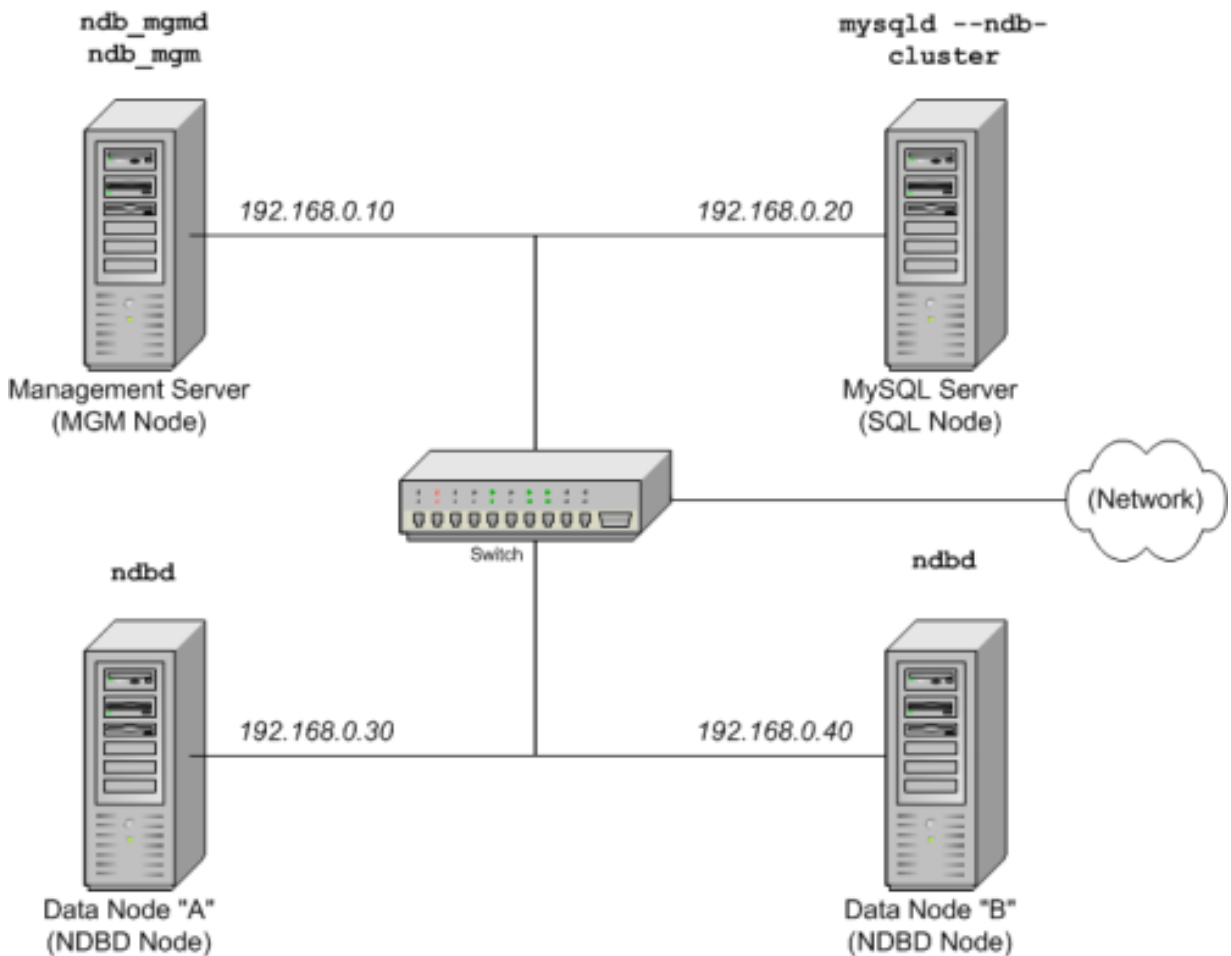

This section covers hardware and software requirements; networking issues; installation of MySQL Cluster; configuration issues; starting, stopping, and restarting the cluster; loading of a sample database; and performing queries.

**Basic assumptions.** This *How-To* makes the following assumptions:

1. The cluster is to be set up with four nodes, each on a separate host, and each with a fixed network address on a typical Ethernet network as shown here:

Node	IP Address
Management (MGMD) node	192.168.0.10
MySQL server (SQL) node	192.168.0.20
Data (NDBD) node "A"	192.168.0.30
Data (NDBD) node "B"	192.168.0.40

This may be made clearer in the following diagram:

In the interest of simplicity (and reliability), this *How-To* uses only numeric IP addresses. However, if DNS resolution is available on your network, it is possible to use host names in lieu of IP addresses in configuring Cluster. Alternatively, you can use the `/etc/hosts` file or your operating system's equivalent for providing a means to do host lookup if such is available.

## Note

A common problem when trying to use host names for Cluster nodes arises because of the way in which some operating systems (including some Linux distributions) set up the system's own host name in the `/etc/hosts` during installation. Consider two machines with the host names `ndb1` and `ndb2`, both in the `cluster` network domain. Red Hat Linux (including some derivatives such as CentOS and Fedora) places the following entries in these machines' `/etc/hosts` files:

```
# ndb1 /etc/hosts:
127.0.0.1 ndb1.cluster ndb1 localhost.localdomain localhost
```

```
# ndb2 /etc/hosts:
127.0.0.1 ndb2.cluster ndb2 localhost.localdomain localhost
```

SUSE Linux (including OpenSUSE) places these entries in the machines' `/etc/hosts` files:

```
# ndb1 /etc/hosts:
127.0.0.1 localhost
127.0.0.2 ndb1.cluster ndb1
```

```
# ndb2 /etc/hosts:
127.0.0.1 localhost
127.0.0.2 ndb2.cluster ndb2
```

In both instances, `ndb1` routes `ndb1.cluster` to a loopback IP address, but gets a public IP address from DNS for `ndb2.cluster`, while `ndb2` routes `ndb2.cluster` to a loopback address and obtains a public address for `ndb1.cluster`. The result is that each data node connects to the management server, but cannot tell when any other data nodes have connected, and so the data nodes appear to hang while starting.

You should also be aware that you cannot mix `localhost` and other host names or IP addresses in `config.ini`. For these reasons, the solution in such cases (other than to use IP addresses for *all* `config.ini` `HostName` entries) is to remove the fully qualified host names from `/etc/hosts` and use these in `config.ini` for all cluster hosts.

- Each host in our scenario is an Intel-based desktop PC running a common, generic Linux distribution installed to disk in a standard configuration, and running no unnecessary services. The core OS with standard TCP/IP networking capabilities should be sufficient. Also for the sake of simplicity, we also assume that the file systems on all hosts are set up identically. In the event that they are not, you will need to adapt these instructions accordingly.
- Standard 100 Mbps or 1 gigabit Ethernet cards are installed on each machine, along with the proper drivers for the cards, and that all four hosts are connected via a standard-issue Ethernet networking appliance such as a switch. (All machines should use network cards with the same throughput. That is, all four machines in the cluster should have 100 Mbps cards *or* all four machines should have 1 Gbps cards.) MySQL Cluster will work in a 100 Mbps network; however, gigabit Ethernet will provide better performance.

Note that MySQL Cluster is *not* intended for use in a network for which throughput is less than 100 Mbps. For this reason (among others), attempting to run a MySQL Cluster over a public network such as the Internet is not likely to be successful, and is not recommended.

- For our sample data, we will use the `world` database which is available for download from the MySQL AB Web site. As this database takes up a relatively small amount of space, we assume that each machine has 256MB RAM, which should be sufficient for running the operating system, host NDB process, and (for the data nodes) for storing the database.

Although we refer to a Linux operating system in this How-To, the instructions and procedures that we provide here should be easily adaptable to other supported operating systems. We also assume that you already know how to perform a minimal installation and configuration of the operating system with networking capability, or that you are able to obtain assistance in this elsewhere if needed.

We discuss MySQL Cluster hardware, software, and networking requirements in somewhat greater detail in the next section. (See [Section 17.2.1, “MySQL Cluster Hardware, Software, and Networking Requirements”](#).)

## 17.2.1. MySQL Cluster Hardware, Software, and Networking Requirements

One of the strengths of MySQL Cluster is that it can be run on commodity hardware and has no unusual requirements in this regard, other than for large amounts of RAM, due to the fact that all live data storage is done in memory. (It is possible to reduce this requirement using Disk Data tables, which were implemented in MySQL 5.1; however, we do not intend to backport this feature to MySQL 5.0.) Naturally, multiple and faster CPUs will enhance performance. Memory requirements for other Cluster processes are relatively small.

The software requirements for Cluster are also modest. Host operating systems do not require any unusual modules, services, applications, or configuration to support MySQL Cluster. For supported operating systems, a standard installation should be sufficient. The MySQL software requirements are simple: all that is needed is a production release of MySQL 5.0 to have Cluster support. It is not necessary to compile MySQL yourself merely to be able to use Cluster. In this *How-To*, we assume that you are using the server binary appropriate to your platform, available via the MySQL software downloads page at <http://dev.mysql.com/downloads/>.

For communication between nodes, Cluster supports TCP/IP networking in any standard topology, and the minimum expected for each host is a standard 100 Mbps Ethernet card, plus a switch, hub, or router to provide network connectivity for the cluster as a whole. We strongly recommend that a MySQL Cluster be run on its own subnet which is not shared with non-Cluster machines for the following reasons:

- Security.** Communications between Cluster nodes are not encrypted or shielded in any way. The only means of protecting transmissions within a MySQL Cluster is to run your Cluster on a protected network. If you intend to use MySQL Cluster for Web applications, the cluster should definitely reside behind your firewall and not in your network's De-Militarized Zone (DMZ) or elsewhere.

See [Section 17.8.1, “MySQL Cluster Security and Networking Issues”](#), for more information.

- Efficiency.** Setting up a MySQL Cluster on a private or protected network allows the cluster to make exclusive use of bandwidth between cluster hosts. Using a separate switch for your MySQL Cluster not only helps protect against unauthorized access to Cluster data, it also ensures that Cluster nodes are shielded from interference caused by transmissions between other computers on the network. For enhanced reliability, you can use dual switches and dual cards to remove the network as a single point of failure; many device drivers support failover for such communication links.

It is also possible to use the high-speed Scalable Coherent Interface (SCI) with MySQL Cluster, but this is not a requirement. See [Section 17.9, “Using High-Speed Interconnects with MySQL Cluster”](#), for more about this protocol and its use with MySQL.

Cluster.

## 17.2.2. MySQL Cluster Multi-Computer Installation

Each MySQL Cluster host computer running an SQL node must have installed on it a MySQL binary. For management nodes and data nodes, it is not necessary to install the MySQL server binary, but management nodes require the management server daemon (`ndb_mgmd`) and data nodes require the data node daemon (`ndbd`). It is also a good idea to install the management client (`ndb_mgm`) on the management server host. This section covers the steps necessary to install the correct binaries for each type of Cluster node.

MySQL AB provides precompiled binaries that support Cluster, and there is generally no need to compile these yourself. However, we also include information relating to installing a MySQL Cluster after building MySQL from source. For setting up a cluster using MySQL's binaries, the first step in the installation process for each cluster host is to download the file `mysql-5.0.84-pc-linux-gnu-i686.tar.gz` from the [MySQL downloads area](#). We assume that you have placed it in each machine's `/var/tmp` directory. (If you do require a custom binary, see [Section 2.16.3, "Installing from the Development Source Tree"](#).)

RPMs are also available for both 32-bit and 64-bit Linux platforms. For a MySQL Cluster, three RPMs are required:

- The **Server** RPM (for example, `MySQL-Server-5.0.84-0.glibc23.i386.rpm`), which supplies the core files needed to run a MySQL Server.
- The **NDB Cluster - Storage engine** RPM (for example, `MySQL-ndb-storage-5.0.84-0.glibc23.i386.rpm`), which supplies the MySQL Cluster data node binary (`ndbd`).
- The **NDB Cluster - Storage engine management** RPM (for example, `MySQL-ndb-management-5.0.84-0.glibc23.i386.rpm`), which provides the MySQL Cluster management server binary (`ndb_mgmd`).

In addition, you should also obtain the **NDB Cluster - Storage engine basic tools** RPM (for example, `MySQL-ndb-tools-5.0.84-0.glibc23.i386.rpm`), which supplies several useful applications for working with a MySQL Cluster. The most important of these is the MySQL Cluster management client (`ndb_mgm`). The **NDB Cluster - Storage engine extra tools** RPM (for example, `MySQL-ndb-extra-5.0.84-0.glibc23.i386.rpm`) contains some additional testing and monitoring programs, but is not required to install a MySQL Cluster. (For more information about these additional programs, see [Section 17.6, "MySQL Cluster Programs"](#).)

The MySQL version number in the RPM file names (shown here as `5.0.84`) can vary according to the version which you are actually using. *It is very important that all of the Cluster RPMs to be installed have the same MySQL version number.* The `glibc` version number (if present — shown here as `glibc23`), and architecture designation (shown here as `i386`) should be appropriate to the machine on which the RPM is to be installed.

See [Section 2.10, "Installing MySQL from RPM Packages on Linux"](#), for general information about installing MySQL using RPMs supplied by MySQL AB.

After installing from RPM, you still need to configure the cluster as discussed in [Section 17.2.3, "MySQL Cluster Multi-Computer Configuration"](#).

### Note

After completing the installation, do not yet start any of the binaries. We show you how to do so following the configuration of all nodes.

**Data and SQL Node Installation — .tar.gz Binary.** On each of the machines designated to host data or SQL nodes, perform the following steps as the system `root` user:

1. Check your `/etc/passwd` and `/etc/group` files (or use whatever tools are provided by your operating system for managing users and groups) to see whether there is already a `mysql` group and `mysql` user on the system. Some OS distributions create these as part of the operating system installation process. If they are not already present, create a new `mysql` user group, and then add a `mysql` user to this group:

```
shell> groupadd mysql
shell> useradd -g mysql mysql
```

The syntax for `useradd` and `groupadd` may differ slightly on different versions of Unix, or they may have different names such as `adduser` and `addgroup`.

2. Change location to the directory containing the downloaded file, unpack the archive, and create a symlink to the `mysql` directory named `mysql`. Note that the actual file and directory names will vary according to the MySQL version number.

```
shell> cd /var/tmp
shell> tar -C /usr/local -xvzf mysql-5.0.84-pc-linux-gnu-i686.tar.gz
shell> ln -s /usr/local/mysql-5.0.84-pc-linux-gnu-i686 /usr/local/mysql
```

3. Change location to the `mysql` directory and run the supplied script for creating the system databases:

```
shell> cd mysql
shell> scripts/mysql_install_db --user=mysql
```

4. Set the necessary permissions for the MySQL server and data directories:

```
shell> chown -R root .
shell> chown -R mysql data
shell> chgrp -R mysql .
```

Note that the data directory on each machine hosting a data node is `/usr/local/mysql/data`. This piece of information is essential when configuring the management node. (See [Section 17.2.3, “MySQL Cluster Multi-Computer Configuration”](#).)

5. Copy the MySQL startup script to the appropriate directory, make it executable, and set it to start when the operating system is booted up:

```
shell> cp support-files/mysql.server /etc/rc.d/init.d/
shell> chmod +x /etc/rc.d/init.d/mysql.server
shell> chkconfig --add mysql.server
```

(The startup scripts directory may vary depending on your operating system and version — for example, in some Linux distributions, it is `/etc/init.d`.)

Here we use Red Hat's `chkconfig` for creating links to the startup scripts; use whatever means is appropriate for this purpose on your operating system and distribution, such as `update-rc.d` on Debian.

Remember that the preceding steps must be performed separately on each machine where an SQL node is to reside.

**SQL node installation — RPM files.** On each machine to be used for hosting a cluster SQL node, install the **MySQL Server RPM** by executing the following command as the system root user, replacing the name shown for the RPM as necessary to match the name of the RPM downloaded from the MySQL AB web site:

```
shell> rpm -Uhv MySQL-server-5.0.84-0.glibc23.i386.rpm
```

This installs the MySQL server binary (`mysqld`) in the `/usr/sbin` directory, as well as all needed MySQL Server support files. It also installs the `mysql.server` and `mysqld_safe` startup scripts in `/usr/share/mysql` and `/usr/bin`, respectively. The RPM installer should take care of general configuration issues (such as creating the `mysql` user and group, if needed) automatically.

**SQL node installation — building from source.** If you compile MySQL with clustering support (for example, by using the `BUILD/compile-platform_name-max` script appropriate to your platform), and perform the default installation (using `make install` as the root user), `mysqld` is placed in `/usr/local/mysql/bin`. Follow the steps given in [Section 2.16, “MySQL Installation Using a Source Distribution”](#) to make `mysqld` ready for use. If you want to run multiple SQL nodes, you can use a copy of the same `mysqld` executable and its associated support files on several machines. The easiest way to do this is to copy the entire `/usr/local/mysql` directory and all directories and files contained within it to the other SQL node host or hosts, then repeat the steps from [Section 2.16, “MySQL Installation Using a Source Distribution”](#) on each machine. If you configure the build with a non-default `--prefix`, you need to adjust the directory accordingly.

**Data node installation — RPM Files.** On a computer that is to host a cluster data node it is necessary to install only the **NDB Cluster - Storage engine RPM**. To do so, copy this RPM to the data node host, and run the following command as the system root user, replacing the name shown for the RPM as necessary to match that of the RPM downloaded from the MySQL AB web site:

```
shell> rpm -Uhv MySQL-ndb-storage-5.0.84-0.glibc23.i386.rpm
```

The previous command installs the MySQL Cluster data node binary (`ndbd`) in the `/usr/sbin` directory.

**Data node installation — building from source.** The only executable required on a data node host is `ndbd` (`mysqld`, for example, does not have to be present on the host machine). By default when doing a source build, this file is placed in the directory `/usr/local/mysql/libexec`. For installing on multiple data node hosts, only `ndbd` need be copied to the other host machine or machines. (This assumes that all data node hosts use the same architecture and operating system; otherwise you may need to compile separately for each different platform.) `ndbd` need not be in any particular location on the host's file system, as long as the location is known.

**Management node installation — .tar.gz binary.** Installation of the management node does not require the `mysqld` binary. Only the binary for the management server is required, which can be found in the downloaded archive. You most likely want to install the management client as well; this can also be found in the `.tar.gz` archive. Again, we assume that you have placed this

archive in `/var/tmp`.

As system `root` (that is, after using `sudo`, `su root`, or your system's equivalent for temporarily assuming the system administrator account's privileges), perform the following steps to install `ndb_mgmd` and `ndb_mgm` on the Cluster management node host:

1. Change location to the `/var/tmp` directory, and extract the `ndb_mgm` and `ndb_mgmd` from the archive into a suitable directory such as `/usr/local/bin`:

```
shell> cd /var/tmp
shell> tar -zxvf mysql-5.0.84-pc-linux-gnu-i686.tar.gz
shell> cd mysql-5.0.84-pc-linux-gnu-i686
shell> cp bin/ndb_mgm* /usr/local/bin
```

(You can safely delete the directory created by unpacking the downloaded archive, and the files it contains, from `/var/tmp` once `ndb_mgm` and `ndb_mgmd` have been copied to the executables directory.)

2. Change location to the directory into which you copied the files, and then make both of them executable:

```
shell> cd /usr/local/bin
shell> chmod +x ndb_mgm*
```

**Management node installation — RPM file.** To install the MySQL Cluster management server, it is necessary only to use the **NDB Cluster - Storage engine management** RPM. Copy this RPM to the computer intended to host the management node, and then install it by running the following command as the system root user (replace the name shown for the RPM as necessary to match that of the **Storage engine management** RPM downloaded from the MySQL AB web site):

```
shell> rpm -Uhv MySQL-ndb-management-5.0.84-0.glibc23.i386.rpm
```

This installs the management server binary (`ndb_mgmd`) to the `/usr/sbin` directory.

You should also install the **NDB** management client, which is supplied by the **Storage engine basic tools** RPM. Copy this RPM to the same computer as the management node, and then install it by running the following command as the system root user (again, replace the name shown for the RPM as necessary to match that of the **Storage engine basic tools** RPM downloaded from the MySQL AB web site):

```
shell> rpm -Uhv MySQL-Cluster-gpl-tools-6.3.26-0.sles10.i586.rpm
```

The **Storage engine basic tools** RPM installs the MySQL Cluster management client (`ndb_mgm`) to the `/usr/bin` directory.

**Management node installation — building from source.** When building from source and running the default `make install`, the management server binary (`ndb_mgmd`) is placed in `/usr/local/mysql/libexec`, while the management client binary (`ndb_mgm`) can be found in `/usr/local/mysql/bin`. Only `ndb_mgmd` is required to be present on a management node host; however, it is also a good idea to have `ndb_mgm` present on the same host machine. Neither of these executables requires a specific location on the host machine's file system.

In [Section 17.2.3, “MySQL Cluster Multi-Computer Configuration”](#), we create configuration files for all of the nodes in our example Cluster.

## 17.2.3. MySQL Cluster Multi-Computer Configuration

For our four-node, four-host MySQL Cluster, it is necessary to write four configuration files, one per node host.

- Each data node or SQL node requires a `my.cnf` file that provides two pieces of information: a *connectstring* that tells the node where to find the management node, and a line telling the MySQL server on this host (the machine hosting the data node) to enable the `NDBCLUSTER` storage engine.

For more information on connectstrings, see [Section 17.3.4.2, “The MySQL Cluster Connectstring”](#).

- The management node needs a `config.ini` file telling it how many replicas to maintain, how much memory to allocate for data and indexes on each data node, where to find the data nodes, where to save data to disk on each data node, and where to find any SQL nodes.

### Configuring the Storage and SQL Nodes

The `my.cnf` file needed for the data nodes is fairly simple. The configuration file should be located in the `/etc` directory and can be edited using any text editor. (Create the file if it does not exist.) For example:

```
shell> vi /etc/my.cnf
```

**Note**

We show `vi` being used here to create the file, but any text editor should work just as well.

For each data node and SQL node in our example setup, `my.cnf` should look like this:

```
# Options for mysqld process:
[mysqld]
ndbcluster                # run NDB storage engine
ndb-connectstring=192.168.0.10 # location of management server

# Options for ndbd process:
[mysql_cluster]
ndb-connectstring=192.168.0.10 # location of management server
```

After entering the preceding information, save this file and exit the text editor. Do this for the machines hosting data node “A”, data node “B”, and the SQL node.

**Important**

Once you have started a `mysqld` process with the `NDBCLUSTER` and `ndb-connectstring` parameters in the `[mysqld]` in the `my.cnf` file as shown previously, you cannot execute any `CREATE TABLE` or `ALTER TABLE` statements without having actually started the cluster. Otherwise, these statements will fail with an error. *This is by design.*

**Configuring the management node.** The first step in configuring the management node is to create the directory in which the configuration file can be found and then to create the file itself. For example (running as `root`):

```
shell> mkdir /var/lib/mysql-cluster
shell> cd /var/lib/mysql-cluster
shell> vi config.ini
```

For our representative setup, the `config.ini` file should read as follows:

```
# Options affecting ndbd processes on all data nodes:
[ndbd default]
NoOfReplicas=2          # Number of replicas
DataMemory=80M         # How much memory to allocate for data storage
IndexMemory=18M        # How much memory to allocate for index storage
                        # For DataMemory and IndexMemory, we have used the
                        # default values. Since the "world" database takes up
                        # only about 500KB, this should be more than enough for
                        # this example Cluster setup.

# TCP/IP options:
[tcp default]
portnumber=2202        # This the default; however, you can use any
                        # port that is free for all the hosts in the cluster
                        # Note: It is recommended beginning with MySQL 5.0 that
                        # you do not specify the portnumber at all and simply allow
                        # the default value to be used instead

# Management process options:
[ndb_mgmd]
hostname=192.168.0.10   # Hostname or IP address of MGM node
datadir=/var/lib/mysql-cluster # Directory for MGM node log files

# Options for data node "A":
[ndbd]
hostname=192.168.0.30   # (one [ndbd] section per data node)
                        # Hostname or IP address
datadir=/usr/local/mysql/data # Directory for this data node's data files

# Options for data node "B":
[ndbd]
hostname=192.168.0.40   # Hostname or IP address
datadir=/usr/local/mysql/data # Directory for this data node's data files

# SQL node options:
[mysqld]
hostname=192.168.0.20   # Hostname or IP address
                        # (additional mysqld connections can be
                        # specified for this node for various
                        # purposes such as running ndb_restore)
```

**Note**

The `world` database can be downloaded from <http://dev.mysql.com/doc/>, where it can be found listed under “Examples”.

After all the configuration files have been created and these minimal options have been specified, you are ready to proceed with starting the cluster and verifying that all processes are running. We discuss how this is done in [Section 17.2.4, “Initial Startup of](#)

MySQL Cluster”.

For more detailed information about the available MySQL Cluster configuration parameters and their uses, see [Section 17.3.4, “MySQL Cluster Configuration Files”](#), and [Section 17.3, “MySQL Cluster Configuration”](#). For configuration of MySQL Cluster as relates to making backups, see [Section 17.7.3.3, “Configuration for MySQL Cluster Backups”](#).

### Note

The default port for Cluster management nodes is 1186; the default port for data nodes is 2202. Beginning with MySQL 5.0.3, this restriction is lifted, and the cluster automatically allocates ports for data nodes from those that are already free.

## 17.2.4. Initial Startup of MySQL Cluster

Starting the cluster is not very difficult after it has been configured. Each cluster node process must be started separately, and on the host where it resides. The management node should be started first, followed by the data nodes, and then finally by any SQL nodes:

1. On the management host, issue the following command from the system shell to start the management node process:

```
shell> ndb_mgmd -f /var/lib/mysql-cluster/config.ini
```

### Note

`ndb_mgmd` must be told where to find its configuration file, using the `-f` or `--config-file` option. (See [Section 17.6.3, “ndb\\_mgmd — The MySQL Cluster Management Server Daemon”](#), for details.)

For additional options which can be used with `ndb_mgmd`, see [Section 17.6.21, “Options Common to MySQL Cluster Programs”](#).

2. On each of the data node hosts, run this command to start the `ndbd` process:

```
shell> ndbd
```

3. If you used RPM files to install MySQL on the cluster host where the SQL node is to reside, you can (and should) use the supplied startup script to start the MySQL server process on the SQL node.

If all has gone well, and the cluster has been set up correctly, the cluster should now be operational. You can test this by invoking the `ndb_mgm` management node client. The output should look like that shown here, although you might see some slight differences in the output depending upon the exact version of MySQL that you are using:

```
shell> ndb_mgm
-- NDB Cluster -- Management Client --
ndb_mgm> SHOW
Connected to Management Server at: localhost:1186
Cluster Configuration
-----
[ndbd(NDB)] 2 node(s)
id=2 @192.168.0.30 (Version: 5.0.84, Nodegroup: 0, Master)
id=3 @192.168.0.40 (Version: 5.0.84, Nodegroup: 0)

[ndb_mgmd(MGM)] 1 node(s)
id=1 @192.168.0.10 (Version: 5.0.84)

[mysqld(API)] 1 node(s)
id=4 @192.168.0.20 (Version: 5.0.84)
```

The SQL node is referenced here as `[mysqld(API)]`, which reflects the fact that the `mysqld` process is acting as a MySQL Cluster API node.

### Note

The IP address shown for a given MySQL Cluster SQL or other API node in the output of `SHOW` is the address used by the SQL or API node to connect to the cluster data nodes, and not to any management node.

You should now be ready to work with databases, tables, and data in MySQL Cluster. See [Section 17.2.5, “Loading Sample Data into MySQL Cluster and Performing Queries”](#), for a brief discussion.

## 17.2.5. Loading Sample Data into MySQL Cluster and Performing Queries

Working with data in MySQL Cluster is not much different from doing so in MySQL without Cluster. There are two points to keep

in mind:

- For a table to be replicated in the cluster, it must use the `NDBCLUSTER` storage engine. To specify this, use the `ENGINE=NDBCLUSTER` or `ENGINE=NDB` option when creating the table:

```
CREATE TABLE tbl_name (col_name column_definitions) ENGINE=NDBCLUSTER;
```

Alternatively, for an existing table that uses a different storage engine, use `ALTER TABLE` to change the table to use `NDBCLUSTER`:

```
ALTER TABLE tbl_name ENGINE=NDBCLUSTER;
```

- Each `NDBCLUSTER` table *must* have a primary key. If no primary key is defined by the user when a table is created, the `NDBCLUSTER` storage engine automatically generates a hidden one.

### Note

This hidden key takes up space just as does any other table index. It is not uncommon to encounter problems due to insufficient memory for accommodating these automatically created indexes.)

If you are importing tables from an existing database using the output of `mysqldump`, you can open the SQL script in a text editor and add the `ENGINE` option to any table creation statements, or replace any existing `ENGINE` (or `TYPE`) options. Suppose that you have the `world` sample database on another MySQL server that does not support MySQL Cluster, and you want to export the `City` table:

```
shell> mysqldump --add-drop-table world City > city_table.sql
```

The resulting `city_table.sql` file will contain this table creation statement (and the `INSERT` statements necessary to import the table data):

```
DROP TABLE IF EXISTS `City`;
CREATE TABLE `City` (
  `ID` int(11) NOT NULL auto_increment,
  `Name` char(35) NOT NULL default '',
  `CountryCode` char(3) NOT NULL default '',
  `District` char(20) NOT NULL default '',
  `Population` int(11) NOT NULL default '0',
  PRIMARY KEY (`ID`)
) ENGINE=MyISAM DEFAULT CHARSET=latin1;

INSERT INTO `City` VALUES (1,'Kabul','AFG','Kabul',1780000);
INSERT INTO `City` VALUES (2,'Qandahar','AFG','Qandahar',237500);
INSERT INTO `City` VALUES (3,'Herat','AFG','Herat',186800);
(remaining INSERT statements omitted)
```

You need to make sure that MySQL uses the `NDBCLUSTER` storage engine for this table. There are two ways that this can be accomplished. One of these is to modify the table definition *before* importing it into the Cluster database. Using the `City` table as an example, modify the `ENGINE` option of the definition as follows:

```
DROP TABLE IF EXISTS `City`;
CREATE TABLE `City` (
  `ID` int(11) NOT NULL auto_increment,
  `Name` char(35) NOT NULL default '',
  `CountryCode` char(3) NOT NULL default '',
  `District` char(20) NOT NULL default '',
  `Population` int(11) NOT NULL default '0',
  PRIMARY KEY (`ID`)
) ENGINE=NDBCLUSTER DEFAULT CHARSET=latin1;

INSERT INTO `City` VALUES (1,'Kabul','AFG','Kabul',1780000);
INSERT INTO `City` VALUES (2,'Qandahar','AFG','Qandahar',237500);
INSERT INTO `City` VALUES (3,'Herat','AFG','Herat',186800);
(remaining INSERT statements omitted)
```

This must be done for the definition of each table that is to be part of the clustered database. The easiest way to accomplish this is to do a search-and-replace on the file that contains the definitions and replace all instances of `TYPE=engine_name` or `ENGINE=engine_name` with `ENGINE=NDBCLUSTER`. If you do not want to modify the file, you can use the unmodified file to create the tables, and then use `ALTER TABLE` to change their storage engine. The particulars are given later in this section.

Assuming that you have already created a database named `world` on the SQL node of the cluster, you can then use the `mysql` command-line client to read `city_table.sql`, and create and populate the corresponding table in the usual manner:

```
shell> mysql world < city_table.sql
```

It is very important to keep in mind that the preceding command must be executed on the host where the SQL node is running (in this case, on the machine with the IP address `192.168.0.20`).

To create a copy of the entire `world` database on the SQL node, use `mysqldump` on the non-cluster server to export the database to a file named `world.sql`; for example, in the `/tmp` directory. Then modify the table definitions as just described and import the file into the SQL node of the cluster like this:

```
shell> mysql world < /tmp/world.sql
```

If you save the file to a different location, adjust the preceding instructions accordingly.

It is important to note that `NDBCLUSTER` in MySQL 5.0 does not support autodiscovery of databases. (See [Section 17.10, “Known Limitations of MySQL Cluster”](#).) This means that, once the `world` database and its tables have been created on one data node, you need to issue the `CREATE DATABASE world` statement (beginning with MySQL 5.0.2, you may use `CREATE SCHEMA world` instead), followed by `FLUSH TABLES` on each SQL node in the cluster. This causes the node to recognize the database and read its table definitions.

Running `SELECT` queries on the SQL node is no different from running them on any other instance of a MySQL server. To run queries from the command line, you first need to log in to the MySQL Monitor in the usual way (specify the `root` password at the `Enter password:` prompt):

```
shell> mysql -u root -p
Enter password:
Welcome to the MySQL monitor.  Commands end with ; or \g.
Your MySQL connection id is 1 to server version: 5.0.84

Type 'help;' or '\h' for help. Type '\c' to clear the buffer.

mysql>
```

We simply use the MySQL server's `root` account and assume that you have followed the standard security precautions for installing a MySQL server, including setting a strong `root` password. For more information, see [Section 2.17.3, “Securing the Initial MySQL Accounts”](#).

It is worth taking into account that Cluster nodes do *not* make use of the MySQL privilege system when accessing one another. Setting or changing MySQL user accounts (including the `root` account) effects only applications that access the SQL node, not interaction between nodes. See [Section 17.8.2, “MySQL Cluster and MySQL Privileges”](#), for more information.

If you did not modify the `ENGINE` clauses in the table definitions prior to importing the SQL script, you should run the following statements at this point:

```
mysql> USE world;
mysql> ALTER TABLE City ENGINE=NDBCLUSTER;
mysql> ALTER TABLE Country ENGINE=NDBCLUSTER;
mysql> ALTER TABLE CountryLanguage ENGINE=NDBCLUSTER;
```

Selecting a database and running a `SELECT` query against a table in that database is also accomplished in the usual manner, as is exiting the MySQL Monitor:

```
mysql> USE world;
mysql> SELECT Name, Population FROM City ORDER BY Population DESC LIMIT 5;
+-----+-----+
| Name      | Population |
+-----+-----+
| Bombay    | 10500000  |
| Seoul     | 9981619   |
| São Paulo | 9968485   |
| Shanghai  | 9696300   |
| Jakarta   | 9604900   |
+-----+-----+
5 rows in set (0.34 sec)

mysql> \q
Bye
shell>
```

Applications that use MySQL can employ standard APIs to access `NDB` tables. It is important to remember that your application must access the SQL node, and not the management or data nodes. This brief example shows how we might execute the `SELECT` statement just shown by using the PHP 5.X `mysqli` extension running on a Web server elsewhere on the network:

```
<!DOCTYPE HTML PUBLIC "-//W3C//DTD HTML 4.01 Transitional//EN"
"http://www.w3.org/TR/html4/loose.dtd">
<html>
<head>
  <meta http-equiv="Content-Type"
        content="text/html; charset=iso-8859-1">
  <title>SIMPLE mysqli SELECT</title>
```

```

</head>
<body>
<?php
# connect to SQL node:
$link = new mysqli('192.168.0.20', 'root', 'root_password', 'world');
# parameters for mysqli constructor are:
#   host, user, password, database

if( mysqli_connect_errno() )
    die("Connect failed: " . mysqli_connect_error());

$query = "SELECT Name, Population
          FROM City
          ORDER BY Population DESC
          LIMIT 5";

# if no errors...
if( $result = $link->query($query) )
{
?>
<table border="1" width="40%" cellpadding="4" cellspacing="1">
  <tbody>
    <tr>
      <th width="10%">City</th>
      <th>Population</th>
    </tr>
  </tbody>
</table>
?>
# then display the results...
while($row = $result->fetch_object())
    printf("<tr>\n  <td align=\"center\">%s</td><td>%d</td>\n</tr>\n",
          $row->Name, $row->Population);
?>
</tbody>
</table>
?>
# ...and verify the number of rows that were retrieved
printf("<p>Affected rows: %d</p>\n", $link->affected_rows);
}
else
# otherwise, tell us what went wrong
echo mysqli_error();

# free the result set and the mysqli connection object
$result->close();
$link->close();
?>
</body>
</html>

```

We assume that the process running on the Web server can reach the IP address of the SQL node.

In a similar fashion, you can use the MySQL C API, Perl-DBI, Python-mysql, or MySQL AB's own Connectors to perform the tasks of data definition and manipulation just as you would normally with MySQL.

## 17.2.6. Safe Shutdown and Restart of MySQL Cluster

To shut down the cluster, enter the following command in a shell on the machine hosting the management node:

```
shell> ndb_mgm -e shutdown
```

The `-e` option here is used to pass a command to the `ndb_mgm` client from the shell. (See [Section 17.6.21, “Options Common to MySQL Cluster Programs”](#), for more information about this option.) The command causes the `ndb_mgm`, `ndb_mgmd`, and any `ndbd` processes to terminate gracefully. Any SQL nodes can be terminated using `mysqladmin shutdown` and other means.

To restart the cluster, run these commands:

- On the management host (192.168.0.10 in our example setup):

```
shell> ndb_mgmd -f /var/lib/mysql-cluster/config.ini
```

- On each of the data node hosts (192.168.0.30 and 192.168.0.40):

```
shell> ndbd
```

- On the SQL host (192.168.0.20):

```
shell> mysqld_safe &
```

In a production setting, it is usually not desirable to shut down the cluster completely. In many cases, even when making configura-

tion changes, or performing upgrades to the cluster hardware or software (or both), which require shutting down individual host machines, it is possible to do so without shutting down the cluster as a whole by performing a *rolling restart* of the cluster. For more information about doing this, see [Section 17.5.1, “Performing a Rolling Restart of a MySQL Cluster”](#).

## 17.3. MySQL Cluster Configuration

A MySQL server that is part of a MySQL Cluster differs in one chief respect from a normal (non-clustered) MySQL server, in that it employs the `NDBCLUSTER` storage engine. This engine is also referred to simply as `NDB`, and the two forms of the name are synonymous.

To avoid unnecessary allocation of resources, the server is configured by default with the `NDB` storage engine disabled. To enable `NDB`, you must modify the server's `my.cnf` configuration file, or start the server with the `--ndbcluster` option.

For more information about `--ndbcluster` and other MySQL server options specific to MySQL Cluster, see [Section 17.4.2, “mysqld Command Options for MySQL Cluster”](#).

The MySQL server is a part of the cluster, so it also must know how to access an MGM node to obtain the cluster configuration data. The default behavior is to look for the MGM node on `localhost`. However, should you need to specify that its location is elsewhere, this can be done in `my.cnf` or on the MySQL server command line. Before the `NDB` storage engine can be used, at least one MGM node must be operational, as well as any desired data nodes.

### 17.3.1. Building MySQL Cluster from Source Code

`NDB`, the Cluster storage engine, is available in binary distributions for Linux, Mac OS X, and Solaris. We are working to make Cluster run on all operating systems supported by MySQL, including Windows.

If you choose to build from a source tarball or one of the MySQL Cluster public development trees, be sure to use the `--with-ndbcluster` option when running `configure`. You can also use the `BUILD/compile-pentium-max` build script. Note that this script includes OpenSSL, so you must either have or obtain OpenSSL to build successfully, or else modify `compile-pentium-max` to exclude this requirement. Of course, you can also just follow the standard instructions for compiling your own binaries, and then perform the usual tests and installation procedure. See [Section 2.16.3, “Installing from the Development Source Tree”](#).

You should also note that `compile-pentium-max` installs MySQL to the directory `/usr/local/mysql`, placing all MySQL Cluster executables, scripts, databases, and support files in subdirectories under this directory. If this is not what you desire, be sure to modify the script accordingly.

### 17.3.2. Installing MySQL Cluster Software

In the next few sections, we assume that you are already familiar with installing MySQL, and here we cover only the differences between configuring MySQL Cluster and configuring MySQL without clustering. (See [Chapter 2, \*Installing and Upgrading MySQL\*](#), if you require more information about the latter.)

You will find Cluster configuration easiest if you have already have all management and data nodes running first; this is likely to be the most time-consuming part of the configuration. Editing the `my.cnf` file is fairly straightforward, and this section will cover only any differences from configuring MySQL without clustering.

### 17.3.3. Quick Test Setup of MySQL Cluster

To familiarize you with the basics, we will describe the simplest possible configuration for a functional MySQL Cluster. After this, you should be able to design your desired setup from the information provided in the other relevant sections of this chapter.

First, you need to create a configuration directory such as `/var/lib/mysql-cluster`, by executing the following command as the system `root` user:

```
shell> mkdir /var/lib/mysql-cluster
```

In this directory, create a file named `config.ini` that contains the following information. Substitute appropriate values for `HostName` and `DataDir` as necessary for your system.

```
# file "config.ini" - showing minimal setup consisting of 1 data node,
# 1 management server, and 3 MySQL servers.
# The empty default sections are not required, and are shown only for
# the sake of completeness.
# Data nodes must provide a hostname but MySQL Servers are not required
# to do so.
# If you don't know the hostname for your machine, use localhost.
# The DataDir parameter also has a default value, but it is recommended to
# set it explicitly.
# Note: [db], [api], and [mgm] are aliases for [ndbd], [mysqld], and [ndb_mgmd],
# respectively. [db] is deprecated and should not be used in new installations.
```

```
[ndbd default]
NoOfReplicas= 1

[mysqld default]
[ndb_mgmd default]
[tcp default]

[ndb_mgmd]
HostName= myhost.example.com

[ndbd]
HostName= myhost.example.com
DataDir= /var/lib/mysql-cluster

[mysqld]
[mysqld]
[mysqld]
```

You can now start the `ndb_mgmd` management server. By default, it attempts to read the `config.ini` file in its current working directory, so change location into the directory where the file is located and then invoke `ndb_mgmd`:

```
shell> cd /var/lib/mysql-cluster
shell> ndb_mgmd
```

Then start a single data node by running `ndbd`:

```
shell> ndbd
```

For command-line options which can be used when starting `ndbd`, see [Section 17.6.21, “Options Common to MySQL Cluster Programs”](#).

By default, `ndbd` looks for the management server at `localhost` on port 1186.

### Note

If you have installed MySQL from a binary tarball, you will need to specify the path of the `ndb_mgmd` and `ndbd` servers explicitly. (Normally, these will be found in `/usr/local/mysql/bin`.)

Finally, change location to the MySQL data directory (usually `/var/lib/mysql` or `/usr/local/mysql/data`), and make sure that the `my.cnf` file contains the option necessary to enable the NDB storage engine:

```
[mysqld]
ndbcluster
```

You can now start the MySQL server as usual:

```
shell> mysqld_safe --user=mysql &
```

Wait a moment to make sure the MySQL server is running properly. If you see the notice `mysql ended`, check the server's `.err` file to find out what went wrong.

If all has gone well so far, you now can start using the cluster. Connect to the server and verify that the `NDBCLUSTER` storage engine is enabled:

```
shell> mysql
Welcome to the MySQL monitor.  Commands end with ; or \g.
Your MySQL connection id is 1 to server version: 5.0.84

Type 'help;' or '\h' for help. Type '\c' to clear the buffer.

mysql> SHOW ENGINES\G
...
***** 12. row *****
Engine: NDBCLUSTER
Support: YES
Comment: Clustered, fault-tolerant, memory-based tables
***** 13. row *****
Engine: NDB
Support: YES
Comment: Alias for NDBCLUSTER
...
```

The row numbers shown in the preceding example output may be different from those shown on your system, depending upon how your server is configured.

Try to create an `NDBCLUSTER` table:

```

shell> mysql
mysql> USE test;
Database changed

mysql> CREATE TABLE ctest (i INT) ENGINE=NDBCLUSTER;
Query OK, 0 rows affected (0.09 sec)

mysql> SHOW CREATE TABLE ctest \G
***** 1. row *****
      Table: ctest
Create Table: CREATE TABLE `ctest` (
  `i` int(11) default NULL
) ENGINE=ndbcluster DEFAULT CHARSET=latin1
1 row in set (0.00 sec)

```

To check that your nodes were set up properly, start the management client:

```
shell> ndb_mgm
```

Use the `SHOW` command from within the management client to obtain a report on the cluster's status:

```

ndb_mgm> SHOW
Cluster Configuration
-----
[ndbd(NDB)]      1 node(s)
id=2             @127.0.0.1 (Version: 3.5.3, Nodegroup: 0, Master)

[ndb_mgmd(MGM)] 1 node(s)
id=1             @127.0.0.1 (Version: 3.5.3)

[mysqld(API)]   3 node(s)
id=3             @127.0.0.1 (Version: 3.5.3)
id=4 (not connected, accepting connect from any host)
id=5 (not connected, accepting connect from any host)

```

At this point, you have successfully set up a working MySQL Cluster. You can now store data in the cluster by using any table created with `ENGINE=NDBCLUSTER` or its alias `ENGINE=NDB`.

## 17.3.4. MySQL Cluster Configuration Files

Configuring MySQL Cluster requires working with two files:

- `my.cnf`: Specifies options for all MySQL Cluster executables. This file, with which you should be familiar with from previous work with MySQL, must be accessible by each executable running in the cluster.
- `config.ini`: This file, sometimes known as the *global configuration file*, is read only by the MySQL Cluster management server, which then distributes the information contained therein to all processes participating in the cluster. `config.ini` contains a description of each node involved in the cluster. This includes configuration parameters for data nodes and configuration parameters for connections between all nodes in the cluster. For a quick reference to the sections that can appear in this file, and what sorts of configuration parameters may be placed in each section, see [Sections of the config.ini File](#).

We are continuously making improvements in Cluster configuration and attempting to simplify this process. Although we strive to maintain backward compatibility, there may be times when introduce an incompatible change. In such cases we will try to let Cluster users know in advance if a change is not backward compatible. If you find such a change and we have not documented it, please report it in the MySQL bugs database using the instructions given in [Section 1.6, “How to Report Bugs or Problems”](#).

### 17.3.4.1. MySQL Cluster Configuration — Basic Example

To support MySQL Cluster, you will need to update `my.cnf` as shown in the following example. You may also specify these parameters on the command line when invoking the executables.

#### Note

The options shown here should not be confused with those that are used in `config.ini` global configuration files. Global configuration options are discussed later in this section.

```

# my.cnf
# example additions to my.cnf for MySQL Cluster
# (valid in MySQL 5.0)

# enable ndbcluster storage engine, and provide connectstring for
# management server host (default port is 1186)
[mysqld]
ndbcluster
ndb-connectstring=ndb_mgmd.mysql.com

```

```
# provide connectstring for management server host (default port: 1186)
[ndbd]
connect-string=ndb_mgmd.mysql.com

# provide connectstring for management server host (default port: 1186)
[ndb_mgm]
connect-string=ndb_mgmd.mysql.com

# provide location of cluster configuration file
[ndb_mgmd]
config-file=/etc/config.ini
```

(For more information on connectstrings, see [Section 17.3.4.2, “The MySQL Cluster Connectstring”](#).)

```
# my.cnf
# example additions to my.cnf for MySQL Cluster
# (will work on all versions)

# enable ndbcluster storage engine, and provide connectstring for management
# server host to the default port 1186
[mysqld]
ndbcluster
ndb-connectstring=ndb_mgmd.mysql.com:1186
```

### Important

Once you have started a `mysqld` process with the `NDBCLUSTER` and `ndb-connectstring` parameters in the `[mysqld]` in the `my.cnf` file as shown previously, you cannot execute any `CREATE TABLE` or `ALTER TABLE` statements without having actually started the cluster. Otherwise, these statements will fail with an error. *This is by design.*

You may also use a separate `[mysql_cluster]` section in the cluster `my.cnf` file for settings to be read and used by all executables:

```
# cluster-specific settings
[mysql_cluster]
ndb-connectstring=ndb_mgmd.mysql.com:1186
```

For additional `NDB` variables that can be set in the `my.cnf` file, see [Section 17.4.3, “MySQL Cluster System Variables”](#).

The MySQL Cluster global configuration file is named `config.ini` by default. It is read by `ndb_mgmd` at startup and can be placed anywhere. Its location and name are specified by using `--config-file=path_name` on the `ndb_mgmd` command line. If the configuration file is not specified, `ndb_mgmd` by default tries to read a file named `config.ini` located in the current working directory.

The global configuration file for MySQL Cluster uses INI format, which consists of sections preceded by section headings (surrounded by square brackets), followed by the appropriate parameter names and values. One deviation from the standard INI format is that the parameter name and value can be separated by a colon (“:”) as well as the equals sign (“=”); however, the equals sign is preferred. Another deviation is that sections are not uniquely identified by section name. Instead, unique sections (such as two different nodes of the same type) are identified by a unique ID specified as a parameter within the section.

Default values are defined for most parameters, and can also be specified in `config.ini`. (*Exception:* The `NoOfReplicas` configuration parameter has no default value, and must always be specified explicitly in the `[ndbd default]` section.) To create a default value section, simply add the word `default` to the section name. For example, an `[ndbd]` section contains parameters that apply to a particular data node, whereas an `[ndbd default]` section contains parameters that apply to all data nodes. Suppose that all data nodes should use the same data memory size. To configure them all, create an `[ndbd default]` section that contains a `DataMemory` line to specify the data memory size.

The global configuration file must define the computers and nodes involved in the cluster and on which computers these nodes are located. An example of a simple configuration file for a cluster consisting of one management server, two data nodes and two MySQL servers is shown here:

```
# file "config.ini" - 2 data nodes and 2 SQL nodes
# This file is placed in the startup directory of ndb_mgmd (the
# management server)
# The first MySQL Server can be started from any host. The second
# can be started only on the host mysqld_5.mysql.com

[ndbd default]
NoOfReplicas= 2
DataDir= /var/lib/mysql-cluster

[ndb_mgmd]
Hostname= ndb_mgmd.mysql.com
DataDir= /var/lib/mysql-cluster

[ndbd]
HostName= ndbd_2.mysql.com
```

```
[ndbd]
HostName= ndbd_3.mysql.com

[mysqld]
[mysqld]
HostName= mysqld_5.mysql.com
```

Each node has its own section in the `config.ini` file. For example, this cluster has two data nodes, so the preceding configuration file contains two `[ndbd]` sections defining these nodes.

### Note

Do not place comments on the same line as a section heading in the `config.ini` file; this causes the management server not to start because it cannot parse the configuration file in such cases.

### Sections of the `config.ini` File

There are six different sections that you can use in the `config.ini` configuration file, as described in the following list:

- `[computer]`: Defines cluster hosts. This is not required to configure a viable MySQL Cluster, but it may be used as a convenience when setting up a large cluster. See [Section 17.3.4.3, “Defining Computers in a MySQL Cluster”](#), for more information.
- `[ndbd]`: Defines a cluster data node (`ndbd` process). See [Section 17.3.4.5, “Defining MySQL Cluster Data Nodes”](#), for details.
- `[mysqld]`: Defines the cluster’s MySQL server nodes (also called SQL or API nodes). For a discussion of SQL node configuration, see [Section 17.3.4.6, “Defining SQL and Other API Nodes in a MySQL Cluster”](#).
- `[mgm]` or `[ndb_mgmd]`: Defines a cluster management server (MGM) node. For information concerning the configuration of MGM nodes, see [Section 17.3.4.4, “Defining a MySQL Cluster Management Server”](#).
- `[tcp]`: Defines a TCP/IP connection between cluster nodes, with TCP/IP being the default connection protocol. Normally, `[tcp]` or `[tcp default]` sections are not required to set up a MySQL Cluster, as the cluster handles this automatically; however, it may be necessary in some situations to override the defaults provided by the cluster. See [Section 17.3.4.7, “MySQL Cluster TCP/IP Connections”](#), for information about available TCP/IP configuration parameters and how to use them. (You may also find [Section 17.3.4.8, “MySQL Cluster TCP/IP Connections Using Direct Connections”](#) to be of interest in some cases.)
- `[shm]`: Defines shared-memory connections between nodes. In MySQL 5.0, it is enabled by default, but should still be considered experimental. For a discussion of SHM interconnects, see [Section 17.3.4.9, “MySQL Cluster Shared-Memory Connections”](#).
- `[sci]`: Defines *Scalable Coherent Interface* connections between cluster data nodes. Such connections require software which, while freely available, is not part of the MySQL Cluster distribution, as well as specialised hardware. See [Section 17.3.4.10, “SCI Transport Connections in MySQL Cluster”](#) for detailed information about SCI interconnects.

You can define `default` values for each section. All Cluster parameter names are case-insensitive, which differs from parameters specified in `my.cnf` or `my.ini` files.

## 17.3.4.2. The MySQL Cluster Connectstring

With the exception of the MySQL Cluster management server (`ndb_mgmd`), each node that is part of a MySQL Cluster requires a *connectstring* that points to the management server’s location. This connectstring is used in establishing a connection to the management server as well as in performing other tasks depending on the node’s role in the cluster. The syntax for a connectstring is as follows:

```
[nodeid=node_id, ]host-definition[, host-definition[, ...]]
host-definition:
  host_name[:port_number]
```

`node_id` is an integer larger than 1 which identifies a node in `config.ini`. `host_name` is a string representing a valid Internet host name or IP address. `port_number` is an integer referring to a TCP/IP port number.

```
example 1 (long):    "nodeid=2,myhost1:1100,myhost2:1100,192.168.0.3:1200"
example 2 (short):  "myhost1"
```

`localhost:1186` is used as the default connectstring value if none is provided. If `port_num` is omitted from the connectstring, the default port is 1186. This port should always be available on the network because it has been assigned by IANA for this pur-

pose (see <http://www.iana.org/assignments/port-numbers> for details).

By listing multiple host definitions, it is possible to designate several redundant management servers. A MySQL Cluster data or API node attempts to contact successive management servers on each host in the order specified, until a successful connection has been established.

There are a number of different ways to specify the connectstring:

- Each executable has its own command-line option which enables specifying the management server at startup. (See the documentation for the respective executable.)
- It is also possible to set the connectstring for all nodes in the cluster at once by placing it in a `[mysql_cluster]` section in the management server's `my.cnf` file.
- For backward compatibility, two other options are available, using the same syntax:
  1. Set the `NDB_CONNECTSTRING` environment variable to contain the connectstring.
  2. Write the connectstring for each executable into a text file named `Ndb.cfg` and place this file in the executable's startup directory.

However, these are now deprecated and should not be used for new installations.

The recommended method for specifying the connectstring is to set it on the command line or in the `my.cnf` file for each executable.

The maximum length of a connectstring is 1024 characters.

### 17.3.4.3. Defining Computers in a MySQL Cluster

The `[computer]` section has no real significance other than serving as a way to avoid the need of defining host names for each node in the system. All parameters mentioned here are required.

- `Id`

This is an integer value, used to refer to the host computer elsewhere in the configuration file. This is not the same as the node ID.

- `HostName`

This is the computer's host name or IP address.

### 17.3.4.4. Defining a MySQL Cluster Management Server

The `[ndb_mgmd]` section is used to configure the behavior of the management server. `[mgm]` can be used as an alias; the two section names are equivalent. All parameters in the following list are optional and assume their default values if omitted.

#### Note

If neither the `ExecuteOnComputer` nor the `HostName` parameter is present, the default value `localhost` will be assumed for both.

- `Id`

Each node in the cluster has a unique identity, which is represented by an integer value in the range 1 to 63 inclusive. This ID is used by all internal cluster messages for addressing the node.

- `ExecuteOnComputer`

This refers to the `Id` set for one of the computers defined in a `[computer]` section of the `config.ini` file.

- `PortNumber`

This is the port number on which the management server listens for configuration requests and management commands.

- `HostName`

Specifying this parameter defines the host name of the computer on which the management node is to reside. To specify a host name other than `localhost`, either this parameter or `ExecuteOnComputer` is required.

- `LogDestination`

This parameter specifies where to send cluster logging information. There are three options in this regard — `CONSOLE`, `SYSLOG`, and `FILE` — with `FILE` being the default:

- `CONSOLE` outputs the log to `stdout`:

```
CONSOLE
```

- `SYSLOG` sends the log to a `syslog` facility, possible values being one of `auth`, `authpriv`, `cron`, `daemon`, `ftp`, `kern`, `lpr`, `mail`, `news`, `syslog`, `user`, `uucp`, `local0`, `local1`, `local2`, `local3`, `local4`, `local5`, `local6`, or `local7`.

### Note

Not every facility is necessarily supported by every operating system.

```
SYSLOG:facility=syslog
```

- `FILE` pipes the cluster log output to a regular file on the same machine. The following values can be specified:

- `filename`: The name of the log file.
- `maxsize`: The maximum size (in bytes) to which the file can grow before logging rolls over to a new file. When this occurs, the old log file is renamed by appending `.N` to the file name, where `N` is the next number not yet used with this name.
- `maxfiles`: The maximum number of log files.

```
FILE:filename=cluster.log,maxsize=1000000,maxfiles=6
```

The default value for the `FILE` parameter is

```
FILE:filename=ndb_node_id_cluster.log,maxsize=1000000,maxfiles=6
```

where `node_id` is the ID of the node.

It is possible to specify multiple log destinations separated by semicolons as shown here:

```
CONSOLE;SYSLOG:facility=local0;FILE:filename=/var/log/mgmd
```

- `ArbitrationRank`

This parameter is used to define which nodes can act as arbitrators. Only management nodes and SQL nodes can be arbitrators. `ArbitrationRank` can take one of the following values:

- `0`: The node will never be used as an arbitrator.
- `1`: The node has high priority; that is, it will be preferred as an arbitrator over low-priority nodes.
- `2`: Indicates a low-priority node which be used as an arbitrator only if a node with a higher priority is not available for that purpose.

Normally, the management server should be configured as an arbitrator by setting its `ArbitrationRank` to 1 (the default value) and that of all SQL nodes to 0.

- `ArbitrationDelay`

An integer value which causes the management server's responses to arbitration requests to be delayed by that number of milliseconds. By default, this value is 0; it is normally not necessary to change it.

- `DataDir`

This specifies the directory where output files from the management server will be placed. These files include cluster log files, process output files, and the daemon's process ID (PID) file. (For log files, this location can be overridden by setting the `FILE` parameter for `LogDestination` as discussed previously in this section.)

The default value for this parameter is the directory in which `ndb_mgmd` is located.

### Note

After making changes in a management node's configuration, it is necessary to perform a rolling restart of the cluster in order for the new configuration to take effect.

To add new management servers to a running MySQL Cluster, it is also necessary to perform a rolling restart of all cluster nodes after modifying any existing `config.ini` files. For more information about issues arising when using multiple management nodes, see [Section 17.10.9, "Limitations Relating to Multiple MySQL Cluster Nodes"](#).

## 17.3.4.5. Defining MySQL Cluster Data Nodes

The `[ndbd]` and `[ndbd default]` sections are used to configure the behavior of the cluster's data nodes.

There are many parameters which control buffer sizes, pool sizes, timeouts, and so forth. The only mandatory parameters are:

- Either `ExecuteOnComputer` or `HostName`, which must be defined in the local `[ndbd]` section.
- The parameter `NoOfReplicas`, which must be defined in the `[ndbd default]` section, as it is common to all Cluster data nodes.

Most data node parameters are set in the `[ndbd default]` section. Only those parameters explicitly stated as being able to set local values are allowed to be changed in the `[ndbd]` section. Where present, `HostName`, `Id` and `ExecuteOnComputer` *must* be defined in the local `[ndbd]` section, and not in any other section of `config.ini`. In other words, settings for these parameters are specific to one data node.

For those parameters affecting memory usage or buffer sizes, it is possible to use `K`, `M`, or `G` as a suffix to indicate units of 1024, 1024×1024, or 1024×1024×1024. (For example, `100K` means  $100 \times 1024 = 102400$ .) Parameter names and values are currently case-sensitive.

**Identifying data nodes.** The `Id` value (that is, the data node identifier) can be allocated on the command line when the node is started or in the configuration file.

- `Id`  
This is the node ID used as the address of the node for all cluster internal messages. For data nodes, this is an integer in the range 1 to 49 inclusive. Each node in the cluster must have a unique identity.
- `ExecuteOnComputer`  
This refers to the `Id` set for one of the computers defined in a `[computer]` section.
- `HostName`  
Specifying this parameter defines the host name of the computer on which the data node is to reside. To specify a host name other than `localhost`, either this parameter or `ExecuteOnComputer` is required.
- `ServerPort` (*OBSOLETE*)  
Each node in the cluster uses a port to connect to other nodes. This port is used also for non-TCP transporters in the connection setup phase. The default port is allocated dynamically in such a way as to ensure that no two nodes on the same computer receive the same port number, so it should not normally be necessary to specify a value for this parameter.
- `NoOfReplicas`  
This global parameter can be set only in the `[ndbd default]` section, and defines the number of replicas for each table

stored in the cluster. This parameter also specifies the size of node groups. A node group is a set of nodes all storing the same information.

Node groups are formed implicitly. The first node group is formed by the set of data nodes with the lowest node IDs, the next node group by the set of the next lowest node identities, and so on. By way of example, assume that we have 4 data nodes and that `NoOfReplicas` is set to 2. The four data nodes have node IDs 2, 3, 4 and 5. Then the first node group is formed from nodes 2 and 3, and the second node group by nodes 4 and 5. It is important to configure the cluster in such a manner that nodes in the same node groups are not placed on the same computer because a single hardware failure would cause the entire cluster to fail.

If no node IDs are provided, the order of the data nodes will be the determining factor for the node group. Whether or not explicit assignments are made, they can be viewed in the output of the management client's `SHOW` command.

There is no default value for `NoOfReplicas`; the maximum possible value is 4. Currently, only the values 1 and 2 are actually supported (see [Bug#18621](#)).

### Important

Setting `NoOfReplicas` to 1 means that there is only a single copy of all Cluster data; in this case, the loss of a single data node causes the cluster to fail because there are no additional copies of the data stored by that node.

The value for this parameter must divide evenly into the number of data nodes in the cluster. For example, if there are two data nodes, then `NoOfReplicas` must be equal to either 1 or 2, since  $2/3$  and  $2/4$  both yield fractional values; if there are four data nodes, then `NoOfReplicas` must be equal to 1, 2, or 4.

- `DataDir`

This parameter specifies the directory where trace files, log files, pid files and error logs are placed.

The default is the data node process working directory.

- `FileSystemPath`

This parameter specifies the directory where all files created for metadata, REDO logs, UNDO logs and data files are placed. The default is the directory specified by `DataDir`.

### Note

This directory must exist before the `ndbd` process is initiated.

The recommended directory hierarchy for MySQL Cluster includes `/var/lib/mysql-cluster`, under which a directory for the node's file system is created. The name of this subdirectory contains the node ID. For example, if the node ID is 2, this subdirectory is named `ndb_2_fs`.

- `BackupDataDir`

This parameter specifies the directory in which backups are placed. If omitted, the default backup location is the directory named `BACKUP` under the location specified by the `FileSystemPath` parameter. (See above.)

## Data Memory, Index Memory, and String Memory

`DataMemory` and `IndexMemory` are `[ndbd]` parameters specifying the size of memory segments used to store the actual records and their indexes. In setting values for these, it is important to understand how `DataMemory` and `IndexMemory` are used, as they usually need to be updated to reflect actual usage by the cluster:

- `DataMemory`

This parameter defines the amount of space (in bytes) available for storing database records. The entire amount specified by this value is allocated in memory, so it is extremely important that the machine has sufficient physical memory to accommodate it.

The memory allocated by `DataMemory` is used to store both the actual records and indexes. Each record is currently of fixed size. (Even `VARCHAR` columns are stored as fixed-width columns.) There is a 16-byte overhead on each record; an additional amount for each record is incurred because it is stored in a 32KB page with 128 byte page overhead (see below). There is also a small amount wasted per page due to the fact that each record is stored in only one page.

The maximum record size is currently 8052 bytes.

The memory space defined by `DataMemory` is also used to store ordered indexes, which use about 10 bytes per record. Each table row is represented in the ordered index. A common error among users is to assume that all indexes are stored in the memory allocated by `IndexMemory`, but this is not the case: Only primary key and unique hash indexes use this memory; ordered indexes use the memory allocated by `DataMemory`. However, creating a primary key or unique hash index also creates an ordered index on the same keys, unless you specify `USING HASH` in the index creation statement. This can be verified by running `ndb_desc -d db_name table_name` in the management client.

The memory space allocated by `DataMemory` consists of 32KB pages, which are allocated to table fragments. Each table is normally partitioned into the same number of fragments as there are data nodes in the cluster. Thus, for each node, there are the same number of fragments as are set in `NoOfReplicas`.

In addition, due to the way in which new pages are allocated when the capacity of the current page is exhausted, there is an additional overhead of approximately 18.75%. When more `DataMemory` is required, more than one new page is allocated, according to the following formula:

```
number of new pages = FLOOR(number of current pages × 0.1875) + 1
```

For example, if 15 pages are currently allocated to a given table and an insert to this table requires additional storage space, the number of new pages allocated to the table is  $FLOOR(15 \times 0.1875) + 1 = FLOOR(2.8125) + 1 = 2 + 1 = 3$ . Now  $15 + 3 = 18$  memory pages are allocated to the table. When the last of these 18 pages becomes full,  $FLOOR(18 \times 0.1875) + 1 = FLOOR(3.3750) + 1 = 3 + 1 = 4$  new pages are allocated, so the total number of pages allocated to the table is now 22.

Once a page has been allocated, it is currently not possible to return it to the pool of free pages, except by deleting the table. (This also means that `DataMemory` pages, once allocated to a given table, cannot be used by other tables.) Performing a node recovery also compresses the partition because all records are inserted into empty partitions from other live nodes.

The `DataMemory` memory space also contains UNDO information: For each update, a copy of the unaltered record is allocated in the `DataMemory`. There is also a reference to each copy in the ordered table indexes. Unique hash indexes are updated only when the unique index columns are updated, in which case a new entry in the index table is inserted and the old entry is deleted upon commit. For this reason, it is also necessary to allocate enough memory to handle the largest transactions performed by applications using the cluster. In any case, performing a few large transactions holds no advantage over using many smaller ones, for the following reasons:

- Large transactions are not any faster than smaller ones
- Large transactions increase the number of operations that are lost and must be repeated in event of transaction failure
- Large transactions use more memory

The default value for `DataMemory` is 80MB; the minimum is 1MB. There is no maximum size, but in reality the maximum size has to be adapted so that the process does not start swapping when the limit is reached. This limit is determined by the amount of physical RAM available on the machine and by the amount of memory that the operating system may commit to any one process. 32-bit operating systems are generally limited to 2–4GB per process; 64-bit operating systems can use more. For large databases, it may be preferable to use a 64-bit operating system for this reason.

#### • `IndexMemory`

This parameter controls the amount of storage used for hash indexes in MySQL Cluster. Hash indexes are always used for primary key indexes, unique indexes, and unique constraints. Note that when defining a primary key and a unique index, two indexes will be created, one of which is a hash index used for all tuple accesses as well as lock handling. It is also used to enforce unique constraints.

The size of the hash index is 25 bytes per record, plus the size of the primary key. For primary keys larger than 32 bytes another 8 bytes is added.

The default value for `IndexMemory` is 18MB. The minimum is 1MB.

#### • `StringMemory`

This parameter determines how much memory is allocated for strings such as table names, and is specified in an `[ndbd]` or `[ndbd default]` section of the `config.ini` file. A value between 0 and 100 inclusive is interpreted as a percent of the maximum default value, which is calculated based on a number of factors including the number of tables, maximum table name size, maximum size of `.FRM` files, `MaxNoOfTriggers`, maximum column name size, and maximum default column value. In general it is safe to assume that the maximum default value is approximately 5 MB for a MySQL Cluster having 1000 tables.

A value greater than `100` is interpreted as a number of bytes.

In MySQL 5.0, the default value is `100` — that is, 100 percent of the default maximum, or roughly 5 MB. It is possible to reduce this value safely, but it should never be less than 5 percent. If you encounter Error 773 `OUT OF STRING MEMORY, PLEASE MODIFY STRINGMEMORY CONFIG PARAMETER: PERMANENT ERROR: SCHEMA ERROR`, this means that you have set the `StringMemory` value too low. `25` (25 percent) is not excessive, and should prevent this error from recurring in all but the most extreme conditions, as when there are hundreds or thousands of `NDB` tables with names whose lengths and columns whose number approach their permitted maximums.

The following example illustrates how memory is used for a table. Consider this table definition:

```
CREATE TABLE example (
  a INT NOT NULL,
  b INT NOT NULL,
  c INT NOT NULL,
  PRIMARY KEY (a),
  UNIQUE (b)
) ENGINE=NDBCLUSTER;
```

For each record, there are 12 bytes of data plus 12 bytes overhead. Having no nullable columns saves 4 bytes of overhead. In addition, we have two ordered indexes on columns `a` and `b` consuming roughly 10 bytes each per record. There is a primary key hash index on the base table using roughly 29 bytes per record. The unique constraint is implemented by a separate table with `b` as primary key and `a` as a column. This other table consumes an additional 29 bytes of index memory per record in the `example` table as well 8 bytes of record data plus 12 bytes of overhead.

Thus, for one million records, we need 58MB for index memory to handle the hash indexes for the primary key and the unique constraint. We also need 64MB for the records of the base table and the unique index table, plus the two ordered index tables.

You can see that hash indexes takes up a fair amount of memory space; however, they provide very fast access to the data in return. They are also used in MySQL Cluster to handle uniqueness constraints.

Currently, the only partitioning algorithm is hashing and ordered indexes are local to each node. Thus, ordered indexes cannot be used to handle uniqueness constraints in the general case.

An important point for both `IndexMemory` and `DataMemory` is that the total database size is the sum of all data memory and all index memory for each node group. Each node group is used to store replicated information, so if there are four nodes with two replicas, there will be two node groups. Thus, the total data memory available is  $2 \times \text{DataMemory}$  for each data node.

It is highly recommended that `DataMemory` and `IndexMemory` be set to the same values for all nodes. Data distribution is even over all nodes in the cluster, so the maximum amount of space available for any node can be no greater than that of the smallest node in the cluster.

`DataMemory` and `IndexMemory` can be changed, but decreasing either of these can be risky; doing so can easily lead to a node or even an entire MySQL Cluster that is unable to restart due to there being insufficient memory space. Increasing these values should be acceptable, but it is recommended that such upgrades are performed in the same manner as a software upgrade, beginning with an update of the configuration file, and then restarting the management server followed by restarting each data node in turn.

Updates do not increase the amount of index memory used. Inserts take effect immediately; however, rows are not actually deleted until the transaction is committed.

**Transaction parameters.** The next three `[ndbd]` parameters that we discuss are important because they affect the number of parallel transactions and the sizes of transactions that can be handled by the system. `MaxNoOfConcurrentTransactions` sets the number of parallel transactions possible in a node. `MaxNoOfConcurrentOperations` sets the number of records that can be in update phase or locked simultaneously.

Both of these parameters (especially `MaxNoOfConcurrentOperations`) are likely targets for users setting specific values and not using the default value. The default value is set for systems using small transactions, to ensure that these do not use excessive memory.

- `MaxNoOfConcurrentTransactions`

Each cluster data node requires a transaction record for each active transaction in the cluster. The task of coordinating transactions is distributed among all of the data nodes. The total number of transaction records in the cluster is the number of transactions in any given node times the number of nodes in the cluster.

Transaction records are allocated to individual MySQL servers. Each connection to a MySQL server requires at least one transaction record, plus an additional transaction object per table accessed by that connection. This means that a reasonable minim-

um for this parameter is

```
MaxNoOfConcurrentTransactions =
  (maximum number of tables accessed in any single transaction + 1)
  * number of cluster SQL nodes
```

For example, suppose that there are 4 SQL nodes using the cluster. A single join involving 5 tables requires 6 transaction records; if there are 5 such joins in a transaction, then  $5 * 6 = 30$  transaction records are required for this transaction, per MySQL server, or  $30 * 4 = 120$  transaction records total.

This parameter must be set to the same value for all cluster data nodes. This is due to the fact that, when a data node fails, the oldest surviving node re-creates the transaction state of all transactions that were ongoing in the failed node.

Changing the value of `MaxNoOfConcurrentTransactions` requires a complete shutdown and restart of the cluster.

The default value is 4096.

#### `MaxNoOfConcurrentOperations`

It is a good idea to adjust the value of this parameter according to the size and number of transactions. When performing transactions of only a few operations each and not involving a great many records, there is no need to set this parameter very high. When performing large transactions involving many records need to set this parameter higher.

Records are kept for each transaction updating cluster data, both in the transaction coordinator and in the nodes where the actual updates are performed. These records contain state information needed to find UNDO records for rollback, lock queues, and other purposes.

This parameter should be set to the number of records to be updated simultaneously in transactions, divided by the number of cluster data nodes. For example, in a cluster which has four data nodes and which is expected to handle 1,000,000 concurrent updates using transactions, you should set this value to  $1000000 / 4 = 250000$ .

Read queries which set locks also cause operation records to be created. Some extra space is allocated within individual nodes to accommodate cases where the distribution is not perfect over the nodes.

When queries make use of the unique hash index, there are actually two operation records used per record in the transaction. The first record represents the read in the index table and the second handles the operation on the base table.

The default value is 32768.

This parameter actually handles two values that can be configured separately. The first of these specifies how many operation records are to be placed with the transaction coordinator. The second part specifies how many operation records are to be local to the database.

A very large transaction performed on an eight-node cluster requires as many operation records in the transaction coordinator as there are reads, updates, and deletes involved in the transaction. However, the operation records of the are spread over all eight nodes. Thus, if it is necessary to configure the system for one very large transaction, it is a good idea to configure the two parts separately. `MaxNoOfConcurrentOperations` will always be used to calculate the number of operation records in the transaction coordinator portion of the node.

It is also important to have an idea of the memory requirements for operation records. These consume about 1KB per record.

#### `MaxNoOfLocalOperations`

By default, this parameter is calculated as  $1.1 \times \text{MaxNoOfConcurrentOperations}$ . This fits systems with many simultaneous transactions, none of them being very large. If there is a need to handle one very large transaction at a time and there are many nodes, it is a good idea to override the default value by explicitly specifying this parameter.

**Transaction temporary storage.** The next set of `[ndbd]` parameters is used to determine temporary storage when executing a statement that is part of a Cluster transaction. All records are released when the statement is completed and the cluster is waiting for the commit or rollback.

The default values for these parameters are adequate for most situations. However, users with a need to support transactions involving large numbers of rows or operations may need to increase these values to enable better parallelism in the system, whereas users whose applications require relatively small transactions can decrease the values to save memory.

#### `MaxNoOfConcurrentIndexOperations`

For queries using a unique hash index, another temporary set of operation records is used during a query's execution phase. This parameter sets the size of that pool of records. Thus, this record is allocated only while executing a part of a query. As soon as this part has been executed, the record is released. The state needed to handle aborts and commits is handled by the normal operation records, where the pool size is set by the parameter `MaxNoOfConcurrentOperations`.

The default value of this parameter is 8192. Only in rare cases of extremely high parallelism using unique hash indexes should it be necessary to increase this value. Using a smaller value is possible and can save memory if the DBA is certain that a high degree of parallelism is not required for the cluster.

- `MaxNoOfFiredTriggers`

The default value of `MaxNoOfFiredTriggers` is 4000, which is sufficient for most situations. In some cases it can even be decreased if the DBA feels certain the need for parallelism in the cluster is not high.

A record is created when an operation is performed that affects a unique hash index. Inserting or deleting a record in a table with unique hash indexes or updating a column that is part of a unique hash index fires an insert or a delete in the index table. The resulting record is used to represent this index table operation while waiting for the original operation that fired it to complete. This operation is short-lived but can still require a large number of records in its pool for situations with many parallel write operations on a base table containing a set of unique hash indexes.

- `TransactionBufferMemory`

The memory affected by this parameter is used for tracking operations fired when updating index tables and reading unique indexes. This memory is used to store the key and column information for these operations. It is only very rarely that the value for this parameter needs to be altered from the default.

The default value for `TransactionBufferMemory` is 1MB.

Normal read and write operations use a similar buffer, whose usage is even more short-lived. The compile-time parameter `ZATTRBUF_FILESIZE` (found in `ndb/src/kernel/blocks/Dbtc/Dbtc.hpp`) set to  $4000 \times 128$  bytes (500KB). A similar buffer for key information, `ZDATABUF_FILESIZE` (also in `Dbtc.hpp`) contains  $4000 \times 16 = 62.5$ KB of buffer space. `Dbtc` is the module that handles transaction coordination.

**Scans and buffering.** There are additional `[ndbd]` parameters in the `Dblqh` module (in `ndb/src/kernel/blocks/Dblqh/Dblqh.hpp`) that affect reads and updates. These include `ZATTRINBUF_FILESIZE`, set by default to  $10000 \times 128$  bytes (1250KB) and `ZDATABUF_FILE_SIZE`, set by default to  $10000 \times 16$  bytes (roughly 156KB) of buffer space. To date, there have been neither any reports from users nor any results from our own extensive tests suggesting that either of these compile-time limits should be increased.

- `MaxNoOfConcurrentScans`

This parameter is used to control the number of parallel scans that can be performed in the cluster. Each transaction coordinator can handle the number of parallel scans defined for this parameter. Each scan query is performed by scanning all partitions in parallel. Each partition scan uses a scan record in the node where the partition is located, the number of records being the value of this parameter times the number of nodes. The cluster should be able to sustain `MaxNoOfConcurrentScans` scans concurrently from all nodes in the cluster.

Scans are actually performed in two cases. The first of these cases occurs when no hash or ordered indexes exists to handle the query, in which case the query is executed by performing a full table scan. The second case is encountered when there is no hash index to support the query but there is an ordered index. Using the ordered index means executing a parallel range scan. The order is kept on the local partitions only, so it is necessary to perform the index scan on all partitions.

The default value of `MaxNoOfConcurrentScans` is 256. The maximum value is 500.

- `MaxNoOfLocalScans`

Specifies the number of local scan records if many scans are not fully parallelized. If the number of local scan records is not provided, it is calculated as the product of `MaxNoOfConcurrentScans` and the number of data nodes in the system. The minimum value is 32.

- `BatchSizePerLocalScan`

This parameter is used to calculate the number of lock records used to handle concurrent scan operations.

The default value is 64; this value has a strong connection to the `ScanBatchSize` defined in the SQL nodes.

- `LongMessageBuffer`

This is an internal buffer used for passing messages within individual nodes and between nodes. Although it is highly unlikely that this would need to be changed, it is configurable. By default, it is set to 1MB.

### Logging and checkpointing

The following `[ndbd]` parameters control log and checkpoint behavior.

- `NoOfFragmentLogFiles`

This parameter sets the number of REDO log files for the node, and thus the amount of space allocated to REDO logging. Because the REDO log files are organized in a ring, it is extremely important that the first and last log files in the set (sometimes referred to as the “head” and “tail” log files, respectively) do not meet. When these approach one another too closely, the node begins aborting all transactions encompassing updates due to a lack of room for new log records.

A REDO log record is not removed until three local checkpoints have been completed since that log record was inserted. Checkpointing frequency is determined by its own set of configuration parameters discussed elsewhere in this chapter.

How these parameters interact and proposals for how to configure them are discussed in [Section 17.3.6, “Configuring MySQL Cluster Parameters for Local Checkpoints”](#).

The default parameter value is 8, which means 8 sets of 4 16MB files for a total of 512MB. In other words, REDO log space is always allocated in blocks of 64MB. In scenarios requiring a great many updates, the value for `NoOfFragmentLogFiles` may need to be set as high as 300 or even higher to provide sufficient space for REDO logs.

If the checkpointing is slow and there are so many writes to the database that the log files are full and the log tail cannot be cut without jeopardizing recovery, all updating transactions are aborted with internal error code 410 (`Out of log file space temporarily`). This condition prevails until a checkpoint has completed and the log tail can be moved forward.

#### Important

This parameter cannot be changed “on the fly”; you must restart the node using `--initial`. If you wish to change this value for all data nodes in a running cluster, you can do so via a rolling node restart (using `--initial` when starting each data node).

- `MaxNoOfOpenFiles`

This parameter sets a ceiling on how many internal threads to allocate for open files. *Any situation requiring a change in this parameter should be reported as a bug.*

The default value is 40.

- `MaxNoOfSavedMessages`

This parameter sets the maximum number of trace files that are kept before overwriting old ones. Trace files are generated when, for whatever reason, the node crashes.

The default is 25 trace files.

**Metadata objects.** The next set of `[ndbd]` parameters defines pool sizes for metadata objects, used to define the maximum number of attributes, tables, indexes, and trigger objects used by indexes, events, and replication between clusters. Note that these act merely as “suggestions” to the cluster, and any that are not specified revert to the default values shown.

- `MaxNoOfAttributes`

Defines the number of attributes that can be defined in the cluster.

The default value is 1000, with the minimum possible value being 32. The maximum is 4294967039. Each attribute consumes around 200 bytes of storage per node due to the fact that all metadata is fully replicated on the servers.

When setting `MaxNoOfAttributes`, it is important to prepare in advance for any `ALTER TABLE` statements that you might want to perform in the future. This is due to the fact, during the execution of `ALTER TABLE` on a Cluster table, 3 times the number of attributes as in the original table are used, and a good practice is to allow double this amount. For example, if the MySQL Cluster table having the greatest number of attributes (`greatest_number_of_attributes`) has 100 attributes, a good starting point for the value of `MaxNoOfAttributes` would be  $6 * \text{greatest\_number\_of\_attributes} = 600$ .

You should also estimate the average number of attributes per table and multiply this by the total number of MySQL Cluster tables. If this value is larger than the value obtained in the previous paragraph, you should use the larger value instead.

Assuming that you can create all desired tables without any problems, you should also verify that this number is sufficient by trying an actual `ALTER TABLE` after configuring the parameter. If this is not successful, increase `MaxNoOfAttributes` by another multiple of `MaxNoOfTables` and test it again.

- `MaxNoOfTables`

A table object is allocated for each table, unique hash index, and ordered index. This parameter sets the maximum number of table objects for the cluster as a whole.

For each attribute that has a `BLOB` data type an extra table is used to store most of the `BLOB` data. These tables also must be taken into account when defining the total number of tables.

The default value of this parameter is 128. The minimum is 8 and the maximum is 1600. Each table object consumes approximately 20KB per node.

- `MaxNoOfOrderedIndexes`

For each ordered index in the cluster, an object is allocated describing what is being indexed and its storage segments. By default, each index so defined also defines an ordered index. Each unique index and primary key has both an ordered index and a hash index.

The default value of this parameter is 128. Each object consumes approximately 10KB of data per node.

- `MaxNoOfUniqueHashIndexes`

For each unique index that is not a primary key, a special table is allocated that maps the unique key to the primary key of the indexed table. By default, an ordered index is also defined for each unique index. To prevent this, you must specify the `USING HASH` option when defining the unique index.

The default value is 64. Each index consumes approximately 15KB per node.

- `MaxNoOfTriggers`

Internal update, insert, and delete triggers are allocated for each unique hash index. (This means that three triggers are created for each unique hash index.) However, an *ordered* index requires only a single trigger object. Backups also use three trigger objects for each normal table in the cluster.

This parameter sets the maximum number of trigger objects in the cluster.

The default value is 768.

- `MaxNoOfIndexes`

This parameter is deprecated in MySQL 5.0; you should use `MaxNoOfOrderedIndexes` and `MaxNoOfUniqueHashIndexes` instead.

This parameter is used only by unique hash indexes. There needs to be one record in this pool for each unique hash index defined in the cluster.

The default value of this parameter is 128.

**Boolean parameters.** The behavior of data nodes is also affected by a set of `[ndbd]` parameters taking on boolean values. These parameters can each be specified as `TRUE` by setting them equal to `1` or `Y`, and as `FALSE` by setting them equal to `0` or `N`.

- [LockPagesInMainMemory](#)

For a number of operating systems, including Solaris and Linux, it is possible to lock a process into memory and so avoid any swapping to disk. This can be used to help guarantee the cluster's real-time characteristics.

Beginning with MySQL 5.0.36, this parameter takes one of the integer values `0`, `1`, or `2`, which act as follows:

- `0`: Disables locking. This is the default value.
- `1`: Performs the lock after allocating memory for the process.
- `2`: Performs the lock before memory for the process is allocated.

Previously, this parameter was a Boolean. `0` or `false` was the default setting, and disabled locking. `1` or `true` enabled locking of the process after its memory was allocated.

### Important

Beginning with MySQL 5.0.36, it is no longer possible to use `true` or `false` for the value of this parameter; when upgrading from a previous version, you must change the value to `0`, `1`, or `2`.

- [StopOnError](#)

This parameter specifies whether an `ndbd` process should exit or perform an automatic restart when an error condition is encountered.

This feature is enabled by default.

- [Diskless](#)

It is possible to specify MySQL Cluster tables as *diskless*, meaning that tables are not checkpointed to disk and that no logging occurs. Such tables exist only in main memory. A consequence of using diskless tables is that neither the tables nor the records in those tables survive a crash. However, when operating in diskless mode, it is possible to run `ndbd` on a diskless computer.

### Important

This feature causes the *entire* cluster to operate in diskless mode.

When this feature is enabled, Cluster online backup is disabled. In addition, a partial start of the cluster is not possible.

`Diskless` is disabled by default.

- [RestartOnErrorInsert](#)

This feature is accessible only when building the debug version where it is possible to insert errors in the execution of individual blocks of code as part of testing.

This feature is disabled by default.

## Controlling Timeouts, Intervals, and Disk Paging

There are a number of [`ndbd`] parameters specifying timeouts and intervals between various actions in Cluster data nodes. Most of the timeout values are specified in milliseconds. Any exceptions to this are mentioned where applicable.

- [TimeBetweenWatchDogCheck](#)

To prevent the main thread from getting stuck in an endless loop at some point, a “watchdog” thread checks the main thread. This parameter specifies the number of milliseconds between checks. If the process remains in the same state after three checks, the watchdog thread terminates it.

This parameter can easily be changed for purposes of experimentation or to adapt to local conditions. It can be specified on a per-node basis although there seems to be little reason for doing so.

The default timeout is 4000 milliseconds (4 seconds).

- [StartPartialTimeout](#)

This parameter specifies how long the Cluster waits for all data nodes to come up before the cluster initialization routine is invoked. This timeout is used to avoid a partial Cluster startup whenever possible.

The default value is 30000 milliseconds (30 seconds). 0 disables the timeout, in which case the cluster may start only if all nodes are available.

- [StartPartitionedTimeout](#)

If the cluster is ready to start after waiting for [StartPartialTimeout](#) milliseconds but is still possibly in a partitioned state, the cluster waits until this timeout has also passed.

The default timeout is 60000 milliseconds (60 seconds).

- [StartFailureTimeout](#)

If a data node has not completed its startup sequence within the time specified by this parameter, the node startup fails. Setting this parameter to 0 (the default value) means that no data node timeout is applied.

For nonzero values, this parameter is measured in milliseconds. For data nodes containing extremely large amounts of data, this parameter should be increased. For example, in the case of a data node containing several gigabytes of data, a period as long as 10–15 minutes (that is, 600000 to 1000000 milliseconds) might be required to perform a node restart.

- [HeartbeatIntervalDbDb](#)

One of the primary methods of discovering failed nodes is by the use of heartbeats. This parameter states how often heartbeat signals are sent and how often to expect to receive them. After missing three heartbeat intervals in a row, the node is declared dead. Thus, the maximum time for discovering a failure through the heartbeat mechanism is four times the heartbeat interval.

The default heartbeat interval is 1500 milliseconds (1.5 seconds). This parameter must not be changed drastically and should not vary widely between nodes. If one node uses 5000 milliseconds and the node watching it uses 1000 milliseconds, obviously the node will be declared dead very quickly. This parameter can be changed during an online software upgrade, but only in small increments.

- [HeartbeatIntervalDbApi](#)

Each data node sends heartbeat signals to each MySQL server (SQL node) to ensure that it remains in contact. If a MySQL server fails to send a heartbeat in time it is declared “dead,” in which case all ongoing transactions are completed and all resources released. The SQL node cannot reconnect until all activities initiated by the previous MySQL instance have been completed. The three-heartbeat criteria for this determination are the same as described for [HeartbeatIntervalDbDb](#).

The default interval is 1500 milliseconds (1.5 seconds). This interval can vary between individual data nodes because each data node watches the MySQL servers connected to it, independently of all other data nodes.

- [TimeBetweenLocalCheckpoints](#)

This parameter is an exception in that it does not specify a time to wait before starting a new local checkpoint; rather, it is used to ensure that local checkpoints are not performed in a cluster where relatively few updates are taking place. In most clusters with high update rates, it is likely that a new local checkpoint is started immediately after the previous one has been completed.

The size of all write operations executed since the start of the previous local checkpoints is added. This parameter is also exceptional in that it is specified as the base-2 logarithm of the number of 4-byte words, so that the default value 20 means 4MB ( $4 \times 2^{20}$ ) of write operations, 21 would mean 8MB, and so on up to a maximum value of 31, which equates to 8GB of write operations.

All the write operations in the cluster are added together. Setting [TimeBetweenLocalCheckpoints](#) to 6 or less means that local checkpoints will be executed continuously without pause, independent of the cluster's workload.

- [TimeBetweenGlobalCheckpoints](#)

When a transaction is committed, it is committed in main memory in all nodes on which the data is mirrored. However, transaction log records are not flushed to disk as part of the commit. The reasoning behind this behavior is that having the transaction safely committed on at least two autonomous host machines should meet reasonable standards for durability.

It is also important to ensure that even the worst of cases — a complete crash of the cluster — is handled properly. To guarantee that this happens, all transactions taking place within a given interval are put into a global checkpoint, which can be thought of as a set of committed transactions that has been flushed to disk. In other words, as part of the commit process, a transaction is placed in a global checkpoint group. Later, this group's log records are flushed to disk, and then the entire group of transactions is safely committed to disk on all computers in the cluster.

This parameter defines the interval between global checkpoints. The default is 2000 milliseconds.

- [TimeBetweenInactiveTransactionAbortCheck](#)

Timeout handling is performed by checking a timer on each transaction once for every interval specified by this parameter. Thus, if this parameter is set to 1000 milliseconds, every transaction will be checked for timing out once per second.

The default value is 1000 milliseconds (1 second).

- [TransactionInactiveTimeout](#)

This parameter states the maximum time that is permitted to lapse between operations in the same transaction before the transaction is aborted.

The default for this parameter is zero (no timeout). For a real-time database that needs to ensure that no transaction keeps locks for too long, this parameter should be set to a relatively small value. The unit is milliseconds.

- [TransactionDeadlockDetectionTimeout](#)

When a node executes a query involving a transaction, the node waits for the other nodes in the cluster to respond before continuing. A failure to respond can occur for any of the following reasons:

- The node is “dead”
- The operation has entered a lock queue
- The node requested to perform the action could be heavily overloaded.

This timeout parameter states how long the transaction coordinator waits for query execution by another node before aborting the transaction, and is important for both node failure handling and deadlock detection. In MySQL 5.0.20 and earlier versions, setting it too high could cause undesirable behavior in situations involving deadlocks and node failure. Beginning with MySQL 5.0.21, active transactions occurring during node failures are actively aborted by the MySQL Cluster Transaction Coordinator, and so high settings are no longer an issue with this parameter.

The default timeout value is 1200 milliseconds (1.2 seconds). The effective minimum value is 100 milliseconds; it is possible to set it as low as 50 milliseconds, but any such value is treated as 100 ms. ([Bug#44099](#))

- [NoOfDiskPagesToDiskAfterRestartTUP](#)

When executing a local checkpoint, the algorithm flushes all data pages to disk. Merely doing so as quickly as possible without any moderation is likely to impose excessive loads on processors, networks, and disks. To control the write speed, this parameter specifies how many pages per 100 milliseconds are to be written. In this context, a “page” is defined as 8KB. This parameter is specified in units of 80KB per second, so setting [NoOfDiskPagesToDiskAfterRestartTUP](#) to a value of 20 entails writing 1.6MB in data pages to disk each second during a local checkpoint. This value includes the writing of UNDO log records for data pages. That is, this parameter handles the limitation of writes from data memory. UNDO log records for index pages are handled by the parameter [NoOfDiskPagesToDiskAfterRestartACC](#). (See the entry for [IndexMemory](#) for information about index pages.)

In short, this parameter specifies how quickly to execute local checkpoints. It operates in conjunction with [NoOfFragmentLogFiles](#), [DataMemory](#), and [IndexMemory](#).

For more information about the interaction between these parameters and possible strategies for choosing appropriate values for them, see [Section 17.3.6, “Configuring MySQL Cluster Parameters for Local Checkpoints”](#).

The default value is 40 (3.2MB of data pages per second).

- [NoOfDiskPagesToDiskAfterRestartACC](#)

This parameter uses the same units as [NoOfDiskPagesToDiskAfterRestartTUP](#) and acts in a similar fashion, but lim-

its the speed of writing index pages from index memory.

The default value of this parameter is 20 (1.6MB of index memory pages per second).

- [NoOfDiskPagesToDiskDuringRestartTUP](#)  
This parameter is used in a fashion similar to [NoOfDiskPagesToDiskAfterRestartTUP](#) and [NoOfDiskPagesToDiskAfterRestartACC](#), only it does so with regard to local checkpoints executed in the node when a node is restarting. A local checkpoint is always performed as part of all node restarts. During a node restart it is possible to write to disk at a higher speed than at other times, because fewer activities are being performed in the node.  
This parameter covers pages written from data memory.  
The default value is 40 (3.2MB per second).
- [NoOfDiskPagesToDiskDuringRestartACC](#)  
Controls the number of index memory pages that can be written to disk during the local checkpoint phase of a node restart.  
As with [NoOfDiskPagesToDiskAfterRestartTUP](#) and [NoOfDiskPagesToDiskAfterRestartACC](#), values for this parameter are expressed in terms of 8KB pages written per 100 milliseconds (80KB/second).  
The default value is 20 (1.6MB per second).
- [ArbitrationTimeout](#)  
This parameter specifies how long data nodes wait for a response from the arbitrator to an arbitration message. If this is exceeded, the network is assumed to have split.  
The default value is 1000 milliseconds (1 second).

**Buffering and logging.** Several [\[ndbd\]](#) configuration parameters corresponding to former compile-time parameters were introduced in MySQL 4.1.5. These enable the advanced user to have more control over the resources used by node processes and to adjust various buffer sizes at need.

These buffers are used as front ends to the file system when writing log records to disk. If the node is running in diskless mode, these parameters can be set to their minimum values without penalty due to the fact that disk writes are “faked” by the NDB storage engine's file system abstraction layer.

- [UndoIndexBuffer](#)  
The UNDO index buffer, whose size is set by this parameter, is used during local checkpoints. The NDB storage engine uses a recovery scheme based on checkpoint consistency in conjunction with an operational REDO log. To produce a consistent checkpoint without blocking the entire system for writes, UNDO logging is done while performing the local checkpoint. UNDO logging is activated on a single table fragment at a time. This optimization is possible because tables are stored entirely in main memory.  
The UNDO index buffer is used for the updates on the primary key hash index. Inserts and deletes rearrange the hash index; the NDB storage engine writes UNDO log records that map all physical changes to an index page so that they can be undone at system restart. It also logs all active insert operations for each fragment at the start of a local checkpoint.  
Reads and updates set lock bits and update a header in the hash index entry. These changes are handled by the page-writing algorithm to ensure that these operations need no UNDO logging.  
This buffer is 2MB by default. The minimum value is 1MB, which is sufficient for most applications. For applications doing extremely large or numerous inserts and deletes together with large transactions and large primary keys, it may be necessary to increase the size of this buffer. If this buffer is too small, the NDB storage engine issues internal error code 677 ([Index UNDO buffers overloaded](#)).

### Important

It is not safe to decrease the value of this parameter during a rolling restart.

- [UndoDataBuffer](#)

This parameter sets the size of the UNDO data buffer, which performs a function similar to that of the UNDO index buffer, except the UNDO data buffer is used with regard to data memory rather than index memory. This buffer is used during the local checkpoint phase of a fragment for inserts, deletes, and updates.

Because UNDO log entries tend to grow larger as more operations are logged, this buffer is also larger than its index memory counterpart, with a default value of 16MB.

This amount of memory may be unnecessarily large for some applications. In such cases, it is possible to decrease this size to a minimum of 1MB.

It is rarely necessary to increase the size of this buffer. If there is such a need, it is a good idea to check whether the disks can actually handle the load caused by database update activity. A lack of sufficient disk space cannot be overcome by increasing the size of this buffer.

If this buffer is too small and gets congested, the NDB storage engine issues internal error code 891 (`DATA UNDO BUFFERS OVERLOADED`).

### Important

It is not safe to decrease the value of this parameter during a rolling restart.

#### RedoBuffer

All update activities also need to be logged. The REDO log makes it possible to replay these updates whenever the system is restarted. The NDB recovery algorithm uses a “fuzzy” checkpoint of the data together with the UNDO log, and then applies the REDO log to play back all changes up to the restoration point.

`RedoBuffer` sets the size of the buffer in which the REDO log is written, and is 8MB by default. The minimum value is 1MB.

If this buffer is too small, the NDB storage engine issues error code 1221 (`REDO log buffers overloaded`).

### Important

It is not safe to decrease the value of this parameter during a rolling restart.

**Controlling log messages.** In managing the cluster, it is very important to be able to control the number of log messages sent for various event types to `stdout`. For each event category, there are 16 possible event levels (numbered 0 through 15). Setting event reporting for a given event category to level 15 means all event reports in that category are sent to `stdout`; setting it to 0 means that there will be no event reports made in that category.

By default, only the startup message is sent to `stdout`, with the remaining event reporting level defaults being set to 0. The reason for this is that these messages are also sent to the management server's cluster log.

An analogous set of levels can be set for the management client to determine which event levels to record in the cluster log.

#### LogLevelStartup

The reporting level for events generated during startup of the process.

The default level is 1.

#### LogLevelShutdown

The reporting level for events generated as part of graceful shutdown of a node.

The default level is 0.

#### LogLevelStatistic

The reporting level for statistical events such as number of primary key reads, number of updates, number of inserts, information relating to buffer usage, and so on.

The default level is 0.

- [LogLevelCheckpoint](#)

The reporting level for events generated by local and global checkpoints.

The default level is 0.
- [LogLevelNodeRestart](#)

The reporting level for events generated during node restart.

The default level is 0.
- [LogLevelConnection](#)

The reporting level for events generated by connections between cluster nodes.

The default level is 0.
- [LogLevelError](#)

The reporting level for events generated by errors and warnings by the cluster as a whole. These errors do not cause any node failure but are still considered worth reporting.

The default level is 0.
- [LogLevelCongestion](#)

The reporting level for events generated by congestion. These errors do not cause node failure but are still considered worth reporting.

The default level is 0.
- [LogLevelInfo](#)

The reporting level for events generated for information about the general state of the cluster.

The default level is 0.

**Backup parameters.** The `[ndbd]` parameters discussed in this section define memory buffers set aside for execution of online backups.

- [BackupDataBufferSize](#)

In creating a backup, there are two buffers used for sending data to the disk. The backup data buffer is used to fill in data recorded by scanning a node's tables. Once this buffer has been filled to the level specified as `BackupWriteSize` (see below), the pages are sent to disk. While flushing data to disk, the backup process can continue filling this buffer until it runs out of space. When this happens, the backup process pauses the scan and waits until some disk writes have completed freed up memory so that scanning may continue.

The default value is 2MB.
- [BackupLogBufferSize](#)

The backup log buffer fulfills a role similar to that played by the backup data buffer, except that it is used for generating a log of all table writes made during execution of the backup. The same principles apply for writing these pages as with the backup data buffer, except that when there is no more space in the backup log buffer, the backup fails. For that reason, the size of the backup log buffer must be large enough to handle the load caused by write activities while the backup is being made. See [Section 17.7.3.3, "Configuration for MySQL Cluster Backups"](#).

The default value for this parameter should be sufficient for most applications. In fact, it is more likely for a backup failure to be caused by insufficient disk write speed than it is for the backup log buffer to become full. If the disk subsystem is not configured for the write load caused by applications, the cluster is unlikely to be able to perform the desired operations.

It is preferable to configure cluster nodes in such a manner that the processor becomes the bottleneck rather than the disks or the network connections.

The default value is 2MB.

- `BackupMemory`

This parameter is simply the sum of `BackupDataBufferSize` and `BackupLogBufferSize`.

The default value is  $2\text{MB} + 2\text{MB} = 4\text{MB}$ .

### Important

If `BackupDataBufferSize` and `BackupLogBufferSize` taken together exceed 4MB, then this parameter must be set explicitly in the `config.ini` file to their sum.

- `BackupWriteSize`

This parameter specifies the default size of messages written to disk by the backup log and backup data buffers.

The default value is 32KB.

- `BackupMaxWriteSize`

This parameter specifies the maximum size of messages written to disk by the backup log and backup data buffers.

The default value is 256KB.

### Important

When specifying these parameters, the following relationships must hold true. Otherwise, the data node will be unable to start.

- `BackupDataBufferSize >= BackupWriteSize + 188KB`
- `BackupLogBufferSize >= BackupWriteSize + 16KB`
- `BackupMaxWriteSize >= BackupWriteSize`

### Note

To add new data nodes to a MySQL Cluster, it is necessary to shut down the cluster completely, update the `config.ini` file, and then restart the cluster (that is, you must perform a system restart). All data node processes must be started with the `--initial` option.

We are working to make it possible to add new data node groups to a running cluster online in a future release; however, we do not plan to implement this change in MySQL 5.0.

## 17.3.4.6. Defining SQL and Other API Nodes in a MySQL Cluster

The `[mysqld]` and `[api]` sections in the `config.ini` file define the behavior of the MySQL servers (SQL nodes) and other applications (API nodes) used to access cluster data. None of the parameters shown is required. If no computer or host name is provided, any host can use this SQL or API node.

Generally speaking, a `[mysqld]` section is used to indicate a MySQL server providing an SQL interface to the cluster, and an `[api]` section is used for applications other than `mysqld` processes accessing cluster data, but the two designations are actually synonymous; you can, for instance, list parameters for a MySQL server acting as an SQL node in an `[api]` section.

### Note

For a discussion of MySQL server options for MySQL Cluster, see [Section 17.4.2, “mysqld Command Options for MySQL Cluster”](#); for information about MySQL server system variables relating to MySQL Cluster, see [Section 17.4.3, “MySQL Cluster System Variables”](#).

- [Id](#)

The `Id` value is used to identify the node in all cluster internal messages. It must be an integer in the range 1 to 63 inclusive, and must be unique among all node IDs within the cluster.

- [ExecuteOnComputer](#)

This refers to the `Id` set for one of the computers (hosts) defined in a `[computer]` section of the configuration file.

- [HostName](#)

Specifying this parameter defines the host name of the computer on which the SQL node (API node) is to reside. To specify a host name, either this parameter or `ExecuteOnComputer` is required.

If no `HostName` or `ExecuteOnComputer` is specified in a given `[mysql]` or `[api]` section of the `config.ini` file, then an SQL or API node may connect using the corresponding “slot” from any host which can establish a network connection to the management server host machine. *This differs from the default behavior for data nodes, where `localhost` is assumed for `HostName` unless otherwise specified.*

- [ArbitrationRank](#)

This parameter defines which nodes can act as arbitrators. Both MGM nodes and SQL nodes can be arbitrators. A value of 0 means that the given node is never used as an arbitrator, a value of 1 gives the node high priority as an arbitrator, and a value of 2 gives it low priority. A normal configuration uses the management server as arbitrator, setting its `ArbitrationRank` to 1 (the default) and those for all SQL nodes to 0.

- [ArbitrationDelay](#)

Setting this parameter to any other value than 0 (the default) means that responses by the arbitrator to arbitration requests will be delayed by the stated number of milliseconds. It is usually not necessary to change this value.

- [BatchByteSize](#)

For queries that are translated into full table scans or range scans on indexes, it is important for best performance to fetch records in properly sized batches. It is possible to set the proper size both in terms of number of records (`BatchSize`) and in terms of bytes (`BatchByteSize`). The actual batch size is limited by both parameters.

The speed at which queries are performed can vary by more than 40% depending upon how this parameter is set. In future releases, MySQL Server will make educated guesses on how to set parameters relating to batch size, based on the query type.

This parameter is measured in bytes and by default is equal to 32KB.

- [BatchSize](#)

This parameter is measured in number of records and is by default set to 64. The maximum size is 992.

- [MaxScanBatchSize](#)

The batch size is the size of each batch sent from each data node. Most scans are performed in parallel to protect the MySQL Server from receiving too much data from many nodes in parallel; this parameter sets a limit to the total batch size over all nodes.

The default value of this parameter is set to 256KB. Its maximum size is 16MB.

You can obtain some information from a MySQL server running as a Cluster SQL node using `SHOW STATUS` in the `mysql` client, as shown here:

```
mysql> SHOW STATUS LIKE 'ndb%';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| Ndb_cluster_node_id | 5 |
| Ndb_config_from_host | 192.168.0.112 |
| Ndb_config_from_port | 1186 |
| Ndb_number_of_storage_nodes | 4 |
+-----+-----+
```

```
+-----+
4 rows in set (0.02 sec)
```

For information about these Cluster system status variables, see [Section 5.1.6, “Server Status Variables”](#).

### Note

To add new SQL or API nodes to the configuration of a running MySQL Cluster, it is necessary to perform a rolling restart of all cluster nodes after adding new `[mysqld]` or `[api]` sections to the `config.ini` file (or files, if you are using more than one management server). This must be done before the new SQL or API nodes can connect to the cluster.

It is *not* necessary to perform any restart of the cluster if new SQL or API nodes can employ previously unused API slots in the cluster configuration to connect to the cluster.

## 17.3.4.7. MySQL Cluster TCP/IP Connections

TCP/IP is the default transport mechanism for all connections between nodes in a MySQL Cluster. Normally it is not necessary to define TCP/IP connections; MySQL Cluster automatically sets up such connections for all data nodes, management nodes, and SQL or API nodes.

### Note

For an exception to this rule, see [Section 17.3.4.8, “MySQL Cluster TCP/IP Connections Using Direct Connections”](#).

To override the default connection parameters, it is necessary to define a connection using one or more `[tcp]` sections in the `config.ini` file. Each `[tcp]` section explicitly defines a TCP/IP connection between two MySQL Cluster nodes, and must contain at a minimum the parameters `NodeId1` and `NodeId2`, as well as any connection parameters to override.

It is also possible to change the default values for these parameters by setting them in the `[tcp default]` section.

### Important

Any `[tcp]` sections in the `config.ini` file should be listed *last*, following all other sections in the file. However, this is not required for a `[tcp default]` section. This requirement is a known issue with the way in which the `config.ini` file is read by the MySQL Cluster management server.

Connection parameters which can be set in `[tcp]` and `[tcp default]` sections of the `config.ini` file are listed here:

- `NodeId1, NodeId2`

To identify a connection between two nodes it is necessary to provide their node IDs in the `[tcp]` section of the configuration file. These are the same unique `Id` values for each of these nodes as described in [Section 17.3.4.6, “Defining SQL and Other API Nodes in a MySQL Cluster”](#).

- `SendBufferMemory`

TCP transporters use a buffer to store all messages before performing the send call to the operating system. When this buffer reaches 64KB its contents are sent; these are also sent when a round of messages have been executed. To handle temporary overload situations it is also possible to define a bigger send buffer.

The default size of the send buffer is 256 KB; 2MB is recommended in most situations in which it is necessary to set this parameter. The minimum size is 64 KB; the theoretical maximum is 4 GB.

- `SendSignalId`

To be able to retrace a distributed message datagram, it is necessary to identify each message. When this parameter is set to `Y`, message IDs are transported over the network. This feature is disabled by default in production builds, and enabled in `-debug` builds.

- `Checksum`

This parameter is a boolean parameter (enabled by setting it to `Y` or `1`, disabled by setting it to `N` or `0`). It is disabled by default. When it is enabled, checksums for all messages are calculated before they placed in the send buffer. This feature ensures that messages are not corrupted while waiting in the send buffer, or by the transport mechanism.

-

**PortNumber** (*OBSOLETE*)

This formerly specified the port number to be used for listening for connections from other nodes. This parameter should no longer be used.

**ReceiveBufferMemory**

Specifies the size of the buffer used when receiving data from the TCP/IP socket.

The default value of this parameter from its of 64 KB; 1M is recommended in most situations where the size of the receive buffer needs to be set. The minimum possible value is 16K; theoretical maximum is 4G.

### 17.3.4.8. MySQL Cluster TCP/IP Connections Using Direct Connections

Setting up a cluster using direct connections between data nodes requires specifying explicitly the crossover IP addresses of the data nodes so connected in the `[tcp]` section of the cluster `config.ini` file.

In the following example, we envision a cluster with at least four hosts, one each for a management server, an SQL node, and two data nodes. The cluster as a whole resides on the `172.23.72.*` subnet of a LAN. In addition to the usual network connections, the two data nodes are connected directly using a standard crossover cable, and communicate with one another directly using IP addresses in the `1.1.0.*` address range as shown:

```
# Management Server
[ndb_mgmd]
Id=1
HostName=172.23.72.20

# SQL Node
[mysqld]
Id=2
HostName=172.23.72.21

# Data Nodes
[ndbd]
Id=3
HostName=172.23.72.22

[ndbd]
Id=4
HostName=172.23.72.23

# TCP/IP Connections
[tcp]
NodeId1=3
NodeId2=4
HostName1=1.1.0.1
HostName2=1.1.0.2
```

The `HostName $N$`  parameter, where  $N$  is an integer, is used only when specifying direct TCP/IP connections.

The use of direct connections between data nodes can improve the cluster's overall efficiency by allowing the data nodes to bypass an Ethernet device such as a switch, hub, or router, thus cutting down on the cluster's latency. It is important to note that to take the best advantage of direct connections in this fashion with more than two data nodes, you must have a direct connection between each data node and every other data node in the same node group.

### 17.3.4.9. MySQL Cluster Shared-Memory Connections

MySQL Cluster attempts to use the shared memory transporter and configure it automatically where possible. (In very early versions of MySQL Cluster, shared memory segments functioned only when the server binary was built using `--with-ndb-shm`.) `[shm]` sections in the `config.ini` file explicitly define shared-memory connections between nodes in the cluster. When explicitly defining shared memory as the connection method, it is necessary to define at least `NodeId1`, `NodeId2` and `ShmKey`. All other parameters have default values that should work well in most cases.

#### Important

*SHM functionality is considered experimental only.* It is not officially supported in any current MySQL Cluster release, and testing results indicate that SHM performance is not appreciably greater than when using TCP/IP for the transporter.

For these reasons, you must determine for yourself or by using our free resources (forums, mailing lists) whether SHM can be made to work correctly in your specific case.

- [NodeId1, NodeId2](#)  
To identify a connection between two nodes it is necessary to provide node identifiers for each of them, as [NodeId1](#) and [NodeId2](#).
- [ShmKey](#)  
When setting up shared memory segments, a node ID, expressed as an integer, is used to identify uniquely the shared memory segment to use for the communication. There is no default value.
- [ShmSize](#)  
Each SHM connection has a shared memory segment where messages between nodes are placed by the sender and read by the reader. The size of this segment is defined by [ShmSize](#). The default value is 1MB.
- [SendSignalId](#)  
To retrace the path of a distributed message, it is necessary to provide each message with a unique identifier. Setting this parameter to **Y** causes these message IDs to be transported over the network as well. This feature is disabled by default in production builds, and enabled in `-debug` builds.
- [Checksum](#)  
This parameter is a boolean (**Y/N**) parameter which is disabled by default. When it is enabled, checksums for all messages are calculated before being placed in the send buffer.  
  
This feature prevents messages from being corrupted while waiting in the send buffer. It also serves as a check against data being corrupted during transport.
- [SigNum](#)  
When using the shared memory transporter, a process sends an operating system signal to the other process when there is new data available in the shared memory. Should that signal conflict with with an existing signal, this parameter can be used to change it. This is a possibility when using SHM due to the fact that different operating systems use different signal numbers.  
  
The default value of [SigNum](#) is 0; therefore, it must be set to avoid errors in the cluster log when using the shared memory transporter. Typically, this parameter is set to 10 in the `[shm default]` section of the `config.ini` file.

### 17.3.4.10. SCI Transport Connections in MySQL Cluster

`[sci]` sections in the `config.ini` file explicitly define SCI (Scalable Coherent Interface) connections between cluster nodes. Using SCI transporters in MySQL Cluster is supported only when the MySQL binaries are built using `--with-ndb-sci=/your/path/to/SCI`. The `path` should point to a directory that contains at a minimum `lib` and `include` directories containing SISI libraries and header files. (See [Section 17.9](#), “Using High-Speed Interconnects with MySQL Cluster” for more information about SCI.)

In addition, SCI requires specialized hardware.

It is strongly recommended to use SCI Transporters only for communication between `ndbd` processes. Note also that using SCI Transporters means that the `ndbd` processes never sleep. For this reason, SCI Transporters should be used only on machines having at least two CPUs dedicated for use by `ndbd` processes. There should be at least one CPU per `ndbd` process, with at least one CPU left in reserve to handle operating system activities.

- [NodeId1, NodeId2](#)  
To identify a connection between two nodes it is necessary to provide node identifiers for each of them, as [NodeId1](#) and [NodeId2](#).
- [Host1SciId0](#)  
This identifies the SCI node ID on the first Cluster node (identified by [NodeId1](#)).

- `Host1SciId1`

It is possible to set up SCI Transporters for failover between two SCI cards which then should use separate networks between the nodes. This identifies the node ID and the second SCI card to be used on the first node.

- `Host2SciId0`

This identifies the SCI node ID on the second Cluster node (identified by `NodeId2`).

- `Host2SciId1`

When using two SCI cards to provide failover, this parameter identifies the second SCI card to be used on the second node.

- `SharedBufferSize`

Each SCI transporter has a shared memory segment used for communication between the two nodes. Setting the size of this segment to the default value of 1MB should be sufficient for most applications. Using a smaller value can lead to problems when performing many parallel inserts; if the shared buffer is too small, this can also result in a crash of the `ndbd` process.

- `SendLimit`

A small buffer in front of the SCI media stores messages before transmitting them over the SCI network. By default, this is set to 8KB. Our benchmarks show that performance is best at 64KB but 16KB reaches within a few percent of this, and there was little if any advantage to increasing it beyond 8KB.

- `SendSignalId`

To trace a distributed message it is necessary to identify each message uniquely. When this parameter is set to `Y`, message IDs are transported over the network. This feature is disabled by default in production builds, and enabled in `-debug` builds.

- `Checksum`

This parameter is a boolean value, and is disabled by default. When `Checksum` is enabled, checksums are calculated for all messages before they are placed in the send buffer. This feature prevents messages from being corrupted while waiting in the send buffer. It also serves as a check against data being corrupted during transport.

## 17.3.5. Overview of MySQL Cluster Configuration Parameters

The next three sections provide summary tables of MySQL Cluster configuration parameters used in the `config.ini` file to govern the cluster's functioning. Each table lists the parameters for one of the Cluster node process types (`ndbd`, `ndb_mgmd`, and `mysqld`), and includes the parameter's type as well as its default, minimum, and maximum values as applicable.

It is also stated what type of restart is required (node restart or system restart) — and whether the restart must be done with `-initial` — to change the value of a given configuration parameter. This information is provided in each table's **Restart Type** column, which contains one of the values shown in this list:

- `N`: Node Restart
- `IN`: Initial Node Restart
- `S`: System Restart
- `IS`: Initial System Restart

When performing a node restart or an initial node restart, all of the cluster's data nodes must be restarted in turn (also referred to as a *rolling restart*). It is possible to update cluster configuration parameters marked `N` or `IN` online — that is, without shutting down the cluster — in this fashion. An initial node restart requires restarting each `ndbd` process with the `--initial` option.

A system restart requires a complete shutdown and restart of the entire cluster. An initial system restart requires taking a backup of the cluster, wiping the cluster file system after shutdown, and then restoring from the backup following the restart.

In any cluster restart, all of the cluster's management servers must be restarted in order for them to read the updated configuration parameter values.

**Important**

Values for numeric cluster parameters can generally be increased without any problems, although it is advisable to do so progressively, making such adjustments in relatively small increments. However, decreasing the values of such parameters — particularly those relating to memory usage and disk space — is not to be undertaken lightly, and it is recommended that you do so only following careful planning and testing. In addition, it is generally the case that parameters relating to memory and disk usage which can be raised using a simple node restart require an initial node restart to be lowered.

Because some of these parameters can be used for configuring more than one type of cluster node, they may appear in more than one of the tables.

**Note**

4294967039 — which often appears as a maximum value in these tables — is defined in the `NDBCLUSTER` sources as `MAX_INT_RNIL` and is equal to `0xFFFFFFFF`, or  $2^{32} - 2^8 - 1$ .

**17.3.5.1. MySQL Cluster Data Node Configuration Parameters**

The following table provides information about parameters used in the `[ndbd]` or `[ndbd default]` sections of a `config.ini` file for configuring MySQL Cluster data nodes. For detailed descriptions and other additional information about each of these parameters, see [Section 17.3.4.5, “Defining MySQL Cluster Data Nodes”](#).

*Restart Type Column Values*

- **N**: Node Restart
- **IN**: Initial Node Restart
- **S**: System Restart
- **IS**: Initial System Restart

See [Section 17.3.5, “Overview of MySQL Cluster Configuration Parameters”](#), for additional explanations of these abbreviations.

**Table 17.1. MySQL Cluster Data Node Configuration Parameters**

Parameter Name	Type / Units	Default Value	Minimum Value	Maximum Value	Restart Type
<a href="#">ArbitrationTimeout</a>	mil- li- sec- onds	1000	10	4294967039	N

<code>TimeBetweenLocalCheckpoints</code>	integer (number of 4-byte words as a base-2 logarithm)	20 (= $4 * 2^{20} = 4\text{MB}$ write operations)	0	31	N
<code>TimeBetweenWatchDogCheck</code>	milliseconds	4000	70	4294967039	N
<code>TransactionBufferMemory</code>	bytes	1M	1K	4294967039	N
<code>TransactionDeadlockDetectionTimeout</code>	milliseconds	1200	100 (Can actually be set as low as 50, but any value less than 100 is treated as 100.)	4294967039	N
<code>TransactionInactiveTimeout</code>	milliseconds	0	0	4294967039	N
<code>UndoDataBuffer</code>	bytes	16M	1M	4294967039	N
<code>UndoIndexBuffer</code>	bytes	2M	1M	4294967039	N

**Note**

To add new data nodes to a MySQL Cluster, it is necessary to shut down the cluster completely, update the `config.ini` file, and then restart the cluster (that is, you must perform a system restart). All data node processes must be started with the `--initial` option.

We are working to make it possible to add new data node groups to a running cluster online in a future release; however, we do not plan to implement this change in MySQL 5.0.

**17.3.5.2. MySQL Cluster Management Node Configuration Parameters**

The following table provides information about parameters used in the `[ndb_mgmd]` or `[mgm]` sections of a `config.ini` file for configuring MySQL Cluster management nodes. For detailed descriptions and other additional information about each of these parameters, see [Section 17.3.4.4, “Defining a MySQL Cluster Management Server”](#).

**Restart Type Column Values**

- **N**: Node Restart
- **IN**: Initial Node Restart

- S: System Restart
- IS: Initial System Restart

See [Section 17.3.5, “Overview of MySQL Cluster Configuration Parameters”](#), for additional explanations of these abbreviations.

**Table 17.2. MySQL Cluster Management Node Configuration Parameters**

Parameter Name	Type / Units	Default Value	Minimum Value	Maximum Value	Restart Type
<a href="#">ArbitrationDelay</a>	mil- li- sec- onds	0	0	4294967039	N
<a href="#">ArbitrationRank</a>	in- teger	1	0	2	N
<a href="#">DataDir</a>	string	. (ndb_mgmd directory)	N/A	N/A	IN
<a href="#">ExecuteOnComputer</a>	in- teger				
<a href="#">HostName</a>	string	localhost	N/A	N/A	IN
<a href="#">Id</a>	in- teger	None	1	63	IS
<a href="#">LogDestination</a>	CON- SOL E, SYS LOG, or FIL E	FILE (see <a href="#">Section 17.3.4.4, “Defining a MySQL Cluster Management Server”</a> )	N/A	N/A	N
<a href="#">PortNumber</a>	in- teger	1186	1	65535	S

#### Note

After making changes in a management node's configuration, it is necessary to perform a rolling restart of the cluster in order for the new configuration to take effect. See [Section 17.3.4.4, “Defining a MySQL Cluster Management Server”](#), for more information.

To add new management servers to a running MySQL Cluster, it is also necessary perform a rolling restart of all cluster nodes after modifying any existing `config.ini` files. For more information about issues arising when using multiple management nodes, see [Section 17.10.9, “Limitations Relating to Multiple MySQL Cluster Nodes”](#).

### 17.3.5.3. MySQL Cluster SQL Node and API Node Configuration Parameters

The following table provides information about parameters used in the `[SQL]` and `[api]` sections of a `config.ini` file for configuring MySQL Cluster SQL nodes and API nodes. For detailed descriptions and other additional information about each of these parameters, see [Section 17.3.4.6, “Defining SQL and Other API Nodes in a MySQL Cluster”](#).

#### Note

For a discussion of MySQL server options for MySQL Cluster, see [Section 17.4.2, “mysqld Command Options for MySQL Cluster”](#); for information about MySQL server system variables relating to MySQL Cluster, see [Section 17.4.3, “MySQL Cluster System Variables”](#).

#### Restart Type Column Values

- N: Node Restart

- **IN**: Initial Node Restart
- **S**: System Restart
- **IS**: Initial System Restart

See [Section 17.3.5, “Overview of MySQL Cluster Configuration Parameters”](#), for additional explanations of these abbreviations.

**Table 17.3. MySQL Cluster SQL Node and API Node Configuration Parameters**

Parameter Name	Type / Units	Default Value	Minimum Value	Maximum Value	Restart Type
<a href="#">ArbitrationDelay</a>	milliseconds	0	0	4294967039	N
<a href="#">ArbitrationRank</a>	integer	0	0	2	N
<a href="#">BatchByteSize</a>	bytes	32K	1K	1M	N
<a href="#">BatchSize</a>	integer	64	1	992	N
<a href="#">ExecuteOnComputer</a>	integer				
<a href="#">HostName</a>	string	<i>none</i>	N/A	N/A	IN
<a href="#">Id</a>	integer	<i>None</i>	1	63	IS
<a href="#">MaxScanBatchSize</a>	bytes	256K	32K	16M	N

#### Note

To add new SQL or API nodes to the configuration of a running MySQL Cluster, it is necessary to perform a rolling restart of all cluster nodes after adding new `[mysqld]` or `[api]` sections to the `config.ini` file (or files, if you are using more than one management server). This must be done before the new SQL or API nodes can connect to the cluster.

It is *not* necessary to perform any restart of the cluster if new SQL or API nodes can employ previously unused API slots in the cluster configuration to connect to the cluster.

### 17.3.6. Configuring MySQL Cluster Parameters for Local Checkpoints

The parameters discussed in [Logging and Checkpointing](#) and in [Data Memory, Index Memory, and String Memory](#) that are used to configure local checkpoints for a MySQL Cluster do not exist in isolation, but rather are very much interdependent on each other. In this section, we illustrate how these parameters — including `DataMemory`, `IndexMemory`, `NoOfDiskPagesToDiskAfterRestartTUP`, `NoOfDiskPagesToDiskAfterRestartACC`, and `NoOfFragmentLogFiles` — relate to one another in a working Cluster.

In this example, we assume that our application performs the following numbers of types of operations per hour:

- 50000 selects
- 15000 inserts
- 15000 updates
- 15000 deletes

We also make the following assumptions about the data used in the application:

- We are working with a single table having 40 columns.
- Each column can hold up to 32 bytes of data.
- A typical `UPDATE` run by the application affects the values of 5 columns.
- No `NULL` values are inserted by the application.

A good starting point is to determine the amount of time that should elapse between local checkpoints (LCPs). It is worth noting that, in the event of a system restart, it takes 40-60 percent of this interval to execute the REDO log — for example, if the time between LCPs is 5 minutes (300 seconds), then it should take 2 to 3 minutes (120 to 180 seconds) for the REDO log to be read.

The maximum amount of data per node can be assumed to be the size of the `DataMemory` parameter. In this example, we assume that this is 2 GB. The `NoOfDiskPagesToDiskAfterRestartTUP` parameter represents the amount of data to be checkpointed per unit time — however, this parameter is actually expressed as the number of 8K memory pages to be checkpointed per 100 milliseconds. 2 GB per 300 seconds is approximately 6.8 MB per second, or 700 KB per 100 milliseconds, which works out to roughly 85 pages per 100 milliseconds.

Similarly, we can calculate `NoOfDiskPagesToDiskAfterRestartACC` in terms of the time for local checkpoints and the amount of memory required for indexes — that is, the `IndexMemory`. Assuming that we allow 512 MB for indexes, this works out to approximately 20 8-KB pages per 100 milliseconds for this parameter.

Next, we need to determine the number of REDO log files required — that is, fragment log files — the corresponding parameter being `NoOfFragmentLogFiles`. We need to make sure that there are sufficient REDO log files for keeping records for at least 3 local checkpoints. In a production setting, there are always uncertainties — for instance, we cannot be sure that disks always operate at top speed or with maximum throughput. For this reason, it is best to err on the side of caution, so we double our requirement and calculate a number of fragment log files which should be enough to keep records covering 6 local checkpoints.

It is also important to remember that the disk also handles writes to the REDO log and UNDO log, so if you find that the amount of data being written to disk as determined by the values of `NoOfDiskPagesToDiskAfterRestartACC` and `NoOfDiskPagesToDiskAfterRestartTUP` is approaching the amount of disk bandwidth available, you may wish to increase the time between local checkpoints.

Given 5 minutes (300 seconds) per local checkpoint, this means that we need to support writing log records at maximum speed for  $6 * 300 = 1800$  seconds. The size of a REDO log record is 72 bytes plus 4 bytes per updated column value plus the maximum size of the updated column, and there is one REDO log record for each table record updated in a transaction, on each node where the data reside. Using the numbers of operations set out previously in this section, we derive the following:

- 50000 select operations per hour yields 0 log records (and thus 0 bytes), since `SELECT` statements are not recorded in the REDO log.
- 15000 `DELETE` statements per hour is approximately 5 delete operations per second. (Since we wish to be conservative in our estimate, we round up here and in the following calculations.) No columns are updated by deletes, so these statements consume only 5 operations \* 72 bytes per operation = 360 bytes per second.
- 15000 `UPDATE` statements per hour is roughly the same as 5 updates per second. Each update uses 72 bytes, plus 4 bytes per column \* 5 columns updated, plus 32 bytes per column \* 5 columns — this works out to  $72 + 20 + 160 = 252$  bytes per operation, and multiplying this by 5 operation per second yields 1260 bytes per second.
- 15000 `INSERT` statements per hour is equivalent to 5 insert operations per second. Each insert requires REDO log space of 72 bytes, plus 4 bytes per record \* 40 columns, plus 32 bytes per column \* 40 columns, which is  $72 + 160 + 1280 = 1512$  bytes per operation. This times 5 operations per second yields 7560 bytes per second.

So the total number of REDO log bytes being written per second is approximately  $0 + 360 + 1260 + 7560 = 9180$  bytes. Multiplied by 1800 seconds, this yields 16524000 bytes required for REDO logging, or approximately 15.75 MB. The unit used for `NoOfFragmentLogFiles` represents a set of 4 16-MB log files — that is, 64 MB. Thus, the minimum value (3) for this parameter is sufficient for the scenario envisioned in this example, since 3 times 64 = 192 MB, or about 12 times what is required; the default value of 8 (or 512 MB) is more than ample in this case.

A copy of each altered table record is kept in the UNDO log. In the scenario discussed above, the UNDO log would not require any more space than what is provided by the default settings. However, given the size of disks, it is sensible to allocate at least 1 GB for it.

## 17.4. MySQL Cluster Options and Variables

This section provides information about MySQL server options, server and status variables that are specific to MySQL Cluster. For general information on using these, and for other options and variables not specific to MySQL Cluster, see [Section 5.1, “The](#)

MySQL Server”.

For MySQL Cluster configuration parameters used in the cluster configuration file (usually named `config.ini`), see [Section 17.3, “MySQL Cluster Configuration”](#).

## 17.4.1. MySQL Cluster Server Option and Variable Reference

The following table provides a list of the command-line options, server and status variables applicable within `mysqld` when it is running as an SQL node in a MySQL Cluster. For a table showing *all* command-line options, server and status variables available for use with `mysqld`, see [Section 5.1.1, “Server Option and Variable Reference”](#).

**Table 17.4. `mysqld` Option/Variable Reference**

Name	Cmd-Line	Option file	System Var	Status Var	Var Scope	Dynamic
<a href="#">Handler_discover</a>				Yes	Both	No
<a href="#">have_ndbcluster</a>			Yes		Global	No
<a href="#">ndb_autoincrement_prefetch_sz</a>	Yes	Yes	Yes		Both	Yes
<a href="#">ndb_cache_check_time</a>	Yes	Yes	Yes		Global	Yes
<a href="#">Ndb_cluster_node_id</a>				Yes	Both	No
<a href="#">Ndb_config_from_host</a>				Yes	Both	No
<a href="#">Ndb_config_from_port</a>				Yes	Both	No
<a href="#">ndb_force_send</a>	Yes	Yes	Yes		Both	Yes
<a href="#">ndb_index_stat_cache_entries</a>	Yes	Yes				
<a href="#">ndb_index_stat_enable</a>	Yes	Yes				
<a href="#">ndb_index_stat_update_freq</a>	Yes	Yes				
<a href="#">ndb-mgmd-host</a>	Yes	Yes				
<a href="#">ndb-nodeid</a>	Yes	Yes		Yes	Global	No
<a href="#">ndb_optimized_node_selection</a>	Yes	Yes				
<a href="#">ndb_report_thresh_binlog_epoch_slip</a>	Yes	Yes				
<a href="#">ndb_report_thresh_binlog_mem_usage</a>	Yes	Yes				
<a href="#">ndb_use_exact_count</a>			Yes		Both	Yes
<a href="#">ndb_use_transactions</a>	Yes	Yes				
<a href="#">ndbcluster</a>	Yes	Yes				

## 17.4.2. `mysqld` Command Options for MySQL Cluster

This section provides descriptions of `mysqld` server options relating to MySQL Cluster. For information about `mysqld` options not specific to MySQL Cluster, and for general information about the use of options with `mysqld`, see [Section 5.1.2, “Server Command Options”](#).

For information about command-line options used with other MySQL Cluster processes (`ndbd`, `ndb_mgmd`, and `ndb_mgm`), see [Section 17.6.21, “Options Common to MySQL Cluster Programs”](#). For information about command-line options used with NDB utility programs (such as `ndb_desc`, `ndb_size.pl`, and `ndb_show_tables`), see [Section 17.6, “MySQL Cluster Programs”](#).

- `--ndb-connectstring=connect_string`

<b>Command Line Format</b>	<code>--ndb-connectstring</code>	
<b>Config File Format</b>	<code>ndb-connectstring</code>	
<b>Value Set</b>	<b>Type</b>	<code>string</code>

When using the `NDBCLUSTER` storage engine, this option specifies the management server that distributes cluster configuration data. See [Section 17.3.4.2, “The MySQL Cluster Connectstring”](#), for syntax.

- `--ndbcluster`

<b>Command Line Format</b>	<code>--ndbcluster</code>	
<b>Config File Format</b>	<code>ndbcluster</code>	
<b>Value Set</b>	<b>Type</b>	<code>boolean</code>
	<b>Default</b>	<code>FALSE</code>

The `NDBCLUSTER` storage engine is necessary for using MySQL Cluster. If a `mysqld` binary includes support for the `NDBCLUSTER` storage engine, the engine is disabled by default. Use the `--ndbcluster` option to enable it. Use `--skip-ndbcluster` to explicitly disable the engine.

- `--ndb-nodeid=#`

<b>Version Introduced</b>	5.0.45	
<b>Command Line Format</b>	<code>--ndb-nodeid=#</code>	
<b>Config File Format</b>	<code>ndb-nodeid</code>	
<b>Variable Name</b>	<code>Ndb_cluster_node_id</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	No	
<b>Value Set (&gt;= 5.0.45)</b>	<b>Type</b>	<code>numeric</code>
	<b>Range</b>	<code>1-63</code>

Set this MySQL server's node ID in a MySQL Cluster. This can be used instead of specifying the node ID as part of the connectstring or in the `config.ini` file, or allowing the cluster to determine an arbitrary node ID. If you use this option, then `--ndb-nodeid` must be specified *before* `--ndb-connectstring`. If `--ndb-nodeid` is used *and* a node ID is specified in the connectstring, then the MySQL server will not be able to connect to the cluster. In addition, if `--nodeid` is used, then either a matching node ID must be found in a `[mysqld]` or `[api]` section of `config.ini`, or there must be an “open” `[mysqld]` or `[api]` section in the file (that is, a section without an `Id` parameter specified).

Regardless of how the node ID is determined, its is shown as the value of the global status variable `Ndb_cluster_node_id` in the output of `SHOW STATUS`, and as `cluster_node_id` in the `connection` row of the output of `SHOW ENGINE NDBCLUSTER STATUS`.

For more information about node IDs for MySQL Cluster SQL nodes, see [Section 17.3.4.6, “Defining SQL and Other API Nodes in a MySQL Cluster”](#).

- `--skip-ndbcluster`

<b>Command Line Format</b>	<code>--skip-ndbcluster</code>
<b>Config File Format</b>	<code>skip-ndbcluster</code>

Disable the `NDBCLUSTER` storage engine. This is the default for binaries that were built with `NDBCLUSTER` storage engine support; the server allocates memory and other resources for this storage engine only if the `--ndbcluster` option is given explicitly. See [Section 17.3.3, “Quick Test Setup of MySQL Cluster”](#), for an example.

### 17.4.3. MySQL Cluster System Variables

This section provides detailed information about MySQL server system variables that are specific to MySQL Cluster and the `NDB` storage engine. For system variables not specific to MySQL Cluster, see [Section 5.1.3, “Server System Variables”](#). For general information on using system variables, see [Section 5.1.5, “Using System Variables”](#).

- `have_ndbcluster`

<b>Variable Name</b>	<code>have_ndbcluster</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	No	
<b>Value Set</b>	<b>Type</b>	<code>boolean</code>

YES if `mysqld` supports `NDBCLUSTER` tables. `DISABLED` if `--skip-ndbcluster` is used.

- `multi_range_count`

<b>Version Introduced</b>	5.0.3	
<b>Command Line Format</b>	<code>--multi_range_count=#</code>	
<b>Config File Format</b>	<code>multi_range_count</code>	
<b>Option Sets Variable</b>	Yes, <code>multi_range_count</code>	
<b>Variable Name</b>	<code>multi_range_count</code>	
<b>Variable Scope</b>	Both	
<b>Dynamic Variable</b>	Yes	
<b>Value Set</b>	<b>Type</b>	numeric
	<b>Default</b>	256
	<b>Range</b>	1-4294967295

The maximum number of ranges to send to a table handler at once during range selects. The default value is 256. Sending multiple ranges to a handler at once can improve the performance of certain selects dramatically. This is especially true for the `NDBCLUSTER` table handler, which needs to send the range requests to all nodes. Sending a batch of those requests at once reduces communication costs significantly.

This variable was added in MySQL 5.0.3.

- `ndb_autoincrement_prefetch_sz`

<b>Command Line Format</b>	<code>--ndb_autoincrement_prefetch_sz</code>	
<b>Config File Format</b>	<code>ndb_autoincrement_prefetch_sz</code>	
<b>Option Sets Variable</b>	Yes, <code>ndb_autoincrement_prefetch_sz</code>	
<b>Variable Name</b>	<code>ndb_autoincrement_prefetch_sz</code>	
<b>Variable Scope</b>	Both	
<b>Dynamic Variable</b>	Yes	
<b>Value Set (&lt;= 5.0.54)</b>	<b>Type</b>	numeric
	<b>Default</b>	32
	<b>Range</b>	1-256
<b>Value Set (&gt;= 5.0.56)</b>	<b>Type</b>	numeric
	<b>Default</b>	1
	<b>Range</b>	1-256

Determines the probability of gaps in an autoincremented column. Set it to `1` to minimize this. Setting it to a high value for optimization — makes inserts faster, but decreases the likelihood that consecutive autoincrement numbers will be used in a batch of inserts. Default value: `32`. Minimum value: `1`.

Beginning with MySQL 5.0.56, this variable affects the number of `AUTO_INCREMENT` IDs that are fetched between statements only. Within a statement, at least 32 IDs are now obtained at a time. The default value for `ndb_autoincrement_prefetch_sz` is now `1`, to increase the speed of statements inserting single rows. ([Bug#31956](#))

- `ndb_cache_check_time`

<b>Command Line Format</b>	<code>--ndb_cache_check_time</code>	
<b>Config File Format</b>	<code>ndb_cache_check_time</code>	
<b>Option Sets Variable</b>	Yes, <code>ndb_cache_check_time</code>	
<b>Variable Name</b>	<code>ndb_cache_check_time</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	Yes	
<b>Value Set</b>	<b>Type</b>	numeric
	<b>Default</b>	

	<b>Default</b>	0
--	----------------	---

The number of milliseconds that elapse between checks of MySQL Cluster SQL nodes by the MySQL query cache. Setting this to 0 (the default and minimum value) means that the query cache checks for validation on every query.

The recommended maximum value for this variable is 1000, which means that the check is performed once per second. A larger value means that the check is performed and possibly invalidated due to updates on different SQL nodes less often. It is generally not desirable to set this to a value greater than 2000.

- `ndb_force_send`

<b>Command Line Format</b>	<code>--ndb-force-send</code>	
<b>Config File Format</b>	<code>ndb_force_send</code>	
<b>Option Sets Variable</b>	Yes, <code>ndb_force_send</code>	
<b>Variable Name</b>	<code>ndb_force_send</code>	
<b>Variable Scope</b>	Both	
<b>Dynamic Variable</b>	Yes	
<b>Value Set</b>	<b>Type</b>	boolean
	<b>Default</b>	TRUE

Forces sending of buffers to **NDB** immediately, without waiting for other threads. Defaults to **ON**.

- `ndb_index_stat_cache_entries`

<b>Command Line Format</b>	<code>--ndb_index_stat_cache_entries</code>	
<b>Config File Format</b>	<code>ndb_index_stat_cache_entries</code>	
<b>Value Set</b>	<b>Type</b>	numeric
	<b>Default</b>	32
	<b>Range</b>	0-4294967295

Sets the granularity of the statistics by determining the number of starting and ending keys to store in the statistics memory cache. Zero means no caching takes place; in this case, the data nodes are always queried directly. Default value: **32**.

- `ndb_index_stat_enable`

<b>Command Line Format</b>	<code>--ndb_index_stat_enable</code>	
<b>Config File Format</b>	<code>ndb_index_stat_enable</code>	
<b>Value Set</b>	<b>Type</b>	boolean
	<b>Default</b>	ON

Use **NDB** index statistics in query optimization. Defaults to **ON**.

- `ndb_index_stat_update_freq`

<b>Command Line Format</b>	<code>--ndb_index_stat_update_freq</code>	
<b>Config File Format</b>	<code>ndb_index_stat_update_freq</code>	
<b>Value Set</b>	<b>Type</b>	numeric
	<b>Default</b>	20
	<b>Range</b>	0-4294967295

How often to query data nodes instead of the statistics cache. For example, a value of **20** (the default) means to direct every 20<sup>th</sup> query to the data nodes.

- `ndb_optimized_node_selection`

<b>Command Line Format</b>	<code>--ndb-optimized-node-selection</code>	
<b>Config File Format</b>	<code>ndb_optimized_node_selection</code>	
<b>Value Set</b>	<b>Type</b>	boolean
	<b>Default</b>	ON

Causes an SQL node to use the “closest” data node as transaction coordinator. For this purpose, a data node having a shared memory connection with the SQL node is considered to be “closest” to the SQL node; the next closest (in order of decreasing proximity) are: TCP connection to `localhost`; SCI connection; TCP connection from a host other than `localhost`.

This option is enabled by default. Set to `0` or `OFF` to disable it, in which case the SQL node uses each data node in the cluster in succession. When this option is disabled each SQL thread attempts to use a given data node 8 times before proceeding to the next one.

- `ndb_report_thresh_binlog_epoch_slip`

<b>Command Line Format</b>	<code>--ndb_report_thresh_binlog_epoch_slip</code>	
<b>Config File Format</b>	<code>ndb_report_thresh_binlog_epoch_slip</code>	
<b>Value Set</b>	<b>Type</b>	numeric
	<b>Default</b>	3
	<b>Range</b>	0-256

This is a threshold on the number of epochs to be behind before reporting binlog status. For example, a value of `3` (the default) means that if the difference between which epoch has been received from the storage nodes and which epoch has been applied to the binlog is 3 or more, a status message will be sent to the cluster log.

- `ndb_report_thresh_binlog_mem_usage`

<b>Command Line Format</b>	<code>--ndb_report_thresh_binlog_mem_usage</code>	
<b>Config File Format</b>	<code>ndb_report_thresh_binlog_mem_usage</code>	
<b>Value Set</b>	<b>Type</b>	numeric
	<b>Default</b>	10
	<b>Range</b>	0-10

This is a threshold on the percentage of free memory remaining before reporting binlog status. For example, a value of `10` (the default) means that if the amount of available memory for receiving binlog data from the data nodes falls below 10%, a status message will be sent to the cluster log.

- `ndb_use_exact_count`

<b>Variable Name</b>	<code>ndb_use_exact_count</code>	
<b>Variable Scope</b>	Both	
<b>Dynamic Variable</b>	Yes	
<b>Value Set</b>	<b>Type</b>	boolean
	<b>Default</b>	ON

Forces `NDB` to use a count of records during `SELECT COUNT(*)` query planning to speed up this type of query. The default value is `ON`. For faster queries overall, disable this feature by setting the value of `ndb_use_exact_count` to `OFF`.

- `ndb_use_transactions`

<b>Command Line Format</b>	<code>--ndb_use_transactions</code>	
<b>Config File Format</b>	<code>ndb_use_transactions</code>	
<b>Value Set</b>	<b>Type</b>	boolean

	<b>Default</b>	ON
--	----------------	----

You can disable [NDB](#) transaction support by setting this variable's values to `OFF` (not recommended). The default is `ON`.

## 17.4.4. MySQL Cluster Status Variables

This section provides detailed information about MySQL server status variables that relate to MySQL Cluster and the [NDB](#) storage engine. For status variables not specific to MySQL Cluster, and for general information on using status variables, see [Section 5.1.6, “Server Status Variables”](#).

- [Handler\\_discover](#)

The MySQL server can ask the [NDBCLUSTER](#) storage engine if it knows about a table with a given name. This is called discovery. [Handler\\_discover](#) indicates the number of times that tables have been discovered via this mechanism.

- [Ndb\\_cluster\\_node\\_id](#)

If the server is acting as a MySQL Cluster node, then the value of this variable is its node ID in the cluster.

If the server is not part of a MySQL Cluster, then the value of this variable is 0.

- [Ndb\\_config\\_from\\_host](#)

If the server is part of a MySQL Cluster, the value of this variable is the host name or IP address of the Cluster management server from which it gets its configuration data.

If the server is not part of a MySQL Cluster, then the value of this variable is an empty string.

Prior to MySQL 5.0.23, this variable was named [Ndb\\_connected\\_host](#).

- [Ndb\\_config\\_from\\_port](#)

If the server is part of a MySQL Cluster, the value of this variable is the number of the port through which it is connected to the Cluster management server from which it gets its configuration data.

If the server is not part of a MySQL Cluster, then the value of this variable is 0.

Prior to MySQL 5.0.23, this variable was named [Ndb\\_connected\\_port](#).

- [Ndb\\_number\\_of\\_data\\_nodes](#)

If the server is part of a MySQL Cluster, the value of this variable is the number of data nodes in the cluster.

If the server is not part of a MySQL Cluster, then the value of this variable is 0.

Prior to MySQL 5.0.29, this variable was named [Ndb\\_number\\_of\\_storage\\_nodes](#).

## 17.5. Upgrading and Downgrading MySQL Cluster

This portion of the MySQL Cluster chapter covers upgrading and downgrading a MySQL Cluster from one MySQL release to another. It discusses different types of Cluster upgrades and downgrades, and provides a Cluster upgrade/downgrade compatibility matrix (see [Section 17.5.2, “MySQL Cluster 5.0 Upgrade and Downgrade Compatibility”](#)). You are expected already to be familiar with installing and configuring a MySQL Cluster prior to attempting an upgrade or downgrade. See [Section 17.3, “MySQL Cluster Configuration”](#).

This section remains in development, and continues to be updated and expanded.

### 17.5.1. Performing a Rolling Restart of a MySQL Cluster

This section discusses how to perform a *rolling restart* of a MySQL Cluster installation, so called because it involves stopping and starting (or restarting) each node in turn, so that the cluster itself remains operational. This is often done as part of a *rolling upgrade* or *rolling downgrade*, where high availability of the cluster is mandatory and no downtime of the cluster as a whole is permissible. Where we refer to upgrades, the information provided here also generally applies to downgrades as well.

There are a number of reasons why a rolling restart might be desirable:

- **Cluster configuration change.** To make a change in the cluster's configuration, such as adding an SQL node to the cluster, or setting a configuration parameter to a new value.
- **Cluster software upgrade/downgrade.** To upgrade the cluster to a newer version of the MySQL Cluster software (or to downgrade it to an older version). This is usually referred to as a “rolling upgrade” (or “rolling downgrade”, when reverting to an older version of MySQL Cluster).
- **Change on node host.** To make changes in the hardware or operating system on which one or more cluster nodes are running
- **Cluster reset.** To reset the cluster because it has reached an undesirable state
- **Freeing of resources.** To allow memory allocated to a table by successive `INSERT` and `DELETE` operations to be freed for re-use by other Cluster tables

The process for performing a rolling restart may be generalised as follows:

1. Stop all cluster management nodes (`ndb_mgmd` processes), reconfigure them, then restart them
2. Stop, reconfigure, then restart each cluster data node (`ndbd` process) in turn
3. Stop, reconfigure, then restart each cluster SQL node (`mysqld` process) in turn

The specifics for implementing a particular rolling upgrade depend upon the actual changes being made. A more detailed view of the process is presented here:

<b>RESTART TYPE:</b>					
<b>Cluster Configuration Change</b>		<b>Cluster Software Upgrade or Downgrade</b>	<b>Change on Node Host</b>	<b>Cluster Reset</b>	
<b>A. Management node (ndb_mgmd) processes...</b>					
1. Stop all ndb_mgmd processes 2. Make changes in global configuration file(s) 3. Start all ndb_mgmd processes		1. Stop all ndb_mgmd processes 2. Replace each ndb_mgmd binary with new version 3. Start ndb_mgmd processes	1. Stop all ndb_mgmd processes 2. Make desired changes in hardware, operating system, or both 3. Start all ndb_mgmd processes	<b>( OR )</b>	
				1. Stop all ndb_mgmd processes 2. Start all ndb_mgmd processes	Restart all ndb_mgmd processes (optional)
<b>B. For each data node (ndbd) process...</b>					
<b>( OR )</b>		1. Stop ndbd 2. Replace ndbd binary with new version 3. Start ndbd	1. Stop ndbd 2. Make desired changes in hardware, operating system, or both 3. Start ndbd	<b>( OR )</b>	
1. Stop ndbd 2. Start ndbd	Restart ndbd			1. Stop ndbd 2. Start ndbd	Restart ndbd
<b>C. For each SQL node (mysqld) process...</b>					
<b>( OR )</b>		1. Stop mysqld 2. Replace mysqld binary with new version 3. Start mysqld	1. Stop mysqld 2. Make desired changes in hardware, operating system, or both 3. Start mysqld	<b>( OR )</b>	
1. Stop mysqld 2. Start mysqld	Restart mysqld			1. Stop mysqld 2. Start mysqld	Restart mysqld

In the previous diagram, **Stop** and **Start** steps indicate that the process must be stopped completely using a shell command (such as `kill` on most Unix systems) or the management client `STOP` command, then started again from a system shell by invoking the `ndbd` or `ndb_mgmd` executable as appropriate. **Restart** indicates the process may be restarted using the `ndb_mgm` management client `RESTART` command.

**Important**

When performing an upgrade or downgrade of the cluster software, you *must* upgrade or downgrade the management nodes *first*, then the data nodes, and finally the SQL nodes. Doing so in any other order may leave the cluster in an unusable state.

## 17.5.2. MySQL Cluster 5.0 Upgrade and Downgrade Compatibility

This section provides information about MySQL Cluster software and table file compatibility between MySQL 5.0 releases with

regard to performing upgrades and downgrades.

**Important**

Only compatibility between MySQL versions with regard to [NDBCLUSTER](#) is taken into account in this section, and there are likely other issues to be considered. *As with any other MySQL software upgrade or downgrade, you are strongly encouraged to review the relevant portions of the MySQL Manual for the MySQL versions from which and to which you intend to migrate, before attempting an upgrade or downgrade of the MySQL Cluster software. See [Section 2.18.1, “Upgrading MySQL”](#).*

The following table shows Cluster upgrade and downgrade compatibility between different releases of MySQL 5.0:

**Notes.**

- MySQL 5.0.2 was the first public release in this series.
- Direct upgrades or downgrades between MySQL Cluster 4.1 and 5.0 are not supported; you must dump all `NDBCLUSTER` tables using `mysqldump`, install the new version of the software, and then reload the tables from the dump.
- Online downgrades from MySQL Cluster 5.0.12 to 5.0.11 (or earlier) are not supported.
- You cannot restore with `ndb_restore` to a MySQL 5.0 Cluster using a backup made from a Cluster running MySQL 5.1. You must use `mysqldump` in such cases.
- There was no public release of MySQL 5.0.23.

## 17.6. MySQL Cluster Programs

Using and managing a MySQL Cluster requires several specialized programs, which we describe in this chapter. We discuss the purposes of these programs in a MySQL Cluster, how to use the programs, and what startup options are available for each of them.

These programs include the MySQL Cluster data, management, and SQL node process daemons (`ndbd`, `ndb_mgmd`, and `mysqld`) and the management client (`ndb_mgm`).

Other NDB utility, diagnostic, and example programs are included with the MySQL Cluster distribution. These include `ndb_restore`, `ndb_show_tables`, and `ndb_config`. These programs are covered later in this chapter.

The last two sections of this chapter contain tables of options used, respectively, with `mysqld` and with the various NDB programs.

### 17.6.1. MySQL Server Usage for MySQL Cluster

`mysqld` is the traditional MySQL server process. To be used with MySQL Cluster, `mysqld` needs to be built with support for the `NDBCLUSTER` storage engine, as it is in the precompiled binaries available from <http://dev.mysql.com/downloads/>. If you build MySQL from source, you must invoke `configure` with the `--with-ndbcluster` option to enable `NDB Cluster` storage engine support.

If the `mysqld` binary has been built with Cluster support, the `NDBCLUSTER` storage engine is still disabled by default. You can use either of two possible options to enable this engine:

- Use `--ndbcluster` as a startup option on the command line when starting `mysqld`.
- Insert a line containing `NDBCLUSTER` in the `[mysqld]` section of your `my.cnf` file.

An easy way to verify that your server is running with the `NDBCLUSTER` storage engine enabled is to issue the `SHOW ENGINES` statement in the MySQL Monitor (`mysql`). You should see the value `YES` as the `Support` value in the row for `NDBCLUSTER`. If you see `NO` in this row or if there is no such row displayed in the output, you are not running an `NDB`-enabled version of MySQL. If you see `DISABLED` in this row, you need to enable it in either one of the two ways just described.

To read cluster configuration data, the MySQL server requires at a minimum three pieces of information:

- The MySQL server's own cluster node ID
- The host name or IP address for the management server (MGM node)
- The number of the TCP/IP port on which it can connect to the management server

Node IDs can be allocated dynamically, so it is not strictly necessary to specify them explicitly.

The `mysqld` parameter `ndb-connectstring` is used to specify the connectstring either on the command line when starting `mysqld` or in `my.cnf`. The connectstring contains the host name or IP address where the management server can be found, as well as the TCP/IP port it uses.

In the following example, `ndb_mgmd.mysql.com` is the host where the management server resides, and the management server listens for cluster messages on port 1186:

```
shell> mysqld --ndbcluster --ndb-connectstring=ndb_mgmd.mysql.com:1186
```

See [Section 17.3.4.2, “The MySQL Cluster Connectstring”](#), for more information on connectstrings.

Given this information, the MySQL server will be a full participant in the cluster. (We often refer to a `mysqld` process running in this manner as an SQL node.) It will be fully aware of all cluster data nodes as well as their status, and will establish connections to all data nodes. In this case, it is able to use any data node as a transaction coordinator and to read and update node data.

You can see in the `mysql` client whether a MySQL server is connected to the cluster using `SHOW PROCESSLIST`. If the MySQL server is connected to the cluster, and you have the `PROCESS` privilege, then the first row of the output is as shown here:

```
mysql> SHOW PROCESSLIST \G
***** 1. row *****
  Id: 1
  User: system user
  Host:
  db:
Command: Daemon
  Time: 1
  State: Waiting for event from ndbcluster
  Info: NULL
```

### Important

To participate in a MySQL Cluster, the `mysqld` process must be started with *both* the options `--ndbcluster` and `--ndb-connectstring` (or their equivalents in `my.cnf`). If `mysqld` is started with only the `--ndbcluster` option, or if it is unable to contact the cluster, it is not possible to work with NDB tables, *nor is it possible to create any new tables regardless of storage engine*. The latter restriction is a safety measure intended to prevent the creation of tables having the same names as NDB tables while the SQL node is not connected to the cluster. If you wish to create tables using a different storage engine while the `mysqld` process is not participating in a MySQL Cluster, you must restart the server *without* the `--ndbcluster` option.

## 17.6.2. `ndbd` — The MySQL Cluster Data Node Daemon

`ndbd` is the process that is used to handle all the data in tables using the NDB Cluster storage engine. This is the process that empowers a data node to accomplish distributed transaction handling, node recovery, checkpointing to disk, online backup, and related tasks.

In a MySQL Cluster, a set of `ndbd` processes cooperate in handling data. These processes can execute on the same computer (host) or on different computers. The correspondences between data nodes and Cluster hosts is completely configurable.

The following list describes command options specific to the MySQL Cluster data node program `ndbd`. For options common to all `NDBCLUSTER` programs, see [Section 17.6.21, “Options Common to MySQL Cluster Programs”](#).

- `--bind-address`

<b>Version Introduced</b>	5.0.29	
<b>Command Line Format</b>	<code>--bind-address=name</code>	
<b>Value Set</b>	<b>Type</b>	<code>string</code>
	<b>Default</b>	

Causes `ndbd` to bind to a specific network interface (host name or IP address). This option has no default value.

This option was added in MySQL 5.0.29.

- `--daemon, -d`

<b>Command Line Format</b>	<code>--daemon</code>	
<b>Value Set</b>	<b>Type</b>	<code>boolean</code>
	<b>Default</b>	<code>TRUE</code>

Instructs `ndbd` to execute as a daemon process. This is the default behavior. `--nodaemon` can be used to prevent the process from running as a daemon.

- `--initial`

<b>Command Line Format</b>	<code>--initial</code>	
<b>Value Set</b>	<b>Type</b>	boolean
	<b>Default</b>	FALSE

Instructs `ndbd` to perform an initial start. An initial start erases any files created for recovery purposes by earlier instances of `ndbd`. It also re-creates recovery log files. Note that on some operating systems this process can take a substantial amount of time.

An `--initial` start is to be used *only* when starting the `ndbd` process under very special circumstances; this is because this option causes all files to be removed from the Cluster file system and all redo log files to be re-created. These circumstances are listed here:

- When performing a software upgrade which has changed the contents of any files.
- When restarting the node with a new version of `ndbd`.
- As a measure of last resort when for some reason the node restart or system restart repeatedly fails. In this case, be aware that this node can no longer be used to restore data due to the destruction of the data files.

### Important

This option does *not* affect any backup files that have already been created by the affected node.

It is permissible to use this option when starting the cluster for the very first time (that is, before any data node files have been created); however, it is *not* necessary to do so.

- `--initial-start`

<b>Version Introduced</b>	5.0.21	
<b>Command Line Format</b>	<code>--initial-start</code>	
<b>Value Set</b>	<b>Type</b>	boolean
	<b>Default</b>	FALSE

This option is used when performing a partial initial start of the cluster. Each node should be started with this option, as well as `--nowait-nodes`.

For example, suppose you have a 4-node cluster whose data nodes have the IDs 2, 3, 4, and 5, and you wish to perform a partial initial start using only nodes 2, 4, and 5 — that is, omitting node 3:

```
ndbd --ndbd-nodeid=2 --nowait-nodes=3 --initial-start
ndbd --ndbd-nodeid=4 --nowait-nodes=3 --initial-start
ndbd --ndbd-nodeid=5 --nowait-nodes=3 --initial-start
```

This option was added in MySQL 5.0.21.

- `--nowait-nodes=node_id_1[, node_id_2[, ...]]`

<b>Version Introduced</b>	5.0.21	
<b>Command Line Format</b>	<code>--nowait-nodes=list</code>	
<b>Value Set</b>	<b>Type</b>	string
	<b>Default</b>	

This option takes a list of data nodes which for which the cluster will not wait for before starting.

This can be used to start the cluster in a partitioned state. For example, to start the cluster with only half of the data nodes (nodes 2, 3, 4, and 5) running in a 4-node cluster, you can start each `ndbd` process with `--nowait-nodes=3,5`. In this case, the cluster starts as soon as nodes 2 and 4 connect, and does *not* wait `StartPartitionedTimeout` milliseconds for nodes 3 and 5 to connect as it would otherwise.

If you wanted to start up the same cluster as in the previous example without one `ndbd` — say, for example, that the host machine for node 3 has suffered a hardware failure — then start nodes 2, 4, and 5 with `--nowait-nodes=3`. Then the cluster will start as soon as nodes 2, 4, and 5 connect and will not wait for node 3 to start.

This option was added in MySQL 5.0.21.

- `--nodaemon`

<b>Command Line Format</b>	<code>--nodaemon</code>	
<b>Value Set</b>	<b>Type</b>	<code>boolean</code>
	<b>Default</b>	<code>FALSE</code>

Instructs `ndbd` not to start as a daemon process. This is useful when `ndbd` is being debugged and you want output to be redirected to the screen.

- `--nostart, -n`

<b>Command Line Format</b>	<code>--nostart</code>	
<b>Value Set</b>	<b>Type</b>	<code>boolean</code>
	<b>Default</b>	<code>FALSE</code>

Instructs `ndbd` not to start automatically. When this option is used, `ndbd` connects to the management server, obtains configuration data from it, and initializes communication objects. However, it does not actually start the execution engine until specifically requested to do so by the management server. This can be accomplished by issuing the proper `START` command in the management client (see [Section 17.7.2, “Commands in the MySQL Cluster Management Client”](#)).

`ndbd` generates a set of log files which are placed in the directory specified by `DataDir` in the `config.ini` configuration file.

These log files are listed below. `node_id` is the node's unique identifier. Note that `node_id` represents the node's unique identifier. For example, `ndb_2_error.log` is the error log generated by the data node whose node ID is 2.

- `ndb_node_id_error.log` is a file containing records of all crashes which the referenced `ndbd` process has encountered. Each record in this file contains a brief error string and a reference to a trace file for this crash. A typical entry in this file might appear as shown here:

```
Date/Time: Saturday 30 July 2004 - 00:20:01
Type of error: error
Message: Internal program error (failed ndbrequire)
Fault ID: 2341
Problem data: DbtupFixAlloc.cpp
Object of reference: DBTUP (Line: 173)
ProgramName: NDB Kernel
ProcessID: 14909
TraceFile: ndb_2_trace.log.2
***EOM***
```

Listings of possible `ndbd` exit codes and messages generated when a data node process shuts down prematurely can be found in [ndbd Error Messages](#).

### Important

*The last entry in the error log file is not necessarily the newest one* (nor is it likely to be). Entries in the error log are *not* listed in chronological order; rather, they correspond to the order of the trace files as determined in the `ndb_node_id_trace.log.next` file (see below). Error log entries are thus overwritten in a cyclical and not sequential fashion.

- `ndb_node_id_trace.log.trace_id` is a trace file describing exactly what happened just before the error occurred. This information is useful for analysis by the MySQL Cluster development team.

It is possible to configure the number of these trace files that will be created before old files are overwritten. `trace_id` is a number which is incremented for each successive trace file.

- `ndb_node_id_trace.log.next` is the file that keeps track of the next trace file number to be assigned.
- `ndb_node_id_out.log` is a file containing any data output by the `ndbd` process. This file is created only if `ndbd` is started as a daemon, which is the default behavior.
- `ndb_node_id.pid` is a file containing the process ID of the `ndbd` process when started as a daemon. It also functions as a lock file to avoid the starting of nodes with the same identifier.
- `ndb_node_id_signal.log` is a file used only in debug versions of `ndbd`, where it is possible to trace all incoming, outgoing, and internal messages with their data in the `ndbd` process.

It is recommended not to use a directory mounted through NFS because in some environments this can cause problems whereby the lock on the `.pid` file remains in effect even after the process has terminated.

To start `ndbd`, it may also be necessary to specify the host name of the management server and the port on which it is listening. Optionally, one may also specify the node ID that the process is to use.

```
shell> ndbd --connect-string="nodeid=2;host=ndb_mgmd.mysql.com:1186"
```

See [Section 17.3.4.2, “The MySQL Cluster Connectstring”](#), for additional information about this issue. [Section 17.6.2, “ndbd — The MySQL Cluster Data Node Daemon”](#), describes other options for `ndbd`.

When `ndbd` starts, it actually initiates two processes. The first of these is called the “angel process”; its only job is to discover when the execution process has been completed, and then to restart the `ndbd` process if it is configured to do so. Thus, if you attempt to kill `ndbd` via the Unix `kill` command, it is necessary to kill both processes, beginning with the angel process. The preferred method of terminating an `ndbd` process is to use the management client and stop the process from there.

The execution process uses one thread for reading, writing, and scanning data, as well as all other activities. This thread is implemented asynchronously so that it can easily handle thousands of concurrent actions. In addition, a watch-dog thread supervises the execution thread to make sure that it does not hang in an endless loop. A pool of threads handles file I/O, with each thread able to handle one open file. Threads can also be used for transporter connections by the transporters in the `ndbd` process. In a multi-processor system performing a large number of operations (including updates), the `ndbd` process can consume up to 2 CPUs if permitted to do so.

For a machine with many CPUs it is possible to use several `ndbd` processes which belong to different node groups; however, such a configuration is still considered experimental and is not supported for MySQL 5.0 in a production setting. See [Section 17.10, “Known Limitations of MySQL Cluster”](#).

### 17.6.3. `ndb_mgmd` — The MySQL Cluster Management Server Daemon

The management server is the process that reads the cluster configuration file and distributes this information to all nodes in the cluster that request it. It also maintains a log of cluster activities. Management clients can connect to the management server and check the cluster's status.

The following list includes options that are specific to `ndb_mgmd`. For options common to all NDB programs, see [Section 17.6.21, “Options Common to MySQL Cluster Programs”](#).

- `--config-file=filename, -f filename`

<b>Command Line Format</b>	<code>-f</code>	
<b>Value Set</b>	<b>Type</b>	<code>filename</code>
	<b>Default</b>	<code>./config.ini</code>

Instructs the management server as to which file it should use for its configuration file. By default, the management server looks for a file named `config.ini` in the same directory as the `ndb_mgmd` executable; otherwise the file name and location must be specified explicitly.

This option also can be given as `-c file_name`, but this shortcut is obsolete and should *not* be used in new installations.

- `--daemon, -d`

<b>Command Line Format</b>	<code>--daemon</code>	
<b>Value Set</b>	<b>Type</b>	<code>boolean</code>

	<b>Default</b>	TRUE
--	----------------	------

Instructs `ndb_mgmd` to start as a daemon process. This is the default behavior.

- `--nodaemon`

<b>Command Line Format</b>	<code>--nodaemon</code>	
<b>Value Set</b>	<b>Type</b>	boolean
	<b>Default</b>	FALSE

Instructs `ndb_mgmd` not to start as a daemon process.

- `--print-full-config, -P`

<b>Version Introduced</b>	5.0.10	
<b>Command Line Format</b>	<code>--print-full-config</code>	
<b>Value Set</b>	<b>Type</b>	boolean
	<b>Default</b>	FALSE

Shows extended information regarding the configuration of the cluster. With this option on the command line the `ndb_mgmd` process prints information about the cluster setup including an extensive list of the cluster configuration sections as well as parameters and their values. Normally used together with the `--config-file (-f)` option.

It is not strictly necessary to specify a connectstring when starting the management server. However, if you are using more than one management server, a connectstring should be provided and each node in the cluster should specify its node ID explicitly.

See [Section 17.3.4.2, “The MySQL Cluster Connectstring”](#), for information about using connectstrings. [Section 17.6.3, “ndb\\_mgmd — The MySQL Cluster Management Server Daemon”](#), describes other options for `ndb_mgmd`.

The following files are created or used by `ndb_mgmd` in its starting directory, and are placed in the `DataDir` as specified in the `config.ini` configuration file. In the list that follows, `node_id` is the unique node identifier.

- `config.ini` is the configuration file for the cluster as a whole. This file is created by the user and read by the management server. [Section 17.3, “MySQL Cluster Configuration”](#), discusses how to set up this file.
- `ndb_node_id_cluster.log` is the cluster events log file. Examples of such events include checkpoint startup and completion, node startup events, node failures, and levels of memory usage. A complete listing of cluster events with descriptions may be found in [Section 17.7, “Management of MySQL Cluster”](#).

When the size of the cluster log reaches one million bytes, the file is renamed to `ndb_node_id_cluster.log.seq_id`, where `seq_id` is the sequence number of the cluster log file. (For example: If files with the sequence numbers 1, 2, and 3 already exist, the next log file is named using the number 4.)

- `ndb_node_id_out.log` is the file used for `stdout` and `stderr` when running the management server as a daemon.
- `ndb_node_id.pid` is the process ID file used when running the management server as a daemon.

## 17.6.4. `ndb_mgm` — The MySQL Cluster Management Client

The `ndb_mgm` management client process is actually not needed to run the cluster. Its value lies in providing a set of commands for checking the cluster's status, starting backups, and performing other administrative functions. The management client accesses the management server using a C API. Advanced users can also employ this API for programming dedicated management processes to perform tasks similar to those performed by `ndb_mgm`.

To start the management client, it is necessary to supply the host name and port number of the management server:

```
shell> ndb_mgm [host_name [port_num]]
```

For example:

```
shell> ndb_mgm ndb_mgmd.mysql.com 1186
```

The default host name and port number are `localhost` and 1186, respectively.

The following list includes options that are specific to `ndb_mgm`. For options common to all NDB programs, see [Section 17.6.21](#), “Options Common to MySQL Cluster Programs”.

- `--try-reconnect=number`

<b>Command Line Format</b>	<code>--try-reconnect=#</code>	
<b>Value Set</b>	<b>Type</b>	<code>boolean</code>
	<b>Default</b>	<code>TRUE</code>

If the connection to the management server is broken, the node tries to reconnect to it every 5 seconds until it succeeds. By using this option, it is possible to limit the number of attempts to `number` before giving up and reporting an error instead.

Additional information about using `ndb_mgm` can be found in [Section 17.6.22.4](#), “Program Options for `ndb_mgm`”, and [Section 17.7.2](#), “Commands in the MySQL Cluster Management Client”.

## 17.6.5. `ndb_config` — Extract MySQL Cluster Configuration Information

This tool extracts configuration information for data nodes, SQL nodes, and API nodes from a cluster management node (and possibly its `config.ini` file).

**Usage:**

```
ndb_config options
```

The `options` available for this utility differ somewhat from those used with the other utilities, and so are listed in their entirety in the next section, followed by some examples.

**Options:**

- `--usage, --help, or -?`

<b>Command Line Format</b>	<code>--help</code>
----------------------------	---------------------

Causes `ndb_config` to print a list of available options, and then exit.

- `--version, -V`

<b>Command Line Format</b>	<code>-V</code>
----------------------------	-----------------

Causes `ndb_config` to print a version information string, and then exit.

- `--ndb-connectstring=connect_string`

<b>Command Line Format</b>	<code>--ndb-connectstring=name</code>	
<b>Value Set</b>	<b>Type</b>	<code>string</code>
	<b>Default</b>	<code>localhost:1186</code>

Specifies the connectstring to use in connecting to the management server. The format for the connectstring is the same as described in [Section 17.3.4.2](#), “The MySQL Cluster Connectstring”, and defaults to `localhost:1186`.

The use of `-c` as a short version for this option is supported for `ndb_config` beginning with MySQL 5.0.29.

- `--config-file=path-to-file`

Gives the path to the management server's configuration file (`config.ini`). This may be a relative or absolute path. If the management node resides on a different host from the one on which `ndb_config` is invoked, then an absolute path must be used.

- `--query=query-options, -q query-options`

<b>Command Line Format</b>	<code>--query=string</code>	
<b>Value Set</b>	<b>Type</b>	<code>string</code>
	<b>Default</b>	

This is a comma-delimited list of *query options* — that is, a list of one or more node attributes to be returned. These include `id` (node ID), `type` (node type — that is, `ndbd`, `mysqld`, or `ndb_mgmd`), and any configuration parameters whose values are to be obtained.

For example, `--query=id,type,indexmemory,datamemory` would return the node ID, node type, `DataMemory`, and `IndexMemory` for each node.

### Note

If a given parameter is not applicable to a certain type of node, then an empty string is returned for the corresponding value. See the examples later in this section for more information.

- `--host=hostname`

<b>Command Line Format</b>	<code>--host=name</code>	
<b>Value Set</b>	<b>Type</b>	<code>string</code>
	<b>Default</b>	

Specifies the host name of the node for which configuration information is to be obtained.

- `--id=node_id, --nodeid=node_id`

<b>Command Line Format</b>	<code>--ndb-nodeid=#</code>	
<b>Value Set</b>	<b>Type</b>	<code>numeric</code>
	<b>Default</b>	<code>0</code>

Used to specify the node ID of the node for which configuration information is to be obtained.

- `--nodes`

<b>Command Line Format</b>	<code>--nodes</code>	
<b>Value Set</b>	<b>Type</b>	<code>boolean</code>
	<b>Default</b>	<code>FALSE</code>

(Tells `ndb_config` to print information from parameters defined in `[ndbd]` sections only. Currently, using this option has no affect, since these are the only values checked, but it may become possible in future to query parameters set in `[tcp]` and other sections of cluster configuration files.)

- `--type=node_type`

<b>Command Line Format</b>	<code>--type=name</code>	
<b>Value Set</b>	<b>Type</b>	<code>enumeration</code>
	<b>Default</b>	
	<b>Valid Values</b>	<code>ndbd, mysqld, ndb_mgmd</code>

Filters results so that only configuration values applying to nodes of the specified *node\_type* (*ndbd*, *mysqld*, or *ndb\_mgmd*) are returned.

- `--fields=delimiter, -f delimiter`

<b>Command Line Format</b>	<code>--fields=string</code>	
<b>Value Set</b>	<b>Type</b>	<code>string</code>
	<b>Default</b>	

Specifies a *delimiter* string used to separate the fields in the result. The default is “,” (the comma character).

#### Note

If the *delimiter* contains spaces or escapes (such as `\n` for the linefeed character), then it must be quoted.

- `--rows=separator, -r separator`

<b>Command Line Format</b>	<code>--rows=string</code>	
<b>Value Set</b>	<b>Type</b>	<code>string</code>
	<b>Default</b>	

Specifies a *separator* string used to separate the rows in the result. The default is a space character.

#### Note

If the *separator* contains spaces or escapes (such as `\n` for the linefeed character), then it must be quoted.

#### Examples:

1. To obtain the node ID and type of each node in the cluster:

```
shell> ./ndb_config --query=id,type --fields=':' --rows='\n'
1:ndbd
2:ndbd
3:ndbd
4:ndbd
5:ndb_mgmd
6:mysqld
7:mysqld
8:mysqld
9:mysqld
```

In this example, we used the `--fields` options to separate the ID and type of each node with a colon character (:), and the `--rows` options to place the values for each node on a new line in the output.

2. To produce a connectstring that can be used by data, SQL, and API nodes to connect to the management server:

```
shell> ./ndb_config --config-file=/usr/local/mysql/cluster-data/config.ini --query=hostname,portnumber --fields=: -
192.168.0.179:1186
```

3. This invocation of `ndb_config` checks only data nodes (using the `--type` option), and shows the values for each node's ID and host name, and its `DataMemory`, `IndexMemory`, and `DataDir` parameters:

```
shell> ./ndb_config --type=ndbd --query=id,host,datamemory,indexmemory,datadir -f ' : ' -r '\n'
1 : 192.168.0.193 : 83886080 : 18874368 : /usr/local/mysql/cluster-data
2 : 192.168.0.112 : 83886080 : 18874368 : /usr/local/mysql/cluster-data
3 : 192.168.0.176 : 83886080 : 18874368 : /usr/local/mysql/cluster-data
4 : 192.168.0.119 : 83886080 : 18874368 : /usr/local/mysql/cluster-data
```

In this example, we used the short options `-f` and `-r` for setting the field delimiter and row separator, respectively.

4. To exclude results from any host except one in particular, use the `--host` option:

```
shell> ./ndb_config --host=192.168.0.176 -f : -r '\n' -q id,type
3:ndbd
```

```
5:ndb_mgmd
```

In this example, we also used the short form `-q` to determine the attributes to be queried.

Similarly, you can limit results to a node with a specific ID using the `--id` or `--nodeid` option.

## 17.6.6. `ndb_cpced` — Automate Testing for NDB Development

This utility is found in the `libexec` directory. It is part of an internal automated test framework used in testing and debugging MySQL Cluster. Because it can control processes on remote systems, it is not advisable to use `ndb_cpced` in a production cluster.

The source files for `ndb_cpced` may be found in the directory `storage/ndb/src/cw/cpced`, in the MySQL source tree.

## 17.6.7. `ndb_delete_all` — Delete All Rows from an NDB Table

`ndb_delete_all` deletes all rows from the given NDB table. In some cases, this can be much faster than `DELETE` or even `TRUNCATE`.

**Usage:**

```
ndb_delete_all -c connect_string tbl_name -d db_name
```

This deletes all rows from the table named `tbl_name` in the database named `db_name`. It is exactly equivalent to executing `TRUNCATE db_name.tbl_name` in MySQL.

**Additional Options:**

- `--transactional, -t`

Use of this option causes the delete operation to be performed as a single transaction.

### Warning

With very large tables, using this option may cause the number of operations available to the cluster to be exceeded.

## 17.6.8. `ndb_desc` — Describe NDB Tables

`ndb_desc` provides a detailed description of one or more NDB tables.

**Usage:**

```
ndb_desc -c connect_string tbl_name -d db_name [-p]
```

**Sample Output:**

MySQL table creation and population statements:

```
USE test;

CREATE TABLE fish (
  id INT(11) NOT NULL AUTO_INCREMENT,
  name VARCHAR(20),

  PRIMARY KEY pk (id),
  UNIQUE KEY uk (name)
) ENGINE=NDBCLUSTER;

INSERT INTO fish VALUES
  ('','guppy'), ('','tuna'), ('','shark'),
  ('','manta ray'), ('','grouper'), ('','puffer');
```

Output from `ndb_desc`:

```
shell> ./ndb_desc -c localhost fish -d test -p
-- fish --
Version: 16777221
Fragment type: 5
K Value: 6
Min load factor: 78
Max load factor: 80
```

```

Temporary table: no
Number of attributes: 2
Number of primary keys: 1
Length of frm data: 268
Row Checksum: 1
Row GCI: 1
TableStatus: Retrieved
-- Attributes --
id Int PRIMARY KEY DISTRIBUTION KEY AT=FIXED ST=MEMORY
name Varchar(20;latin1_swedish_ci) NULL AT=SHORT_VAR ST=MEMORY

-- Indexes --
PRIMARY KEY(id) - UniqueHashIndex
uk(name) - OrderedIndex
PRIMARY(id) - OrderedIndex
uk$unique(name) - UniqueHashIndex

-- Per partition info --
Partition Row count Commit count Frag fixed memory Frag varsized memory
2          2          2          65536          327680
1          2          2          65536          327680
3          2          2          65536          327680

NDBT_ProgramExit: 0 - OK

```

**Additional Options:**

- `--extra-partition-info, -p`  
Prints additional information about the table's partitions.
- Information about multiple tables can be obtained in a single invocation of `ndb_desc` by using their names, separated by spaces. All of the tables must be in the same database.

## 17.6.9. `ndb_drop_index` — Drop Index from an NDB Table

`ndb_drop_index` drops the specified index from an NDB table. *It is recommended that you use this utility only as an example for writing NDB API applications* — see the Warning later in this section for details.

**Usage:**

```
ndb_drop_index -c connect_string table_name index -d db_name
```

The statement shown above drops the index named `index` from the `table` in the `database`.

**Additional Options:** None that are specific to this application.

**Warning**

*Operations performed on Cluster table indexes using the NDB API are not visible to MySQL and make the table unusable by a MySQL server. If you use this program to drop an index, then try to access the table from an SQL node, an error results, as shown here:*

```

shell> ./ndb_drop_index -c localhost dogs ix -d ctest1
Dropping index dogs/idx...OK

NDBT_ProgramExit: 0 - OK

shell> ./mysql -u jon -p ctest1
Enter password: *****
Reading table information for completion of table and column names
You can turn off this feature to get a quicker startup with -A

Welcome to the MySQL monitor.  Commands end with ; or \g.
Your MySQL connection id is 7 to server version: 5.1.12-beta-20060817

Type 'help;' or '\h' for help. Type '\c' to clear the buffer.

mysql> SHOW TABLES;
+-----+
| Tables_in_ctest1 |
+-----+
| a                 |
| bt1               |
| bt2               |
| dogs              |
| employees         |
| fish              |
+-----+
6 rows in set (0.00 sec)

mysql> SELECT * FROM dogs;
ERROR 1296 (HY000): GOT ERROR 4243 'INDEX NOT FOUND' FROM NDBCLUSTER

```

In such a case, your *only* option for making the table available to MySQL again is to drop the table and re-create it. You can use either the SQL statement `DROP TABLE` or the `ndb_drop_table` utility (see [Section 17.6.10, “ndb\\_drop\\_table — Drop an NDB Table”](#)) to drop the table.

## 17.6.10. `ndb_drop_table` — Drop an NDB Table

`ndb_drop_table` drops the specified NDB table. (If you try to use this on a table created with a storage engine other than NDB, it fails with the error `723: NO SUCH TABLE EXISTS.`) This operation is extremely fast — in some cases, it can be an order of magnitude faster than using `DROP TABLE` on an NDB table from MySQL.

**Usage:**

```
ndb_drop_table -c connect_string tbl_name -d db_name
```

**Additional Options:** None.

## 17.6.11. `ndb_error_reporter` — NDB Error-Reporting Utility

`ndb_error_reporter` creates an archive from data node and management node log files that can be used to help diagnose bugs or other problems with a cluster. *It is highly recommended that you make use of this utility when filing reports of bugs in MySQL Cluster.*

**Usage:**

```
ndb_error_reporter path/to/config-file [username] [--fs]
```

This utility is intended for use on a management node host, and requires the path to the management host configuration file (`config.ini`). Optionally, you can supply the name of a user that is able to access the cluster's data nodes via SSH, in order to copy the data node log files. `ndb_error_reporter` then includes all of these files in archive that is created in the same directory in which it is run. The archive is named `ndb_error_report_YYYYMMDDHHMMSS.tar.bz2`, where `YYYYMMDDHHMMSS` is a datetime string.

If the `--fs` is used, then the data node file systems are also copied to the management host and included in the archive that is produced by this script. As data node file systems can be extremely large even after being compressed, we ask that you please do *not* send archives created using this option to MySQL AB unless you are specifically requested to do so.

<b>Command Line Format</b>	<code>--fs</code>	
<b>Value Set</b>	<b>Type</b>	boolean
	<b>Default</b>	FALSE

## 17.6.12. `ndb_print_backup_file` — Print NDB Backup File Contents

`ndb_print_backup_file` obtains diagnostic information from a cluster backup file.

**Usage:**

```
ndb_print_backup_file file_name
```

`file_name` is the name of a cluster backup file. This can be any of the files (`.Data`, `.ctl`, or `.log` file) found in a cluster backup directory. These files are found in the data node's backup directory under the subdirectory `BACKUP-#`, where `#` is the sequence number for the backup. For more information about cluster backup files and their contents, see [Section 17.7.3.1, “MySQL Cluster Backup Concepts”](#).

Like `ndb_print_schema_file` and `ndb_print_sys_file` (and unlike most of the other NDB utilities that are intended to be run on a management server host or to connect to a management server) `ndb_print_backup_file` must be run on a cluster data node, since it accesses the data node file system directly. Because it does not make use of the management server, this utility can be used when the management server is not running, and even when the cluster has been completely shut down.

**Additional Options:** None.

## 17.6.13. `ndb_print_schema_file` — Print NDB Schema File Contents

`ndb_print_schema_file` obtains diagnostic information from a cluster schema file.

**Usage:**

```
ndb_print_schema_file file_name
```

*file\_name* is the name of a cluster schema file. For more information about cluster schema files, see [Cluster Data Node FileSystemDir Files](#).

Like `ndb_print_backup_file` and `ndb_print_sys_file` (and unlike most of the other NDB utilities that are intended to be run on a management server host or to connect to a management server) `ndb_schema_backup_file` must be run on a cluster data node, since it accesses the data node file system directly. Because it does not make use of the management server, this utility can be used when the management server is not running, and even when the cluster has been completely shut down.

**Additional Options:** None.

## 17.6.14. `ndb_print_sys_file` — Print NDB System File Contents

`ndb_print_sys_file` obtains diagnostic information from a MySQL Cluster system file.

**Usage:**

```
ndb_print_sys_file file_name
```

*file\_name* is the name of a cluster system file (sysfile). Cluster system files are located in a data node's data directory (`DataDir`); the path under this directory to system files matches the pattern `ndb_#_fs/D#/DBDIH/P#.sysfile`. In each case, the # represents a number (not necessarily the same number). For more information, see [Cluster Data Node FileSystemDir Files](#).

Like `ndb_print_backup_file` and `ndb_print_schema_file` (and unlike most of the other NDB utilities that are intended to be run on a management server host or to connect to a management server) `ndb_print_backup_file` must be run on a cluster data node, since it accesses the data node file system directly. Because it does not make use of the management server, this utility can be used when the management server is not running, and even when the cluster has been completely shut down.

**Additional Options:** None.

## 17.6.15. `ndb_restore` — Restore a MySQL Cluster Backup

The cluster restoration program is implemented as a separate command-line utility `ndb_restore`, which can normally be found in the MySQL `bin` directory. This program reads the files created as a result of the backup and inserts the stored information into the database.

`ndb_restore` must be executed once for each of the backup files that were created by the `START BACKUP` command used to create the backup (see [Section 17.7.3.2, “Using The MySQL Cluster Management Client to Create a Backup”](#)). This is equal to the number of data nodes in the cluster at the time that the backup was created.

**Note**

Before using `ndb_restore`, it is recommended that the cluster be running in single user mode, unless you are restoring multiple data nodes in parallel. See [Section 17.7.6, “MySQL Cluster Single User Mode”](#), for more information about single user mode.

Typical options for this utility are shown here:

```
ndb_restore [-c connectstring] -n
node_id [-m] -b backup_id -r --backup_path=/path/to/backup/files
```

The `-c` option is used to specify a connectstring which tells `ndb_restore` where to locate the cluster management server. (See [Section 17.3.4.2, “The MySQL Cluster Connectstring”](#), for information on connectstrings.) If this option is not used, then `ndb_restore` attempts to connect to a management server on `localhost:1186`. This utility acts as a cluster API node, and so requires a free connection “slot” to connect to the cluster management server. This means that there must be at least one `[api]` or `[mysqld]` section that can be used by it in the cluster `config.ini` file. It is a good idea to keep at least one empty `[api]` or `[mysqld]` section in `config.ini` that is not being used for a MySQL server or other application for this reason (see [Section 17.3.4.6, “Defining SQL and Other API Nodes in a MySQL Cluster”](#)).

You can verify that `ndb_restore` is connected to the cluster by using the `SHOW` command in the `ndb_mgm` management client. You can also accomplish this from a system shell, as shown here:

```
shell> ndb_mgm -e "SHOW"
```

`-n` is used to specify the node ID of the data node on which the backups were taken.

The first time you run the `ndb_restore` restoration program, you also need to restore the metadata. In other words, you must re-create the database tables — this can be done by running it with the `-m` option. Note that the cluster should have an empty database when starting to restore a backup. (In other words, you should start `ndbd` with `--initial` prior to performing the restore.)

The `-b` option is used to specify the ID or sequence number of the backup, and is the same number shown by the management client in the `Backup backup_id completed` message displayed upon completion of a backup. (See [Section 17.7.3.2, “Using The MySQL Cluster Management Client to Create a Backup”](#).)

### Important

When restoring cluster backups, you must be sure to restore all data nodes from backups having the same backup ID. Using files from different backups will at best result in restoring the cluster to an inconsistent state, and may fail altogether.

The path to the backup directory is required; this is supplied to `ndb_restore` using the `--backup_path` option, and must include the subdirectory corresponding to the ID backup of the backup to be restored. For example, if the data node's `DataDir` is `/var/lib/mysql-cluster`, then the backup directory is `/var/lib/mysql-cluster/BACKUP`, and the backup files for the backup with the ID 3 can be found in `/var/lib/mysql-cluster/BACKUP/BACKUP-3`. The path may be absolute or relative to the directory in which the `ndb_restore` executable is located.

### Note

Previous to MySQL 5.0.38, the path to the backup directory was specified as shown here, with `backup_path=` being optional:

```
[backup_path=]/path/to/backup/files
```

Beginning with MySQL 5.0.38, this syntax changed to `--backup_path=/path/to/backup/files`, to conform more closely with options used by other MySQL programs; `--backup_id` is required, and there is no short form for this option.

It is possible to restore a backup to a database with a different configuration than it was created from. For example, suppose that a backup with backup ID 12, created in a cluster with two database nodes having the node IDs 2 and 3, is to be restored to a cluster with four nodes. Then `ndb_restore` must be run twice — once for each database node in the cluster where the backup was taken. However, `ndb_restore` cannot always restore backups made from a cluster running one version of MySQL to a cluster running a different MySQL version. See [Section 17.5.2, “MySQL Cluster 5.0 Upgrade and Downgrade Compatibility”](#), for more information.

### Important

It is not possible to restore a backup made from a newer version of MySQL Cluster using an older version of `ndb_restore`. You can restore a backup made from a newer version of MySQL to an older cluster, but you must use a copy of `ndb_restore` from the newer MySQL Cluster version to do so.

For example, to restore a cluster backup taken from a cluster running MySQL 5.0.45 to a cluster running MySQL Cluster 5.0.41, you must use a copy of `ndb_restore` from the 5.0.45 distribution.

For more rapid restoration, the data may be restored in parallel, provided that there is a sufficient number of cluster connections available. That is, when restoring to multiple nodes in parallel, you must have an `[api]` or `[mysqld]` section in the cluster `config.ini` file available for each concurrent `ndb_restore` process. However, the data files must always be applied before the logs.

Most of the options available for this program are shown in the following table:

Long Form	Short Form	Description	Default Value
<code>--backup-id</code>	<code>-b</code>	Backup sequence ID	<i>None</i>
<code>--backup_path</code> (added in MySQL 5.0.38; previously this was <code>backup_path</code> — see Note in text)	<i>None</i>	Path to backup files	<i>None</i>
<code>--character-sets-dir</code>	<i>None</i>	Specify the directory where character set information can be found	<i>None</i>
<code>--connect</code> , <code>-connectstring</code> , or <code>-ndb-connectstring</code>	<code>-c</code> or <code>-C</code>	Set the connectstring in	<code>localhost:1186</code>

		] format	
<code>--core-file</code>	<i>None</i>	Write a core file in the event of an error	<code>TRUE</code>
<code>--debug</code>	<code>-#</code>	Output debug log	<code>d:t:0,/tmp/ndb_restore.trace</code>
<code>--help</code> or <code>--usage</code>	<code>-?</code>	Display help message with available options and current values, then exit	[N/A]
<code>--ndb-mgmd-host</code>	<i>None</i>	Set the host and port in <code>host[:port]</code> format for the management server to connect to; this is the same as <code>--connect</code> , <code>--connectstring</code> , or <code>--ndb-connectstring</code> , but without a way to specify the <code>nodeid</code>	<i>None</i>
<code>--ndb-nodeid</code>	<i>None</i>	Specify a node ID for the <code>ndb_restore</code> process	<code>0</code>
<code>- - ndb-optim- ized-node-selection</code>	<i>None</i>	Optimize selection of nodes for transactions	<code>TRUE</code>
<code>--ndb-shm</code>	<i>None</i>	Use shared memory connections when available	<code>FALSE</code>
<code>--nodeid</code>	<code>-n</code>	Use backup files from node with the specified ID	<code>0</code>
<code>--parallelism</code>	<code>-p</code>	Set from 1 to 1024 parallel transactions to be used during the restoration process	<code>128</code>
<code>--print</code>	<i>None</i>	Print metadata, data, and log to <code>stdout</code>	<code>FALSE</code>
<code>--print_data</code>	<i>None</i>	Print data to <code>stdout</code>	<code>FALSE</code>
<code>--print_log</code>	<i>None</i>	Print log to <code>stdout</code>	<code>FALSE</code>
<code>--print_meta</code>	<i>None</i>	Print metadata to <code>stdout</code>	<code>FALSE</code>
<code>--restore_data</code>	<code>-r</code>	Restore data and logs	<code>FALSE</code>
<code>--restore_meta</code>	<code>-m</code>	Restore table metadata	<code>FALSE</code>
<code>--version</code>	<code>-V</code>	Output version information and exit	[N/A]

Beginning with MySQL 5.0.40, several additional options are available for use with the `--print_data` option in generating data dumps, either to `stdout`, or to a file. These are similar to some of the options used with `mysqldump`, and are shown in the following table:

Long Form	Short Form	Description	Default Value
<code>--tab</code>	<code>-T</code>	Creates dumpfiles, one per table, each named <code>tbl_name.txt</code> . Takes as its argument the path to the directory where the files should be saved (required; use <code>.</code> for the current directory).	<i>None</i>
<code>--fields-enclosed-by</code>	<i>None</i>	String used to enclose all column values	<i>None</i>
<code>- - fields-option- ally-enclosed-by</code>	<i>None</i>	String used to enclose column values containing character data (such as <code>CHAR</code> , <code>VARCHAR</code> , <code>BINARY</code> , <code>TEXT</code> , or <code>ENUM</code> )	<i>None</i>
<code>- -fields-terminated-by</code>	<i>None</i>	String used to separate column values	<code>\t</code> (tab character)
<code>--hex</code>	<i>None</i>	Use hex format for binary values	[N/A]
<code>--lines-terminated-by</code>	<i>None</i>	String used to terminate each line	<code>\n</code> (linefeed character)
<code>--append</code>	<i>None</i>	When used with <code>--tab</code> , causes the data to be appended to existing files of the same name	[N/A]

### Note

If a table has no explicit primary key, then the output generated when using the `--print` includes the table's hidden primary key.

Beginning with MySQL 5.0.40, it is possible to restore selected databases, or to restore selected tables from a given database using

the syntax shown here:

```
ndb_restore other_options db_name_1 [db_name_2 [, db_name_3] [, ...] | tbl_name_1 [, tbl_name_2] [, ...]
```

In other words, you can specify either of the following to be restored:

- All tables from one or more databases
- One or more tables from a single database

**Error reporting.** `ndb_restore` reports both temporary and permanent errors. In the case of temporary errors, it may be able to recover from them. Beginning with MySQL 5.0.29, it reports `Restore successful, but encountered temporary error, please look at configuration` in such cases.

## 17.6.16. `ndb_select_all` — Print Rows from an NDB Table

`ndb_select_all` prints all rows from an NDB table to `stdout`.

Usage:

```
ndb_select_all -c connect_string tbl_name -d db_name [> file_name]
```

**Additional Options:**

- `--lock=lock_type, -l lock_type`

Employs a lock when reading the table. Possible values for *lock\_type* are:

- 0: Read lock
- 1: Read lock with hold
- 2: Exclusive read lock

There is no default value for this option.

- `--order=index_name, -o index_name`

Orders the output according to the index named *index\_name*. Note that this is the name of an index, not of a column, and that the index must have been explicitly named when created.

- `--descending, -z`

Sorts the output in descending order. This option can be used only in conjunction with the `-o` (`--order`) option.

- `--header=FALSE`

Excludes column headers from the output.

- `--useHexFormat -x`

Causes all numeric values to be displayed in hexadecimal format. This does not affect the output of numerals contained in strings or datetime values.

- `--delimiter=character, -D character`

Causes the *character* to be used as a column delimiter. Only table data columns are separated by this delimiter.

The default delimiter is the tab character.

- `--rowid`

Adds a `ROWID` column providing information about the fragments in which rows are stored.

- `--gci`

Adds a column to the output showing the global checkpoint at which each row was last updated. See [Section 17.12, “MySQL Cluster Glossary”](#), and [Section 17.7.4.2, “MySQL Cluster Log Events”](#), for more information about checkpoints.

- `--tupscan, -t`  
Scan the table in the order of the tuples.
- `--nodata`  
Causes any table data to be omitted.

**Sample Output:**Output from a MySQL `SELECT` statement:

```
mysql> SELECT * FROM ctest1.fish;
+----+-----+
| id | name  |
+----+-----+
| 3  | shark |
| 6  | puffer|
| 2  | tuna  |
| 4  | manta ray |
| 5  | grouper |
| 1  | guppy |
+----+-----+
6 rows in set (0.04 sec)
```

Output from the equivalent invocation of `ndb_select_all`:

```
shell> ./ndb_select_all -c localhost fish -d ctest1
id      name
3       [shark]
6       [puffer]
2       [tuna]
4       [manta ray]
5       [grouper]
1       [guppy]
6 rows returned
NDBT_ProgramExit: 0 - OK
```

Note that all string values are enclosed by square brackets (“[...]”) in the output of `ndb_select_all`. For a further example, consider the table created and populated as shown here:

```
CREATE TABLE dogs (
  id INT(11) NOT NULL AUTO_INCREMENT,
  name VARCHAR(25) NOT NULL,
  breed VARCHAR(50) NOT NULL,
  PRIMARY KEY pk (id),
  KEY ix (name)
)
ENGINE=NDBCLUSTER;

INSERT INTO dogs VALUES
  ('', 'Lassie', 'collie'),
  ('', 'Scooby-Doo', 'Great Dane'),
  ('', 'Rin-Tin-Tin', 'Alsatian'),
  ('', 'Rosscoe', 'Mutt');
```

This demonstrates the use of several additional `ndb_select_all` options:

```
shell> ./ndb_select_all -d ctest1 dogs -o ix -z --gci
GCI      id name      breed
834461   2 [Scooby-Doo] [Great Dane]
834478   4 [Rosscoe]    [Mutt]
834463   3 [Rin-Tin-Tin] [Alsatian]
835657   1 [Lassie]     [Collie]
4 rows returned
NDBT_ProgramExit: 0 - OK
```

## 17.6.17. `ndb_select_count` — Print Row Counts for NDB Tables

`ndb_select_count` prints the number of rows in one or more NDB tables. With a single table, the result is equivalent to that obtained by using the MySQL statement `SELECT COUNT(*) FROM tbl_name`.

**Usage:**

```
ndb_select_count [-c connect_string] -ddb_name tbl_name[, tbl_name2[, ...]]
```

**Additional Options:** None that are specific to this application. However, you can obtain row counts from multiple tables in the

same database by listing the table names separated by spaces when invoking this command, as shown under **Sample Output**.

**Sample Output:**

```
shell> ./ndb_select_count -c localhost -d ctest1 fish dogs
6 records in table fish
4 records in table dogs
NDBT_ProgramExit: 0 - OK
```

## 17.6.18. `ndb_show_tables` — Display List of NDB Tables

`ndb_show_tables` displays a list of all NDB database objects in the cluster. By default, this includes not only both user-created tables and NDB system tables, but NDB-specific indexes, and internal triggers, as well.

**Usage:**

```
ndb_show_tables [-c connect_string]
```

**Additional Options:**

- `--loops, -l`

Specifies the number of times the utility should execute. This is 1 when this option is not specified, but if you do use the option, you must supply an integer argument for it.

- `--parsable, -p`

Using this option causes the output to be in a format suitable for use with `LOAD DATA INFILE`.

- `--type, -t`

Can be used to restrict the output to one type of object, specified by an integer type code as shown here:

- **1:** System table
- **2:** User-created table
- **3:** Unique hash index

Any other value causes all NDB database objects to be listed (the default).

- `--unqualified, -u`

If specified, this causes unqualified object names to be displayed.

**Note**

Only user-created Cluster tables may be accessed from MySQL; system tables such as `SYSTAB_0` are not visible to `mysqld`. However, you can examine the contents of system tables using NDB API applications such as `ndb_select_all` (see [Section 17.6.16, “ndb\\_select\\_all — Print Rows from an NDB Table”](#)).

## 17.6.19. `ndb_size.pl` — NDBCLUSTER Size Requirement Estimator

This is a Perl script that can be used to estimate the amount of space that would be required by a MySQL database if it were converted to use the `NDBCLUSTER` storage engine. Unlike the other utilities discussed in this section, it does not require access to a MySQL Cluster (in fact, there is no reason for it to do so). However, it does need to access the MySQL server on which the database to be tested resides.

**Requirements:**

- A running MySQL server. The server instance does not have to provide support for MySQL Cluster.
- A working installation of Perl.
- The `DBI` and `HTML::Template` modules, both of which can be obtained from CPAN if they are not already part of your Perl installation. (Many Linux and other operating system distributions provide their own packages for one or both of these libraries.)

- The `ndb_size.tpl` template file, which you should be able to find in the `share/mysql` directory of your MySQL installation. This file should be copied or moved into the same directory as `ndb_size.pl` — if it is not there already — before running the script.
- A MySQL user account having the necessary privileges. If you do not wish to use an existing account, then creating one using `GRANT USAGE ON db_name.*` — where `db_name` is the name of the database to be examined — is sufficient for this purpose.

`ndb_size.pl` and `ndb_size.tpl` can also be found in the MySQL sources in `storage/ndb/tools`. If these files are not present in your MySQL installation, you can obtain them from the [MySQL Forge project page](#).

**Usage:**

```
perl ndb_size.pl db_name hostname username password > file_name.html
```

The command shown connects to the MySQL server at `hostname` using the account of the user `username` having the password `password`, analyzes all of the tables in database `db_name`, and generates a report in HTML format which is directed to the file `file_name.html`. (Without the redirection, the output is sent to `stdout`.) This figure shows a portion of the generated `ndb_size.html` output file, as viewed in a Web browser:

## MySQL Cluster analysis for world

This is an automated analysis of the DBI:mysql:database=world;host=192.168.0.176 database for migration into MySQL Cluster. No warranty is made to the accuracy of the information.

This information should be valid for MySQL 4.1 and 5.0. Since 5.1 is not a final release yet, the numbers should be used as a guide only.

### Parameter Settings

**NOTE** the configuration parameters below do not take into account system tables and other requirements.

Parameter	4.1	5.0	5.1
DataMemory (kb)	544	544	544
IndexMemory (kb)	192	136	136
MaxNoOfTables	3	3	3
MaxNoOfAttributes	24	24	24
MaxNoOfOrderedIndexes	3	3	3
MaxNoOfUniqueHashIndexes	3	3	3
MaxNoOfTriggers	12	12	12

### Memory usage because of parameters

Usage is in kilobytes. Actual usage will vary as you should set the parameters larger than those listed in the table above.

Parameter	4.1	5.0	5.1
Attributes	5	5	5
Tables	60	60	60
OrderedIndexes	30	30	30
UniqueHashIndexes	45	45	45

### Table List

- [City](#)
- [Country](#)
- [CountryLanguage](#)

### City

Column	Type	Size	Key	4.1 NDB Size	5.0 NDB Size	5.1 NDB Size
ID	int	11	PRI	4	4	4
District	char	20		20	20	20
Name	char	35		36	36	36
Population	int	11		4	4	4
CountryCode	char	3		4	4	4

### Indexes

We assume that indexes are ORDERED (not created USING HASH). If order is not required, 10 bytes of data memory can be saved per row if the index is created USING HASH

Index	Type	Columns	4.1 IdxMem	5.0 IdxMem	5.1 IdxMem	4.1 DatMem	5.0 DatMem	5.1 DatMem
PRIMARY	BTREE	ID	29	25	25	10	10	10

### DataMemory Usage

	4.1	5.0	5.1
Row Overhead	16	16	16
Column DataMemory/Row	68	68	68
Index DataMemory/Row	10	10	10
Total DataMemory/Row	94	94	94
Rows per 32 kb page	347	347	347
Current number of rows	4079	4079	4079
Total DataMemory (kb)	384	384	384

### IndexMemory Usage

	4.1	5.0	5.1
IndexMemory/Row	29	25	25
Rows per 8kb page	282	327	327
Current number of rows	4079	4079	4079
Total IndexMemory (kb)	120	104	104

The output from this script includes:

- Minimum values for the `DataMemory`, `IndexMemory`, `MaxNoOfTables`, `MaxNoOfAttributes`, `MaxNoOfOrderedIndexes`, `MaxNoOfUniqueHashIndexes`, and `MaxNoOfTriggers` configuration parameters required to accommodate the tables analyzed.
- Memory requirements for all of the tables, attributes, ordered indexes, and unique hash indexes defined in the database.
- The `IndexMemory` and `DataMemory` required per table and table row.

## 17.6.20. `ndb_waiter` — Wait for MySQL Cluster to Reach a Given Status

`ndb_waiter` repeatedly (each 100 milliseconds) prints out the status of all cluster data nodes until either the cluster reaches a given status or the `--timeout` limit is exceeded, then exits. By default, it waits for the cluster to achieve `STARTED` status, in which all nodes have started and connected to the cluster. This can be overridden using the `--no-contact` and `--not-started` options (see [Additional Options](#)).

The node states reported by this utility are as follows:

- `NO_CONTACT`: The node cannot be contacted.
- `UNKNOWN`: The node can be contacted, but its status is not yet known. Usually, this means that the node has received a `START` or `RESTART` command from the management server, but has not yet acted on it.
- `NOT_STARTED`: The node has stopped, but remains in contact with the cluster. This is seen when restarting the node using the management client's `RESTART` command.
- `STARTING`: The node's `ndbd` process has started, but the node has not yet joined the cluster.
- `STARTED`: The node is operational, and has joined the cluster.
- `SHUTTING_DOWN`: The node is shutting down.
- `SINGLE USER MODE`: This is shown for all cluster data nodes when the cluster is in single user mode.

### Usage:

```
ndb_waiter [-c connect_string]
```

### Additional Options:

- `--no-contact, -n`

Instead of waiting for the `STARTED` state, `ndb_waiter` continues running until the cluster reaches `NO_CONTACT` status before exiting.

- `--not-started`

Instead of waiting for the `STARTED` state, `ndb_waiter` continues running until the cluster reaches `NOT_STARTED` status before exiting.

- `--timeout=seconds, -t seconds`

Time to wait. The program exits if the desired state is not achieved within this number of seconds. The default is 120 seconds (1200 reporting cycles).

**Sample Output.** Shown here is the output from `ndb_waiter` when run against a 4-node cluster in which two nodes have been shut down and then started again manually. Duplicate reports (indicated by "...") are omitted.

```
shell> ./ndb_waiter -c localhost
Connecting to mgmsrv at (localhost)
State node 1 STARTED
State node 2 NO_CONTACT
State node 3 STARTED
State node 4 NO_CONTACT
Waiting for cluster enter state STARTED
```

```

...
State node 1 STARTED
State node 2 UNKNOWN
State node 3 STARTED
State node 4 NO_CONTACT
Waiting for cluster enter state STARTED
...
State node 1 STARTED
State node 2 STARTING
State node 3 STARTED
State node 4 NO_CONTACT
Waiting for cluster enter state STARTED
...
State node 1 STARTED
State node 2 STARTING
State node 3 STARTED
State node 4 UNKNOWN
Waiting for cluster enter state STARTED
...
State node 1 STARTED
State node 2 STARTING
State node 3 STARTED
State node 4 STARTING
Waiting for cluster enter state STARTED
...
State node 1 STARTED
State node 2 STARTED
State node 3 STARTED
State node 4 STARTING
Waiting for cluster enter state STARTED
...
State node 1 STARTED
State node 2 STARTED
State node 3 STARTED
State node 4 STARTED
Waiting for cluster enter state STARTED
NDBT_ProgramExit: 0 - OK

```

**Note**

If no connectstring is specified, then `ndb_waiter` tries to connect to a management on `localhost`, and reports `Connecting to mgmsrv at (null)`.

## 17.6.21. Options Common to MySQL Cluster Programs

All MySQL Cluster programs (except for `mysqld`) take the options described in this section. Users of earlier MySQL Cluster versions should note that some of these options have been changed to make them consistent with one another as well as with `mysqld`. You can use the `--help` option with any MySQL Cluster program to view a list of the options which it supports.

The options in the following list are common to all MySQL Cluster executables.

For options specific to individual NDB programs, see [Section 17.6, “MySQL Cluster Programs”](#).

See [Section 17.4.2, “mysqld Command Options for MySQL Cluster”](#), for `mysqld` options relating to MySQL Cluster.

- `--help --usage, -?`

<b>Command Line Format</b>	<code>--help</code>
----------------------------	---------------------

Prints a short list with descriptions of the available command options.

- `--character-sets-dir=name`

<b>Command Line Format</b>	<code>--character-sets-dir=name</code>	
<b>Value Set</b>	<b>Type</b>	<code>filename</code>

	<b>Default</b>	
--	----------------	--

Tells the program where to find character set information.

- `--connect-string=connect_string, -c connect_string`  
`connect_string` sets the connectstring to the management server as a command option.

```
shell> ndbd --connect-string="nodeid=2;host=ndb_mgmd.mysql.com:1186"
```

For more information, see [Section 17.3.4.2, “The MySQL Cluster Connectstring”](#).

- `--core-file`

<b>Command Line Format</b>	<code>--core-file</code>	
<b>Value Set</b>	<b>Type</b>	<code>boolean</code>
	<b>Default</b>	<code>FALSE</code>

Write a core file if the program dies. The name and location of the core file are system-dependent. (For MySQL Cluster programs nodes running on Linux, the default location is the program's working directory — for a data node, this is the node's `DataDir`.) For some systems, there may be restrictions or limitations; for example, it might be necessary to execute `ulimit -c unlimited` before starting the server. Consult your system documentation for detailed information.

If MySQL Cluster was built using the `--debug` option for `configure`, then `--core-file` is enabled by default. For regular builds, `--core-file` is disabled by default.

- `--debug[=options]`

<b>Command Line Format</b>	<code>--debug=options</code>
----------------------------	------------------------------

This option can be used only for versions compiled with debugging enabled. It is used to enable output from debug calls in the same manner as for the `mysqld` process.

- `--execute=command, -e command`

<b>Command Line Format</b>	<code>--execute=name</code>
----------------------------	-----------------------------

Can be used to send a command to a Cluster executable from the system shell. For example, either of the following:

```
shell> ndb_mgm -e "SHOW"
```

or

```
shell> ndb_mgm --execute="SHOW"
```

is equivalent to

```
ndb_mgm> SHOW
```

This is analogous to how the `--execute` or `-e` option works with the `mysql` command-line client. See [Section 4.2.3.1, “Using Options on the Command Line”](#).

- `--ndb-mgmd-host=host[:port]`

Can be used to set the host and port number of the management server to connect to.

- `--ndb-nodeid=#`

Sets this node's MySQL Cluster node ID. *The range of permitted values depends on the type of the node (data, management, or API) and the version of the MySQL Cluster software which is running on it.* See [Section 17.10.2, “Limits and Differences of MySQL Cluster from Standard MySQL Limits”](#), for more information.

- `--ndb-optimized-node-selection`

<b>Command Line Format</b>	<code>--ndb-optimized-node-selection</code>	
<b>Value Set</b>	<b>Type</b>	boolean
	<b>Default</b>	TRUE

Optimize selection of nodes for transactions. Enabled by default.

- `--version, -V`

<b>Command Line Format</b>	<code>-V</code>
----------------------------	-----------------

Prints the MySQL Cluster version number of the executable. The version number is relevant because not all versions can be used together, and the MySQL Cluster startup process verifies that the versions of the binaries being used can co-exist in the same cluster. This is also important when performing an online (rolling) software upgrade or downgrade of MySQL Cluster. (See [Section 17.5.1, “Performing a Rolling Restart of a MySQL Cluster”](#)).

## 17.6.22. Summary Tables of NDB Program Options

The next few sections contain summary tables providing basic information about command-line options used with MySQL Cluster programs.

### 17.6.22.1. Common Options for MySQL Cluster Programs

**Table 17.5.** `ndb_common` Option Reference

Format	Description	Introduc- tion	Deprec- ated	Removed
<code>- -character-sets-dir=name</code>	Directory where character sets are			
<code>- -ndb-connectstring=name</code>	Set connect string for connecting to <code>ndb_mgmd</code> . Syntax: <code>[nodeid=&lt;id&gt;:][host=&lt;hostname&gt;[:&lt;port&gt;]</code> . Overrides specifying entries in <code>NDB_CONNECTSTRING</code> and <code>my.cnf</code>			
<code>--core-file</code>	Write core on errors (defaults to TRUE in debug builds)			
<code>--debug=options</code>	Enable output from debug calls. Can be used only for versions compiled with debugging enabled			
<code>--execute=name</code>	Execute command and exit			
<code>--help</code>	Display help message and exit			
<code>--ndb-mgmd-host=name</code>	Set host and port for connecting to <code>ndb_mgmd</code> . Syntax: <code>&lt;hostname&gt;[:&lt;port&gt;]</code> . Overrides specifying entries in <code>NDB_CONNECTSTRING</code> and <code>my.cnf</code>			
<code>- - ndb-optim- ized-node-selection</code>	Select nodes for transactions in a more optimal way			
<code>--ndb-nodeid=#</code>	Set node id for this node			
<code>-V</code>	Output version information and exit			

For options specific to individual MySQL Cluster programs, see [Section 17.6.21, “Options Common to MySQL Cluster Programs”](#).

### 17.6.22.2. Program Options for `ndbd`

**Table 17.6. `ndbd` Option Reference**

Format	Description	Introduc- tion	Deprec- ated	Removed
<code>--bind-address=name</code>	Local bind address	5.0.29		
<code>--daemon</code>	Start <code>ndbd</code> as daemon (default); override with <code>--nodaemon</code>			
<code>--foreground</code>	Run <code>ndbd</code> in foreground, provided for debugging purposes (implies <code>--nodaemon</code> )			
<code>--initial</code>	Perform initial start of <code>ndbd</code> , including cleaning the file system. Consult the documentation before using this option			
<code>--initial-start</code>	Perform partial initial start (requires <code>--nowait-nodes</code> )	5.0.21		
<code>--nodaemon</code>	Do not start <code>ndbd</code> as daemon; provided for testing purposes			
<code>--nostart</code>	Don't start <code>ndbd</code> immediately; <code>ndbd</code> waits for command to start from <code>ndb_mgmd</code>			
<code>--nowait-nodes=list</code>	Nodes that will not be waited for during start (comma-separated list of node IDs)	5.0.21		

For more information about `ndbd`, see [Section 17.6.2, “`ndbd` — The MySQL Cluster Data Node Daemon](#)”. For options common to all MySQL Cluster programs, see [Section 17.6.21, “Options Common to MySQL Cluster Programs](#)”.

### 17.6.22.3. Program Options for `ndb_mgmd`

**Table 17.7. `ndb_mgmd` Option Reference**

Format	Description	Introduc- tion	Deprec- ated	Removed
<code>-f</code>	Specify the cluster configuration file; in NDB-6.4.0 and later, needs <code>--reload</code> or <code>--initial</code> to override configuration cache if present			
<code>--daemon</code>	Run <code>ndb_mgmd</code> in daemon mode (default)			
<code>--interactive</code>	Run <code>ndb_mgmd</code> in interactive mode (not officially supported in production; for testing purposes only)			
<code>--mycnf</code>	Read cluster configuration data from the <code>my.cnf</code> file			
<code>--no-nodeid-checks</code>	Do not provide any node id checks			
<code>--nodaemon</code>	Do not run <code>ndb_mgmd</code> as a daemon			
<code>--print-full-config</code>	Print full configuration and exit	5.0.10		

For more information about `ndb_mgmd`, see [Section 17.6.3, “`ndb\_mgmd` — The MySQL Cluster Management Server Daemon](#)”. For options common to all MySQL Cluster programs, see [Section 17.6.21, “Options Common to MySQL Cluster Programs](#)”.

### 17.6.22.4. Program Options for `ndb_mgm`

**Table 17.8. `ndb_mgm` Option Reference**

Format	Description	Introduc- tion	Deprec- ated	Removed
<code>--try-reconnect=#</code>	Specify number of tries for connecting to <code>ndb_mgmd</code> (0 = infinite)			

For more information about `ndb_mgm`, see [Section 17.6.4, “`ndb\_mgm` — The MySQL Cluster Management Client](#)”. For options common to all MySQL Cluster programs, see [Section 17.6.21, “Options Common to MySQL Cluster Programs](#)”.

### 17.6.22.5. Program Options for `ndb_config`

**Table 17.9. `ndb_config` Option Reference**

Format	Description	Introduction	Deprecated	Removed
--connections	Print connection information only			
--fields=string	Field separator			
--host=name	Specify host			
--mycnf	Read configuration data from my.cnf file			
--nodeid	Get configuration of node with this ID			
--nodes	Print node information only			
	Short form for --ndb-connectstring	5.0.33		
--config-file=path	Set the path to config.ini file			
--query=string	One or more query options (attributes)			
--rows=string	Row separator			
--type=name	Specify node type			

For more information about `ndb_config`, see [Section 17.6.5, “ndb\\_config — Extract MySQL Cluster Configuration Information”](#). For options common to all MySQL Cluster programs, see [Section 17.6.21, “Options Common to MySQL Cluster Programs”](#).

### 17.6.22.6. Program Options for `ndb_error_reporter`

**Table 17.10. `ndb_error_reporter` Option Reference**

Format	Description	Introduction	Deprecated	Removed
--fs	Include file system data in error report; can use a large amount of disk space			

For more information about `ndb_error_reporter`, see [Section 17.6.11, “ndb\\_error\\_reporter — NDB Error-Reporting Utility”](#). For options common to all MySQL Cluster programs, see [Section 17.6.21, “Options Common to MySQL Cluster Programs”](#).

### 17.6.22.7. Program Options for `ndb_restore`

**Table 17.11. `ndb_restore` Option Reference**

Format	Description	Introduction	Deprecated	Removed
--append	Append data to a tab-delimited file	5.0.40		
--backup_path=path	Path to backup files directory			
--backupid=#	Restore from the backup with the given ID			
--connect	Same as connectstring			
--restore_data	Restore table data and logs into NDB Cluster using the NDB API			
--dont_ignore_systab_0	Do not ignore system table during restore. Experimental only; not for production use			
- -fields-enclosed-by=char	Fields are enclosed with the indicated character	5.0.40		
- - fields-optionally-enclosed-by	Fields are optionally enclosed with the indicated character	5.0.40		
- - fields-terminated-by=char	Fields are terminated by the indicated character	5.0.40		
--hex	Print binary types in hexadecimal format	5.0.40		

Format	Description	Introduction	Deprecated	Removed
- - lines-terminated-by=char	Lines are terminated by the indicated character	5.0.40		
--restore_meta	Restore metadata to NDB Cluster using the NDB API			
- - ndb-node-group-map=map	Nodegroup map for NDBCLUSTER storage engine. Syntax: list of (source_nodegroup, destination_nodegroup)			
--no-restore-disk-objects	Do not restore Disk Data objects such as tablespaces and log file groups			
--nodeid=#	Back up files from node with this ID			
--parallelism=#	Number of parallel transactions during restoration of data			
- -preserve-trailing-spaces	Allow preservation of trailing spaces (including padding) when CHAR is promoted to VARCHAR or BINARY is promoted to VARBINARY			
--print	Print metadata, data and log to stdout (equivalent to - -print_meta --print_data --print_log)			
--print_data	Print data to stdout			
--print_log	Print to stdout			
--print_metadata	Print metadata to stdout			
--promote-attributes	Allow attributes to be promoted when restoring data from backup			
--restore_epoch	Restore epoch info into the status table. Convenient on a MySQL Cluster replication slave for starting replication. The row in mysql.ndb_apply_status with id 0 will be updated/inserted.			
--tab=path	Creates tab separated a .txt file for each table in the given path	5.0.40		
--verbose=#	Control level of verbosity in output			

For more information about `ndb_restore`, see [Section 17.6.15, “ndb\\_restore — Restore a MySQL Cluster Backup”](#). For options common to all NDB programs, see [Section 17.6.21, “Options Common to MySQL Cluster Programs”](#).

### 17.6.22.8. Program Options for `ndb_show_tables`

**Table 17.12. `ndb_show_tables` Option Reference**

Format	Description	Introduction	Deprecated	Removed
--database=string	Specifies the database in which the table is found			
--loops=#	Number of times to repeat output			
--show-temp-status	Show table temporary flag			
--parsable	Return output suitable for MySQL LOAD DATA INFILE statement			
--type=#	Limit output to objects of this type			
--unqualified	Do not qualify table names			

For more information about `ndb_show_tables`, see [Section 17.6.18, “ndb\\_show\\_tables — Display List of NDB Tables”](#). For options common to all MySQL Cluster programs, see [Section 17.6.21, “Options Common to MySQL Cluster Programs”](#).

### 17.6.22.9. Program Options for `ndb_size.pl`

**Table 17.13. `ndb_size.pl` Option Reference**

Format	Description	Introduc- tion	Deprec- ated	Removed
<code>--database=dbname</code>	The database or databases to examine; accepts a comma-delimited list; the default is ALL (use all databases found on the server)			
<code>--excludedbs=db-list</code>	Skip any databases in a comma-separated list of databases			
<code>--excludetables=tbl-list</code>	Skip any tables in a comma-separated list of tables			
<code>--format=string</code>	Set output format (text or HTML)			
<code>--hostname[:port]</code>	Specify host and optional port as host[:port]			
<code>--loadqueries=file</code>	Loads all queries from the file specified; does not connect to a database			
<code>--password=string</code>	Specify a MySQL user password			
<code>--savequeries=file</code>	Saves all queries to the database into the file specified			
<code>--user=string</code>	Specify a MySQL user name			

For more information about `ndb_size.pl`, see [Section 17.6.19, “ndb\\_size.pl — NDBCLUSTER Size Requirement Estimator”](#). For options common to all MySQL Cluster programs, see [Section 17.6.21, “Options Common to MySQL Cluster Programs”](#).

## 17.7. Management of MySQL Cluster

Managing a MySQL Cluster involves a number of tasks, the first of which is to configure and start MySQL Cluster. This is covered in [Section 17.3, “MySQL Cluster Configuration”](#), and [Section 17.6, “MySQL Cluster Programs”](#).

The following sections cover the management of a running MySQL Cluster.

For information about security issues relating to management and deployment of a MySQL Cluster, see [Section 17.8, “MySQL Cluster Security Issues”](#).

There are essentially two methods of actively managing a running MySQL Cluster. The first of these is through the use of commands entered into the management client whereby cluster status can be checked, log levels changed, backups started and stopped, and nodes stopped and started. The second method involves studying the contents of the cluster log `ndb_node_id_cluster.log`; this is usually found in the management server's `DataDir` directory, but this location can be overridden using the `LogDestination` option — see [Section 17.3.4.4, “Defining a MySQL Cluster Management Server”](#), for details. (Recall that `node_id` represents the unique identifier of the node whose activity is being logged.) The cluster log contains event reports generated by `ndbd`. It is also possible to send cluster log entries to a Unix system log.

In addition, some aspects of the cluster's operation can be monitored from an SQL node using the `SHOW ENGINE NDB STATUS` statement. See [Section 12.5.5.12, “SHOW ENGINE Syntax”](#), for more information.

### 17.7.1. Summary of MySQL Cluster Start Phases

This section provides a simplified outline of the steps involved when MySQL Cluster data nodes are started. More complete information can be found in [MySQL Cluster Start Phases](#).

These phases are the same as those reported in the output from the `node_id STATUS` command in the management client. (See [Section 17.7.2, “Commands in the MySQL Cluster Management Client”](#), for more information about this command.)

**Start types.** There are several different startup types and modes, as shown here:

- **Initial Start.** The cluster starts with a clean file system on all data nodes. This occurs either when the cluster started for the very first time, or when all data nodes are restarted using the `--initial` option.

#### Note

Disk Data files are not removed when restarting a node using `--initial`.

- **System Restart.** The cluster starts and reads data stored in the data nodes. This occurs when the cluster has been shut down after having been in use, when it is desired for the cluster to resume operations from the point where it left off.
- **Node Restart.** This is the online restart of a cluster node while the cluster itself is running.
- **Initial Node Restart.** This is the same as a node restart, except that the node is reinitialized and started with a clean file system.

**Setup and initialization (Phase -1).** Prior to startup, each data node (`ndbd` process) must be initialized. Initialization consists of the following steps:

1. Obtain a node ID
2. Fetch configuration data
3. Allocate ports to be used for inter-node communications
4. Allocate memory according to settings obtained from the configuration file

When a data node or SQL node first connects to the management node, it reserves a cluster node ID. To make sure that no other node allocates the same node ID, this ID is retained until the node has managed to connect to the cluster and at least one `ndbd` reports that this node is connected. This retention of the node ID is guarded by the connection between the node in question and `ndb_mgmd`.

Normally, in the event of a problem with the node, the node disconnects from the management server, the socket used for the connection is closed, and the reserved node ID is freed. However, if a node is disconnected abruptly — for example, due to a hardware failure in one of the cluster hosts, or because of network issues — the normal closing of the socket by the operating system may not take place. In this case, the node ID continues to be reserved and not released until a TCP timeout occurs 10 or so minutes later.

To take care of this problem, you can use `PURGE STALE SESSIONS`. Running this statement forces all reserved node IDs to be checked; any that are not being used by nodes actually connected to the cluster are then freed.

Beginning with MySQL 5.1.11, timeout handling of node ID assignments is implemented. This performs the ID usage checks automatically after approximately 20 seconds, so that `PURGE STALE SESSIONS` should no longer be necessary in a normal Cluster start.

After each data node has been initialized, the cluster startup process can proceed. The stages which the cluster goes through during this process are listed here:

- **Phase 0.** The `NDBFS` and `NDBCNTR` blocks start (see [NDB Kernel Blocks](#)). The cluster file system is cleared, if the cluster was started with the `--initial` option.
- **Phase 1.** In this stage, all remaining `NDB` kernel blocks are started. Cluster connections are set up, inter-block communications are established, and Cluster heartbeats are started. In the case of a node restart, API node connections are also checked.

#### Note

When one or more nodes hang in Phase 1 while the remaining node or nodes hang in Phase 2, this often indicates network problems. One possible cause of such issues is one or more cluster hosts having multiple network interfaces. Another common source of problems causing this condition is the blocking of TCP/IP ports needed for communications between cluster nodes. In the latter case, this is often due to a misconfigured firewall.

- **Phase 2.** The `NDBCNTR` kernel block checks the states of all existing nodes. The master node is chosen, and the cluster schema file is initialized.
- **Phase 3.** The `DBLQH` and `DBTC` kernel blocks set up communications between them. The startup type is determined; if this is a restart, the `DBDIH` block obtains permission to perform the restart.
- **Phase 4.** For an initial start or initial node restart, the redo log files are created. The number of these files is equal to `NoOfFragmentLogFiles`.

For a system restart:

- Read schema or schemas.
- Read data from the local checkpoint.
- Apply all redo information until the latest restorable global checkpoint has been reached.

For a node restart, find the tail of the redo log.

- **Phase 5.** Most of the database-related portion of a data node start is performed during this phase. For an initial start or system restart, a local checkpoint is executed, followed by a global checkpoint. Periodic checks of memory usage begin during this phase, and any required node takeovers are performed.
- **Phase 6.** In this phase, node groups are defined and set up.

- **Phase 7.** The arbitrator node is selected and begins to function. The next backup ID is set, as is the backup disk write speed. Nodes reaching this start phase are marked as *Started*. It is now possible for API nodes (including SQL nodes) to connect to the cluster. connect.
- **Phase 8.** If this is a system restart, all indexes are rebuilt (by *DBDIH*).
- **Phase 9.** The node internal startup variables are reset.
- **Phase 100 (OBSOLETE).** Formerly, it was at this point during a node restart or initial node restart that API nodes could connect to the node and begin to receive events. Currently, this phase is empty.
- **Phase 101.** At this point in a node restart or initial node restart, event delivery is handed over to the node joining the cluster. The newly-joined node takes over responsibility for delivering its primary data to subscribers. This phase is also referred to as *SUMA handover phase*.

After this process is completed for an initial start or system restart, transaction handling is enabled. For a node restart or initial node restart, completion of the startup process means that the node may now act as a transaction coordinator.

## 17.7.2. Commands in the MySQL Cluster Management Client

In addition to the central configuration file, a cluster may also be controlled through a command-line interface available through the management client *ndb\_mgm*. This is the primary administrative interface to a running cluster.

Commands for the event logs are given in [Section 17.7.4, “Event Reports Generated in MySQL Cluster”](#); commands for creating backups and restoring from them are provided in [Section 17.7.3, “Online Backup of MySQL Cluster”](#).

The management client has the following basic commands. In the listing that follows, *node\_id* denotes either a database node ID or the keyword *ALL*, which indicates that the command should be applied to all of the cluster's data nodes.

- *HELP*

Displays information on all available commands.

- *SHOW*

Displays information on the cluster's status.

### Note

In a cluster where multiple management nodes are in use, this command displays information only for data nodes that are actually connected to the current management server.

- *node\_id START*

Brings online the data node identified by *node\_id* (or all data nodes).

Beginning with MySQL 5.0.19, this command can also be used to individual management nodes online.

### Note

*ALL START* continues to affect data nodes only.

### Important

To use this command to bring a data node online, the data node must have been started using *ndbd --nstart* or *ndbd -n*.

- *node\_id STOP*

Stops the data node identified by *node\_id* (or all data nodes).

Beginning with MySQL 5.0.19, this command can also be used to stop individual management nodes.

### Note

**ALL STOP** continues to affect data nodes only.

A node affected by this command disconnects from the cluster, and its associated `ndbd` or `ndb_mgmd` process terminates.

- `node_id RESTART [-n] [-i] [-a]`

Restarts the data node identified by `node_id` (or all data nodes).

Using the `-i` option with `RESTART` causes the data node to perform an initial restart; that is, the node's file system is deleted and recreated. The effect is the same as that obtained from stopping the data node process and then starting it again using `ndbd --initial` from the system shell.

Using the `-n` option causes the data node process to be restarted, but the data node is not actually brought online until the appropriate `START` command is issued. The effect of this option is the same as that obtained from stopping the data node and then starting it again using `ndbd --nostart` or `ndbd -n` from the system shell.

Using the `-a` causes all current transactions relying on this node to be aborted. No GCP check is done when the node rejoins the cluster.

- `node_id STATUS`

Displays status information for the data node identified by `node_id` (or for all data nodes).

- `ENTER SINGLE USER MODE node_id`

Enters single user mode, whereby only the MySQL server identified by the node ID `node_id` is allowed to access the database.

### Important

Do not attempt to have data nodes join the cluster while it is running in single user mode. Doing so can cause subsequent multiple node failures. Beginning with MySQL 5.0.29, it is no longer possible to add nodes while in single user mode. (See [Bug#20395](#) for more information.)

- `EXIT SINGLE USER MODE`

Exits single user mode, allowing all SQL nodes (that is, all running `mysqld` processes) to access the database.

### Note

It is possible to use `EXIT SINGLE USER MODE` even when not in single user mode, although the command has no effect in this case.

- `QUIT, EXIT`

Terminates the management client.

This command does not affect any nodes connected to the cluster.

- `SHUTDOWN`

Shuts down all cluster data nodes and management nodes. To exit the management client after this has been done, use `EXIT` or `QUIT`.

This command does *not* shut down any SQL nodes or API nodes that are connected to the cluster.

## 17.7.3. Online Backup of MySQL Cluster

This section describes how to create a backup and how to restore the database from a backup at a later time.

### 17.7.3.1. MySQL Cluster Backup Concepts

A backup is a snapshot of the database at a given time. The backup consists of three main parts:

- **Metadata.** The names and definitions of all database tables
- **Table records.** The data actually stored in the database tables at the time that the backup was made
- **Transaction log.** A sequential record telling how and when data was stored in the database

Each of these parts is saved on all nodes participating in the backup. During backup, each node saves these three parts into three files on disk:

- `BACKUP-backup_id.node_id.ctl`

A control file containing control information and metadata. Each node saves the same table definitions (for all tables in the cluster) to its own version of this file.

- `BACKUP-backup_id-0.node_id.data`

A data file containing the table records, which are saved on a per-fragment basis. That is, different nodes save different fragments during the backup. The file saved by each node starts with a header that states the tables to which the records belong. Following the list of records there is a footer containing a checksum for all records.

- `BACKUP-backup_id.node_id.log`

A log file containing records of committed transactions. Only transactions on tables stored in the backup are stored in the log. Nodes involved in the backup save different records because different nodes host different database fragments.

In the listing above, `backup_id` stands for the backup identifier and `node_id` is the unique identifier for the node creating the file.

### 17.7.3.2. Using The MySQL Cluster Management Client to Create a Backup

Before starting a backup, make sure that the cluster is properly configured for performing one. (See [Section 17.7.3.3, “Configuration for MySQL Cluster Backups”](#).)

The `START BACKUP` command is used to create a backup:

```
START BACKUP [backup_id] [wait_option]
wait_option:
WAIT {STARTED | COMPLETED} | NOWAIT
```

Successive backups are automatically identified sequentially, so the `backup_id`, an integer greater than or equal to 1, is optional; if it is omitted, the next available value is used. If an existing `backup_id` value is used, the backup fails with the error `BACKUP FAILED: FILE ALREADY EXISTS`. If used, the `backup_id` must follow `START BACKUP` immediately, before any other options are used.

The maximum supported value for `backup_id` in MySQL 5.0 is 2147483648 ( $2^{31}$ ). ([Bug#43042](#))

#### Note

If you start a backup using `ndb_mgm -e "START BACKUP"`, the `backup_id` is required.

The `wait_option` can be used to determine when control is returned to the management client after a `START BACKUP` command is issued, as shown in the following list:

- If `NOWAIT` is specified, the management client displays a prompt immediately, as seen here:

```
ndb_mgm> START BACKUP NOWAIT
ndb_mgm>
```

In this case, the management client can be used even while it prints progress information from the backup process.

- With `WAIT STARTED` the management client waits until the backup has started before returning control to the user, as shown here:

```
ndb_mgm> START BACKUP WAIT STARTED
Waiting for started, this may take several minutes
Node 2: Backup 3 started from node 1
ndb_mgm>
```

- **WAIT COMPLETED** causes the management client to wait until the backup process is complete before returning control to the user.

**WAIT COMPLETED** is the default.

The procedure for creating a backup consists of the following steps:

1. Start the management client (`ndb_mgm`), if it not running already.
2. Execute the **START BACKUP** command. This produces several lines of output indicating the progress of the backup, as shown here:

```
ndb_mgm> START BACKUP
Waiting for completed, this may take several minutes
Node 2: Backup 1 started from node 1
Node 2: Backup 1 started from node 1 completed
  StartGCP: 177 StopGCP: 180
  #Records: 7362 #LogRecords: 0
  Data: 453648 bytes Log: 0 bytes
ndb_mgm>
```

3. When the backup has started the management client displays this message:

```
Backup backup_id started from node node_id
```

*backup\_id* is the unique identifier for this particular backup. This identifier is saved in the cluster log, if it has not been configured otherwise. *node\_id* is the identifier of the management server that is coordinating the backup with the data nodes. At this point in the backup process the cluster has received and processed the backup request. It does not mean that the backup has finished. An example of this statement is shown here:

```
Node 2: Backup 1 started from node 1
```

4. The management client indicates with a message like this one that the backup has started:

```
Backup backup_id started from node node_id completed
```

As is the case for the notification that the backup has started, *backup\_id* is the unique identifier for this particular backup, and *node\_id* is the node ID of the management server that is coordinating the backup with the data nodes. This output is accompanied by additional information including relevant global checkpoints, the number of records backed up, and the size of the data, as shown here:

```
Node 2: Backup 1 started from node 1 completed
  StartGCP: 177 StopGCP: 180
  #Records: 7362 #LogRecords: 0
  Data: 453648 bytes Log: 0 bytes
```

It is also possible to perform a backup from the system shell by invoking `ndb_mgm` with the `-e` or `--execute` option, as shown in this example:

```
shell> ndb_mgm -e "START BACKUP 6 WAIT COMPLETED"
```

When using **START BACKUP** in this way, you must specify the backup ID.

Cluster backups are created by default in the **BACKUP** subdirectory of the `DataDir` on each data node. This can be overridden for one or more data nodes individually, or for all cluster data nodes in the `config.ini` file using the `BackupDataDir` configuration parameter as discussed in [Identifying Data Nodes](#). The backup files created for a backup with a given *backup\_id* are stored in a subdirectory named `BACKUP-backup_id` in the backup directory.

To abort a backup that is already in progress:

1. Start the management client.
2. Execute this command:

```
ndb_mgm> ABORT BACKUP backup_id
```

The number *backup\_id* is the identifier of the backup that was included in the response of the management client when the backup was started (in the message `Backup backup_id started from node management_node_id`).

- The management client will acknowledge the abort request with `Abort of backup backup_id ordered`.

#### Note

At this point, the management client has not yet received a response from the cluster data nodes to this request, and the backup has not yet actually been aborted.

- After the backup has been aborted, the management client will report this fact in a manner similar to what is shown here:

```
Node 1: Backup 3 started from 5 has been aborted. Error: 1321 - Backup aborted by user request: Permanent error: U
Node 3: Backup 3 started from 5 has been aborted. Error: 1323 - 1323: Permanent error: Internal error
Node 2: Backup 3 started from 5 has been aborted. Error: 1323 - 1323: Permanent error: Internal error
Node 4: Backup 3 started from 5 has been aborted. Error: 1323 - 1323: Permanent error: Internal error
```

In this example, we have shown sample output for a cluster with 4 data nodes, where the sequence number of the backup to be aborted is 3, and the management node to which the cluster management client is connected has the node ID 5. The first node to complete its part in aborting the backup reports that the reason for the abort was due to a request by the user. (The remaining nodes report that the backup was aborted due to an unspecified internal error.)

#### Note

There is no guarantee that the cluster nodes respond to an `ABORT BACKUP` command in any particular order.

The `Backup backup_id started from node management_node_id has been aborted` messages mean that the backup has been terminated and that all files relating to this backup have been removed from the cluster file system.

It is also possible to abort a backup in progress from a system shell using this command:

```
shell> ndb_mgm -e "ABORT BACKUP backup_id"
```

#### Note

If there is no backup having the ID *backup\_id* running when an `ABORT BACKUP` is issued, the management client makes no response, nor is it indicated in the cluster log that an invalid abort command was sent.

### 17.7.3.3. Configuration for MySQL Cluster Backups

Five configuration parameters are essential for backup:

- `BackupDataBufferSize`

The amount of memory used to buffer data before it is written to disk.
- `BackupLogBufferSize`

The amount of memory used to buffer log records before these are written to disk.
- `BackupMemory`

The total memory allocated in a database node for backups. This should be the sum of the memory allocated for the backup data buffer and the backup log buffer.
- `BackupWriteSize`

The default size of blocks written to disk. This applies for both the backup data buffer and the backup log buffer.
- `BackupMaxWriteSize`

The maximum size of blocks written to disk. This applies for both the backup data buffer and the backup log buffer.

More detailed information about these parameters can be found in [Backup Parameters](#).

### 17.7.3.4. MySQL Cluster Backup Troubleshooting

If an error code is returned when issuing a backup request, the most likely cause is insufficient memory or disk space. You should check that there is enough memory allocated for the backup.

#### Important

If you have set [BackupDataBufferSize](#) and [BackupLogBufferSize](#) and their sum is greater than 4MB, then you must also set [BackupMemory](#) as well. See [BackupMemory](#).

You should also make sure that there is sufficient space on the hard drive partition of the backup target.

[NDB](#) does not support repeatable reads, which can cause problems with the restoration process. Although the backup process is “hot”, restoring a MySQL Cluster from backup is not a 100% “hot” process. This is due to the fact that, for the duration of the restore process, running transactions get non-repeatable reads from the restored data. This means that the state of the data is inconsistent while the restore is in progress.

#### MySQL Enterprise

MySQL Enterprise subscribers will find more information about Cluster backup in the Knowledge Base article, [How Do I Backup my Cluster Database](#). Access to the MySQL Knowledge Base collection of articles is one of the advantages of subscribing to MySQL Enterprise. For more information, see <http://www.mysql.com/products/enterprise/advisors.html>.

## 17.7.4. Event Reports Generated in MySQL Cluster

In this section, we discuss the types of event logs provided by MySQL Cluster, and the types of events that are logged.

MySQL Cluster provides two types of event log:

- The *cluster log*, which includes events generated by all cluster nodes. The cluster log is the log recommended for most uses because it provides logging information for an entire cluster in a single location.

By default, the cluster log is saved to a file named `ndb_node_id_cluster.log`, (where *node\_id* is the node ID of the management server) in the same directory where the `ndb_mgm` binary resides.

Cluster logging information can also be sent to `stdout` or a `syslog` facility in addition to or instead of being saved to a file, as determined by the values set for the `DataDir` and `LogDestination` configuration parameters. See [Section 17.3.4.4, “Defining a MySQL Cluster Management Server”](#), for more information about these parameters.

- *Node logs* are local to each node.

Output generated by node event logging is written to the file `ndb_node_id_out.log` (where *node\_id* is the node's node ID) in the node's `DataDir`. Node event logs are generated for both management nodes and data nodes.

Node logs are intended to be used only during application development, or for debugging application code.

Both types of event logs can be set to log different subsets of events.

Each reportable event can be distinguished according to three different criteria:

- *Category*: This can be any one of the following values: `STARTUP`, `SHUTDOWN`, `STATISTICS`, `CHECKPOINT`, `NODERE-START`, `CONNECTION`, `ERROR`, or `INFO`.
- *Priority*: This is represented by one of the numbers from 1 to 15 inclusive, where 1 indicates “most important” and 15 “least important.”
- *Severity Level*: This can be any one of the following values: `ALERT`, `CRITICAL`, `ERROR`, `WARNING`, `INFO`, or `DEBUG`.

Both the cluster log and the node log can be filtered on these properties.

The format used in the cluster log is as shown here:

```

2007-01-26 19:35:55 [MgmSrvr] INFO -- Node 1: Data usage is 2%(60 32K pages of total 2560)
2007-01-26 19:35:55 [MgmSrvr] INFO -- Node 1: Index usage is 1%(24 8K pages of total 2336)
2007-01-26 19:35:55 [MgmSrvr] INFO -- Node 1: Resource 0 min: 0 max: 639 curr: 0
2007-01-26 19:35:55 [MgmSrvr] INFO -- Node 2: Data usage is 2%(76 32K pages of total 2560)
2007-01-26 19:35:55 [MgmSrvr] INFO -- Node 2: Index usage is 1%(24 8K pages of total 2336)
2007-01-26 19:35:55 [MgmSrvr] INFO -- Node 2: Resource 0 min: 0 max: 639 curr: 0
2007-01-26 19:35:55 [MgmSrvr] INFO -- Node 3: Data usage is 2%(58 32K pages of total 2560)
2007-01-26 19:35:55 [MgmSrvr] INFO -- Node 3: Index usage is 1%(25 8K pages of total 2336)
2007-01-26 19:35:55 [MgmSrvr] INFO -- Node 3: Resource 0 min: 0 max: 639 curr: 0
2007-01-26 19:35:55 [MgmSrvr] INFO -- Node 4: Data usage is 2%(74 32K pages of total 2560)
2007-01-26 19:35:55 [MgmSrvr] INFO -- Node 4: Index usage is 1%(25 8K pages of total 2336)
2007-01-26 19:35:55 [MgmSrvr] INFO -- Node 4: Resource 0 min: 0 max: 639 curr: 0
2007-01-26 19:39:42 [MgmSrvr] INFO -- Node 4: Node 9 Connected
2007-01-26 19:39:42 [MgmSrvr] INFO -- Node 1: Node 9 Connected
2007-01-26 19:39:42 [MgmSrvr] INFO -- Node 1: Node 9: API version 5.1.15
2007-01-26 19:39:42 [MgmSrvr] INFO -- Node 2: Node 9 Connected
2007-01-26 19:39:42 [MgmSrvr] INFO -- Node 2: Node 9: API version 5.1.15
2007-01-26 19:39:42 [MgmSrvr] INFO -- Node 3: Node 9 Connected
2007-01-26 19:39:42 [MgmSrvr] INFO -- Node 3: Node 9: API version 5.1.15
2007-01-26 19:39:42 [MgmSrvr] INFO -- Node 4: Node 9: API version 5.1.15
2007-01-26 19:59:22 [MgmSrvr] ALERT -- Node 2: Node 7 Disconnected
2007-01-26 19:59:22 [MgmSrvr] ALERT -- Node 2: Node 7 Disconnected

```

Each line in the cluster log contains the following information:

- A timestamp in `YYYY-MM-DD HH:MM:SS` format.
- The type of node which is performing the logging. In the cluster log, this is always `[MgmSrvr]`.
- The severity of the event.
- The ID of the node reporting the event.
- A description of the event. The most common types of events to appear in the log are connections and disconnections between different nodes in the cluster, and when checkpoints occur. In some cases, the description may contain status information.

### 17.7.4.1. MySQL Cluster Logging Management Commands

The following management commands are related to the cluster log:

- `CLUSTERLOG ON`  
Turns the cluster log on.
- `CLUSTERLOG OFF`  
Turns the cluster log off.
- `CLUSTERLOG INFO`  
Provides information about cluster log settings.
- `node_id CLUSTERLOG category=threshold`  
Logs `category` events with priority less than or equal to `threshold` in the cluster log.
- `CLUSTERLOG FILTER severity_level`  
Toggles cluster logging of events of the specified `severity_level`.

The following table describes the default setting (for all data nodes) of the cluster log category threshold. If an event has a priority with a value lower than or equal to the priority threshold, it is reported in the cluster log.

Note that events are reported per data node, and that the threshold can be set to different values on different nodes.

Category	Default threshold (All data nodes)
STARTUP	7
SHUTDOWN	7
STATISTICS	7

CHECKPOINT	7
NODERESTART	7
CONNECTION	7
ERROR	15
INFO	7

The `STATISTICS` category can provide a great deal of useful data. See [Section 17.7.4.3, “Using `CLUSTERLOG STATISTICS` in the MySQL Cluster Management Client”](#), for more information.

Thresholds are used to filter events within each category. For example, a `STARTUP` event with a priority of 3 is not logged unless the threshold for `STARTUP` is set to 3 or higher. Only events with priority 3 or lower are sent if the threshold is 3.

The following table shows the event severity levels.

### Note

These correspond to Unix `syslog` levels, except for `LOG_EMERG` and `LOG_NOTICE`, which are not used or mapped.

1	ALERT	A condition that should be corrected immediately, such as a corrupted system database
2	CRITICAL	Critical conditions, such as device errors or insufficient resources
3	ERROR	Conditions that should be corrected, such as configuration errors
4	WARNING	Conditions that are not errors, but that might require special handling
5	INFO	Informational messages
6	DEBUG	Debugging messages used for <code>NDBCLUSTER</code> development

Event severity levels can be turned on or off (using `CLUSTERLOG FILTER` — see above). If a severity level is turned on, then all events with a priority less than or equal to the category thresholds are logged. If the severity level is turned off then no events belonging to that severity level are logged.

### Important

Cluster log levels are set on a per `ndb_mgmd`, per subscriber basis. This means that, in a MySQL Cluster with multiple management servers, using a `CLUSTERLOG` command in an instance of `ndb_mgm` connected to one management server affects only logs generated by that management server but not by any of the others. This also means that, should one of the management servers be restarted, only logs generated by that management server are affected by the resetting of log levels caused by the restart.

## 17.7.4.2. MySQL Cluster Log Events

An event report reported in the event logs has the following format:

```
datetime [string] severity -- message
```

For example:

```
09:19:30 2005-07-24 [NDB] INFO -- Node 4 Start phase 4 completed
```

This section discusses all reportable events, ordered by category and severity level within each category.

In the event descriptions, GCP and LCP mean “Global Checkpoint” and “Local Checkpoint”, respectively.

### CONNECTION Events

These events are associated with connections between Cluster nodes.

Event	Priority	Severity Level	Description
data nodes connected	8	INFO	Data nodes connected
data nodes disconnected	8	INFO	Data nodes disconnected
Communication closed	8	INFO	SQL node or data node connection closed

Communication opened	8	INFO	SQL node or data node connection opened
----------------------	---	------	---

### CHECKPOINT Events

The logging messages shown here are associated with checkpoints.

Event	Priority	Severity Level	Description
LCP stopped in calc keep GCI	0	ALERT	LCP stopped
Local checkpoint fragment completed	11	INFO	LCP on a fragment has been completed
Global checkpoint completed	10	INFO	GCP finished
Global checkpoint started	9	INFO	Start of GCP: REDO log is written to disk
Local checkpoint completed	8	INFO	LCP completed normally
Local checkpoint started	7	INFO	Start of LCP: data written to disk
Report undo log blocked	7	INFO	UNDO logging blocked; buffer near overflow

### STARTUP Events

The following events are generated in response to the startup of a node or of the cluster and of its success or failure. They also provide information relating to the progress of the startup process, including information concerning logging activities.

Event	Priority	Severity Level	Description
Internal start signal received STTORY	15	INFO	Blocks received after completion of restart
Undo records executed	15	INFO	
New REDO log started	10	INFO	GCI keep <i>X</i> , newest restorable GCI <i>Y</i>
New log started	10	INFO	Log part <i>X</i> , start MB <i>Y</i> , stop MB <i>Z</i>
Node has been refused for inclusion in the cluster	8	INFO	Node cannot be included in cluster due to misconfiguration, inability to establish communication, or other problem
data node neighbors	8	INFO	Shows neighboring data nodes
data node start phase <i>X</i> completed	4	INFO	A data node start phase has been completed
Node has been successfully included into the cluster	3	INFO	Displays the node, managing node, and dynamic ID
data node start phases initiated	1	INFO	NDB Cluster nodes starting
data node all start phases completed	1	INFO	NDB Cluster nodes started
data node shutdown initiated	1	INFO	Shutdown of data node has commenced
data node shutdown aborted	1	INFO	Unable to shut down data node normally

### NODERESTART Events

The following events are generated when restarting a node and relate to the success or failure of the node restart process.

Event	Priority	Severity Level	Description
Node failure phase completed	8	ALERT	Reports completion of node failure phases
Node has failed, node state was <i>X</i>	8	ALERT	Reports that a node has failed
Report arbitrator results	2	ALERT	There are eight different possible results for arbitration attempts: <ul style="list-style-type: none"> <li>Arbitration check failed — less than 1/2 nodes left</li> <li>Arbitration check succeeded — node group majority</li> <li>Arbitration check failed — missing node group</li> </ul>

			<ul style="list-style-type: none"> <li>• Network partitioning — arbitration required</li> <li>• Arbitration succeeded — affirmative response from node <i>X</i></li> <li>• Arbitration failed - negative response from node <i>X</i></li> <li>• Network partitioning - no arbitrator available</li> <li>• Network partitioning - no arbitrator configured</li> </ul>
Completed copying a fragment	10	INFO	
Completed copying of dictionary information	8	INFO	
Completed copying distribution information	8	INFO	
Starting to copy fragments	8	INFO	
Completed copying all fragments	8	INFO	
GCP takeover started	7	INFO	
GCP takeover completed	7	INFO	
LCP takeover started	7	INFO	
LCP takeover completed (state = <i>X</i> )	7	INFO	
Report whether an arbitrator is found or not	6	INFO	<p>There are seven different possible outcomes when seeking an arbitrator:</p> <ul style="list-style-type: none"> <li>• Management server restarts arbitration thread [state=<i>X</i>]</li> <li>• Prepare arbitrator node <i>X</i> [ticket=<i>Y</i>]</li> <li>• Receive arbitrator node <i>X</i> [ticket=<i>Y</i>]</li> <li>• Started arbitrator node <i>X</i> [ticket=<i>Y</i>]</li> <li>• Lost arbitrator node <i>X</i> - process failure [state=<i>Y</i>]</li> <li>• Lost arbitrator node <i>X</i> - process exit [state=<i>Y</i>]</li> <li>• Lost arbitrator node <i>X</i> &lt;error msg&gt; [state=<i>Y</i>]</li> </ul>

### STATISTICS Events

The following events are of a statistical nature. They provide information such as numbers of transactions and other operations, amount of data sent or received by individual nodes, and memory usage.

Event	Priority	Severity Level	Description
Report job scheduling statistics	9	INFO	Mean internal job scheduling statistics
Sent number of bytes	9	INFO	Mean number of bytes sent to node <i>X</i>
Received # of bytes	9	INFO	Mean number of bytes received from node <i>X</i>
Report transaction statistics	8	INFO	Numbers of: transactions, commits, reads, simple reads, writes, concurrent operations, attribute information, and aborts
Report operations	8	INFO	Number of operations
Report table create	7	INFO	
Memory usage	5	INFO	Data and index memory usage (80%, 90%, and 100%)

### ERROR Events

These events relate to Cluster errors and warnings. The presence of one or more of these generally indicates that a major malfunction or failure has occurred.

Event	Priority	Severity	Description
Dead due to missed heartbeat	8	ALERT	Node <i>X</i> declared “dead” due to missed heartbeat
Transporter errors	2	ERROR	
Transporter warnings	8	WARNING	
Missed heartbeats	8	WARNING	Node <i>X</i> missed heartbeat # <i>Y</i>
General warning events	2	WARNING	

#### INFO Events

These events provide general information about the state of the cluster and activities associated with Cluster maintenance, such as logging and heartbeat transmission.

Event	Priority	Severity	Description
Sent heartbeat	12	INFO	Heartbeat sent to node <i>X</i>
Create log bytes	11	INFO	Log part, log file, MB
General information events	2	INFO	

### 17.7.4.3. Using `CLUSTERLOG STATISTICS` in the MySQL Cluster Management Client

The NDB management client's `CLUSTERLOG STATISTICS` command can provide a number of useful statistics in its output. Counters providing information about the state of the cluster are updated at 5-second reporting intervals by the transaction coordinator (TC) and the local query handler (LQH), and written to the cluster log.

**Transaction coordinator statistics.** Each transaction has one transaction coordinator, which is chosen by one of the following methods:

- In a round-robin fashion
- By communication proximity

#### Note

You can determine which TC selection method is used for transactions started from a given SQL node using the `ndb_optimized_node_selection` system variable. For more information, see [Section 17.4.3, “MySQL Cluster System Variables”](#).

All operations within the same transaction use the same transaction coordinator, which reports the following statistics:

- **Trans count.** This is the number transactions started in the last interval using this TC as the transaction coordinator. Any of these transactions may have committed, have been aborted, or remain uncommitted at the end of the reporting interval.

#### Note

Transactions do not migrate between TCs.

- **Commit count.** This is the number of transactions using this TC as the transaction coordinator that were committed in the last reporting interval. Because some transactions committed in this reporting interval may have started in a previous reporting interval, it is possible for `Commit count` to be greater than `Trans count`.
- **Read count.** This is the number of primary key read operations using this TC as the transaction coordinator that were started in the last reporting interval, including simple reads. This count also includes reads performed as part of unique index operations. A unique index read operation generates 2 primary key read operations — 1 for the hidden unique index table, and 1 for the table on which the read takes place.
- **Simple read count.** This is the number of simple read operations using this TC as the transaction coordinator that were started in the last reporting interval. This is a subset of `Read count`. Because the value of `Simple read count` is incremented at a different point in time from `Read count`, it can lag behind `Read count` slightly, so it is conceivable that `Simple read count` is not equal to `Read count` for a given reporting interval, even if all reads made during that time were in fact simple reads.

- **Write count.** This is the number of primary key write operations using this TC as the transaction coordinator that were started in the last reporting interval. This includes all inserts, updates, writes and deletes, as well as writes performed as part of unique index operations.

#### Note

A unique index update operation can generate multiple PK read and write operations on the index table and on the base table.

- **AttrInfoCount.** This is the number of 32-bit data words received in the last reporting interval for primary key operations using this TC as the transaction coordinator. For reads, this is proportional to the number of columns requested. For inserts and updates, this is proportional to the number of columns written, and the size of their data. For delete operations, this is usually zero. Unique index operations generate multiple PK operations and so increase this count. However, data words sent to describe the PK operation itself, and the key information sent, are *not* counted here. Attribute information sent to describe columns to read for scans, or to describe ScanFilters, is also not counted in **AttrInfoCount**.
- **Concurrent Operations.** This is the number of primary key or scan operations using this TC as the transaction coordinator that were started during the last reporting interval but that were not completed. Operations increment this counter when they are started and decrement it when they are completed; this occurs after the transaction commits. Dirty reads and writes — as well as failed operations — decrement this counter. The maximum value that **Concurrent Operations** can have is the maximum number of operations that a TC block can support; currently, this is  $(2 * \text{MaxNoOfConcurrentOperations}) + 16 + \text{MaxNoOfConcurrentTransactions}$ . (For more information about these configuration parameters, see the *Transaction Parameters* section of [Section 17.3.4.5, “Defining MySQL Cluster Data Nodes”](#).)
- **Abort count.** This is the number of transactions using this TC as the transaction coordinator that were aborted during the last reporting interval. Because some transactions that were aborted in the last reporting interval may have started in a previous reporting interval, **Abort count** can sometimes be greater than **Trans count**.
- **Scans.** This is the number of table scans using this TC as the transaction coordinator that were started during the last reporting interval. This does not include range scans (that is, ordered index scans).
- **Range scans.** This is the number of ordered index scans using this TC as the transaction coordinator that were started in the last reporting interval.

**Local query handler statistics (Operations).** There is 1 cluster event per local query handler block (that is, 1 per data node process). Operations are recorded in the LQH where the data they are operating on resides.

#### Note

A single transaction may operate on data stored in multiple LQH blocks.

The **Operations** statistic provides the number of local operations performed by this LQH block in the last reporting interval, and includes all types of read and write operations (insert, update, write, and delete operations). This also includes operations used to replicate writes — for example, in a 2-replica cluster, the write to the primary replica is recorded in the primary LQH, and the write to the backup will be recorded in the backup LQH. Unique key operations may result in multiple local operations; however, this does *not* include local operations generated as a result of a table scan or ordered index scan, which are not counted.

**Process scheduler statistics.** In addition to the statistics reported by the transaction coordinator and local query handler, each **nd-bd** process has a scheduler which also provides useful metrics relating to the performance of a MySQL Cluster. This scheduler runs in an infinite loop; during each loop the scheduler performs the following tasks:

1. Read any incoming messages from sockets into a job buffer.
2. Check whether there are any timed messages to be executed; if so, put these into the job buffer as well.
3. Execute (in a loop) any messages in the job buffer.
4. Send any distributed messages that were generated by executing the messages in the job buffer.
5. Wait for any new incoming messages.

Process scheduler statistics include the following:

- **Mean Loop Counter.** This is the number of loops executed in the third step from the preceding list. This statistic increases in size as the utilization of the TCP/IP buffer improves. You can use this to monitor changes in performance as you add new data node processes.
- **Mean send size and Mean receive size.** These statistics allow you to gauge the efficiency of, respectively writes and reads between nodes. The values are given in bytes. Higher values mean a lower cost per byte sent or received; the maxim-

um value is 64K.

To cause all cluster log statistics to be logged, you can use the following command in the [NDB](#) management client:

```
ndb_mgm> ALL CLUSTERLOG STATISTICS=15
```

### Note

Setting the threshold for `STATISTICS` to 15 causes the cluster log to become very verbose, and to grow quite rapidly in size, in direct proportion to the number of cluster nodes and the amount of activity in the MySQL Cluster.

For more information about MySQL Cluster management client commands relating to logging and reporting, see [Section 17.7.4.1, “MySQL Cluster Logging Management Commands”](#).

## 17.7.5. MySQL Cluster Log Messages

This section contains information about the messages written to the cluster log in response to different cluster log events. It provides additional, more specific information on [NDB](#) transporter errors.

### 17.7.5.1. MySQL Cluster — Messages in the Cluster Log

The following table lists the most common [NDB](#) cluster log messages. For information about the cluster log, log events, and event types, see [Section 17.7.4, “Event Reports Generated in MySQL Cluster”](#). These log messages also correspond to log event types in the MGM API; see [The `Ndb\_logevent\_type` Type](#), for related information of interest to Cluster API developers.

<p><b>Log Message.</b> <code>Node mgm_node_id: Node data_node_id Connected</code></p> <p><b>Description.</b> The data node having node ID <code>node_id</code> has connected to the management server (node <code>mgm_node_id</code>).</p>	<p><b>Event Name.</b> <code>Connected</code></p> <p><b>Event Type.</b> <code>Connection</code></p> <p><b>Priority.</b> 8</p> <p><b>Severity.</b> <code>INFO</code></p>
<p><b>Log Message.</b> <code>Node mgm_node_id: Node data_node_id Disconnected</code></p> <p><b>Description.</b> The data node having node ID <code>data_node_id</code> has disconnected from the management server (node <code>mgm_node_id</code>).</p>	<p><b>Event Name.</b> <code>Disconnected</code></p> <p><b>Event Type.</b> <code>Connection</code></p> <p><b>Priority.</b> 8</p> <p><b>Severity.</b> <code>ALERT</code></p>
<p><b>Log Message.</b> <code>Node data_node_id: Communication to Node api_node_id closed</code></p> <p><b>Description.</b> The API node or SQL node having node ID <code>api_node_id</code> is no longer communicating with data node <code>data_node_id</code>.</p>	<p><b>Event Name.</b> <code>CommunicationClosed</code></p> <p><b>Event Type.</b> <code>Connection</code></p> <p><b>Priority.</b> 8</p> <p><b>Severity.</b> <code>INFO</code></p>
<p><b>Log Message.</b> <code>Node data_node_id: Communication to Node api_node_id opened</code></p> <p><b>Description.</b> The API node or SQL node having node ID <code>api_node_id</code> is now communicating with data node <code>data_node_id</code>.</p>	<p><b>Event Name.</b> <code>CommunicationOpened</code></p> <p><b>Event Type.</b> <code>Connection</code></p> <p><b>Priority.</b> 8</p> <p><b>Severity.</b> <code>INFO</code></p>

## 17.7.5.2. MySQL Cluster — NDB Transporter Errors

This section lists error codes, names, and messages that are written to the cluster log in the event of transporter errors.

Error Code	Error Name	Error Text
0x00	TE_NO_ERROR	NO ERROR
0x01	TE_ERROR_CLOSING_SOCKET	ERROR FOUND DURING CLOSING OF SOCKET
0x02	TE_ERROR_IN_SELECT_BEFORE_ACCEPT	ERROR FOUND BEFORE ACCEPT. THE TRANSPORTER WILL RETRY
0x03	TE_INVALID_MESSAGE_LENGTH	ERROR FOUND IN MESSAGE (INVALID MESSAGE LENGTH)
0x04	TE_INVALID_CHECKSUM	ERROR FOUND IN MESSAGE (CHECKSUM)
0x05	TE_COULD_NOT_CREATE_SOCKET	ERROR FOUND WHILE CREATING SOCKET (CAN'T CREATE SOCKET)
0x06	TE_COULD_NOT_BIND_SOCKET	ERROR FOUND WHILE BINDING SERVER SOCKET
0x07	TE_LISTEN_FAILED	ERROR FOUND WHILE LISTENING TO SERVER SOCKET
0x08	TE_ACCEPT_RETURN_ERROR	ERROR FOUND DURING ACCEPT (ACCEPT RETURN ERROR)
0x0b	TE_SHM_DISCONNECT	THE REMOTE NODE HAS DISCONNECTED
0x0c	TE_SHM_IPC_STAT	UNABLE TO CHECK SHM SEGMENT
0x0d	TE_SHM_UNABLE_TO_CREATE_SEGMENT	UNABLE TO CREATE SHM SEGMENT
0x0e	TE_SHM_UNABLE_TO_ATTACH_SEGMENT	UNABLE TO ATTACH SHM SEGMENT
0x0f	TE_SHM_UNABLE_TO_REMOVE_SEGMENT	UNABLE TO REMOVE SHM SEGMENT
0x10	TE_TOO_SMALL_SIGID	SIG ID TOO SMALL
0x11	TE_TOO_LARGE_SIGID	SIG ID TOO LARGE
0x12	TE_WAIT_STACK_FULL	WAIT STACK WAS FULL
0x13	TE_RECEIVE_BUFFER_FULL	RECEIVE BUFFER WAS FULL
0x14	TE_SIGNAL_LOST_SEND_BUFFER_FULL	SEND BUFFER WAS FULL, AND TRYING TO FORCE SEND FAILS
0x15	TE_SIGNAL_LOST	SEND FAILED FOR UNKNOWN REASON (SIGNAL LOST)
0x16	TE_SEND_BUFFER_FULL	THE SEND BUFFER WAS FULL, BUT SLEEPING FOR A WHILE SOLVED
0x0017	TE_SCI_LINK_ERROR	THERE IS NO LINK FROM THIS NODE TO THE SWITCH
0x18	TE_SCI_UNABLE_TO_START_SEQUENCE	COULD NOT START A SEQUENCE, BECAUSE SYSTEM RESOURCES ARE EXHAUSTED OR NO SEQUENCE HAS BEEN CREATED
0x19	TE_SCI_UNABLE_TO_REMOVE_SEQUENCE	COULD NOT REMOVE A SEQUENCE
0x1a	TE_SCI_UNABLE_TO_CREATE_SEQUENCE	COULD NOT CREATE A SEQUENCE, BECAUSE SYSTEM RESOURCES ARE EXHAUSTED. MUST REBOOT
0x1b	TE_SCI_UNRECOVERABLE_DATA_TX_ERROR	TRIED TO SEND DATA ON REDUNDANT LINK BUT FAILED
0x1c	TE_SCI_CANNOT_INIT_LOCALSEGMENT	CANNOT INITIALIZE LOCAL SEGMENT
0x1d	TE_SCI_CANNOT_MAP_REMOTESEGMENT	CANNOT MAP REMOTE SEGMENT
0x1e	TE_SCI_UNABLE_TO_UNMAP_SEGMENT	CANNOT FREE THE RESOURCES USED BY THIS SEGMENT (STEP 1)
0x1f	TE_SCI_UNABLE_TO_REMOVE_SEGMENT	CANNOT FREE THE RESOURCES USED

Error Code	Error Name	Error Text
		BY THIS SEGMENT (STEP 2)
0x20	<b>TE_SCI_UNABLE_TO_DISCONNECT_SEGMENT</b>	CANNOT DISCONNECT FROM A REMOTE SEGMENT
0x21	<b>TE_SHM_IPC_PERMANENT</b>	SHM IPC PERMANENT ERROR
0x22	<b>TE_SCI_UNABLE_TO_CLOSE_CHANNEL</b>	UNABLE TO CLOSE THE SCI CHANNEL AND THE RESOURCES ALLOCATED

## 17.7.6. MySQL Cluster Single User Mode

*Single user mode* allows the database administrator to restrict access to the database system to a single API node, such as a MySQL server (SQL node) or an instance of `ndb_restore`. When entering single user mode, connections to all other API nodes are closed gracefully and all running transactions are aborted. No new transactions are permitted to start.

Once the cluster has entered single user mode, only the designated API node is granted access to the database.

You can use the `ALL STATUS` command to see when the cluster has entered single user mode.

Example:

```
ndb_mgm> ENTER SINGLE USER MODE 5
```

After this command has executed and the cluster has entered single user mode, the API node whose node ID is `5` becomes the cluster's only permitted user.

The node specified in the preceding command must be an API node; attempting to specify any other type of node will be rejected.

### Note

When the preceding command is invoked, all transactions running on the designated node are aborted, the connection is closed, and the server must be restarted.

The command `EXIT SINGLE USER MODE` changes the state of the cluster's data nodes from single user mode to normal mode. API nodes — such as MySQL Servers — waiting for a connection (that is, waiting for the cluster to become ready and available), are again permitted to connect. The API node denoted as the single-user node continues to run (if still connected) during and after the state change.

Example:

```
ndb_mgm> EXIT SINGLE USER MODE
```

There are two recommended ways to handle a node failure when running in single user mode:

- Method 1:
  1. Finish all single user mode transactions
  2. Issue the `EXIT SINGLE USER MODE` command
  3. Restart the cluster's data nodes
- Method 2:
 

Restart database nodes prior to entering single user mode.

## 17.7.7. Quick Reference: MySQL Cluster SQL Statements

This section discusses several SQL statements that can prove useful in managing and monitoring a MySQL server that is connected to a MySQL Cluster, and in some cases provide information about the cluster itself.

- `SHOW ENGINE NDB STATUS, SHOW ENGINE NDBCLUSTER STATUS`

The output of this statement contains information about the server's connection to the cluster, creation and usage of MySQL Cluster objects, and binary logging for MySQL Cluster replication.

See [Section 12.5.5.12, “SHOW ENGINE Syntax”](#), for a usage example and more detailed information.

- `SHOW ENGINES [LIKE 'NDB%']`

This statement can be used to determine whether or not clustering support is enabled in the MySQL server, and if so, whether it is active.

See [Section 12.5.5.13, “SHOW ENGINES Syntax”](#), for more detailed information.

- `SHOW VARIABLES LIKE 'NDB%'`

This statement provides a list of most server system variables relating to the `NDB` storage engine, and their values, as shown here:

```
mysql> SHOW VARIABLES LIKE 'NDB%';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| ndb_autoincrement_prefetch_sz | 32 |
| ndb_cache_check_time | 0 |
| ndb_extra_logging | 0 |
| ndb_force_send | ON |
| ndb_index_stat_cache_entries | 32 |
| ndb_index_stat_enable | OFF |
| ndb_index_stat_update_freq | 20 |
| ndb_report_thresh_binlog_epoch_slip | 3 |
| ndb_report_thresh_binlog_mem_usage | 10 |
| ndb_use_copying_alter_table | OFF |
| ndb_use_exact_count | ON |
| ndb_use_transactions | ON |
+-----+-----+
```

See [Section 5.1.3, “Server System Variables”](#), for more information.

- `SHOW STATUS LIKE 'NDB%'`

This statement shows at a glance whether or not the MySQL server is acting as a cluster SQL node, and if so, it provides the MySQL server's cluster node ID, the host name and port for the cluster management server to which it is connected, and the number of data nodes in the cluster, as shown here:

```
mysql> SHOW STATUS LIKE 'NDB%';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| Ndb_cluster_node_id | 10 |
| Ndb_config_from_host | 192.168.0.103 |
| Ndb_config_from_port | 1186 |
| Ndb_number_of_data_nodes | 4 |
+-----+-----+
```

If the MySQL server was built with clustering support, but it is not connected to a cluster, all rows in the output of this statement contain a zero or an empty string:

```
mysql> SHOW STATUS LIKE 'NDB%';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| Ndb_cluster_node_id | 0 |
| Ndb_config_from_host | 0 |
| Ndb_config_from_port | 0 |
| Ndb_number_of_data_nodes | 0 |
+-----+-----+
```

See also [Section 12.5.5.32, “SHOW STATUS Syntax”](#).

## 17.8. MySQL Cluster Security Issues

This section discusses security considerations to take into account when setting up and running MySQL Cluster.

Topics to be covered in this chapter include the following:

- MySQL Cluster and network security issues
- Configuration issues relating to running MySQL Cluster securely
- MySQL Cluster and the MySQL privilege system
- MySQL standard security procedures as applicable to MySQL Cluster

## 17.8.1. MySQL Cluster Security and Networking Issues

In this section, we discuss basic network security issues as they relate to MySQL Cluster. It is extremely important to remember that MySQL Cluster “out of the box” is not secure; you or your network administrator must take the proper steps to insure that your cluster cannot be compromised over the network.

Cluster communication protocols are inherently insecure, and no encryption or similar security measures are used in communications between nodes in the cluster. Because network speed and latency have a direct impact on the cluster’s efficiency, it is also not advisable to employ SSL or other encryption to network connections between nodes, as such schemes will effectively slow communications.

It is also true that no authentication is used for controlling API node access to a MySQL Cluster. As with encryption, the overhead of imposing authentication requirements would have an adverse impact on Cluster performance.

In addition, there is no checking of the source IP address for either of the following when accessing the cluster:

- SQL or API nodes using “free slots” created by empty `[mysqld]` or `[api]` sections in the `config.ini` file

This means that, if there are any empty `[mysqld]` or `[api]` sections in the `config.ini` file, then any API nodes (including SQL nodes) that know the management server’s host name (or IP address) and port can connect to the cluster and access its data without restriction. (See [Section 17.8.2, “MySQL Cluster and MySQL Privileges”](#), for more information about this and related issues.)

### Note

You can exercise some control over SQL and API node access to the cluster by specifying a `HostName` parameter for all `[mysqld]` and `[api]` sections in the `config.ini` file. However, this also means that, should you wish to connect an API node to the cluster from a previously unused host, you need to add an `[api]` section containing its host name to the `config.ini` file.

More information is available [elsewhere in this chapter](#) about the `HostName` parameter. Also see [Section 17.3.3, “Quick Test Setup of MySQL Cluster”](#), for configuration examples using `HostName` with API nodes.

- Any `ndb_mgm` client

This means that any cluster management client that is given the management server’s host name (or IP address) and port (if not the standard port) can connect to the cluster and execute any management client command. This includes commands such as `ALL STOP` and `SHUTDOWN`.

For these reasons, it is necessary to protect the cluster on the network level. The safest network configuration for Cluster is one which isolates connections between Cluster nodes from any other network communications. This can be accomplished by any of the following methods:

1. Keeping Cluster nodes on a network that is physically separate from any public networks. This option is the most dependable; however, it is the most expensive to implement.

We show an example of a MySQL Cluster setup using such a physically segregated network here:

This setup has two networks, one private (solid box) for the Cluster management servers and data nodes, and one public (dotted box) where the SQL nodes reside. (We show the management and data nodes connected using a gigabit switch since this provides the best performance.) Both networks are protected from the outside by a hardware firewall, sometimes also known as a *network-based firewall*.

This network setup is safest because no packets can reach the cluster's management or data nodes from outside the network — and none of the cluster's internal communications can reach the outside — without going through the SQL nodes, as long as the SQL nodes do not allow any packets to be forwarded. This means, of course, that all SQL nodes must be secured against hacking attempts.

### Important

With regard to potential security vulnerabilities, an SQL node is no different from any other MySQL server. See [Section 5.3.2, “Making MySQL Secure Against Attackers”](#), for a description of techniques you can use to secure MySQL servers.

- Using one or more software firewalls (also known as *host-based firewalls*) to control which packets pass through to the cluster from portions of the network that do not require access to it. In this type of setup, a software firewall must be installed on every host in the cluster which might otherwise be accessible from outside the local network.

The host-based option is the least expensive to implement, but relies purely on software to provide protection and so is the most difficult to keep secure.

This type of network setup for MySQL Cluster is illustrated here:

Using this type of network setup means that there are two zones of MySQL Cluster hosts. Each cluster host must be able to communicate with all of the other machines in the cluster, but only those hosting SQL nodes (dotted box) can be permitted to have any contact with the outside, while those in the zone containing the data nodes and management nodes (solid box) must be isolated from any machines that are not part of the cluster. Applications using the cluster and user of those applications must *not* be permitted to have direct access to the management and data node hosts.

To accomplish this, you must set up software firewalls that limit the traffic to the type or types shown in the following table, according to the type of node that is running on each cluster host computer:

Type of Node to be Accessed	Traffic to Allow
SQL or API node	<ul style="list-style-type: none"> <li>It originates from the IP address of a management or data node (using any TCP or UDP port).</li> <li>It originates from within the network in which the cluster resides and is on the port that your application is using.</li> </ul>
Data node or Management node	<ul style="list-style-type: none"> <li>It originates from the IP address of a management or data node (using any TCP or UDP port).</li> <li>It originates from the IP address of an SQL or API node.</li> </ul>

Any traffic other than that shown in the table for a given node type should be denied.

The specifics of configuring a firewall vary from firewall application to firewall application, and are beyond the scope of this Manual. `iptables` is a very common and reliable firewall application, which is often used with `APF` as a front end to make configuration easier. You can (and should) consult the documentation for the software firewall that you employ, should you choose to implement a MySQL Cluster network setup of this type, or of a “mixed” type as discussed under the next item.

- It is also possible to employ a combination of the first two methods, using both hardware and software to secure the cluster — that is, using both network-based and host-based firewalls. This is between the first two schemes in terms of both security level and cost. This type of network setup keeps the cluster behind the hardware firewall, but allows incoming packets to travel beyond the router connecting all cluster hosts in order to reach the SQL nodes.

One possible network deployment of a MySQL Cluster using hardware and software firewalls in combination is shown here:

In this case, you can set the rules in the hardware firewall to deny any external traffic except to SQL nodes and API nodes, and then allow traffic to them only on the ports required by your application.

Whatever network configuration you use, remember that your objective from the viewpoint of keeping the cluster secure remains the same — to prevent any unessential traffic from reaching the cluster while ensuring the most efficient communication between the nodes in the cluster.

Because MySQL Cluster requires large numbers of ports to be open for communications between nodes, the recommended option is to use a segregated network. This represents the simplest way to prevent unwanted traffic from reaching the cluster.

#### Note

If you wish to administer a MySQL Cluster remotely (that is, from outside the local network), the recommended way to do this is to use `ssh` or another secure login shell to access an SQL node host. From this host, you can then run the management client to access the management server safely, from within the Cluster's own local network.

Even though it is possible to do so in theory, it is *not* recommended to use `ndb_mgm` to manage a Cluster directly from outside the local network on which the Cluster is running. Since neither authentication nor encryption takes place between the management client and the management server, this represents an extremely insecure means of managing the cluster, and is almost certain to be compromised sooner or later.

## 17.8.2. MySQL Cluster and MySQL Privileges

In this section, we discuss how the MySQL privilege system works in relation to MySQL Cluster and the implications of this for keeping a MySQL Cluster secure.

Standard MySQL privileges apply to MySQL Cluster tables. This includes all MySQL privilege types (`SELECT` privilege, `UPDATE` privilege, `DELETE` privilege, and so on) granted on the database, table, and column level. As with any other MySQL Server,

user and privilege information is stored in the `mysql` system database. The SQL statements used to grant and revoke privileges on NDB tables, databases containing such tables, and columns within such tables are identical in all respects with the `GRANT` and `REVOKE` statements used in connection with database objects involving any (other) MySQL storage engine. The same thing is true with respect to the `CREATE USER` and `DROP USER` statements.

It is important to keep in mind that the MySQL grant tables use the `MyISAM` storage engine. Because of this, those tables are not duplicated or shared among MySQL servers acting as SQL nodes in a MySQL Cluster. By way of example, suppose that two SQL nodes **A** and **B** are connected to the same MySQL Cluster, which has an NDB table named `mytable` in a database named `mydb`, and that you execute an SQL statement on server **A** that creates a new user `jon@localhost` and grants this user the `SELECT` privilege on that table:

```
mysql> GRANT SELECT ON mydb.mytable
-> TO jon@localhost IDENTIFIED BY 'mypass';
```

This user is *not* created on server **B**. In order for this to take place, the statement must also be run on server **B**. Similarly, statements run on server **A** and affecting the privileges of existing users on server **A** do not affect users on server **B** unless those statements are actually run on server **B** as well.

In other words, *changes in users and their privileges do not automatically propagate between SQL nodes*. Synchronization of privileges between SQL nodes must be done either manually or by scripting an application that periodically synchronizes the privilege tables on all SQL nodes in the cluster.

Conversely, because there is no way in MySQL to deny privileges (privileges can either be revoked or not granted in the first place, but not denied as such), there is no special protection for NDB tables on one SQL node from users that have privileges on another SQL node. The most far-reaching example of this is the MySQL `root` account, which can perform any action on any database object. In combination with empty `[mysqld]` or `[api]` sections of the `config.ini` file, this account can be especially dangerous. To understand why, consider the following scenario:

- The `config.ini` file contains at least one empty `[mysqld]` or `[api]` section. This means that the Cluster management server performs no checking of the host from which a MySQL Server (or other API node) accesses the MySQL Cluster.
- There is no firewall, or the firewall fails to protect against access to the Cluster from hosts external to the network.
- The host name or IP address of the Cluster's management server is known or can be determined from outside the network.

If these conditions are true, then anyone, anywhere can start a MySQL Server with `--ndbcluster - -ndb-connectstring=management_host` and access the Cluster. Using the MySQL `root` account, this person can then perform the following actions:

- Execute a `SHOW DATABASES` statement to obtain a list of all databases that exist in the cluster
- Execute a `SHOW TABLES FROM some_database` statement to obtain a list of all NDB tables in a given database
- Run any legal MySQL statements on any of those tables, such as:
  - `SELECT * FROM some_table` to read all the data from any table
  - `DELETE FROM some_table` to delete all the data from a table
  - `DESCRIBE some_table` or `SHOW CREATE TABLE some_table` to determine the table schema
  - `UPDATE some_table SET column1 = any_value1` to fill a table column with “garbage” data; this could actually cause much greater damage than simply deleting all the data

Even more insidious variations might include statements like these:

```
UPDATE some_table SET an_int_column = an_int_column + 1
```

or

```
UPDATE some_table SET a_varchar_column = REVERSE(a_varchar_column)
```

Such malicious statements are limited only by the imagination of the attacker.

The only tables that would be safe from this sort of mayhem would be those tables that were created using storage engines other than NDB, and so not visible to a “rogue” SQL node.

## Note

A user who can log in as `root` can also access the `INFORMATION_SCHEMA` database and its tables, and so obtain information about databases, tables, stored routines, scheduled events, and any other database objects for which metadata is stored in `INFORMATION_SCHEMA`.

It is also a very good idea to use different passwords for the `root` accounts on different cluster SQL nodes.

In sum, you cannot have a safe MySQL Cluster if it is directly accessible from outside your local network.

### Important

*Never leave the MySQL root account password empty.* This is just as true when running MySQL as a MySQL Cluster SQL node as it is when running it as a standalone (non-Cluster) MySQL Server, and should be done as part of the MySQL installation process before configuring the MySQL Server as an SQL node in a MySQL Cluster.

You should never convert the system tables in the `mysql` database to use the `NDB` storage engine. There are a number of reasons why you should not do this, but the most important reason is this: *Many of the SQL statements that affect `mysql` tables storing information about user privileges, stored routines, scheduled events, and other database objects cease to function if these tables are changed to use any storage engine other than `MyISAM`.* This is a consequence of various MySQL Server internals which are not expected to change in the foreseeable future.

If you need to synchronize `mysql` system tables between SQL nodes, you can use standard MySQL replication to do so, or employ a script to copy table entries between the MySQL servers.

**Summary.** The two most important points to remember regarding the MySQL privilege system with regard to MySQL Cluster are:

1. Users and privileges established on one SQL node do not automatically exist or take effect on other SQL nodes in the cluster. Conversely, removing a user or privilege on one SQL node in the cluster does not remove the user or privilege from any other SQL nodes.
2. Once a MySQL user is granted privileges on an `NDB` table from one SQL node in a MySQL Cluster, that user can “see” any data in that table regardless of the SQL node from which the data originated.

## 17.8.3. MySQL Cluster and MySQL Security Procedures

In this section, we discuss MySQL standard security procedures as they apply to running MySQL Cluster.

In general, any standard procedure for running MySQL securely also applies to running a MySQL Server as part of a MySQL Cluster. First and foremost, you should always run a MySQL Server as the `mysql` system user; this is no different from running MySQL in a standard (non-Cluster) environment. The `mysql` system account should be uniquely and clearly defined. Fortunately, this is the default behavior for a new MySQL installation. You can verify that the `mysqld` process is running as the system user `mysql` by using the system command such as the one shown here:

```
shell> ps aux | grep mysql
root      10467  0.0  0.1   3616  1380 pts/3    S    11:53   0:00 \
/bin/sh ./mysqld_safe --ndbcluster --ndb-connectstring=localhost:1186
mysql     10512  0.2  2.5  58528 26636 pts/3    Sl   11:53   0:00 \
/usr/local/mysql/libexec/mysqld --basedir=/usr/local/mysql \
--datadir=/usr/local/mysql/var --user=mysql --ndbcluster \
--ndb-connectstring=localhost:1186 --pid-file=/usr/local/mysql/var/mothra.pid \
--log-error=/usr/local/mysql/var/mothra.err
jon       10579  0.0  0.0   2736   688 pts/0    S+   11:54   0:00 grep mysql
```

If the `mysqld` process is running as any other user than `mysql`, you should immediately shut it down and restart it as the `mysql` user. If this user does not exist on the system, the `mysql` user account should be created, and this user should be part of the `mysql` user group; in this case, you should also make sure that the MySQL `DataDir` on this system is owned by the `mysql` user, and that the SQL node's `my.cnf` file includes `user=mysql` in the `[mysqld]` section. Alternatively, you can start the server with `-user=mysql` on the command line, but it is preferable to use the `my.cnf` option, since you might forget to use the command-line option and so have `mysqld` running as another user unintentionally. The `mysqld_safe` startup script forces MySQL to run as the `mysql` user.

### Important

Never run `mysqld` as the system root user. Doing so means that potentially any file on the system can be read by MySQL, and thus — should MySQL be compromised — by an attacker.

As mentioned in the previous section (see [Section 17.8.2, “MySQL Cluster and MySQL Privileges”](#)), you should always set a root password for the MySQL Server as soon as you have it running. You should also delete the anonymous user account that is installed by default. You can accomplish these tasks via the following statements:

```
shell> mysql -u root
mysql> UPDATE mysql.user
```

```

-> SET Password=PASSWORD('secure_password')
-> WHERE User='root';

mysql> DELETE FROM mysql.user
-> WHERE User='';

mysql> FLUSH PRIVILEGES;

```

Be very careful when executing the `DELETE` statement not to omit the `WHERE` clause, or you risk deleting *all* MySQL users. Be sure to run the `FLUSH PRIVILEGES` statement as soon as you have modified the `mysql.user` table, so that the changes take immediate effect. Without `FLUSH PRIVILEGES`, the changes do not take effect until the next time that the server is restarted.

### Note

Many of the MySQL Cluster utilities such as `ndb_show_tables`, `ndb_desc`, and `ndb_select_all` also work without authentication and can reveal table names, schemas, and data. By default these are installed on Unix-style systems with the permissions `wxr-xr-x` (755), which means they can be executed by any user that can access the `mysql/bin` directory.

See [Section 17.6, “MySQL Cluster Programs”](#), for more information about these utilities.

## 17.9. Using High-Speed Interconnects with MySQL Cluster

Even before design of `NDBCLUSTER` began in 1996, it was evident that one of the major problems to be encountered in building parallel databases would be communication between the nodes in the network. For this reason, `NDBCLUSTER` was designed from the very beginning to allow for the use of a number of different data transport mechanisms. In this Manual, we use the term *transporter* for these.

The MySQL Cluster codebase includes support for four different transporters:

- *TCP/IP using 100 Mbps or gigabit Ethernet*, as discussed in [Section 17.3.4.7, “MySQL Cluster TCP/IP Connections”](#).
- *Direct (machine-to-machine) TCP/IP*; although this transporter uses the same TCP/IP protocol as mentioned in the previous item, it requires setting up the hardware differently and is configured differently as well. For this reason, it is considered a separate transport mechanism for MySQL Cluster. See [Section 17.3.4.8, “MySQL Cluster TCP/IP Connections Using Direct Connections”](#), for details.
- *Shared memory (SHM)*. For more information about SHM, see [Section 17.3.4.9, “MySQL Cluster Shared-Memory Connections”](#).
- *Scalable Coherent Interface (SCI)*, as described in the next section of this chapter, [Section 17.3.4.10, “SCI Transport Connections in MySQL Cluster”](#).

Most users today employ TCP/IP over Ethernet because it is ubiquitous. TCP/IP is also by far the best-tested transporter for use with MySQL Cluster.

We are working to make sure that communication with the `ndbd` process is made in “chunks” that are as large as possible because this benefits all types of data transmission.

For users who desire it, it is also possible to use cluster interconnects to enhance performance even further. There are two ways to achieve this: Either a custom transporter can be designed to handle this case, or you can use socket implementations that bypass the TCP/IP stack to one extent or another. We have experimented with both of these techniques using the SCI (Scalable Coherent Interface) technology developed by [Dolphin Interconnect Solutions](#).

### 17.9.1. Configuring MySQL Cluster to use SCI Sockets

It is possible employing Scalable Coherent Interface (SCI) technology to achieve a significant increase in connection speeds and throughput between MySQL Cluster data and SQL nodes. To use SCI, it is necessary to obtain and install Dolphin SCI network cards and to use the drivers and other software supplied by Dolphin. You can get information on obtaining these, from [Dolphin Interconnect Solutions](#). SCI SuperSocket or SCI Transporter support is available for 32-bit and 64-bit Linux, Solaris, and other platforms. See the Dolphin documentation referenced later in this section for more detailed information regarding platforms supported for SCI.

### Note

Prior to MySQL 5.0.66, there were issues with building MySQL Cluster with SCI support (see [Bug#25470](#)), but these have been resolved due to work contributed by Dolphin. SCI Sockets are now correctly supported for MySQL Cluster hosts running recent versions of Linux using the `-max` builds, and versions of MySQL Cluster with SCI Transporter support can be built using either of `compile-amd64-max-sci` or `compile-pentium64-max-sci`. Both of these build scripts can be found in the `BUILD` directory of the MySQL Cluster source trees; it should not be difficult

to adapt them for other platforms. Generally, all that is necessary is to compile MySQL Cluster with SCI Transporter support is to configure the MySQL Cluster build using `--with-ndb-sci=/opt/DIS`.

Once you have acquired the required Dolphin hardware and software, you can obtain detailed information on how to adapt a MySQL Cluster configured for normal TCP/IP communication to use SCI from the *Dolphin Express for MySQL Installation and Reference Guide*, available for download at [http://docsrva.mysql.com/public/DIS\\_install\\_guide\\_book.pdf](http://docsrva.mysql.com/public/DIS_install_guide_book.pdf) (PDF file, 94 pages, 753 KB). This document provides instructions for installing the SCI hardware and software, as well as information concerning network topology and configuration.

## 17.9.2. MySQL Cluster Interconnects and Performance

The `ndbd` process has a number of simple constructs which are used to access the data in a MySQL Cluster. We have created a very simple benchmark to check the performance of each of these and the effects which various interconnects have on their performance.

There are four access methods:

- **Primary key access.** This is access of a record through its primary key. In the simplest case, only one record is accessed at a time, which means that the full cost of setting up a number of TCP/IP messages and a number of costs for context switching are borne by this single request. In the case where multiple primary key accesses are sent in one batch, those accesses share the cost of setting up the necessary TCP/IP messages and context switches. If the TCP/IP messages are for different destinations, additional TCP/IP messages need to be set up.
- **Unique key access.** Unique key accesses are similar to primary key accesses, except that a unique key access is executed as a read on an index table followed by a primary key access on the table. However, only one request is sent from the MySQL Server, and the read of the index table is handled by `ndbd`. Such requests also benefit from batching.
- **Full table scan.** When no indexes exist for a lookup on a table, a full table scan is performed. This is sent as a single request to the `ndbd` process, which then divides the table scan into a set of parallel scans on all cluster `ndbd` processes. In future versions of MySQL Cluster, an SQL node will be able to filter some of these scans.
- **Range scan using ordered index**

When an ordered index is used, it performs a scan in the same manner as the full table scan, except that it scans only those records which are in the range used by the query transmitted by the MySQL server (SQL node). All partitions are scanned in parallel when all bound index attributes include all attributes in the partitioning key.

With benchmarks developed internally by MySQL for testing simple and batched primary and unique key accesses, we have found that using SCI sockets improves performance by approximately 100% over TCP/IP, except in rare instances when communication performance is not an issue. This can occur when scan filters make up most of processing time or when very large batches of primary key accesses are achieved. In that case, the CPU processing in the `ndbd` processes becomes a fairly large part of the overhead.

Using the SCI transporter instead of SCI Sockets is only of interest in communicating between `ndbd` processes. Using the SCI transporter is also only of interest if a CPU can be dedicated to the `ndbd` process because the SCI transporter ensures that this process will never go to sleep. It is also important to ensure that the `ndbd` process priority is set in such a way that the process does not lose priority due to running for an extended period of time, as can be done by locking processes to CPUs in Linux 2.6. If such a configuration is possible, the `ndbd` process will benefit by 10–70% as compared with using SCI sockets. (The larger figures will be seen when performing updates and probably on parallel scan operations as well.)

There are several other optimized socket implementations for computer clusters, including Myrinet, Gigabit Ethernet, Infiniband and the VIA interface. However, we have tested MySQL Cluster so far only with SCI sockets. See [Section 17.9.1, “Configuring MySQL Cluster to use SCI Sockets”](#), for information on how to set up SCI sockets using ordinary TCP/IP for MySQL Cluster.

## 17.10. Known Limitations of MySQL Cluster

In the sections that follow, we discuss known limitations of MySQL Cluster in MySQL 5.0 releases as compared with the features available when using the `MyISAM` and `InnoDB` storage engines. Currently, there are no plans to address these in coming releases of MySQL 5.0; however, we will attempt to supply fixes for these issues in subsequent release series. If you check the “Cluster” category in the MySQL bugs database at <http://bugs.mysql.com>, you can find known bugs in the following categories under “MySQL Server:” in the MySQL bugs database at <http://bugs.mysql.com>, which we intend to correct in upcoming releases of MySQL Cluster:

- Cluster
- Cluster Direct API (NDBAPI)

- Cluster Disk Data
- Cluster Replication

This information is intended to be complete with respect to the conditions just set forth. You can report any discrepancies that you encounter to the MySQL bugs database using the instructions given in [Section 1.6, “How to Report Bugs or Problems”](#). If we do not plan to fix the problem in MySQL 5.0, we will add it to the list.

See [Section 17.10.10, “Previous MySQL Cluster Issues Resolved in MySQL 5.0”](#) for a list of issues in MySQL Cluster in MySQL 4.1 that have been resolved in the current version.

## 17.10.1. Non-Compliance with SQL Syntax in MySQL Cluster

Some SQL statements relating to certain MySQL features produce errors when used with [NDB](#) tables, as described in the following list:

- **Temporary tables.** Temporary tables are not supported. Trying either to create a temporary table that uses the [NDB](#) storage engine or to alter an existing temporary table to use [NDB](#) fails with the error `TABLE STORAGE ENGINE 'NDBCLUSTER' DOES NOT SUPPORT THE CREATE OPTION 'TEMPORARY'`.

- **Indexes and keys in [NDB](#) tables.** Keys and indexes on MySQL Cluster tables are subject to the following limitations:

- **TEXT and BLOB columns.** You cannot create indexes on [NDB](#) table columns that use any of the [TEXT](#) or [BLOB](#) data types.
- **FULLTEXT indexes.** The [NDB](#) storage engine does not support [FULLTEXT](#) indexes, which are possible for [MyISAM](#) tables only.

However, you can create indexes on [VARCHAR](#) columns of [NDB](#) tables.

- **BIT columns.** A [BIT](#) column cannot be a primary key, unique key, or index, nor can it be part of a composite primary key, unique key, or index.
- **AUTO\_INCREMENT columns.** Like other MySQL storage engines, the [NDB](#) storage engine can handle a maximum of one [AUTO\\_INCREMENT](#) column per table. However, in the case of a Cluster table with no explicit primary key, an [AUTO\\_INCREMENT](#) column is automatically defined and used as a “hidden” primary key. For this reason, you cannot define a table that has an explicit [AUTO\\_INCREMENT](#) column unless that column is also declared using the [PRIMARY KEY](#) option. Attempting to create a table with an [AUTO\\_INCREMENT](#) column that is not the table's primary key, and using the [NDB](#) storage engine, fails with an error.
- **MySQL Cluster and geometry data types.** Geometry datatypes ([WKT](#) and [WKB](#)) are supported in [NDB](#) tables in MySQL 5.0. However, spatial indexes are not supported.

## 17.10.2. Limits and Differences of MySQL Cluster from Standard MySQL Limits

In this section, we list limits found in MySQL Cluster that either differ from limits found in, or that are not found in, standard MySQL.

- **Memory usage and recovery.** Memory consumed when data is inserted into an [NDB](#) table is not automatically recovered when deleted, as it is with other storage engines. Instead, the following rules hold true:
  - A [DELETE](#) statement on an [NDB](#) table makes the memory formerly used by the deleted rows available for re-use by inserts on the same table only. This memory cannot be used by other [NDB](#) tables.
  - A [DROP TABLE](#) or [TRUNCATE](#) operation on an [NDB](#) table frees the memory that was used by this table for re-use by any [NDB](#) table, either by the same table or by another [NDB](#) table.

### Note

Recall that [TRUNCATE](#) drops and re-creates the table. See [Section 12.2.10, “TRUNCATE Syntax”](#).

Memory freed by [DELETE](#) operations but still allocated to a specific table can also be made available for general re-use by performing a rolling restart of the cluster. See [Section 17.5.1, “Performing a Rolling Restart of a MySQL Cluster”](#).

- **Limits imposed by the cluster's configuration.** A number of hard limits exist which are configurable, but available main memory in the cluster sets limits. See the complete list of configuration parameters in [Section 17.3.4, “MySQL Cluster](#)

[Configuration Files](#)". Most configuration parameters can be upgraded online. These hard limits include:

- Database memory size and index memory size (`DataMemory` and `IndexMemory`, respectively).

`DataMemory` is allocated as 32KB pages. As each `DataMemory` page is used, it is assigned to a specific table; once allocated, this memory cannot be freed except by dropping the table.

See [Section 17.3.4.5, "Defining MySQL Cluster Data Nodes"](#), for further information about `DataMemory` and `IndexMemory`.

- The maximum number of operations that can be performed per transaction is set using the configuration parameters `MaxNoOfConcurrentOperations` and `MaxNoOfLocalOperations`.

### Note

Bulk loading, `TRUNCATE TABLE`, and `ALTER TABLE` are handled as special cases by running multiple transactions, and so are not subject to this limitation.

- Different limits related to tables and indexes. For example, the maximum number of ordered indexes per table is determined by `MaxNoOfOrderedIndexes`.
- **Memory usage.** All Cluster table rows are of fixed length. This means (for example) that if a table has one or more `VARCHAR` fields containing only relatively small values, more memory and disk space is required when using the `NDB` storage engine than would be the case for the same table and data using the `MyISAM` engine. (In other words, in the case of a `VARCHAR` column, the column requires the same amount of storage as a `CHAR` column of the same size.)
- **Node and data object maximums.** The following limits apply to numbers of cluster nodes and metadata objects:
  - The maximum number of data nodes is 48.
 

A data node must have a node ID in the range of 1-49, inclusive. (Management and API nodes may use any integer in the range of 1-63 inclusive as a node ID.)
  - The total maximum number of nodes in a MySQL Cluster is 63. This number includes all SQL nodes (MySQL Servers), API nodes (applications accessing the cluster other than MySQL servers), data nodes, and management servers.
  - The maximum number of metadata objects in MySQL 5.0 Cluster is 20320. This limit is hard-coded.

## 17.10.3. Limits Relating to Transaction Handling in MySQL Cluster

A number of limitations exist in MySQL Cluster with regard to the handling of transactions. These include the following:

- **Transaction isolation level.** The `NDBCLUSTER` storage engine supports only the `READ COMMITTED` transaction isolation level. (`InnoDB`, for example, supports `READ COMMITTED`, `READ UNCOMMITTED`, `REPEATABLE READ`, and `SERIALIZABLE`.) See [Section 17.7.3.4, "MySQL Cluster Backup Troubleshooting"](#), for information on how this can affect backing up and restoring Cluster databases.)

### Important

If a `SELECT` from a Cluster table includes a `BLOB` or `TEXT` column, the `READ COMMITTED` transaction isolation level is converted to a read with read lock. This is done to guarantee consistency, due to the fact that parts of the values stored in columns of these types are actually read from a separate table.

- **Rollbacks.** There are no partial transactions, and no partial rollbacks of transactions. A duplicate key or similar error aborts the entire transaction, and subsequent statements raise `ERROR 1296 (HY000): GOT ERROR 4350 'TRANSACTION ALREADY ABORTED' FROM NDBCLUSTER`. In such cases, you must issue an explicit `ROLLBACK` and retry the entire transaction.

This behavior differs from that of other transactional storage engines such as `InnoDB` that may roll back individual statements.

- **Transactions and memory usage.** As noted elsewhere in this chapter, MySQL Cluster does not handle large transactions well; it is better to perform a number of small transactions with a few operations each than to attempt a single large transaction containing a great many operations. Among other considerations, large transactions require very large amounts of memory. Because of this, the transactional behaviour of a number of MySQL statements is effected as described in the following list:
  - `TRUNCATE` is not transactional when used on `NDB` tables. If a `TRUNCATE` fails to empty the table, then it must be re-run until it is successful.

- **DELETE FROM** (even with no **WHERE** clause) *is* transactional. For tables containing a great many rows, you may find that performance is improved by using several **DELETE FROM ... LIMIT ...** statements to “chunk” the delete operation. If your objective is to empty the table, then you may wish to use **TRUNCATE** instead.
- **LOAD DATA statements.** **LOAD DATA INFILE** is not transactional when used on **NDB** tables.

### Important

When executing a **LOAD DATA INFILE** statement, the **NDB** engine performs commits at irregular intervals that enable better utilization of the communication network. It is not possible to know ahead of time when such commits take place.

**LOAD DATA FROM MASTER** is not supported in MySQL Cluster.

- **ALTER TABLE and transactions.** When copying an **NDB** table as part of an **ALTER TABLE**, the creation of the copy is non-transactional. (In any case, this operation is rolled back when the copy is deleted.)

## 17.10.4. MySQL Cluster Error Handling

Starting, stopping, or restarting a node may give rise to temporary errors causing some transactions to fail. These include the following cases:

- **Temporary errors.** When first starting a node, it is possible that you may see Error 1204 **TEMPORARY FAILURE, DISTRIBUTION CHANGED** and similar temporary errors.
- **Errors due to node failure.** The stopping or failure of any data node can result in a number of different node failure errors. (However, there should be no aborted transactions when performing a planned shutdown of the cluster.)

In either of these cases, any errors that are generated must be handled within the application. This should be done by retrying the transaction.

See also [Section 17.10.2, “Limits and Differences of MySQL Cluster from Standard MySQL Limits”](#).

## 17.10.5. Limits Associated with Database Objects in MySQL Cluster

Some database objects such as tables and indexes have different limitations when using the **NDBCLUSTER** storage engine:

- **Identifiers.** Database names, table names and attribute names cannot be as long in **NDB** tables as when using other table handlers. Attribute names are truncated to 31 characters, and if not unique after truncation give rise to errors. Database names and table names can total a maximum of 122 characters. In other words, the maximum length for an **NDB** table name is 122 characters, less the number of characters in the name of the database of which that table is a part.
- **Table names containing special characters.** **NDB** tables whose names contain characters other than letters, numbers, dashes, and underscores and which are created on one SQL node may not be discovered correctly by other SQL nodes. ([Bug#31470](#))
- **Number of tables and other database objects.** The maximum number of tables in a Cluster database in MySQL 5.0 is limited to 1792. The maximum number of *all* **NDBCLUSTER** database objects in a single MySQL Cluster — including databases, tables, and indexes — is limited to 20320.
- **Attributes per table.** The maximum number of attributes (that is, columns and indexes) per table is limited to 128.
- **Attributes per key.** The maximum number of attributes per key is 32.
- **Row size.** The maximum permitted size of any one row is 8KB. Note that each **BLOB** or **TEXT** column contributes  $256 + 8 = 264$  bytes towards this total.

## 17.10.6. Unsupported or Missing Features in MySQL Cluster

A number of features supported by other storage engines are not supported for **NDB** tables. Trying to use any of these features in MySQL Cluster does not cause errors in or of itself; however, errors may occur in applications that expects the features to be supported or enforced:

- **Foreign key constraints.** The foreign key construct is ignored, just as it is in **MyISAM** tables.

- **OPTIMIZE operations.** `OPTIMIZE` operations are not supported.
- **LOAD TABLE ... FROM MASTER.** `LOAD TABLE ... FROM MASTER` is not supported.
- **Savepoints and rollbacks.** Savepoints and rollbacks to savepoints are ignored as in `MyISAM`.
- **Durability of commits.** There are no durable commits on disk. Commits are replicated, but there is no guarantee that logs are flushed to disk on commit.
- **Replication.** Replication is not supported.

### Note

See [Section 17.10.3, “Limits Relating to Transaction Handling in MySQL Cluster”](#), for more information relating to limitations on transaction handling in `NDB`.

## 17.10.7. Limitations Relating to Performance in MySQL Cluster

The following performance issues are specific to or especially pronounced in MySQL Cluster:

- **Range scans.** There are query performance issues due to sequential access to the `NDB` storage engine; it is also relatively more expensive to do many range scans than it is with either `MyISAM` or `InnoDB`.
- **Reliability of Records in range.** The `Records in range` statistic is available but is not completely tested or officially supported. This may result in non-optimal query plans in some cases. If necessary, you can employ `USE INDEX` or `FORCE INDEX` to alter the execution plan. See [Section 12.2.8.2, “Index Hint Syntax”](#), for more information on how to do this.
- **Unique hash indexes.** Unique hash indexes created with `USING HASH` cannot be used for accessing a table if `NULL` is given as part of the key.

## 17.10.8. Issues Exclusive to MySQL Cluster

The following are limitations specific to the `NDBCLUSTER` storage engine:

- **Machine architecture.** The following issues relate to physical architecture of cluster hosts:
  - All machines used in the cluster must have the same architecture. That is, all machines hosting nodes must be either big-endian or little-endian, and you cannot use a mixture of both. For example, you cannot have a management node running on a PowerPC which directs a data node that is running on an x86 machine. This restriction does not apply to machines simply running `mysql` or other clients that may be accessing the cluster's `SQL` nodes.
  - **Adding and dropping of data nodes.** Online adding or dropping of data nodes is not currently possible. In such cases, the entire cluster must be restarted.
  - **Backup and restore between architectures.** It is also not possible to perform a Cluster backup and restore between different architectures. For example, you cannot back up a cluster running on a big-endian platform and then restore from that backup to a cluster running on a little-endian system. ([Bug#19255](#))
- **Online schema changes.** It is not possible to make online schema changes such as those accomplished using `ALTER TABLE` or `CREATE INDEX`, as the `NDB Cluster` engine does not support autodiscovery of such changes. (However, you can import or create a table that uses a different storage engine, and then convert it to `NDB` using `ALTER TABLE tbl_name ENGINE=NDBCLUSTER`. In such a case, you must issue a `FLUSH TABLES` statement to force the cluster to pick up the change.)
- **Binary logging.** MySQL Cluster has the following limitations or restrictions with regard to binary logging:
  - `sql_log_bin` has no effect on data operations; however, it is supported for schema operations.
  - MySQL Cluster cannot produce a binlog for tables having `BLOB` columns but no primary key.
  - Only the following schema operations are logged in a cluster binlog which is *not* on the `mysqld` executing the statement:
    - `CREATE TABLE`
    - `ALTER TABLE`
    - `DROP TABLE`

- [CREATE DATABASE / CREATE SCHEMA](#)
- [DROP DATABASE / DROP SCHEMA](#)

See also [Section 17.10.9, “Limitations Relating to Multiple MySQL Cluster Nodes”](#).

## 17.10.9. Limitations Relating to Multiple MySQL Cluster Nodes

**Multiple SQL nodes.** The following are issues relating to the use of multiple MySQL servers as MySQL Cluster SQL nodes, and are specific to the `NDBCLUSTER` storage engine:

- **No distributed table locks.** A `LOCK TABLES` works only for the SQL node on which the lock is issued; no other SQL node in the cluster “sees” this lock. This is also true for a lock issued by any statement that locks tables as part of its operations. (See next item for an example.)
- **ALTER TABLE operations.** `ALTER TABLE` is not fully locking when running multiple MySQL servers (SQL nodes). (As discussed in the previous item, MySQL Cluster does not support distributed table locks.)
- **Replication.** MySQL replication will not work correctly if updates are done on multiple MySQL servers. However, if the database partitioning scheme is done at the application level and no transactions take place across these partitions, replication can be made to work.
- **Database autodiscovery.** Autodiscovery of databases is not supported for multiple MySQL servers accessing the same MySQL Cluster. However, autodiscovery of tables is supported in such cases. What this means is that after a database named `db_name` is created or imported using one MySQL server, you should issue a `CREATE DATABASE db_name` statement on each additional MySQL server that accesses the same MySQL Cluster. (As of MySQL 5.0.2, you may also use `CREATE SCHEMA db_name`.) Once this has been done for a given MySQL server, that server should be able to detect the database tables without error.
- **DDL operations.** DDL operations (such as `CREATE TABLE` or `ALTER TABLE`) are not safe from data node failures. If a data node fails while trying to perform one of these, the data dictionary is locked and no further DDL statements can be executed without restarting the cluster.

**Multiple management nodes.** When using multiple management servers:

- You must give nodes explicit IDs in connectstrings because automatic allocation of node IDs does not work across multiple management servers.
- In addition, all API nodes (including MySQL servers acting as SQL nodes), should list all management servers using the same order in their connectstrings.
- You must take extreme care to have the same configurations for all management servers. No special checks for this are performed by the cluster.
  - Prior to MySQL 5.0.14, all data nodes had to be restarted after bringing up the cluster in order for the management nodes to be able to see one another.

(See [Bug#12307](#) and [Bug#13070](#) for more information.)

**Multiple data node processes.** While it is possible to run multiple cluster processes concurrently on a single host, it is not always advisable to do so for reasons of performance and high availability, as well as other considerations. In particular, in MySQL 5.0, we do not support for production use any MySQL Cluster deployment in which more than one `ndbd` process is run on a single physical machine.

### Note

We may support multiple data nodes per host in a future MySQL release, following additional testing. However, in MySQL 5.0, such configurations can be considered experimental only.

**Multiple network addresses.** Multiple network addresses per data node are not supported. Use of these is liable to cause problems: In the event of a data node failure, an SQL node waits for confirmation that the data node went down but never receives it because another route to that data node remains open. This can effectively make the cluster inoperable.

### Note

It is possible to use multiple network hardware *interfaces* (such as Ethernet cards) for a single data node, but these must be bound to the same address. This also means that it not possible to use more than one `[tcp]` section per connection in the `config.ini` file. See [Section 17.3.4.7, “MySQL Cluster TCP/IP Connections”](#), for more information.

## 17.10.10. Previous MySQL Cluster Issues Resolved in MySQL 5.0

The following Cluster limitations in MySQL 4.1 have been resolved in MySQL 5.0 as shown below:

- **Character set support.** The `NDBCLUSTER` storage engine supports all character sets and collations available in MySQL 5.0.
- **Character set directory.** Beginning with MySQL 5.0.21, it is possible to install MySQL with Cluster support to a non-default location and change the search path for font description files using either the `--basedir` or `--character-sets-dir` options. (Previously, `nbd` in MySQL 5.0 searched only the default path — typically `/usr/local/mysql/share/mysql/charsets` — for character sets.)
- **Metadata objects.** Prior to MySQL 5.0.6, the maximum number of metadata objects possible was 1600. Beginning with MySQL 5.0.6, this limit is increased to 20320.
- **Column indexes using prefixes.** MySQL Cluster in MySQL 5.0 supports column indexes that make use of prefixes.
- **Query cache.** Unlike the case in MySQL 4.1, the Cluster storage engine in MySQL 5.0 supports MySQL’s query cache. See [Section 7.5.5, “The MySQL Query Cache”](#).
- **IGNORE and REPLACE functionality.** In MySQL 5.0.19 and earlier, `INSERT IGNORE`, `UPDATE IGNORE`, and `REPLACE` were supported only for primary keys, but not for unique keys. It was possible to work around this issue by removing the constraint, then dropping the unique index, performing any inserts, and then adding the unique index again.  
  
This limitation was removed for `INSERT IGNORE` and `REPLACE` in MySQL 5.0.20. (See [Bug#17431](#).)
- **auto\_increment\_increment and auto\_increment\_offset.** The `auto_increment_increment` and `auto_increment_offset` server system variables are supported for `NDBCLUSTER` tables beginning with MySQL 5.0.46.

## 17.11. MySQL Cluster Development Roadmap

In this section, we discuss changes in the implementation of MySQL Cluster in MySQL 5.0 as compared to MySQL 4.1. We will also discuss our roadmap for further improvements to MySQL Cluster as currently planned for MySQL 5.1.

There are relatively few changes between the NDB Cluster storage engine implementations in MySQL 4.1 and in 5.0, so the upgrade path should be relatively quick and painless.

All significantly new features being developed for MySQL Cluster are going into the MySQL Cluster NDB 6.x trees. For information on changes in the Cluster implementations in MySQL versions 5.1 and later, see [MySQL Cluster NDB 6.X/7.X](#).

### 17.11.1. MySQL Cluster Changes in MySQL 5.0

MySQL Cluster in MySQL 5.0 contains a number of features added since MySQL 4.1 that are likely to be of interest:

- **Condition pushdown.** Consider the following query:

```
SELECT * FROM t1 WHERE non_indexed_attribute = 1;
```

This query uses a full table scan and the condition is evaluated in the cluster's data nodes. Thus, it is not necessary to send the records across the network for evaluation. (That is, function transport is used, rather than data transport.) Please note that this feature is currently disabled by default (pending more thorough testing), but it should work in most cases. This feature can be enabled through the use of the `SET engine_condition_pushdown = On` statement. Alternatively, you can run `mysqld` with the this feature enabled by starting the MySQL server with the `--engine-condition-pushdown` option.

A major benefit of this change is that queries can be executed in parallel. This means that queries against non-indexed columns can run faster than previously by a factor of as much as 5 to 10 times, *times the number of data nodes*, because multiple CPUs can work on the query in parallel.

You can use `EXPLAIN` to determine when condition pushdown is being used. See [Section 12.3.2, “EXPLAIN Syntax”](#).

- **Decreased IndexMemory Usage:** In MySQL 5.0, each record consumes approximately 25 bytes of index memory, and every unique index uses 25 bytes per record of index memory (in addition to some data memory because these are stored in a separate table). This is because the primary key is not stored in the index memory anymore.

- **Query Cache Enabled for MySQL Cluster:** See [Section 7.5.5, “The MySQL Query Cache”](#), for information on configuring and using the query cache.
- **New optimizations.** One optimization that merits particular attention is that a batched read interface is now used in some queries. For example, consider the following query:

```
SELECT * FROM t1 WHERE primary_key IN (1,2,3,4,5,6,7,8,9,10);
```

This query will be executed 2 to 3 times more quickly than in previous MySQL Cluster versions due to the fact that all 10 key lookups are sent in a single batch rather than one at a time.

- **Limit On Number of Metadata Objects:** Beginning with MySQL 5.0.6, each Cluster database may contain a maximum of 20320 metadata objects — this includes database tables, system tables, indexes and [BLOB](#) values. (Previously, this number was 1600.)

## 17.11.2. MySQL 5.1 Development Roadmap for MySQL Cluster

What is said here is a status report based on recent commits to the MySQL 5.1 source tree. It should be noted all 5.1 development is subject to change.

There are currently 4 major new features being developed for MySQL 5.1:

1. **Integration of MySQL Cluster into MySQL replication:** This will make it possible to update from any MySQL Server in the cluster and still have the MySQL Replication handled by one of the MySQL Servers in the cluster, with the state of the slave side remaining consistent with the cluster acting as the master.
2. **Support for disk-based records:** Records on disk will be supported. Indexed fields including the primary key hash index must still be stored in RAM but all other fields can be on disk.
3. **Variable-sized records.** A column defined as `VARCHAR(255)` currently uses 260 bytes of storage independent of what is stored in any particular record. In MySQL 5.1 Cluster tables, only the portion of the column actually taken up by the record will be stored. This will make possible a reduction in space requirements for such columns by a factor of 5 in many cases.
4. **User-defined partitioning.** Users will be able to define partitions based on columns that are part of the primary key. The MySQL Server will be able to discover whether it is possible to prune away some of the partitions from the `WHERE` clause. Partitioning based on `KEY`, `HASH`, `RANGE`, and `LIST` handlers will be possible, as well as subpartitioning. This feature should also be available for many other handlers, and not only [NDB Cluster](#).

In addition, we are working to increase the 8KB size limit for rows containing columns of types other than `BLOB` or `TEXT` in Cluster tables. This is due to the fact that rows are currently fixed in size and the page size is 32,768 bytes (minus 128 bytes for the row header). Currently, this means that if we allowed more than 8KB per record, any remaining space (up to approximately 14,000 bytes) would be left empty. In MySQL 5.1, we plan to fix this limitation so that using more than 8KB in a given row does not result in the remainder of the page being wasted.

## 17.12. MySQL Cluster Glossary

The following terms are useful to an understanding of MySQL Cluster or have specialized meanings when used in relation to it.

- **Cluster.** In its generic sense, a cluster is a set of computers functioning as a unit and working together to accomplish a single task.

**NDBCLUSTER.** This is the storage engine used in MySQL to implement data storage, retrieval, and management distributed among several computers.

**MySQL Cluster.** This refers to a group of computers working together using the [NDB](#) storage engine to support a distributed MySQL database in a *shared-nothing architecture* using *in-memory storage*.

- **Configuration files.** Text files containing directives and information regarding the cluster, its hosts, and its nodes. These are read by the cluster's management nodes when the cluster is started. See [Section 17.3.4, “MySQL Cluster Configuration Files”](#), for details.
- **Backup.** A complete copy of all cluster data, transactions and logs, saved to disk or other long-term storage.
- **Restore.** Returning the cluster to a previous state, as stored in a backup.
- **Checkpoint.** Generally speaking, when data is saved to disk, it is said that a checkpoint has been reached. More specific to

---

Cluster, it is a point in time where all committed transactions are stored on disk. With regard to the [NDB](#) storage engine, there are two types of checkpoints which work together to ensure that a consistent view of the cluster's data is maintained:

- **Local Checkpoint (LCP).** This is a checkpoint that is specific to a single node; however, LCP's take place for all nodes in the cluster more or less concurrently. An LCP involves saving all of a node's data to disk, and so usually occurs every few minutes. The precise interval varies, and depends upon the amount of data stored by the node, the level of cluster activity, and other factors.
- **Global Checkpoint (GCP).** A GCP occurs every few seconds, when transactions for all nodes are synchronized and the redo-log is flushed to disk.
- **Cluster host.** A computer making up part of a MySQL Cluster. A cluster has both a *physical* structure and a *logical* structure. Physically, the cluster consists of a number of computers, known as *cluster hosts* (or more simply as *hosts*. See also **Node** and **Node group** below.
- **Node.** This refers to a logical or functional unit of MySQL Cluster, and is sometimes also referred to as a *cluster node*. In the context of MySQL Cluster, we use the term “node” to indicate a *process* rather than a physical component of the cluster. There are three node types required to implement a working MySQL Cluster:
  - **Management nodes.** Manages the other nodes within the MySQL Cluster. It provides configuration data to the other nodes; starts and stops nodes; handles network partitioning; creates backups and restores from them, and so forth.
  - **SQL nodes.** Instances of MySQL Server which serve as front ends to data kept in the cluster's **data nodes**. Clients desiring to store, retrieve, or update data can access an SQL node just as they would any other MySQL Server, employing the usual MySQL authentication methods and APIs; the underlying distribution of data between node groups is transparent to users and applications. SQL nodes access the cluster's databases as a whole without regard to the data's distribution across different data nodes or cluster hosts.
  - **Data nodes.** These nodes store the actual data. Table data fragments are stored in a set of node groups; each node group stores a different subset of the table data. Each of the nodes making up a node group stores a replica of the fragment for which that node group is responsible. Currently, a single cluster can support up to 48 data nodes total.

It is possible for more than one node to co-exist on a single machine. (In fact, it is even possible to set up a complete cluster on one machine, although one would almost certainly *not* want to do this in a production environment.) It may be helpful to remember that, when working with MySQL Cluster, the term *host* refers to a physical component of the cluster whereas a *node* is a logical or functional component (that is, a process).

**Note Regarding Terms.** In older versions of the MySQL Cluster documentation, data nodes were sometimes referred to as “database nodes”. The term “storage nodes” has also been used. In addition, SQL nodes were sometimes known as “client nodes”. This older terminology has been deprecated to minimize confusion, and for this reason should be avoided. They are also often referred to as “API nodes” — an SQL node is actually an API node that provides an SQL interface to the cluster.

- **Node group.** A set of data nodes. All data nodes in a node group contain the same data (fragments), and all nodes in a single group should reside on different hosts. It is possible to control which nodes belong to which node groups.

For more information, see [Section 17.1.2, “MySQL Cluster Nodes, Node Groups, Replicas, and Partitions”](#).

- **Node failure.** MySQL Cluster is not solely dependent upon the functioning of any single node making up the cluster; the cluster can continue to run if one or more nodes fail. The precise number of node failures that a given cluster can tolerate depends upon the number of nodes and the cluster's configuration.
- **Node restart.** The process of restarting a failed cluster node.
- **Initial node restart.** The process of starting a cluster node with its file system removed. This is sometimes used in the course of software upgrades and in other special circumstances.
- **System crash (or system failure).** This can occur when so many cluster nodes have failed that the cluster's state can no longer be guaranteed.
- **System restart.** The process of restarting the cluster and reinitializing its state from disk logs and checkpoints. This is required after either a planned or an unplanned shutdown of the cluster.
- **Fragment.** A portion of a database table; in the [NDB](#) storage engine, a table is broken up into and stored as a number of fragments. A fragment is sometimes also called a “partition”; however, “fragment” is the preferred term. Tables are fragmented in MySQL Cluster in order to facilitate load balancing between machines and nodes.
- **Replica.** Under the [NDB](#) storage engine, each table fragment has number of replicas stored on other data nodes in order to provide redundancy. Currently, there may be up four replicas per fragment.
- **Transporter.** A protocol providing data transfer between nodes. MySQL Cluster currently supports four different types of transporter connections:

- **TCP/IP.** This is, of course, the familiar network protocol that underlies HTTP, FTP (and so on) on the Internet. TCP/IP can be used for both local and remote connections.
- **SCI.** Scalable Coherent Interface is a high-speed protocol used in building multiprocessor systems and parallel-processing applications. Use of SCI with MySQL Cluster requires specialized hardware, as discussed in [Section 17.9.1, “Configuring MySQL Cluster to use SCI Sockets”](#). For a basic introduction to SCI, see [this essay at dolphins.com](#).
- **SHM.** Unix-style **shared memory** segments. Where supported, SHM is used automatically to connect nodes running on the same host. The [Unix man page for shmop\(2\)](#) is a good place to begin obtaining additional information about this topic.

### Note

The cluster transporter is internal to the cluster. Applications using MySQL Cluster communicate with SQL nodes just as they do with any other version of MySQL Server (via TCP/IP, or through the use of Unix socket files or Windows named pipes). Queries can be sent and results retrieved using the standard MySQL client APIs.

- **NDB.** This stands for **Network Database**, and refers to the storage engine used to enable MySQL Cluster. The **NDB** storage engine supports all the usual MySQL data types and SQL statements, and is ACID-compliant. This engine also provides full support for transactions (commits and rollbacks).
- **Shared-nothing architecture.** The ideal architecture for a MySQL Cluster. In a true shared-nothing setup, each node runs on a separate host. The advantage such an arrangement is that there no single host or node can act as single point of failure or as a performance bottle neck for the system as a whole.
- **In-memory storage.** All data stored in each data node is kept in memory on the node's host computer. For each data node in the cluster, you must have available an amount of RAM equal to the size of the database times the number of replicas, divided by the number of data nodes. Thus, if the database takes up 1GB of memory, and you want to set up the cluster with four replicas and eight data nodes, a minimum of 500MB memory will be required per node. Note that this is in addition to any requirements for the operating system and any other applications that might be running on the host.

In MySQL 5.1 and MySQL Cluster NDB 6.x, it is also possible to create *Disk Data* tables where non-indexed columns are stored on disk, thus reducing the memory footprint required by the cluster. Note that indexes and indexed column data are still stored in RAM. See [MySQL Cluster Disk Data Tables](#).

- **Table.** As is usual in the context of a relational database, the term “table” denotes a set of identically structured records. In MySQL Cluster, a database table is stored in a data node as a set of fragments, each of which is replicated on additional data nodes. The set of data nodes replicating the same fragment or set of fragments is referred to as a *node group*.
- **Cluster programs.** These are command-line programs used in running, configuring, and administering MySQL Cluster. They include both server daemons:

- `ndbd`:

The data node daemon (runs a data node process)

- `ndb_mgmd`:

The management server daemon (runs a management server process)

and client programs:

- `ndb_mgm`:

The management client (provides an interface for executing management commands)

- `ndb_waiter`:

Used to verify status of all nodes in a cluster

- `ndb_restore`:

Restores cluster data from backup

For more about these programs and their uses, see [Section 17.6, “MySQL Cluster Programs”](#).

- **Event log.** MySQL Cluster logs events by category (startup, shutdown, errors, checkpoints, and so on), priority, and severity. A complete listing of all reportable events may be found in [Section 17.7.4, “Event Reports Generated in MySQL Cluster”](#). Event logs are of two types:
  - **Cluster log.** Keeps a record of all desired reportable events for the cluster as a whole.

- **Node log.** A separate log which is also kept for each individual node.

Under normal circumstances, it is necessary and sufficient to keep and examine only the cluster log. The node logs need be consulted only for application development and debugging purposes.

- **Angel process.** When a data node is started, `ndbd` actually starts two processes. One of these is known as the “angel” process; its purpose is to check to make sure that the main `ndbd` process continues to run, and to restart the main process if it should stop for any reason.
- **Watchdog thread.** Each `ndbd` process has an internal *watchdog thread* which monitors the main worker thread, ensuring forward progress and a timely response to cluster protocols such as the cluster heartbeat. If the `ndbd` process is not being woken up promptly by the operating system when its sleep time expires, `INFO` and `WARNING` events, which are identifiable because they contain “Watchdog:...”, are written to the cluster log. Such messages are usually a symptom of an overloaded system; you should see what else is running on the system, and whether the `ndbd process` is being swapped out to disk. If `ndbd` cannot wake up regularly then it cannot respond to heartbeat messages on time, and other nodes eventually consider it “dead” due to the missed heartbeats, causing it to be excluded from the cluster.

---

# Chapter 18. Stored Programs and Views

This chapter discusses stored programs and views, which are database objects defined in terms of SQL code that is stored on the server for later invocation.

Stored programs include these objects:

- Stored routines, that is, stored procedures and functions. A stored function is used much like a built-in function. you invoke it in an expression and it returns a value during expression evaluation. A stored procedure is invoked using the `CALL` statement. A procedure does not have a return value but can modify its parameters for later inspection by the caller. It can also generate result sets to be returned to the client program.
- Triggers. A trigger is a named database object that is associated with a table and that is activated when a particular event occurs for the table, such as an insert or update.

Views are stored queries that when invoked produce a result set. A view acts as a virtual table.

This chapter describes how to use each type of stored program and views. Additional information about SQL syntax for statements related to these objects is available in the following locations:

- For each object type, there are `CREATE`, `ALTER`, and `DROP` statements that control which objects exist and how they are defined. See [Section 12.1, “Data Definition Statements”](#).
- The `CALL` statement is used to invoke stored procedures. See [Section 12.2.1, “CALL Syntax”](#).
- Stored program definitions contain a body that may use compound statements, loops, conditionals, and declared variables. See [Section 12.8, “MySQL Compound-Statement Syntax”](#).

## 18.1. Defining Stored Programs

Each stored program contains a body that consists of an SQL statement. This statement may be a compound statement made up of several statements separated by semicolon (`;`) characters. For example, the following stored procedure has a body made up of a `BEGIN . . . END` block that contains a `SET` statement and a `REPEAT` loop that itself contains another `SET` statement:

```
CREATE PROCEDURE dorepeat(p1 INT)
BEGIN
  SET @x = 0;
  REPEAT SET @x = @x + 1; UNTIL @x > p1 END REPEAT;
END
```

If you use the `mysql` client program to define a stored program that contains the semicolon characters within its definition, a problem arises. By default, `mysql` itself recognizes semicolon as a statement delimiter, so you must redefine the delimiter temporarily to cause `mysql` to pass the entire stored program definition to the server.

To redefine the `mysql` delimiter, use the `delimiter` command. The following example shows how to do this for the `dorepeat()` procedure just shown. The delimiter is changed to `//` to enable the entire definition to be passed to the server as a single statement, and then restored to `;` before invoking the procedure. This allows the `;` delimiter used in the procedure body to be passed through to the server rather than being interpreted by `mysql` itself.

```
mysql> delimiter //
mysql> CREATE PROCEDURE dorepeat(p1 INT)
-> BEGIN
->   SET @x = 0;
->   REPEAT SET @x = @x + 1; UNTIL @x > p1 END REPEAT;
-> END
-> //
Query OK, 0 rows affected (0.00 sec)

mysql> delimiter ;
mysql> CALL dorepeat(1000);
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT @x;
+-----+
| @x    |
+-----+
| 1001  |
+-----+
1 row in set (0.00 sec)
```

You can redefine the delimiter to a string other than `//`, and the delimiter can consist of a single character or multiple characters. You should avoid the use of the backslash ("`\`") character because that is the escape character for MySQL.

The following is an example of a function that takes a parameter, performs an operation using an SQL function, and returns the result. In this case, it is unnecessary to use `delimiter` because the function definition contains no internal `;` statement delimiters:

```
mysql> CREATE FUNCTION hello (s CHAR(20))
mysql> RETURNS CHAR(50) DETERMINISTIC
-> RETURN CONCAT('Hello, ',s,'!');
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT hello('world');
+-----+
| hello('world') |
+-----+
| Hello, world!  |
+-----+
1 row in set (0.00 sec)
```

## 18.2. Using Stored Routines (Procedures and Functions)

Stored routines (procedures and functions) are supported in MySQL 5.0. A stored routine is a set of SQL statements that can be stored in the server. Once this has been done, clients don't need to keep reissuing the individual statements but can refer to the stored routine instead.

Stored routines require the `proc` table in the `mysql` database. This table is created during the MySQL 5.0 installation procedure. If you are upgrading to MySQL 5.0 from an earlier version, be sure to update your grant tables to make sure that the `proc` table exists. See [Section 4.4.9, “mysql\\_upgrade — Check Tables for MySQL Upgrade”](#).

### MySQL Enterprise

For expert advice on using stored procedures and functions subscribe to the MySQL Enterprise Monitor. For more information, see <http://www.mysql.com/products/enterprise/advisors.html>.

Stored routines can be particularly useful in certain situations:

- When multiple client applications are written in different languages or work on different platforms, but need to perform the same database operations.
- When security is paramount. Banks, for example, use stored procedures and functions for all common operations. This provides a consistent and secure environment, and routines can ensure that each operation is properly logged. In such a setup, applications and users would have no access to the database tables directly, but can only execute specific stored routines.

Stored routines can provide improved performance because less information needs to be sent between the server and the client. The tradeoff is that this does increase the load on the database server because more of the work is done on the server side and less is done on the client (application) side. Consider this if many client machines (such as Web servers) are serviced by only one or a few database servers.

Stored routines also allow you to have libraries of functions in the database server. This is a feature shared by modern application languages that allow such design internally (for example, by using classes). Using these client application language features is beneficial for the programmer even outside the scope of database use.

MySQL follows the SQL:2003 syntax for stored routines, which is also used by IBM's DB2.

The MySQL implementation of stored routines is still in progress. All syntax described here is supported and any limitations and extensions are documented where appropriate.

### Additional resources

- You may find the [Stored Procedures User Forum](#) of use when working with stored procedures and functions.
- For answers to some commonly asked questions regarding stored routines in MySQL, see [Section A.4, “MySQL 5.0 FAQ — Stored Procedures and Functions”](#).
- There are some restrictions on the use of stored routines. See [Section F.1, “Restrictions on Stored Routines and Triggers”](#).
- Binary logging for stored routines takes place as described in [Section 18.5, “Binary Logging of Stored Programs”](#).

### 18.2.1. Stored Routine Syntax

A stored routine is either a procedure or a function. Stored routines are created with the `CREATE PROCEDURE` and `CREATE FUNCTION` statements (see [Section 12.1.9, “CREATE PROCEDURE and CREATE FUNCTION Syntax”](#)). A procedure is invoked using a `CALL` statement (see [Section 12.2.1, “CALL Syntax”](#)), and can only pass back values using output variables. A function can be called from inside a statement just like any other function (that is, by invoking the function's name), and can return a scalar value. The body of a stored routine can use compound statements (see [Section 12.8, “MySQL Compound-Statement Syntax”](#)).

Stored routines can be dropped with the `DROP PROCEDURE` and `DROP FUNCTION` statements (see [Section 12.1.16, “DROP PROCEDURE and DROP FUNCTION Syntax”](#)), and altered with the `ALTER PROCEDURE` and `ALTER FUNCTION` statements (see [Section 12.1.3, “ALTER PROCEDURE Syntax”](#)).

As of MySQL 5.0.1, a stored procedure or function is associated with a particular database. This has several implications:

- When the routine is invoked, an implicit `USE db_name` is performed (and undone when the routine terminates). `USE` statements within stored routines are disallowed.
- You can qualify routine names with the database name. This can be used to refer to a routine that is not in the current database. For example, to invoke a stored procedure `p` or function `f` that is associated with the `test` database, you can say `CALL test.p()` or `test.f()`.
- When a database is dropped, all stored routines associated with it are dropped as well.

(In MySQL 5.0.0, stored routines are global and not associated with a database. They inherit the default database from the caller. If a `USE db_name` is executed within the routine, the original default database is restored upon routine exit.)

Stored functions cannot be recursive.

Recursion in stored procedures is allowed but disabled by default. To enable recursion, set the `max_sp_recursion_depth` server system variable to a value greater than zero. Stored procedure recursion increases the demand on thread stack space. If you increase the value of `max_sp_recursion_depth`, it may be necessary to increase thread stack size by increasing the value of `thread_stack` at server startup. See [Section 5.1.3, “Server System Variables”](#), for more information.

MySQL supports the very useful extension that allows the use of regular `SELECT` statements (that is, without using cursors or local variables) inside a stored procedure. The result set of such a query is simply sent directly to the client. Multiple `SELECT` statements generate multiple result sets, so the client must use a MySQL client library that supports multiple result sets. This means the client must use a client library from a version of MySQL at least as recent as 4.1. The client should also specify the `CLIENT_MULTI_RESULTS` option when it connects. For C programs, this can be done with the `mysql_real_connect()` C API function. See [Section 20.9.3.52, “mysql\\_real\\_connect\(\)”](#), and [Section 20.9.12, “C API Support for Multiple Statement Execution”](#).

#### MySQL Enterprise

MySQL Enterprise subscribers will find numerous articles about stored routines in the MySQL Enterprise Knowledge Base. Access to this collection of articles is one of the advantages of subscribing to MySQL Enterprise. For more information, see <http://www.mysql.com/products/enterprise/advisors.html>.

## 18.2.2. Stored Routines and MySQL Privileges

Beginning with MySQL 5.0.3, the grant system takes stored routines into account as follows:

- The `CREATE ROUTINE` privilege is needed to create stored routines.
- The `ALTER ROUTINE` privilege is needed to alter or drop stored routines. This privilege is granted automatically to the creator of a routine if necessary, and dropped when the routine creator drops the routine.
- The `EXECUTE` privilege is required to execute stored routines. However, this privilege is granted automatically to the creator of a routine if necessary (and dropped when the creator drops the routine). Also, the default `SQL SECURITY` characteristic for a routine is `DEFINER`, which enables users who have access to the database with which the routine is associated to execute the routine.
- If the `automatic_sp_privileges` system variable is 0, the `EXECUTE` and `ALTER ROUTINE` privileges are not automatically granted and dropped.

The server manipulates the `mysql.proc` table in response to statements that create, alter, or drop stored routines. It is not supported that the server will notice manual manipulation of this table.

## 18.2.3. Stored Routine Metadata

Metadata about stored routines can be obtained as follows:

- Query the `ROUTINES` table of the `INFORMATION_SCHEMA` database. See [Section 19.14, “The INFORMATION\\_SCHEMA ROUTINES Table”](#).
- Use the `SHOW CREATE PROCEDURE` and `SHOW CREATE FUNCTION` statements to see routine definitions. See [Section 12.5.5.8, “SHOW CREATE PROCEDURE Syntax”](#).
- Use the `SHOW PROCEDURE STATUS` and `SHOW FUNCTION STATUS` statements to see routine characteristics. See [Section 12.5.5.26, “SHOW PROCEDURE STATUS Syntax”](#).
- `INFORMATION_SCHEMA` does not have a `PARAMETERS` table until MySQL 6.0, so applications that need to acquire routine parameter information at runtime must use workarounds such as parsing the output of `SHOW CREATE` statements or the `param_list` column of the `mysql.proc` table. `param_list` contents can be processed from within a stored routine, unlike the output from `SHOW`.

## 18.2.4. Stored Procedures, Functions, Triggers, and `LAST_INSERT_ID()`

Within the body of a stored routine (procedure or function) or a trigger, the value of `LAST_INSERT_ID()` changes the same way as for statements executed outside the body of these kinds of objects (see [Section 11.10.3, “Information Functions”](#)). The effect of a stored routine or trigger upon the value of `LAST_INSERT_ID()` that is seen by following statements depends on the kind of routine:

- If a stored procedure executes statements that change the value of `LAST_INSERT_ID()`, the changed value is seen by statements that follow the procedure call.
- For stored functions and triggers that change the value, the value is restored when the function or trigger ends, so following statements do not see a changed value.

## 18.3. Using Triggers

Support for triggers is included beginning with MySQL 5.0.2. A trigger is a named database object that is associated with a table, and that activates when a particular event occurs for the table. Some uses for triggers are to perform checks of values to be inserted into a table or to perform calculations on values involved in an update.

A trigger is defined to activate when an `INSERT`, `DELETE`, or `UPDATE` statement executes for the associated table. A trigger can be set to activate either before or after the triggering statement. For example, you can have a trigger activate before each row that is inserted into a table or after each row that is updated.

### Important

MySQL triggers are activated by SQL statements *only*. They are not activated by changes in tables made by APIs that do not transmit SQL statements to the MySQL Server; in particular, they are not activated by updates made using the `NDB` API.

To use triggers if you have upgraded to MySQL 5.0 from an older release that did not support triggers, you should upgrade your grant tables so that they contain the trigger-related privileges. See [Section 4.4.9, “mysql\\_upgrade — Check Tables for MySQL Upgrade”](#).

The following discussion describes the syntax for creating and dropping triggers, and shows some examples of how to use them.

### Additional resources

- You may find the [Triggers User Forum](#) of use when working with views.
- For answers to some commonly asked questions regarding triggers in MySQL, see [Section A.5, “MySQL 5.0 FAQ — Triggers”](#).
- There are some restrictions on the use of triggers; see [Section F.1, “Restrictions on Stored Routines and Triggers”](#).
- Binary logging for triggers takes place as described in [Section 18.5, “Binary Logging of Stored Programs”](#).

### 18.3.1. Trigger Syntax

To create a trigger or drop a trigger, use the `CREATE TRIGGER` or `DROP TRIGGER` statement. The syntax for these statements is described in [Section 12.1.11, “CREATE TRIGGER Syntax”](#), and [Section 12.1.18, “DROP TRIGGER Syntax”](#).

Here is a simple example that associates a trigger with a table for `INSERT` statements. The trigger acts as an accumulator, summing the values inserted into one of the columns of the table.

```
mysql> CREATE TABLE account (acct_num INT, amount DECIMAL(10,2));
Query OK, 0 rows affected (0.03 sec)

mysql> CREATE TRIGGER ins_sum BEFORE INSERT ON account
-> FOR EACH ROW SET @sum = @sum + NEW.amount;
Query OK, 0 rows affected (0.06 sec)
```

The `CREATE TRIGGER` statement creates a trigger named `ins_sum` that is associated with the `account` table. It also includes clauses that specify the trigger activation time, the triggering event, and what to do with the trigger activates:

- The keyword `BEFORE` indicates the trigger action time. In this case, the trigger should activate before each row inserted into the table. The other allowable keyword here is `AFTER`.
- The keyword `INSERT` indicates the event that activates the trigger. In the example, `INSERT` statements cause trigger activation. You can also create triggers for `DELETE` and `UPDATE` statements.
- The statement following `FOR EACH ROW` defines the statement to execute each time the trigger activates, which occurs once for each row affected by the triggering statement. In the example, the triggered statement is a simple `SET` that accumulates the values inserted into the `amount` column. The statement refers to the column as `NEW.amount` which means “the value of the `amount` column to be inserted into the new row.”

To use the trigger, set the accumulator variable to zero, execute an `INSERT` statement, and then see what value the variable has afterward:

```
mysql> SET @sum = 0;
mysql> INSERT INTO account VALUES(137,14.98),(141,1937.50),(97,-100.00);
mysql> SELECT @sum AS 'Total amount inserted';
+-----+
| Total amount inserted |
+-----+
| 1852.48                |
+-----+
```

In this case, the value of `@sum` after the `INSERT` statement has executed is `14.98 + 1937.50 - 100`, or `1852.48`.

To destroy the trigger, use a `DROP TRIGGER` statement. You must specify the schema name if the trigger is not in the default schema:

```
mysql> DROP TRIGGER test.ins_sum;
```

Triggers for a table are also dropped if you drop the table.

Trigger names exist in the schema namespace, meaning that all triggers must have unique names within a schema. Triggers in different schemas can have the same name.

In addition to the requirement that trigger names be unique for a schema, there are other limitations on the types of triggers you can create. In particular, you cannot have two triggers for a table that have the same activation time and activation event. For example, you cannot define two `BEFORE INSERT` triggers or two `AFTER UPDATE` triggers for a table. This should rarely be a significant limitation, because it is possible to define a trigger that executes multiple statements by using the `BEGIN . . . END` compound statement construct after `FOR EACH ROW`. (An example appears later in this section.)

The `OLD` and `NEW` keywords enable you to access columns in the rows affected by a trigger. (`OLD` and `NEW` are not case sensitive.) In an `INSERT` trigger, only `NEW.col_name` can be used; there is no old row. In a `DELETE` trigger, only `OLD.col_name` can be used; there is no new row. In an `UPDATE` trigger, you can use `OLD.col_name` to refer to the columns of a row before it is updated and `NEW.col_name` to refer to the columns of the row after it is updated.

A column named with `OLD` is read only. You can refer to it (if you have the `SELECT` privilege), but not modify it. A column named with `NEW` can be referred to if you have the `SELECT` privilege for it. In a `BEFORE` trigger, you can also change its value with `SET NEW.col_name = value` if you have the `UPDATE` privilege for it. This means you can use a trigger to modify the values to be inserted into a new row or that are used to update a row.

In a `BEFORE` trigger, the `NEW` value for an `AUTO_INCREMENT` column is 0, not the automatically generated sequence number that will be generated when the new record actually is inserted.

`OLD` and `NEW` are MySQL extensions to triggers.

By using the `BEGIN . . . END` construct, you can define a trigger that executes multiple statements. Within the `BEGIN` block, you also can use other syntax that is allowed within stored routines such as conditionals and loops. However, just as for stored routines, if you use the `mysql` program to define a trigger that executes multiple statements, it is necessary to redefine the `mysql` statement delimiter so that you can use the `;` statement delimiter within the trigger definition. The following example illustrates these points. It defines an `UPDATE` trigger that checks the new value to be used for updating each row, and modifies the value to be within the range from 0 to 100. This must be a `BEFORE` trigger because the value needs to be checked before it is used to update the row:

```
mysql> delimiter //
mysql> CREATE TRIGGER upd_check BEFORE UPDATE ON account
-> FOR EACH ROW
-> BEGIN
->     IF NEW.amount < 0 THEN
->         SET NEW.amount = 0;
->     ELSEIF NEW.amount > 100 THEN
->         SET NEW.amount = 100;
->     END IF;
-> END;//
mysql> delimiter ;
```

It can be easier to define a stored procedure separately and then invoke it from the trigger using a simple `CALL` statement. This is also advantageous if you want to invoke the same routine from within several triggers.

There are some limitations on what can appear in statements that a trigger executes when activated:

- The trigger cannot use the `CALL` statement to invoke stored procedures that return data to the client or that use dynamic SQL. (Stored procedures are allowed to return data to the trigger through `OUT` or `INOUT` parameters.)
- The trigger cannot use statements that explicitly or implicitly begin or end a transaction such as `START TRANSACTION`, `COMMIT`, or `ROLLBACK`.
- Prior to MySQL 5.0.10, triggers cannot contain direct references to tables by name.

MySQL handles errors during trigger execution as follows:

- If a `BEFORE` trigger fails, the operation on the corresponding row is not performed.
- A `BEFORE` trigger is activated by the *attempt* to insert or modify the row, regardless of whether the attempt subsequently succeeds.
- An `AFTER` trigger is executed only if the `BEFORE` trigger (if any) and the row operation both execute successfully.
- An error during either a `BEFORE` or `AFTER` trigger results in failure of the entire statement that caused trigger invocation.
- For transactional tables, failure of a statement should cause rollback of all changes performed by the statement. Failure of a trigger causes the statement to fail, so trigger failure also causes rollback. For non-transactional tables, such rollback cannot be done, so although the statement fails, any changes performed prior to the point of the error remain in effect.

## 18.3.2. Trigger Metadata

Metadata about triggers can be obtained as follows:

- Query the `TRIGGERS` table of the `INFORMATION_SCHEMA` database. See [Section 19.16, “The INFORMATION\\_SCHEMA TRIGGERS Table”](#).
- Use the `SHOW TRIGGERS` statement. See [Section 12.5.5.35, “SHOW TRIGGERS Syntax”](#).

## 18.4. Using Views

Views (including updatable views) are available in MySQL Server 5.0. Views are stored queries that when invoked produce a result set. A view acts as a virtual table. Views are available in binary releases from 5.0.1 and up.

To use views if you have upgraded to MySQL 5.0.1 from an older release, you should upgrade your grant tables so that they contain the view-related privileges. See [Section 4.4.9, “mysql\\_upgrade — Check Tables for MySQL Upgrade”](#).

The following discussion describes the syntax for creating and dropping views, and shows some examples of how to use them.

**Additional resources**

- You may find the [Views User Forum](#) of use when working with views.
- For answers to some commonly asked questions regarding views in MySQL, see [Section A.6, “MySQL 5.0 FAQ — Views”](#).
- There are some restrictions on the use of views; see [Section F.4, “Restrictions on Views”](#).

**18.4.1. View Syntax**

The `CREATE VIEW` statement creates a new view (see [Section 12.1.12, “CREATE VIEW Syntax”](#)). To alter the definition of a view or drop a view, use `ALTER VIEW` (see [Section 12.1.5, “ALTER VIEW Syntax”](#)), or `DROP VIEW` (see [Section 12.1.19, “DROP VIEW Syntax”](#)).

A view can be created from many kinds of `SELECT` statements. It can refer to base tables or other views. It can use joins, `UNION`, and subqueries. The `SELECT` need not even refer to any tables. The following example defines a view that selects two columns from another table, as well as an expression calculated from those columns:

```
mysql> CREATE TABLE t (qty INT, price INT);
mysql> INSERT INTO t VALUES(3, 50), (5, 60);
mysql> CREATE VIEW v AS SELECT qty, price, qty*price AS value FROM t;
mysql> SELECT * FROM v;
+----+-----+-----+
| qty | price | value |
+----+-----+-----+
| 3   | 50    | 150   |
| 5   | 60    | 300   |
+----+-----+-----+
mysql> SELECT * FROM v WHERE qty = 5;
+----+-----+-----+
| qty | price | value |
+----+-----+-----+
| 5   | 60    | 300   |
+----+-----+-----+
```

**18.4.2. View Processing Algorithms**

The optional `ALGORITHM` clause for `CREATE VIEW` or `ALTER VIEW` is a MySQL extension to standard SQL. It affects how MySQL processes the view. `ALGORITHM` takes three values: `MERGE`, `TEMPTABLE`, or `UNDEFINED`. The default algorithm is `UNDEFINED` if no `ALGORITHM` clause is present.

For `MERGE`, the text of a statement that refers to the view and the view definition are merged such that parts of the view definition replace corresponding parts of the statement.

For `TEMPTABLE`, the results from the view are retrieved into a temporary table, which then is used to execute the statement.

For `UNDEFINED`, MySQL chooses which algorithm to use. It prefers `MERGE` over `TEMPTABLE` if possible, because `MERGE` is usually more efficient and because a view cannot be updatable if a temporary table is used.

A reason to choose `TEMPTABLE` explicitly is that locks can be released on underlying tables after the temporary table has been created and before it is used to finish processing the statement. This might result in quicker lock release than the `MERGE` algorithm so that other clients that use the view are not blocked as long.

A view algorithm can be `UNDEFINED` for three reasons:

- No `ALGORITHM` clause is present in the `CREATE VIEW` statement.
- The `CREATE VIEW` statement has an explicit `ALGORITHM = UNDEFINED` clause.
- `ALGORITHM = MERGE` is specified for a view that can be processed only with a temporary table. In this case, MySQL generates a warning and sets the algorithm to `UNDEFINED`.

As mentioned earlier, `MERGE` is handled by merging corresponding parts of a view definition into the statement that refers to the view. The following examples briefly illustrate how the `MERGE` algorithm works. The examples assume that there is a view `v_merge` that has this definition:

```
CREATE ALGORITHM = MERGE VIEW v_merge (vc1, vc2) AS
SELECT c1, c2 FROM t WHERE c3 > 100;
```

Example 1: Suppose that we issue this statement:

```
SELECT * FROM v_merge;
```

MySQL handles the statement as follows:

- `v_merge` becomes `t`
- `*` becomes `vc1, vc2`, which corresponds to `c1, c2`
- The view `WHERE` clause is added

The resulting statement to be executed becomes:

```
SELECT c1, c2 FROM t WHERE c3 > 100;
```

Example 2: Suppose that we issue this statement:

```
SELECT * FROM v_merge WHERE vc1 < 100;
```

This statement is handled similarly to the previous one, except that `vc1 < 100` becomes `c1 < 100` and the view `WHERE` clause is added to the statement `WHERE` clause using an `AND` connective (and parentheses are added to make sure the parts of the clause are executed with correct precedence). The resulting statement to be executed becomes:

```
SELECT c1, c2 FROM t WHERE (c3 > 100) AND (c1 < 100);
```

Effectively, the statement to be executed has a `WHERE` clause of this form:

```
WHERE (select WHERE) AND (view WHERE)
```

If the `MERGE` algorithm cannot be used, a temporary table must be used instead. `MERGE` cannot be used if the view contains any of the following constructs:

- Aggregate functions (`SUM()`, `MIN()`, `MAX()`, `COUNT()`, and so forth)
- `DISTINCT`
- `GROUP BY`
- `HAVING`
- `LIMIT`
- `UNION` or `UNION ALL`
- Subquery in the select list
- Refers only to literal values (in this case, there is no underlying table)

### 18.4.3. Updatable and Insertable Views

Some views are updatable. That is, you can use them in statements such as `UPDATE`, `DELETE`, or `INSERT` to update the contents of the underlying table. For a view to be updatable, there must be a one-to-one relationship between the rows in the view and the rows in the underlying table. There are also certain other constructs that make a view non-updatable. To be more specific, a view is not updatable if it contains any of the following:

- Aggregate functions (`SUM()`, `MIN()`, `MAX()`, `COUNT()`, and so forth)
- `DISTINCT`
- `GROUP BY`
- `HAVING`
- `UNION` or `UNION ALL`

- Subquery in the select list
- Certain joins (see additional join discussion later in this section)
- Non-updatable view in the `FROM` clause
- A subquery in the `WHERE` clause that refers to a table in the `FROM` clause
- Refers only to literal values (in this case, there is no underlying table to update)
- Uses `ALGORITHM = TEMPTABLE` (use of a temporary table always makes a view non-updatable)
- Multiple references to any column of a base table.

With respect to insertability (being updatable with `INSERT` statements), an updatable view is insertable if it also satisfies these additional requirements for the view columns:

- There must be no duplicate view column names.
- The view must contain all columns in the base table that do not have a default value.
- The view columns must be simple column references and not derived columns. A derived column is one that is not a simple column reference but is derived from an expression. These are examples of derived columns:

```
3.14159
col1 + 3
UPPER(col2)
col3 / col4
(subquery)
```

A view that has a mix of simple column references and derived columns is not insertable, but it can be updatable if you update only those columns that are not derived. Consider this view:

```
CREATE VIEW v AS SELECT col1, 1 AS col2 FROM t;
```

This view is not insertable because `col2` is derived from an expression. But it is updatable if the update does not try to update `col2`. This update is allowable:

```
UPDATE v SET col1 = 0;
```

This update is not allowable because it attempts to update a derived column:

```
UPDATE v SET col2 = 0;
```

It is sometimes possible for a multiple-table view to be updatable, assuming that it can be processed with the `MERGE` algorithm. For this to work, the view must use an inner join (not an outer join or a `UNION`). Also, only a single table in the view definition can be updated, so the `SET` clause must name only columns from one of the tables in the view. Views that use `UNION ALL` are disallowed even though they might be theoretically updatable, because the implementation uses temporary tables to process them.

For a multiple-table updatable view, `INSERT` can work if it inserts into a single table. `DELETE` is not supported.

`INSERT DELAYED` is not supported for views.

If a table contains an `AUTO_INCREMENT` column, inserting into an insertable view on the table that does not include the `AUTO_INCREMENT` column does not change the value of `LAST_INSERT_ID()`, because the side effects of inserting default values into columns not part of the view should not be visible.

The `WITH CHECK OPTION` clause can be given for an updatable view to prevent inserts or updates to rows except those for which the `WHERE` clause in the `select_statement` is true.

In a `WITH CHECK OPTION` clause for an updatable view, the `LOCAL` and `CASCADED` keywords determine the scope of check testing when the view is defined in terms of another view. The `LOCAL` keyword restricts the `CHECK OPTION` only to the view being defined. `CASCADED` causes the checks for underlying views to be evaluated as well. When neither keyword is given, the default is `CASCADED`. Consider the definitions for the following table and set of views:

```
mysql> CREATE TABLE t1 (a INT);
mysql> CREATE VIEW v1 AS SELECT * FROM t1 WHERE a < 2
-> WITH CHECK OPTION;
mysql> CREATE VIEW v2 AS SELECT * FROM v1 WHERE a > 0
```

```
-> WITH LOCAL CHECK OPTION;
mysql> CREATE VIEW v3 AS SELECT * FROM v1 WHERE a > 0
-> WITH CASCADED CHECK OPTION;
```

Here the `v2` and `v3` views are defined in terms of another view, `v1`. `v2` has a `LOCAL` check option, so inserts are tested only against the `v2` check. `v3` has a `CASCADED` check option, so inserts are tested not only against its own check, but against those of underlying views. The following statements illustrate these differences:

```
mysql> INSERT INTO v2 VALUES (2);
Query OK, 1 row affected (0.00 sec)
mysql> INSERT INTO v3 VALUES (2);
ERROR 1369 (HY000): CHECK OPTION failed 'test.v3'
```

MySQL sets a flag, called the view updatability flag, at `CREATE VIEW` time. The flag is set to `YES` (true) if `UPDATE` and `DELETE` (and similar operations) are legal for the view. Otherwise, the flag is set to `NO` (false). The `IS_UPDATABLE` column in the `INFORMATION_SCHEMA.VIEWS` table displays the status of this flag. It means that the server always knows whether a view is updatable. If the view is not updatable, statements such `UPDATE`, `DELETE`, and `INSERT` are illegal and will be rejected. (Note that even if a view is updatable, it might not be possible to insert into it, as described elsewhere in this section.)

The updatability of views may be affected by the value of the `updatable_views_with_limit` system variable. See [Section 5.1.3, “Server System Variables”](#).

## 18.4.4. View Metadata

Metadata about views can be obtained as follows:

- Query the `VIEWS` table of the `INFORMATION_SCHEMA` database. See [Section 19.15, “The INFORMATION\\_SCHEMA VIEWS Table”](#).
- Use the `SHOW CREATE VIEW` statement. See [Section 12.5.5.10, “SHOW CREATE VIEW Syntax”](#).

## 18.5. Binary Logging of Stored Programs

The binary log contains information about SQL statements that modify database contents. This information is stored in the form of “events” that describe the modifications. The binary log has two important purposes:

- For replication, the binary log is used on master replication servers as a record of the statements to be sent to slave servers. The master server sends the events contained in its binary log to its slaves, which execute those events to make the same data changes that were made on the master. See [Section 16.4, “Replication Implementation Overview”](#).
- Certain data recovery operations require use of the binary log. After a backup file has been restored, the events in the binary log that were recorded after the backup was made are re-executed. These events bring databases up to date from the point of the backup. See [Section 6.2.2, “Using Backups for Recovery”](#).

However, there are certain binary logging issues that apply with respect to stored programs (stored procedures and functions, and triggers):

- Logging occurs at the statement level. In some cases, it is possible that a statement will affect different sets of rows on a master and a slave.
- Replicated statements executed on a slave are processed by the slave SQL thread, which has full privileges. It is possible for a procedure to follow different execution paths on master and slave servers, so a user can write a routine containing a dangerous statement that will execute only on the slave where it is processed by a thread that has full privileges.
- If a stored program that modifies data is non-deterministic, it is not repeatable. This can result in different data on a master and slave, or cause restored data to differ from the original data.

This section describes how MySQL 5.0 handles binary logging for stored programs. The discussion first states the current conditions that the implementation places on the use of stored programs, and what you can do to avoid problems. Then it summarizes the changes that have taken place in the logging implementation. Finally, implementation details are given that provide information about when and why various changes were made. These details show how several aspects of the current logging behavior were implemented in response to shortcomings identified in earlier versions of MySQL.

In general, the issues described here occur due to the fact that binary logging occurs at the SQL statement level. MySQL 5.1 implements row-level binary logging, which solves or alleviates these issues because the log contains changes made to individual rows

as a result of executing SQL statements.

Unless noted otherwise, the remarks here assume that you have enabled binary logging by starting the server with the `--log-bin` option. (See [Section 5.2.3, “The Binary Log”](#).) If the binary log is not enabled, replication is not possible, nor is the binary log available for data recovery.

The current conditions on the use of stored functions in MySQL 5.0 can be summarized as follows. These conditions do not apply to stored procedures and they do not apply unless binary logging is enabled.

- To create or alter a stored function, you must have the `SUPER` privilege, in addition to the `CREATE ROUTINE` or `ALTER ROUTINE` privilege that is normally required.
- When you create a stored function, you must declare either that it is deterministic or that it does not modify data. Otherwise, it may be unsafe for data recovery or replication.

By default, for a `CREATE FUNCTION` statement to be accepted, at least one of `DETERMINISTIC`, `NO SQL`, or `READS SQL DATA` must be specified explicitly. Otherwise an error occurs:

```
ERROR 1418 (HY000): This function has none of DETERMINISTIC, NO SQL,
or READS SQL DATA in its declaration and binary logging is enabled
(you *might* want to use the less safe log_bin_trust_function_creators
variable)
```

This function is deterministic (and does not modify data), so it is safe:

```
CREATE FUNCTION f1(i INT)
RETURNS INT
DETERMINISTIC
READS SQL DATA
BEGIN
    RETURN i;
END;
```

This function uses `UUID()`, which is not deterministic, so the function also is not deterministic and is not safe:

```
CREATE FUNCTION f2()
RETURNS CHAR(36) CHARACTER SET utf8
BEGIN
    RETURN UUID();
END;
```

This function modifies data, so it may not be safe:

```
CREATE FUNCTION f3(p_id INT)
RETURNS INT
BEGIN
    UPDATE t SET modtime = NOW() WHERE id = p_id;
    RETURN ROW_COUNT();
END;
```

Assessment of the nature of a function is based on the “honesty” of the creator: MySQL does not check that a function declared `DETERMINISTIC` is free of statements that produce non-deterministic results.

- To relax the preceding conditions on function creation (that you must have the `SUPER` privilege and that a function must be declared deterministic or to not modify data), set the global `log_bin_trust_function_creators` system variable to 1. By default, this variable has a value of 0, but you can change it like this:

```
mysql> SET GLOBAL log_bin_trust_function_creators = 1;
```

You can also set this variable by using the `--log-bin-trust-function-creators=1` option when starting the server.

If binary logging is not enabled, `log_bin_trust_function_creators` does not apply and `SUPER` is not required for routine creation.

- For information about built-in functions that may be unsafe for replication (and thus cause stored functions that use them to be unsafe as well), see [Section 16.3.1, “Replication Features and Issues”](#).

Triggers are similar to stored functions, so the preceding remarks regarding functions also apply to triggers with the following exception: `CREATE TRIGGER` does not have an optional `DETERMINISTIC` characteristic, so triggers are assumed to be always deterministic. However, this assumption might in some cases be invalid. For example, the `UUID()` function is non-deterministic (and does not replicate). You should be careful about using such functions in triggers.

Triggers can update tables, so error messages similar to those for stored functions occur with `CREATE TRIGGER` if you do not have the required privileges. On the slave side, the slave uses the trigger `DEFINER` attribute to determine which user is considered to be the creator of the trigger.

The rest of this section provides details on the development of stored routine logging. You need not read it unless you are interested in the background on the rationale for the current logging-related conditions on stored routine use.

The development of stored routine logging in MySQL 5.0 can be summarized as follows:

- Before MySQL 5.0.6: In the initial implementation of stored routine logging, statements that create stored routines and `CALL` statements are not logged. These omissions can cause problems for replication and data recovery.
- MySQL 5.0.6: Statements that create stored routines and `CALL` statements are logged. Stored function invocations are logged when they occur in statements that update data (because those statements are logged). However, function invocations are not logged when they occur in statements such as `SELECT` that do not change data, even if a data change occurs within a function itself; this can cause problems. Under some circumstances, functions and procedures can have different effects if executed at different times or on different (master and slave) machines, and thus can be unsafe for data recovery or replication. To handle this, measures are implemented to allow identification of safe routines and to prevent creation of unsafe routines except by users with sufficient privileges.
- MySQL 5.0.12: For stored functions, when a function invocation that changes data occurs within a non-logged statement such as `SELECT`, the server logs a `DO func_name()` statement that invokes the function so that the function gets executed during data recovery or replication to slave servers. For stored procedures, the server does not log `CALL` statements. Instead, it logs individual statements within a procedure that are executed as a result of a `CALL`. This eliminates problems that may occur when a procedure would follow a different execution path on a slave than on the master.
- MySQL 5.0.16: The procedure logging changes made in 5.0.12 allow the conditions on unsafe routines to be relaxed for stored procedures. Consequently, the user interface for controlling these conditions is revised to apply only to functions. Procedure creators are no longer bound by them.
- MySQL 5.0.17: Logging of stored functions as `DO func_name()` statements (per the changes made in 5.0.12) are logged as `SELECT func_name()` statements instead for better control over error checking.

**Routine logging before MySQL 5.0.6:** Statements that create and use stored routines are not written to the binary log, but statements invoked within stored routines are logged. Suppose that you issue the following statements:

```
CREATE PROCEDURE mysp INSERT INTO t VALUES(1);
CALL mysp();
```

For this example, only the `INSERT` statement appears in the binary log. The `CREATE PROCEDURE` and `CALL` statements do not appear. The absence of routine-related statements in the binary log means that stored routines are not replicated correctly. It also means that for a data recovery operation, re-executing events in the binary log does not recover stored routines.

**Routine logging changes in MySQL 5.0.6:** To address the absence of logging for stored routine creation and `CALL` statements (and the consequent replication and data recovery concerns), the characteristics of binary logging for stored routines were changed as described here. (Some of the items in the following list point out issues that are dealt with in later versions.)

- The server writes `CREATE PROCEDURE`, `CREATE FUNCTION`, `ALTER PROCEDURE`, `ALTER FUNCTION`, `DROP PROCEDURE`, and `DROP FUNCTION` statements to the binary log. Also, the server logs `CALL` statements, not the statements executed within procedures. Suppose that you issue the following statements:

```
CREATE PROCEDURE mysp INSERT INTO t VALUES(1);
CALL mysp();
```

For this example, the `CREATE PROCEDURE` and `CALL` statements appear in the binary log, but the `INSERT` statement does not appear. This corrects the problem that occurred before MySQL 5.0.6 such that only the `INSERT` was logged.

- Logging `CALL` statements has a security implication for replication, which arises from two factors:
  - Statements executed on a slave are processed by the slave SQL thread which has full privileges.
  - It is possible for a procedure to follow different execution paths on master and slave servers.

The implication is that although a user must have the `CREATE ROUTINE` privilege to create a routine, the user can write a routine containing a dangerous statement that will execute only on the slave where it is processed by a thread that has full privileges. For example, if the master and slave servers have server ID values of 1 and 2, respectively, a user on the master server could create and invoke an unsafe procedure `unsafe_sp()` as follows:

```
mysql> delimiter //
mysql> CREATE PROCEDURE unsafe_sp ()
-> BEGIN
-> IF @@server_id=2 THEN DROP DATABASE accounting; END IF;
-> END;
-> //
mysql> delimiter ;
mysql> CALL unsafe_sp();
```

The `CREATE PROCEDURE` and `CALL` statements are written to the binary log, so the slave will execute them. Because the slave SQL thread has full privileges, it will execute the `DROP DATABASE` statement that drops the `accounting` database. Thus, the `CALL` statement has different effects on the master and slave and is not replication-safe.

The preceding example uses a stored procedure, but similar problems can occur for stored functions that are invoked within statements that are written to the binary log: Function invocation has different effects on the master and slave.

To guard against this danger for servers that have binary logging enabled, MySQL 5.0.6 introduces the requirement that stored procedure and function creators must have the `SUPER` privilege, in addition to the usual `CREATE ROUTINE` privilege that is required. Similarly, to use `ALTER PROCEDURE` or `ALTER FUNCTION`, you must have the `SUPER` privilege in addition to the `ALTER ROUTINE` privilege. Without the `SUPER` privilege, an error will occur:

```
ERROR 1419 (HY000): You do not have the SUPER privilege and
binary logging is enabled (you *might* want to use the less safe
log_bin_trust_routine_creators variable)
```

If you do not want to require routine creators to have the `SUPER` privilege (for example, if all users with the `CREATE ROUTINE` privilege on your system are experienced application developers), set the global `log_bin_trust_routine_creators` system variable to 1. You can also set this variable by using the `-log-bin-trust-routine-creators=1` option when starting the server. If binary logging is not enabled, `log_bin_trust_routine_creators` does not apply and `SUPER` is not required for routine creation.

- If a routine that performs updates is non-deterministic, it is not repeatable. This can have two undesirable effects:
  - It will make a slave different from the master.
  - Restored data will be different from the original data.

To deal with these problems, MySQL enforces the following requirement: On a master server, creation and alteration of a routine is refused unless you declare the routine to be deterministic or to not modify data. Two sets of routine characteristics apply here:

- The `DETERMINISTIC` and `NOT DETERMINISTIC` characteristics indicate whether a routine always produces the same result for given inputs. The default is `NOT DETERMINISTIC` if neither characteristic is given. To declare that a routine is deterministic, you must specify `DETERMINISTIC` explicitly.
- The `CONTAINS SQL`, `NO SQL`, `READS SQL DATA`, and `MODIFIES SQL DATA` characteristics provide information about whether the routine reads or writes data. Either `NO SQL` or `READS SQL DATA` indicates that a routine does not change data, but you must specify one of these explicitly because the default is `CONTAINS SQL` if no characteristic is given.

By default, for a `CREATE PROCEDURE` or `CREATE FUNCTION` statement to be accepted, at least one of `DETERMINISTIC`, `NO SQL`, or `READS SQL DATA` must be specified explicitly. Otherwise an error occurs:

```
ERROR 1418 (HY000): This routine has none of DETERMINISTIC, NO SQL,
or READS SQL DATA in its declaration and binary logging is enabled
(you *might* want to use the less safe log_bin_trust_routine_creators
variable)
```

If you set `log_bin_trust_routine_creators` to 1, the requirement that routines be deterministic or not modify data is dropped.

- A `CALL` statement is written to the binary log if the routine returns no error, but not otherwise. When a routine that modifies data fails, you get this warning:

```
ERROR 1417 (HY000): A routine failed and has neither NO SQL nor
READS SQL DATA in its declaration and binary logging is enabled; if
non-transactional tables were updated, the binary log will miss their
changes
```

This logging behavior has the potential to cause problems. If a routine partly modifies a non-transactional table (such as a `MyISAM` table) and returns an error, the binary log will not reflect these changes. To protect against this, you should use transactional tables in the routine and modify the tables within transactions.

If you use the `IGNORE` keyword with `INSERT`, `DELETE`, or `UPDATE` to ignore errors within a routine, a partial update might occur but no error will result. Such statements are logged and they replicate normally.

- Although statements normally are not written to the binary log if they are rolled back, `CALL` statements are logged even when they occur within a rolled-back transaction. This can result in a `CALL` being rolled back on the master but executed on slaves.
- If a stored function is invoked within a statement such as `SELECT` that does not modify data, execution of the function is not written to the binary log, even if the function itself modifies data. This logging behavior has the potential to cause problems. Suppose that a function `myfunc()` is defined as follows:

```
CREATE FUNCTION myfunc () RETURNS INT DETERMINISTIC
BEGIN
  INSERT INTO t (i) VALUES(1);
  RETURN 0;
END;
```

Given that definition, the following statement is not written to the binary log because it is a `SELECT`. Nevertheless, it modifies the table `t` because `myfunc()` modifies `t`:

```
SELECT myfunc();
```

A workaround for this problem is to invoke functions that do updates only within statements that do updates (and which therefore are written to the binary log). Note that although the `DO` statement sometimes is executed for the side effect of evaluating an expression, `DO` is not a workaround here because it is not written to the binary log.

- On slave servers, `--replicate-*-table` rules do not apply to `CALL` statements or to statements within stored routines. These statements are always replicated. If such statements contain references to tables that do not exist on the slave, they could have undesirable effects when executed on the slave.

**Routine logging changes in MySQL 5.0.12:** The changes in 5.0.12 address several problems that were present in earlier versions:

- Stored function invocations in non-logged statements such as `SELECT` were not being logged, even when a function itself changed data.
- Stored procedure logging at the `CALL` level could cause different effects on a master and slave if a procedure took different execution paths on the two machines.
- `CALL` statements were logged even when they occurred within a rolled-back transaction.

To deal with these issues, MySQL 5.0.12 implements the following changes to function and procedure logging:

- A stored function invocation is logged as a `DO` statement if the function changes data and occurs within a statement that would not otherwise be logged. This corrects the problem of non-replication of data changes that result from use of stored functions in non-logged statements. For example, `SELECT` statements are not written to the binary log, but a `SELECT` might invoke a stored function that makes changes. To handle this, a `DO func_name()` statement is written to the binary log when the given function makes a change. Suppose that the following statements are executed on the master:

```
CREATE FUNCTION f1(a INT) RETURNS INT
BEGIN
  IF (a < 3) THEN
    INSERT INTO t2 VALUES (a);
  END IF;
  RETURN 0;
END;

CREATE TABLE t1 (a INT);
INSERT INTO t1 VALUES (1),(2),(3);

SELECT f1(a) FROM t1;
```

When the `SELECT` statement executes, the function `f1()` is invoked three times. Two of those invocations insert a row, and MySQL logs a `DO` statement for each of them. That is, MySQL writes the following statements to the binary log:

```
DO f1(1);
DO f1(2);
```

The server also logs a `DO` statement for a stored function invocation when the function invokes a stored procedure that causes an error. In this case, the server writes the `DO` statement to the log along with the expected error code. On the slave, if the same error occurs, that is the expected result and replication continues. Otherwise, replication stops.

Note: See later in this section for changes made in MySQL 5.0.19: These logged `DO func_name()` statements are logged as `SELECT func_name()` statements instead.

- Stored procedure calls are logged at the statement level rather than at the `CALL` level. That is, the server does not log the `CALL` statement, it logs those statements within the procedure that actually execute. As a result, the same changes that occur on the master will be observed on slave servers. This eliminates the problems that could result from a procedure having different execution paths on different machines. For example, the `DROP DATABASE` problem shown earlier for the `unsafe_sp()` procedure does not occur and the routine is no longer replication-unsafe because it has the same effect on master and slave servers.

In general, statements executed within a stored procedure are written to the binary log using the same rules that would apply were the statements to be executed in standalone fashion. Some special care is taken when logging procedure statements because statement execution within procedures is not quite the same as in non-procedure context:

- A statement to be logged might contain references to local procedure variables. These variables do not exist outside of stored procedure context, so a statement that refers to such a variable cannot be logged literally. Instead, each reference to a local variable is replaced by this construct for logging purposes:

```
NAME_CONST(var_name, var_value)
```

`var_name` is the local variable name, and `var_value` is a constant indicating the value that the variable has at the time the statement is logged. `NAME_CONST()` has a value of `var_value`, and a “name” of `var_name`. Thus, if you invoke this function directly, you get a result like this:

```
mysql> SELECT NAME_CONST('myname', 14);
+-----+
| myname |
+-----+
|      14 |
+-----+
```

`NAME_CONST()` allows a logged standalone statement to be executed on a slave with the same effect as the original statement that was executed on the master within a stored procedure.

The use of `NAME_CONST()` can result in a problem for `CREATE TABLE ... SELECT` statements when the source column expressions refer to local variables. Converting these references to `NAME_CONST()` expressions can result in column names that are different on the master and slave servers, or names that are too long to be legal column identifiers. A workaround is to supply aliases for columns that refer to local variables. Consider this statement when `myvar` has a value of 1:

```
CREATE TABLE t1 SELECT myvar;
```

That will be rewritten as follows:

```
CREATE TABLE t1 SELECT NAME_CONST(myvar, 1);
```

To ensure that the master and slave tables have the same column names, write the statement like this:

```
CREATE TABLE t1 SELECT myvar AS myvar;
```

The rewritten statement becomes:

```
CREATE TABLE t1 SELECT NAME_CONST(myvar, 1) AS myvar;
```

- A statement to be logged might contain references to user-defined variables. To handle this, MySQL writes a `SET` statement to the binary log to make sure that the variable exists on the slave with the same value as on the master. For example, if a statement refers to a variable `@my_var`, that statement will be preceded in the binary log by the following statement, where `value` is the value of `@my_var` on the master:

```
SET @my_var = value;
```

- Procedure calls can occur within a committed or rolled-back transaction. Previously, `CALL` statements were logged even if they occurred within a rolled-back transaction. As of MySQL 5.0.12, transactional context is accounted for so that the transactional aspects of procedure execution are replicated correctly. That is, the server logs those statements within the procedure that actually execute and modify data, and also logs `BEGIN`, `COMMIT`, and `ROLLBACK` statements as necessary. For example, if a procedure updates only transactional tables and is executed within a transaction that is rolled back, those updates are not logged. If the procedure occurs within a committed transaction, `BEGIN` and `COMMIT` statements are logged with the updates. For a procedure that executes within a rolled-back transaction, its statements are logged using the same rules that would apply if the statements were executed in standalone fashion:

- Updates to transactional tables are not logged.
- Updates to non-transactional tables are logged because rollback does not cancel them.
- Updates to a mix of transactional and non-transactional tables are logged surrounded by `BEGIN` and `ROLLBACK` so that slaves will make the same changes and rollbacks as on the master.
- A stored procedure call is *not* written to the binary log at the statement level if the procedure is invoked from within a stored function. In that case, the only thing logged is the statement that invokes the function (if it occurs within a statement that is logged) or a `DO` statement (if it occurs within a statement that is not logged). For this reason, care still should be exercised in the use of stored functions that invoke a procedure, even if the procedure is otherwise safe in itself.
- Because procedure logging occurs at the statement level rather than at the `CALL` level, interpretation of the `--replicate-*-table` options is revised to apply only to stored functions. They no longer apply to stored procedures, except those procedures that are invoked from within functions.

**Routine logging changes in MySQL 5.0.16:** In 5.0.12, a change was introduced to log stored procedure calls at the statement level rather than at the `CALL` level. This change eliminates the requirement that procedures be identified as safe. The requirement now exists only for stored functions, because they still appear in the binary log as function invocations rather than as the statements executed within the function. To reflect the lifting of the restriction on stored procedures, the `log_bin_trust_routine_creators` system variable is renamed to `log_bin_trust_function_creators` and the `--log-bin-trust-routine-creators` server option is renamed to `--log-bin-trust-function-creators`. (For backward compatibility, the old names are recognized but result in a warning.) Error messages that now apply only to functions and not to routines in general are re-worded.

**Routine logging changes in MySQL 5.0.19:** In 5.0.12, a change was introduced to log a stored function invocation as `DO func_name()` if the invocation changes data and occurs within a non-logged statement, or if the function invokes a stored procedure that produces an error. In 5.0.19, these invocations are logged as `SELECT func_name()` instead. The change to `SELECT` was made because use of `DO` was found to yield insufficient control over error code checking.

---

## Chapter 19. INFORMATION\_SCHEMA Tables

`INFORMATION_SCHEMA` provides access to database metadata.

*Metadata* is data about the data, such as the name of a database or table, the data type of a column, or access privileges. Other terms that sometimes are used for this information are *data dictionary* and *system catalog*.

`INFORMATION_SCHEMA` is the information database, the place that stores information about all the other databases that the MySQL server maintains. Inside `INFORMATION_SCHEMA` there are several read-only tables. They are actually views, not base tables, so there are no files associated with them.

In effect, we have a database named `INFORMATION_SCHEMA`, although the server does not create a database directory with that name. It is possible to select `INFORMATION_SCHEMA` as the default database with a `USE` statement, but it is possible only to read the contents of tables. You cannot insert into them, update them, or delete from them.

Here is an example of a statement that retrieves information from `INFORMATION_SCHEMA`:

```
mysql> SELECT table_name, table_type, engine
-> FROM information_schema.tables
-> WHERE table_schema = 'db5'
-> ORDER BY table_name DESC;
```

table_name	table_type	engine
v56	VIEW	NULL
v3	VIEW	NULL
v2	VIEW	NULL
v	VIEW	NULL
tables	BASE TABLE	MyISAM
t7	BASE TABLE	MyISAM
t3	BASE TABLE	MyISAM
t2	BASE TABLE	MyISAM
t	BASE TABLE	MyISAM
pk	BASE TABLE	InnoDB
loop	BASE TABLE	MyISAM
kurs	BASE TABLE	MyISAM
k	BASE TABLE	MyISAM
into	BASE TABLE	MyISAM
goto	BASE TABLE	MyISAM
fk2	BASE TABLE	InnoDB
fk	BASE TABLE	InnoDB

17 rows in set (0.01 sec)

Explanation: The statement requests a list of all the tables in database `db5`, in reverse alphabetical order, showing just three pieces of information: the name of the table, its type, and its storage engine.

Each MySQL user has the right to access these tables, but can see only the rows in the tables that correspond to objects for which the user has the proper access privileges. In some cases (for example, the `ROUTINE_DEFINITION` column in the `INFORMATION_SCHEMA.ROUTINES` table), users who have insufficient privileges will see `NULL`.

The `SELECT . . . FROM INFORMATION_SCHEMA` statement is intended as a more consistent way to provide access to the information provided by the various `SHOW` statements that MySQL supports (`SHOW DATABASES`, `SHOW TABLES`, and so forth). Using `SELECT` has these advantages, compared to `SHOW`:

- It conforms to Codd's rules. That is, all access is done on tables.
- Nobody needs to learn a new statement syntax. Because they already know how `SELECT` works, they only need to learn the object names.
- The implementor need not worry about adding keywords.
- There are millions of possible output variations, instead of just one. This provides more flexibility for applications that have varying requirements about what metadata they need.
- Migration is easier because every other DBMS does it this way.

However, because `SHOW` is popular with MySQL employees and users, and because it might be confusing were it to disappear, the advantages of conventional syntax are not a sufficient reason to eliminate `SHOW`. In fact, along with the implementation of `INFORMATION_SCHEMA`, there are enhancements to `SHOW` as well. These are described in [Section 19.19, "Extensions to SHOW Statements"](#).

There is no difference between the privileges required for `SHOW` statements and those required to select information from `INFORMATION_SCHEMA`. In either case, you have to have some privilege on an object in order to see information about it.

The implementation for the `INFORMATION_SCHEMA` table structures in MySQL follows the ANSI/ISO SQL:2003 standard Part 11 *Schemata*. Our intent is approximate compliance with SQL:2003 core feature F021 *Basic information schema*.

Users of SQL Server 2000 (which also follows the standard) may notice a strong similarity. However, MySQL has omitted many columns that are not relevant for our implementation, and added columns that are MySQL-specific. One such column is the `ENGINE` column in the `INFORMATION_SCHEMA.TABLES` table.

Although other DBMSs use a variety of names, like `syscat` or `system`, the standard name is `INFORMATION_SCHEMA`.

The following sections describe each of the tables and columns that are in `INFORMATION_SCHEMA`. For each column, there are three pieces of information:

- “`INFORMATION_SCHEMA` Name” indicates the name for the column in the `INFORMATION_SCHEMA` table. This corresponds to the standard SQL name unless the “Remarks” field says “MySQL extension.”
- “`SHOW` Name” indicates the equivalent field name in the closest `SHOW` statement, if there is one.
- “Remarks” provides additional information where applicable. If this field is `NULL`, it means that the value of the column is always `NULL`. If this field says “MySQL extension,” the column is a MySQL extension to standard SQL.

To avoid using any name that is reserved in the standard or in DB2, SQL Server, or Oracle, we changed the names of some columns marked “MySQL extension”. (For example, we changed `COLLATION` to `TABLE_COLLATION` in the `TABLES` table.) See the list of reserved words near the end of this article: [http://web.archive.org/web/20070409075643rn\\_1/www.dbazine.com/db2/db2-disarticles/gulutzan5](http://web.archive.org/web/20070409075643rn_1/www.dbazine.com/db2/db2-disarticles/gulutzan5).

The definition for character columns (for example, `TABLES.TABLE_NAME`) is generally `VARCHAR(N) CHARACTER SET utf8` where `N` is at least 64. MySQL uses the default collation for this character set (`utf8_general_ci`) for all searches, sorts, comparisons, and other string operations on such columns. If the default collation is not correct for your needs, you can force a suitable collation with a `COLLATE` clause (Section 9.1.6.1, “Using `COLLATE` in SQL Statements”).

Each section indicates what `SHOW` statement is equivalent to a `SELECT` that retrieves information from `INFORMATION_SCHEMA`, if there is such a statement. For `SHOW` statements that display information for the current database if you omit a `FROM db_name` clause, you can often select information for the current database by adding an `AND TABLE_SCHEMA = CURRENT_DATABASE()` condition to the `WHERE` clause of a query that retrieves information from an `INFORMATION_SCHEMA` table.

### Note

At present, there are some missing columns and some columns out of order. We are working on this and updating the documentation as changes are made.

For answers to questions that are often asked concerning the `INFORMATION_SCHEMA` database, see Section A.7, “MySQL 5.0 FAQ — `INFORMATION_SCHEMA`”.

## 19.1. The `INFORMATION_SCHEMA.SCHEMATA` Table

A schema is a database, so the `SCHEMATA` table provides information about databases.

<code>INFORMATION_SCHEMA</code> Name	<code>SHOW</code> Name	Remarks
<code>CATALOG_NAME</code>		<code>NULL</code>
<code>SCHEMA_NAME</code>		Database
<code>DEFAULT_CHARACTER_SET_NAME</code>		
<code>DEFAULT_COLLATION_NAME</code>		
<code>SQL_PATH</code>		<code>NULL</code>

### Notes:

- `DEFAULT_COLLATION_NAME` was added in MySQL 5.0.6.

The following statements are equivalent:

```
SELECT SCHEMA_NAME AS `Database`
FROM INFORMATION_SCHEMA.SCHEMATA
[WHERE SCHEMA_NAME LIKE 'wild']
```

```
SHOW DATABASES
[LIKE 'wild']
```

## 19.2. The INFORMATION\_SCHEMA TABLES Table

The `TABLES` table provides information about tables in databases.

INFORMATION_SCHEMA Name	SHOW Name	Remarks
TABLE_CATALOG		NULL
TABLE_SCHEMA	Table_...	
TABLE_NAME	Table_...	
TABLE_TYPE		
ENGINE	Engine	MySQL extension
VERSION	Version	The version number of the table's <code>.frm</code> file, MySQL extension
ROW_FORMAT	Row_format	MySQL extension
TABLE_ROWS	Rows	MySQL extension
AVG_ROW_LENGTH	Avg_row_length	MySQL extension
DATA_LENGTH	Data_length	MySQL extension
MAX_DATA_LENGTH	Max_data_length	MySQL extension
INDEX_LENGTH	Index_length	MySQL extension
DATA_FREE	Data_free	MySQL extension
AUTO_INCREMENT	Auto_increment	MySQL extension
CREATE_TIME	Create_time	MySQL extension
UPDATE_TIME	Update_time	MySQL extension
CHECK_TIME	Check_time	MySQL extension
TABLE_COLLATION	Collation	MySQL extension
CHECKSUM	Checksum	MySQL extension
CREATE_OPTIONS	Create_options	MySQL extension
TABLE_COMMENT	Comment	MySQL extension

### Notes:

- `TABLE_SCHEMA` and `TABLE_NAME` are a single field in a `SHOW` display, for example `Table_in_db1`.
- `TABLE_TYPE` should be `BASE TABLE` or `VIEW`. Currently, the `TABLES` table does not list `TEMPORARY` tables.
- The `TABLE_ROWS` column is `NULL` if the table is in the `INFORMATION_SCHEMA` database.  
For `InnoDB` tables, the row count is only a rough estimate used in SQL optimization.
- We have nothing for the table's default character set. `TABLE_COLLATION` is close, because collation names begin with a character set name.

The following statements are equivalent:

```
SELECT table_name FROM INFORMATION_SCHEMA.TABLES
WHERE table_schema = 'db_name'
[AND table_name LIKE 'wild']

SHOW TABLES
FROM db_name
[LIKE 'wild']
```

## 19.3. The INFORMATION\_SCHEMA COLUMNS Table

The `COLUMNS` table provides information about columns in tables.

INFORMATION_SCHEMA Name	SHOW Name	Remarks
TABLE_CATALOG		NULL
TABLE_SCHEMA		
TABLE_NAME		
COLUMN_NAME	Field	
ORDINAL_POSITION		see notes
COLUMN_DEFAULT	Default	
IS_NULLABLE	Null	
DATA_TYPE	Type	
CHARACTER_MAXIMUM_LENGTH	Type	
CHARACTER_OCTET_LENGTH		
NUMERIC_PRECISION	Type	
NUMERIC_SCALE	Type	
CHARACTER_SET_NAME		
COLLATION_NAME	Collation	
COLUMN_TYPE	Type	MySQL extension
COLUMN_KEY	Key	MySQL extension
EXTRA	Extra	MySQL extension
PRIVILEGES	Privileges	MySQL extension
COLUMN_COMMENT	Comment	MySQL extension

**Notes:**

- In `SHOW`, the `Type` display includes values from several different `COLUMNS` columns.
- `ORDINAL_POSITION` is necessary because you might want to say `ORDER BY ORDINAL_POSITION`. Unlike `SHOW, SELECT` does not have automatic ordering.
- `CHARACTER_OCTET_LENGTH` should be the same as `CHARACTER_MAXIMUM_LENGTH`, except for multi-byte character sets.
- `CHARACTER_SET_NAME` can be derived from `Collation`. For example, if you say `SHOW FULL COLUMNS FROM t`, and you see in the `Collation` column a value of `latin1_swedish_ci`, the character set is what is before the first underscore: `latin1`.

The following statements are nearly equivalent:

```
SELECT COLUMN_NAME, DATA_TYPE, IS_NULLABLE, COLUMN_DEFAULT
FROM INFORMATION_SCHEMA.COLUMNS
WHERE table_name = 'tbl_name'
[AND table_schema = 'db_name']
[AND column_name LIKE 'wild']

SHOW COLUMNS
FROM tbl_name
[FROM db_name]
[LIKE 'wild']
```

## 19.4. The INFORMATION\_SCHEMA STATISTICS Table

The `STATISTICS` table provides information about table indexes.

INFORMATION_SCHEMA Name	SHOW Name	Remarks
TABLE_CATALOG		NULL
TABLE_SCHEMA		= Database
TABLE_NAME	Table	
NON_UNIQUE	Non_unique	
INDEX_SCHEMA		= Database

INDEX_NAME	Key_name	
SEQ_IN_INDEX	Seq_in_index	
COLUMN_NAME	Column_name	
COLLATION	Collation	
CARDINALITY	Cardinality	
SUB_PART	Sub_part	MySQL extension
PACKED	Packed	MySQL extension
NULLABLE	Null	MySQL extension
INDEX_TYPE	Index_type	MySQL extension
COMMENT	Comment	MySQL extension

**Notes:**

- There is no standard table for indexes. The preceding list is similar to what SQL Server 2000 returns for `sp_statistics`, except that we replaced the name `QUALIFIER` with `CATALOG` and we replaced the name `OWNER` with `SCHEMA`.

Clearly, the preceding table and the output from `SHOW INDEX` are derived from the same parent. So the correlation is already close.

The following statements are equivalent:

```
SELECT * FROM INFORMATION_SCHEMA.STATISTICS
  WHERE table_name = 'tbl_name'
  AND table_schema = 'db_name'

SHOW INDEX
  FROM tbl_name
  FROM db_name
```

## 19.5. The INFORMATION\_SCHEMA USER\_PRIVILEGES Table

The `USER_PRIVILEGES` table provides information about global privileges. This information comes from the `mysql.user` grant table.

INFORMATION_SCHEMA Name	SHOW Name	Remarks
GRANTEE		'user_name'@'host_name' value, MySQL extension
TABLE_CATALOG		NULL, MySQL extension
PRIVILEGE_TYPE		MySQL extension
IS_GRANTABLE		MySQL extension

**Notes:**

- This is a non-standard table. It takes its values from the `mysql.user` table.

## 19.6. The INFORMATION\_SCHEMA SCHEMA\_PRIVILEGES Table

The `SCHEMA_PRIVILEGES` table provides information about schema (database) privileges. This information comes from the `mysql.db` grant table.

INFORMATION_SCHEMA Name	SHOW Name	Remarks
GRANTEE		'user_name'@'host_name' value, MySQL extension
TABLE_CATALOG		NULL, MySQL extension
TABLE_SCHEMA		MySQL extension
PRIVILEGE_TYPE		MySQL extension

IS_GRANTABLE		MySQL extension
--------------	--	-----------------

**Notes:**

- This is a non-standard table. It takes its values from the `mysql.db` table.

## 19.7. The INFORMATION\_SCHEMA TABLE\_PRIVILEGES Table

The `TABLE_PRIVILEGES` table provides information about table privileges. This information comes from the `mysql.tables_priv` grant table.

INFORMATION_SCHEMA Name	SHOW Name	Remarks
GRANTEE		'user_name'@'host_name' value
TABLE_CATALOG		NULL
TABLE_SCHEMA		
TABLE_NAME		
PRIVILEGE_TYPE		
IS_GRANTABLE		

**Notes:**

- `PRIVILEGE_TYPE` can contain one (and only one) of these values: `SELECT`, `INSERT`, `UPDATE`, `REFERENCES`, `ALTER`, `INDEX`, `DROP`, `CREATE VIEW`.

The following statements are *not* equivalent:

```
SELECT ... FROM INFORMATION_SCHEMA.TABLE_PRIVILEGES
SHOW GRANTS ...
```

## 19.8. The INFORMATION\_SCHEMA COLUMN\_PRIVILEGES Table

The `COLUMN_PRIVILEGES` table provides information about column privileges. This information comes from the `mysql.columns_priv` grant table.

INFORMATION_SCHEMA Name	SHOW Name	Remarks
GRANTEE		'user_name'@'host_name' value
TABLE_CATALOG		NULL
TABLE_SCHEMA		
TABLE_NAME		
COLUMN_NAME		
PRIVILEGE_TYPE		
IS_GRANTABLE		

**Notes:**

- In the output from `SHOW FULL COLUMNS`, the privileges are all in one field and in lowercase, for example, `select,insert,update,references`. In `COLUMN_PRIVILEGES`, there is one privilege per row, in uppercase.
- `PRIVILEGE_TYPE` can contain one (and only one) of these values: `SELECT`, `INSERT`, `UPDATE`, `REFERENCES`.
- If the user has `GRANT OPTION` privilege, `IS_GRANTABLE` should be `YES`. Otherwise, `IS_GRANTABLE` should be `NO`. The output does not list `GRANT OPTION` as a separate privilege.

The following statements are *not* equivalent:

```
SELECT ... FROM INFORMATION_SCHEMA.COLUMN_PRIVILEGES
SHOW GRANTS ...
```

## 19.9. The INFORMATION\_SCHEMA CHARACTER\_SETS Table

The `CHARACTER_SETS` table provides information about available character sets.

INFORMATION_SCHEMA Name	SHOW Name	Remarks
<code>CHARACTER_SET_NAME</code>	Charset	
<code>DEFAULT_COLLATE_NAME</code>	Default collation	
<code>DESCRIPTION</code>	Description	MySQL extension
<code>MAXLEN</code>	Maxlen	MySQL extension

The following statements are equivalent:

```
SELECT * FROM INFORMATION_SCHEMA.CHARACTER_SETS
  [WHERE name LIKE 'wild']

SHOW CHARACTER SET
  [LIKE 'wild']
```

## 19.10. The INFORMATION\_SCHEMA COLLATIONS Table

The `COLLATIONS` table provides information about collations for each character set.

INFORMATION_SCHEMA Name	SHOW Name	Remarks
<code>COLLATION_NAME</code>	Collation	
<code>CHARACTER_SET_NAME</code>	Charset	MySQL extension
<code>ID</code>	Id	MySQL extension
<code>IS_DEFAULT</code>	Default	MySQL extension
<code>IS_COMPILED</code>	Compiled	MySQL extension
<code>SORTLEN</code>	Sortlen	MySQL extension

The following statements are equivalent:

```
SELECT COLLATION_NAME FROM INFORMATION_SCHEMA.COLLATIONS
  [WHERE collation_name LIKE 'wild']

SHOW COLLATION
  [LIKE 'wild']
```

## 19.11. The INFORMATION\_SCHEMA COLLATION\_CHARACTER\_SET\_APPLICABILITY Table

The `COLLATION_CHARACTER_SET_APPLICABILITY` table indicates what character set is applicable for what collation. The columns are equivalent to the first two display fields that we get from `SHOW COLLATION`.

INFORMATION_SCHEMA Name	SHOW Name	Remarks
<code>COLLATION_NAME</code>	Collation	
<code>CHARACTER_SET_NAME</code>	Charset	

## 19.12. The INFORMATION\_SCHEMA TABLE\_CONSTRAINTS Table

The `TABLE_CONSTRAINTS` table describes which tables have constraints.

INFORMATION_SCHEMA Name	SHOW Name	Remarks
CONSTRAINT_CATALOG		NULL
CONSTRAINT_SCHEMA		
CONSTRAINT_NAME		
TABLE_SCHEMA		
TABLE_NAME		
CONSTRAINT_TYPE		

**Notes:**

- The `CONSTRAINT_TYPE` value can be `UNIQUE`, `PRIMARY KEY`, or `FOREIGN KEY`.
- The `UNIQUE` and `PRIMARY KEY` information is about the same as what you get from the `Key_name` field in the output from `SHOW INDEX` when the `Non_unique` field is 0.
- The `CONSTRAINT_TYPE` column can contain one of these values: `UNIQUE`, `PRIMARY KEY`, `FOREIGN KEY`, `CHECK`. This is a `CHAR` (not `ENUM`) column. The `CHECK` value is not available until we support `CHECK`.

## 19.13. The INFORMATION\_SCHEMA KEY\_COLUMN\_USAGE Table

The `KEY_COLUMN_USAGE` table describes which key columns have constraints.

INFORMATION_SCHEMA Name	SHOW Name	Remarks
CONSTRAINT_CATALOG		NULL
CONSTRAINT_SCHEMA		
CONSTRAINT_NAME		
TABLE_CATALOG		
TABLE_SCHEMA		
TABLE_NAME		
COLUMN_NAME		
ORDINAL_POSITION		
POSITION_IN_UNIQUE_CONSTRAINT		
REFERENCED_TABLE_SCHEMA		
REFERENCED_TABLE_NAME		
REFERENCED_COLUMN_NAME		

**Notes:**

- If the constraint is a foreign key, then this is the column of the foreign key, not the column that the foreign key references.
- The value of `ORDINAL_POSITION` is the column's position within the constraint, not the column's position within the table. Column positions are numbered beginning with 1.
- The value of `POSITION_IN_UNIQUE_CONSTRAINT` is `NULL` for unique and primary-key constraints. For foreign-key constraints, it is the ordinal position in key of the table that is being referenced.

For example, suppose that there are two tables name `t1` and `t3` that have the following definitions:

```
CREATE TABLE t1
(
  s1 INT,
  s2 INT,
  s3 INT,
  PRIMARY KEY(s3)
) ENGINE=InnoDB;

CREATE TABLE t3
(
  s1 INT,
  s2 INT,
```

```
s3 INT,
KEY(s1),
CONSTRAINT CO FOREIGN KEY (s2) REFERENCES t1(s3)
) ENGINE=InnoDB;
```

For those two tables, the `KEY_COLUMN_USAGE` table has two rows:

- One row with `CONSTRAINT_NAME = 'PRIMARY'`, `TABLE_NAME = 't1'`, `COLUMN_NAME = 's3'`, `ORDINAL_POSITION = 1`, `POSITION_IN_UNIQUE_CONSTRAINT = NULL`.
- One row with `CONSTRAINT_NAME = 'CO'`, `TABLE_NAME = 't3'`, `COLUMN_NAME = 's2'`, `ORDINAL_POSITION = 1`, `POSITION_IN_UNIQUE_CONSTRAINT = 1`.
- `REFERENCED_TABLE_SCHEMA`, `REFERENCED_TABLE_NAME`, and `REFERENCED_COLUMN_NAME` were added in MySQL 5.0.6.

## 19.14. The INFORMATION\_SCHEMA ROUTINES Table

The `ROUTINES` table provides information about stored routines (both procedures and functions). The `ROUTINES` table does not include user-defined functions (UDFs) at this time.

The column named “`mysql.proc name`” indicates the `mysql.proc` table column that corresponds to the `INFORMATION_SCHEMA.ROUTINES` table column, if any.

INFORMATION_SCHEMA Name	mysql.proc Name	Remarks
SPECIFIC_NAME	specific_name	
ROUTINE_CATALOG		NULL
ROUTINE_SCHEMA	db	
ROUTINE_NAME	name	
ROUTINE_TYPE	type	{PROCEDURE FUNCTION}
DTD_IDENTIFIER		data type descriptor
ROUTINE_BODY		SQL
ROUTINE_DEFINITION	body	
EXTERNAL_NAME		NULL
EXTERNAL_LANGUAGE	language	NULL
PARAMETER_STYLE		SQL
IS_DETERMINISTIC	is_deterministic	
SQL_DATA_ACCESS	sql_data_access	
SQL_PATH		NULL
SECURITY_TYPE	security_type	
CREATED	created	
LAST_ALTERED	modified	
SQL_MODE	sql_mode	MySQL extension
ROUTINE_COMMENT	comment	MySQL extension
DEFINER	definer	MySQL extension

### Notes:

- MySQL calculates `EXTERNAL_LANGUAGE` thus:
  - If `mysql.proc.language = 'SQL'`, `EXTERNAL_LANGUAGE` is `NULL`
  - Otherwise, `EXTERNAL_LANGUAGE` is what is in `mysql.proc.language`. However, we do not have external languages yet, so it is always `NULL`.

## 19.15. The INFORMATION\_SCHEMA VIEWS Table

The `VIEWS` table provides information about views in databases. You must have the `SHOW VIEW` privilege to access this table.

INFORMATION_SCHEMA Name	SHOW Name	Remarks
TABLE_CATALOG		NULL
TABLE_SCHEMA		
TABLE_NAME		
VIEW_DEFINITION		
CHECK_OPTION		
IS_UPDATABLE		
DEFINER		
SECURITY_TYPE		

### Notes:

- The `VIEW_DEFINITION` column has most of what you see in the `Create Table` field that `SHOW CREATE VIEW` produces. Skip the words before `SELECT` and skip the words `WITH CHECK OPTION`. Suppose that the original statement was:

```
CREATE VIEW v AS
  SELECT s2,s1 FROM t
  WHERE s1 > 5
  ORDER BY s1
  WITH CHECK OPTION;
```

Then the view definition looks like this:

```
SELECT s2,s1 FROM t WHERE s1 > 5 ORDER BY s1
```

- The `CHECK_OPTION` column has a value of `NONE`, `CASCADE`, or `LOCAL`.
- MySQL sets a flag, called the view updatability flag, at `CREATE VIEW` time. The flag is set to `YES` (true) if `UPDATE` and `DELETE` (and similar operations) are legal for the view. Otherwise, the flag is set to `NO` (false). The `IS_UPDATABLE` column in the `VIEWS` table displays the status of this flag. It means that the server always knows whether a view is updatable. If the view is not updatable, statements such `UPDATE`, `DELETE`, and `INSERT` are illegal and will be rejected. (Note that even if a view is updatable, it might not be possible to insert into it; for details, refer to [Section 12.1.12, “CREATE VIEW Syntax”](#).)
- The `DEFINER` and `SECURITY_TYPE` columns were added in MySQL 5.0.14. `DEFINER` indicates who defined the view. `SECURITY_TYPE` has a value of `DEFINER` or `INVOKER`.

MySQL lets you use different `sql_mode` settings to tell the server the type of SQL syntax to support. For example, you might use the `ANSI` SQL mode to ensure MySQL correctly interprets the standard SQL concatenation operator, the double bar (`||`), in your queries. If you then create a view that concatenates items, you might worry that changing the `sql_mode` setting to a value different from `ANSI` could cause the view to become invalid. But this is not the case. No matter how you write out a view definition, MySQL always stores it the same way, in a canonical form. Here is an example that shows how the server changes a double bar concatenation operator to a `CONCAT()` function:

```
mysql> SET sql_mode = 'ANSI';
Query OK, 0 rows affected (0.00 sec)

mysql> CREATE VIEW test.v AS SELECT 'a' || 'b' as coll;
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT VIEW_DEFINITION FROM INFORMATION_SCHEMA.VIEWS
  -> WHERE TABLE_SCHEMA = 'test' AND TABLE_NAME = 'v';
+-----+
| VIEW_DEFINITION |
+-----+
| select concat('a','b') AS `coll` |
+-----+
1 row in set (0.00 sec)
```

The advantage of storing a view definition in canonical form is that changes made later to the value of `sql_mode` will not affect the results from the view. However an additional consequence is that comments prior to `SELECT` are stripped from the definition by the server.

## 19.16. The INFORMATION\_SCHEMA TRIGGERS Table

The `TRIGGERS` table provides information about triggers. You must have the `SUPER` privilege to access this table.

INFORMATION_SCHEMA Name	SHOW Name	Remarks
TRIGGER_CATALOG		NULL
TRIGGER_SCHEMA		
TRIGGER_NAME	Trigger	
EVENT_MANIPULATION	Event	
EVENT_OBJECT_CATALOG		NULL
EVENT_OBJECT_SCHEMA		
EVENT_OBJECT_TABLE	Table	
ACTION_ORDER		0
ACTION_CONDITION		NULL
ACTION_STATEMENT	Statement	
ACTION_ORIENTATION		ROW
ACTION_TIMING	Timing	
ACTION_REFERENCE_OLD_TABLE		NULL
ACTION_REFERENCE_NEW_TABLE		NULL
ACTION_REFERENCE_OLD_ROW		OLD
ACTION_REFERENCE_NEW_ROW		NEW
CREATED		NULL (0)
SQL_MODE		MySQL extension
DEFINER		MySQL extension

### Notes:

- The `TRIGGERS` table was added in MySQL 5.0.10.
- The `TRIGGER_SCHEMA` and `TRIGGER_NAME` columns contain the name of the database in which the trigger occurs and the trigger name, respectively.
- The `EVENT_MANIPULATION` column contains one of the values `'INSERT'`, `'DELETE'`, or `'UPDATE'`.
- As noted in [Section 18.3, “Using Triggers”](#), every trigger is associated with exactly one table. The `EVENT_OBJECT_SCHEMA` and `EVENT_OBJECT_TABLE` columns contain the database in which this table occurs, and the table's name.
- The `ACTION_ORDER` statement contains the ordinal position of the trigger's action within the list of all similar triggers on the same table. Currently, this value is always 0, because it is not possible to have more than one trigger with the same `EVENT_MANIPULATION` and `ACTION_TIMING` on the same table.
- The `ACTION_STATEMENT` column contains the statement to be executed when the trigger is invoked. This is the same as the text displayed in the `Statement` column of the output from `SHOW TRIGGERS`. Note that this text uses UTF-8 encoding.
- The `ACTION_ORIENTATION` column always contains the value `'ROW'`.
- The `ACTION_TIMING` column contains one of the two values `'BEFORE'` or `'AFTER'`.
- The columns `ACTION_REFERENCE_OLD_ROW` and `ACTION_REFERENCE_NEW_ROW` contain the old and new column identifiers, respectively. This means that `ACTION_REFERENCE_OLD_ROW` always contains the value `'OLD'` and `ACTION_REFERENCE_NEW_ROW` always contains the value `'NEW'`.
- The `SQL_MODE` column shows the server SQL mode that was in effect at the time when the trigger was created (and thus which remains in effect for this trigger whenever it is invoked, *regardless of the current server SQL mode*). The possible range of values for this column is the same as that of the `sql_mode` system variable. See [Section 5.1.7, “Server SQL Modes”](#).
- The `DEFINER` column was added in MySQL 5.0.17. `DEFINER` indicates who defined the trigger.
- The following columns currently always contain `NULL`: `TRIGGER_CATALOG`, `EVENT_OBJECT_CATALOG`, `ACTION_CONDITION`, `ACTION_REFERENCE_OLD_TABLE`, `ACTION_REFERENCE_NEW_TABLE`, and `CREATED`.

Example, using the `ins_sum` trigger defined in [Section 18.3, “Using Triggers”](#):

```
mysql> SELECT * FROM INFORMATION_SCHEMA.TRIGGERS\G
***** 1. row *****
      TRIGGER_CATALOG: NULL
      TRIGGER_SCHEMA: test
      TRIGGER_NAME: ins_sum
      EVENT_MANIPULATION: INSERT
      EVENT_OBJECT_CATALOG: NULL
      EVENT_OBJECT_SCHEMA: test
      EVENT_OBJECT_TABLE: account
      ACTION_ORDER: 0
      ACTION_CONDITION: NULL
      ACTION_STATEMENT: SET @sum = @sum + NEW.amount
      ACTION_ORIENTATION: ROW
      ACTION_TIMING: BEFORE
      ACTION_REFERENCE_OLD_TABLE: NULL
      ACTION_REFERENCE_NEW_TABLE: NULL
      ACTION_REFERENCE_OLD_ROW: OLD
      ACTION_REFERENCE_NEW_ROW: NEW
      CREATED: NULL
      SQL_MODE:
      DEFINER: me@localhost
```

See also [Section 12.5.5.35, “SHOW TRIGGERS Syntax”](#).

## 19.17. The INFORMATION\_SCHEMA PROFILING Table

This section does not apply to MySQL Enterprise Server users.

The `PROFILING` table provides statement profiling information. Its contents correspond to the information produced by the `SHOW PROFILES` and `SHOW PROFILE` statements (see [Section 12.5.5.29, “SHOW PROFILES Syntax”](#)). The table is empty unless the `profiling` session variable is set to 1.

INFORMATION_SCHEMA Name	SHOW Name	Remarks
QUERY_ID	Query_ID	
SEQ		
STATE	Status	
DURATION	Duration	
CPU_USER	CPU_user	
CPU_SYSTEM	CPU_system	
CONTEXT_VOLUNTARY	Context_voluntary	
CONTEXT_INVOLUNTARY	Context_involuntary	
BLOCK_OPS_IN	Block_ops_in	
BLOCK_OPS_OUT	Block_ops_out	
MESSAGES_SENT	Messages_sent	
MESSAGES_RECEIVED	Messages_received	
PAGE_FAULTS_MAJOR	Page_faults_major	
PAGE_FAULTS_MINOR	Page_faults_minor	
SWAPS	Swaps	
SOURCE_FUNCTION	Source_function	
SOURCE_FILE	Source_file	
SOURCE_LINE	Source_line	

### Notes:

- The `PROFILING` table was added in MySQL 5.0.37.
- `QUERY_ID` is a numeric statement identifier.
- `SEQ` is a sequence number indicating the display order for rows with the same `QUERY_ID` value.
- `STATE` is the profiling state to which the row measurements apply.

- `DURATION` indicates how long statement execution remained in the given state, in seconds.
- `CPU_USER` and `CPU_SYSTEM` indicate user and system CPU use, in seconds.
- `CONTEXT_VOLUNTARY` and `CONTEXT_INVOLUNTARY` indicate how many voluntary and involuntary context switches occurred.
- `BLOCK_OPS_IN` and `BLOCK_OPS_OUT` indicate the number of block input and output operations.
- `MESSAGES_SENT` and `MESSAGES_RECEIVED` indicate the number of communication messages sent and received.
- `PAGE_FAULTS_MAJOR` and `PAGE_FAULTS_MINOR` indicate the number of major and minor page faults.
- `SWAPS` indicates how many swaps occurred.
- `SOURCE_FUNCTION`, `SOURCE_FILE`, and `SOURCE_LINE` provide information indicating where in the source code the profiled state executes.

## 19.18. Other INFORMATION\_SCHEMA Tables

We intend to implement additional `INFORMATION_SCHEMA` tables. In particular, we acknowledge the need for the `PARAMETERS` and `REFERENTIAL_CONSTRAINTS` tables. (`REFERENTIAL_CONSTRAINTS` is implemented in MySQL 5.1, and `PARAMETERS` is implemented in MySQL 6.0.)

## 19.19. Extensions to SHOW Statements

Some extensions to `SHOW` statements accompany the implementation of `INFORMATION_SCHEMA`:

- `SHOW` can be used to get information about the structure of `INFORMATION_SCHEMA` itself.
- Several `SHOW` statements accept a `WHERE` clause that provides more flexibility in specifying which rows to display.

These extensions are available beginning with MySQL 5.0.3.

`INFORMATION_SCHEMA` is an information database, so its name is included in the output from `SHOW DATABASES`. Similarly, `SHOW TABLES` can be used with `INFORMATION_SCHEMA` to obtain a list of its tables:

```
mysql> SHOW TABLES FROM INFORMATION_SCHEMA;
+-----+
| Tables_in_information_schema |
+-----+
| CHARACTER_SETS              |
| COLLATIONS                  |
| COLLATION_CHARACTER_SET_APPLICABILITY |
| COLUMNS                    |
| COLUMN_PRIVILEGES           |
| KEY_COLUMN_USAGE            |
| ROUTINES                    |
| SCHEMATA                    |
| SCHEMA_PRIVILEGES           |
| STATISTICS                  |
| TABLES                     |
| TABLE_CONSTRAINTS          |
| TABLE_PRIVILEGES           |
| TRIGGERS                    |
| USER_PRIVILEGES             |
| VIEWS                        |
+-----+
16 rows in set (0.00 sec)
```

`SHOW COLUMNS` and `DESCRIBE` can display information about the columns in individual `INFORMATION_SCHEMA` tables.

`SHOW` statements that accept a `LIKE` clause to limit the rows displayed have been extended to allow a `WHERE` clause that enables specification of more general conditions that selected rows must satisfy:

```
SHOW CHARACTER SET
SHOW COLLATION
SHOW COLUMNS
SHOW DATABASES
SHOW FUNCTION STATUS
SHOW INDEX
SHOW OPEN TABLES
SHOW PROCEDURE STATUS
SHOW STATUS
SHOW TABLE STATUS
```

```
SHOW TABLES
SHOW VARIABLES
```

The `WHERE` clause, if present, is evaluated against the column names displayed by the `SHOW` statement. For example, the `SHOW CHARACTER SET` statement produces these output columns:

```
mysql> SHOW CHARACTER SET;
+-----+-----+-----+-----+
| Charset | Description | Default collation | Maxlen |
+-----+-----+-----+-----+
| big5    | Big5 Traditional Chinese | big5_chinese_ci | 2 |
| dec8    | DEC West European | dec8_swedish_ci | 1 |
| cp850   | DOS West European | cp850_general_ci | 1 |
| hp8     | HP West European | hp8_english_ci | 1 |
| koi8r   | KOI8-R Relcom Russian | koi8r_general_ci | 1 |
| latin1  | cp1252 West European | latin1_swedish_ci | 1 |
| latin2  | ISO 8859-2 Central European | latin2_general_ci | 1 |
| ...
```

To use a `WHERE` clause with `SHOW CHARACTER SET`, you would refer to those column names. As an example, the following statement displays information about character sets for which the default collation contains the string `'japanese'`:

```
mysql> SHOW CHARACTER SET WHERE `Default collation` LIKE '%japanese%';
+-----+-----+-----+-----+
| Charset | Description | Default collation | Maxlen |
+-----+-----+-----+-----+
| ujis    | EUC-JP Japanese | ujis_japanese_ci | 3 |
| sjis    | Shift-JIS Japanese | sjis_japanese_ci | 2 |
| cp932   | SJIS for Windows Japanese | cp932_japanese_ci | 2 |
| eucjpms | UJIS for Windows Japanese | eucjpms_japanese_ci | 3 |
+-----+-----+-----+-----+
```

This statement displays the multi-byte character sets:

```
mysql> SHOW CHARACTER SET WHERE Maxlen > 1;
+-----+-----+-----+-----+
| Charset | Description | Default collation | Maxlen |
+-----+-----+-----+-----+
| big5    | Big5 Traditional Chinese | big5_chinese_ci | 2 |
| ujis    | EUC-JP Japanese | ujis_japanese_ci | 3 |
| sjis    | Shift-JIS Japanese | sjis_japanese_ci | 2 |
| euckr   | EUC-KR Korean | euckr_korean_ci | 2 |
| gb2312  | GB2312 Simplified Chinese | gb2312_chinese_ci | 2 |
| gbk     | GBK Simplified Chinese | gbk_chinese_ci | 2 |
| utf8    | UTF-8 Unicode | utf8_general_ci | 3 |
| ucs2    | UCS-2 Unicode | ucs2_general_ci | 2 |
| cp932   | SJIS for Windows Japanese | cp932_japanese_ci | 2 |
| eucjpms | UJIS for Windows Japanese | eucjpms_japanese_ci | 3 |
+-----+-----+-----+-----+
```

---

## Chapter 20. Connectors and APIs

MySQL Connectors provide connectivity to the MySQL server for client programs. APIs provide low-level access to the MySQL protocol and MySQL resources. Both Connectors and the APIs enable you to connect and execute MySQL statements from another language or environment, including Java (JDBC), ODBC, Perl, Python, PHP, Ruby, and native C and embedded MySQL instances.

### Note

Connector version numbers do not correlate with MySQL Server version numbers. See also [Table 20.2, “MySQL Connector versions and MySQL Server versions”](#).

A number of connectors are developed by MySQL:

- Connector/ODBC provides driver support for connecting to a MySQL server using the Open Database Connectivity (ODBC) API. Support is available for ODBC connectivity from Windows, Unix and Mac OS X platforms.
- Connector/NET enables developers to create .NET applications that use data stored in a MySQL database. Connector/NET implements a fully-functional ADO.NET interface and provides support for use with ADO.NET aware tools. Applications that want to use Connector/NET can be written in any of the supported .NET languages.

The MySQL Visual Studio Plugin works with Connector/NET and Visual Studio 2005. The plugin is a MySQL DDEX Provider, which means that you can use the schema and data manipulation tools within Visual Studio to create and edit objects within a MySQL database.

- Connector/J provides driver support for connecting to MySQL from a Java application using the standard Java Database Connectivity (JDBC) API.
- Connector/MXJ is a tool that enables easy deployment and management of MySQL server and database through your Java application.
- Connector/C++ is a tool that enables easy deployment and management of MySQL server and database through your C++ application.
- Connector/C is a stand-alone replacement for the MySQL Client Library ([libmysql](#)).
- Connector/OpenOffice.org is a tool that enables OpenOffice.org applications to connect to MySQL server.

There are two direct access methods for using MySQL natively within a C application:

- The C API provides low-level access to the MySQL protocol through the [libmysql](#) client library; this is the primary method used to connect to an instance of the MySQL server, and is used both by MySQL command line clients and many of the APIs also detailed in this section. MySQL Connector/C can now also be used for this purpose.
- [libmysqld](#) is an embedded MySQL server library that enables you to embed an instance of the MySQL server into your C applications.

If you need to access MySQL from a C application, or build an interface to MySQL for a language not supported by the Connectors or APIs in this chapter, the C API is where you would start. A number of programmers utilities are available to help with the process, and also covered in this section.

The remaining APIs provide an interface to MySQL from specific application languages. These solutions are not developed or supported by MySQL. Basic information on their usage and abilities is provided here for reference purposes only.

All the language APIs are developed using one of two methods, using [libmysql](#) or by building a *native driver*. The two solutions offer different benefits:

- Using [libmysql](#) offers complete compatibility with MySQL as it uses the same libraries as the MySQL client applications. However, the feature set is limited to the implementation and interfaces exposed through [libmysql](#) and the performance may be lower as data is copied between the native language, and the MySQL API components. MySQL Connector/C is a possible alternative to using [libmysql](#).
- *Native drivers* are an implementation of the MySQL network protocol entirely within the host language or environment. Native drivers are fast, as there is less copying of data between components, and they can offer advanced functionality not available through the standard MySQL API. Native drivers are also easier to build and deploy, as you do not need a copy of the MySQL client libraries to build the native driver components.

A list of many of the libraries and interfaces available for MySQL are shown in the table. See Table 20.1, “MySQL APIs and Interfaces”.

**Table 20.1. MySQL APIs and Interfaces**

Environment	API	Type	Notes
Ada	MySQL Bindings for GNU Ada	<code>libmysql</code>	See <a href="#">MySQL Bindings for GNU Ada</a>

Scheme	<code>Myscsh</code>	<code>libmysql</code>	See <a href="#">Myscsh</a> .
SPL	<code>sql_mysql</code>	<code>libmysql</code>	See <a href="#">sql_mysql</a> for SPL.
Tcl	MySQLtcl	<code>libmysql</code>	See <a href="#">Section 20.15, “MySQL Tcl API”</a> .

**Table 20.2. MySQL Connector versions and MySQL Server versions**

Connector	Connector version	MySQL Server version
Connector/C++	1.0.5 (Beta)	5.1, 5.4, 6.0

Connector	Connector version	MySQL Server version
Connector/OpenOffice.org	1.0 (Alpha)	5.0, 5.1, 5.4, 6.0
Connector/J	5.1	4.1, 5.0, 5.1, 5.4, 6.0
Connector/NET	1.0	4.0, 5.0
Connector/NET	5.2	4.0, 4.1, 5.0, 5.1, 5.4, 6.0
Connector/NET	5.3	4.1, 5.0, 5.1, 5.4, 6.0
Connector/ODBC	3.51 (Unicode not supported)	4.1, 5.0, 5.1, 5.4, 6.0
Connector/ODBC	5.1	4.1, 5.0, 5.1, 5.4, 6.0

## 20.1. MySQL Connector/ODBC

The MySQL Connector/ODBC is the name for the family of MySQL ODBC drivers (previously called MyODBC drivers) that provide access to a MySQL database using the industry standard Open Database Connectivity (ODBC) API. This reference covers Connector/ODBC 3.51 and Connector/ODBC 5.1. Both releases provide an ODBC compliant interface to MySQL Server.

MySQL Connector/ODBC provides both driver-manager based and native interfaces to the MySQL database, which full support for MySQL functionality, including stored procedures, transactions and, with Connector/ODBC 5.1, full Unicode compliance.

For more information on the ODBC API standard and how to use it, refer to <http://support.microsoft.com/kb/110093>.

The application development part of this reference assumes a good working knowledge of C, general DBMS knowledge, and finally, but not least, familiarity with MySQL. For more information about MySQL functionality and its syntax, refer to <http://dev.mysql.com/doc/>.

Typically, you need to install Connector/ODBC only on Windows machines. For Unix and Mac OS X you can use the native MySQL network or named pipe to communicate with your MySQL database. You may need Connector/ODBC for Unix or Mac OS X if you have an application that requires an ODBC interface to communicate with the database. Applications that require ODBC to communicate with MySQL include ColdFusion, Microsoft Office, and Filemaker Pro.

### Key topics:

- For help installing Connector/ODBC see [Section 20.1.3, “Connector/ODBC Installation”](#).
- For information on the configuration options, see [Section 20.1.4.2, “Connector/ODBC Connection Parameters”](#).
- For more information on connecting to a MySQL database from a Windows host using Connector/ODBC see [Section 20.1.5.2, “Step-by-step Guide to Connecting to a MySQL Database through Connector/ODBC”](#).
- If you want to use Microsoft Access as an interface to a MySQL database using Connector/ODBC see [Section 20.1.5.4, “Using Connector/ODBC with Microsoft Access”](#).
- General tips on using Connector/ODBC, including obtaining the last auto-increment ID see [Section 20.1.7.1, “Connector/ODBC General Functionality”](#).
- For tips and common questions on using Connector/ODBC with specific application see [Section 20.1.7.2, “Connector/ODBC Application Specific Tips”](#).
- For a general list of Frequently Asked Questions see [Section 20.1.7.3, “Connector/ODBC Errors and Resolutions \(FAQ\)”](#).
- Additional support when using Connector/ODBC is available, see [Section 20.1.8, “Connector/ODBC Support”](#).

### MySQL Enterprise

MySQL Enterprise subscribers will find more information about MySQL and ODBC in the Knowledge Base articles about [ODBC](#). Access to the MySQL Knowledge Base collection of articles is one of the advantages of subscribing to MySQL Enterprise. For more information, see <http://www.mysql.com/products/enterprise/advisors.html>.

### 20.1.1. Connector/ODBC Versions

There are currently two version of Connector/ODBC available:

- Connector/ODBC 5.1, currently in GA status, is a partial rewrite of the of the 3.51 code base and is designed to work with all versions of MySQL from 4.1. Connector/ODBC 5.1 will be a complete implementation of the ODBC Core interface, plus more

Level 1 and Level 2 functionality of the ODBC specification than that currently supported by Connector/ODBC 3.51. See [Section 20.1.2.1, “Connector/ODBC Roadmap”](#).

Connector/ODBC 5.1 also includes the following changes and improvements over the 3.51 release:

- Improved support on Windows 64-bit platforms.
- Full Unicode support at the driver level. This includes support for the `SQL_WCHAR` datatype, and support for Unicode login, password and DSN configurations. For more information, see [Microsoft Knowledgebase Article #716246](#).
- Support for the `SQL_NUMERIC_STRUCT` datatype, which provides easier access to the precise definition of numeric values. For more information, see [Microsoft Knowledgebase Article #714556](#)
- Native Windows setup library. This replaces the Qt library based interface for configuring DSN information within the ODBC Data Sources application.
- Support for the ODBC descriptor, which improves the handling and metadata of columns and parameter data. For more information, see [Microsoft Knowledgebase Article #716339](#).
- Connector/ODBC 3.51 is the current release of the 32-bit ODBC driver, also known as the MySQL ODBC 3.51 driver. Connector/ODBC 3.51 has support for ODBC 3.5x specification level 1 (complete core API + level 2 features) in order to continue to provide all functionality of ODBC for accessing MySQL.

The manual for versions of Connector/ODBC older than 3.51 can be located in the corresponding binary or source distribution. Please note that versions of Connector/ODBC earlier than the 3.51 revision were not fully compliant with the ODBC specification.

#### Note

Development on Connector/ODBC 5.0 was stopped due to development issues. Connector/ODBC 5.1 is now the current development release.

#### Note

From this section onward, the primary focus of this guide is the Connector/ODBC 3.51 and Connector/ODBC 5.1 drivers.

#### Note

Version numbers for MySQL products are formatted as X.X.X. However, Windows tools (Control Panel, properties display) may show the version numbers as XX.XX.XX. For example, the official MySQL formatted version number 5.0.9 may be displayed by Windows tools as 5.00.09. The two versions are the same; only the number display format is different.

## 20.1.2. Connector/ODBC Introduction

ODBC (Open Database Connectivity) provides a way for client programs to access a wide range of databases or data sources. ODBC is a standardized API that allows connections to SQL database servers. It was developed according to the specifications of the SQL Access Group and defines a set of function calls, error codes, and data types that can be used to develop database-independent applications. ODBC usually is used when database independence or simultaneous access to different data sources is required.

For more information about ODBC, refer to <http://support.microsoft.com/kb/110093>.

### 20.1.2.1. Connector/ODBC Roadmap

Connector/ODBC 5.1 is currently in development and will be a complete implementation of the ODBC Core interface, plus more Level 1 and Level 2 functionality of the ODBC specification than that currently supported by Connector/ODBC 3.51.

The following functionality was added or changed as part of 5.1:

- Add support for `SQL_NUMERIC_STRUCT`: [MSDN Article 714556](#).
- Replace installer library with new implementation (from v5 tree).
- Implement native Windows setup library.
- Implement `SQLCancel()` ([Bug#15601](#)): [MSDN Article 714112](#).

The following functionality will be added in a version after 5.1:

- Implement native Mac OS X setup library.
- Replace OPTIONS flags with individual DSN settings (but support OPTIONS for backwards-compatibility).
- Fix support for SQLBIGINT ([Bug#28887](#)): [MSDN Article 714121](#).
- Make diagnostics support standards-compliant: [MSDN Article 711021](#).
- Add support for SQL\_ATTR\_METADATA\_ID: [MSDN Article 716447](#).
- Implement SQLBrowseConnect(): [MSDN Article 714565](#), [MSDN Article 712446](#).
- Implement arrays of parameters: [MSDN Article 711818](#).

### **20.1.2.2. General Information About ODBC and Connector/ODBC**

Open Database Connectivity (ODBC) is a widely accepted application-programming interface (API) for database access. It is based on the Call-Level Interface (CLI) specifications from X/Open and ISO/IEC for database APIs and uses Structured Query Language (SQL) as its database access language.

A survey of ODBC functions supported by Connector/ODBC is given at [Section 20.1.6.1, "Connector/ODBC API Reference"](#). For general information about ODBC, see <http://support.microsoft.com/kb/110093>.

#### **20.1.2.2.1. Connector/ODBC Architecture**

The Connector/ODBC architecture is based on five components, as shown in the following diagram:

- **Application:**

The Application uses the ODBC API to access the data from the MySQL server. The ODBC API in turn uses the communicates with the Driver Manager. The Application communicates with the Driver Manager using the standard ODBC calls. The Application does not care where the data is stored, how it is stored, or even how the system is configured to access the data. It needs to know only the Data Source Name (DSN).

A number of tasks are common to all applications, no matter how they use ODBC. These tasks are:

- Selecting the MySQL server and connecting to it
- Submitting SQL statements for execution
- Retrieving results (if any)
- Processing errors
- Committing or rolling back the transaction enclosing the SQL statement
- Disconnecting from the MySQL server

Because most data access work is done with SQL, the primary tasks for applications that use ODBC are submitting SQL statements and retrieving any results generated by those statements.

- **Driver manager:**

The Driver Manager is a library that manages communication between application and driver or drivers. It performs the following tasks:

- Resolves Data Source Names (DSN). The DSN is a configuration string that identifies a given database driver, database, database host and optionally authentication information that enables an ODBC application to connect to a database using a standardized reference.

Because the database connectivity information is identified by the DSN, any ODBC compliant application can connect to the data source using the same DSN reference. This eliminates the need to separately configure each application that needs access to a given database; instead you instruct the application to use a pre-configured DSN.

- Loading and unloading of the driver required to access a specific database as defined within the DSN. For example, if you have configured a DSN that connects to a MySQL database then the driver manager will load the Connector/ODBC driver to enable the ODBC API to communicate with the MySQL host.
- Processes ODBC function calls or passes them to the driver for processing.

- **Connector/ODBC Driver:**

The Connector/ODBC driver is a library that implements the functions supported by the ODBC API. It processes ODBC function calls, submits SQL requests to MySQL server, and returns results back to the application. If necessary, the driver modifies an application's request so that the request conforms to syntax supported by MySQL.

- **DSN Configuration:**

The ODBC configuration file stores the driver and database information required to connect to the server. It is used by the Driver Manager to determine which driver to be loaded according to the definition in the DSN. The driver uses this to read connection parameters based on the DSN specified. For more information, [Section 20.1.4, “Connector/ODBC Configuration”](#).

- **MySQL Server:**

The MySQL database where the information is stored. The database is used as the source of the data (during queries) and the destination for data (during inserts and updates).

### 20.1.2.2.2. ODBC Driver Managers

An ODBC Driver Manager is a library that manages communication between the ODBC-aware application and any drivers. Its main functionality includes:

- Resolving Data Source Names (DSN).
- Driver loading and unloading.
- Processing ODBC function calls or passing them to the driver.

Both Windows and Mac OS X include ODBC driver managers with the operating system. Most ODBC Driver Manager implementations also include an administration application that makes the configuration of DSN and drivers easier. Examples and information on these managers, including Unix ODBC driver managers are listed below:

- Microsoft Windows ODBC Driver Manager (`odbc32.dll`), <http://support.microsoft.com/kb/110093>.
- Mac OS X includes [ODBC Administrator](#), a GUI application that provides a simpler configuration mechanism for the Unix iODBC Driver Manager. You can configure DSN and driver information either through ODBC Administrator or through the iODBC configuration files. This also means that you can test ODBC Administrator configurations using the `iodbctest` command. <http://www.apple.com>.
- [unixODBC Driver Manager for Unix](#) (`libodbc.so`). See <http://www.unixodbc.org>, for more information. The [unixODBC Driver Manager](#) includes the Connector/ODBC driver 3.51 in the installation package, starting with version [unixODBC 2.1.2](#).
- [iODBC ODBC Driver Manager for Unix](#) (`libiodbc.so`), see <http://www.iodbc.org>, for more information.

## 20.1.3. Connector/ODBC Installation

You can install the Connector/ODBC drivers using two different methods, a binary installation and a source installation. The binary

installation is the easiest and most straightforward method of installation. Using the source installation methods should only be necessary on platforms where a binary installation package is not available, or in situations where you want to customize or modify the installation process or Connector/ODBC drivers before installation.

### Where to Get Connector/ODBC

Sun Microsystems, Inc distributes its MySQL products under the General Public License (GPL). You can get a copy of the latest version of Connector/ODBC binaries and sources from our Web site at <http://dev.mysql.com/downloads/>.

For more information about Connector/ODBC, visit <http://www.mysql.com/products/myodbc/>.

For more information about licensing, visit <http://www.mysql.com/company/legal/licensing/>.

### Supported Platforms

Connector/ODBC can be used on all major platforms supported by MySQL. You can install it on:

- Windows 95, 98, Me, NT, 2000, XP, and 2003
- All Unix-like Operating Systems, including: AIX, Amiga, BSDI, DEC, FreeBSD, HP-UX 10/11, Linux, NetBSD, OpenBSD, OS/2, SGI Irix, Solaris, SunOS, SCO OpenServer, SCO UnixWare, Tru64 Unix
- Mac OS X and Mac OS X Server

Using a binary distribution offers the most straightforward method for installing Connector/ODBC. If you want more control over the driver, the installation location and or to customize elements of the driver you will need to build and install from the source.

If a binary distribution is not available for a particular platform build the driver from the original source code. You can contribute the binaries you create to MySQL by sending a mail message to [<myodbc@lists.mysql.com>](mailto:myodbc@lists.mysql.com), so that it becomes available for other users.

#### Note

On all non-Windows platforms except Mac OS X, the driver is built against `unixODBC` and is expecting a 2-byte `SQLWCHAR`, not 4 bytes as `iODBC` is using. For this reason, the binaries are **only** compatible with `unixODBC` and you will need to recompile the driver against `iODBC` if you wish to use them together. For further information see [Section 20.1.2.2.2, “ODBC Driver Managers”](#).

For further instructions:

Platform	Binary	Source
Windows	<a href="#">Installation Instructions</a>	<a href="#">Build Instructions</a>
Unix/Linux	<a href="#">Installation Instructions</a>	<a href="#">Build Instructions</a>
Mac OS X	<a href="#">Installation Instructions</a>	

### 20.1.3.1. Installing Connector/ODBC from a Binary Distribution on Windows

Before installing the Connector/ODBC drivers on Windows you should ensure that your Microsoft Data Access Components (MDAC) are up to date. You can obtain the latest version from the [Microsoft Data Access and Storage Web site](#).

There are three available distribution types to use when installing for Windows. The contents in each case are identical, it is only the installation method which is different.

- Zipped installer consists of a Zipped package containing a standalone installation application. To install from this package, you must unzip the installer, and then run the installation application. See [Section 20.1.3.1.1, “Installing the Windows Connector/ODBC Driver using an installer”](#) to complete the installation.
- MSI installer, an installation file that can be used with the installer included in Windows 2000, Windows XP and Windows Server 2003. See [Section 20.1.3.1.1, “Installing the Windows Connector/ODBC Driver using an installer”](#) to complete the installation.
- Zipped DLL package, containing the DLL files that need must be manually installed. See [Section 20.1.3.1.2, “Installing the Windows Connector/ODBC Driver using the Zipped DLL package”](#) to complete the installation.

**Note**

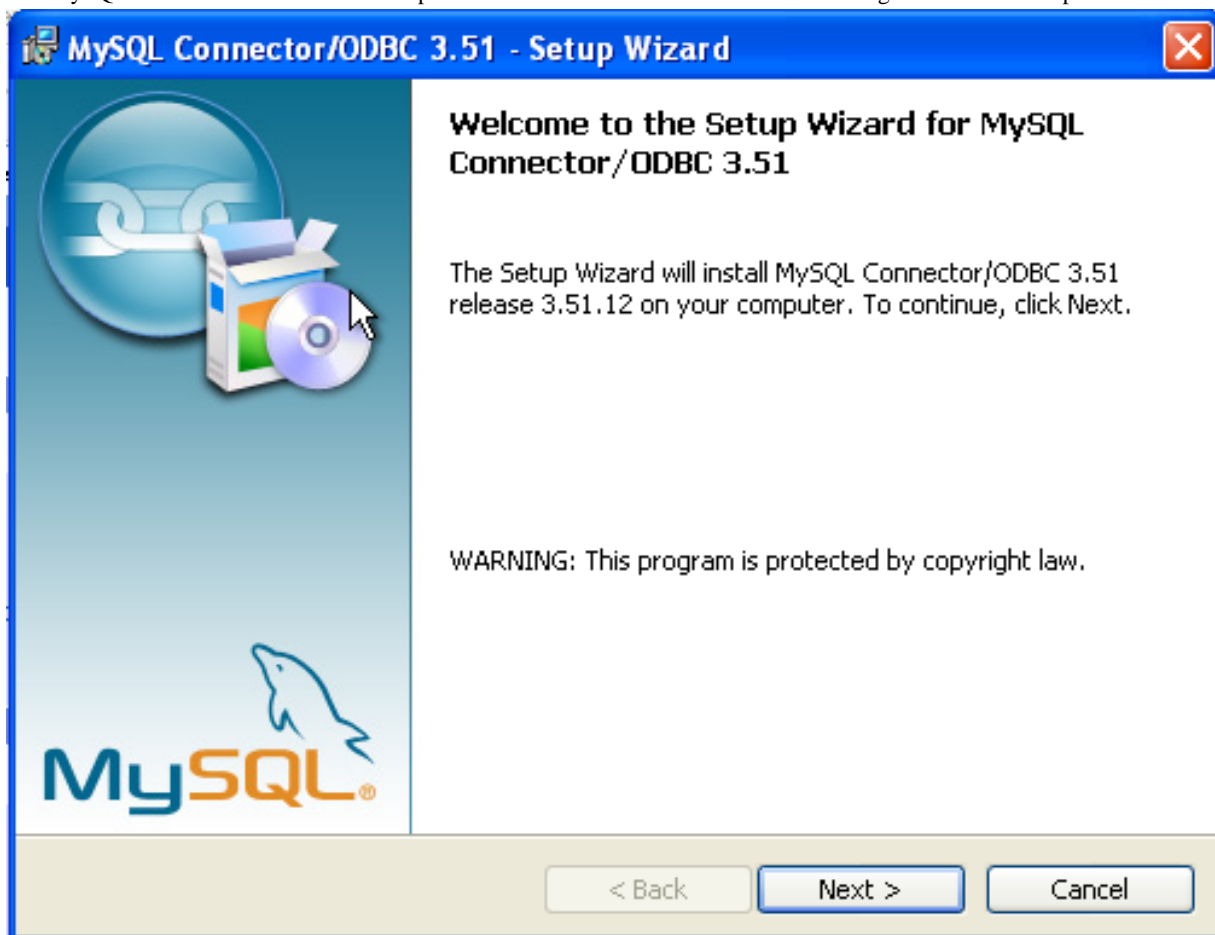

An OLEDB/ODBC driver for Windows 64-bit is available from [Microsoft Downloads](#).

**20.1.3.1.1. Installing the Windows Connector/ODBC Driver using an installer**

The installer packages offer a very simple method for installing the Connector/ODBC drivers. If you have downloaded the zipped installer then you must extract the installer application. The basic installation process is identical for both installers.

You should follow these steps to complete the installation:

1. Double click on the standalone installer that you extracted, or the MSI file you downloaded.
2. The MySQL Connector/ODBC 3.51 - Setup Wizard will start. Click the NEXT button to begin the installation process.

3. You will need to choose the installation type. The Typical installation provides the standard files you will need to connect to a MySQL database using ODBC. The Complete option installs all the available files, including debug and utility components. It is recommended you choose one of these two options to complete the installation. If choose one of these methods, click NEXT and then proceed to step 5.

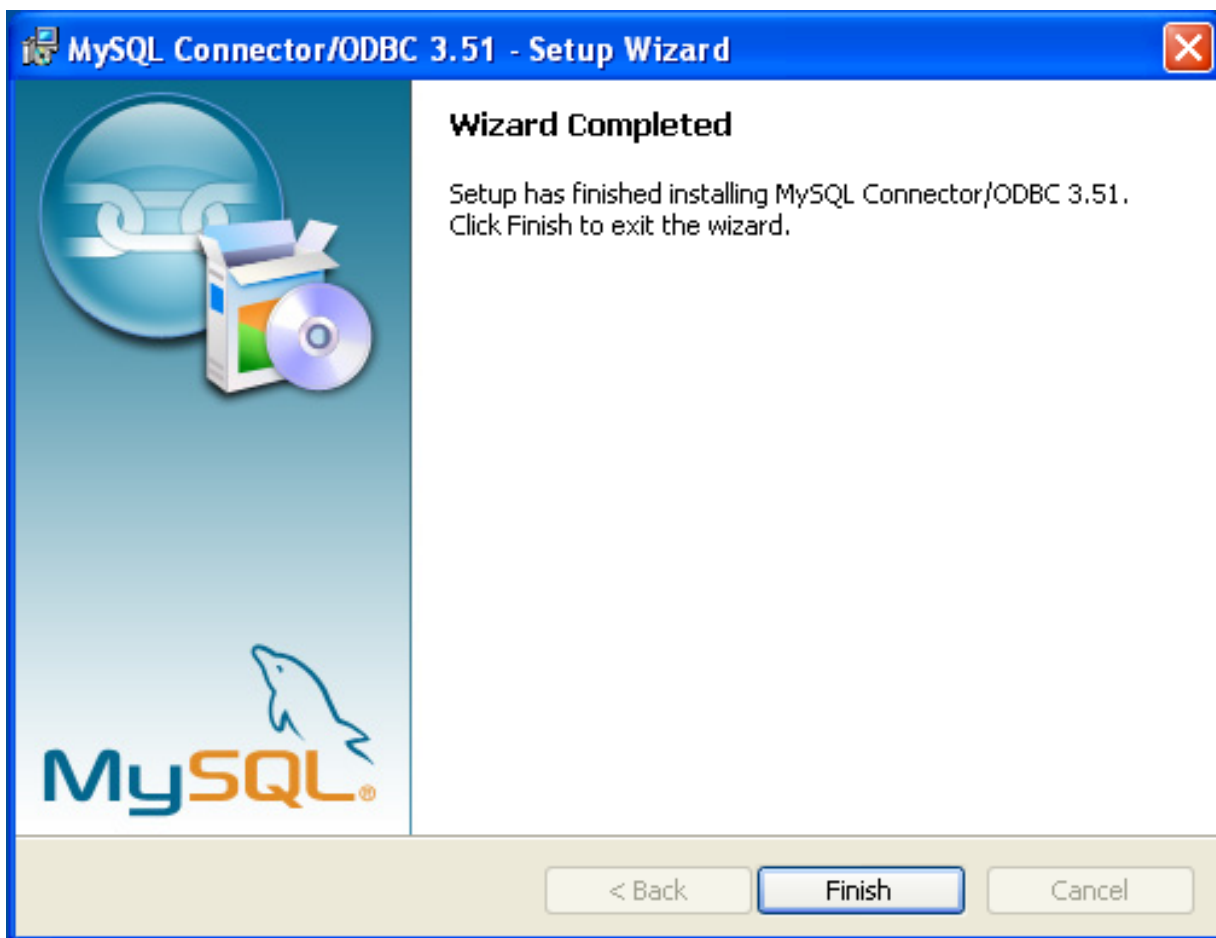

You may also choose a Custom installation, which enables you to select the individual components that you want to install. You have chosen this method, click NEXT and then proceed to step 4.

4. If you have chosen a custom installation, use the pop-ups to select which components to install and then click NEXT to install the necessary files.

5. Once the files have copied to your machine, the installation is complete. Click FINISH to exit the installer.

Now the installation is complete, you can continue to configure your ODBC connections using [Section 20.1.4, “Connector/ODBC Configuration”](#).

#### 20.1.3.1.2. Installing the Windows Connector/ODBC Driver using the Zipped DLL package

If you have downloaded the Zipped DLL package then you must install the individual files required for Connector/ODBC operation manually. Once you have unzipped the installation files, you can either perform this operation by hand, executing each statement individually, or you can use the included Batch file to perform an installation to the default locations.

To install using the Batch file:

1. Unzip the Connector/ODBC Zipped DLL package.
2. Open a Command Prompt.
3. Change to the directory created when you unzipped the Connector/ODBC Zipped DLL package.
4. Run `Install.bat`:

```
c:\> Install.bat
```

This will copy the necessary files into the default location, and then register the Connector/ODBC driver with the Windows ODBC manager.

If you want to copy the files to an alternative location - for example, to run or test different versions of the Connector/ODBC driver on the same machine, then you must copy the files by hand. It is however not recommended to install these files in a non-standard location. To copy the files by hand to the default installation location use the following steps:

1. Unzip the Connector/ODBC Zipped DLL package.

2. Open a Command Prompt.
3. Change to the directory created when you unzipped the Connector/ODBC Zipped DLL package.
4. Copy the library files to a suitable directory. The default is to copy them into the default Windows system directory `\Windows\System32`:

```
C:\> copy lib\myodbc3S.dll \Windows\System32
C:\> copy lib\myodbc3S.lib \Windows\System32
C:\> copy lib\myodbc3.dll \Windows\System32
C:\> copy lib\myodbc3.lib \Windows\System32
```

5. Copy the Connector/ODBC tools. These must be placed into a directory that is in the system `PATH`. The default is to install these into the Windows system directory `\Windows\System32`:

```
C:\> copy bin\myodbc3i.exe \Windows\System32
C:\> copy bin\myodbc3m.exe \Windows\System32
C:\> copy bin\myodbc3c.exe \Windows\System32
```

6. Optionally copy the help files. For these files to be accessible through the help system, they must be installed in the Windows system directory:

```
C:\> copy doc\*.hlp \Windows\System32
```

7. Finally, you must register the Connector/ODBC driver with the ODBC manager:

```
C:\> myodbc3i -a -d -t"MySQL ODBC 3.51 Driver;\
DRIVER=myodbc3.dll;SETUP=myodbc3S.dll"
```

You must change the references to the DLL files and command location in the above statement if you have not installed these files into the default location.

### 20.1.3.2. Installing Connector/ODBC from a Binary Distribution on Unix

There are two methods available for installing Connector/ODBC on Unix from a binary distribution. For most Unix environments you will need to use the tarball distribution. For Linux systems, there is also an RPM distribution available.

#### Note

To install Connector/ODBC 5.1 on Unix you require unixODBC 2.2.12 or later to be installed.

#### 20.1.3.2.1. Installing Connector/ODBC from a Binary Tarball Distribution

To install the driver from a tarball distribution (`.tar.gz` file), download the latest version of the driver for your operating system and follow these steps that demonstrate the process using the Linux version of the tarball:

```
shell> su root
shell> gunzip mysql-connector-odbc-3.51.11-i686-pc-linux.tar.gz
shell> tar xvf mysql-connector-odbc-3.51.11-i686-pc-linux.tar
shell> cd mysql-connector-odbc-3.51.11-i686-pc-linux
```

Read the installation instructions in the `INSTALL` file and execute these commands.

Then proceed on to [Section 20.1.4.5, “Configuring a Connector/ODBC DSN on Unix”](#), to configure the DSN for Connector/ODBC. For more information, refer to the `INSTALL` file that comes with your distribution.

#### 20.1.3.2.2. Installing Connector/ODBC from an RPM Distribution

To install or upgrade Connector/ODBC from an RPM distribution on Linux, simply download the RPM distribution of the latest version of Connector/ODBC and follow the instructions below. Use `su root` to become `root`, then install the RPM file.

If you are installing for the first time:

```
shell> su root
shell> rpm -ivh mysql-connector-odbc-3.51.12.i386.rpm
```

If the driver exists, upgrade it like this:

```
shell> su root
shell> rpm -Uvh mysql-connector-odbc-3.51.12.i386.rpm
```

If there is any dependency error for MySQL client library, `libmysqlclient`, simply ignore it by supplying the `--nodeps` option, and then make sure the MySQL client shared library is in the path or set through `LD_LIBRARY_PATH`.

This installs the driver libraries and related documents to `/usr/local/lib` and `/usr/share/doc/MyODBC`, respectively. Proceed onto [Section 20.1.4.5, “Configuring a Connector/ODBC DSN on Unix”](#).

To **uninstall** the driver, become `root` and execute an `rpm` command:

```
shell> su root
shell> rpm -e mysql-connector-odbc
```

### 20.1.3.3. Installing Connector/ODBC from a Binary Distribution on Mac OS X

Mac OS X is based on the FreeBSD operating system, and you can normally use the MySQL network port for connecting to MySQL servers on other hosts. Installing the Connector/ODBC driver enables you to connect to MySQL databases on any platform through the ODBC interface. You should only need to install the Connector/ODBC driver when your application requires an ODBC interface. Applications that require or can use ODBC (and therefore the Connector/ODBC driver) include ColdFusion, Filemaker Pro, 4th Dimension and many other applications.

Mac OS X includes its own ODBC manager, based on the `iODBC` manager. Mac OS X includes an administration tool that provides easier administration of ODBC drivers and configuration, updating the underlying `iODBC` configuration files.

The method for installing Connector/ODBC on Mac OS X depends on the version on Connector/ODBC you are using. For Connector/ODBC 3.51.14 and later, the package is provided as a compressed tar archive that you must manually install. For Connector/ODBC 3.51.13 and earlier the software was provided on a compressed disk image (`.dmg`) file and included an installer.

In either case, the driver is designed to work with the `iODBC` driver manager included with Mac OS X.

To install Connector/ODBC 3.51.14 and later:

1. Download the installation file. Note that versions are available for both PowerPC and Intel platforms.
2. Extract the archive:

```
shell> tar zxf mysql-connector-odbc-3.51.16-osx10.4-x86-32bit.tar.gz
```

3. The directory created will contain two subdirectories, `lib` and `bin`. You need to copy these to a suitable location such as `/usr/local`:

```
shell> cp bin/* /usr/local/bin
shell> cp lib/* /usr/local/lib
```

4. Finally, you must register the driver with `iODBC` using the `myodbc3i` tool you just installed:

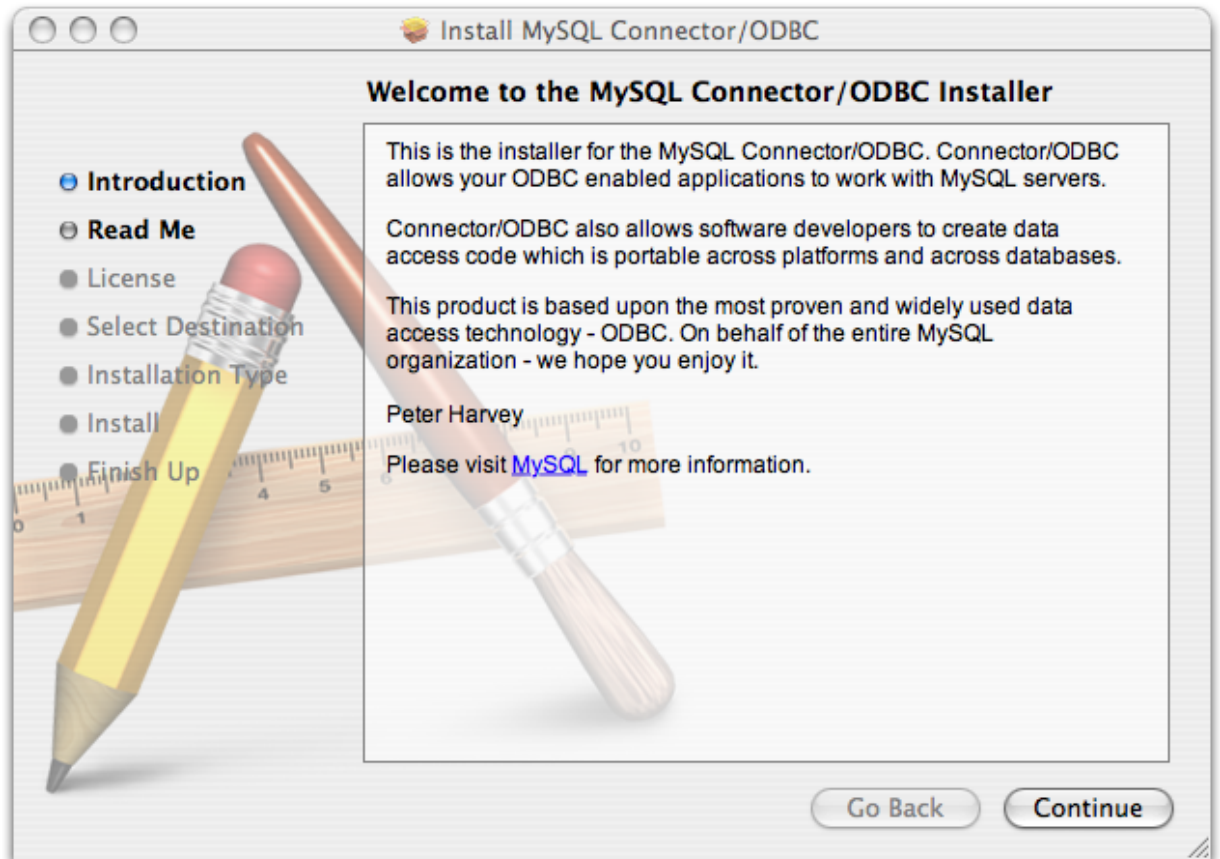

```
shell> myodbc3i -a -d -t"MySQL ODBC 3.51 Driver;Driver=/usr/local/lib/libmyodbc3.so;Setup=/usr/local/lib/libmyodbc3i"
```

You can verify the installed drivers either by using the ODBC Administrator application or the `myodbc3i` utility:

```
shell> myodbc3i -q -d
```

To install Connector/ODBC 3.51.13 and earlier, follow these steps:

1. Download the file to your computer and double-click on the downloaded image file.
2. Within the disk image you will find an installer package (with the `.pkg` extension). Double click on this file to start the Mac OS X installer.
3. You will be presented with the installer welcome message. Click the `CONTINUE` button to begin the installation process.

4. Please take the time to read the Important Information as it contains guidance on how to complete the installation process. Once you have read the notice and collected the necessary information, click CONTINUE.

- Connector/ODBC drivers are made available under the GNU General Public License. Please read the license if you are not familiar with it before continuing installation. Click CONTINUE to approve the license (you will be asked to confirm that decision) and continue the installation.

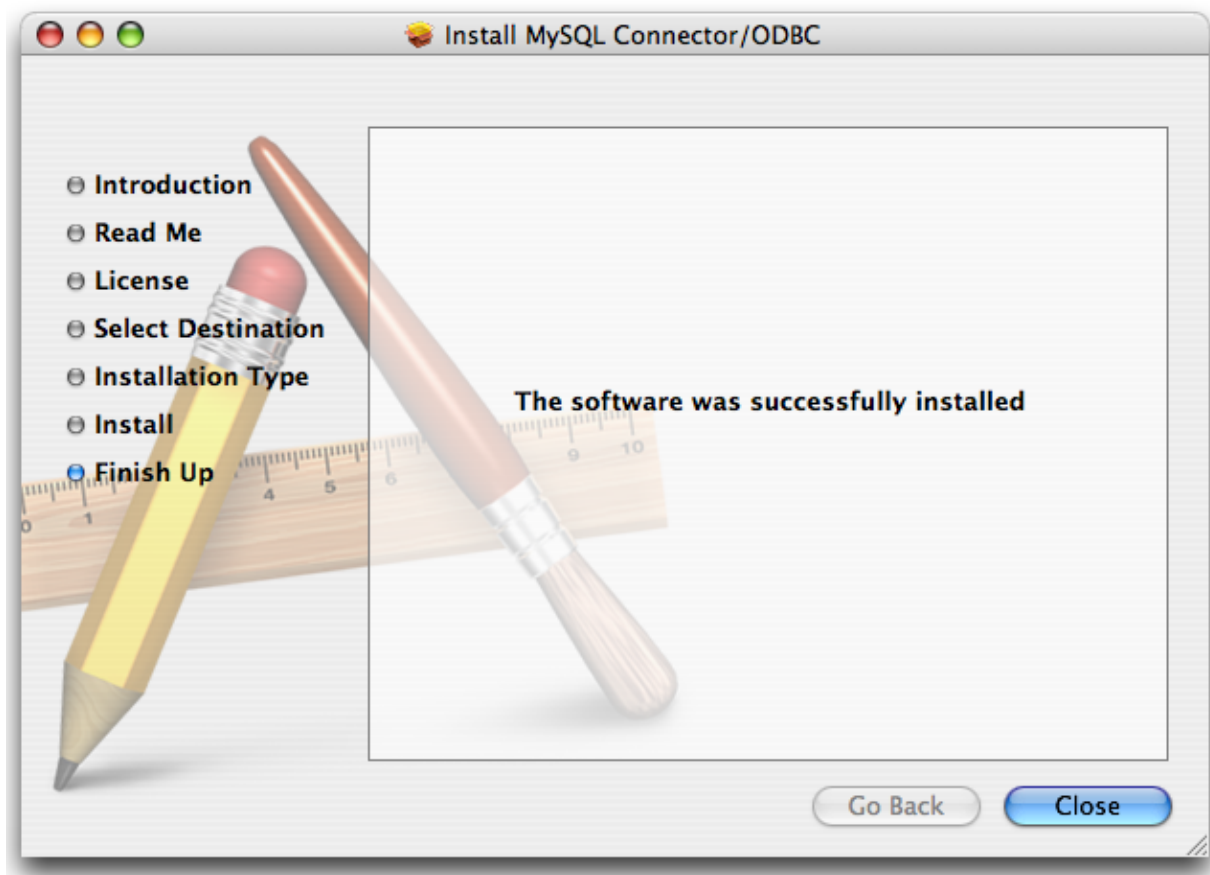

- Choose a location to install the Connector/ODBC drivers and the ODBC Administrator application. You must install the files onto a drive with an operating system and you may be limited in the choices available. Select the drive you want to use, and then click CONTINUE.

7. The installer will automatically select the files that need to be installed on your machine. Click **INSTALL** to continue. The installer will copy the necessary files to your machine. A progress bar will be shown indicating the installation progress.

8. When installation has been completed you will get a window like the one shown below. Click CLOSE to close and quit the installer.

#### 20.1.3.4. Installing Connector/ODBC from a Source Distribution on Windows

You should only need to install Connector/ODBC from source on Windows if you want to change or modify the source or installation. If you are unsure whether to install from source, please use the binary installation detailed in [Section 20.1.3.1, “Installing Connector/ODBC from a Binary Distribution on Windows”](#).

Installing Connector/ODBC from source on Windows requires a number of different tools and packages:

- MDAC, Microsoft Data Access SDK from <http://support.microsoft.com/kb/110093>.
- Suitable C compiler, such as Microsoft Visual C++ or the C compiler included with Microsoft Visual Studio.
- Compatible `make` tool. Microsoft's `nmake` is used in the examples in this section.
- MySQL client libraries and include files from MySQL 4.0.0 or higher. (Preferably MySQL 4.0.16 or higher). This is required because Connector/ODBC uses new calls and structures that exist only starting from this version of the library. To get the client libraries and include files, visit <http://dev.mysql.com/downloads/>.

##### 20.1.3.4.1. Building Connector/ODBC 3.51

Connector/ODBC source distributions include `Makefiles` that require the `nmake` or other `make` utility. In the distribution, you can find `Makefile` for building the release version and `Makefile_debug` for building debugging versions of the driver libraries and DLLs.

To build the driver, use this procedure:

1. Download and extract the sources to a folder, then change directory into that folder. The following command assumes the folder is named `myodbc3-src`:

```
C:\> cd myodbc3-src
```

2. Edit `Makefile` to specify the correct path for the MySQL client libraries and header files. Then use the following commands to build and install the release version:

```
C:\> nmake -f Makefile
C:\> nmake -f Makefile install
```

`nmake -f Makefile` builds the release version of the driver and places the binaries in subdirectory called `Release`.

`nmake -f Makefile install` installs (copies) the driver DLLs and libraries (`myodbc3.dll`, `myodbc3.lib`) to your system directory.

3. To build the debug version, use `Makefile_Debug` rather than `Makefile`, as shown below:

```
C:\> nmake -f Makefile_debug
C:\> nmake -f Makefile_debug install
```

4. You can clean and rebuild the driver by using:

```
C:\> nmake -f Makefile clean
C:\> nmake -f Makefile install
```

### Note

- Make sure to specify the correct MySQL client libraries and header files path in the Makefiles (set the `MYSQL_LIB_PATH` and `MYSQL_INCLUDE_PATH` variables). The default header file path is assumed to be `C:\mysql\include`. The default library path is assumed to be `C:\mysql\lib\opt` for release DLLs and `C:\mysql\lib\debug` for debug versions.
- For the complete usage of `nmake`, visit [http://msdn.microsoft.com/library/default.asp?url=/library/en-us/dv\\_vcce4/html/evgrfRunningNMAKE.asp](http://msdn.microsoft.com/library/default.asp?url=/library/en-us/dv_vcce4/html/evgrfRunningNMAKE.asp).
- If you are using the Subversion tree for compiling, all Windows-specific `Makefiles` are named as `Win_Makefile*`.

### 20.1.3.4.2. Testing

After the driver libraries are copied/installed to the system directory, you can test whether the libraries are properly built by using the samples provided in the `samples` subdirectory:

```
C:\> cd samples
C:\> nmake -f Makefile all
```

### 20.1.3.5. Installing Connector/ODBC from a Source Distribution on Unix

You need the following tools to build MySQL from source on Unix:

- A working ANSI C++ compiler. `gcc` 2.95.2 or later, SGI C++, and SunPro C++ are some of the compilers that are known to work.
- A good `make` program. GNU `make` is always recommended and is sometimes required.
- MySQL client libraries and include files from MySQL 4.0.0 or higher. (Preferably MySQL 4.0.16 or higher). This is required because Connector/ODBC uses new calls and structures that exist only starting from this version of the library. To get the client libraries and include files, visit <http://dev.mysql.com/downloads/>.

If you have built your own MySQL server and/or client libraries from source then you must have used the `-enable-thread-safe-client` option to `configure` when the libraries were built.

You should also ensure that the `libmysqlclient` library were built and installed as a shared library.

- A compatible ODBC manager must be installed. Connector/ODBC is known to work with the `iODBC` and `unixODBC` managers. See [Section 20.1.2.2.2, “ODBC Driver Managers”](#), for more information.
- If you are using a character set that isn't compiled into the MySQL client library then you need to install the MySQL character

definitions from the `charsets` directory into `SHAREDIR` (by default, `/usr/local/mysql/share/mysql/charsets`). These should be in place if you have installed the MySQL server on the same machine. See [Section 9.1, “Character Set Support”](#), for more information on character set support.

Once you have all the required files, unpack the source files to a separate directory, you then have to run `configure` and build the library using `make`.

### 20.1.3.5.1. Typical `configure` Options

The `configure` script gives you a great deal of control over how you configure your Connector/ODBC build. Typically you do this using options on the `configure` command line. You can also affect `configure` using certain environment variables. For a list of options and environment variables supported by `configure`, run this command:

```
shell> ./configure --help
```

Some of the more commonly used `configure` options are described here:

1. To compile Connector/ODBC, you need to supply the MySQL client include and library files path using the `--with-mysql-path=DIR` option, where `DIR` is the directory where MySQL is installed.

MySQL compile options can be determined by running `DIR/bin/mysql_config`.

2. Supply the standard header and library files path for your ODBC Driver Manager (`iODBC` or `unixODBC`).

- If you are using `iODBC` and `iODBC` is not installed in its default location (`/usr/local`), you might have to use the `--with-iodbc=DIR` option, where `DIR` is the directory where `iODBC` is installed.

If the `iODBC` headers do not reside in `DIR/include`, you can use the `--with-iodbc-includes=INCDIR` option to specify their location.

The applies to libraries. If they are not in `DIR/lib`, you can use the `--with-iodbc-libs=LIBDIR` option.

- If you are using `unixODBC`, use the `--with-unixODBC=DIR` option (case sensitive) to make `configure` look for `unixODBC` instead of `iODBC` by default, `DIR` is the directory where `unixODBC` is installed.

If the `unixODBC` headers and libraries aren't located in `DIR/include` and `DIR/lib`, use the `--with-unixODBC-includes=INCDIR` and `--with-unixODBC-libs=LIBDIR` options.

3. You might want to specify an installation prefix other than `/usr/local`. For example, to install the Connector/ODBC drivers in `/usr/local/odbc/lib`, use the `--prefix=/usr/local/odbc` option.

The final configuration command looks something like this:

```
shell> ./configure --prefix=/usr/local \
  --with-iodbc=/usr/local \
  --with-mysql-path=/usr/local/mysql
```

### 20.1.3.5.2. Additional `configure` Options

There are a number of other options that you need, or want, to set when configuring the Connector/ODBC driver before it is built.

- To link the driver with MySQL thread safe client libraries `libmysqlclient_r.so` or `libmysqlclient_r.a`, you must specify the following `configure` option:

```
--enable-thread-safe
```

and can be disabled (default) using

```
--disable-thread-safe
```

This option enables the building of the driver thread-safe library `libmyodbc3_r.so` from by linking with MySQL thread-safe client library `libmysqlclient_r.so` (The extensions are OS dependent).

If the compilation with the thread-safe option fails, it may be because the correct thread-libraries on the system could not be located. You should set the value of `LIBS` to point to the correct thread library for your system.

```
LIBS="-lpthread" ./configure ..
```

- You can enable or disable the shared and static versions of Connector/ODBC using these options:

```
--enable-shared[=yes/no]
--disable-shared
--enable-static[=yes/no]
--disable-static
```

- By default, all the binary distributions are built as non-debugging versions (configured with `--without-debug`).

To enable debugging information, build the driver from source distribution and use the `--with-debug` option when you run `configure`.

- This option is available only for source trees that have been obtained from the Subversion repository. This option does not apply to the packaged source distributions.

By default, the driver is built with the `--without-docs` option. If you would like the documentation to be built, then execute `configure` with:

```
--with-docs
```

### 20.1.3.5.3. Building and Compilation

To build the driver libraries, you have to just execute `make`.

```
shell> make
```

If any errors occur, correct them and continue the build process. If you aren't able to build, then send a detailed email to [myodbc@lists.mysql.com](mailto:myodbc@lists.mysql.com) for further assistance.

### 20.1.3.5.4. Building Shared Libraries

On most platforms, MySQL does not build or support `.so` (shared) client libraries by default. This is based on our experience of problems when building shared libraries.

In cases like this, you have to download the MySQL distribution and configure it with these options:

```
--without-server --enable-shared
```

To build shared driver libraries, you must specify the `--enable-shared` option for `configure`. By default, `configure` does not enable this option.

If you have configured with the `--disable-shared` option, you can build the `.so` file from the static libraries using the following commands:

```
shell> cd mysql-connector-odbc-3.51.01
shell> make
shell> cd driver
shell> CC=/usr/bin/gcc \
    $CC -bundle -flat_namespace -undefined error \
    -o .libs/libmyodbc3-3.51.01.so \
    catalog.o connect.o cursor.o dll.o error.o execute.o \
    handle.o info.o misc.o myodbc3.o options.o prepare.o \
    results.o transact.o utility.o \
    -L/usr/local/mysql/lib/mysql/ \
    -L/usr/local/iodbc/lib/ \
    -lz -lc -lmysqlclient -liodbcinst
```

Make sure to change `-liodbcinst` to `-lodbcinst` if you are using `unixODBC` instead of `iODBC`, and configure the library paths accordingly.

This builds and places the `libmyodbc3-3.51.01.so` file in the `.libs` directory. Copy this file to the Connector/ODBC library installation directory (`/usr/local/lib` (or the `lib` directory under the installation directory that you supplied with the `-prefix`)).

```
shell> cd .libs
shell> cp libmyodbc3-3.51.01.so /usr/local/lib
shell> cd /usr/local/lib
shell> ln -s libmyodbc3-3.51.01.so libmyodbc3.so
```

To build the thread-safe driver library:

```
shell> CC=/usr/bin/gcc \
  $CC -bundle -flat_namespace -undefined error
  -o .libs/libmyodbc3_r-3.51.01.so
  catalog.o connect.o cursor.o dll.o error.o execute.o
  handle.o info.o misc.o myodbc3.o options.o prepare.o
  results.o transact.o utility.o
  -L/usr/local/mysql/lib/mysql/
  -L/usr/local/iodbc/lib/
  -lz -lc -lmysqlclient_r -liodbcinst
```

### 20.1.3.5.5. Installing Driver Libraries

To install the driver libraries, execute the following command:

```
shell> make install
```

That command installs one of the following sets of libraries:

For Connector/ODBC 3.51:

- `libmyodbc3.so`
- `libmyodbc3-3.51.01.so`, where 3.51.01 is the version of the driver
- `libmyodbc3.a`

For thread-safe Connector/ODBC 3.51:

- `libmyodbc3_r.so`
- `libmyodbc3-3_r.51.01.so`
- `libmyodbc3_r.a`

For more information on build process, refer to the `INSTALL` file that comes with the source distribution. Note that if you are trying to use the `make` from Sun, you may end up with errors. On the other hand, GNU `gmake` should work fine on all platforms.

### 20.1.3.5.6. Testing Connector/ODBC on Unix

To run the basic samples provided in the distribution with the libraries that you built, use the following command:

```
shell> make test
```

Before running the tests, create the DSN 'myodbc3' in `odbc.ini` and set the environment variable `ODBCINI` to the correct `odbc.ini` file; and MySQL server is running. You can find a sample `odbc.ini` with the driver distribution.

You can even modify the `samples/run-samples` script to pass the desired DSN, UID, and PASSWORD values as the command-line arguments to each sample.

### 20.1.3.5.7. Building Connector/ODBC from Source on Mac OS X

To build the driver on Mac OS X (Darwin), make use of the following `configure` example:

```
shell> ./configure --prefix=/usr/local
  --with-unixODBC=/usr/local
  --with-mysql-path=/usr/local/mysql
  --disable-shared
  --enable-gui=no
  --host=powerpc-apple
```

The command assumes that the `unixODBC` and MySQL are installed in the default locations. If not, configure accordingly.

On Mac OS X, `--enable-shared` builds `.dylib` files by default. You can build `.so` files like this:

```
shell> make
shell> cd driver
shell> CC=/usr/bin/gcc \
  $CC -bundle -flat_namespace -undefined error
```

```
-o .libs/libmyodbc3-3.51.01.so *.o
-L/usr/local/mysql/lib/
-L/usr/local/iodbc/lib
-liodbcinst -lmysqlclient -lz -lc
```

To build the thread-safe driver library:

```
shell> CC=/usr/bin/gcc \
$CC -bundle -flat_namespace -undefined error
-o .libs/libmyodbc3-3.51.01.so *.o
-L/usr/local/mysql/lib/
-L/usr/local/iodbc/lib
-liodbcinst -lmysqlclient_r -lz -lc -lpthread
```

Make sure to change the `-liodbcinst` to `-lodbcinst` in case of using `unixODBC` instead of `iODBC` and configure the libraries path accordingly.

In Apple's version of GCC, both `cc` and `gcc` are actually symbolic links to `gcc3`.

Copy this library to the `$prefix/lib` directory and symlink to `libmyodbc3.so`.

You can cross-check the output shared-library properties using this command:

```
shell> otool -LD .libs/libmyodbc3-3.51.01.so
```

### 20.1.3.5.8. Building Connector/ODBC from Source on HP-UX

To build the driver on HP-UX 10.x or 11.x, make use of the following `configure` example:

If using `cc`:

```
shell> CC="cc" \
CFLAGS="+z" \
LDFLAGS="-Wl,+b:-Wl,+s" \
./configure --prefix=/usr/local
--with-unixodbc=/usr/local
--with-mysql-path=/usr/local/mysql/lib/mysql
--enable-shared
--enable-thread-safe
```

If using `gcc`:

```
shell> CC="gcc" \
LDFLAGS="-Wl,+b:-Wl,+s" \
./configure --prefix=/usr/local
--with-unixodbc=/usr/local
--with-mysql-path=/usr/local/mysql
--enable-shared
--enable-thread-safe
```

Once the driver is built, cross-check its attributes using `chatr .libs/libmyodbc3.sl` to determine whether you need to have set the MySQL client library path using the `SHLIB_PATH` environment variable. For static versions, ignore all shared-library options and run `configure` with the `--disable-shared` option.

### 20.1.3.5.9. Building Connector/ODBC from Source on AIX

To build the driver on AIX, make use of the following `configure` example:

```
shell> ./configure --prefix=/usr/local
--with-unixodbc=/usr/local
--with-mysql-path=/usr/local/mysql
--disable-shared
--enable-thread-safe
```

#### Note

For more information about how to build and set up the static and shared libraries across the different platforms refer to 'Using static and shared libraries across platforms'.

### 20.1.3.6. Installing Connector/ODBC from the Development Source Tree

#### Caution

You should read this section only if you are interested in helping us test our new code. If you just want to get MySQL Connector/ODBC up and running on your system, you should use a standard release distribution.

To be able to access the Connector/ODBC source tree, you must have Subversion installed. Subversion is freely available from <http://subversion.tigris.org/>.

To build from the source trees, you need the following tools:

- autoconf 2.52 (or newer)
- automake 1.4 (or newer)
- libtool 1.4 (or newer)
- m4

The most recent development source tree is available from our public Subversion trees at <http://dev.mysql.com/tech-resources/sources.html>.

To checkout out the Connector/ODBC sources, change to the directory where you want the copy of the Connector/ODBC tree to be stored, then use the following command:

```
shell> svn co http://svn.mysql.com/svnpublic/connector-odbc3
```

You should now have a copy of the entire Connector/ODBC source tree in the directory `connector-odbc3`. To build from this source tree on Unix or Linux follow these steps:

```
shell> cd connector-odbc3
shell> aclocal
shell> autoheader
shell> autoconf
shell> automake;
shell> ./configure # Add your favorite options here
shell> make
```

For more information on how to build, refer to the `INSTALL` file located in the same directory. For more information on options to `configure`, see [Section 20.1.3.5.1, “Typical configure Options”](#)

When the build is done, run `make install` to install the Connector/ODBC 3.51 driver on your system.

If you have gotten to the `make` stage and the distribution does not compile, please report it to [<myodbc@lists.mysql.com>](mailto:<myodbc@lists.mysql.com>).

On Windows, make use of Windows Makefiles `WIN-Makefile` and `WIN-Makefile_debug` in building the driver. For more information, see [Section 20.1.3.4, “Installing Connector/ODBC from a Source Distribution on Windows”](#).

After the initial checkout operation to get the source tree, you should run `svn update` periodically update your source according to the latest version.

## 20.1.4. Connector/ODBC Configuration

Before you connect to a MySQL database using the Connector/ODBC driver you must configure an ODBC *Data Source Name*. The DSN associates the various configuration parameters required to communicate with a database to a specific name. You use the DSN in an application to communicate with the database, rather than specifying individual parameters within the application itself. DSN information can be user specific, system specific, or provided in a special file. ODBC data source names are configured in different ways, depending on your platform and ODBC driver.

### 20.1.4.1. Data Source Names

A Data Source Name associates the configuration parameters for communicating with a specific database. Generally a DSN consists of the following parameters:

- Name
- Host Name
- Database Name
- Login
- Password

In addition, different ODBC drivers, including Connector/ODBC, may accept additional driver-specific options and parameters.

There are three types of DSN:

- A *System DSN* is a global DSN definition that is available to any user and application on a particular system. A System DSN can normally only be configured by a systems administrator, or by a user who has specific permissions that let them create System DSNs.
- A *User DSN* is specific to an individual user, and can be used to store database connectivity information that the user regularly uses.
- A *File DSN* uses a simple file to define the DSN configuration. File DSNs can be shared between users and machines and are therefore more practical when installing or deploying DSN information as part of an application across many machines.

DSN information is stored in different locations depending on your platform and environment.

### 20.1.4.2. Connector/ODBC Connection Parameters

You can specify the parameters in the following tables for Connector/ODBC when configuring a DSN. Users on Windows can use the Options and Advanced panels when configuring a DSN to set these parameters; see the table for information on which options relate to which fields and checkboxes. On Unix and Mac OS X, use the parameter name and value as the keyword/value pair in the DSN configuration. Alternatively, you can set these parameters within the `InConnectionString` argument in the `SQLDriverConnect()` call.

Parameter	Default Value	Comment
<code>user</code>	ODBC	The user name used to connect to MySQL.
<code>uid</code>	ODBC	Synonymous with <code>user</code> . Added in 3.51.16.
<code>server</code>	<code>localhost</code>	The host name of the MySQL server.
<code>database</code>		The default database.
<code>option</code>	0	Options that specify how Connector/ODBC should work. See below.
<code>port</code>	3306	The TCP/IP port to use if <code>server</code> is not <code>localhost</code> .
<code>initstmt</code>		Initial statement. A statement to execute when connecting to MySQL. In version 3.51 the parameter is called <code>stmt</code> . Note, the driver supports the initial statement being executed only at the time of the initial connection.
<code>password</code>		The password for the <code>user</code> account on <code>server</code> .
<code>pwd</code>		Synonymous with <code>password</code> . Added in 3.51.16.
<code>socket</code>		The Unix socket file or Windows named pipe to connect to if <code>server</code> is <code>localhost</code> .
<code>sslca</code>		The path to a file with a list of trust SSL CAs. Added in 3.51.16.
<code>sslcapath</code>		The path to a directory that contains trusted SSL CA certificates in PEM format. Added in 3.51.16.
<code>sslcert</code>		The name of the SSL certificate file to use for establishing a secure connection. Added in 3.51.16.
<code>sslcipher</code>		A list of allowable ciphers to use for SSL encryption. The cipher list has the same format as the <code>openssl ciphers</code> command. Added in 3.51.16.
<code>sslkey</code>		The name of the SSL key file to use for establishing a secure connection. Added in 3.51.16.
<code>charset</code>		The character set to use for the connection. Added in 3.51.17.
<code>sslverify</code>		If set to 1, the SSL certificate will be verified when used with the MySQL connection. If not set, then the default behaviour is to ignore SSL certificate verification.
<code>readtimeout</code>		The timeout in seconds for attempts to read from the server. Each attempt uses this timeout value and there are retries if necessary, so the total effective timeout value is three times the option value. You can set the value so that a lost connection can be detected earlier than the TCP/IP <code>Close_Wait_Timeout</code> value of 10 minutes. This option works only for TCP/IP connections, and only for Windows prior to MySQL 5.1.12. Corresponds to the <code>MYSQL_OPT_READ_TIMEOUT</code> option of the MySQL Client Library. This option was added in Connector/ODBC 3.51.27.
<code>writetimeout</code>		The timeout in seconds for attempts to write to the server. Each attempt uses this timeout value and there are <code>net_retry_count</code> retries if necessary, so the total

Parameter	Default Value	Comment
		effective timeout value is <code>net_retry_count</code> times the option value. This option works only for TCP/IP connections, and only for Windows prior to MySQL 5.1.12. Corresponds to the <code>MYSQL_OPT_WRITE_TIMEOUT</code> option of the MySQL Client Library. This option was added in Connector/ODBC 3.51.27.

## Note

The SSL configuration parameters can also be automatically loaded from a `my.ini` or `my.cnf` file.

The `option` argument is used to tell Connector/ODBC that the client isn't 100% ODBC compliant. On Windows, you normally select options by toggling the checkboxes in the connection screen, but you can also select them in the `option` argument. The following options are listed in the order in which they appear in the Connector/ODBC connect screen.

Value	Flagname	GUI Option	Description
1	<code>FLAG_FIELD_LENGTH</code>	Do not Optimize Column Width	The client cannot handle that Connector/ODBC returns the real width of a column. This option was removed in 3.51.18.
2	<code>FLAG_FOUND_ROWS</code>	Return Matching Rows	The client cannot handle that MySQL returns the true value of affected rows. If this flag is set, MySQL returns "found rows" instead. You must have MySQL 3.21.14 or newer to get this to work.
4	<code>FLAG_DEBUG</code>	Trace Driver Calls To myodbc.log	Make a debug log in <code>C:\myodbc.log</code> on Windows, or <code>/tmp/myodbc.log</code> on Unix variants. This option was removed in Connector/ODBC 3.51.18.
8	<code>FLAG_BIG_PACKETS</code>	Allow Big Results	Do not set any packet limit for results and bind parameters. Without this option, parameter binding will be truncated to 255 characters.
16	<code>FLAG_NO_PROMPT</code>	Do not Prompt Upon Connect	Do not prompt for questions even if driver would like to prompt.
32	<code>FLAG_DYNAMIC_CURSOR</code>	Enable Dynamic Cursor	Enable or disable the dynamic cursor support.
64	<code>FLAG_NO_SCHEMA</code>	Ignore # in Table Name	Ignore use of database name in <code>db_name.tbl_name.col_name</code> .
128	<code>FLAG_NO_DEFAULT_CURSOR</code>	User Manager Cursors	Force use of ODBC manager cursors (experimental).
256	<code>FLAG_NO_LOCALE</code>	Do not Use Set Locale	Disable the use of extended fetch (experimental).
512	<code>FLAG_PAD_SPACE</code>	Pad Char To Full Length	Pad <code>CHAR</code> columns to full column length.
1024	<code>FLAG_FULL_COLUMN_NAMES</code>	Return Table Names for SQLDescribeCol	<code>SQLDescribeCol()</code> returns fully qualified column names.
2048	<code>FLAG_COMPRESSED_PROTO</code>	Use Compressed Protocol	Use the compressed client/server protocol.
4096	<code>FLAG_IGNORE_SPACE</code>	Ignore Space After Function Names	Tell server to ignore space after function name and before "(" (needed by PowerBuilder). This makes all function names keywords.
8192	<code>FLAG_NAMED_PIPE</code>	Force Use of Named Pipes	Connect with named pipes to a <code>mysqld</code> server running on NT.
16384	<code>FLAG_NO_BIGINT</code>	Change BIGINT Columns to Int	Change <code>BIGINT</code> columns to <code>INT</code> columns (some applications cannot handle <code>BIGINT</code> ).
32768	<code>FLAG_NO_CATALOG</code>	No Catalog	Forces results from the catalog functions, such as <code>SQLTables</code> , to always return <code>NULL</code> and the driver to report that catalogs are not supported.
65536	<code>FLAG_USE_MYCNF</code>	Read Options From my.cnf	Read parameters from the <code>[client]</code> and <code>[odbc]</code> groups from <code>my.cnf</code> .
131072	<code>FLAG_SAFE</code>	Safe	Add some extra safety checks.
262144	<code>FLAG_NO_TRANSACTIONS</code>	Disable transactions	Disable transactions.
524288	<code>FLAG_LOG_QUERY</code>	Save queries to myodbc.sql	Enable query logging to <code>c:\myodbc.sql(/tmp/myodbc.sql)</code> file. (Enabled only in debug mode.)

1048576	FLAG_NO_CACHE	Do not Cache Result (forward only cursors)	Do not cache the results locally in the driver, instead read from server ( <code>mysql_use_result()</code> ). This works only for forward-only cursors. This option is very important in dealing with large tables when you do not want the driver to cache the entire result set.
2097152	FLAG_FORWARD_CURSOR	Force Use Of Forward Only Cursors	Force the use of <code>Forward-only</code> cursor type. In case of applications setting the default static/dynamic cursor type, and one wants the driver to use non-cache result sets, then this option ensures the forward-only cursor behavior.
4194304	FLAG_AUTO_RECONNECT	Enable auto-reconnect.	Enables auto-reconnection functionality. You should not use this option with transactions, since a auto reconnection during a incomplete transaction may cause corruption. Note that an auto-reconnected connection will not inherit the same settings and environment as the original. This option was added in Connector/ODBC 3.51.13.
8388608	FLAG_AUTO_IS_NULL	Flag Auto Is Null	<p>When <code>FLAG_AUTO_IS_NULL</code> is set, the driver does not change the default value of <code>sql_auto_is_null</code>, leaving it at 1, so you get the MySQL default, not the SQL standard behavior.</p> <p>When <code>FLAG_AUTO_IS_NULL</code> is not set, the driver changes the default value of <code>SQL_AUTO_IS_NULL</code> to 0 after connecting, so you get the SQL standard, not the MySQL default behaviour.</p> <p>Thus, omitting the flag disables the compatibility option and forces SQL standard behaviour.</p> <p>See <code>IS NULL</code>. This option was added in Connector/ODBC 3.51.13.</p>
16777216	FLAG_ZERO_DATE_TO_MIN	Flag Zero Date to Min	Translates zero dates ( <code>XXXX-00-00</code> ) into the minimum date values supported by ODBC, <code>XXXX-01-01</code> . This resolves an issue where some statements will not work because the date returned and the minimum ODBC date value are incompatible. This option was added in Connector/ODBC 3.51.17.
33554432	FLAG_MIN_DATE_TO_ZERO	Flag Min Date to Zero	Translates the minimum ODBC date value ( <code>XXXX-01-01</code> ) to the zero date format supported by MySQL ( <code>XXXX-00-00</code> ). This resolves an issue where some statements will not work because the date returned and the minimum ODBC date value are incompatible. This option was added in Connector/ODBC 3.51.17.
67108864	FLAG_MULTI_STATEMENTS	Allow multiple statements	Enables support for batched statements. This option was added in Connector/ODBC 3.51.18.
134217728	FLAG_COLUMN_SIZE_S32	Limit column size to 32-bit value	Limits the column size to a signed 32-bit value to prevent problems with larger column sizes in applications that do not support them. This option is automatically enabled when working with ADO applications. This option was added in Connector/ODBC 3.51.22.
268435456	FLAG_NO_BINARY_RESULT	Always handle binary function results as character data	When set this option disables charset 63 for columns with an empty <code>org_table</code> . This option was added in Connector/ODBC 3.51.26.

To select multiple options, add together their values. For example, setting `option` to 12 (4+8) gives you debugging without packet limits.

The following table shows some recommended `option` values for various configurations.

Configuration	Option Value
Microsoft Access, Visual Basic	3
Driver trace generation (Debug mode)	4
Microsoft Access (with improved DELETE queries)	35
Large tables with too many rows	2049
Sybase PowerBuilder	135168

---

Query log generation (Debug mode)	524288
Generate driver trace as well as query log (Debug mode)	524292
Large tables with no-cache results	3145731

### 20.1.4.3. Configuring a Connector/ODBC DSN on Windows

The [ODBC Data Source Administrator](#) within Windows enables you to create DSNs, check driver installation and configure ODBC systems such as tracing (used for debugging) and connection pooling.

Different editions and versions of Windows store the [ODBC Data Source Administrator](#) in different locations depending on the version of Windows that you are using.

To open the [ODBC Data Source Administrator](#) in Windows Server 2003:

**Tip**

Because it is possible to create DSN using either the 32-bit or 64-bit driver, but using the same DNS identifier, it is advisable to include the driver being used within the DSN identifier. This will help you to identify the DSN when using it from applications such as Excel that are only compatible with the 32-bit driver. For example, you might add [Using32bitCODBC](#) to the DSN identifier for the 32-bit interface and [Using64bitCODBC](#) for those using the 64-bit Connector/ODBC driver.

1. On the [Start](#) menu, choose [Administrative Tools](#), and then click [Data Sources \(ODBC\)](#).

To open the [ODBC Data Source Administrator](#) in Windows 2000 Server or Windows 2000 Professional:

1. On the [Start](#) menu, choose [Settings](#), and then click [Control Panel](#).
2. In [Control Panel](#), click [Administrative Tools](#).
3. In [Administrative Tools](#), click [Data Sources \(ODBC\)](#).

To open the [ODBC Data Source Administrator](#) on Windows XP:

1. On the [Start](#) menu, click [Control Panel](#).
2. In the [Control Panel](#) when in [Category View](#) click [Performance and Maintenance](#) and then click [Administrative Tools](#). If you are viewing the [Control Panel](#) in [Classic View](#), click [Administrative Tools](#).
3. In [Administrative Tools](#), click [Data Sources \(ODBC\)](#).

Irrespective of your Windows version, you should be presented the [ODBC Data Source Administrator](#) window:

Within Windows XP, you can add the [Administrative Tools](#) folder to your START menu to make it easier to locate the ODBC Data Source Administrator. To do this:

1. Right click on the START menu.
2. Select [Properties](#).
3. Click CUSTOMIZE....
4. Select the ADVANCED tab.
5. Within [Start menu items](#), within the [System Administrative Tools](#) section, select [Display on the All Programs menu](#).

Within both Windows Server 2003 and Windows XP you may want to permanently add the [ODBC Data Source Administrator](#) to your START menu. To do this, locate the [Data Sources \(ODBC\)](#) icon using the methods shown, then right-click on the icon and then choose PIN TO START MENU.

The interfaces for the 3.51 and 5.1 versions of the Connector/ODBC driver are different, although the fields and information that you need to enter remain the same.

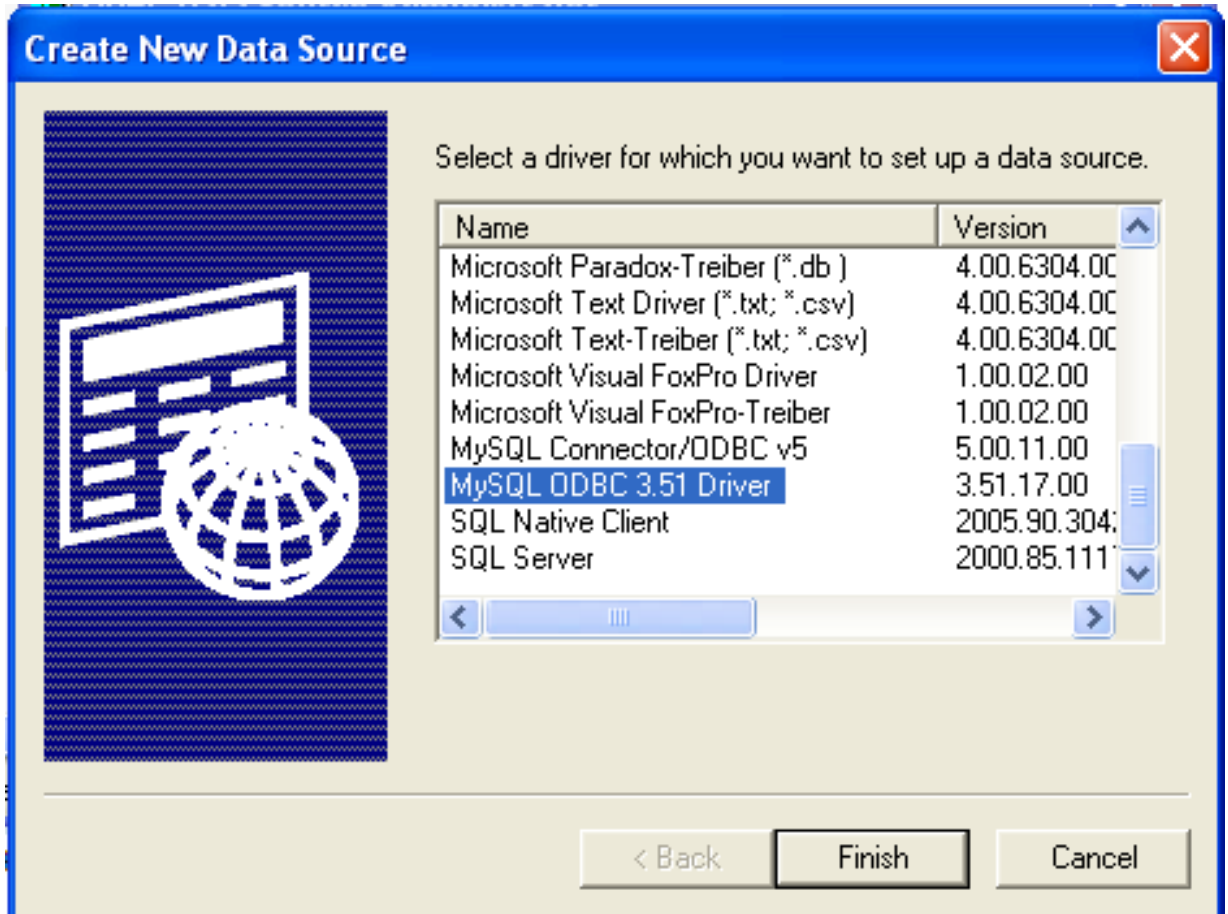

To configure a DSN using Connector/ODBC 3.51.x or Connector/ODBC 5.1.0, see [Section 20.1.4.3.1, "Configuring a Connector/ODBC 3.51 DSN on Windows"](#).

To configure a DSN using Connector/ODBC 5.1.1 or later, see [Section 20.1.4.3.2, "Configuring a Connector/ODBC 5.1 DSN on Windows"](#).

### 20.1.4.3.1. Configuring a Connector/ODBC 3.51 DSN on Windows

To add and configure a new Connector/ODBC data source on Windows, use the [ODBC Data Source Administrator](#):

1. Open the [ODBC Data Source Administrator](#).
2. To create a System DSN (which will be available to all users) , select the [System DSN](#) tab. To create a User DSN, which will be unique only to the current user, click the [ADD...](#) button.
3. You will need to select the ODBC driver for this DSN.

Select [MySQL ODBC 3.51 Driver](#), then click [FINISH](#).

4. You now need to configure the specific fields for the DSN you are creating through the [Add Data Source Name](#) dialog.

In the **DATA SOURCE NAME** box, enter the name of the data source you want to access. It can be any valid name that you choose.

5. In the **DESCRIPTION** box, enter some text to help identify the connection.
6. In the **SERVER** field, enter the name of the MySQL server host that you want to access. By default, it is `localhost`.
7. In the **USER** field, enter the user name to use for this connection.
8. In the **PASSWORD** field, enter the corresponding password for this connection.
9. The **DATABASE** pop-up should automatically populate with the list of databases that the user has permissions to access.
10. Click OK to save the DSN.

A completed DSN configuration may look like this:

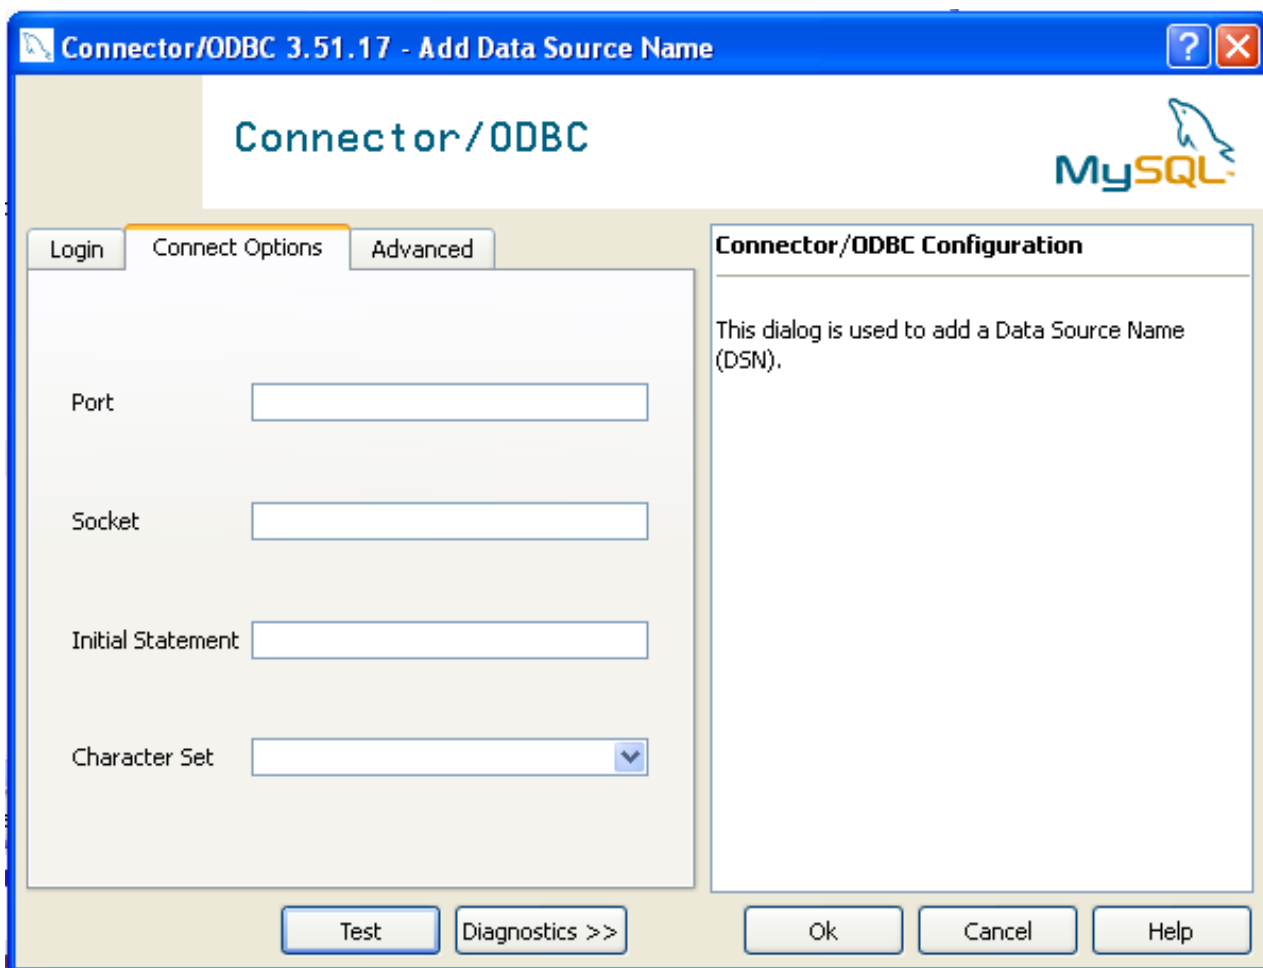

You can verify the connection using the parameters you have entered by clicking the TEST button. If the connection could be made successfully, you will be notified with a `Success; connection was made!` dialog.

If the connection failed, you can obtain more information on the test and why it may have failed by clicking the DIAGNOSTICS... button to show additional error messages.

You can configure a number of options for a specific DSN by using either the CONNECT OPTIONS or ADVANCED tabs in the DSN configuration dialog.

The three options you can configure are:

- **PORT** sets the TCP/IP port number to use when communicating with MySQL. Communication with MySQL uses port 3306 by default. If your server is configured to use a different TCP/IP port, you must specify that port number here.
- **SOCKET** sets the name or location of a specific socket or Windows pipe to use when communicating with MySQL.
- **INITIAL STATEMENT** defines an SQL statement that will be executed when the connection to MySQL is opened. You can use this to set MySQL options for your connection, such as disabling autocommit.
- **CHARACTER SET** is a pop-up list from which you can select the default character set to be used with this connection. The Character Set option was added in 3.5.17.

The **ADVANCED** tab enables you to configure Connector/ODBC connection parameters. Refer to [Section 20.1.4.2, “Connector/ODBC Connection Parameters”](#), for information about the meaning of these options.

#### 20.1.4.3.2. Configuring a Connector/ODBC 5.1 DSN on Windows

The DSN configuration when using Connector/ODBC 5.1.1 and later has a slightly different layout. Also, due to the native Unicode support within Connector/ODBC 5.1, you no longer need to specify the initial character set to be used with your connection.

To configure a DSN using the Connector/ODBC 5.1.1 or later driver:

1. Open the [ODBC Data Source Administrator](#).
2. To create a System DSN (which will be available to all users), select the **SYSTEM DSN** tab. To create a User DSN, which will be unique only to the current user, click the **ADD...** button.
3. You will need to select the ODBC driver for this DSN.

Select **MySQL ODBC 3.51 Driver**, then click FINISH.

4. You now need to configure the specific fields for the DSN you are creating through the [Connection Parameters](#) dialog.

MySQL Connector/ODBC Data Source Configuration

MySQL Connector/ODBC

Connection Parameters

Data Source Name:

Description:

Server:  Port:

User:

Password:

Database:

In the **DATA SOURCE NAME** box, enter the name of the data source you want to access. It can be any valid name that you choose.

5. In the **DESCRIPTION** box, enter some text to help identify the connection.
6. In the **SERVER** field, enter the name of the MySQL server host that you want to access. By default, it is `localhost`.
7. In the **USER** field, enter the user name to use for this connection.
8. In the **PASSWORD** field, enter the corresponding password for this connection.
9. The **DATABASE** pop-up should automatically populate with the list of databases that the user has permissions to access.
10. To communicate over a different TCP/IP port than the default (3306), change the value of the **PORT**.
11. Click OK to save the DSN.

You can verify the connection using the parameters you have entered by clicking the **TEST** button. If the connection could be made successfully, you will be notified with a `Success; connection was made!` dialog.

You can configure a number of options for a specific DSN by using the **DETAILS** button.

MySQL Connector/ODBC Data Source Configuration

MySQL Connector/ODBC

Connection Parameters

Data Source Name:

Description:

Server:  Port:

User:

Password:

Database:

Flags 1 | Flags 2 | Flags 3 | Debug | SSL Settings

- Return matched rows instead of affected rows
- Allow big result sets
- Use compression
- Treat BIGINT columns as INT columns
- Enable safe options (see documentation)
- Enable automatic reconnect
- Enable SQL\_AUTO\_IS\_NULL

The **DETAILS** button opens a tabbed display which allows you to set additional options:

- **FLAGS 1**, **FLAGS 2**, and **FLAGS 3** enable you to select the additional flags for the DSN connection. For more information on these flags, see [Section 20.1.4.2, “Connector/ODBC Connection Parameters”](#).
- **DEBUG** allows you to enable ODBC debugging to record the queries you execute through the DSN to the `myodbc.sql` file. For more information, see [Section 20.1.4.8, “Getting an ODBC Trace File”](#).
- **SSL SETTINGS** configures the additional options required for using the Secure Sockets Layer (SSL) when communicating with MySQL server. Note that you must have enabled SSL and configured the MySQL server with suitable certificates to communicate over SSL.

The **ADVANCED** tab enables you to configure Connector/ODBC connection parameters. Refer to [Section 20.1.4.2, “Connector/ODBC Connection Parameters”](#), for information about the meaning of these options.

### 20.1.4.3.3. Errors and Debugging

This section answers Connector/ODBC connection-related questions.

- **While configuring a Connector/ODBC DSN, a [Could Not Load Translator or Setup Library](#) error occurs**

For more information, refer to [MS KnowledgeBase Article\(Q260558\)](#). Also, make sure you have the latest valid `ct13d32.dll` in your system directory.

- On Windows, the default `myodbc3.dll` is compiled for optimal performance. If you want to debug Connector/ODBC 3.51 (for example, to enable tracing), you should instead use `myodbc3d.dll`. To install this file, copy `myodbc3d.dll` over the installed `myodbc3.dll` file. Make sure to revert back to the release version of the driver DLL once you are done with the debugging because the debug version may cause performance issues. Note that the `myodbc3d.dll` isn't included in Connector/ODBC 3.51.07 through 3.51.11. If you are using one of these versions, you should copy that DLL from a previous version (for example, 3.51.06).

### 20.1.4.4. Configuring a Connector/ODBC DSN on Mac OS X

To configure a DSN on Mac OS X you can either use the `myodbc3i` utility, edit the `odbc.ini` file within the `Library/ODBC` directory of the user or the should use the ODBC Administrator. If you have Mac OS X 10.2 or earlier, refer to [Section 20.1.4.5, “Configuring a Connector/ODBC DSN on Unix”](#). Select whether you want to create a User DSN or a System DSN. If you want to add a System DSN, you may need to authenticate with the system. You must click the padlock and enter a user and password with administrator privileges.

For correct operation of ODBC Administrator, you should ensure that the `/Library/ODBC/odbc.ini` file used to set up ODBC connectivity and DSNs are writable by the `admin` group. If this file is not writable by this group then the ODBC Administrator may fail, or may appear to have worked but not generated the correct entry.

### Warning

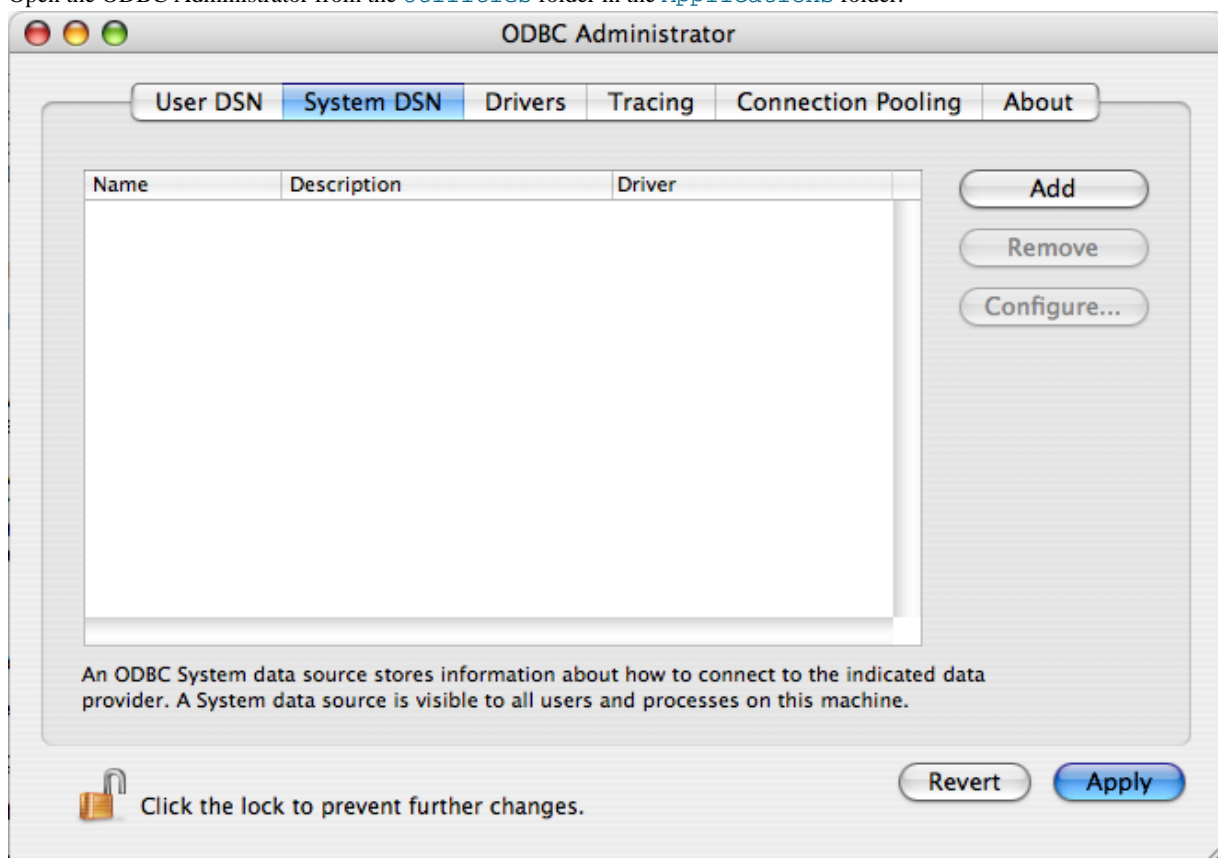

There are known issues with the OS X ODBC Administrator and Connector/ODBC that may prevent you from creating a DSN using this method. In this case you should use the command-line or edit the `odbc.ini` file directly. Note that existing DSNs or those that you create via the `myodbc3i` or `myodbc-installertool` can still be checked and edited using ODBC Administrator.

To create a DSN using the `myodbc3i` utility, you need only specify the DSN type and the DSN connection string. For example:

```
shell> myodbc3i -a -s -t "DSN=mydb;DRIVER=MySQL ODBC 3.51 Driver;SERVER=mysql;USER=username;PASSWORD=pass"
```

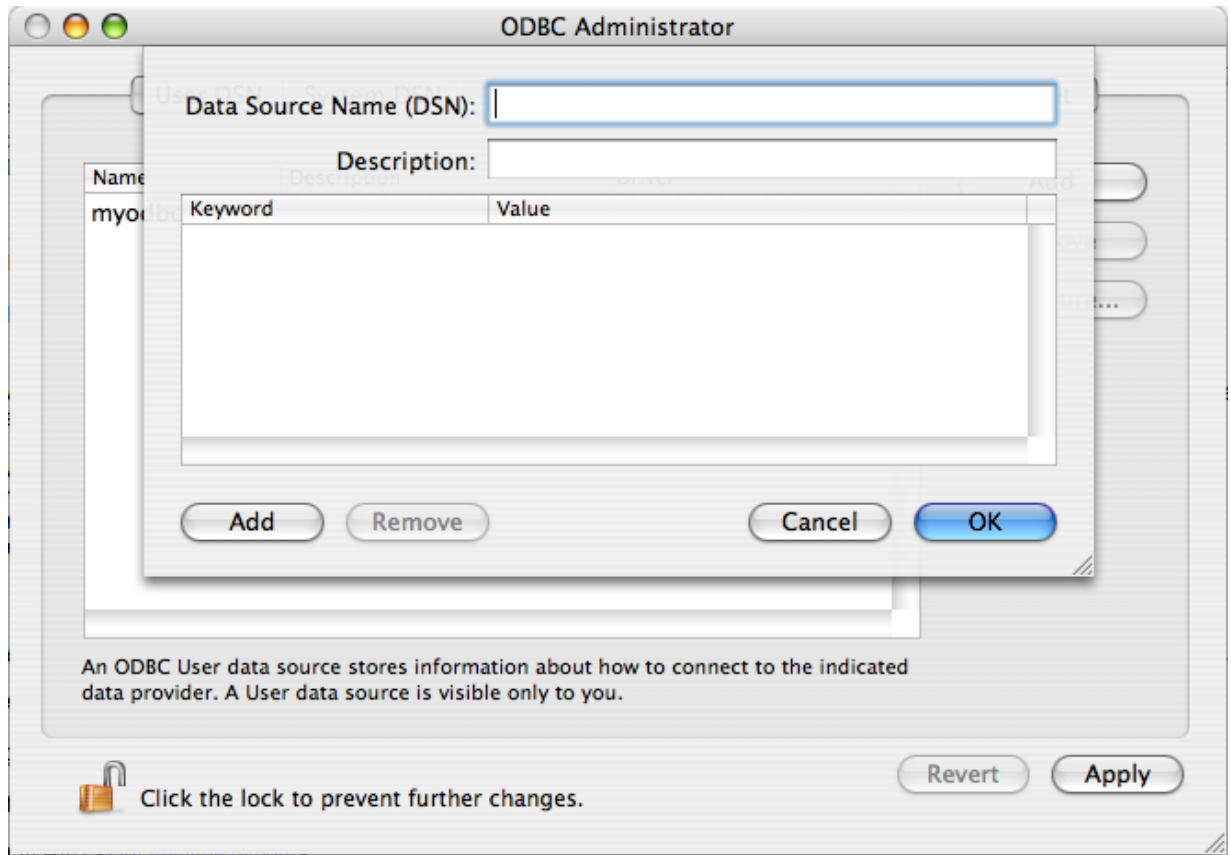

To use ODBC Administrator:

1. Open the ODBC Administrator from the `Utilities` folder in the `Applications` folder.

2. On the User DSN or System DSN panel, click ADD.
3. Select the Connector/ODBC driver and click OK.
4. You will be presented with the `Data Source Name` dialog. Enter The `Data Source Name` and an optional `Description` for the DSN.

5. Click ADD to add a new keyword/value pair to the panel. You should configure at least four pairs to specify the `server`, `username`, `password` and `database` connection parameters. See [Section 20.1.4.2, “Connector/ODBC Connection Parameters”](#).
6. Click OK to add the DSN to the list of configured data source names.

A completed DSN configuration may look like this:

You can configure additional ODBC options to your DSN by adding further keyword/value pairs and setting the corresponding values. See [Section 20.1.4.2, “Connector/ODBC Connection Parameters”](#).

### 20.1.4.5. Configuring a Connector/ODBC DSN on Unix

On [Unix](#), you configure DSN entries directly in the `odbc.ini` file. Here is a typical `odbc.ini` file that configures `myodbc3` as the DSN name for Connector/ODBC 3.51:

```
;
; odbc.ini configuration for Connector/ODBC and Connector/ODBC 3.51 drivers
;

[ODBC Data Sources]
myodbc3      = MyODBC 3.51 Driver DSN

[myodbc3]
Driver       = /usr/local/lib/libmyodbc3.so
Description = Connector/ODBC 3.51 Driver DSN
SERVER      = localhost
PORT        =
USER        = root
Password    =
Database    = test
OPTION      = 3
SOCKET      =

[Default]
Driver       = /usr/local/lib/libmyodbc3.so
Description = Connector/ODBC 3.51 Driver DSN
SERVER      = localhost
PORT        =
USER        = root
Password    =
Database    = test
OPTION      = 3
SOCKET      =
```

Refer to the [Section 20.1.4.2, “Connector/ODBC Connection Parameters”](#), for the list of connection parameters that can be supplied.

#### Note

If you are using `unixODBC`, you can use the following tools to set up the DSN:

- ODBCConfig GUI tool([HOWTO: ODBCConfig](#))
- `odbcinst`

In some cases when using `unixODBC`, you might get this error:

```
Data source name not found and no default driver specified
```

If this happens, make sure the `ODBCINI` and `ODBCSYSINI` environment variables are pointing to the right `odbc.ini` file. For example, if your `odbc.ini` file is located in `/usr/local/etc`, set the environment variables like this:

```
export ODBCINI=/usr/local/etc/odbc.ini
export ODBCSYSINI=/usr/local/etc
```

### 20.1.4.6. Connecting Without a Predefined DSN

You can connect to the MySQL server using `SQLDriverConnect`, by specifying the `DRIVER` name field. Here are the connection strings for Connector/ODBC using DSN-Less connections:

#### For Connector/ODBC 3.51:

```
ConnectionString = "DRIVER={MySQL ODBC 3.51 Driver};\
SERVER=localhost;\
DATABASE=test;\
USER=venu;\
PASSWORD=venu;\
OPTION=3;"
```

If your programming language converts backslash followed by whitespace to a space, it is preferable to specify the connection string as a single long string, or to use a concatenation of multiple strings that does not add spaces in between. For example:

```
ConnectionString = "DRIVER={MySQL ODBC 3.51 Driver};"
```

```
"SERVER=localhost;"  
"DATABASE=test;"  
"USER=venu;"  
"PASSWORD=venu;"  
"OPTION=3;"
```

**Note.** Note that on Mac OS X you may need to specify the full path to the Connector/ODBC driver library.

Refer to the [Section 20.1.4.2, “Connector/ODBC Connection Parameters”](#), for the list of connection parameters that can be supplied.

### 20.1.4.7. ODBC Connection Pooling

Connection pooling enables the ODBC driver to re-use existing connections to a given database from a pool of connections, instead of opening a new connection each time the database is accessed. By enabling connection pooling you can improve the overall performance of your application by lowering the time taken to open a connection to a database in the connection pool.

For more information about connection pooling: <http://support.microsoft.com/default.aspx?scid=kb;EN-US;q169470>.

### 20.1.4.8. Getting an ODBC Trace File

If you encounter difficulties or problems with Connector/ODBC, you should start by making a log file from the [ODBC Manager](#) and Connector/ODBC. This is called *tracing*, and is enabled through the ODBC Manager. The procedure for this differs for Windows, Mac OS X and Unix.

#### 20.1.4.8.1. Enabling ODBC Tracing on Windows

To enable the trace option on Windows:

1. The [Tracing](#) tab of the ODBC Data Source Administrator dialog box enables you to configure the way ODBC function calls are traced.

2. When you activate tracing from the [Tracing](#) tab, the [Driver Manager](#) logs all ODBC function calls for all subsequently run applications.
3. ODBC function calls from applications running before tracing is activated are not logged. ODBC function calls are recorded in a log file you specify.
4. Tracing ceases only after you click [Stop Tracing Now](#). Remember that while tracing is on, the log file continues to increase in size and that tracing affects the performance of all your ODBC applications.

#### 20.1.4.8.2. Enabling ODBC Tracing on Mac OS X

To enable the trace option on Mac OS X 10.3 or later you should use the [Tracing](#) tab within ODBC Administrator .

1. Open the ODBC Administrator.
2. Select the [Tracing](#) tab.

3. Select the `Enable Tracing` checkbox.
4. Enter the location where you want to save the Tracing log. If you want to append information to an existing log file, click the `CHOOSE...` button.

### 20.1.4.8.3. Enabling ODBC Tracing on Unix

To enable the trace option on Mac OS X 10.2 (or earlier) or Unix you must add the `trace` option to the ODBC configuration:

1. On Unix, you need to explicitly set the `Trace` option in the `ODBC.INI` file.

Set the tracing `ON` or `OFF` by using `TraceFile` and `Trace` parameters in `odbc.ini` as shown below:

```
TraceFile = /tmp/odbc.trace
Trace     = 1
```

`TraceFile` specifies the name and full path of the trace file and `Trace` is set to `ON` or `OFF`. You can also use `1` or `YES` for `ON` and `0` or `NO` for `OFF`. If you are using `ODBCConfig` from `unixODBC`, then follow the instructions for tracing `unixODBC` calls at [HOWTO-ODBCConfig](#).

### 20.1.4.8.4. Enabling a Connector/ODBC Log

To generate a Connector/ODBC log, do the following:

1. Within Windows, enable the `Trace Connector/ODBC` option flag in the Connector/ODBC connect/configure screen. The log is written to file `C:\myodbc.log`. If the trace option is not remembered when you are going back to the above screen, it means that you are not using the `myodbcd.dll` driver, see [Section 20.1.4.3.3, "Errors and Debugging"](#).

On Mac OS X, Unix, or if you are using DSN-Less connection, then you need to supply `OPTION=4` in the connection string or set the corresponding keyword/value pair in the DSN.

2. Start your application and try to get it to fail. Then check the Connector/ODBC trace file to find out what could be wrong.

If you need help determining what is wrong, see [Section 20.1.8.1, “Connector/ODBC Community Support”](#).

## 20.1.5. Connector/ODBC Examples

Once you have configured a DSN to provide access to a database, how you access and use that connection is dependent on the application or programming language. As ODBC is a standardized interface, any application or language that supports ODBC can use the DSN and connect to the configured database.

### 20.1.5.1. Basic Connector/ODBC Application Steps

Interacting with a MySQL server from an applications using the Connector/ODBC typically involves the following operations:

- Configure the Connector/ODBC DSN
- Connect to MySQL server
- Initialization operations
- Execute SQL statements
- Retrieve results
- Perform Transactions
- Disconnect from the server

Most applications use some variation of these steps. The basic application steps are shown in the following diagram:

### 20.1.5.2. Step-by-step Guide to Connecting to a MySQL Database through Connector/ODBC

A typical installation situation where you would install Connector/ODBC is when you want to access a database on a Linux or Unix host from a Windows machine.

As an example of the process required to set up access between two machines, the steps below take you through the basic steps. These instructions assume that you want to connect to system ALPHA from system BETA with a user name and password of `my-user` and `mypassword`.

On system ALPHA (the MySQL server) follow these steps:

1. Start the MySQL server.
2. Use `GRANT` to set up an account with a user name of `myuser` that can connect from system BETA using a password of `my-user` to the database `test`:

```
GRANT ALL ON test.* to 'myuser'@'BETA' IDENTIFIED BY 'mypassword';
```

For more information about MySQL privileges, refer to [Section 5.5, “MySQL User Account Management”](#).

On system BETA (the Connector/ODBC client), follow these steps:

1. Configure a Connector/ODBC DSN using parameters that match the server, database and authentication information that you have just configured on system ALPHA.

Parameter	Value	Comment
DSN	remote_test	A name to identify the connection.
SERVER	ALPHA	The address of the remote server.
DATABASE	test	The name of the default database.
USER	myuser	The user name configured for access to this database.
PASSWORD	mypassword	The password for <code>myuser</code> .

2. Using an ODBC-capable application, such as Microsoft Office, connect to the MySQL server using the DSN you have just created. If the connection fails, use tracing to examine the connection process. See [Section 20.1.4.8, “Getting an ODBC Trace File”](#), for more information.

### 20.1.5.3. Connector/ODBC and Third-Party ODBC Tools

Once you have configured your Connector/ODBC DSN, you can access your MySQL database through any application that supports the ODBC interface, including programming languages and third-party applications. This section contains guides and help on using Connector/ODBC with various ODBC-compatible tools and applications, including Microsoft Word, Microsoft Excel and Adobe/Macromedia ColdFusion.

Connector/ODBC has been tested with the following applications.

Publisher	Application	Notes
Adobe	ColdFusion	Formerly Macromedia ColdFusion
Borland	C++ Builder	
	Builder 4	
	Delphi	
Business Objects	Crystal Reports	
Claris	Filemaker Pro	
Corel	Paradox	
Computer Associates	Visual Objects	Also known as CAVO
	AllFusion ERwin Data Modeler	
Gupta	Team Developer	Previously known as Centura Team Developer; Gupta SQL/Windows
Gensym	G2-ODBC Bridge	
Inline	iHTML	
Lotus	Notes	Versions 4.5 and 4.6
Microsoft	Access	
	Excel	
	Visio Enterprise	
	Visual C++	
	Visual Basic	

	ODBC.NET	Using C#, Visual Basic, C++
	FoxPro	
	Visual Interdev	
OpenOffice.org	OpenOffice.org	
Perl	DBD::ODBC	
Pervasive Software	DataJunction	
Sambar Technologies	Sambar Server	
SPSS	SPSS	
SoftVelocity	Clarion	
SQLExpress	SQLExpress for Xbase++	
Sun	StarOffice	
SunSystems	Vision	
Sybase	PowerBuilder	
	PowerDesigner	
theKompany.com	Data Architect	

If you know of any other applications that work with Connector/ODBC, please send mail to [<myodbc@lists.mysql.com>](mailto:myodbc@lists.mysql.com) about them.

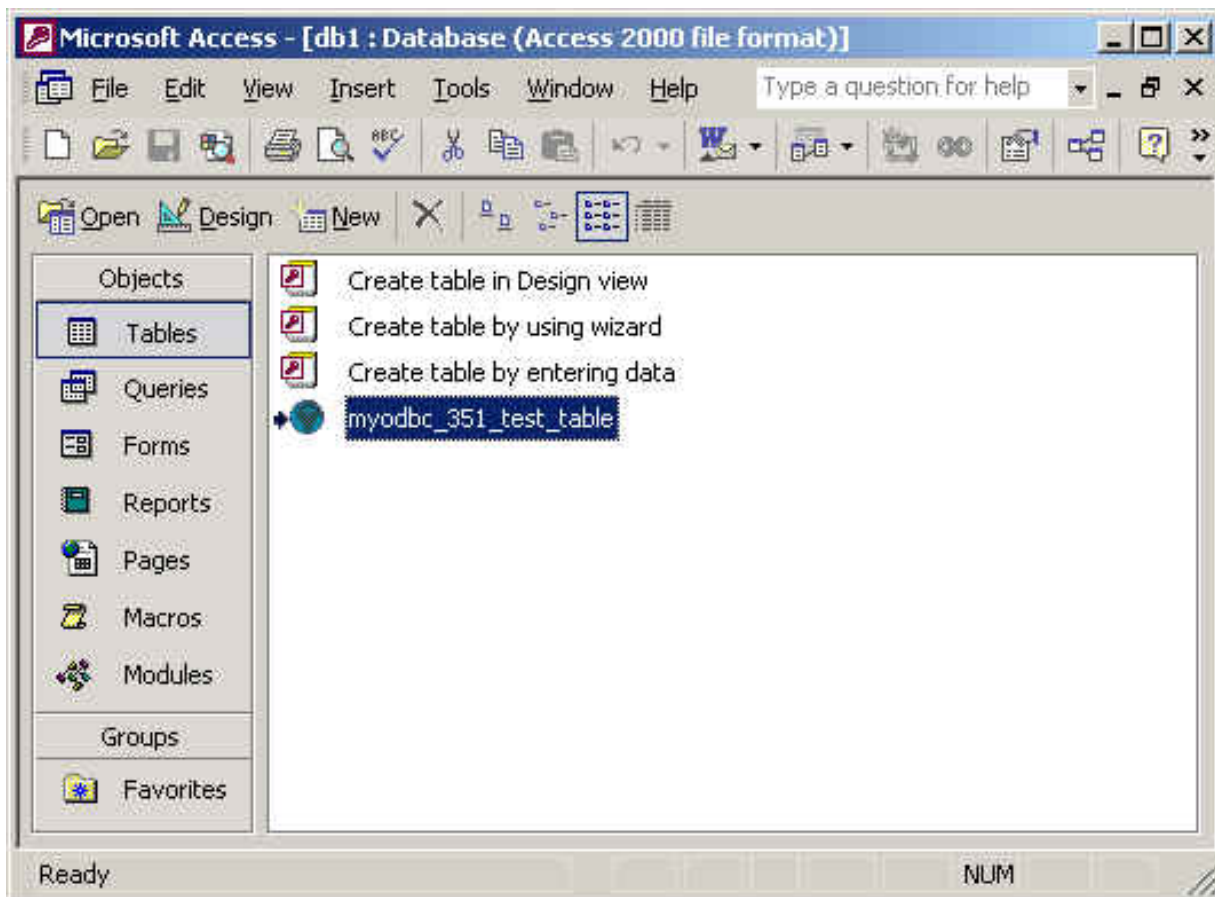

#### 20.1.5.4. Using Connector/ODBC with Microsoft Access

You can use MySQL database with Microsoft Access using Connector/ODBC. The MySQL database can be used as an import source, an export source, or as a linked table for direct use within an Access application, so you can use Access as the front-end interface to a MySQL database.

##### 20.1.5.4.1. Exporting Access Data to MySQL

To export a table of data from an Access database to MySQL, follow these instructions:

1. When you open an Access database or an Access project, a Database window appears. It displays shortcuts for creating new database objects and opening existing objects.

2. Click the name of the [table](#) or [query](#) you want to export, and then in the **File** menu, select **Export**.
3. In the **Export Object Type Object name To** dialog box, in the **Save As Type** box, select **ODBC Databases ()** as shown here:

4. In the **Export** dialog box, enter a name for the file (or use the suggested name), and then select **OK**.
5. The **Select Data Source** dialog box is displayed; it lists the defined data sources for any ODBC drivers installed on your computer. Click either the **File Data Source** or **Machine Data Source** tab, and then double-click the **Connector/ODBC** or **Connector/ODBC 3.51** data source that you want to export to. To define a new data source for **Connector/ODBC**, please see [Section 20.1.4.3, "Configuring a Connector/ODBC DSN on Windows"](#).

#### Note

Ensure that the information that you are exporting to the MySQL table is valid for the corresponding MySQL data types. Values that are outside of the supported range of the MySQL data type but valid within Access may trigger an "overflow" error during the export.

Microsoft Access connects to the MySQL Server through this data source and exports new tables and or data.

#### 20.1.5.4.2. Importing MySQL Data to Access

To import a table or tables from MySQL to Access, follow these instructions:

1. Open a database, or switch to the Database window for the open database.
2. To import tables, on the **File** menu, point to **Get External Data**, and then click **Import**.
3. In the **Import** dialog box, in the Files Of Type box, select **ODBC DATABASES ()**. The Select Data Source dialog box lists the defined data sources **THE SELECT DATA SOURCE** dialog box is displayed; it lists the defined data source names.
4. If the ODBC data source that you selected requires you to log on, enter your login ID and password (additional information might also be required), and then click **OK**.
5. Microsoft Access connects to the MySQL server through **ODBC data source** and displays the list of tables that you can **import**.
6. Click each table that you want to **import**, and then click **OK**.

### 20.1.5.4.3. Using Microsoft Access as a Front-end to MySQL

You can use Microsoft Access as a front end to a MySQL database by linking tables within your Microsoft Access database to tables that exist within your MySQL database. When a query is requested on a table within Access, ODBC is used to execute the queries on the MySQL database instead.

**To create a linked table:**

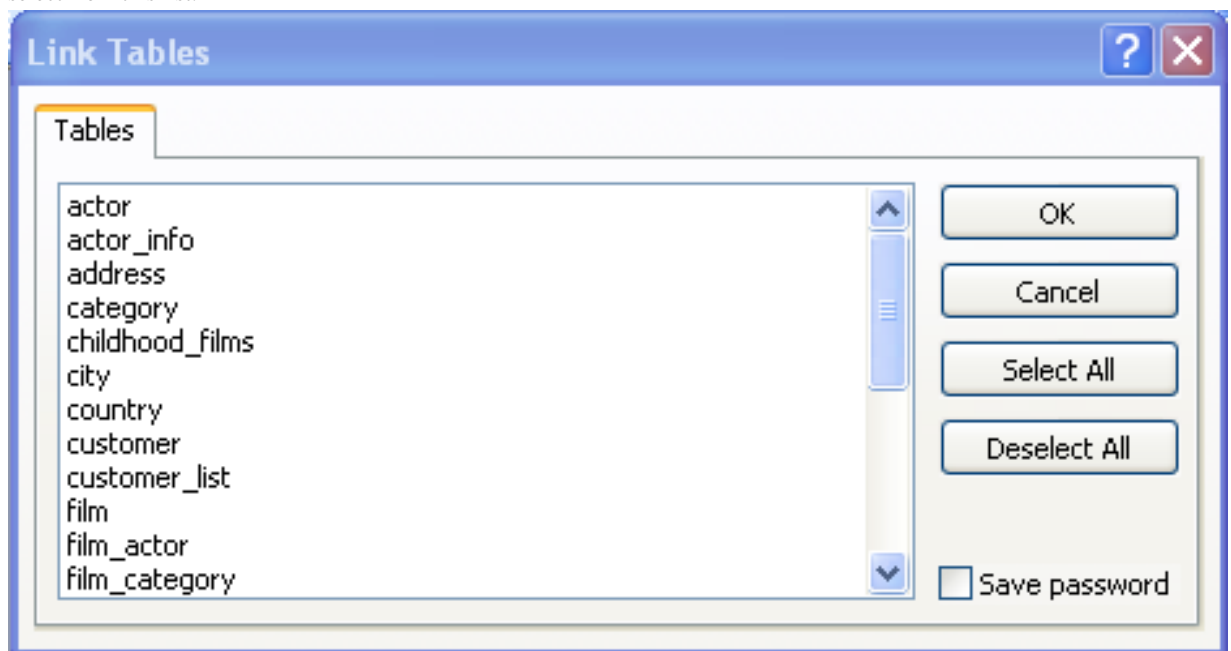

1. Open the Access database that you want to link to MySQL.
2. From the **FILE**, choose **GET EXTERNAL DATA->LINK TABLES**.

3. From the browser, choose **ODBC DATABASES ()** from the **FILES OF TYPE** pop-up.
4. In the **SELECT DATA SOURCE** window, choose an existing DSN, either from a **FILE DATA SOURCE** or **MACHINE DATA SOURCE**. You can also create a new DSN using the **NEW...** button. For more information on creating a DSN see [Section 20.1.4.3, "Configuring a Connector/ODBC DSN on Windows"](#).

5. In the **LINK TABLES** dialog, select one or more tables from the MySQL database. A link will be created to each table that you select from this list.

- If Microsoft Access is unable to determine the unique record identifier for a table automatically then it may ask you to confirm the column, or combination of columns, to be used to uniquely identify each row from the source table. Select the columns you want to use and click OK.

Once the process has been completed, you can now build interfaces and queries to the linked tables just as you would for any Access database.

Use the following procedure to view or to refresh links when the structure or location of a linked table has changed. The Linked Table Manager lists the paths to all currently linked tables.

**To view or refresh links:**

- Open the database that contains links to MySQL tables.
- On the **Tools** menu, point to **Add-ins (Database Utilities)** in Access 2000 or newer, and then click **Linked Table Manager**.
- Select the check box for the tables whose links you want to refresh.
- Click OK to refresh the links.

Microsoft Access confirms a successful refresh or, if the table wasn't found, displays the **Select New Location of <table name>** dialog box in which you can specify its the table's new location. If several selected tables have moved to the new location that you specify, the Linked Table Manager searches that location for all selected tables, and updates all links in one step.

**To change the path for a set of linked tables:**

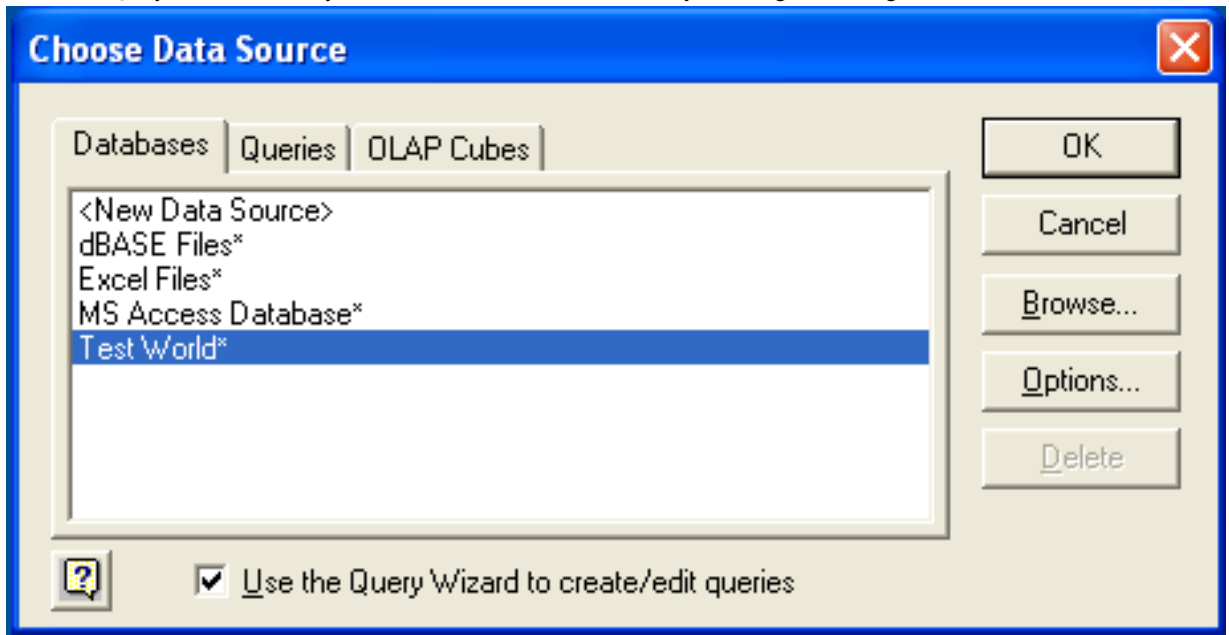

- Open the database that contains links to tables.
- On the **Tools** menu, point to **Add-ins (Database Utilities)** in Access 2000 or newer, and then click **Linked Table Manager**.
- Select the **Always Prompt For A New Location** check box.
- Select the check box for the tables whose links you want to change, and then click **OK**.
- In the **Select New Location of <table name>** dialog box, specify the new location, click **Open**, and then click **OK**.

### 20.1.5.5. Using Connector/ODBC with Microsoft Word or Excel

You can use Microsoft Word and Microsoft Excel to access information from a MySQL database using Connector/ODBC. Within Microsoft Word, this facility is most useful when importing data for mailmerge, or for tables and data to be included in reports. Within Microsoft Excel, you can execute queries on your MySQL server and import the data directly into an Excel Worksheet, presenting the data as a series of rows and columns.

With both applications, data is accessed and imported into the application using Microsoft Query, which enables you to execute a query through an ODBC source. You use Microsoft Query to build the SQL statement to be executed, selecting the tables, fields, selection criteria and sort order. For example, to insert information from a table in the World test database into an Excel spreadsheet, using the DSN samples shown in [Section 20.1.4, "Connector/ODBC Configuration"](#):

1. Create a new Worksheet.
2. From the **Data** menu, choose **Import External Data**, and then select **New Database Query**.
3. Microsoft Query will start. First, you need to choose the data source, by selecting an existing Data Source Name.

4. Within the **Query Wizard**, you must choose the columns that you want to import. The list of tables available to the user configured through the DSN is shown on the left, the columns that will be added to your query are shown on the right. The columns you choose are equivalent to those in the first section of a **SELECT** query. Click **NEXT** to continue.

5. You can filter rows from the query (the equivalent of a `WHERE` clause) using the `Filter Data` dialog. Click `NEXT` to continue.

6. Select an (optional) sort order for the data. This is equivalent to using a `ORDER BY` clause in your SQL query. You can select up to three fields for sorting the information returned by the query. Click `NEXT` to continue.

**Query Wizard - Sort Order**

Specify how you want your data sorted.  
If you don't want to sort the data, click Next.

Sort by  
Name  Ascending  Descending

Then by  Ascending  Descending

Then by  Ascending  Descending

< Back Next > Cancel

7. Select the destination for your query. You can select to return the data Microsoft Excel, where you can choose a worksheet and cell where the data will be inserted; you can continue to view the query and results within Microsoft Query, where you can edit the SQL query and further filter and sort the information returned; or you can create an OLAP Cube from the query, which can then be used directly within Microsoft Excel. Click FINISH.

**Query Wizard - Finish**

What would you like to do next?

Return Data to Microsoft Office Excel  View data or edit query in Microsoft Query  Create an OLAP Cube from this query

Save Query...

< Back Finish Cancel

The same process can be used to import data into a Word document, where the data will be inserted as a table. This can be used for mail merge purposes (where the field data is read from a Word table), or where you want to include data and reports within a report or other document.

### 20.1.5.6. Using Connector/ODBC with Crystal Reports

Crystal Reports can use an ODBC DSN to connect to a database from which you to extract data and information for reporting purposes.

### Note

There is a known issue with certain versions of Crystal Reports where the application is unable to open and browse tables and fields through an ODBC connection. Before using Crystal Reports with MySQL, please ensure that you have update to the latest version, including any outstanding service packs and hotfixes. For more information on this issue, see the [Business\) Objects Knowledgebase](#) for more information.

For example, to create a simple crosstab report within Crystal Reports XI, you should follow these steps:

1. Create a DSN using the [Data Sources \(ODBC\)](#) tool. You can either specify a complete database, including user name and password, or you can build a basic DSN and use Crystal Reports to set the user name and password.

For the purposes of this example, a DSN that provides a connection to an instance of the MySQL Sakila sample database has been created.

2. Open Crystal Reports and create a new project, or an open an existing reporting project into which you want to insert data from your MySQL data source.
3. Start the Cross-Tab Report Wizard, either by clicking on the option on the Start Page. Expand the **CREATE NEW CONNECTION** folder, then expand the **ODBC (RDO)** folder to obtain a list of ODBC data sources.

You will be asked to select a data source.

4. When you first expand the **ODBC (RDO)** folder you will be presented the Data Source Selection screen. From here you can select either a pre-configured DSN, open a file-based DSN or enter and manual connection string. For this example, the **SAKILA** DSN will be used.

If the DSN contains a user name/password combination, or you want to use different authentication credentials, click **NEXT** to enter the user name and password that you want to use. Otherwise, click **FINISH** to continue the data source selection wizard.

5. You will be returned the Cross-Tab Report Creation Wizard. You now need to select the database and tables that you want to include in your report. For our example, we will expand the selected Sakila database. Click the `city` table and use the `>` button to add the table to the report. Then repeat the action with the `country` table. Alternatively you can select multiple tables and add them to the report.

Finally, you can select the parent **SAKILA** resource and add of the tables to the report.

Once you have selected the tables you want to include, click **NEXT** to continue.

6. Crystal Reports will now read the table definitions and automatically identify the links between the tables. The identification of links between tables enables Crystal Reports to automatically lookup and summarize information based on all the tables in the database according to your query. If Crystal Reports is unable to perform the linking itself, you can manually create the links between fields in the tables you have selected.

Click NEXT to continue the process.

7. You can now select the columns and rows that you wish to include within the Cross-Tab report. Drag and drop or use the > buttons to add fields to each area of the report. In the example shown, we will report on cities, organized by country, incorporating a count of the number of cities within each country. If you want to browse the data, select a field and click the BROWSE DATA... button.

Click NEXT to create a graph of the results. Since we are not creating a graph from this data, click FINISH to generate the report.

8. The finished report will be shown, a sample of the output from the Sakila sample database is shown below.

		<b>Total</b>
<b>Total</b>		600
<b>Afghanistan</b>	<b>Total</b>	1
	<b>Kabul</b>	1
<b>Algeria</b>	<b>Total</b>	3
	<b>Batna</b>	1
	<b>Bchar</b>	1
	<b>Skikda</b>	1
<b>American Samoa</b>	<b>Total</b>	1
	<b>Tafuna</b>	1
<b>Angola</b>	<b>Total</b>	2
	<b>Benguela</b>	1
	<b>Namibe</b>	1
<b>Anguilla</b>	<b>Total</b>	1
	<b>South Hill</b>	1
<b>Argentina</b>	<b>Total</b>	13
	<b>Almirante Brow</b>	1

Once the ODBC connection has been opened within Crystal Reports, you can browse and add any fields within the available tables into your reports.

### 20.1.5.7. Connector/ODBC Programming

With a suitable ODBC Manager and the Connector/ODBC driver installed, any programming language or environment that can support ODBC should be able to connect to a MySQL database through Connector/ODBC.

This includes, but is certainly not limited to, Microsoft support languages (including Visual Basic, C# and interfaces such as ODBC.NET), Perl (through the DBI module, and the DBD::ODBC driver).

#### 20.1.5.7.1. Using Connector/ODBC with Visual Basic Using ADO, DAO and RDO

This section contains simple examples of the use of MySQL ODBC 3.51 Driver with ADO, DAO and RDO.

### 20.1.5.7.1.1. ADO: `rs.addNew`, `rs.delete`, and `rs.update`

The following ADO (ActiveX Data Objects) example creates a table `my_ado` and demonstrates the use of `rs.addNew`, `rs.delete`, and `rs.update`.

```
Private Sub myodbc_ado_Click()

Dim conn As ADODB.Connection
Dim rs As ADODB.Recordset
Dim fld As ADODB.Field
Dim sql As String

'connect to MySQL server using MySQL ODBC 3.51 Driver
Set conn = New ADODB.Connection
conn.ConnectionString = "DRIVER={MySQL ODBC 3.51 Driver};" _
& "SERVER=localhost;" _
& "DATABASE=test;" _
& "UID=venu;PWD=venu; OPTION=3"

conn.Open

'create table
conn.Execute "DROP TABLE IF EXISTS my_ado"
conn.Execute "CREATE TABLE my_ado(id int not null primary key, name varchar(20)," _
& "txt text, dt date, tm time, ts timestamp)"

'direct insert
conn.Execute "INSERT INTO my_ado(id,name,txt) values(1,100,'venu')"
conn.Execute "INSERT INTO my_ado(id,name,txt) values(2,200,'MySQL')"
conn.Execute "INSERT INTO my_ado(id,name,txt) values(3,300,'Delete'"

Set rs = New ADODB.Recordset
rs.CursorLocation = adUseServer

'fetch the initial table ..
rs.Open "SELECT * FROM my_ado", conn
Debug.Print rs.RecordCount
rs.MoveFirst
Debug.Print String(50, "-") & "Initial my_ado Result Set " & String(50, "-")
For Each fld In rs.Fields
Debug.Print fld.Name,
Next
Debug.Print

Do Until rs.EOF
For Each fld In rs.Fields
Debug.Print fld.Value,
Next
rs.MoveNext
Debug.Print
Loop
rs.Close

'rs insert
rs.Open "select * from my_ado", conn, adOpenDynamic, adLockOptimistic
rs.AddNew
rs!Name = "Monty"
rs!txt = "Insert row"
rs.Update
rs.Close

'rs update
rs.Open "SELECT * FROM my_ado"
rs!Name = "update"
rs!txt = "updated-row"
rs.Update
rs.Close

'rs update second time..
rs.Open "SELECT * FROM my_ado"
rs!Name = "update"
rs!txt = "updated-second-time"
rs.Update
rs.Close

'rs delete
rs.Open "SELECT * FROM my_ado"
rs.MoveNext
rs.MoveNext
rs.Delete
rs.Close

'fetch the updated table ..
rs.Open "SELECT * FROM my_ado", conn
Debug.Print rs.RecordCount
rs.MoveFirst
Debug.Print String(50, "-") & "Updated my_ado Result Set " & String(50, "-")
For Each fld In rs.Fields
Debug.Print fld.Name,
Next
Debug.Print

Do Until rs.EOF
For Each fld In rs.Fields
Debug.Print fld.Value,
```

```

Next
rs.MoveNext
Debug.Print
Loop
rs.Close
conn.Close
End Sub

```

### 20.1.5.7.1.2. DAO: `rs.addNew`, `rs.update`, and Scrolling

The following DAO (Data Access Objects) example creates a table `my_dao` and demonstrates the use of `rs.addNew`, `rs.update`, and result set scrolling.

```

Private Sub myodbc_dao_Click()

Dim ws As Workspace
Dim conn As Connection
Dim queryDef As queryDef
Dim str As String

'connect to MySQL using MySQL ODBC 3.51 Driver
Set ws = DBEngine.CreateWorkspace("", "venu", "venu", dbUseODBC)
str = "odbc;DRIVER={MySQL ODBC 3.51 Driver};_"
& "SERVER=localhost;_"
& "DATABASE=test;_"
& "UID=venu;PWD=venu; OPTION=3"
Set conn = ws.OpenConnection("test", dbDriverNoPrompt, False, str)

'Create table my_dao
Set queryDef = conn.CreateQueryDef("", "drop table if exists my_dao")
queryDef.Execute

Set queryDef = conn.CreateQueryDef("", "create table my_dao(Id INT AUTO_INCREMENT PRIMARY KEY, " _
& "Ts TIMESTAMP(14) NOT NULL, Name varchar(20), Id2 INT)")
queryDef.Execute

'Insert new records using rs.addNew
Set rs = conn.OpenRecordset("my_dao")
Dim i As Integer

For i = 10 To 15
rs.AddNew
rs!Name = "insert record" & i
rs!Id2 = i
rs.Update
Next i
rs.Close

'rs update..
Set rs = conn.OpenRecordset("my_dao")
rs.Edit
rs!Name = "updated-string"
rs.Update
rs.Close

'fetch the table back...
Set rs = conn.OpenRecordset("my_dao", dbOpenDynamic)
str = "Results:"
rs.MoveFirst
While Not rs.EOF
str = " " & rs!Id & " , " & rs!Name & " , " & rs!Ts & " , " & rs!Id2
Debug.Print "DATA:" & str
rs.MoveNext
Wend

'rs Scrolling
rs.MoveFirst
str = " FIRST ROW: " & rs!Id & " , " & rs!Name & " , " & rs!Ts & " , " & rs!Id2
Debug.Print str

rs.MoveLast
str = " LAST ROW: " & rs!Id & " , " & rs!Name & " , " & rs!Ts & " , " & rs!Id2
Debug.Print str

rs.MovePrevious
str = " LAST-1 ROW: " & rs!Id & " , " & rs!Name & " , " & rs!Ts & " , " & rs!Id2
Debug.Print str

'free all resources
rs.Close
queryDef.Close
conn.Close
ws.Close

End Sub

```

### 20.1.5.7.1.3. RDO: `rs.addNew` and `rs.update`

The following RDO (Remote Data Objects) example creates a table `my_rdo` and demonstrates the use of `rs.addNew` and `rs.update`.

```

Dim rs As rdoResultset
Dim cn As New rdoConnection
Dim cl As rdoColumn
Dim SQL As String

'cn.Connect = "DSN=test;"
cn.Connect = "DRIVER={MySQL ODBC 3.51 Driver};"_
& "SERVER=localhost;"_
& "DATABASE=test;"_
& "UID=venu;PWD=venu; OPTION=3"

cn.CursorDriver = rdUseOdbc
cn.EstablishConnection rdDriverPrompt

'drop table my_rdo
SQL = "drop table if exists my_rdo"
cn.Execute SQL, rdExecDirect

'create table my_rdo
SQL = "create table my_rdo(id int, name varchar(20))"
cn.Execute SQL, rdExecDirect

'insert - direct
SQL = "insert into my_rdo values (100,'venu')"
cn.Execute SQL, rdExecDirect

SQL = "insert into my_rdo values (200,'MySQL')"
cn.Execute SQL, rdExecDirect

'rs insert
SQL = "select * from my_rdo"
Set rs = cn.OpenResultset(SQL, rdOpenStatic, rdConcurRowVer, rdExecDirect)
rs.AddNew
rs!id = 300
rs!Name = "Insert1"
rs.Update
rs.Close

'rs insert
SQL = "select * from my_rdo"
Set rs = cn.OpenResultset(SQL, rdOpenStatic, rdConcurRowVer, rdExecDirect)
rs.AddNew
rs!id = 400
rs!Name = "Insert 2"
rs.Update
rs.Close

'rs update
SQL = "select * from my_rdo"
Set rs = cn.OpenResultset(SQL, rdOpenStatic, rdConcurRowVer, rdExecDirect)
rs.Edit
rs!id = 999
rs!Name = "updated"
rs.Update
rs.Close

'fetch back...
SQL = "select * from my_rdo"
Set rs = cn.OpenResultset(SQL, rdOpenStatic, rdConcurRowVer, rdExecDirect)
Do Until rs.EOF
For Each cl In rs.rdoColumns
Debug.Print cl.Value,
Next
rs.MoveNext
Debug.Print
Loop
Debug.Print "Row count="; rs.RowCount

'close
rs.Close
cn.Close

End Sub

```

### 20.1.5.7.2. Using Connector/ODBC with .NET

This section contains simple examples that demonstrate the use of Connector/ODBC drivers with ODBC.NET.

#### 20.1.5.7.2.1. Using Connector/ODBC with ODBC.NET and C# (C sharp)

The following sample creates a table `my_odbc_net` and demonstrates its use in C#.

```

/**
 * @sample      : mycon.cs
 * @purpose     : Demo sample for ODBC.NET using Connector/ODBC
 * @author      : Venu, <myodbc@lists.mysql.com>
 *
 * (C) Copyright MySQL AB, 1995-2006
 *
 **/

```

```

/* build command
 *
 * csc /t:exe
 * /out:mycon.exe mycon.cs
 * /r:Microsoft.Data.Odbc.dll
 */

using Console = System.Console;
using Microsoft.Data.Odbc;

namespace myodbc3
{
    class mycon
    {
        static void Main(string[] args)
        {
            try
            {
                //Connection string for Connector/ODBC 3.51
                string MyConString = "DRIVER={MySQL ODBC 3.51 Driver};" +
                    "SERVER=localhost;" +
                    "DATABASE=test;" +
                    "UID=venu;" +
                    "PASSWORD=venu;" +
                    "OPTION=3";

                //Connect to MySQL using Connector/ODBC
                OdbcConnection MyConnection = new OdbcConnection(MyConString);
                MyConnection.Open();

                Console.WriteLine("\n !!! success, connected successfully !!!\n");

                //Display connection information
                Console.WriteLine("Connection Information:");
                Console.WriteLine("\tConnection String:" +
                    MyConnection.ConnectionString);
                Console.WriteLine("\tConnection Timeout:" +
                    MyConnection.ConnectionTimeout);
                Console.WriteLine("\tDatabase:" +
                    MyConnection.Database);
                Console.WriteLine("\tDataSource:" +
                    MyConnection.DataSource);
                Console.WriteLine("\tDriver:" +
                    MyConnection.Driver);
                Console.WriteLine("\tServerVersion:" +
                    MyConnection.ServerVersion);

                //Create a sample table
                OdbcCommand MyCommand =
                    new OdbcCommand("DROP TABLE IF EXISTS my_odbc_net",
                    MyConnection);
                MyCommand.ExecuteNonQuery();
                MyCommand.CommandText =
                    "CREATE TABLE my_odbc_net(id int, name varchar(20), idb bigint)";
                MyCommand.ExecuteNonQuery();

                //Insert
                MyCommand.CommandText =
                    "INSERT INTO my_odbc_net VALUES(10,'venu', 300)";
                Console.WriteLine("INSERT, Total rows affected:" +
                    MyCommand.ExecuteNonQuery());

                //Insert
                MyCommand.CommandText =
                    "INSERT INTO my_odbc_net VALUES(20,'mysql',400)";
                Console.WriteLine("INSERT, Total rows affected:" +
                    MyCommand.ExecuteNonQuery());

                //Insert
                MyCommand.CommandText =
                    "INSERT INTO my_odbc_net VALUES(20,'mysql',500)";
                Console.WriteLine("INSERT, Total rows affected:" +
                    MyCommand.ExecuteNonQuery());

                //Update
                MyCommand.CommandText =
                    "UPDATE my_odbc_net SET id=999 WHERE id=20";
                Console.WriteLine("Update, Total rows affected:" +
                    MyCommand.ExecuteNonQuery());

                //COUNT(*)
                MyCommand.CommandText =
                    "SELECT COUNT(*) as TRows FROM my_odbc_net";
                Console.WriteLine("Total Rows:" +
                    MyCommand.ExecuteScalar());

                //Fetch
                MyCommand.CommandText = "SELECT * FROM my_odbc_net";
                OdbcDataReader MyDataReader;
                MyDataReader = MyCommand.ExecuteReader();
                while (MyDataReader.Read())
                {
                    if(string.Compare(MyConnection.Driver,"myodbc3.dll") == 0) {
                        //Supported only by Connector/ODBC 3.51
                        Console.WriteLine("Data:" + MyDataReader.GetInt32(0) + " " +
                            MyDataReader.GetString(1) + " " +
                            MyDataReader.GetInt64(2));
                    }
                }
            }
        }
    }
}

```

```
        else {
            //BIGINTs not supported by Connector/ODBC
            Console.WriteLine("Data:" + MyDataReader.GetInt32(0) + " " +
                MyDataReader.GetString(1) + " " +
                MyDataReader.GetInt32(2));
        }
    }

    //Close all resources
    MyDataReader.Close();
    MyConnection.Close();
}
catch (OdbcException MyOdbcException) //Catch any ODBC exception ..
{
    for (int i=0; i < MyOdbcException.Errors.Count; i++)
    {
        Console.WriteLine("ERROR #" + i + "\n" +
            "Message: " +
            MyOdbcException.Errors[i].Message + "\n" +
            "Native: " +
            MyOdbcException.Errors[i].NativeError.ToString() + "\n" +
            "Source: " +

'Catch ODBC Exception
Catch MyOdbcException As OdbcException
Dim i As Integer
Console.WriteLine(MyOdbcException.ToString)

'Catch program exception
Catch MyException As Exception
Console.WriteLine(MyException.ToString)
End Try
End Sub

```

## 20.1.6. Connector/ODBC Reference

This section provides reference material for the Connector/ODBC API, showing supported functions and methods, supported MySQL column types and the corresponding native type in Connector/ODBC, and the error codes returned by Connector/ODBC when a fault occurs.

### 20.1.6.1. Connector/ODBC API Reference

This section summarizes ODBC routines, categorized by functionality.

For the complete ODBC API reference, please refer to the ODBC Programmer's Reference at <http://msdn.microsoft.com/en-us/library/ms714177.aspx>.

An application can call [SQLGetInfo](#) function to obtain conformance information about Connector/ODBC. To obtain information about support for a specific function in the driver, an application can call [SQLGetFunctions](#).

#### Note

For backward compatibility, the Connector/ODBC 3.51 driver supports all deprecated functions.

The following tables list Connector/ODBC API calls grouped by task:

#### Connecting to a data source

Function name	C/ODBC 3.51	Standard	Purpose
<a href="#">SQLAllocHandle</a>	Yes	ISO 92	Obtains an environment, connection, statement, or descriptor handle.
<a href="#">SQLConnect</a>	Yes	ISO 92	Connects to a specific driver by data source name, user ID, and password.
<a href="#">SQLDriverConnect</a>	Yes	ODBC	Connects to a specific driver by connection string or requests that the Driver Manager and driver display connection dialog boxes for the user.

<a href="#">SQLAllocEnv</a>	Yes	Deprecated	Obtains an environment handle allocated from driver.
<a href="#">SQLAllocConnect</a>	Yes	Deprecated	Obtains a connection handle

#### Obtaining information about a driver and data source

Function name	C/ODBC 3.51	Standard	Purpose
<a href="#">SQLDataSources</a>	No	ISO 92	Returns the list of available data sources, handled by the Driver Manager
<a href="#">SQLDrivers</a>	No	ODBC	Returns the list of installed drivers and their attributes, handles by Driver Manager
<a href="#">SQLGetInfo</a>	Yes	ISO 92	Returns information about a specific driver and data source.
<a href="#">SQLGetFunctions</a>	Yes	ISO 92	Returns supported driver functions.
<a href="#">SQLGetTypeInfo</a>	Yes	ISO 92	Returns information about supported data types.

#### Setting and retrieving driver attributes

Function name	C/ODBC 3.51	Standard	Purpose
<a href="#">SQLSetConnectAttr</a>	Yes	ISO 92	Sets a connection attribute.
<a href="#">SQLGetConnectAttr</a>	Yes	ISO 92	Returns the value of a connection attribute.
<a href="#">SQLSetConnectOption</a>	Yes	Deprecated	Sets a connection option
<a href="#">SQLGetConnectOption</a>	Yes	Deprecated	Returns the value of a connection option
<a href="#">SQLSetEnvAttr</a>	Yes	ISO 92	Sets an environment attribute.
<a href="#">SQLGetEnvAttr</a>	Yes	ISO 92	Returns the value of an environment attribute.
<a href="#">SQLSetStmtAttr</a>	Yes	ISO 92	Sets a statement attribute.
<a href="#">SQLGetStmtAttr</a>	Yes	ISO 92	Returns the value of a statement attribute.
<a href="#">SQLSetStmtOption</a>	Yes	Deprecated	Sets a statement option
<a href="#">SQLGetStmtOption</a>	Yes	Deprecated	Returns the value of a statement option

#### Preparing SQL requests

Function name	C/ODBC 3.51	Standard	Purpose
<a href="#">SQLAllocStmt</a>	Yes	Deprecated	Allocates a statement handle
<a href="#">SQLPrepare</a>	Yes	ISO 92	Prepares an SQL statement for later execution.
<a href="#">SQLBindParameter</a>	Yes	ODBC	Assigns storage for a parameter in an SQL statement.
<a href="#">SQLGetCursorName</a>	Yes	ISO 92	Returns the cursor name associated with a statement handle.
<a href="#">SQLSetCursorName</a>	Yes	ISO 92	Specifies a cursor name.
<a href="#">SQLSetScrollOptions</a>	Yes	ODBC	Sets options that control cursor behavior.

#### Submitting requests

Function name	C/ODBC 3.51	Standard	Purpose
<a href="#">SQLExecute</a>	Yes	ISO 92	Executes a prepared statement.
<a href="#">SQLExecDirect</a>	Yes	ISO 92	Executes a statement
<a href="#">SQLNativeSql</a>	Yes	ODBC	Returns the text of an SQL statement as translated by the driver.
<a href="#">SQLDescribeParam</a>	Yes	ODBC	Returns the description for a specific parameter in a statement.
<a href="#">SQLNumParams</a>	Yes	ISO 92	Returns the number of parameters in a statement.
<a href="#">SQLParamData</a>	Yes	ISO 92	Used in conjunction with <a href="#">SQLPutData</a> to supply parameter data at execution time. (Useful for long data values.)

SQLPutData	Yes	ISO 92	Sends part or all of a data value for a parameter. (Useful for long data values.)
------------	-----	--------	---

#### Retrieving results and information about results

Function name	C/ODBC 3.51	Standard	Purpose
SQLRowCount	Yes	ISO 92	Returns the number of rows affected by an insert, update, or delete request.
SQLNumResultCols	Yes	ISO 92	Returns the number of columns in the result set.
SQLDescribeCol	Yes	ISO 92	Describes a column in the result set.
SQLColAttribute	Yes	ISO 92	Describes attributes of a column in the result set.
SQLColAttributes	Yes	Deprecated	Describes attributes of a column in the result set.
SQLFetch	Yes	ISO 92	Returns multiple result rows.
SQLFetchScroll	Yes	ISO 92	Returns scrollable result rows.
SQLExtendedFetch	Yes	Deprecated	Returns scrollable result rows.
SQLSetPos	Yes	ODBC	Positions a cursor within a fetched block of data and allows an application to refresh data in the rowset or to update or delete data in the result set.
SQLBulkOperations	Yes	ODBC	Performs bulk insertions and bulk bookmark operations, including update, delete, and fetch by bookmark.

#### Retrieving error or diagnostic information

Function name	C/ODBC 3.51	Standard	Purpose
SQLError	Yes	Deprecated	Returns additional error or status information
SQLGetDiagField	Yes	ISO 92	Returns additional diagnostic information (a single field of the diagnostic data structure).
SQLGetDiagRec	Yes	ISO 92	Returns additional diagnostic information (multiple fields of the diagnostic data structure).

#### Obtaining information about the data source's system tables (catalog functions) item

Function name	C/ODBC 3.51	Standard	Purpose
SQLColumnPrivileges	Yes	ODBC	Returns a list of columns and associated privileges for one or more tables.
SQLColumns	Yes	X/Open	Returns the list of column names in specified tables.
SQLForeignKeys	Yes	ODBC	Returns a list of column names that make up foreign keys, if they exist for a specified table.
SQLPrimaryKeys	Yes	ODBC	Returns the list of column names that make up the primary key for a table.
SQLSpecialColumns	Yes	X/Open	Returns information about the optimal set of columns that uniquely identifies a row in a specified table, or the columns that are automatically updated when any value in the row is updated by a transaction.
SQLStatistics	Yes	ISO 92	Returns statistics about a single table and the list of indexes associated with the table.
SQLTablePrivileges	Yes	ODBC	Returns a list of tables and the privileges associated with each table.
SQLTables	Yes	X/Open	Returns the list of table names stored in a specific data source.

#### Performing transactions

Function name	C/ODBC 3.51	Standard	Purpose
<a href="#">SQLTransact</a>	Yes	Deprecated	Commits or rolls back a transaction
<a href="#">SQLEndTran</a>	Yes	ISO 92	Commits or rolls back a transaction.

#### Terminating a statement

Function name	C/ODBC 3.51	Standard	Purpose
<a href="#">SQLFreeStmt</a>	Yes	ISO 92	Ends statement processing, discards pending results, and, optionally, frees all resources associated with the statement handle.
<a href="#">SQLCloseCursor</a>	Yes	ISO 92	Closes a cursor that has been opened on a statement handle.
<a href="#">SQLCancel</a>	Yes	ISO 92	Cancels an SQL statement.

#### Terminating a connection

Function name	C/ODBC 3.51	Standard	Purpose
<a href="#">SQLDisconnect</a>	Yes	ISO 92	Closes the connection.
<a href="#">SQLFreeHandle</a>	Yes	ISO 92	Releases an environment, connection, statement, or descriptor handle.
<a href="#">SQLFreeConnect</a>	Yes	Deprecated	Releases connection handle
<a href="#">SQLFreeEnv</a>	Yes	Deprecated	Releases an environment handle

## 20.1.6.2. Connector/ODBC Data Types

The following table illustrates how driver maps the server data types to default SQL and C data types.

Native Value	SQL Type	C Type
<code>bigint unsigned</code>	<code>SQL_BIGINT</code>	<code>SQL_C_UBIGINT</code>
<code>bigint</code>	<code>SQL_BIGINT</code>	<code>SQL_C_SBIGINT</code>
<code>bit</code>	<code>SQL_BIT</code>	<code>SQL_C_BIT</code>
<code>bit</code>	<code>SQL_CHAR</code>	<code>SQL_C_CHAR</code>
<code>blob</code>	<code>SQL_LONGVARBINARY</code>	<code>SQL_C_BINARY</code>
<code>bool</code>	<code>SQL_CHAR</code>	<code>SQL_C_CHAR</code>
<code>char</code>	<code>SQL_CHAR</code>	<code>SQL_C_CHAR</code>
<code>date</code>	<code>SQL_DATE</code>	<code>SQL_C_DATE</code>
<code>datetime</code>	<code>SQL_TIMESTAMP</code>	<code>SQL_C_TIMESTAMP</code>
<code>decimal</code>	<code>SQL_DECIMAL</code>	<code>SQL_C_CHAR</code>
<code>double precision</code>	<code>SQL_DOUBLE</code>	<code>SQL_C_DOUBLE</code>
<code>double</code>	<code>SQL_FLOAT</code>	<code>SQL_C_DOUBLE</code>
<code>enum</code>	<code>SQL_VARCHAR</code>	<code>SQL_C_CHAR</code>
<code>float</code>	<code>SQL_REAL</code>	<code>SQL_C_FLOAT</code>
<code>int unsigned</code>	<code>SQL_INTEGER</code>	<code>SQL_C_ULONG</code>
<code>int</code>	<code>SQL_INTEGER</code>	<code>SQL_C_SLONG</code>
<code>integer unsigned</code>	<code>SQL_INTEGER</code>	<code>SQL_C_ULONG</code>
<code>integer</code>	<code>SQL_INTEGER</code>	<code>SQL_C_SLONG</code>
<code>long varbinary</code>	<code>SQL_LONGVARBINARY</code>	<code>SQL_C_BINARY</code>
<code>long varchar</code>	<code>SQL_LONGVARCHAR</code>	<code>SQL_C_CHAR</code>
<code>longblob</code>	<code>SQL_LONGVARBINARY</code>	<code>SQL_C_BINARY</code>
<code>longtext</code>	<code>SQL_LONGVARCHAR</code>	<code>SQL_C_CHAR</code>

mediumblob	SQL_LONGVARIABLE	SQL_C_BINARY
mediumint unsigned	SQL_INTEGER	SQL_C_ULONG
mediumint	SQL_INTEGER	SQL_C_SLONG
mediumtext	SQL_LONGVARCHAR	SQL_C_CHAR
numeric	SQL_NUMERIC	SQL_C_CHAR
real	SQL_FLOAT	SQL_C_DOUBLE
set	SQL_VARCHAR	SQL_C_CHAR
smallint unsigned	SQL_SMALLINT	SQL_C_USHORT
smallint	SQL_SMALLINT	SQL_C_SSHORT
text	SQL_LONGVARCHAR	SQL_C_CHAR
time	SQL_TIME	SQL_C_TIME
timestamp	SQL_TIMESTAMP	SQL_C_TIMESTAMP
tinyblob	SQL_LONGVARIABLE	SQL_C_BINARY
tinyint unsigned	SQL_TINYINT	SQL_C_UTINYINT
tinyint	SQL_TINYINT	SQL_C_STINYINT
tinytext	SQL_LONGVARCHAR	SQL_C_CHAR
varchar	SQL_VARCHAR	SQL_C_CHAR
year	SQL_SMALLINT	SQL_C_SHORT

### 20.1.6.3. Connector/ODBC Error Codes

The following tables lists the error codes returned by the driver apart from the server errors.

Native Code	SQLSTATE 2	SQLSTATE 3	Error Message
500	01000	01000	General warning
501	01004	01004	String data, right truncated
502	01S02	01S02	Option value changed
503	01S03	01S03	No rows updated/deleted
504	01S04	01S04	More than one row updated/deleted
505	01S06	01S06	Attempt to fetch before the result set returned the first row set
506	07001	07002	<code>SQLBindParameter</code> not used for all parameters
507	07005	07005	Prepared statement not a cursor-specification

## 20.1.7. Connector/ODBC Notes and Tips

Here are some common notes and tips for using Connector/ODBC within different environments, applications and tools. The notes provided here are based on the experiences of Connector/ODBC developers and users.

### 20.1.7.1. Connector/ODBC General Functionality

This section provides help with common queries and areas of functionality in MySQL and how to use them with Connector/ODBC.

#### 20.1.7.1.1. Obtaining Auto-Increment Values

Obtaining the value of column that uses `AUTO_INCREMENT` after an `INSERT` statement can be achieved in a number of different ways. To obtain the value immediately after an `INSERT`, use a `SELECT` query with the `LAST_INSERT_ID()` function.

For example, using Connector/ODBC you would execute two separate statements, the `INSERT` statement and the `SELECT` query to obtain the auto-increment value.

```
INSERT INTO tbl (auto,text) VALUES(NULL,'text');
SELECT LAST_INSERT_ID();
```

If you do not require the value within your application, but do require the value as part of another `INSERT`, the entire process can be handled by executing the following statements:

```
INSERT INTO tbl (auto,text) VALUES(NULL,'text');
INSERT INTO tbl2 (id,text) VALUES(LAST_INSERT_ID(),'text');
```

Certain ODBC applications (including Delphi and Access) may have trouble obtaining the auto-increment value using the previous examples. In this case, try the following statement as an alternative:

```
SELECT * FROM tbl WHERE auto IS NULL;
```

See [Section 20.9.10.3, “How to Get the Unique ID for the Last Inserted Row”](#).

#### 20.1.7.1.2. Dynamic Cursor Support

Support for the `dynamic cursor` is provided in Connector/ODBC 3.51, but dynamic cursors are not enabled by default. You can enable this function within Windows by selecting the `Enable Dynamic Cursor` checkbox within the ODBC Data Source Administrator.

On other platforms, you can enable the dynamic cursor by adding [32](#) to the `OPTION` value when creating the DSN.

### 20.1.7.1.3. Connector/ODBC Performance

The Connector/ODBC driver has been optimized to provide very fast performance. If you experience problems with the performance of Connector/ODBC, or notice a large amount of disk activity for simple queries, there are a number of aspects you should check:

- Ensure that `ODBC Tracing` is not enabled. With tracing enabled, a lot of information is recorded in the tracing file by the ODBC Manager. You can check, and disable, tracing within Windows using the TRACING panel of the ODBC Data Source Administrator. Within Mac OS X, check the TRACING panel of ODBC Administrator. See [Section 20.1.4.8, “Getting an ODBC Trace File”](#).
- Make sure you are using the standard version of the driver, and not the debug version. The debug version includes additional checks and reporting measures.
- Disable the Connector/ODBC driver trace and query logs. These options are enabled for each DSN, so make sure to examine only the DSN that you are using in your application. Within Windows, you can disable the Connector/ODBC and query logs by modifying the DSN configuration. Within Mac OS X and Unix, ensure that the driver trace (option value 4) and query logging (option value 524288) are not enabled.

### 20.1.7.1.4. Setting ODBC Query Timeout in Windows

For more information on how to set the query timeout on Microsoft Windows when executing queries through an ODBC connection, read the Microsoft knowledgebase document at <http://support.microsoft.com/default.aspx?scid=kb%3Ben-us%3B153756>.

### 20.1.7.2. Connector/ODBC Application Specific Tips

Most programs should work with Connector/ODBC, but for each of those listed here, there are specific notes and tips to improve or enhance the way you work with Connector/ODBC and these applications.

With all applications you should ensure that you are using the latest Connector/ODBC drivers, ODBC Manager and any supporting libraries and interfaces used by your application. For example, on Windows, using the latest version of Microsoft Data Access Components (MDAC) will improve the compatibility with ODBC in general, and with the Connector/ODBC driver.

#### 20.1.7.2.1. Using Connector/ODBC with Microsoft Applications

The majority of Microsoft applications have been tested with Connector/ODBC, including Microsoft Office, Microsoft Access and the various programming languages supported within ASP and Microsoft Visual Studio.

##### 20.1.7.2.1.1. Microsoft Access

To improve the integration between Microsoft Access and MySQL through Connector/ODBC:

- For all versions of Access, you should enable the Connector/ODBC `Return matching rows` option. For Access 2.0, you should additionally enable the `Simulate ODBC 1.0` option.
- You should have a `TIMESTAMP` column in all tables that you want to be able to update. For maximum portability, do not use a length specification in the column declaration (which is unsupported within MySQL in versions earlier than 4.1).
- You should have a primary key in each MySQL table you want to use with Access. If not, new or updated rows may show up as `#DELETED#`.
- Use only `DOUBLE` float fields. Access fails when comparing with single-precision floats. The symptom usually is that new or updated rows may show up as `#DELETED#` or that you cannot find or update rows.
- If you are using Connector/ODBC to link to a table that has a `BIGINT` column, the results are displayed as `#DELETED#`. The work around solution is:
  - Have one more dummy column with `TIMESTAMP` as the data type.
  - Select the `Change BIGINT columns to INT` option in the connection dialog in ODBC DSN Administrator.
  - Delete the table link from Access and re-create it.

Old records may still display as `#DELETED#`, but newly added/updated records are displayed properly.

- If you still get the error [Another user has changed your data](#) after adding a `TIMESTAMP` column, the following trick may help you:

Do not use a `table` data sheet view. Instead, create a form with the fields you want, and use that `form` data sheet view. You should set the `DefaultValue` property for the `TIMESTAMP` column to `NOW()`. It may be a good idea to hide the `TIMESTAMP` column from view so your users are not confused.

- In some cases, Access may generate SQL statements that MySQL cannot understand. You can fix this by selecting "`Query|SQLSpecific|Pass-Through`" from the Access menu.
- On Windows NT, Access reports `BLOB` columns as `OLE OBJECTS`. If you want to have `MEMO` columns instead, you should change `BLOB` columns to `TEXT` with `ALTER TABLE`.
- Access cannot always handle the MySQL `DATE` column properly. If you have a problem with these, change the columns to `DATETIME`.
- If you have in Access a column defined as `BYTE`, Access tries to export this as `TINYINT` instead of `TINYINT UNSIGNED`. This gives you problems if you have values larger than 127 in the column.
- If you have very large (long) tables in Access, it might take a very long time to open them. Or you might run low on virtual memory and eventually get an `ODBC Query Failed` error and the table cannot open. To deal with this, select the following options:
  - Return Matching Rows (2)
  - Allow BIG Results (8).

These add up to a value of 10 (`OPTION=10`).

Some external articles and tips that may be useful when using Access, ODBC and Connector/ODBC:

- Read [How to Trap ODBC Login Error Messages in Access](#)
- [Optimizing Access ODBC Applications](#)
  - [Optimizing for Client/Server Performance](#)
  - [Tips for Converting Applications to Using ODBCdirect](#)
  - [Tips for Optimizing Queries on Attached SQL Tables](#)
- For a list of tools that can be used with Access and ODBC data sources, refer to [converters](#) section for list of available tools.

#### MySQL Enterprise

MySQL Enterprise subscribers will find more information about using ODBC with Access in Knowledge Base articles such as [Use MySQL-Specific Syntax with Microsoft Access](#). To subscribe to MySQL Enterprise see <http://www.mysql.com/products/enterprise/advisors.html>.

### 20.1.7.2.1.2. Microsoft Excel and Column Types

If you have problems importing data into Microsoft Excel, particularly numerical, date, and time values, this is probably because of a bug in Excel, where the column type of the source data is used to determine the data type when that data is inserted into a cell within the worksheet. The result is that Excel incorrectly identifies the content and this affects both the display format and the data when it is used within calculations.

To address this issue, use the `CONCAT()` function in your queries. The use of `CONCAT()` forces Excel to treat the value as a string, which Excel will then parse and usually correctly identify the embedded information.

However, even with this option, some data may be incorrectly formatted, even though the source data remains unchanged. Use the [Format Cells](#) option within Excel to change the format of the displayed information.

### 20.1.7.2.1.3. Microsoft Visual Basic

To be able to update a table, you must define a primary key for the table.

Visual Basic with ADO cannot handle big integers. This means that some queries like `SHOW PROCESSLIST` do not work properly. The fix is to use `OPTION=16384` in the ODBC connect string or to select the `Change BIGINT columns to INT` option in the Connector/ODBC connect screen. You may also want to select the [Return matching rows](#) option.

**MySQL Enterprise**

MySQL Enterprise subscribers can find a discussion about using VBA in the Knowledge Base article, [MySQL-Specific Syntax with VBA](http://www.mysql.com/products/enterprise/advisors.html). To subscribe to MySQL Enterprise see <http://www.mysql.com/products/enterprise/advisors.html>.

**20.1.7.2.1.4. Microsoft Visual InterDev**

If you have a `BIGINT` in your result, you may get the error `[Microsoft][ODBC Driver Manager] Driver does not support this parameter`. Try selecting the `Change BIGINT columns to INT` option in the Connector/ODBC connect screen.

**20.1.7.2.1.5. Visual Objects**

You should select the `Don't optimize column widths` option.

**20.1.7.2.1.6. Microsoft ADO**

When you are coding with the ADO API and Connector/ODBC, you need to pay attention to some default properties that aren't supported by the MySQL server. For example, using the `CursorLocation Property` as `adUseServer` returns a result of `-1` for the `RecordCount Property`. To have the right value, you need to set this property to `adUseClient`, as shown in the VB code here:

```
Dim myconn As New ADO.Connection
Dim myrs As New Recordset
Dim mySQL As String
Dim myrows As Long

myconn.Open "DSN=MyODBCsample"
mySQL = "SELECT * from user"
myrs.Source = mySQL
Set myrs.ActiveConnection = myconn
myrs.CursorLocation = adUseClient
myrs.Open
myrows = myrs.RecordCount

myrs.Close
myconn.Close
```

Another workaround is to use a `SELECT COUNT( *)` statement for a similar query to get the correct row count.

To find the number of rows affected by a specific SQL statement in ADO, use the `RecordsAffected` property in the ADO `execute` method. For more information on the usage of `execute` method, refer to <http://msdn.microsoft.com/library/default.asp?url=/library/en-us/ado270/htm/mdmthcnnextexecute.asp>.

For information, see [ActiveX Data Objects\(ADO\) Frequently Asked Questions](#).

**20.1.7.2.1.7. Using Connector/ODBC with Active Server Pages (ASP)**

You should select the `Return matching rows` option in the DSN.

For more information about how to access MySQL via ASP using Connector/ODBC, refer to the following articles:

- [Using MyODBC To Access Your MySQL Database Via ASP](#)
- [ASP and MySQL at DWAM.NT](#)

A Frequently Asked Questions list for ASP can be found at <http://support.microsoft.com/default.aspx?scid=/Support/ActiveServer/faq/data/adofaq.asp>.

**20.1.7.2.1.8. Using Connector/ODBC with Visual Basic (ADO, DAO and RDO) and ASP**

Some articles that may help with Visual Basic and ASP:

- [MySQL BLOB columns and Visual Basic 6](#) by Mike Hillyer (<mike@openwin.org>).
- [How to map Visual basic data type to MySQL types](#) by Mike Hillyer (<mike@openwin.org>).

**20.1.7.2.2. Using Connector/ODBC with Borland Applications**

With all Borland applications where the Borland Database Engine (BDE) is used, follow these steps to improve compatibility:

- Update to BDE 3.2 or newer.
- Enable the `Don't optimize column widths` option in the DSN.
- Enabled the `Return matching rows` option in the DSN.

#### 20.1.7.2.2.1. Using Connector/ODBC with Borland Builder 4

When you start a query, you can use the `Active` property or the `Open` method. Note that `Active` starts by automatically issuing a `SELECT * FROM ...` query. That may not be a good thing if your tables are large.

#### 20.1.7.2.2.2. Using Connector/ODBC with Delphi

Also, here is some potentially useful Delphi code that sets up both an ODBC entry and a BDE entry for Connector/ODBC. The BDE entry requires a BDE Alias Editor that is free at a Delphi Super Page near you. (Thanks to Bryan Brunton <bryan@flesherfab.com> for this):

```
fReg:= TRegistry.Create;
fReg.OpenKey('\Software\ODBC\ODBC.INI\DocumentsFab', True);
fReg.WriteString('Database', 'Documents');
fReg.WriteString('Description', '');
fReg.WriteString('Driver', 'C:\WINNT\System32\myodbc.dll');
fReg.WriteString('Flag', '1');
fReg.WriteString('Password', '');
fReg.WriteString('Port', '');
fReg.WriteString('Server', 'xmark');
fReg.WriteString('User', 'winuser');
fReg.OpenKey('\Software\ODBC\ODBC.INI\ODBC Data Sources', True);
fReg.WriteString('DocumentsFab', 'MySQL');
fReg.CloseKey;
fReg.Free;

Memo1.Lines.Add('DATABASE NAME=');
Memo1.Lines.Add('USER NAME=');
Memo1.Lines.Add('ODBC DSN=DocumentsFab');
Memo1.Lines.Add('OPEN MODE=READ/WRITE');
Memo1.Lines.Add('BATCH COUNT=200');
Memo1.Lines.Add('LANGDRIVER=');
Memo1.Lines.Add('MAX ROWS=-1');
Memo1.Lines.Add('SCHEMA CACHE DIR=');
Memo1.Lines.Add('SCHEMA CACHE SIZE=8');
Memo1.Lines.Add('SCHEMA CACHE TIME=-1');
Memo1.Lines.Add('SQLPASSTHRU MODE=SHARED AUTOCOMMIT');
Memo1.Lines.Add('SQLQRYMODE=');
Memo1.Lines.Add('ENABLE SCHEMA CACHE=FALSE');
Memo1.Lines.Add('ENABLE BCD=FALSE');
Memo1.Lines.Add('ROWSET SIZE=20');
Memo1.Lines.Add('BLOBS TO CACHE=64');
Memo1.Lines.Add('BLOB SIZE=32');

AliasEditor.Add('DocumentsFab', 'MySQL', Memo1.Lines);
```

#### 20.1.7.2.2.3. Using Connector/ODBC with C++ Builder

Tested with BDE 3.0. The only known problem is that when the table schema changes, query fields are not updated. BDE, however, does not seem to recognize primary keys, only the index named `PRIMARY`, although this has not been a problem.

#### 20.1.7.2.3. Using Connector/ODBC with ColdFusion

The following information is taken from the ColdFusion documentation:

Use the following information to configure ColdFusion Server for Linux to use the `unixODBC` driver with Connector/ODBC for MySQL data sources. You can download Connector/ODBC at <http://dev.mysql.com/downloads/connector/odbc/>.

ColdFusion version 4.5.1 allows you to use the ColdFusion Administrator to add the MySQL data source. However, the driver is not included with ColdFusion version 4.5.1. Before the MySQL driver appears in the ODBC data sources drop-down list, you must build and copy the Connector/ODBC driver to `/opt/coldfusion/lib/libmyodbc.so`.

The Contrib directory contains the program `mysdn-xxx.zip` which allows you to build and remove the DSN registry file for the Connector/ODBC driver on ColdFusion applications.

For more information and guides on using ColdFusion and Connector/ODBC, see the following external sites:

- [Troubleshooting Data Sources and Database Connectivity for Unix Platforms](#).

#### 20.1.7.2.4. Using Connector/ODBC with OpenOffice.org

Open Office (<http://www.openoffice.org>) [How-to: MySQL + OpenOffice](#). [How-to: OpenOffice + MyODBC + unixODBC](#).

#### 20.1.7.2.5. Using Connector/ODBC with Sambar Server

Sambar Server (<http://www.sambarserver.info>) [How-to: MyODBC + SambarServer + MySQL](#).

#### 20.1.7.2.6. Using Connector/ODBC with Pervasive Software DataJunction

You have to change it to output `VARCHAR` rather than `ENUM`, as it exports the latter in a manner that causes MySQL problems.

#### 20.1.7.2.7. Using Connector/ODBC with SunSystems Vision

You should select the `Return matching rows` option.

### 20.1.7.3. Connector/ODBC Errors and Resolutions (FAQ)

The following section details some common errors and their suggested fix or alternative solution. If you are still experiencing problems, use the Connector/ODBC mailing list; see [Section 20.1.8.1, “Connector/ODBC Community Support”](#).

Many problems can be resolved by upgrading your Connector/ODBC drivers to the latest available release. On Windows, you should also make sure that you have the latest versions of the Microsoft Data Access Components (MDAC) installed.

#### Questions

- [20.1.7.3.1](#): I have installed Connector/ODBC on Windows XP x64 Edition or Windows Server 2003 R2 x64. The installation completed successfully, but the Connector/ODBC driver does not appear in `ODBC Data Source Administrator`.
- [20.1.7.3.2](#): When connecting or using the TEST button in `ODBC Data Source Administrator` I get error 10061 (Cannot connect to server)
- [20.1.7.3.3](#): The following error is reported when using transactions: `Transactions are not enabled`
- [20.1.7.3.4](#): Access reports records as `#DELETED#` when inserting or updating records in linked tables.
- [20.1.7.3.5](#): How do I handle Write Conflicts or Row Location errors?
- [20.1.7.3.6](#): Exporting data from Access 97 to MySQL reports a `Syntax Error`.
- [20.1.7.3.7](#): Exporting data from Microsoft DTS to MySQL reports a `Syntax Error`.
- [20.1.7.3.8](#): Using ODBC.NET with Connector/ODBC, while fetching empty string (0 length), it starts giving the `SQL_NO_DATA` exception.
- [20.1.7.3.9](#): Using `SELECT COUNT(*) FROM tbl_name` within Visual Basic and ASP returns an error.
- [20.1.7.3.10](#): Using the `AppendChunk()` or `GetChunk()` ADO methods, the `Multiple-step operation generated errors. Check each status value` error is returned.
- [20.1.7.3.11](#): Access Returns `Another user had modified the record that you have modified while editing records on a Linked Table`.
- [20.1.7.3.12](#): When linking an application directly to the Connector/ODBC library under Unix/Linux, the application crashes.
- [20.1.7.3.13](#): Applications in the Microsoft Office suite are unable to update tables that have `DATE` or `TIMESTAMP` columns.
- [20.1.7.3.14](#): When connecting Connector/ODBC 5.x (Beta) to a MySQL 4.x server, the error `1044 Access denied for user 'xxx'@'%' to database 'information_schema'` is returned.
- [20.1.7.3.15](#): When calling `SQLTables`, the error `S1T00` is returned, but I cannot find this in the list of error numbers for Connector/ODBC.
- [20.1.7.3.16](#): When linking to tables in Access 2000 and generating links to tables programmatically, rather than through the table designer interface, you may get errors about tables not existing.
- [20.1.7.3.17](#): When I try to use batched statements, the execution of the batched statements fails.
- [20.1.7.3.18](#): When connecting to a MySQL server using ADODB and Excel, occasionally the application fails to communicate with the server and the error `Got an error reading communication packets` appears in the error log.
- [20.1.7.3.19](#): When using some applications to access a MySQL server using C/ODBC and outer joins, an error is reported re-

garding the Outer Join Escape Sequence.

- [20.1.7.3.20](#): I can correctly store extended characters in the database (Hebrew/CJK) using C/ODBC 5.1, but when I retrieve the data, the text is not formatted correctly and I get garbled characters.
- [20.1.7.3.21](#): I have a duplicate MySQL Connector/ODBC entry within my **INSTALLED PROGRAMS** list, but I cannot delete one of them.
- [20.1.7.3.22](#): When submitting queries with parameter binding using `UPDATE`, my field values are being truncated to 255 characters.
- [20.1.7.3.23](#): Is it possible to disable data-at-execution using a flag?

## Questions and Answers

### **20.1.7.3.1: I have installed Connector/ODBC on Windows XP x64 Edition or Windows Server 2003 R2 x64. The installation completed successfully, but the Connector/ODBC driver does not appear in ODBC Data Source Administrator.**

This is not a bug, but is related to the way Windows x64 editions operate with the ODBC driver. On Windows x64 editions, the Connector/ODBC driver is installed in the `%SystemRoot%\SysWOW64` folder. However, the default `ODBC Data Source Administrator` that is available through the `Administrative Tools` or `Control Panel` in Windows x64 Editions is located in the `%SystemRoot%\system32` folder, and only searches this folder for ODBC drivers.

On Windows x64 editions, you should use the ODBC administration tool located at `%SystemRoot%\SysWOW64\odbcad32.exe`, this will correctly locate the installed Connector/ODBC drivers and enable you to create a Connector/ODBC DSN.

This issue was originally reported as [Bug#20301](#).

### **20.1.7.3.2: When connecting or using the TEST button in ODBC Data Source Administrator I get error 10061 (Cannot connect to server)**

This error can be raised by a number of different issues, including server problems, network problems, and firewall and port blocking problems. For more information, see [Section B.1.2.2](#), “Can't connect to [local] MySQL server”.

### **20.1.7.3.3: The following error is reported when using transactions: Transactions are not enabled**

This error indicates that you are trying to use transactions with a MySQL table that does not support transactions. Transactions are supported within MySQL when using the `InnoDB` database engine. In versions of MySQL before MySQL 5.1 you may also use the `BDB` engine.

You should check the following before continuing:

- Verify that your MySQL server supports a transactional database engine. Use `SHOW ENGINES` to obtain a list of the available engine types.
- Verify that the tables you are updating use a transaction database engine.
- Ensure that you have not enabled the `disable transactions` option in your DSN.

### **20.1.7.3.4: Access reports records as #DELETED# when inserting or updating records in linked tables.**

If the inserted or updated records are shown as `#DELETED#` in the access, then:

- If you are using Access 2000, you should get and install the newest (version 2.6 or higher) Microsoft MDAC ([Microsoft Data Access Components](#)) from <http://support.microsoft.com/kb/110093>. This fixes a bug in Access that when you export data to MySQL, the table and column names aren't specified.

You should also get and apply the Microsoft Jet 4.0 Service Pack 5 (SP5) which can be found at <http://support.microsoft.com/default.aspx?scid=kb;EN-US;q239114>. This fixes some cases where columns are marked as `#DELETED#` in Access.

- For all versions of Access, you should enable the Connector/ODBC `Return matching rows` option. For Access 2.0, you should additionally enable the `Simulate ODBC 1.0` option.
- You should have a timestamp in all tables that you want to be able to update.
- You should have a primary key in the table. If not, new or updated rows may show up as `#DELETED#`.

- Use only `DOUBLE` float fields. Access fails when comparing with single-precision floats. The symptom usually is that new or updated rows may show up as `#DELETED#` or that you cannot find or update rows.
- If you are using Connector/ODBC to link to a table that has a `BIGINT` column, the results are displayed as `#DELETED`. The work around solution is:
  - Have one more dummy column with `TIMESTAMP` as the data type.
  - Select the `Change BIGINT columns to INT` option in the connection dialog in ODBC DSN Administrator.
  - Delete the table link from Access and re-create it.

Old records still display as `#DELETED#`, but newly added/updated records are displayed properly.

#### 20.1.7.3.5: How do I handle Write Conflicts or Row Location errors?

If you see the following errors, select the `Return Matching Rows` option in the DSN configuration dialog, or specify `OPTION=2`, as the connection parameter:

```
Write Conflict. Another user has changed your data.
Row cannot be located for updating. Some values may have been changed
since it was last read.
```

#### 20.1.7.3.6: Exporting data from Access 97 to MySQL reports a Syntax Error.

This error is specific to Access 97 and versions of Connector/ODBC earlier than 3.51.02. Update to the latest version of the Connector/ODBC driver to resolve this problem.

#### 20.1.7.3.7: Exporting data from Microsoft DTS to MySQL reports a Syntax Error.

This error occurs only with MySQL tables using the `TEXT` or `VARCHAR` data types. You can fix this error by upgrading your Connector/ODBC driver to version 3.51.02 or higher.

#### 20.1.7.3.8: Using ODBC.NET with Connector/ODBC, while fetching empty string (0 length), it starts giving the SQL\_NO\_DATA exception.

You can get the patch that addresses this problem from <http://support.microsoft.com/default.aspx?scid=kb;EN-US;q319243>.

#### 20.1.7.3.9: Using `SELECT COUNT(*) FROM tbl_name` within Visual Basic and ASP returns an error.

This error occurs because the `COUNT(*)` expression is returning a `BIGINT`, and ADO cannot make sense of a number this big. Select the `Change BIGINT columns to INT` option (option value 16384).

#### 20.1.7.3.10: Using the `AppendChunk()` or `GetChunk()` ADO methods, the Multiple-step operation generated errors. Check each status value error is returned.

The `GetChunk()` and `AppendChunk()` methods from ADO doesn't work as expected when the cursor location is specified as `adUseServer`. On the other hand, you can overcome this error by using `adUseClient`.

A simple example can be found from [http://www.dwam.net/iishelp/ado/docs/adomth02\\_4.htm](http://www.dwam.net/iishelp/ado/docs/adomth02_4.htm)

#### 20.1.7.3.11: Access Returns Another user had modified the record that you have modified while editing records on a Linked Table.

In most cases, this can be solved by doing one of the following things:

- Add a primary key for the table if one doesn't exist.
- Add a timestamp column if one doesn't exist.
- Only use double-precision float fields. Some programs may fail when they compare single-precision floats.

If these strategies do not help, you should start by making a log file from the ODBC manager (the log you get when requesting logs from ODBCADMIN) and a Connector/ODBC log to help you figure out why things go wrong. For instructions, see [Section 20.1.4.8, "Getting an ODBC Trace File"](#).

#### 20.1.7.3.12: When linking an application directly to the Connector/ODBC library under Unix/Linux, the application crashes.

Connector/ODBC 3.51 under Unix/Linux is not compatible with direct application linking. You must use a driver manager, such as iODBC or unixODBC to connect to an ODBC source.

**20.1.7.3.13: Applications in the Microsoft Office suite are unable to update tables that have `DATE` or `TIMESTAMP` columns.**

This is a known issue with Connector/ODBC. You must ensure that the field has a default value (rather than `NULL` and that the default value is non-zero (i.e. the default value is not `0000-00-00 00:00:00`).

**20.1.7.3.14: When connecting Connector/ODBC 5.x (Beta) to a MySQL 4.x server, the error `1044 Access denied for user 'xxx'@'%' to database 'information_schema'` is returned.**

Connector/ODBC 5.x is designed to work with MySQL 5.0 or later, taking advantage of the `INFORMATION_SCHEMA` database to determine data definition information. Support for MySQL 4.1 is planned for the final release.

**20.1.7.3.15: When calling `SQLTables`, the error `S1T00` is returned, but I cannot find this in the list of error numbers for Connector/ODBC.**

The `S1T00` error indicates that a general timeout has occurred within the ODBC system and is not a MySQL error. Typically it indicates that the connection you are using is stale, the server is too busy to accept your request or that the server has gone away.

**20.1.7.3.16: When linking to tables in Access 2000 and generating links to tables programmatically, rather than through the table designer interface, you may get errors about tables not existing.**

There is a known issue with a specific version of the `msjet40.dll` that exhibits this issue. The version affected is 4.0.9025.0. Reverting to an older version will enable you to create the links. If you have recently updated your version, check your `WINDOWS` directory for the older version of the file and copy it to the drivers directory.

**20.1.7.3.17: When I try to use batched statements, the execution of the batched statements fails.**

Batched statement support was added in 3.51.18. Support for batched statements is not enabled by default. You must enable option `FLAG_MULTI_STATEMENTS`, value 67108864, or select the `ALLOW MULTIPLE STATEMENTS` flag within a GUI configuration.

**20.1.7.3.18: When connecting to a MySQL server using `ADODB` and Excel, occasionally the application fails to communicate with the server and the error `Got an error reading communication packets` appears in the error log.**

This error may be related to Keyboard Logger 1.1 from PanteraSoft.com, which is known to interfere with the network communication between MySQL Connector/ODBC and MySQL.

**20.1.7.3.19: When using some applications to access a MySQL server using `C/ODBC` and outer joins, an error is reported regarding the Outer Join Escape Sequence.**

This is a known issue with MySQL Connector/ODBC which is not correctly parsing the "Outer Join Escape Sequence", as per the specs at [Microsoft ODBC Specs](#). Currently, Connector/ODBC will return value `> 0` when asked for `SQL_OJ_CAPABILITIES` even though no parsing takes place in the driver to handle the outer join escape sequence.

**20.1.7.3.20: I can correctly store extended characters in the database (Hebrew/CJK) using `C/ODBC 5.1`, but when I retrieve the data, the text is not formatted correctly and I get garbled characters.**

When using ASP and UTF8 characters you should add the following to your ASP files to ensure that the data returned is correctly encoded:

```
Response.CodePage = 65001
Response.CharSet = "utf-8"
```

**20.1.7.3.21: I have a duplicate MySQL Connector/ODBC entry within my `INSTALLED PROGRAMS` list, but I cannot delete one of them.**

This problem can occur when you upgrade an existing Connector/ODBC installation, rather than removing and then installing the updated version.

### Warning

To fix the problem you should use any working uninstallers to remove existing installations and then may have to edit the contents of the registry. Make sure you have a backup of your registry information before attempting any editing of the registry contents.

**20.1.7.3.22: When submitting queries with parameter binding using `UPDATE`, my field values are being truncated to 255 characters.**

You should ensure that the `FLAG_BIG_PACKETS` option is set for your connection. This removes the 255 character limitation on bound parameters.

### 20.1.7.3.23: Is it possible to disable data-at-execution using a flag?

If you do not wish to use data-at-execution, simply remove the corresponding calls. For example:

```
SQLLEN ylen = SQL_LEN_DATA_AT_EXEC(10);
SQLBindCol(hstmt,2,SQL_C_BINARY, buf, 10, &ylen);
```

Would become:

```
SQLBindCol(hstmt,2,SQL_C_BINARY, buf, 10, NULL);
```

Note that in the call to `SQLBindCol()`, `&ylen` has been replaced by `NULL`.

For further information please refer to the [MSDN documentation](#) for `SQLBindCol()`.

## 20.1.8. Connector/ODBC Support

There are many different places where you can get support for using Connector/ODBC. You should always try the Connector/ODBC Mailing List or Connector/ODBC Forum. See [Section 20.1.8.1, “Connector/ODBC Community Support”](#), for help before reporting a specific bug or issue to MySQL.

### 20.1.8.1. Connector/ODBC Community Support

Sun Microsystems, Inc. provides assistance to the user community by means of its mailing lists. For Connector/ODBC-related issues, you can get help from experienced users by using the `<myodbc@lists.mysql.com>` mailing list. Archives are available online at <http://lists.mysql.com/myodbc>.

For information about subscribing to MySQL mailing lists or to browse list archives, visit <http://lists.mysql.com/>. See [Section 1.5.1, “MySQL Mailing Lists”](#).

Community support from experienced users is also available through the [ODBC Forum](#). You may also find help from other users in the other MySQL Forums, located at <http://forums.mysql.com>. See [Section 1.5.2, “MySQL Community Support at the MySQL Forums”](#).

### 20.1.8.2. How to Report Connector/ODBC Problems or Bugs

If you encounter difficulties or problems with Connector/ODBC, you should start by making a log file from the [ODBC Manager](#) (the log you get when requesting logs from `ODBC ADMIN`) and Connector/ODBC. The procedure for doing this is described in [Section 20.1.4.8, “Getting an ODBC Trace File”](#).

Check the Connector/ODBC trace file to find out what could be wrong. You should be able to determine what statements were issued by searching for the string `>mysql_real_query` in the `myodbc.log` file.

You should also try issuing the statements from the `mysql` client program or from `admindemo`. This helps you determine whether the error is in Connector/ODBC or MySQL.

If you find out something is wrong, please only send the relevant rows (maximum 40 rows) to the `myodbc` mailing list. See [Section 1.5.1, “MySQL Mailing Lists”](#). Please never send the whole Connector/ODBC or ODBC log file!

You should ideally include the following information with the email:

- Operating system and version
- Connector/ODBC version
- ODBC Driver Manager type and version
- MySQL server version
- ODBC trace from Driver Manager
- Connector/ODBC log file from Connector/ODBC driver
- Simple reproducible sample

Remember that the more information you can supply to us, the more likely it is that we can fix the problem!

Also, before posting the bug, check the MyODBC mailing list archive at <http://lists.mysql.com/myodbc>.

If you are unable to find out what is wrong, the last option is to create an archive in `tar` or Zip format that contains a Connector/ODBC trace file, the ODBC log file, and a `README` file that explains the problem. You can send this to <ftp://ftp.mysql.com/pub/mysql/upload/>. Only MySQL engineers have access to the files you upload, and we are very discreet with the data.

If you can create a program that also demonstrates the problem, please include it in the archive as well.

If the program works with another SQL server, you should include an ODBC log file where you perform exactly the same SQL statements so that we can compare the results between the two systems.

Remember that the more information you can supply to us, the more likely it is that we can fix the problem.

### 20.1.8.3. How to Submit a Connector/ODBC Patch

You can send a patch or suggest a better solution for any existing code or problems by sending a mail message to [<myodbc@lists.mysql.com>](mailto:myodbc@lists.mysql.com).

### 20.1.8.4. Connector/ODBC Change History

The Connector/ODBC Change History (Changelog) is located with the main Changelog for MySQL. See [Section E.4, “MySQL Connector/ODBC \(MyODBC\) Change History”](#).

### 20.1.8.5. Credits

These are the developers that have worked on the Connector/ODBC and Connector/ODBC 3.51 Drivers from MySQL AB.

- Michael (Monty) Widenius
- Venu Anuganti
- Peter Harvey

## 20.2. MySQL Connector/NET

Connector/NET enables developers to easily create .NET applications that require secure, high-performance data connectivity with MySQL. It implements the required ADO.NET interfaces and integrates into ADO.NET aware tools. Developers can build applications using their choice of .NET languages. Connector/NET is a fully managed ADO.NET driver written in 100% pure C#.

Connector/NET includes full support for:

- MySQL 6.0 features
- MySQL 5.1 features
- MySQL 5.0 features (such as stored procedures)
- MySQL 4.1 features (server-side prepared statements, Unicode, and shared memory access, and so forth)
- Large-packet support for sending and receiving rows and BLOBs up to 2 gigabytes in size.
- Protocol compression which allows for compressing the data stream between the client and server.
- Support for connecting using TCP/IP sockets, named pipes, or shared memory on Windows.
- Support for connecting using TCP/IP sockets or Unix sockets on Unix.
- Support for the Open Source Mono framework developed by Novell.
- Fully managed, does not utilize the MySQL client library.

This document is intended as a user's guide to Connector/NET and includes a full syntax reference. Syntax information is also included within the [Documentation.chm](#) file included with the Connector/NET distribution.

If you are using MySQL 5.0 or later, and Visual Studio as your development environment, you may want also want to use the MySQL Visual Studio Plugin. The plugin acts as a DDEX (Data Designer Extensibility) provider, enabling you to use the data design tools within Visual Studio to manipulate the schema and objects within a MySQL database. For more information, see [Sec-](#)

tion 20.2.3, “Visual Studio User Guide”.

### Note

Connector/NET 5.1.2 and later include the Visual Studio Plugin by default.

#### Key topics:

- For connection string properties when using the `MySqlConnection` class, see [Section 20.2.4.5, “Connector/NET Connection String Options Reference”](#).

## 20.2.1. Connector/NET Versions

There are several versions of Connector/NET available:

- Connector/NET 1.0 includes support for MySQL 4.0, and MySQL 5.0 features, and full compatibility with the ADO.NET driver interface.
- Connector/NET 5.0 includes support for MySQL 4.0, MySQL 4.1, MySQL 5.0 and MySQL 5.1 features. Connector/NET 5.0 also includes full support for the ADO.Net 2.0 interfaces and subclasses, includes support for the usage advisor and performance monitor (PerfMon) hooks.
- Connector/NET 5.1 includes support for MySQL 4.0, MySQL 5.0, MySQL 5.1 and MySQL 6.0 (Falcon Preview) features. Connector/NET 5.1 also includes support for a new membership/role provider, Compact Framework 2.0, a new stored procedure parser and improvements to `GetSchema`. Connector/NET 5.1 also includes the Visual Studio Plugin as a standard installable component.
- Connector/NET 5.2 includes support for MySQL 4.0, MySQL 5.0, MySQL 5.1 and MySQL 6.0 (Falcon Preview) features. Connector/NET 5.2 also includes support for a new membership/role provider, Compact Framework 2.0, a new stored procedure parser and improvements to `GetSchema`. Connector/NET 5.2 also includes the Visual Studio Plugin as a standard installable component.
- Connector/NET 6.0 includes support for MySQL 4.0, MySQL 5.0, MySQL 5.1 and MySQL 6.0. Connector/NET 6.0 is currently available as an Alpha release.

The latest source code for Connector/NET can be downloaded from the MySQL public Subversion server. For further details see [Section 20.2.2.3, “Installing Connector/NET from the source code”](#).

The following table shows the .NET Framework version required, and MySQL Server version supported by Connector/NET:

Connector/NET version	ADO.NET version supported	.NET Framework version required	MySQL Server version supported
1.0	1.x	1.x	4.0, 5.0
5.0	1.x+	1.x+	4.0, 5.0
5.1	1.x+	1.x+	4.0, 5.0, 5.1, 6.0
5.2	1.x+	1.x+	4.0, 5.0, 5.1, 6.0
6.0	2.x+	2.x+	4.0, 5.0, 5.1, 6.0

### Note

Version numbers for MySQL products are formatted as X.X.X. However, Windows tools (Control Panel, properties display) may show the version numbers as XX.XX.XX. For example, the official MySQL formatted version number 5.0.9 may be displayed by Windows tools as 5.00.09. The two versions are the same; only the number display format is different.

## 20.2.2. Connector/NET Installation

Connector/NET runs on any platform that supports the .NET framework. The .NET framework is primarily supported on recent versions of Microsoft Windows, and is supported on Linux through the Open Source Mono framework (see <http://www.mono-project.com>).

Connector/NET is available for download from <http://dev.mysql.com/downloads/connector/net/5.2.html>.

## 20.2.2.1. Installing Connector/NET on Windows

On Windows, installation is supported either through a binary installation process or by downloading a Zip file with the Connector/NET components.

Before installing, you should ensure that your system is up to date, including installing the latest version of the .NET Framework.

### 20.2.2.1.1. Installing Connector/NET using the Installer

Using the installer is the most straightforward method of installing Connector/NET on Windows and the installed components include the source code, test code and full reference documentation.

Connector/NET is installed through the use of a Windows Installer (.msi) installation package, which can be used to install Connector/NET on all Windows operating systems. The MSI package is contained within a ZIP archive named `mysql-connector-net-version.zip`, where `version` indicates the Connector/NET version.

To install Connector/NET:

1. Double click on the MSI installer file extracted from the Zip you downloaded. Click NEXT to start the installation.

2. You must choose the type of installation that you want to perform.

For most situations, the Typical installation will be suitable. Click the TYPICAL button and proceed to Step 5. A Complete installation installs all the available files. To conduct a Complete installation, click the COMPLETE button and proceed to step 5. If you want to customize your installation, including choosing the components to install and some installation options, click the CUSTOM button and proceed to Step 3.

The Connector/NET installer will register the connector within the Global Assembly Cache (GAC) - this will make the Connector/NET component available to all applications, not just those where you explicitly reference the Connector/NET component. The installer will also create the necessary links in the Start menu to the documentation and release notes.

3. If you have chosen a custom installation, you can select the individual components that you want to install, including the core interface component, supporting documentation (a CHM file) samples and examples and the source code. Select the items, and their installation level, and then click NEXT to continue the installation.

#### Note

For Connector/NET 1.0.8 or lower and Connector 5.0.4 and lower the installer will attempt to install binaries for both 1.x and 2.x of the .NET Framework. If you only have one version of the framework installed, the connector installation may fail. If this happens, you can choose the framework version to be installed through the custom installation step.

4. You will be given a final opportunity to confirm the installation. Click **INSTALL** to copy and install the files onto your machine.

5. Once the installation has been completed, click FINISH to exit the installer.

Unless you choose otherwise, Connector/NET is installed in `C:\Program Files\MySQL\MySQL Connector Net X.X.X`, where `X.X.X` is replaced with the version of Connector/NET you are installing. New installations do not overwrite existing versions of Connector/NET.

Depending on your installation type, the installed components will include some or all of the following components:

- `bin` - Connector/NET MySQL libraries for different versions of the .NET environment.
- `docs` - contains a CHM of the Connector/NET documentation.
- `samples` - sample code and applications that use the Connector/NET component.
- `src` - the source code for the Connector/NET component.

You may also use the `/quiet` or `/q` command-line option with the `msiexec` tool to install the Connector/NET package automatically (using the default options) with no notification to the user. Using this method the user cannot select options. Additionally, no prompts, messages or dialog boxes will be displayed.

```
C:\> msiexec /package conector-net.msi /quiet
```

To provide a progress bar to the user during automatic installation, use the `/passive` option.

### 20.2.2.1.2. Installing Connector/NET using the Zip packages

If you are having problems running the installer, you can download a Zip file without an installer as an alternative. That file is called `mysql-connector-net-version-noinstall.zip`. Once downloaded, you can extract the files to a location of your choice.

The file contains the following directories:

- [bin](#) - Connector/NET MySQL libraries for different versions of the .NET environment.
- [Docs](#) - contains a CHM of the Connector/NET documentation.
- [Samples](#) - sample code and applications that use the Connector/NET component.

Connector/NET 6.0.x has a different directory structure:

- [Assemblies](#) - contains a collection of DLLs that make up the connector functionality.
- [Documentation](#) - contains the Connector/NET documentation as a CHM file.
- [Samples](#) - sample code and applications that use the Connector/NET component.

There is also another Zip file available for download called [mysql-connector-net-version-src.zip](#). This file contains the source code distribution.

The file contains the following directories:

- [Documentation](#) - This folder contains the source files to build the documentation into the compiled HTML (CHM) format.
- [Installer](#) - This folder contains the source files to build the Connector/NET installer program.
- [MySQL.Data](#) - This folder contains the source files for the core data provider.
- [MySQL.VisualStudio](#) - This folder contains the source files for the Microsoft Visual Studio extensions.
- [MySQL.Web](#) - This folder contains the source files for the web providers. This includes code for the membership provider, role provider and profile provider. These are used in ASP.NET web sites.
- [Samples](#) - This folder contains the source files for several example applications.
- [Tests](#) - This folder contains a spreadsheet listing test cases.
- [VisualStudio](#) - Contains resources used by the Visual Studio plug in.

Finally, you need to ensure that [MySQL.Data.dll](#) is accessible to your program at build time (and run time). If using Microsoft Visual Studio you will need to add [MySQL.Data](#) as a Reference to your project.

### 20.2.2.2. Installing Connector/NET on Unix with Mono

There is no installer available for installing the Connector/NET component on your Unix installation. Before installing, please ensure that you have a working Mono project installation. You can test whether your system has Mono installed by typing:

```
shell> mono --version
```

The version of the Mono JIT compiler will be displayed.

To compile C# source code you will also need to make sure a Mono C# compiler, is installed. Note that there are two Mono C# compilers available, [mcs](#), which accesses the 1.0-profile libraries, and [gmcs](#), which accesses the 2.0-profile libraries.

To install Connector/NET on Unix/Mono:

1. Download the [mysql-connector-net-version-noinstall.zip](#) and extract the contents to a directory of your choice, for example: [~/connector-net/](#).
2. In the directory where you unzipped the connector to, change into the [bin](#) directory. Ensure the file [MySQL.Data.dll](#) is present.
3. You must register the Connector/NET component, [MySQL.Data](#), in the Global Assembly Cache (GAC). In the current directory enter the [gacutil](#) command:

```
root-shell> gacutil /i MySQL.Data.dll
```

This will register [MySQL.Data](#) into the GAC. You can check this by listing the contents of [/usr/lib/mono/gac](#), where

you will find `MySQL.Data` if the registration has been successful.

You are now ready to compile your application. You must ensure that when you compile your application you include the Connector/NET component using the `-r:` command-line option. For example:

```
shell> gmcsc -r:System.dll -r:System.Data.dll -r:MySQL.Data.dll HelloWorld.cs
```

Note, the assemblies that need to be referenced will depend on the requirements of the application, but applications using Connector/NET will need to provide `-r:MySQL.Data` as a minimum.

You can further check your installation by running the compiled program, for example:

```
shell> mono HelloWorld.exe
```

### 20.2.2.3. Installing Connector/NET from the source code

#### Caution

You should read this section only if you are interested in helping us test our new code. If you just want to get Connector/NET up and running on your system, you should use a standard release distribution.

#### Obtaining the source code

To be able to access the Connector/NET source tree, you must have Subversion installed. Subversion is freely available from <http://subversion.tigris.org/>.

The most recent development source tree is available from our public Subversion trees at <http://dev.mysql.com/tech-resources/sources.html>.

To checkout out the Connector/NET sources, change to the directory where you want the copy of the Connector/NET tree to be stored, then use the following command:

```
shell> svn co http://svn.mysql.com/svnpublic/connector-net
```

Source packages are also available on the downloads page.

#### Building the source code on Windows

The following procedure can be used to build the connector on Microsoft Windows.

- Obtain the source code, either from the Subversion server, or through one of the prepared source code packages.
- Navigate to the root of the source code tree.
- A Microsoft Visual Studio 2005 solution file is available to build the connector, this is called `MySQL-VS2005.sln`. Click on this file to load the solution into Visual Studio.
- Select **BUILD**, **BUILD SOLUTION** from the main menu to build the solution.

#### Building the source code on Unix

Support for building Connector/NET on Mono/Unix is currently not available.

## 20.2.3. Visual Studio User Guide

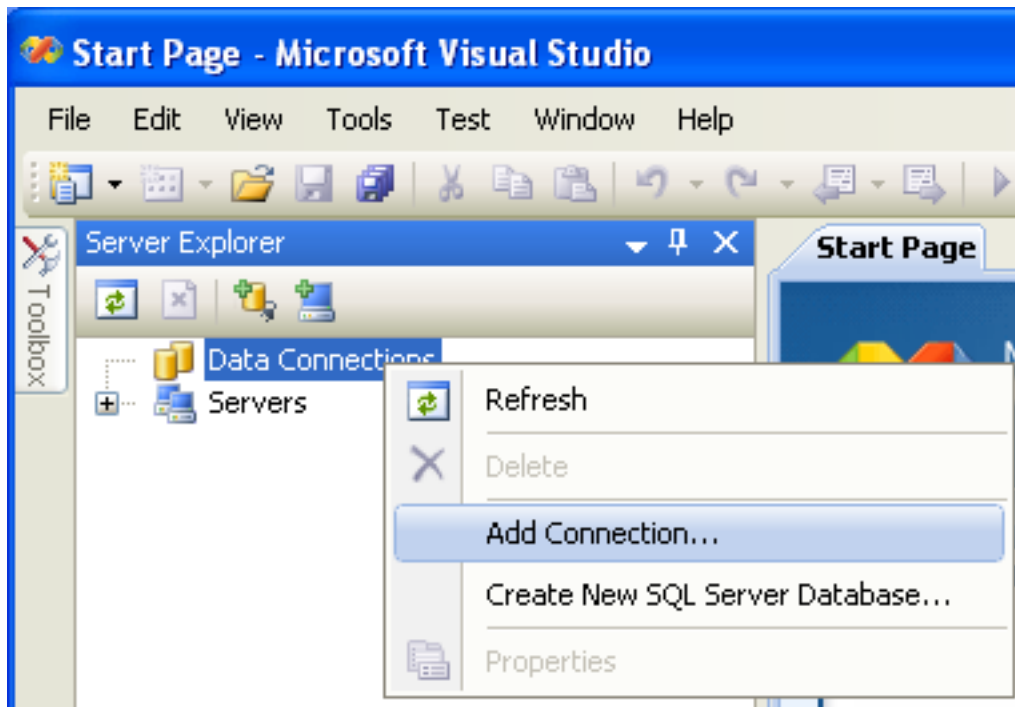

### 20.2.3.1. Making a connection

Once the connector is installed, you can use it to create, modify, and delete connections to MySQL databases. To create a connection with a MySQL database, perform the following steps:

- Start Visual Studio, and open the Server Explorer window (**VIEW**, **SERVER EXPLORER** option in the main Visual Studio menu, or **Ctrl+W, L** hot keys).
- Right-click on the Data Connections node, and choose the **ADD CONNECTION...** menu item.

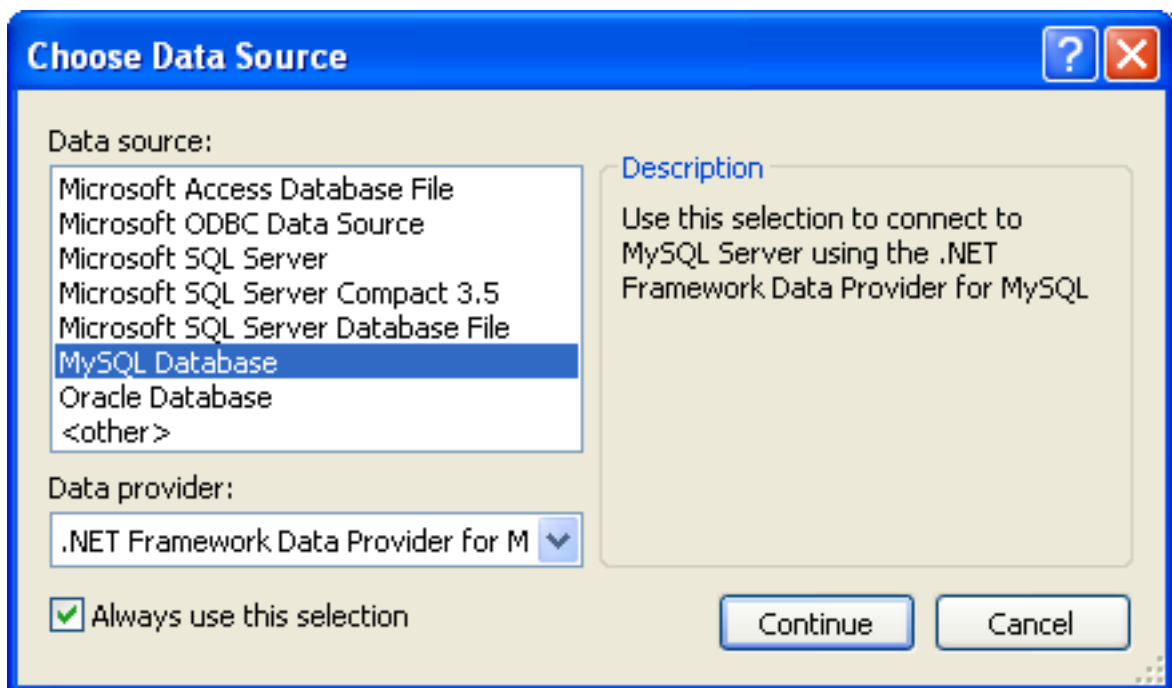

- Add Connection dialog opens. Press the CHANGE button to choose MySQL Database as a data source.

**Figure 20.1. Add Connection Context Menu**

- Change Data Source dialog opens. Choose MySQL Database in the list of data sources (or the <other> option, if MySQL Database is absent), and then choose .NET Framework Data Provider for MySQL in the combo box of data providers.

**Figure 20.2. Choose Data Source**

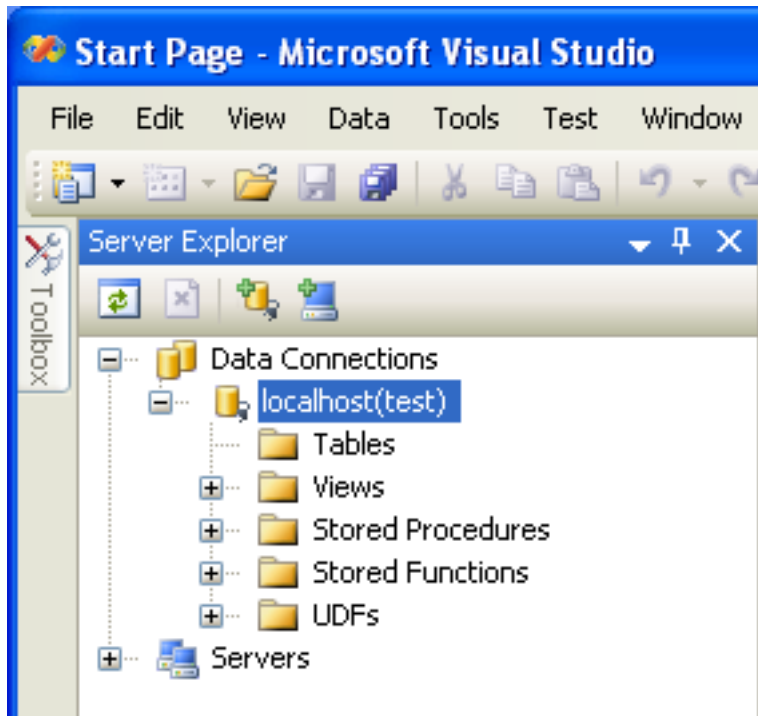

- Input the connection settings: the server host name (for example, localhost if the MySQL server is installed on the local machine), the user name, the password, and the default schema name. Note that you must specify the default schema name to open the connection.

**Figure 20.3. Add Connection Dialog**

- You can also set the port to connect with the MySQL server by pressing the **ADVANCED** button. To test connection with the MySQL server, set the server host name, the user name, and the password, and press the **TEST CONNECTION** button. If the test succeeds, the success confirmation dialog opens.
- After you set all settings and test the connection, press **OK**. The newly created connection is displayed in Server Explorer. Now you can work with the MySQL server through standard Server Explorer GUI.

**Figure 20.4. New Data Connection**

After the connection is successfully established, all settings are saved for future use. When you start Visual Studio for the next time, just open the connection node in Server Explorer to establish a connection to the MySQL server again.

To modify and delete a connection, use the Server Explorer context menu for the corresponding node. You can modify any of the settings just by overwriting the existing values with new ones. Note that the connection may be modified or deleted only if no active editor for its objects is opened: otherwise you may lose your data.

### 20.2.3.2. Editing Tables

Connector/Net contains a table editor, which enables the visual creation and modification of tables.

The Table Designer can be accessed through a mouse action on table-type node of Server Explorer. To create a new table, right-click on the **TABLES** node (under the connection node) and choose the **CREATE TABLE** command from the context menu.

To modify an existing table, double-click on the node of the table you wish to modify, or right-click on this node and choose the **DESIGN** item from the context menu. Either of the commands opens the Table Designer.

The table editor is implemented in the manner of the well-known Query Browser Table Editor, but with minor differences.

**Figure 20.5. Editing New Table**

Table Designer consists of the following parts:

- Columns Editor - a data grid on top of the Table Designer. Use the Columns grid for column creation, modification, and deletion.
- Indexes tab - a tab on bottom of the Table Designer. Use the Indexes tab for indexes management.
- Foreign Keys tab - a tab on bottom of the Table Designer. Use the Foreign Keys tab for foreign keys management.
- Column Details tab - a tab on bottom of the Table Designer. Use the Column Details tab to set advanced column options.
- Properties window - a standard Visual Studio Properties window, where the properties of the edited table are displayed. Use the Properties window to set the table properties.

Each of these areas is discussed in more detail in subsequent sections.

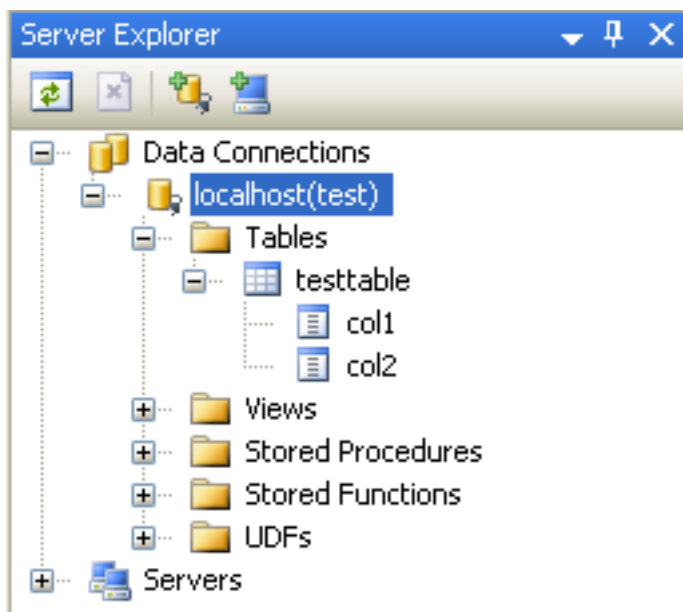

To save changes you have made in the Table Designer, use either SAVE or SAVE ALL button of the Visual Studio main toolbar, or just press **Ctrl+S**. If you have not already named the table you will be prompted to do so.

**Figure 20.6. Choose Table Name**

Once created you can view the table in the Server Explorer.

**Figure 20.7. Newly Created Table**

The Table Designer main menu allows you to set a Primary Key column, edit Relationships such as Foreign Keys, and create Indexes.

**Figure 20.8. Table Designer Main Menu**

### 20.2.3.2.1. Column Editor

You can use the Column Editor to set or change the name, data type, default value, and other properties of a table column. To set

the focus to a needed cell of a grid, use the mouse click. Also you can move through the grid using **Tab** and **Shift+Tab** keys.

To set or change the name, data type, default value and comment of a column, activate the appropriate cell and type the desired value.

To set or unset flag-type column properties (**NOT NULL**, auto incremented, flags), check or uncheck the corresponding check boxes. Note that the set of column flags depends on its data type.

To reorder columns, index columns or foreign key columns in the Column Editor, select the whole column you wish to reorder by clicking on the selector column on the left of the column grid. Then move the column by using **Ctrl+Up** (to move the column up) or **Ctrl+Down** (to move the column down) keys.

To delete a column, select it by clicking on the selector column on the left of the column grid, then press the **Delete** button on a keyboard.

### 20.2.3.2.2. Editing Indexes

Indexes management is performed via the **INDEXES/KEYS** dialog.

To add an index, select **TABLE DESIGNER, INDEXES/KEYS...** from the main menu, and click **ADD** to add a new index. You can then set the index name, index kind, index type, and a set of index columns.

**Figure 20.9. Indexes Dialog**

To remove an index, select it in the list box on the left, and click the **DELETE** button.

To change index settings, select the needed index in the list box on the left. The detailed information about the index is displayed in the panel on the right hand side. Change the desired values.

### 20.2.3.2.3. Editing Foreign Keys

Foreign Keys management is performed via the **FOREIGN KEY RELATIONSHIPS** dialog.

To add a foreign key, select **TABLE DESIGNER, RELATIONSHIPS...** from the main menu. This displays the **FOREIGN KEY RELATIONSHIP** dialog. Click **ADD**. You can then set the foreign key name, referenced table name, foreign key columns, and actions upon update and delete.

To remove a foreign key, select it in the list box on the left, and click the **DELETE** button.

To change foreign key settings, select the required foreign key in the list box on the left. The detailed information about the foreign key is displayed in the right hand panel. Change the desired values.

**Figure 20.10. Foreign Key Relationships Dialog**

#### 20.2.3.2.4. Column Properties

The **COLUMN PROPERTIES** tab can be used to set column options. In addition to the general column properties presented in the Column Editor, in the **COLUMN PROPERTIES** tab you can set additional properties such as Character Set, Collation and Precision.

#### 20.2.3.2.5. Table Properties

To bring up Table Properties select the table and right click to activate the context menu. Select **PROPERTIES**. The **TABLE PROPERTIES** dockable window will be displayed.

**Figure 20.11. Table Properties Menu Item**

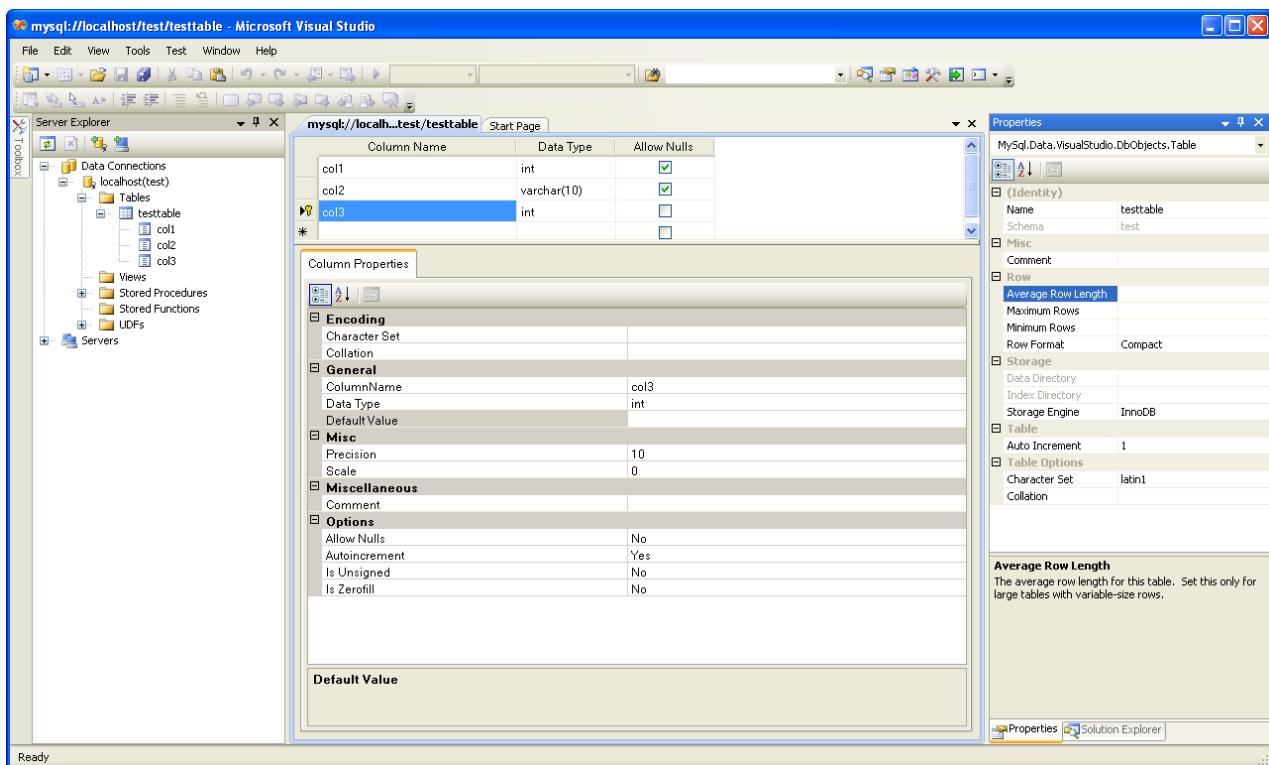

The following table properties can be set:

- Auto Increment
- Average Row Length
- Character Set
- Collation
- Comment
- Data Directory
- Index Directory
- Maximum Rows
- Minimum Rows
- Name
- Row Format
- Schema
- Storage Engine

The property [Schema](#) is read only.

**Figure 20.12. Table Properties**

### 20.2.3.3. Editing Views

To create a new view, right click the Views node under the connection node in Server Explorer. From the node's context menu, choose the CREATE VIEW command. This command opens the SQL Editor.

**Figure 20.13. Editing View SQL**

You can then enter the SQL for your view.

**Figure 20.14. View SQL Added**

To modify an existing view, double click on a node of the view you wish to modify, or right click on this node and choose the ALTER VIEW command from a context menu. Either of the commands opens the SQL Editor.

All other view properties can be set in the Properties window. These properties are:

- Catalog
- Check Option

- Definer
- Definition
- Definer
- Is Updatable
- Name
- Schema
- Security Type

Some of these properties can have arbitrary text values, others accept values from a predefined set. In the latter case you set the desired value with an embedded combobox.

The properties `Is Updatable` and `Schema` are readonly.

To save changes you have made, use either `SAVE` or `SAVE ALL` buttons of the Visual Studio main toolbar, or just press `Ctrl+S`.

**Figure 20.15. View SQL Saved**

#### 20.2.3.4. Editing Stored Procedures and Functions

To create a new stored procedure, right-click on the **STORED PROCEDURES** node under the connection node in Server Explorer. From the node's context menu, choose the **CREATE ROUTINE** command. This command opens the SQL Editor.

**Figure 20.16. Edit Stored Procedure SQL**

```
mysql://localh...oredProcedure1 Start Page
CREATE PROCEDURE StoredProcedure1
/*
(
parameter1 INT
OUT parameter2 datatype
)
*/
BEGIN
END|
```

To create a new stored function, right-click on the **FUNCTIONS** node under the connection node in Server Explorer. From the node's context menu, choose the **CREATE ROUTINE** command.

To modify an existing stored routine (procedure or function), double-click on the node of the routine you wish to modify, or right-click on this node and choose the **ALTER ROUTINE** command from the context menu. Either of the commands opens the SQL Editor.

To create or alter the routine definition using SQL Editor, type this definition in the SQL Editor using standard SQL. All other routine properties can be set in the Properties window. These properties are:

- Body
- Catalog
- Comment
- Creation Time
- Data Access
- Definer
- Definition
- External Name
- External Language
- Is Deterministic
- Last Modified
- Name
- Parameter Style
- Returns
- Schema
- Security Type
- Specific Name
- SQL Mode
- SQL Path
- Type

Some of these properties can have arbitrary text values, others accept values from a predefined set. In the latter case set the desired value using the embedded combo box.

You can also set all the options directly in the SQL Editor, using the standard **CREATE PROCEDURE** or **CREATE FUNCTION** statement. However, it is recommended to use the Properties window instead.

To save changes you have made, use either **SAVE** or **SAVE ALL** buttons of the Visual Studio main toolbar, or just press **Ctrl+S**.

**Figure 20.17. Stored Procedure SQL Saved**

### 20.2.3.5. Editing Triggers

To create a new trigger, right-click on the node of the table, for which you wish to add a trigger. From the node's context menu, choose the **CREATE TRIGGER** command. This command opens the SQL Editor.

To modify an existing trigger, double-click on the node of the trigger you wish to modify, or right-click on this node and choose the **ALTER TRIGGER** command from the context menu. Either of the commands opens the SQL Editor.

To create or alter the trigger definition using SQL Editor, type the trigger statement in the SQL Editor using standard SQL.

#### Note

You should enter only the trigger statement, that is, the part of the **CREATE TRIGGER** query that is placed after the **FOR EACH ROW** clause.

All other trigger properties are set in the Properties window. These properties are:

- Definer
- Event Manipulation
- Name
- Timing

Some of these properties can have arbitrary text values, others accept values from a predefined set. In the latter case set the desired value using the embedded combo box.

The properties **Event Table**, **Schema**, and **Server** in the Properties window are read only.

To save changes you have made, use either **SAVE** or **SAVE ALL** buttons of the Visual Studio main toolbar, or just press **Ctrl+S**. Before changes are saved, you will be asked to confirm the execution of the corresponding SQL query in a confirmation dialog.

### 20.2.3.6. Editing User Defined Functions (UDF)

To create a new User Defined Function (UDF), right-click on the **UDFS** node under the connection node in Server Explorer. From the node's context menu, choose the **CREATE UDF** command. This command opens the UDF Editor.

To modify an existing UDF, double-click on the node of the UDF you wish to modify, or right-click on this node and choose the **ALTER UDF** command from the context menu. Either of the commands opens the UDF Editor.

The UDF editor allows you to set the following properties:

- Name
- So-name (DLL name)
- Return type

- Is Aggregate

There are text fields for both names, a combo box for the return type, and a check box to indicate if the UDF is aggregate. All these options are also accessible via the Properties window.

The property `Server` in the Properties window is read only.

To save changes you have made, use either `SAVE` or `SAVE ALL` buttons of the Visual Studio main toolbar, or just press **Ctrl+S**. Before changes are saved, you will be asked to confirm the execution of the corresponding SQL query in a confirmation dialog.

### 20.2.3.7. Cloning Database Objects

Tables, views, stored procedures, and functions can be cloned using the appropriate Clone command from the context menu: `CLONE TABLE`, `CLONE VIEW`, `CLONE ROUTINE`. The clone commands open the corresponding editor for a new object: the `TABLE EDITOR` for cloning a table, and the `SQL EDITOR` for cloning a view or a routine.

The editor is filled with values of the original object. You can modify these values in a usual manner.

To save the cloned object, use either `Save` or `Save All` buttons of the Visual Studio main toolbar, or just press **Ctrl+S**. Before changes are saved, you will be asked to confirm the execution of the corresponding SQL query in a confirmation dialog.

### 20.2.3.8. Dropping Database Objects

Tables, views, stored routines, triggers, and UDFs can be dropped with the appropriate Drop command selected from its context menu: `DROP TABLE`, `DROP VIEW`, `DROP ROUTINE`, `DROP TRIGGER`, `DROP UDF`.

You will be asked to confirm the execution of the corresponding drop query in a confirmation dialog.

Dropping of multiple objects is not supported.

### 20.2.3.9. Using the ADO.NET Entity Framework

Connector/NET 6.0 introduced support for the ADO.NET Entity Framework. ADO.NET Entity Framework was included with .NET Framework 3.5 Service Pack 1, and Visual Studio 2008 Service Pack 1. ADO.NET Entity Framework was released on 11th August 2008.

ADO.NET Entity Framework provides an Object Relational Mapping (ORM) service, mapping the relational database schema to objects. The ADO.NET Entity Framework defines several layers, these can be summarized as:

- **Logical** - this layer defines the relational data and is defined by the Store Schema Definition Language (SSDL).
- **Conceptual** - this layer defines the .NET classes and is defined by the Conceptual Schema Definition Language (CSDL)
- **Mapping** - this layer defines the mapping from .NET classes to relational tables and associations, and is defined by Mapping Specification Language (MSL).

Connector/NET integrates with Visual Studio 2008 to provide a range of helpful tools to assist the developer.

A full treatment of ADO.NET Entity Framework is beyond the scope of this manual. You are encouraged to review the [Microsoft ADO.NET Entity Framework documentation](#).

#### 20.2.3.9.1. Tutorial: Using an Entity Framework Entity as a Windows Forms Data Source

In this tutorial you will learn how to create a Windows Forms Data Source from an Entity in an Entity Data Model. This tutorial assumes that you have installed the World example database, which can be downloaded from the [MySQL Documentation page](#). You can also find details on how to install the database on the same page. It will also be convenient for you to create a connection to the World database after it is installed. For instructions on how to do this see [Section 20.2.3.1, "Making a connection"](#).

##### Creating a new Windows Forms application

The first step is to create a new Windows Forms application.

1. In Visual Studio, select `FILE`, `NEW`, `PROJECT` from the main menu.
2. Choose the `WINDOWS FORMS APPLICATION` installed template. Click `OK`. The solution is created.

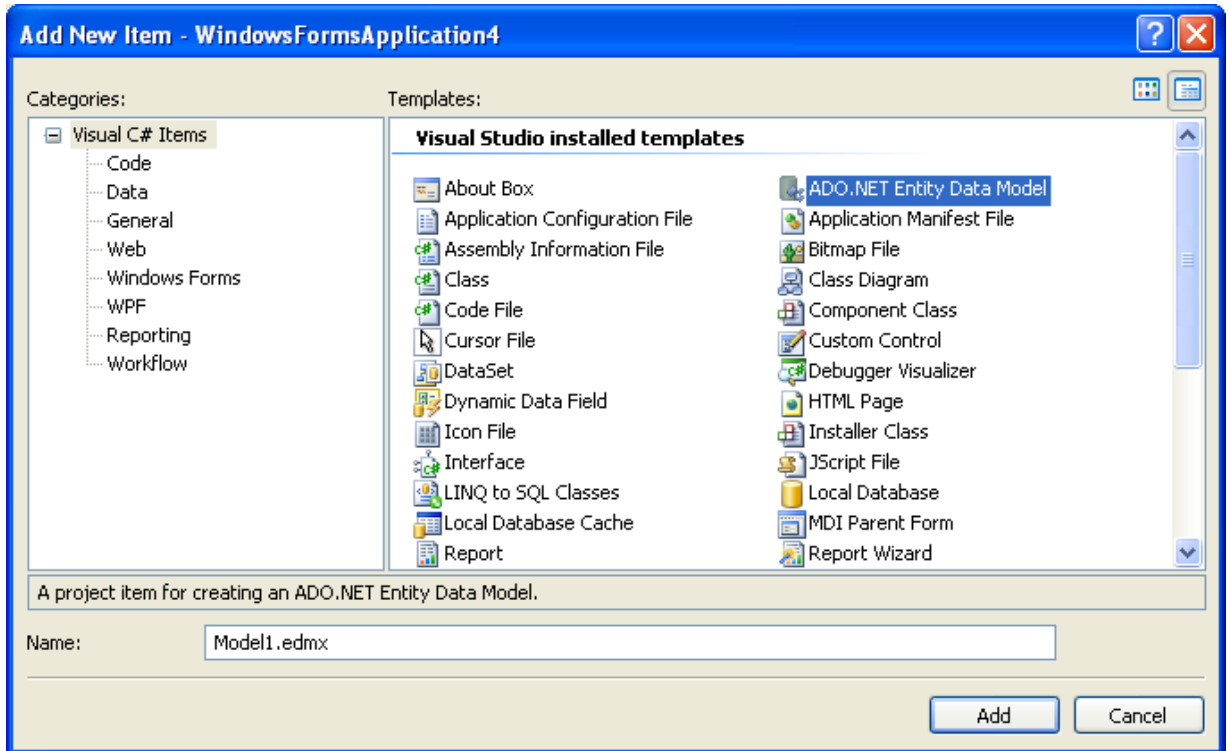

### Adding an Entity Data Model

You will now add an Entity Data Model to your solution.

1. In the Solution Explorer, right click on your application and select **ADD, NEW ITEM...**. From **VISUAL STUDIO INSTALLED TEMPLATES** select **ADO.NET ENTITY DATA MODEL**. Click **ADD**.

**Figure 20.18. Add Entity Data Model**

2. You will now see the Entity Data Model Wizard. You will use the wizard to generate the Entity Data Model from the world example database. Select the icon **GENERATE FROM DATABASE**. Click **NEXT**.

**Figure 20.19. Entity Data Model Wizard Screen 1**

3. You can now select the connection you made earlier to the World database. If you have not already done so, you can create the new connection at this time by clicking on NEW CONNECTION.... For further instructions on creating a connection to a database see [Section 20.2.3.1, "Making a connection"](#).

**Figure 20.20. Entity Data Model Wizard Screen 2**

4. Make a note of the entity connection settings to be used in App.Config, as these will be used later to write the necessary control code.
5. Click NEXT.
6. The Entity Data Model Wizard connects to the database. You are then presented with a tree structure of the database. From this you can select the object you would like to include in your model. If you had created Views and Stored Routines these will be displayed along with any tables. In this example you just need to select the tables. Click FINISH to create the model and exit the wizard.

**Figure 20.21. Entity Data Model Wizard Screen 3**

7. Visual Studio will generate the model and then display it.

**Figure 20.22. Entity Data Model Diagram**

8. From the Visual Studio main menu select **BUILD, BUILD SOLUTION**, to ensure that everything compiles correctly so far.

### Adding a new Data Source

You will now add a new Data Source to your project and see how it can be used to read and write to the database.

1. From the Visual Studio main menu select **DATA, ADD NEW DATA SOURCE...**. You will be presented with the Data Source Configuration Wizard.

**Figure 20.23. Entity Data Source Configuration Wizard Screen 1**

2. Select the **OBJECT** icon. Click NEXT.
3. You will now select the Object you wish to bind to. Expand the tree. In this tutorial you will select the city table. Once the city table has been selected click NEXT.

**Figure 20.24. Entity Data Source Configuration Wizard Screen 2**

4. The wizard will confirm that the city object is to be added. Click FINISH.

**Figure 20.25. Entity Data Source Configuration Wizard Screen 3**

5. The city object will be display in the Data Sources panel. If the Data Sources panel is not displayed, select DATA, SHOW DATA SOURCES from the Visual Studio main menu. The docked panel will then be displayed.

**Figure 20.26. Data Sources**

### Using the Data Source in a Windows Form

You will now learn how to use the Data Source in a Windows Form.

1. In the Data Sources panel select the Data Source you just created and drag and drop it onto the Form Designer. By default the Data Source object will be added as a Data Grid View control. Note that the Data Grid View control is bound to the `cityBindingSource` and the Navigator control is bound to `cityBindingNavigator`.

Figure 20.27. Data Form Designer

2. Save and rebuild the solution before continuing.

### Adding Code to Populate the Data Grid View

You are now ready to add code to ensure that the Data Grid View control will be populated with data from the City database table.

1. Double click the form to access its code.
2. Add code to instantiate the Entity Data Model's EntityContainer object and retrieve data from the database to populate the control.

Figure 20.28. Adding Code to the Form

3. Save and rebuild the solution.
4. Run the solution. Ensure the grid is populated and you can navigate the database.

**Figure 20.29. The Populated Grid Control**

## Adding Code to Save Changes to the Database

You will now add code to enable you to save changes to the database.

The Binding source component ensures that changes made in the Data Grid View control are also made to the Entity classes bound to it. However, that data needs to be saved back from the entities to the database itself. This can be achieved by the enabling of the Save button in the Navigator control, and the addition of some code.

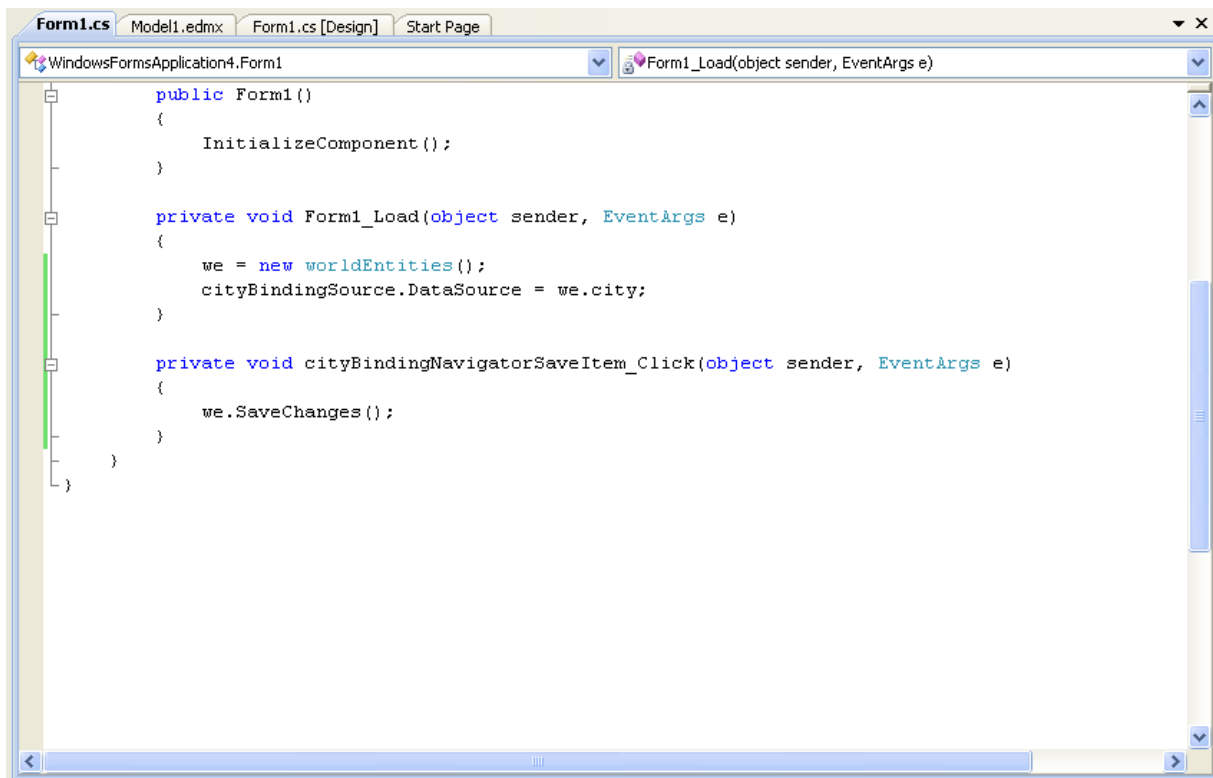

1. In the Form Designer click on the Save icon in the Form toolbar and ensure that its Enabled property is set to True.

**Figure 20.30. Save Button Enabled**

2. Double click the Save icon in the Form toolbar to display its code.
3. You now need to add code to ensure that data is saved to the database when the save button is click in the application.

**Figure 20.31. Adding Save Code to the Form**

4. Once the code has been added, save the solution and rebuild it. Run the application and verify that changes made in the grid are saved.

### 20.2.3.9.2. Tutorial: Databinding in ASP.NET using LINQ on Entities

In this tutorial you create an ASP.NET web page that binds LINQ queries to entities using the Entity Framework mapping.

If you have not already done so, you should install the World example database prior to attempting this tutorial. Instructions on where to obtain the database and instructions on how to install it where given in the tutorial [Section 20.2.3.9.1, "Tutorial: Using an Entity Framework Entity as a Windows Forms Data Source"](#).

#### Creating an ASP.NET web site

In this part of the tutorial you will create an ASP.NET web site. The web site will use the World database. The main web page will feature a drop down list from which you can select a country, data about that country's cities will then be displayed in a grid view control.

1. From the Visual Studio main menu select **FILE, NEW, WEB SITE....**
2. From the Visual Studio installed templates select **ASP.NET WEB SITE**. Click OK. You will be presented with the Source view of your web page by default.
3. Click the Design view tab situated underneath the Source view panel.

#### Figure 20.32. The Design Tab

4. In the Design view panel, enter some text to decorate the blank web page.
5. Click on Toolbox. From the list of controls select **DROPDOWNLIST**. Drag and drop the control to a location beneath the text on your web page.

**Figure 20.33. Drop Down List**

6. From the **DROPDOWNLIST** control's context menu, ensure that the **ENABLE AUTOPOSTBACK** check box is enabled. This will ensure the control's event handler is called when an item is selected. The user's choice will in turn be used to populate the **GRIDVIEW** control.

**Figure 20.34. Enable AutoPostBack**

- From the Toolbox select the **GRIDVIEW** control.

**Figure 20.35. Grid View Control**

Drag and drop the Grid View control to a location just below the Drop Down List you already placed.

**Figure 20.36. Placed Grid View Control**

- At this point it is recommended that you save your solution, and build the solution to ensure that there are no errors.
- If you run the solution you will see that the text and drop down list are displayed, but the list is empty. Also, the grid view does not appear at all. Adding this functionality is described in the following sections.

At this stage you have a web site that will build, but further functionality is required. The next step will be to use the Entity Framework to create a mapping from the World database into entities that you can control programmatically.

### Creating an ADO.NET Entity Data Model

In this stage of the tutorial you will add an ADO.NET Entity Data Model to your project, using the World database at the storage level. The procedure for doing this is described in the tutorial [Section 20.2.3.9.1, “Tutorial: Using an Entity Framework Entity as a Windows Forms Data Source”](#), and so will not be repeated here.

### Populating a Drop Data List Box with using the results of a entity LINQ query

In this part of the tutorial you will write code to populate the DropDownList control. When the web page loads the data to populate the list will be achieved by using the results of a LINQ query on the model created previously.

1. In the Design view panel, double click on any blank area. This brings up the [Page\\_Load](#) method.
2. Modify the relevant section of code according to the following listing:

```
...
public partial class _Default : System.Web.UI.Page
{
    worldModel.worldEntities we;

    protected void Page_Load(object sender, EventArgs e)
    {
        we = new worldModel.worldEntities();

        if (!IsPostBack)
        {
            var countryQuery = from c in we.country
                               orderby c.Name
                               select new { c.Code, c.Name };
            DropDownList1.DataValueField = "Code";
            DropDownList1.DataTextField = "Name";
            DropDownList1.DataSource = countryQuery;
            DataBind();
        }
    }
}
...
```

Note that the list control only needs to be populated when the page first loads. The conditional code ensures that if the page is subsequently reloaded, the list control is not repopulated, which would cause the user selection to be lost.

3. Save the solution, build it and run it. You should see the list control has been populated. You can select an item, but as yet the grid view control does not appear.

At this point you have a working Drop Down List control, populated by a LINQ query on your entity data model.

### Populating a Grid View control using an entity LINQ query

In the last part of this tutorial you will populate the Grid View Control using a LINQ query on your entity data model.

1. In the Design view double click on the **DROPDOWNLIST** control. This causes its [SelectedIndexChanged](#) code to be displayed. This method is called when a user selects an item in the list control and thus fires an AutoPostBack event.
2. Modify the relevant section of code accordingly to the following listing:

```
...
protected void DropDownList1_SelectedIndexChanged(object sender, EventArgs e)
{
    var cityQuery = from c in we.city
                    where c.CountryCode == DropDownList1.SelectedValue
                    orderby c.Name
                    select new { c.Name, c.Population, c.CountryCode };
    GridView1.DataSource = cityQuery;
    DataBind();
}
...
```

The grid view control is populated from the result of the LINQ query on the entity data model.

3. As a check compare your code to that shown in the following screenshot:

### Figure 20.37. Source Code

```
protected void Page_Load(object sender, EventArgs e)
{
    we = new worldModel.worldEntities();

    if (!IsPostBack)
    {
        var countryQuery = from c in we.country
                           orderby c.Name
                           select new { c.Code, c.Name };
        DropDownList1.DataValueField = "Code";
        DropDownList1.DataTextField = "Name";
        DropDownList1.DataSource = countryQuery;
        DataBind();
    }
}

protected void DropDownList1_SelectedIndexChanged(object sender, EventArgs e)
{
    var cityQuery = from c in we.city
                    where c.CountryCode == DropDownList1.SelectedValue
                    orderby c.Name
                    select new { c.Name, c.Population, c.CountryCode };
    GridView1.DataSource = cityQuery;
    DataBind();
}
```

4. Save, build and run the solution. As you select a country you will see its cities are displayed in the grid view control.

**Figure 20.38. The Working Web Site**

In this tutorial you have seen how to create an ASP.NET web site, you have also seen how you can access a MySQL database via LINQ queries on an entity data model.

## 20.2.4. Connector/NET Programming

Connector/NET comprises several classes that are used to connect to the database, execute queries and statements, and manage query results.

The following are the major classes of Connector/NET:

- [MySqlCommand](#): Represents an SQL statement to execute against a MySQL database.
- [MySqlCommandBuilder](#): Automatically generates single-table commands used to reconcile changes made to a DataSet with the associated MySQL database.
- [MySqlConnection](#): Represents an open connection to a MySQL Server database.
- [MySqlDataAdapter](#): Represents a set of data commands and a database connection that are used to fill a data set and update a MySQL database.
- [MySqlDataReader](#): Provides a means of reading a forward-only stream of rows from a MySQL database.
- [MySqlException](#): The exception that is thrown when MySQL returns an error.

- [MySQLHelper](#): Helper class that makes it easier to work with the provider.
- [MySQLTransaction](#): Represents an SQL transaction to be made in a MySQL database.

In the following sections you will learn about some common use cases for Connector/NET, including BLOB handling, date handling, and using Connector/NET with common tools such as Crystal Reports.

### 20.2.4.1. Tutorial: An Introduction to Connector/NET Programming

This section provides a gentle introduction to programming with Connector/NET. The example code is written in C#, and is designed to work on both Microsoft .NET Framework and Mono.

This tutorial is designed to get you up and running with Connector/NET as quickly as possible, it does not go into detail on any particular topic. However, the following sections of this manual describe each of the topics introduced in this tutorial in more detail. In this tutorial you are encouraged to type in and run the code, modifying it as required for your setup.

This tutorial assumes you have MySQL and Connector/NET already installed. It also assumes that you have installed the World example database, which can be downloaded from the [MySQL Documentation page](#). You can also find details on how to install the database on the same page.

#### Note

Before compiling the example code make sure that you have added References to your project as required. The References required are [System](#), [System.Data](#) and [MySQL.Data](#).

#### 20.2.4.1.1. The MySqlConnection Object

For your Connector/NET application to connect to a MySQL database it needs to establish a connection. This is achieved through the use of a [MySqlConnection](#) object.

The MySqlConnection constructor takes a connection string as one of its parameters. The connection string provides necessary information to make the connection to the MySQL database. The connection string is discussed more fully in [Section 20.2.4.2, "Connecting to MySQL Using Connector/NET"](#). A reference containing a list of supported connection string options can also be found in [Section 20.2.4.5, "Connector/NET Connection String Options Reference"](#).

The following code shows how to create a connection object.

```
using System;
using System.Data;

using MySql.Data;
using MySql.Data.MySqlClient;

public class Tutorial1
{
    public static void Main()
    {
        string connStr = "server=localhost;user=root;database=world;port=3306;password=*****";
        MySqlConnection conn = new MySqlConnection(connStr);
        try
        {
            Console.WriteLine("Connecting to MySQL...");
            conn.Open();
            // Perform database operations
            conn.Close();
        }
        catch (Exception ex)
        {
            Console.WriteLine(ex.ToString());
        }
        Console.WriteLine("Done.");
    }
}
```

When the [MySqlConnection](#) constructor is invoked it returns a connection object, which is used for subsequent database operations. The first operation in this example is to open the connection. This needs to be done before further operations take place. Before the application exits the connection to the database needs to be closed by calling [Close](#) on the connection object.

Sometimes an attempt to perform an [Open](#) on a connection object can fail, this will generate an exception that can be handled via standard exception handling code.

In this section you have learned how to create a connection to a MySQL database, and open and close the corresponding connection object.

#### 20.2.4.1.2. The MySqlCommand Object

Once a connection has been established with the MySQL database, the next step is to carry out the desired database operations. This can be achieved through the use of the [MySQLCommand](#) object.

You will see how to create a [MySQLCommand](#) object. Once it has been created there are three main methods of interest that you can call:

- **ExecuteReader** - used to query the database. Results are usually returned in a [MySQLDataReader](#) object, created by [ExecuteReader](#).
- **ExecuteNonQuery** - used to insert and delete data.
- **ExecuteScalar** - used to return a single value.

Once a [MySQLCommand](#) object has been created, you will call one of the above methods on it to carry out a database operation, such as perform a query. The results are usually returned into a [MySQLDataReader](#) object, and then processed, for example the results might be displayed. The following code demonstrates how this could be done.

```
using System;
using System.Data;

using MySql.Data;
using MySql.Data.MySqlClient;

public class Tutorial2
{
    public static void Main()
    {
        string connStr = "server=localhost;user=root;database=world;port=3306;password=*****";
        MySqlConnection conn = new MySqlConnection(connStr);
        try
        {
            Console.WriteLine("Connecting to MySQL...");
            conn.Open();

            string sql = "SELECT Name, HeadOfState FROM Country WHERE Continent='Oceania'";
            MySqlCommand cmd = new MySqlCommand(sql, conn);
            MySQLDataReader rdr = cmd.ExecuteReader();

            while (rdr.Read())
            {
                Console.WriteLine(rdr[0]+" -- "+rdr[1]);
            }

            rdr.Close();
            conn.Close();
        }
        catch (Exception ex)
        {
            Console.WriteLine(ex.ToString());
        }
        Console.WriteLine("Done.");
    }
}
```

When a connection has been created and opened, the code then creates a [MySQLCommand](#) object. Note that the SQL query to be executed is passed to the [MySQLCommand](#) constructor. The [ExecuteReader](#) method is then used to generate a [MySQLReader](#) object. The [MySQLReader](#) object contains the results generated by the SQL executed on the command object. Once the results have been obtained in a [MySQLReader](#) object, the results can be processed. In this case the information is simply printed out as part of a [while](#) loop. Finally, the [MySQLReader](#) object is disposed of by running its [Close](#) method on it.

In the next example you will see how to use the [ExecuteNonQuery](#) method.

The procedure for performing an [ExecuteNonQuery](#) method call is simpler, as there is no need to create an object to store results. This is because [ExecuteNonQuery](#) is only used for inserting, updating and deleting data. The following example illustrates a simple update to the Country table:

```
using System;
using System.Data;

using MySql.Data;
using MySql.Data.MySqlClient;

public class Tutorial3
{
    public static void Main()
    {
        string connStr = "server=localhost;user=root;database=world;port=3306;password=*****";
        MySqlConnection conn = new MySqlConnection(connStr);
        try
        {
            Console.WriteLine("Connecting to MySQL...");
            conn.Open();
```

```

        string sql = "INSERT INTO Country (Name, HeadOfState, Continent) VALUES ('Disneyland','Mickey Mouse', 'Nor');
        MySqlCommand cmd = new MySqlCommand(sql, conn);
        cmd.ExecuteNonQuery();

        conn.Close();
    }
    catch (Exception ex)
    {
        Console.WriteLine(ex.ToString());
    }
    Console.WriteLine("Done.");
}
}

```

The query is constructed, the command object created and the [ExecuteNonQuery](#) method called on the command object. You can access your MySQL database with the MySQL Client program and verify that the update was carried out correctly.

Finally, you will see how the [ExecuteScalar](#) method can be used to return a single value. Again, this is straightforward, as a [MySqlDataReader](#) object is not required to store results, a simple variable will do. The following code illustrates how to use [ExecuteScalar](#):

```

using System;
using System.Data;

using MySql.Data;
using MySql.Data.MySqlClient;

public class Tutorial4
{
    public static void Main()
    {
        string connStr = "server=localhost;user=root;database=world;port=3306;password=*****";
        MySqlConnection conn = new MySqlConnection(connStr);
        try
        {
            Console.WriteLine("Connecting to MySQL...");
            conn.Open();

            string sql = "SELECT COUNT(*) FROM Country";
            MySqlCommand cmd = new MySqlCommand(sql, conn);
            object result = cmd.ExecuteScalar();
            if (result != null)
            {
                int r = Convert.ToInt32(result);
                Console.WriteLine("Number of countries in the World database is: " + r);
            }

            conn.Close();
        }
        catch (Exception ex)
        {
            Console.WriteLine(ex.ToString());
        }
        Console.WriteLine("Done.");
    }
}

```

This example uses a simple query to count the rows in the Country table. The result is obtained by calling [ExecuteScalar](#) on the command object.

### 20.2.4.1.3. Working with Decoupled Data

Previously, when using [MySqlDataReader](#), the connection to the database was continually maintained, unless explicitly closed. It is also possible to work in a manner where a connection is only established when needed. For example, in this mode, a connection could be established in order to read a chunk of data, the data could then be modified by the application as required. A connection could then be reestablished only if and when the application needs to write data back to the database. This decouples the working data set from the database.

This decouple mode of working with data is supported by Connector/NET. There are several parts involved in allowing this method to work:

- **Data Set** - The Data Set is the area in which data is loaded in order to read or modify it. A [DataSet](#) object is instantiated, which can store multiple tables of data.
- **Data Adapter** - The Data Adapter is the interface between the Data Set and the database itself. The Data Adapter is responsible for efficiently managing connections to the database, opening and closing them as required. The Data Adapter is created by instantiating an object of the [MySqlDataAdapter](#) class. The [MySqlDataAdapter](#) object has two main methods: [Fill](#) which reads data into the Data Set, and [Update](#), which writes data from the Data Set to the database.
- **Command Builder** - The Command Builder is a support object. The Command Builder works in conjunction with the Data

Adapter. When a `MySqlDataAdapter` object is created it is typically given an initial SELECT statement. From this SELECT statement the Command Builder can work out the corresponding INSERT, UPDATE and DELETE statements that would be required should the database need to be updated. To create the Command Builder an object of the class `MySqlCommandBuilder` is created.

Each of these classes will now be discussed in more detail.

### Instantiating a DataSet object

A `DataSet` object can be created simply, as shown in the following example code snippet:

```
DataSet dsCountry;
...
dsCountry = new DataSet();
```

Although this creates the `DataSet` object it has not yet filled it with data. For that a Data Adapter is required.

### Instantiating a MySqlDataAdapter object

The `MySqlDataAdapter` can be created as illustrated by the following example:

```
MySqlDataAdapter daCountry;
...
string sql = "SELECT Code, Name, HeadOfState FROM Country WHERE Continent='North America'";
daCountry = new MySqlDataAdapter (sql, conn);
```

Note, the `MySqlDataAdapter` is given the SQL specifying the data you wish to work with.

### Instantiating a MySqlCommandBuilder object

Once the `MySqlDataAdapter` has been created, it is necessary to generate the additional statements required for inserting, updating and deleting data. There are several ways to do this, but in this tutorial you will see how this can most easily be done with `MySqlCommandBuilder`. The following code snippet illustrates how this is done:

```
MySqlCommandBuilder cb = new MySqlCommandBuilder(daCountry);
```

Note that the `MySqlDataAdapter` object is passed as a parameter to the command builder.

### Filling the Data Set

In order to do anything useful with the data from your database, you need to load it into a Data Set. This is one of the jobs of the `MySqlDataAdapter` object, and is carried out with its `Fill` method. The following example code illustrates this:

```
DataSet dsCountry;
...
dsCountry = new DataSet();
...
daCountry.Fill(dsCountry, "Country");
```

Note the `Fill` method is a `MySqlDataAdapter` method, the Data Adapter knows how to establish a connection with the database and retrieve the required data, and then populates the Data Set when the `Fill` method is called. The second parameter "Country" is the table in the Data Set to update.

### Updating the Data Set

The data in the Data Set can now be manipulated by the application as required. At some point, changes to data will need to be written back to the database. This is achieved through a `MySqlDataAdapter` method, the `Update` method.

```
daCountry.Update(dsCountry, "Country");
```

Again, the Data Set and the table within the Data Set to update are specified.

### Working Example

The interactions between the `DataSet`, `MySqlDataAdapter` and `MySqlCommandBuilder` classes can be a little confusing, so their operation can perhaps be best illustrated by working code.

In this example, data from the World database is read into a Data Grid View control. Here, the data can be viewed and changed before clicking an update button. The update button then activates code to write changes back to the database. The code uses the principles explained above. The application was built using the Microsoft Visual Studio in order to place and create the user interface

controls, but the main code that uses the key classes described above is shown below, and is portable.

```
using System;
using System.Collections.Generic;
using System.ComponentModel;
using System.Data;
using System.Drawing;
using System.Linq;
using System.Text;
using System.Windows.Forms;

using MySql.Data;
using MySql.Data.MySqlClient;

namespace WindowsFormsApplication5
{
    public partial class Form1 : Form
    {
        MySqlDataAdapter daCountry;
        DataSet dsCountry;

        public Form1()
        {
            InitializeComponent();
        }

        private void Form1_Load(object sender, EventArgs e)
        {
            string connStr = "server=localhost;user=root;database=world;port=3306;password=*****";
            MySqlConnection conn = new MySqlConnection(connStr);
            try
            {
                label2.Text = "Connecting to MySQL...";

                string sql = "SELECT Code, Name, HeadOfState FROM Country WHERE Continent='North America'";
                daCountry = new MySqlDataAdapter (sql, conn);
                MySqlCommandBuilder cb = new MySqlCommandBuilder(daCountry);

                dsCountry = new DataSet();
                daCountry.Fill(dsCountry, "Country");
                dataGridView1.DataSource = dsCountry;
                dataGridView1.DataMember = "Country";
            }
            catch (Exception ex)
            {
                label2.Text = ex.ToString();
            }
        }

        private void button1_Click(object sender, EventArgs e)
        {
            daCountry.Update(dsCountry, "Country");
            label2.Text = "MySQL Database Updated!";
        }
    }
}
```

The application running is shown below:

**Figure 20.39. World Database Application**

#### 20.2.4.1.4. Working with Parameters

This part of the tutorial shows you how to use parameters in your Connector/NET application.

Although it is possible to build SQL query strings directly from user input, this is not advisable as it does not prevent from erroneous or malicious information being entered. It is safer to use parameters as they will be processed as field data only. For example, imagine the following query was constructed from user input:

```
string sql = "SELECT Name, HeadOfState FROM Country WHERE Continent = "+user_continent;
```

If the string `user_continent` came from a Text Box control, there would potentially be no control over the string entered by the user. The user could enter a string that generates a run time error, or in the worst case actually harms the system. When using parameters it is not possible to do this because a parameter is only ever treated as a field parameter, rather than an arbitrary piece of SQL code.

The same query written using a parameter for user input would be:

```
string sql = "SELECT Name, HeadOfState FROM Country WHERE Continent = @Continent";
```

Note that the parameter is preceded by an '@' symbol to indicate it is to be treated as a parameter.

As well as marking the position of the parameter in the query string, it is necessary to create a parameter object that can be passed to the Command object. In Connector/NET the class `MySqlParameter` is used for this purpose. The use of `MySqlParameter` is best illustrated by a small code snippet:

```

MySQLParameter param = new MySQLParameter();
param.ParameterName = "@Continent";
param.Value = "North America";
cmd.Parameters.Add(param);

```

In this example the string "North America" is supplied as the parameter value statically, but in a more practical example it would come from a user input control. Once the parameter has its name and value set it needs to be added to the Command object using the [Add](#) method.

A further example illustrates this:

```

using System;
using System.Data;

using MySql.Data;
using MySql.Data.MySqlClient;

public class Tutorial5
{
    public static void Main()
    {
        string connStr = "server=localhost;user=root;database=world;port=3306;password=*****";
        MySqlConnection conn = new MySqlConnection(connStr);
        try
        {
            Console.WriteLine("Connecting to MySQL...");
            conn.Open();

            string sql = "SELECT Name, HeadOfState FROM Country WHERE Continent=@Continent";
            MySqlCommand cmd = new MySqlCommand(sql, conn);

            Console.WriteLine("Enter a continent e.g. 'North America', 'Europe': ");
            string user_input = Console.ReadLine();

            MySQLParameter param = new MySQLParameter();
            param.ParameterName = "@Continent";
            param.Value = user_input;
            cmd.Parameters.Add(param);

            MySqlDataReader rdr = cmd.ExecuteReader();

            while (rdr.Read())
            {
                Console.WriteLine(rdr["Name"]+" --- "+rdr["HeadOfState"]);
            }

            conn.Close();
        }
        catch (Exception ex)
        {
            Console.WriteLine(ex.ToString());
        }
        Console.WriteLine("Done.");
    }
}

```

In this part of the tutorial you have see how to use parameters to make your code more secure.

### 20.2.4.1.5. Working with Stored Procedures

In this section you will see how to work with Stored Procedures. This section assumes you have a basic understanding of what a Stored Procedure is, and how to create one.

For the purposes of this tutorial, you will create a simple Stored Procedure to see how it can be called from Connector/NET. In the MySQL Client program, connect to the World database and enter the following Stored Procedure:

```

DELIMITER //
CREATE PROCEDURE country_hos
(IN con CHAR(20))
BEGIN
    SELECT Name, HeadOfState FROM Country
    WHERE Continent = con;
END //
DELIMITER ;

```

Test the Stored Procedure works as expected by typing the following into the MySQL Client program:

```
CALL country_hos('Europe');
```

Note that The Stored Routine takes a single parameter, which is the continent you wish to restrict your search to.

Having confirmed that the Stored Procedure is present and correct you can now move on to seeing how it can be accessed from Connector/NET.

Calling a Stored Procedure from your Connector/NET application is similar to techniques you have seen earlier in this tutorial. A `MySQLCommand` object is created, but rather than taking a SQL query as a parameter it takes the name of the Stored Procedure to call. The `MySQLCommand` object also needs to be set to the type of Stored Procedure. This is illustrated by the following code snippet:

```
string rtn = "country_hos";
MySQLCommand cmd = new MySQLCommand(rtn, conn);
cmd.CommandType = CommandType.StoredProcedure;
```

In this case you also need to pass a parameter to the Stored Procedure. This can be achieved using the techniques seen in the previous section on parameters, [Section 20.2.4.1.4, "Working with Parameters"](#). This is shown in the following code snippet:

```
MySQLParameter param = new MySQLParameter();
param.ParameterName = "@con";
param.Value = "Europe";
cmd.Parameters.Add(param);
```

The value of the parameter `@con` could more realistically have come from a user input control, but for simplicity it is set as a static string in this example.

At this point everything is set up and all that now needs to be done is to call the routine. This can be achieved using techniques also learned in earlier sections, but in this case the `ExecuteReader` method of the `MySQLCommand` object is used.

Complete working code for the Stored Procedure example is shown below:

```
using System;
using System.Data;

using MySql.Data;
using MySql.Data.MySqlClient;

public class Tutorial6
{
    public static void Main()
    {
        string connStr = "server=localhost;user=root;database=world;port=3306;password=*****";
        MySqlConnection conn = new MySqlConnection(connStr);
        try
        {
            Console.WriteLine("Connecting to MySQL...");
            conn.Open();

            string rtn = "country_hos";
            MySQLCommand cmd = new MySQLCommand(rtn, conn);
            cmd.CommandType = CommandType.StoredProcedure;
            MySQLParameter param = new MySQLParameter();
            param.ParameterName = "@con";
            param.Value = "Europe";
            cmd.Parameters.Add(param);

            MySQLDataReader rdr = cmd.ExecuteReader();
            while (rdr.Read())
            {
                Console.WriteLine(rdr[0] + " --- " + rdr[1]);
            }
            conn.Close();
        }
        catch (Exception ex)
        {
            Console.WriteLine(ex.ToString());
        }
        Console.WriteLine("Done.");
    }
}
```

In this section you have seen how to call a Stored Procedure from Connector/NET. For the moment, this concludes our introductory tutorial on programming with Connector/NET.

## 20.2.4.2. Connecting to MySQL Using Connector/NET

### Introduction

All interaction between a .NET application and the MySQL server is routed through a `MySQLConnection` object. Before your application can interact with the server, a `MySQLConnection` object must be instantiated, configured, and opened.

Even when using the `MySQLHelper` class, a `MySQLConnection` object is created by the helper class.

In this section, we will describe how to connect to MySQL using the `MySQLConnection` object.

## 20.2.4.3. Creating a Connection String

The `MySqlConnection` object is configured using a connection string. A connection string contains several key/value pairs, separated by semicolons. Each key/value pair is joined with an equals sign.

The following is a sample connection string:

```
Server=127.0.0.1;Uid=root;Pwd=12345;Database=test;
```

In this example, the `MySqlConnection` object is configured to connect to a MySQL server at `127.0.0.1`, with a user name of `root` and a password of `12345`. The default database for all statements will be the `test` database.

The following options are available:

### Note

Using the '@' symbol for parameters is now the preferred approach although the old pattern of using '?' is still supported.

Please be aware however that using '@' can cause conflicts when user variables are also used. To help with this situation please see the documentation on the [Allow User Variables](#) connection string option, which can be found here: [Section 20.2.4.3, "Creating a Connection String"](#). The `Old Syntax` connection string option has now been deprecated.

## 20.2.4.3.1. Opening a Connection

Once you have created a connection string it can be used to open a connection to the MySQL server.

The following code is used to create a `MySqlConnection` object, assign the connection string, and open the connection.

### Visual Basic Example

```
Dim conn As New MySql.Data.MySqlClient.MySqlConnection
Dim myConnectionString as String

myConnectionString = "server=127.0.0.1;" _
    & "uid=root;" _
    & "pwd=12345;" _
    & "database=test;"

Try
    conn.ConnectionString = myConnectionString
    conn.Open()
Catch ex As MySql.Data.MySqlClient.MySqlException
    MessageBox.Show(ex.Message)
End Try
```

### C# Example

```
MySql.Data.MySqlClient.MySqlConnection conn;
string myConnectionString;

myConnectionString = "server=127.0.0.1;uid=root;" +
    "pwd=12345;database=test;";

try
{
    conn = new MySql.Data.MySqlClient.MySqlConnection();
    conn.ConnectionString = myConnectionString;
    conn.Open();
}
catch (MySql.Data.MySqlClient.MySqlException ex)
{
    MessageBox.Show(ex.Message);
}
```

You can also pass the connection string to the constructor of the `MySqlConnection` class:

### Visual Basic Example

```
Dim myConnectionString as String

myConnectionString = "server=127.0.0.1;" _
    & "uid=root;" _
    & "pwd=12345;" _
    & "database=test;"

Try
    Dim conn As New MySql.Data.MySqlClient.MySqlConnection(myConnectionString)
    conn.Open()
```

```
Catch ex As MySql.Data.MySqlClient.MySqlException
    MessageBox.Show(ex.Message)
End Try
```

### C# Example

```
MySql.Data.MySqlClient.MySqlConnection conn;
string myConnectionString;

myConnectionString = "server=127.0.0.1;uid=root;" +
    "pwd=12345;database=test;";

try
{
    conn = new MySql.Data.MySqlClient.MySqlConnection(myConnectionString);
    conn.Open();
}
catch (MySql.Data.MySqlClient.MySqlException ex)
{
    MessageBox.Show(ex.Message);
}
```

Once the connection is open it can be used by the other Connector/.NET classes to communicate with the MySQL server.

### 20.2.4.3.2. Handling Connection Errors

Because connecting to an external server is unpredictable, it is important to add error handling to your .NET application. When there is an error connecting, the `MySqlConnection` class will return a `MySqlException` object. This object has two properties that are of interest when handling errors:

- **Message:** A message that describes the current exception.
- **Number:** The MySQL error number.

When handling errors, you can your application's response based on the error number. The two most common error numbers when connecting are as follows:

- **0:** Cannot connect to server.
- **1045:** Invalid user name and/or password.

The following code shows how to adapt the application's response based on the actual error:

#### Visual Basic Example

```
Dim myConnectionString as String

myConnectionString = "server=127.0.0.1;" _
    & "uid=root;" _
    & "pwd=12345;" _
    & "database=test;"

Try
    Dim conn As New MySql.Data.MySqlClient.MySqlConnection(myConnectionString)
    conn.Open()
Catch ex As MySql.Data.MySqlClient.MySqlException
    Select Case ex.Number
        Case 0
            MessageBox.Show("Cannot connect to server. Contact administrator")
        Case 1045
            MessageBox.Show("Invalid username/password, please try again")
    End Select
End Try
```

### C# Example

```
MySql.Data.MySqlClient.MySqlConnection conn;
string myConnectionString;

myConnectionString = "server=127.0.0.1;uid=root;" +
    "pwd=12345;database=test;";

try
{
    conn = new MySql.Data.MySqlClient.MySqlConnection(myConnectionString);
    conn.Open();
}
```

```

}
catch (MySql.Data.MySqlClient.MySqlException ex)
{
    switch (ex.Number)
    {
        case 0:
            MessageBox.Show("Cannot connect to server. Contact administrator");
        case 1045:
            MessageBox.Show("Invalid username/password, please try again");
    }
}

```

### Important

Note that if you are using multilanguage databases you must specify the character set in the connection string. If you do not specify the character set, the connection defaults to the `latin1` charset. You can specify the character set as part of the connection string, for example:

```

MySqlConnection myConnection = new MySqlConnection("server=127.0.0.1;uid=root;" +
"pwd=12345;database=test;Charset=latin1;");

```

## 20.2.4.4. Using Connector/NET with Connection Pooling

The Connector/NET supports connection pooling. This is enabled by default, but can be turned off via connection string options. See [Section 20.2.4.3, “Creating a Connection String”](#) for further information.

Connection pooling works by keeping the native connection to the server live when the client disposes of a `MySqlConnection`. Subsequently, if a new `MySqlConnection` object is opened, it will be created from the connection pool, rather than creating a new native connection. This improves performance.

To work as designed, it is best to let the connection pooling system manage all connections. You should not create a globally accessible instance of `MySqlConnection` and then manually open and close it. This interferes with the way the pooling works and can lead to unpredictable results or even exceptions.

One approach that simplifies things is to avoid manually creating a `MySqlConnection` object. Instead use the overloaded methods that take a connection string as an argument. Using this approach, Connector/NET will automatically create, open, close and destroy connections, using the connection pooling system for best performance.

Typed Datasets and the `MembershipProvider` and `RoleProvider` classes use this approach. Most classes that have methods that take a `MySqlConnection` as an argument, also have methods that take a connection string as an argument. This includes `MySqlDataAdapter`.

Instead of manually creating `MySqlCommand` objects, you can use the static methods of the `MySqlHelper` class. These take a connection string as an argument, and they fully support connection pooling.

## 20.2.4.5. Connector/NET Connection String Options Reference

Name	Default	Description
<code>Allow Batch</code>	true	When true, multiple SQL statements can be sent with one command execution. -Note- Starting with MySQL 4.1.1, batch statements should be separated by the server-defined separator character. Commands sent to earlier versions of MySQL should be separated with ';'.
<code>Allow User Variables</code>	false	Setting this to <code>true</code> indicates that the provider expects user variables in the SQL. This option was added in Connector/NET version 5.2.2.
<code>Allow Zero Datetime</code>	false	True to have <code>MySqlDataReader.GetValue()</code> return a <code>MySqlDateTime</code> for date or datetime columns that have illegal values. False will cause a <code>System.DateTime</code> object to be returned for legal values and an exception will be thrown for illegal values.
<code>AutoEnlist</code>	true	
<code>BlobAsUTF8ExcludePattern</code>	null	
<code>BlobAsUTF8IncludePattern</code>	null	
<code>CharSet, Character Set</code>		Specifies the character set that should be used to encode all queries sent to the server. Resultsets are still returned in the character set of the data returned.
<code>Connect Timeout, Connection Timeout</code>	15	The length of time (in seconds) to wait for a connection to the server before terminating the attempt and generating an error.
<code>Connection Reset</code>	false	

Convert Zero Datetime	false	True to have <code>MySqlDataReader.GetValue()</code> and <code>MySqlDataReader.GetDateTime()</code> return <code>DateTime.MinValue</code> for date or datetime columns that have illegal values.
Default Command Timeout		Sets the default value of the command timeout to be used. This does not supercede the individual command timeout property on an individual command object. If you set the command timeout property, that will be used. This option was added in Connector/NET 5.1.4
Encrypt, UseSSL	false	For Connector/NET 5.0.3 and later, when <code>true</code> , SSL encryption is used for all data sent between the client and server if the server has a certificate installed. Recognized values are <code>true</code> , <code>false</code> , <code>yes</code> , and <code>no</code> . In versions before 5.0.3, this option had no effect.
FunctionsReturnString	false	
Host, Server, Data Source, Data-Source, Address, Addr, Network Address	localhost	The name or network address of the instance of MySQL to which to connect. Multiple hosts can be specified separated by <code>&amp;</code> . This can be useful where multiple MySQL servers are configured for replication and you are not concerned about the precise server you are connecting to. No attempt is made by the provider to synchronize writes to the database so care should be taken when using this option. In Unix environment with Mono, this can be a fully qualified path to MySQL socket file name. With this configuration, the Unix socket will be used instead of TCP/IP socket. Currently only a single socket name can be given so accessing MySQL in a replicated environment using Unix sockets is not currently supported.
Ignore Prepare	true	When true, instructs the provider to ignore any calls to <code>MySqlCommand.Prepare()</code> . This option is provided to prevent issues with corruption of the statements when use with server side prepared statements. If you want to use server-side prepare statements, set this option to false. This option was added in Connector/NET 5.0.3 and Connector/NET 1.0.9.
Initial Catalog, Database	mysql	The name of the database to use intially
InteractiveSession	false	
Logging	false	When true, various pieces of information is output to any configured <code>TraceListeners</code> .
Old Syntax, OldSyntax	false	Allows use of <code>'@'</code> symbol as a parameter marker. See <code>MySqlCommand</code> for more info. This option was deprecated in Connector/NET 5.2.2. All future code should be written using the <code>'@'</code> symbol.
Password, pwd		The password for the MySQL account being used.
Persist Security Info	false	When set to <code>false</code> or <code>no</code> (strongly recommended), security-sensitive information, such as the password, is not returned as part of the connection if the connection is open or has ever been in an open state. Re-setting the connection string resets all connection string values including the password. Recognized values are <code>true</code> , <code>false</code> , <code>yes</code> , and <code>no</code> .
Pipe Name, Pipe	mysql	When set to the name of a named pipe, the <code>MySqlConnection</code> will attempt to connect to MySQL on that named pipe. This settings only applies to the Windows platform.
Port	3306	The port MySQL is using to listen for connections. This value is ignored if Unix socket is used.
Procedure Cache Size	25	Sets the size of the stored procedure cache. By default, Connector/NET will store the metadata (input/output datatypes) about the last 25 stored procedures used. To disable the stored procedure cache, set the value to zero (0). This option was added in Connector/NET 5.0.2 and Connector/NET 1.0.9.
Protocol	socket	Specifies the type of connection to make to the server. Values can be: <code>socket</code> or <code>tcp</code> for a socket connection, <code>pipe</code> for a named pipe connection, <code>unix</code> for a Unix socket connection, <code>memory</code> to use MySQL shared memory.
Respect Binary Flags	true	Setting this option to <code>false</code> means that Connector/NET will ignore a column's binary flags as set by the server. This option was added in Connector/NET version 5.1.3.
Shared Memory Name	MYSQL	The name of the shared memory object to use for communication if the connection protocol is set to memory.

<code>TreatBlobsAsUTF8</code>	false	
<code>Treat Tiny As Boolean</code>	true	Setting this value to <code>false</code> indicates that <code>TINYINT(1)</code> will be treated as an <code>INT</code> . See also <a href="#">Section 10.1.1, “Overview of Numeric Types”</a> for a further explanation of the <code>TINYINT</code> and <code>BOOL</code> data types.
<code>Use Affected Rows</code>	false	When <code>true</code> the connection will report changed rows instead of found rows. This option was added in Connector/NET version 5.2.6.
<code>Use Procedure Bodies</code>	true	Setting this option to <code>false</code> indicates that the user connecting to the database does not have the <code>SELECT</code> privileges for the <code>mysql.proc</code> (stored procedures) table. When set to <code>false</code> , Connector/NET will not rely on this information being available when the procedure is called. Because Connector/NET will be unable to determine this information, you should explicitly set the types of all the parameters before the call and the parameters should be added to the command in the exact same order as they appear in the procedure definition. This option was added in Connector/NET 5.0.4 and Connector/NET 1.0.10.
<code>User Id, Username, Uid, User name</code>		The MySQL login account being used.
<code>Use Compression</code>	false	Setting this option to <code>true</code> enables compression of packets exchanged between the client and the server. This exchange is defined by the MySQL client-server protocol.  Compression is used if both client and server support ZLIB compression, and the client has requested compression using this option.  A compressed packet header is: packet length (3 bytes), packet number (1 byte), and Uncompressed Packet Length (3 bytes). The Uncompressed Packet Length is the number of bytes in the original, uncompressed packet. If this is zero then the data in this packet has not been compressed. When the compression protocol is in use, either the client or the server may compress packets. However, compression will not occur if the compressed length is greater than the original length. Thus, some packets will contain compressed data while other packets will not.
<code>Use Usage Advisor</code>	false	
<code>Use Performance Monitor</code>	false	

The following table lists the valid names for connection pooling values within the `ConnectionString`. For more information about connection pooling, see [Connection Pooling](#) for the MySQL Data Provider.

Name	Default	Description
<code>Cache Server Configuration, CacheServerConfiguration, CacheServerConfig</code>	false	Specifies whether server variables should be updated when a pooled connection is returned. Turning this one will yield faster opens but will also not catch any server changes made by other connections.
<code>Connection Lifetime</code>	0	When a connection is returned to the pool, its creation time is compared with the current time, and the connection is destroyed if that time span (in seconds) exceeds the value specified by <code>Connection Lifetime</code> . This is useful in clustered configurations to force load balancing between a running server and a server just brought online. A value of zero (0) causes pooled connections to have the maximum connection timeout.
<code>Max Pool Size</code>	100	The maximum number of connections allowed in the pool.
<code>Min Pool Size</code>	0	The minimum number of connections allowed in the pool.
<code>Pooling</code>	true	When <code>true</code> , the <code>MySqlConnection</code> object is drawn from the appropriate pool, or if necessary, is created and added to the appropriate pool. Recognized values are <code>true</code> , <code>false</code> , <code>yes</code> , and <code>no</code> .
<code>Reset Pooled Connections, ResetConnections, ResetPooledConnections</code>	true	Specifies whether a ping and a reset should be sent to the server before a pooled connection is returned. Not resetting will yield faster connection opens but also will not clear out session items such as temp tables.

#### 20.2.4.6. Using the Connector/NET with Prepared Statements

## Introduction

As of MySQL 4.1, it is possible to use prepared statements with Connector/NET. Use of prepared statements can provide significant performance improvements on queries that are executed more than once.

Prepared execution is faster than direct execution for statements executed more than once, primarily because the query is parsed only once. In the case of direct execution, the query is parsed every time it is executed. Prepared execution also can provide a reduction of network traffic because for each execution of the prepared statement, it is necessary only to send the data for the parameters.

Another advantage of prepared statements is that it uses a binary protocol that makes data transfer between client and server more efficient.

### 20.2.4.6.1. Preparing Statements in Connector/NET

To prepare a statement, create a command object and set the `.CommandText` property to your query.

After entering your statement, call the `.Prepare` method of the `MySQLCommand` object. After the statement is prepared, add parameters for each of the dynamic elements in the query.

After you enter your query and enter parameters, execute the statement using the `.ExecuteNonQuery()`, `.ExecuteScalar()`, or `.ExecuteReader` methods.

For subsequent executions, you need only modify the values of the parameters and call the execute method again, there is no need to set the `.CommandText` property or redefine the parameters.

#### Visual Basic Example

```
Dim conn As New MySqlConnection
Dim cmd As New MySqlCommand

conn.ConnectionString = strConnection

Try
    conn.Open()
    cmd.Connection = conn

    cmd.CommandText = "INSERT INTO myTable VALUES(NULL, @number, @text)"
    cmd.Prepare()

    cmd.Parameters.Add("@number", 1)
    cmd.Parameters.Add("@text", "One")

    For i = 1 To 1000
        cmd.Parameters["@number"].Value = i
        cmd.Parameters["@text"].Value = "A string value"

        cmd.ExecuteNonQuery()
    Next
Catch ex As MySqlException
    MessageBox.Show("Error " & ex.Number & " has occurred: " & ex.Message, "Error", MessageBoxButtons.OK, MessageBoxIcon.Error)
End Try
```

#### C# Example

```
MySQL.Data.MySqlClient.MySqlConnection conn;
MySQL.Data.MySqlClient.MySqlCommand cmd;

conn = new MySQL.Data.MySqlClient.MySqlConnection();
cmd = new MySQL.Data.MySqlClient.MySqlCommand();

conn.ConnectionString = strConnection;

try
{
    conn.Open();
    cmd.Connection = conn;

    cmd.CommandText = "INSERT INTO myTable VALUES(NULL, @number, @text)";
    cmd.Prepare();

    cmd.Parameters.Add("@number", 1);
    cmd.Parameters.Add("@text", "One");

    for (int i=1; i <= 1000; i++)
    {
        cmd.Parameters["@number"].Value = i;
        cmd.Parameters["@text"].Value = "A string value";

        cmd.ExecuteNonQuery();
    }
}
catch (MySQL.Data.MySqlClient.MySqlException ex)
```

```
{
    MessageBox.Show("Error " + ex.Number + " has occurred: " + ex.Message,
        "Error", MessageBoxButtons.OK, MessageBoxIcon.Error);
}
```

## 20.2.4.7. Accessing Stored Procedures with Connector/NET

### Introduction

With the release of MySQL version 5 the MySQL server now supports stored procedures with the SQL 2003 stored procedure syntax.

A stored procedure is a set of SQL statements that can be stored in the server. Once this has been done, clients do not need to keep reissuing the individual statements but can refer to the stored procedure instead.

Stored procedures can be particularly useful in situations such as the following:

- When multiple client applications are written in different languages or work on different platforms, but need to perform the same database operations.
- When security is paramount. Banks, for example, use stored procedures for all common operations. This provides a consistent and secure environment, and procedures can ensure that each operation is properly logged. In such a setup, applications and users would not get any access to the database tables directly, but can only execute specific stored procedures.

Connector/NET supports the calling of stored procedures through the `MySqlCommand` object. Data can be passed in and out of a MySQL stored procedure through use of the `MySqlCommand.Parameters` collection.

### Note

When you call a stored procedure, the command object makes an additional `SELECT` call to determine the parameters of the stored procedure. You must ensure that the user calling the procedure has the `SELECT` privilege on the `mysql.proc` table to enable them to verify the parameters. Failure to do this will result in an error when calling the procedure.

This section will not provide in-depth information on creating Stored Procedures. For such information, please refer to <http://dev.mysql.com/doc/mysql/en/stored-routines.html>.

A sample application demonstrating how to use stored procedures with Connector/NET can be found in the `Samples` directory of your Connector/NET installation.

### 20.2.4.7.1. Creating Stored Procedures from Connector/NET

Stored procedures in MySQL can be created using a variety of tools. First, stored procedures can be created using the `mysql` command-line client. Second, stored procedures can be created using the `MySQL Query Browser` GUI client. Finally, stored procedures can be created using the `.ExecuteNonQuery` method of the `MySqlCommand` object:

#### Visual Basic Example

```
Dim conn As New MySqlConnection
Dim cmd As New MySqlCommand

conn.ConnectionString = "server=127.0.0.1;" _
    & "uid=root;" _
    & "pwd=12345;" _
    & "database=test"

Try
    conn.Open()
    cmd.Connection = conn

    cmd.CommandText = "CREATE PROCEDURE add_emp(" _
        & "IN fname VARCHAR(20), IN lname VARCHAR(20), IN bday DATETIME, OUT empno INT) " _
        & "BEGIN INSERT INTO emp(first_name, last_name, birthdate) " _
        & "VALUES(fname, lname, DATE(bday)); SET empno = LAST_INSERT_ID(); END"

    cmd.ExecuteNonQuery()
Catch ex As MySqlException
    MessageBox.Show("Error " & ex.Number & " has occurred: " & ex.Message, "Error", MessageBoxButtons.OK, MessageBoxIcon.Error)
End Try
```

#### C# Example

```
MySql.Data.MySqlClient.MySqlConnection conn;
MySql.Data.MySqlClient.MySqlCommand cmd;
```

```

conn = new MySql.Data.MySqlClient.MySqlConnection();
cmd = new MySql.Data.MySqlClient.MySqlCommand();

conn.ConnectionString = "server=127.0.0.1;uid=root;" +
    "pwd=12345;database=test;";

try
{
    conn.Open();
    cmd.Connection = conn;

    cmd.CommandText = "CREATE PROCEDURE add_emp(" +
        "IN fname VARCHAR(20), IN lname VARCHAR(20), IN bday DATETIME, OUT empno INT) " +
        "BEGIN INSERT INTO emp(first_name, last_name, birthdate) " +
        "VALUES(fname, lname, DATE(bday)); SET empno = LAST_INSERT_ID(); END";

    cmd.ExecuteNonQuery();
}
catch (MySql.Data.MySqlClient.MySqlException ex)
{
    MessageBox.Show("Error " + ex.Number + " has occurred: " + ex.Message,
        "Error", MessageBoxButtons.OK, MessageBoxIcon.Error);
}

```

It should be noted that, unlike the command-line and GUI clients, you are not required to specify a special delimiter when creating stored procedures in Connector/NET.

### 20.2.4.7.2. Calling a Stored Procedure from Connector/NET

To call a stored procedure using Connector/NET, create a `MySqlCommand` object and pass the stored procedure name as the `.CommandText` property. Set the `.CommandType` property to `CommandType.StoredProcedure`.

After the stored procedure is named, create one `MySqlCommand` parameter for every parameter in the stored procedure. `IN` parameters are defined with the parameter name and the object containing the value, `OUT` parameters are defined with the parameter name and the datatype that is expected to be returned. All parameters need the parameter direction defined.

After defining parameters, call the stored procedure by using the `MySqlCommand.ExecuteNonQuery()` method:

#### Visual Basic Example

```

Dim conn As New MySqlConnection
Dim cmd As New MySqlCommand

conn.ConnectionString = "server=127.0.0.1;" & _
    & "uid=root;" & _
    & "pwd=12345;" & _
    & "database=test"

Try
    conn.Open()
    cmd.Connection = conn

    cmd.CommandText = "add_emp"
    cmd.CommandType = CommandType.StoredProcedure

    cmd.Parameters.Add("@lname", 'Jones')
    cmd.Parameters["@lname"].Direction = ParameterDirection.Input

    cmd.Parameters.Add("@fname", 'Tom')
    cmd.Parameters["@fname"].Direction = ParameterDirection.Input

    cmd.Parameters.Add("@bday", #12/13/1977 2:17:36 PM#)
    cmd.Parameters["@bday"].Direction = ParameterDirection.Input

    cmd.Parameters.Add("@empno", MySqlDbType.Int32)
    cmd.Parameters["@empno"].Direction = ParameterDirection.Output

    cmd.ExecuteNonQuery()

    MessageBox.Show(cmd.Parameters["@empno"].Value)
Catch ex As MySqlException
    MessageBox.Show("Error " & ex.Number & " has occurred: " & ex.Message, "Error", MessageBoxButtons.OK, MessageBoxIcon.Error)
End Try

```

#### C# Example

```

MySql.Data.MySqlClient.MySqlConnection conn;
MySql.Data.MySqlClient.MySqlCommand cmd;

conn = new MySql.Data.MySqlClient.MySqlConnection();
cmd = new MySql.Data.MySqlClient.MySqlCommand();

conn.ConnectionString = "server=127.0.0.1;uid=root;" +
    "pwd=12345;database=test;";

try
{

```

```

conn.Open();
cmd.Connection = conn;

cmd.CommandText = "add_emp";
cmd.CommandType = CommandType.StoredProcedure;

cmd.Parameters.Add("@lname", "Jones");
cmd.Parameters["@lname"].Direction = ParameterDirection.Input;

cmd.Parameters.Add("@fname", "Tom");
cmd.Parameters["@fname"].Direction = ParameterDirection.Input;

cmd.Parameters.Add("@bday", DateTime.Parse("12/13/1977 2:17:36 PM"));
cmd.Parameters["@bday"].Direction = ParameterDirection.Input;

cmd.Parameters.Add("@empno", MySqlDbType.Int32);
cmd.Parameters["@empno"].Direction = ParameterDirection.Output;

cmd.ExecuteNonQuery();

MessageBox.Show(cmd.Parameters["@empno"].Value);
}
catch (MySql.Data.MySqlClient.MySqlException ex)
{
    MessageBox.Show("Error " + ex.Number + " has occurred: " + ex.Message,
        "Error", MessageBoxButtons.OK, MessageBoxIcon.Error);
}

```

Once the stored procedure is called, the values of output parameters can be retrieved by using the `.Value` property of the `MySqlConnector.Parameters` collection.

## 20.2.4.8. Handling BLOB Data With Connector/NET

### Introduction

One common use for MySQL is the storage of binary data in **BLOB** columns. MySQL supports four different BLOB datatypes: `TINYBLOB`, `BLOB`, `MEDIUMBLOB`, and `LONGBLOB`.

Data stored in a BLOB column can be accessed using Connector/NET and manipulated using client-side code. There are no special requirements for using Connector/NET with BLOB data.

Simple code examples will be presented within this section, and a full sample application can be found in the `Samples` directory of the Connector/NET installation.

### 20.2.4.8.1. Preparing the MySQL Server

The first step in using MySQL with BLOB data is to configure the server. Let's start by creating a table to be accessed. In my file tables, I usually have four columns: an `AUTO_INCREMENT` column of appropriate size (`UNSIGNED SMALLINT`) to serve as a primary key to identify the file, a `VARCHAR` column that stores the file name, an `UNSIGNED MEDIUMINT` column that stores the size of the file, and a `MEDIUMBLOB` column that stores the file itself. For this example, I will use the following table definition:

```

CREATE TABLE file(
file_id SMALLINT UNSIGNED AUTO_INCREMENT NOT NULL PRIMARY KEY,
file_name VARCHAR(64) NOT NULL,
file_size MEDIUMINT UNSIGNED NOT NULL,
file MEDIUMBLOB NOT NULL);

```

After creating a table, you may need to modify the `max_allowed_packet` system variable. This variable determines how large of a packet (i.e. a single row) can be sent to the MySQL server. By default, the server will only accept a maximum size of 1 meg from our client application. If you do not intend to exceed 1 meg, this should be fine. If you do intend to exceed 1 meg in your file transfers, this number has to be increased.

The `max_allowed_packet` option can be modified using MySQL Administrator's Startup Variables screen. Adjust the Maximum allowed option in the Memory section of the Networking tab to an appropriate setting. After adjusting the value, click the `APPLY CHANGES` button and restart the server using the `Service Control` screen of MySQL Administrator. You can also adjust this value directly in the `my.cnf` file (add a line that reads `max_allowed_packet=xxM`), or use the `SET max_allowed_packet=xxM`; syntax from within MySQL.

Try to be conservative when setting `max_allowed_packet`, as transfers of BLOB data can take some time to complete. Try to set a value that will be adequate for your intended use and increase the value if necessary.

### 20.2.4.8.2. Writing a File to the Database

To write a file to a database we need to convert the file to a byte array, then use the byte array as a parameter to an `INSERT` query.

The following code opens a file using a `FileStream` object, reads it into a byte array, and inserts it into the `file` table:

## Visual Basic Example

```

Dim conn As New MySqlConnection
Dim cmd As New MySqlCommand

Dim SQL As String

Dim FileSize As UInt32
Dim rawData() As Byte
Dim fs As FileStream

conn.ConnectionString = "server=127.0.0.1;" _
    & "uid=root;" _
    & "pwd=12345;" _
    & "database=test"

Try
    fs = New FileStream("c:\image.png", FileMode.Open, FileAccess.Read)
    FileSize = fs.Length

    rawData = New Byte(FileSize) {}
    fs.Read(rawData, 0, FileSize)
    fs.Close()

    conn.Open()

    SQL = "INSERT INTO file VALUES(NULL, @FileName, @FileSize, @File)"

    cmd.Connection = conn
    cmd.CommandText = SQL
    cmd.Parameters.Add("@FileName", strFileName)
    cmd.Parameters.Add("@FileSize", FileSize)
    cmd.Parameters.Add("@File", rawData)

    cmd.ExecuteNonQuery()

    MessageBox.Show("File Inserted into database successfully!", _
        "Success!", MessageBoxButtons.OK, MessageBoxIcon.Asterisk)

    conn.Close()
Catch ex As Exception
    MessageBox.Show("There was an error: " & ex.Message, "Error", _
        MessageBoxButtons.OK, MessageBoxIcon.Error)
End Try

```

## C# Example

```

MySQL.Data.MySqlClient.MySqlConnection conn;
MySQL.Data.MySqlClient.MySqlCommand cmd;

conn = new MySQL.Data.MySqlClient.MySqlConnection();
cmd = new MySQL.Data.MySqlClient.MySqlCommand();

string SQL;
UInt32 FileSize;
byte[] rawData;
FileStream fs;

conn.ConnectionString = "server=127.0.0.1;uid=root;" +
    "pwd=12345;database=test;";

try
{
    fs = new FileStream(@"c:\image.png", FileMode.Open, FileAccess.Read);
    FileSize = fs.Length;

    rawData = new byte[FileSize];
    fs.Read(rawData, 0, FileSize);
    fs.Close();

    conn.Open();

    SQL = "INSERT INTO file VALUES(NULL, @FileName, @FileSize, @File)";

    cmd.Connection = conn;
    cmd.CommandText = SQL;
    cmd.Parameters.Add("@FileName", strFileName);
    cmd.Parameters.Add("@FileSize", FileSize);
    cmd.Parameters.Add("@File", rawData);

    cmd.ExecuteNonQuery();

    MessageBox.Show("File Inserted into database successfully!",
        "Success!", MessageBoxButtons.OK, MessageBoxIcon.Asterisk);

    conn.Close();
}
catch (MySQL.Data.MySqlClient.MySqlException ex)
{
    MessageBox.Show("Error " + ex.Number + " has occurred: " + ex.Message,
        "Error", MessageBoxButtons.OK, MessageBoxIcon.Error);
}

```

The `Read` method of the `FileStream` object is used to load the file into a byte array which is sized according to the `Length` property of the `FileStream` object.

After assigning the byte array as a parameter of the `MySQLCommand` object, the `ExecuteNonQuery` method is called and the BLOB is inserted into the `file` table.

### 20.2.4.8.3. Reading a BLOB from the Database to a File on Disk

Once a file is loaded into the `file` table, we can use the `MySQLDataReader` class to retrieve it.

The following code retrieves a row from the `file` table, then loads the data into a `FileStream` object to be written to disk:

#### Visual Basic Example

```
Dim conn As New MySqlConnection
Dim cmd As New MySqlCommand
Dim myData As MySQLDataReader
Dim SQL As String
Dim rawData() As Byte
Dim FileSize As UInt32
Dim fs As FileStream

conn.ConnectionString = "server=127.0.0.1;" _
    & "uid=root;" _
    & "pwd=12345;" _
    & "database=test"

SQL = "SELECT file_name, file_size, file FROM file"

Try
    conn.Open()

    cmd.Connection = conn
    cmd.CommandText = SQL

    myData = cmd.ExecuteReader

    If Not myData.HasRows Then Throw New Exception("There are no BLOBs to save")

    myData.Read()

    FileSize = myData.GetUInt32(myData.GetOrdinal("file_size"))
    rawData = New Byte(FileSize) {}

    myData.GetBytes(myData.GetOrdinal("file"), 0, rawData, 0, FileSize)

    fs = New FileStream("C:\newfile.png", FileMode.OpenOrCreate, FileAccess.Write)
    fs.Write(rawData, 0, FileSize)
    fs.Close()

    MessageBox.Show("File successfully written to disk!", "Success!", MessageBoxButtons.OK, MessageBoxIcon.Asterisk)

    myData.Close()
    conn.Close()
Catch ex As Exception
    MessageBox.Show("There was an error: " & ex.Message, "Error", MessageBoxButtons.OK, MessageBoxIcon.Error)
End Try
```

#### C# Example

```
MySQL.Data.MySqlClient.MySqlConnection conn;
MySQL.Data.MySqlClient.MySqlCommand cmd;
MySQL.Data.MySqlClient.MySQLDataReader myData;

conn = new MySQL.Data.MySqlClient.MySqlConnection();
cmd = new MySQL.Data.MySqlClient.MySqlCommand();

string SQL;
UInt32 FileSize;
byte[] rawData;
FileStream fs;

conn.ConnectionString = "server=127.0.0.1;uid=root;" +
    "pwd=12345;database=test;";

SQL = "SELECT file_name, file_size, file FROM file";

try
{
    conn.Open();

    cmd.Connection = conn;
    cmd.CommandText = SQL;

    myData = cmd.ExecuteReader();

    if (! myData.HasRows)
        throw new Exception("There are no BLOBs to save");
```

```

myData.Read();
FileSize = myData.GetUInt32(myData.GetOrdinal("file_size"));
rawData = new byte[FileSize];

myData.GetBytes(myData.GetOrdinal("file"), 0, rawData, 0, FileSize);

fs = new FileStream(@"C:\newfile.png", FileMode.OpenOrCreate, FileAccess.Write);
fs.Write(rawData, 0, FileSize);
fs.Close();

MessageBox.Show("File successfully written to disk!",
    "Success!", MessageBoxButtons.OK, MessageBoxIcon.Asterisk);

myData.Close();
conn.Close();
}
catch (MySql.Data.MySqlClient.MySqlException ex)
{
    MessageBox.Show("Error " + ex.Number + " has occurred: " + ex.Message,
        "Error", MessageBoxButtons.OK, MessageBoxIcon.Error);
}

```

After connecting, the contents of the `file` table are loaded into a `MySqlDataReader` object. The `GetBytes` method of the `MySqlDataReader` is used to load the BLOB into a byte array, which is then written to disk using a `FileStream` object.

The `GetOrdinal` method of the `MySqlDataReader` can be used to determine the integer index of a named column. Use of the `GetOrdinal` method prevents errors if the column order of the `SELECT` query is changed.

## 20.2.4.9. Using Connector/NET with Crystal Reports

### Introduction

Crystal Reports is a common tool used by Windows application developers to perform reporting and document generation. In this section we will show how to use Crystal Reports XI with MySQL and Connector/NET.

### 20.2.4.9.1. Creating a Data Source

When creating a report in Crystal Reports there are two options for accessing the MySQL data while designing your report.

The first option is to use Connector/ODBC as an ADO data source when designing your report. You will be able to browse your database and choose tables and fields using drag and drop to build your report. The disadvantage of this approach is that additional work must be performed within your application to produce a data set that matches the one expected by your report.

The second option is to create a data set in VB.NET and save it as XML. This XML file can then be used to design a report. This works quite well when displaying the report in your application, but is less versatile at design time because you must choose all relevant columns when creating the data set. If you forget a column you must re-create the data set before the column can be added to the report.

The following code can be used to create a data set from a query and write it to disk:

#### Visual Basic Example

```

Dim myData As New DataSet
Dim conn As New MySqlConnection
Dim cmd As New MySqlCommand
Dim myAdapter As New MySqlDataAdapter

conn.ConnectionString = "server=127.0.0.1;" _
    & "uid=root;" _
    & "pwd=12345;" _
    & "database=world"

Try
    conn.Open()
    cmd.CommandText = "SELECT city.name AS cityName, city.population AS CityPopulation, " _
        & "country.name, country.population, country.continent " _
        & "FROM country, city ORDER BY country.continent, country.name"
    cmd.Connection = conn

    myAdapter.SelectCommand = cmd
    myAdapter.Fill(myData)

    myData.WriteXml("C:\dataset.xml", XmlWriteMode.WriteSchema)
Catch ex As Exception
    MessageBox.Show(ex.Message, "Report could not be created", MessageBoxButtons.OK, MessageBoxIcon.Error)
End Try

```

#### C# Example

```

DataSet myData = new DataSet();
MySQL.Data.MySqlClient.MySqlConnection conn;
MySQL.Data.MySqlClient.MySqlCommand cmd;
MySQL.Data.MySqlClient.MySqlDataAdapter myAdapter;

conn = new MySQL.Data.MySqlClient.MySqlConnection();
cmd = new MySQL.Data.MySqlClient.MySqlCommand();
myAdapter = new MySQL.Data.MySqlClient.MySqlDataAdapter();

conn.ConnectionString = "server=127.0.0.1;uid=root;" +
    "pwd=12345;database=test;";

try
{
    cmd.CommandText = "SELECT city.name AS cityName, city.population AS CityPopulation, " +
        "country.name, country.population, country.continent " +
        "FROM country, city ORDER BY country.continent, country.name";
    cmd.Connection = conn;

    myAdapter.SelectCommand = cmd;
    myAdapter.Fill(myData);

    myData.WriteXml(@"C:\dataset.xml", XmlWriteMode.WriteSchema);
}
catch (MySQL.Data.MySqlClient.MySqlException ex)
{
    MessageBox.Show(ex.Message, "Report could not be created",
        MessageBoxButtons.OK, MessageBoxIcon.Error);
}

```

The resulting XML file can be used as an ADO.NET XML datasource when designing your report.

If you choose to design your reports using Connector/ODBC, it can be downloaded from [dev.mysql.com](http://dev.mysql.com).

### 20.2.4.9.2. Creating the Report

For most purposes the Standard Report wizard should help with the initial creation of a report. To start the wizard, open Crystal Reports and choose the New > Standard Report option from the File menu.

The wizard will first prompt you for a data source. If you are using Connector/ODBC as your data source, use the OLEDB provider for ODBC option from the OLE DB (ADO) tree instead of the ODBC (RDO) tree when choosing a data source. If using a saved data set, choose the ADO.NET (XML) option and browse to your saved data set.

The remainder of the report creation process is done automatically by the wizard.

After the report is created, choose the Report Options... entry of the File menu. Un-check the Save Data With Report option. This prevents saved data from interfering with the loading of data within our application.

### 20.2.4.9.3. Displaying the Report

To display a report we first populate a data set with the data needed for the report, then load the report and bind it to the data set. Finally we pass the report to the crViewer control for display to the user.

The following references are needed in a project that displays a report:

- CrystalDecisions.CrystalReports.Engine
- CrystalDecisions.ReportSource
- CrystalDecisions.Shared
- CrystalDecisions.Windows.Forms

The following code assumes that you created your report using a data set saved using the code shown in [Section 20.2.4.9.1, "Creating a Data Source"](#), and have a crViewer control on your form named `myViewer`.

#### Visual Basic Example

```

Imports CrystalDecisions.CrystalReports.Engine
Imports System.Data
Imports MySQL.Data.MySqlClient

Dim myReport As New ReportDocument
Dim myData As New DataSet
Dim conn As New MySqlConnection
Dim cmd As New MySqlCommand
Dim myAdapter As New MySqlDataAdapter

conn.ConnectionString = _

```

```

"server=127.0.0.1;" _
& "uid=root;" _
& "pwd=12345;" _
& "database=test"

Try
    conn.Open()

    cmd.CommandText = "SELECT city.name AS cityName, city.population AS CityPopulation, " _
        & "country.name, country.population, country.continent " _
        & "FROM country, city ORDER BY country.continent, country.name"
    cmd.Connection = conn

    myAdapter.SelectCommand = cmd
    myAdapter.Fill(myData)

    myReport.Load(".\world_report.rpt")
    myReport.SetDataSource(myData)
    myViewer.ReportSource = myReport
Catch ex As Exception
    MessageBox.Show(ex.Message, "Report could not be created", MessageBoxButtons.OK, MessageBoxIcon.Error)
End Try

```

### C# Example

```

using CrystalDecisions.CrystalReports.Engine;
using System.Data;
using MySql.Data.MySqlClient;

ReportDocument myReport = new ReportDocument();
DataSet myData = new DataSet();
MySql.Data.MySqlClient.MySqlConnection conn;
MySql.Data.MySqlClient.MySqlCommand cmd;
MySql.Data.MySqlClient.MySqlDataAdapter myAdapter;

conn = new MySql.Data.MySqlClient.MySqlConnection();
cmd = new MySql.Data.MySqlClient.MySqlCommand();
myAdapter = new MySql.Data.MySqlClient.MySqlDataAdapter();

conn.ConnectionString = "server=127.0.0.1;uid=root;" +
    "pwd=12345;database=test;";

try
{
    cmd.CommandText = "SELECT city.name AS cityName, city.population AS CityPopulation, " +
        "country.name, country.population, country.continent " +
        "FROM country, city ORDER BY country.continent, country.name";
    cmd.Connection = conn;

    myAdapter.SelectCommand = cmd;
    myAdapter.Fill(myData);

    myReport.Load(@".\world_report.rpt");
    myReport.SetDataSource(myData);
    myViewer.ReportSource = myReport;
}
catch (MySql.Data.MySqlClient.MySqlException ex)
{
    MessageBox.Show(ex.Message, "Report could not be created",
        MessageBoxButtons.OK, MessageBoxIcon.Error);
}

```

A new data set is generated using the same query used to generate the previously saved data set. Once the data set is filled, a `ReportDocument` is used to load the report file and bind it to the data set. The `ReportDocument` is then passed as the `ReportSource` of the `crViewer`.

This same approach is taken when a report is created from a single table using Connector/ODBC. The data set replaces the table used in the report and the report is displayed properly.

When a report is created from multiple tables using Connector/ODBC, a data set with multiple tables must be created in our application. This allows each table in the report data source to be replaced with a report in the data set.

We populate a data set with multiple tables by providing multiple `SELECT` statements in our `MySqlCommand` object. These `SELECT` statements are based on the SQL query shown in Crystal Reports in the Database menu's Show SQL Query option. Assume the following query:

```

SELECT `country`.`Name`, `country`.`Continent`, `country`.`Population`, `city`.`Name`, `city`.`Population`
FROM `world`.`country` `country` LEFT OUTER JOIN `world`.`city` `city` ON `country`.`Code`=`city`.`CountryCode`
ORDER BY `country`.`Continent`, `country`.`Name`, `city`.`Name`

```

This query is converted to two `SELECT` queries and displayed with the following code:

### Visual Basic Example

```

Imports CrystalDecisions.CrystalReports.Engine
Imports System.Data

```

```
Imports MySql.Data.MySqlClient

Dim myReport As New ReportDocument
Dim myData As New DataSet
Dim conn As New MySqlConnection
Dim cmd As New MySqlCommand
Dim myAdapter As New MySqlDataAdapter

conn.ConnectionString = "server=127.0.0.1;" _
    & "uid=root;" _
    & "pwd=12345;" _
    & "database=world"

Try
    conn.Open()
    cmd.CommandText = "SELECT name, population, countrycode FROM city ORDER BY countrycode, name;" _
        & "SELECT name, population, code, continent FROM country ORDER BY continent, name"
    cmd.Connection = conn

    myAdapter.SelectCommand = cmd
    myAdapter.Fill(myData)

    myReport.Load(".\world_report.rpt")
    myReport.Database.Tables(0).SetDataSource(myData.Tables(0))
    myReport.Database.Tables(1).SetDataSource(myData.Tables(1))
    myViewer.ReportSource = myReport
Catch ex As Exception
    MessageBox.Show(ex.Message, "Report could not be created", MessageBoxButtons.OK, MessageBoxIcon.Error)
End Try
```

### C# Example

```
using CrystalDecisions.CrystalReports.Engine;
using System.Data;
using MySql.Data.MySqlClient;

ReportDocument myReport = new ReportDocument();
DataSet myData = new DataSet();
MySql.Data.MySqlClient.MySqlConnection conn;
MySql.Data.MySqlClient.MySqlCommand cmd;
MySql.Data.MySqlClient.MySqlDataAdapter myAdapter;

conn = new MySql.Data.MySqlClient.MySqlConnection();
cmd = new MySql.Data.MySqlClient.MySqlCommand();
myAdapter = new MySql.Data.MySqlClient.MySqlDataAdapter();

conn.ConnectionString = "server=127.0.0.1;uid=root;" +
    "pwd=12345;database=test;";

try
{
    cmd.CommandText = "SELECT name, population, countrycode FROM city ORDER " +
        "BY countrycode, name; SELECT name, population, code, continent FROM " +
        "country ORDER BY continent, name";
    cmd.Connection = conn;

    myAdapter.SelectCommand = cmd;
    myAdapter.Fill(myData);

    myReport.Load(@".\world_report.rpt");
    myReport.Database.Tables(0).SetDataSource(myData.Tables(0));
    myReport.Database.Tables(1).SetDataSource(myData.Tables(1));
    myViewer.ReportSource = myReport;
}
catch (MySql.Data.MySqlClient.MySqlException ex)
{
    MessageBox.Show(ex.Message, "Report could not be created",
        MessageBoxButtons.OK, MessageBoxIcon.Error);
}
```

It is important to order the [SELECT](#) queries in alphabetical order, as this is the order the report will expect its source tables to be in. One `SetDataSource` statement is needed for each table in the report.

This approach can cause performance problems because Crystal Reports must bind the tables together on the client-side, which will be slower than using a pre-saved data set.

## 20.2.4.10. Handling Date and Time Information in Connector/NET

### Introduction

MySQL and the .NET languages handle date and time information differently, with MySQL allowing dates that cannot be represented by a .NET data type, such as '0000-00-00 00:00:00'. These differences can cause problems if not properly handled.

In this section we will demonstrate how to properly handle date and time information when using Connector/NET.

#### 20.2.4.10.1. Problems when Using Invalid Dates

The differences in date handling can cause problems for developers who use invalid dates. Invalid MySQL dates cannot be loaded into native .NET `DateTime` objects, including `NULL` dates.

Because of this issue, .NET `DataSet` objects cannot be populated by the `Fill` method of the `MySqlDataAdapter` class as invalid dates will cause a `System.ArgumentOutOfRangeException` exception to occur.

### 20.2.4.10.2. Restricting Invalid Dates

The best solution to the date problem is to restrict users from entering invalid dates. This can be done on either the client or the server side.

Restricting invalid dates on the client side is as simple as always using the .NET `DateTime` class to handle dates. The `DateTime` class will only allow valid dates, ensuring that the values in your database are also valid. The disadvantage of this is that it is not useful in a mixed environment where .NET and non .NET code are used to manipulate the database, as each application must perform its own date validation.

Users of MySQL 5.0.2 and higher can use the new `traditional` SQL mode to restrict invalid date values. For information on using the `traditional` SQL mode, see [Section 5.1.7, “Server SQL Modes”](#).

### 20.2.4.10.3. Handling Invalid Dates

Although it is strongly recommended that you avoid the use of invalid dates within your .NET application, it is possible to use invalid dates by means of the `MySqlDateTime` datatype.

The `MySqlDateTime` datatype supports the same date values that are supported by the MySQL server. The default behavior of Connector/NET is to return a .NET `DateTime` object for valid date values, and return an error for invalid dates. This default can be modified to cause Connector/NET to return `MySqlDateTime` objects for invalid dates.

To instruct Connector/NET to return a `MySqlDateTime` object for invalid dates, add the following line to your connection string:

```
Allow Zero Datetime=True
```

Please note that the use of the `MySqlDateTime` class can still be problematic. The following are some known issues:

1. Data binding for invalid dates can still cause errors (zero dates like 0000-00-00 do not seem to have this problem).
2. The `ToString` method return a date formatted in the standard MySQL format (for example, 2005-02-23 08:50:25). This differs from the `ToString` behavior of the .NET `DateTime` class.
3. The `MySqlDateTime` class supports `NULL` dates, while the .NET `DateTime` class does not. This can cause errors when trying to convert a `MySqlDateTime` to a `DateTime` if you do not check for `NULL` first.

Because of the known issues, the best recommendation is still to use only valid dates in your application.

### 20.2.4.10.4. Handling NULL Dates

The .NET `DateTime` datatype cannot handle `NULL` values. As such, when assigning values from a query to a `DateTime` variable, you must first check whether the value is in fact `NULL`.

When using a `MySqlDataReader`, use the `.IsDBNull` method to check whether a value is `NULL` before making the assignment:

#### Visual Basic Example

```
If Not myReader.IsDBNull(myReader.GetOrdinal("mytime")) Then
    myTime = myReader.GetDateTime(myReader.GetOrdinal("mytime"))
Else
    myTime = DateTime.MinValue
End If
```

#### C# Example

```
if (! myReader.IsDBNull(myReader.GetOrdinal("mytime")))
    myTime = myReader.GetDateTime(myReader.GetOrdinal("mytime"));
else
    myTime = DateTime.MinValue;
```

`NULL` values will work in a data set and can be bound to form controls without special handling.

### 20.2.4.11. ASP.NET Provider Model

MySQL Connector/Net provides support for the ASP.NET 2.0 provider model. This model allows application developers to focus on the business logic of their application instead of having to recreate such boilerplate items as membership and roles support. Currently, only membership and role providers are supplied although session state and profile providers will be provided in upcoming releases.

#### Installing The Providers

The installation of Connector/Net 5.1 or later will install the providers and register them in your machine's .NET configuration file. The providers are implemented in the file `mysql.web.dll` and this file can be found in your Connector/Net installation folder. There is no need to run any type of SQL script to setup the database as the providers create and maintain the proper schema automatically.

#### Using The Providers

The easiest way to start using the providers is to use the ASP.NET configuration tool that is available on the Solution Explorer toolbar when you have a website project loaded.

In the web pages that open you will be able to select the MySQL membership and roles provider by indicating that you want to pick a custom provider for each area.

When the provider is installed, it creates a dummy connection string named `LocalMySqlServer`. This has to be done so that the provider will work in the ASP.NET configuration tool. However, you will want to override this connection string in your `web.config` file. You do this by first removing the dummy connection string and then adding in the proper one. Here is an example:

```
<connectionStrings>
  <remove name="LocalMySqlServer" />
  <add name="LocalMySqlServer" connectionString="server=xxx;uid=xxx;pwd=xxx" />
</connectionStrings>
```

#### Distribution

To use the providers on a production server you will need to distribute the `MySql.Data` and the `MySql.Web` assemblies and either register them in the remote system's Global Assembly Cache or keep them in your application's bin folder.

### 20.2.4.12. Binary/Nonbinary Issues

There are certain situations where MySQL will return incorrect metadata about one or more columns. More specifically, the server will sometimes report that a column is binary when it is not and vice versa. In these situations, it becomes practically impossible for the connector to be able to correctly identify the correct metadata.

Some examples of situations that may return incorrect metadata are:

- Execution of `SHOW PROCESSLIST`. Some of the columns will be returned as binary even though they only hold string data.
- When a temp table is used to process a resultset, some columns may be returned with incorrect binary flags.
- Some server functions such `DATE_FORMAT` will incorrectly return the column as binary.

With the availability of `BINARY` and `VARBINARY` data types it is important that we respect the metadata returned by the server. However, we are aware that some existing applications may break with this change so we are creating a connection string option to enable or disable it. By default, Connector/Net 5.1 will respect the binary flags returned by the server. This will mean that you may need to make small changes to your application to accommodate this change.

In the event that the changes required to your application would be too large, you can add `'respect binary flags=false'` to your connection string. This will cause the connector to use the prior behavior. In a nutshell, that behavior was that any column that is marked as string, regardless of binary flags, will be returned as string. Only columns that are specifically marked as `BLOB` will be returned as `BLOB`.

### 20.2.4.13. Character Sets

#### Treating Binary Blobs As UTF8

MySQL doesn't currently support 4 byte UTF8 sequences. This makes it difficult to represent some multi-byte languages such as Japanese. To try and alleviate this, Connector/Net now supports a mode where binary blobs can be treated as strings.

To do this, you set the 'Treat Blobs As UTF8' connection string keyword to yes. This is all that needs to be done to enable conversion of all binary blobs to UTF8 strings. If you wish to convert only some of your blob columns, then you can make use of the 'BlobAsUTF8IncludePattern' and 'BlobAsUTF8ExcludePattern' keywords. These should be set to the regular expression pattern that matches the column names you wish to include or exclude respectively.

One thing to note is that the regular expression patterns can both match a single column. When this happens, the include pattern is applied before the exclude pattern. The result, in this case, would be that the column would be excluded. You should also be aware that this mode does not apply to columns of type `BINARY` or `VARBINARY` and also do not apply to nonbinary `BLOB` columns.

Currently this mode only applies to reading strings out of MySQL. To insert 4-byte UTF8 strings into blob columns you will need to use the `.NET Encoding.GetBytes` function to convert your string to a series of bytes. You can then set this byte array as a parameter for a `BLOB` column.

#### 20.2.4.14. Working with medium trust

.NET applications operate under a given trust level. Normal desktop applications operate under full trust while web applications that are hosted in shared environments are normally run under the medium trust level. Some hosting providers host shared applications in their own app pools and allow the application to run under full trust, but this seems to be the exception rather than the rule.

Connector/Net versions prior to 5.0.8 and 5.1.3 were not compatible with medium trust hosting. Starting with these versions, Connector/Net can be used under medium trust hosting that has been modified to allow the use of sockets for communication. By default, medium trust does not include `SocketPermission`. Connector/Net uses sockets to talk with the MySQL server so it is required that a new trust level be created that is an exact clone of medium trust but that has `SocketPermission` added.

### 20.2.5. Connector/NET Support

The developers of Connector/NET greatly value the input of our users in the software development process. If you find Connector/NET lacking some feature important to you, or if you discover a bug and need to file a bug report, please use the instructions in [Section 1.6, "How to Report Bugs or Problems"](#).

#### 20.2.5.1. Connector/NET Community Support

- Community support for Connector/NET can be found through the forums at <http://forums.mysql.com>.
- Community support for Connector/NET can also be found through the mailing lists at <http://lists.mysql.com>.
- Paid support is available from Sun Microsystems, Inc. Additional information is available at <http://www.mysql.com/support/>.

#### 20.2.5.2. How to report Connector/NET Problems or Bugs

If you encounter difficulties or problems with Connector/NET, contact the Connector/NET community [Section 20.2.5.1, "Connector/NET Community Support"](#).

You should first try to execute the same SQL statements and commands from the `mysql` client program or from `admindemo`. This helps you determine whether the error is in Connector/NET or MySQL.

If reporting a problem, you should ideally include the following information with the email:

- Operating system and version
- Connector/NET version
- MySQL server version
- Copies of error messages or other unexpected output
- Simple reproducible sample

Remember that the more information you can supply to us, the more likely it is that we can fix the problem.

If you believe the problem to be a bug, then you must report the bug through <http://bugs.mysql.com/>.

#### 20.2.5.3. Connector/NET Change History

The Connector/NET Change History (Changelog) is located with the main Changelog for MySQL. See [Section E.5, "MySQL Con-](#)

ector/NET Change History”.

## 20.2.6. Connector/NET FAQ

### Questions

- [20.2.6.1](#): How do I obtain the value of an auto-incremented column?

### Questions and Answers

#### 20.2.6.1: How do I obtain the value of an auto-incremented column?

When using the `commandBuilder` you should make sure that you set the `ReturnGeneratedIdentifiers` property to `true`.

Then, you can use an active view on a table to access the updated ID. For example:

```
conn = new MySql.Data.MySqlClient.MySqlConnection();
cmd = new MySql.Data.MySqlClient.MySqlCommand();
da = new MySql.Data.MySqlClient.MySqlDataAdapter();
cmdBuilder = new MySql.Data.MySqlClient.MySqlCommandBuilder();
SystemDataDataSet = new System.Data.DataSet();
SystemDataDataView = new System.Data.DataView();
...
cmd.Connection = conn;
cmd.CommandText = "SELECT * FROM contacts";
da.SelectCommand = cmd;
da.Fill(SystemDataDataSet, "contacts");
cmdBuilder.DataAdapter = da;
cmdBuilder.ReturnGeneratedIdentifiers = true;
cmdBuilder.DataAdapter.SelectCommand.CommandText = "SELECT * FROM contacts";
cmdBuilder.RefreshSchema();

SystemDataDataView = SystemDataDataSet.Tables["contacts"].DefaultView;

SystemDataDataRow = SystemDataDataView.Table.NewRow();
SystemDataDataRow["status"] = 1;

SystemDataDataView.Table.Rows.Add(SystemDataDataRow);
da.Update(SystemDataDataSet, "contacts");
System.Console.WriteLine("ID after update: " + SystemDataDataRow["id"]);
```

The `SystemDataDataRow` object in this instance provides the interface to the updated auto-increment value in the `id` column.

## 20.3. MySQL Visual Studio Plugin

The MySQL Visual Studio Plugin is a DDEX provider; a plug-in for Visual Studio 2005 that allows developers to maintain database structures, and supports built-in data-driven application development tools.

The current version of the MySQL Visual Studio Plugin includes only database maintenance tools. Data-driven application development tools are not supported.

The MySQL DDEX Provider operates as a standard extension to the Visual Studio Data Designer functionality available through the Server Explorer menu of Visual Studio 2005, and enables developers to create database objects and data within a MySQL database.

The MySQL Visual Studio Plugin is designed to work with MySQL version 5.0, but is also compatible with MySQL 4.1.1 and provides limited compatibility with MySQL 5.1.

### 20.3.1. Installing the MySQL Visual Studio Plugin

The MySQL Visual Studio Plugin requires one of Visual Studio 2005 Standard, Professional or Team Developer Edition to be installed. Other editions of Visual Studio 2005 are not supported.

#### Note

Starting with Connector/NET 5.1.2, the Visual Studio Plugin is included in the installation. If you have installed Connector/NET 5.1.2, then you do not need to separately install the Visual Studio Plugin.

Here is the list of components that should already be installed before starting the installation of the MySQL Visual Studio Plugin:

- Visual Studio 2005 Standard, Professional or Team Developer Edition.

- MySQL Server 4.1.1 or later (either installed on the same machine, or a separate server).
- MySQL Connector/NET 5.0.

**Note**

When installing Connector/NET you must ensure that the connector is installed into the Global Assembly Cache (GAC). The Connector/NET installer handles this for you automatically, but in a custom installation the option may have been disabled.

The user used to connect to the MySQL server must have the following privileges to use the functionality provided by the MySQL Visual Studio Plugin:

- The `SELECT` privilege for the `INFORMATION_SCHEMA` database.
- The `EXECUTE` privilege for the `SHOW CREATE TABLE` statement.
- The `SELECT` privilege for the `mysql.proc` table (required for operations with stored procedures and functions).
- The `SELECT` privilege for the `mysql.func` table (required for operations with User Defined Functions (UDF)).
- The `EXECUTE` privilege for the `SHOW ENGINE STATUS` statement (required for retrieving extended error information).
- Appropriate privileges for performed operations (e.g. the `SELECT` privilege is required to browse data from a table etc.).

The MySQL Visual Studio Plugin is delivered as a MSI package that can be used to install, uninstall or reinstall the Provider. If you are not using Windows XP or Windows Server 2003 you upgrade the Windows Installer system to the latest version (see <http://support.microsoft.com/default.aspx?scid=kb;EN-US;292539> for details).

The MSI-package is named `MySQL.VisualStudio.msi`. To install the MySQL Visual Studio Plugin, right click on the MSI file and select `INSTALL`. The installation process is as follow:

1. The standard Welcome dialog is opened. Click Next to continue installation.
2. The License agreement (GNU GPL) window is opened. Accept the agreement and click NEXT to continue.
3. The destination folder choice dialog is opened. Here you can point out the folder where the MySQL Visual Studio Plugin will be installed. The default destination folder is `%ProgramFilesDir%\MySQL\MySQL DDEX Data Provider`, where `%ProgramFilesDir%` is the Program Files folder of the installation machine. After choosing the destination folder, click NEXT to continue.
4. The installer will ask to confirm that installation. Click Install to start installation process.
5. The installation will now take place. At the end of this step the Visual Studio command table is rebuilt (this process may take several minutes).
6. Once installation is complete, click FINISH to end the installation process.

To uninstall the MySQL Visual Studio Plugin, you can use either Add/Remove Programs component of the Control Panel or the same MSI-package. Choose the **REMOVE** option, and the Provider will be uninstalled automatically.

To repair the Provider, right click the MSI-package and choose the `REPAIR` option. The MySQL Visual Studio Plugin will be repaired automatically.

The installation package includes the following files:

- `MySQL.VisualStudio.dll` — the MySQL DDEX Provider assembly.
- `MySQL.Data.dll` — the assembly containing the MySQL Connector .NET which is used by the Provider.
- `MySQL.VisualStudio.dll.config` — the configuration file for the MySQL Visual Studio Plugin. This file contains default values for the provider GUI layout.

**Note**

Do not remove this file before the first use of the Provider.

- [Register.reg](#) — the file with registry entries that can be used to register the MySQL DDEX Provider in the case of the manual installation.
- [Install.js](#) — the script used to register the Connector .NET as an ADO.NET data provider in the machine.config file.
- [Release notes.doc](#) — the document with release notes.

To install the Provider manually, copy all files of the installation package in a desired folder, then set the full path to the Provider assembly as a value of the CodeBase entry. For example:

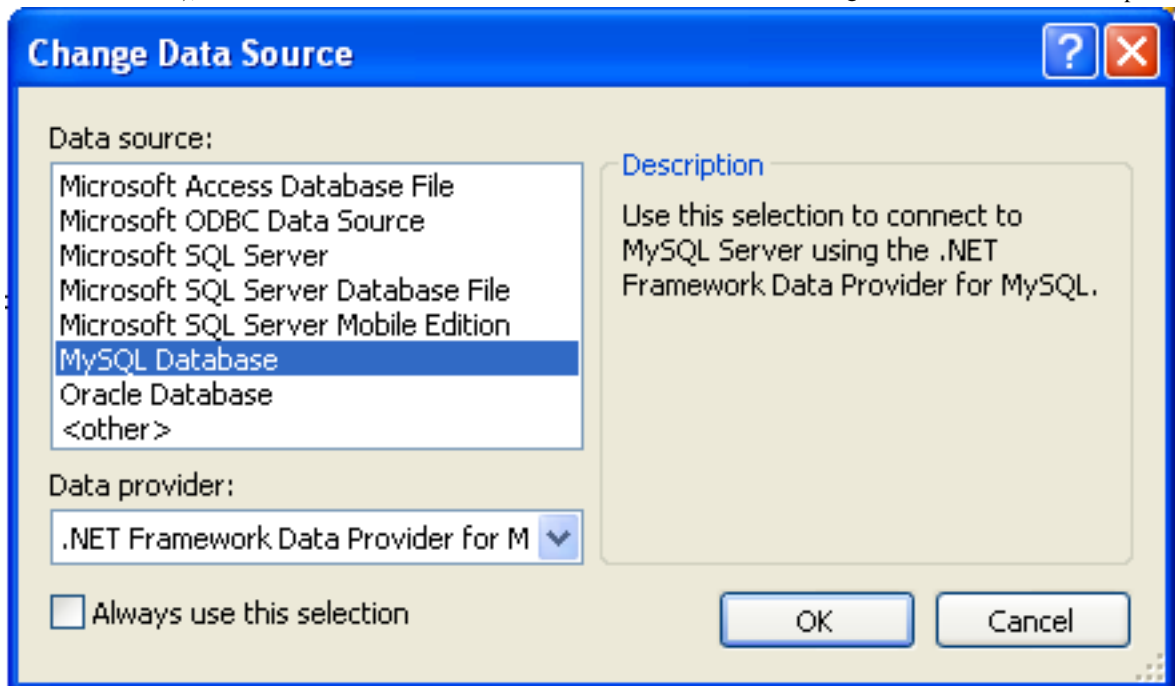

```
[HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\VisualStudio\8.0\Packages\{79A115C9-B133-4891-9E7B-242509DAD272}]@="MySQL.Data.
"InprocServer32"="C:\WINNT\system32\mscoree.dll"
"Class"="MySQL.Data.VisualStudio.MySqlDataProviderPackage"
"CodeBase"="C:\MySQLDdexProvider\MySQL.VisualStudio.dll"
```

Then import information from the Register.reg file to the registry by clicking of the file. At the confirmation dialog choose Yes. Next you must run the command `devenv.exe /setup` within a Command Prompt to rebuild the Visual Studio command table.

### 20.3.2. Creating a connection to the MySQL server

Once the MySQL Visual Studio Plugin is installed, you can use it to create, modify and delete connections to MySQL databases. To create a connection with a MySQL database, perform the following steps:

1. Start Visual Studio 2005 and open Server Explorer window by choosing the **SERVER EXPLORER** option from the **VIEW** menu.
2. Right click on the **DATA CONNECTIONS** node and choose the **ADD CONNECTION** button.
3. The Add Connection dialog is opened. Press the **CHANGE** button to choose MySQL Database as a data source.
4. Change Data Source dialog is opened. Choose MySQL Database in the list of data sources (or the **other** option, if MySQL Database is absent), and then choose **.NET FRAMEWORK DATA PROVIDER FOR MYSQL** in the combo box of data providers.

Press OK to confirm your choice.

5. Enter the connection settings: the server host name (for example, localhost if the MySQL server is installed on the local machine), the user name, the password, and the default database schema. Note that you must specify the default schema name to open the connection.

6. You can also set the port to connect with the MySQL server by pressing the **ADVANCED** button. To test a connection with the MySQL server, set the server host name, the user name, and the password, and press the **TEST CONNECTION** button. If the test fails, check the connection values that you have supplied are correct and that the corresponding user and privileges have been configured on the MySQL server.
7. After you set all settings and test the connection, press **OK**. The newly created connection is displayed in Server Explorer. Now you can work with the MySQL server through standard Server Explorer interface.

After a connection is successfully established, all the connection settings are saved. When you next open Visual Studio, the connection to the MySQL server will appear within Server Explorer so that you can re-establish a connection to the MySQL server.

To modify and delete a connection, use the **SERVER EXPLORER** context menu for the corresponding node. You can modify any of the settings just by overwriting the existing values with new ones. Note that a connection should be modified or deleted only if no active editor for its objects is opened. Otherwise your data could be lost.

### 20.3.3. Using the MySQL Visual Studio Plugin

To work with a MySQL server using the MySQL Visual Studio Plugin, open the Visual Studio 2005, open the **SERVER EXPLORER**, and select the required connection. The working area of the MySQL Visual Studio Plugin consists of three parts.

- Database objects (tables, views, stored routines, triggers, and user defined functions) are displayed in the Server Explorer tree. Here you can choose an object and edit its properties and definition.
- Properties of a selected database object are displayed in the **PROPERTIES** panel. Certain properties can be edited directly within this window.
- The editor panel provides direct access to the SQL statement and definition of specific objects. For example, the SQL statements within a stored procedure definition are shown and edited within this panel.

### 20.3.3.1. Editing Tables

The Table Editor can be accessed through a mouse action on table-type node of Server Explorer. To create a new table, right click on the **TABLES** node (under the connection node) and choose the **CREATE TABLE** command from a context menu. To modify an existing table, double click on a node of the table you wish to modify, or right click on this node and choose the **ALTER TABLE** command from a context menu. Either of the commands opens the Table Editor.

The MySQL Visual Studio Plugin Table Editor is implemented in a similar fashion to the standard Query Browser Table Editor, but with minor differences.

The Table Editor consists of the following parts:

- Columns Editor — for column creation, modification and deletion.
- Indexes tab — for table/column index management.
- Foreign Keys tab — for configuration of foreign keys.
- Column Details tab — used to set advanced column options.
- Properties window — used to set table properties.

To save changes you have made in the Table Editor, use either Save or Save All buttons of the Visual Studio main toolbar, or just press **Ctrl+S**. Before changes are saved, a confirmation dialog will be displayed to confirm that you want to update the corresponding object within the MySQL database.

### 20.3.3.1.1. Column Editor

You can use the Column Editor to set or change the name, data type, default value and other properties of a table column. To set the properties of an individual column, select the column using the mouse. Alternatively, you can move through the grid using **Tab** and **Shift+Tab** keys.

- To set or change the name, data type, default value and comment of a column, select the appropriate cell and edit the desired value.
- To set or unset flag-type column properties (i.e., primary key, **NOT NULL**, auto-incremented, flags), check or uncheck the corresponding checkboxes. Note that the available column flags will depend on the columns data type.
- To reorder columns, index columns or foreign key columns in the Column Editor, select the whole column you wish to reorder by clicking on the selector column at the left of the column grid. Then move the column by using **Ctrl+Up** (to move the

column up) and **Ctrl+Down** (to move the column down) keys.

- To delete a column, select it by clicking on the selector column at the left of the column grid, then press the **Delete** button on a keyboard.

### 20.3.3.1.2. Indexes tab

Index management is performed via the Indexes tab.

- To add an index, press the + button and set the properties in the **INDEX SETTINGS** groupbox at the right. You can set the index name, index kind, index type and a set of index columns.
- To remove an index, select the index from the list and press the - button.
- To change index settings, select the index from the list; detailed information about the index is displayed in the **INDEX SETTINGS** panel.

You cannot change a table column to an index column using drag and drop. Instead, you can add new index columns to a table and set their table columns by using the embedded editor within the Indexes tab

### 20.3.3.1.3. Foreign Keys tab

Foreign Key management is performed via the Foreign Keys tab.

- To add a foreign key, press the + button and set properties in the **FOREIGN KEYS SETTINGS** panel. You can set the foreign key name, referenced table name, foreign key columns and actions on update and delete.
- To remove a foreign key, select the foreign key and press the - button.
- To change foreign key settings, select the foreign key and use the **FOREIGN KEYS SETTINGS** panel to edit the properties.
- When a foreign key is changed, the MySQL Visual Studio Plugin generates two queries: the first query drops the changed keys and the second one recreates the new values. The reason for such a behavior is to avoid the [Bug#8377](#) and [Bug#8919](#).

#### Note

If changed values are for some reason inconsistent and cause the second query to fail, all affected foreign keys will be dropped. If this is the case, the MySQL Visual Studio Plugin will mark them as new in the Table Editor, and you will have to recreate them later. But if you close the Table Editor without saving, these foreign keys will be lost.

### 20.3.3.1.4. Column Details tab

The Column Details tab can be used to set column options. Besides the main column properties that are presented in the Column Editor, in the Column Details tab you can set two additional properties options: the character set and the collation sequence.

### 20.3.3.1.5. Table Properties window

There is no separate tab for table options and advanced options. All table options can be browsed and changed using the **PROPERTIES** window of Visual Studio 2005.

The following table properties can be set:

- **AUTO INCREMENT**
- **AVERAGE ROW LENGTH**
- **CHARACTER SET**
- **CHECKSUM FOR ROWS**
- **COLLATION**
- **COMMENT**
- **CONNECTION**

- **DATA DIRECTORY**
- **DELAY KEY UPDATES**
- **ENGINE**
- **INDEX DIRECTORY**
- **INSERT METHOD**
- **MAXIMUM ROWS**
- **MINIMUM ROWS**
- **NAME**
- **PACK KEYS**
- **PASSWORD**
- **ROW FORMAT**
- **UNION**

Some of these properties can have arbitrary text values, others accept values from a predefined set.

The properties **SCHEMA** and **SERVER** are read only.

### 20.3.3.2. Editing Table Data

The Table Data Editor, allows a user to browse, create and edit data of tables. The Table Data Editor is implemented as a simple data grid with auto generated columns.

To access the Table Data Editor, right click on a node representing the table or view in Server Explorer. From the nodes context menu, choose the **BROWSE** or **EDIT DATA** command. For tables and updatable views, this command opens the Table Data Editor in edit mode. For non-updatable views, this command opens the Table Data Editor in read-only mode.

When in the edit mode, you can modify table data by modifying the displayed table contents directly. To add a row, set desired values in the last row of the grid. To modify values, set new values in appropriate cells. To delete a row, select it by clicking on the selector column at the left of the grid, then press the **DELETE** button.

To save changes you have made in the Table Data Editor, use either **SAVE** or **SAVE ALL** buttons of the Visual Studio main toolbar, or just press **Ctrl+S**. A confirmation dialog will confirm whether you want the changes saved to the database.

### 20.3.3.3. Editing Views

To create a new view, right click the Views node under the connection node in Server Explorer. From the nodes context menu, choose the **CREATE VIEW** command. This command opens the SQL Editor.

To modify an existing view, double click on a node of the view you wish to modify, or right click on this node and choose the **ALTER VIEW** command from a context menu. Either of the commands opens the SQL Editor.

To create or alter the view definition using SQL Editor, type the appropriate SQL statement in the SQL Editor.

#### **Note**

You should enter only the defining statement itself, without the **CREATE VIEW AS** preface.

All other view properties can be set in the **PROPERTIES** window. These properties are:

- **ALGORITHM**
- **CHECK OPTION**
- **DEFINER**
- **NAME**
- **SECURITY TYPE**

Some of these properties can have arbitrary text values, others accept values from a predefined set.

The properties **IS UPDATABLE**, **SCHEMA** and **SERVER** are readonly.

To save changes you have made, use either **SAVE** or **SAVE ALL** buttons of the Visual Studio main toolbar, or just press **Ctrl+S**. A confirmation dialog will confirm whether you want the changes saved to the database.

#### 20.3.3.4. Editing Stored Procedures and Functions

To create a new stored procedure, right click the Stored Procedures node under the connection node in Server Explorer. From the nodes context menu, choose the **CREATE ROUTINE** command. This command opens the SQL Editor.

To create a new stored function, right click the **FUNCTIONS** node under the connection node in Server Explorer. From the node's context menu, choose the **CREATE ROUTINE** command.

To modify an existing stored routine (procedure or function), double click on a node of the routine you wish to modify, or right click on this node and choose the **ALTER ROUTINE** command from a context menu. Either of the commands opens the SQL Editor.

To create or alter the routine definition using SQL Editor, type this definition in the SQL Editor using standard SQL.

All other routine properties can be set in the **PROPERTIES** window. These properties are:

- Comment
- Data Access
- Definer
- Is Deterministic
- Security Type

Some of these properties can have arbitrary text values, others accept values only from a predefined set.

Also you can set all the options directly in the SQL Editor, using the standard **CREATE PROCEDURE** or **CREATE FUNCTION** statement. However, it is recommended to use the **PROPERTIES** window instead.

#### Note

You should never add the **CREATE** preface to the routine definition.

The properties **NAME**, **SCHEMA** and **SERVER** in the **PROPERTIES** window are read-only. Set or change the procedure name in the SQL editor.

To save changes you have made, use either **SAVE** or **SAVE ALL** buttons of the Visual Studio main toolbar, or just press **Ctrl+S**. A confirmation dialog will confirm whether you want the changes saved to the database..

#### 20.3.3.5. Editing Triggers

To create a new trigger, right click on a node of a table for which you wish to add a trigger. From the node's context menu, choose the **CREATE TRIGGER** command. This command opens the SQL Editor.

To modify an existing trigger, double click on a node of the trigger you wish to modify, or right click on this node and choose the **ALTER TRIGGER** command from a context menu. Either of the commands opens the SQL Editor.

To create or alter the trigger definition using SQL Editor, type the trigger statement in the SQL Editor using standard SQL.

#### Note

You should enter only the trigger statement, that is the part of the **CREATE TRIGGER** query that is placed after the **FOR EACH ROW** clause.

All other trigger properties are set in the **PROPERTIES** window. These properties are:

- **DEFINER**
- **EVENT MANIPULATION**

- **NAME**
- **TIMING**

Some of these properties can have arbitrary text values, others accept values only from a predefined set.

The properties **EVENT TABLE**, **SCHEMA** and **SERVER** in the **PROPERTIES** window are read-only.

To save changes you have made, use either **SAVE** or **SAVE ALL** buttons of the Visual Studio main toolbar, or just press **Ctrl+S**. A confirmation dialog will confirm whether you want the changes saved to the database.

### 20.3.3.6. Editing User Defined Functions (UDF)

To create a new User Defined Function (UDF), right click the UDFs node under the connection node in Server Explorer. From the node's context menu, choose the **CREATE UDF** command. This command opens the UDF Editor.

To modify an existing UDF, double click on a node of the UDF you wish to modify, or right click on this node and choose the **Alter UDF** command from a context menu. Either of the commands opens the UDF Editor.

The UDF editor allows you to set the following properties through the properties panel:

- **NAME**
- **SO-NAME (DLL NAME)**
- **RETURN TYPE**
- **IS AGGREGATE**

The property **Server** in the **PROPERTIES** window is read-only.

To save changes you have made, use either **SAVE** or **SAVE ALL** buttons of the Visual Studio main toolbar, or just press **Ctrl+S**. A confirmation dialog will confirm whether you want the changes saved to the database.

### 20.3.3.7. Dropping database objects

Tables, views, stored routines, triggers, and UDFs can be dropped with the appropriate **DROP** command from its context menu: **DROP TABLE**, **DROP VIEW**, **DROP ROUTINE**, **DROP TRIGGER**, **DROP UDF**.

You will be asked to confirm the execution of the corresponding drop query in a confirmation dialog.

Dropping of multiple objects is not supported.

### 20.3.3.8. Cloning database objects

Tables, views, stored procedures and functions can be cloned with the appropriate **CLONE** command from its context menu: **CLONE TABLE**, **CLONE VIEW**, **CLONE ROUTINE**. The clone commands open the corresponding editor for a new object: the **TABLE EDITOR** for cloning a table and the **SQL Editor** for cloning a view or a routine.

To save the cloned object, use either **SAVE** or **SAVE ALL** buttons of the Visual Studio main toolbar, or just press **Ctrl+S**. A confirmation dialog will confirm whether you want the changes saved to the database.

## 20.3.4. Visual Studio Plugin Support

If you have a comment, or if you discover a bug, please, use our MySQL bug tracking system (<http://bugs.mysql.com>) to report problem or add your suggestion.

### 20.3.4.1. Visual Studio Plugin FAQ

#### Questions

- **20.3.4.1.1:** When creating a connection, typing the connection details causes the connection window to immediately close.

#### Questions and Answers

**20.3.4.1.1: When creating a connection, typing the connection details causes the connection window to immediately close.**

There are known issues with versions of Connector/NET earlier than 5.0.2. Connector/NET 1.0.x is known not to work. If you have any of these versions installed, or have previously upgraded from an earlier version, uninstall Connector/NET completely and then install Connector/NET 5.0.2.

## 20.4. MySQL Connector/J

MySQL provides connectivity for client applications developed in the Java programming language via a JDBC driver, which is called MySQL Connector/J.

MySQL Connector/J is a JDBC Type 4 driver. Different versions are available that are compatible with the JDBC 3.0 and JDBC 4.0 specifications. The Type 4 designation means that the driver is pure-Java implementation of the MySQL protocol and does not rely on the MySQL client libraries.

Although JDBC is useful by itself, we would hope that if you are not familiar with JDBC that after reading the first few sections of this manual, that you would avoid using naked JDBC for all but the most trivial problems and consider using one of the popular persistence frameworks such as [Hibernate](#), [Spring's JDBC templates](#) or [Ibatis SQL Maps](#) to do the majority of repetitive work and heavier lifting that is sometimes required with JDBC.

This section is not designed to be a complete JDBC tutorial. If you need more information about using JDBC you might be interested in the following online tutorials that are more in-depth than the information presented here:

- [JDBC Basics](#) — A tutorial from Sun covering beginner topics in JDBC
- [JDBC Short Course](#) — A more in-depth tutorial from Sun and JGuru

### Key topics:

- For help with connection strings, connection options setting up your connection through JDBC, see [Section 20.4.4.1, “Driver/Datasource Class Names, URL Syntax and Configuration Properties for Connector/J”](#).
- For tips on using Connector/J and JDBC with generic J2EE toolkits, see [Section 20.4.5.2, “Using Connector/J with J2EE and Other Java Frameworks”](#).
- Developers using the Tomcat server platform, see [Section 20.4.5.2.2, “Using Connector/J with Tomcat”](#).
- Developers using JBoss, see [Section 20.4.5.2.3, “Using Connector/J with JBoss”](#).
- Developers using Spring, see [Section 20.4.5.2.4, “Using Connector/J with Spring”](#).

### MySQL Enterprise

MySQL Enterprise subscribers will find more information about using JDBC with MySQL in the Knowledge Base articles about [JDBC](#). Access to the MySQL Knowledge Base collection of articles is one of the advantages of subscribing to MySQL Enterprise. For more information, see <http://www.mysql.com/products/enterprise/advisors.html>.

### 20.4.1. Connector/J Versions

There are currently four versions of MySQL Connector/J available:

- Connector/J 5.1 is the Type 4 pure Java JDBC driver, which conforms to the JDBC 3.0 and JDBC 4.0 specifications. It provides compatibility with all the functionality of MySQL, including 4.1, 5.0, 5.1 and the 6.0 alpha release featuring the new Falcon storage engine. Connector/J 5.1 provides ease of development features, including auto-registration with the Driver Manager, standardized validity checks, categorized SQLExceptions, support for the JDBC-4.0 XML processing, per connection client information, [NCHAR](#), [NVARCHAR](#) and [NCLOB](#) types. This release also includes all bug fixes up to and including Connector/J 5.0.6.
- Connector/J 5.0 provides support for all the functionality offered by Connector/J 3.1 and includes distributed transaction (XA) support.
- Connector/J 3.1 was designed for connectivity to MySQL 4.1 and MySQL 5.0 servers and provides support for all the functionality in MySQL 5.0 except distributed transaction (XA) support.
- Connector/J 3.0 provides core functionality and was designed with connectivity to MySQL 3.x or MySQL 4.1 servers, although

it will provide basic compatibility with later versions of MySQL. Connector/J 3.0 does not support server-side prepared statements, and does not support any of the features in versions of MySQL later than 4.1.

The following table summarizes the Connector/J versions available:

Connector/J version	Driver Type	JDBC version	MySQL Server version	Status
5.1	4	3.0, 4.0	4.1, 5.0, 5.1, 6.0	Recommended version
5.0	4	3.0	4.1, 5.0	Released version
3.1	4	3.0	4.1, 5.0	Obsolete
3.0	4	3.0	3.x, 4.1	Obsolete

The current recommended version for Connector/J is 5.1. This guide covers all four connector versions, with specific notes given where a setting applies to a specific option.

### 20.4.1.1. Java Versions Supported

The following table summarizes Connector/J Java dependencies:

Connector/J version	Java RTE required	JDK required (to build source code)
5.1	1.4.x, 1.5.x, 1.6.x	1.6.x and 1.5.x (or older)
5.0	1.3.x, 1.4.x, 1.5.x, 1.6.x	1.4.2, 1.5.x, 1.6.x
3.1	1.2.x, 1.3.x, 1.4.x, 1.5.x, 1.6.x	1.4.2, 1.5.x, 1.6.x
3.0	1.2.x, 1.3.x, 1.4.x, 1.5.x, 1.6.x	1.4.2, 1.5.x, 1.6.x

MySQL Connector/J does not support JDK-1.1.x or JDK-1.0.x.

Because of the implementation of `java.sql.Savepoint`, Connector/J 3.1.0 and newer will not run on a Java runtime older than 1.4 unless the class verifier is turned off (by setting the `-Xverify:none` option to the Java runtime). This is because the class verifier will try to load the class definition for `java.sql.Savepoint` even though it is not accessed by the driver unless you actually use savepoint functionality.

Caching functionality provided by Connector/J 3.1.0 or newer is also not available on JVMs older than 1.4.x, as it relies on `java.util.LinkedHashMap` which was first available in JDK-1.4.0.

If you are building Connector/J from source code using the source distribution (see [Section 20.4.2.4, “Installing from the Development Source Tree”](#)) then you must use JDK 1.4.2 or newer to compile the Connector package. For Connector/J 5.1 you must have both JDK-1.6.x. and JDK-1.5.x installed in order to be able to build the source code.

## 20.4.2. Connector/J Installation

You can install the Connector/J package using either the binary or source distribution. The binary distribution provides the easiest method for installation; the source distribution enables you to customize your installation further. With either solution, you must manually add the Connector/J location to your Java `CLASSPATH`.

If you are upgrading from a previous version, read the upgrade information before continuing. See [Section 20.4.2.3, “Upgrading from an Older Version”](#).

### 20.4.2.1. Installing Connector/J from a Binary Distribution

The easiest method of installation is to use the binary distribution of the Connector/J package. The binary distribution is available either as a Tar/Gzip or Zip file which you must extract to a suitable location and then optionally make the information about the package available by changing your `CLASSPATH` (see [Section 20.4.2.2, “Installing the Driver and Configuring the CLASSPATH”](#)).

MySQL Connector/J is distributed as a .zip or .tar.gz archive containing the sources, the class files, and the JAR archive named `mysql-connector-java-[version]-bin.jar`, and starting with Connector/J 3.1.8 a debug build of the driver in a file named `mysql-connector-java-[version]-bin-g.jar`.

Starting with Connector/J 3.1.9, the `.class` files that constitute the JAR files are only included as part of the driver JAR file.

You should not use the debug build of the driver unless instructed to do so when reporting a problem or a bug to MySQL AB, as it

is not designed to be run in production environments, and will have adverse performance impact when used. The debug binary also depends on the Aspect/J runtime library, which is located in the `src/lib/aspectjrt.jar` file that comes with the Connector/J distribution.

You will need to use the appropriate graphical or command-line utility to extract the distribution (for example, WinZip for the .zip archive, and `tar` for the .tar.gz archive). Because there are potentially long file names in the distribution, we use the GNU tar archive format. You will need to use GNU tar (or an application that understands the GNU tar archive format) to unpack the .tar.gz variant of the distribution.

### 20.4.2.2. Installing the Driver and Configuring the CLASSPATH

Once you have extracted the distribution archive, you can install the driver by placing `mysql-connector-java-[version]-bin.jar` in your classpath, either by adding the full path to it to your `CLASSPATH` environment variable, or by directly specifying it with the command line switch `-cp` when starting your JVM.

If you are going to use the driver with the JDBC DriverManager, you would use `com.mysql.jdbc.Driver` as the class that implements `java.sql.Driver`.

You can set the `CLASSPATH` environment variable under UNIX, Linux or Mac OS X either locally for a user within their `.profile`, `.login` or other login file. You can also set it globally by editing the global `/etc/profile` file.

For example, under a C shell (csh, tcsh) you would add the Connector/J driver to your `CLASSPATH` using the following:

```
shell> setenv CLASSPATH /path/mysql-connector-java-[ver]-bin.jar:$CLASSPATH
```

Or with a Bourne-compatible shell (sh, ksh, bash):

```
shell> export set CLASSPATH=/path/mysql-connector-java-[ver]-bin.jar:$CLASSPATH
```

Within Windows 2000, Windows XP, Windows Server 2003 and Windows Vista, you must set the environment variable through the System Control Panel.

If you want to use MySQL Connector/J with an application server such as GlassFish, Tomcat or JBoss, you will have to read your vendor's documentation for more information on how to configure third-party class libraries, as most application servers ignore the `CLASSPATH` environment variable. For configuration examples for some J2EE application servers, see [Section 20.4.5.2, "Using Connector/J with J2EE and Other Java Frameworks"](#). However, the authoritative source for JDBC connection pool configuration information for your particular application server is the documentation for that application server.

If you are developing servlets or JSPs, and your application server is J2EE-compliant, you can put the driver's .jar file in the `WEB-INF/lib` subdirectory of your webapp, as this is a standard location for third party class libraries in J2EE web applications.

You can also use the `MysqlDataSource` or `MysqlConnectionPoolDataSource` classes in the `com.mysql.jdbc.jdbc2.optional` package, if your J2EE application server supports or requires them. Starting with Connector/J 5.0.0, the `javax.sql.XADataSource` interface is implemented via the `com.mysql.jdbc.jdbc2.optional.MysqlXADataSource` class, which supports XA distributed transactions when used in combination with MySQL server version 5.0.

The various `MysqlDataSource` classes support the following parameters (through standard set mutators):

- user
- password
- serverName (see the previous section about fail-over hosts)
- databaseName
- port

### 20.4.2.3. Upgrading from an Older Version

We try to keep the upgrade process as easy as possible, however as is the case with any software, sometimes changes need to be made in new versions to support new features, improve existing functionality, or comply with new standards.

This section has information about what users who are upgrading from one version of Connector/J to another (or to a new version of the MySQL server, with respect to JDBC functionality) should be aware of.

### 20.4.2.3.1. Upgrading from MySQL Connector/J 3.0 to 3.1

Connector/J 3.1 is designed to be backward-compatible with Connector/J 3.0 as much as possible. Major changes are isolated to new functionality exposed in MySQL-4.1 and newer, which includes Unicode character sets, server-side prepared statements, SQL-State codes returned in error messages by the server and various performance enhancements that can be enabled or disabled via configuration properties.

- **Unicode Character Sets** — See the next section, as well as [Section 9.1, “Character Set Support”](#), for information on this new feature of MySQL. If you have something misconfigured, it will usually show up as an error with a message similar to `Illegal mix of collations`.
- **Server-side Prepared Statements** — Connector/J 3.1 will automatically detect and use server-side prepared statements when they are available (MySQL server version 4.1.0 and newer).

Starting with version 3.1.7, the driver scans SQL you are preparing via all variants of `Connection.prepareStatement()` to determine if it is a supported type of statement to prepare on the server side, and if it is not supported by the server, it instead prepares it as a client-side emulated prepared statement. You can disable this feature by passing `emulateUnsupportedPstmts=false` in your JDBC URL.

If your application encounters issues with server-side prepared statements, you can revert to the older client-side emulated prepared statement code that is still presently used for MySQL servers older than 4.1.0 with the connection property `useServerPrepStmts=false`

- **Datetimes** with all-zero components (`0000-00-00 . . .`) — These values can not be represented reliably in Java. Connector/J 3.0.x always converted them to NULL when being read from a `ResultSet`.

Connector/J 3.1 throws an exception by default when these values are encountered as this is the most correct behavior according to the JDBC and SQL standards. This behavior can be modified using the `zeroDateTimeBehavior` configuration property. The allowable values are:

- `exception` (the default), which throws an `SQLException` with an `SQLState` of `S1009`.
- `convertToNull`, which returns `NULL` instead of the date.
- `round`, which rounds the date to the nearest closest value which is `0001-01-01`.

Starting with Connector/J 3.1.7, `ResultSet.getString()` can be decoupled from this behavior via `noDatetimeStringSync=true` (the default value is `false`) so that you can retrieve the unaltered all-zero value as a `String`. It should be noted that this also precludes using any time zone conversions, therefore the driver will not allow you to enable `noDatetimeStringSync` and `useTimezone` at the same time.

- **New SQLState Codes** — Connector/J 3.1 uses SQL:1999 `SQLState` codes returned by the MySQL server (if supported), which are different from the legacy X/Open state codes that Connector/J 3.0 uses. If connected to a MySQL server older than MySQL-4.1.0 (the oldest version to return `SQLStates` as part of the error code), the driver will use a built-in mapping. You can revert to the old mapping by using the configuration property `useSqlStateCodes=false`.
- **`ResultSet.getString()`** — Calling `ResultSet.getString()` on a `BLOB` column will now return the address of the `byte[]` array that represents it, instead of a `String` representation of the `BLOB`. `BLOB` values have no character set, so they cannot be converted to `java.lang.Strings` without data loss or corruption.

To store strings in MySQL with LOB behavior, use one of the `TEXT` types, which the driver will treat as a `java.sql.Clob`.

- **Debug builds** — Starting with Connector/J 3.1.8 a debug build of the driver in a file named `mysql-connector-java-[version]-bin-g.jar` is shipped alongside the normal binary jar file that is named `mysql-connector-java-[version]-bin.jar`.

Starting with Connector/J 3.1.9, we do not ship the `.class` files unbundled, they are only available in the JAR archives that ship with the driver.

You should not use the debug build of the driver unless instructed to do so when reporting a problem or bug, as it is not designed to be run in production environments, and will have adverse performance impact when used. The debug binary also depends on the Aspect/J runtime library, which is located in the `src/lib/aspectjrt.jar` file that comes with the Connector/J distribution.

### 20.4.2.3.2. Upgrading to MySQL Connector/J 5.1.x

- In Connector/J 5.0.x and earlier, the alias for a table in a `SELECT` statement is returned when accessing the result set metadata

using `ResultSetMetaData.getColumnNames()`. This behavior however is not JDBC compliant, and in Connector/J 5.1 this behavior was changed so that the original table name, rather than the alias, is returned.

The JDBC-compliant behavior is designed to let API users reconstruct the DML statement based on the metadata within `ResultSet` and `ResultSetMetaData`.

You can get the alias for a column in a result set by calling `ResultSetMetaData.getColumnLabel()`. If you want to use the old non-compliant behavior with `ResultSetMetaData.getColumnNames()`, use the `useOldAliasMetadataBehavior` option and set the value to `true`.

In Connector/J 5.0.x the default value of `useOldAliasMetadataBehavior` was true, but in Connector/J 5.1 this was changed to a default value of false.

### 20.4.2.3.3. JDBC-Specific Issues When Upgrading to MySQL Server 4.1 or Newer

- *Using the UTF-8 Character Encoding* - Prior to MySQL server version 4.1, the UTF-8 character encoding was not supported by the server, however the JDBC driver could use it, allowing storage of multiple character sets in latin1 tables on the server.

Starting with MySQL-4.1, this functionality is deprecated. If you have applications that rely on this functionality, and can not upgrade them to use the official Unicode character support in MySQL server version 4.1 or newer, you should add the following property to your connection URL:

```
useOldUTF8Behavior=true
```

- *Server-side Prepared Statements* - Connector/J 3.1 will automatically detect and use server-side prepared statements when they are available (MySQL server version 4.1.0 and newer). If your application encounters issues with server-side prepared statements, you can revert to the older client-side emulated prepared statement code that is still presently used for MySQL servers older than 4.1.0 with the following connection property:

```
useServerPrepStmts=false
```

### 20.4.2.4. Installing from the Development Source Tree

#### Caution

You should read this section only if you are interested in helping us test our new code. If you just want to get MySQL Connector/J up and running on your system, you should use a standard binary release distribution.

To install MySQL Connector/J from the development source tree, make sure that you have the following prerequisites:

- A Bazaar client, to check out the sources from our Launchpad repository (available from <http://bazaar-vcs.org/>).
- Apache Ant version 1.7 or newer (available from <http://ant.apache.org/>).
- JDK 1.4.2 or later. Although MySQL Connector/J can be used with older JDKs, to compile it from source you must have at least JDK 1.4.2. If you are building Connector/J 5.1 you will need JDK 1.6.x and an older JDK such as JDK 1.5.x. You will then need to point your `JAVA_HOME` environment variable at the older installation.

The source code repository for MySQL Connector/J is located on Launchpad at <https://code.launchpad.net/connectorj>.

To check out and compile a specific branch of MySQL Connector/J, follow these steps:

1. Check out the latest code from the branch that you want with one of the following commands.

To check out the latest development branch use:

```
shell> bzz branch lp:connectorj
```

This creates a `connectorj` subdirectory in the current directory that contains the latest sources for the requested branch.

To check out the latest 5.1 code use:

```
shell> bzz branch lp:connectorj/5.1
```

This will create a [5.1](#) subdirectory in the current directory containing the latest 5.1 code.

2. If you are building Connector/J 5.1 make sure that you have both JDK 1.6.x installed and an older JDK such as JDK 1.5.x. This is because Connector/J supports both JDBC 3.0 (which was prior to JDK 1.6.x) and JDBC 4.0. Set your `JAVA_HOME` environment variable to the path of the older JDK installation.
3. Change location to either the `connectorj` or `5.1` directory, depending on which branch you want to build, to make it your current working directory. For example:

```
shell> cd connectorj
```

4. If you are building Connector/J 5.1 you need to edit the `build.xml` to reflect the location of your JDK 1.6.x installation. The lines that you need to change are:

```
<property name="com.mysql.jdbc.java6.javac" value="C:\jvms\jdk1.6.0\bin\javac.exe" />
<property name="com.mysql.jdbc.java6.rtjar" value="C:\jvms\jdk1.6.0\jre\lib\rt.jar" />
```

Alternatively, you can set the value of these property names through the Ant `-D` option.

5. Issue the following command to compile the driver and create a `.jar` file suitable for installation:

```
shell> ant dist
```

This creates a `build` directory in the current directory, where all build output will go. A directory is created in the `build` directory that includes the version number of the sources you are building from. This directory contains the sources, compiled `.class` files, and a `.jar` file suitable for deployment. For other possible targets, including ones that will create a fully packaged distribution, issue the following command:

```
shell> ant -projecthelp
```

6. A newly created `.jar` file containing the JDBC driver will be placed in the directory `build/mysql-connector-java-[version]`.

Install the newly created JDBC driver as you would a binary `.jar` file that you download from MySQL by following the instructions in [Section 20.4.2.2](#), “Installing the Driver and Configuring the `CLASSPATH`”.

A package containing both the binary and source code for Connector/J 5.1 can also be found at the following location: [Connector/J 5.1 Download](#)

## 20.4.3. Connector/J Examples

Examples of using Connector/J are located throughout this document, this section provides a summary and links to these examples.

- [Example 20.1](#), “Connector/J: Obtaining a connection from the `DriverManager`”
- [Example 20.2](#), “Connector/J: Using `java.sql.Statement` to execute a `SELECT` query”
- [Example 20.3](#), “Connector/J: Calling Stored Procedures”
- [Example 20.4](#), “Connector/J: Using `Connection.prepareStatement()`”
- [Example 20.5](#), “Connector/J: Registering output parameters”
- [Example 20.6](#), “Connector/J: Setting `CallableStatement` input parameters”
- [Example 20.7](#), “Connector/J: Retrieving results and output parameter values”

## 20.4.4. Connector/J (JDBC) Reference

This section of the manual contains reference material for MySQL Connector/J, some of which is automatically generated during the Connector/J build process.

### 20.4.4.1. Driver/Datasource Class Names, URL Syntax and Configuration Properties for Connector/J

The name of the class that implements `java.sql.Driver` in MySQL Connector/J is `com.mysql.jdbc.Driver`. The `org.gjt.mm.mysql.Driver` class name is also usable to remain backward-compatible with MM.MySQL. You should use this class name when registering the driver, or when otherwise configuring software to use MySQL Connector/J.

The JDBC URL format for MySQL Connector/J is as follows, with items in square brackets ([, ]) being optional:

```
jdbc:mysql://[host][,failoverhost...][:port]/[database] »
[?propertyName1[=propertyValue1][&propertyName2[=propertyValue2]...
```

If the host name is not specified, it defaults to 127.0.0.1. If the port is not specified, it defaults to 3306, the default port number for MySQL servers.

```
jdbc:mysql://[host:port],[host:port].../[database] »
[?propertyName1[=propertyValue1][&propertyName2[=propertyValue2]...
```

If the database is not specified, the connection will be made with no default database. In this case, you will need to either call the `setCatalog()` method on the Connection instance or fully-specify table names using the database name (i.e. `SELECT dbname.tablename.colname FROM dbname.tablename...`) in your SQL. Not specifying the database to use upon connection is generally only useful when building tools that work with multiple databases, such as GUI database managers.

MySQL Connector/J has fail-over support. This allows the driver to fail-over to any number of slave hosts and still perform read-only queries. Fail-over only happens when the connection is in an `autoCommit(true)` state, because fail-over can not happen reliably when a transaction is in progress. Most application servers and connection pools set `autoCommit` to `true` at the end of every transaction/connection use.

The fail-over functionality has the following behavior:

- If the URL property `autoReconnect` is `false`: Failover only happens at connection initialization, and failback occurs when the driver determines that the first host has become available again.
- If the URL property `autoReconnect` is `true`: Failover happens when the driver determines that the connection has failed (before every query), and falls back to the first host when it determines that the host has become available again (after `queriesBeforeRetryMaster` queries have been issued).

In either case, whenever you are connected to a "failed-over" server, the connection will be set to read-only state, so queries that would modify data will have exceptions thrown (the query will **never** be processed by the MySQL server).

Configuration properties define how Connector/J will make a connection to a MySQL server. Unless otherwise noted, properties can be set for a `DataSource` object or for a `Connection` object.

Configuration Properties can be set in one of the following ways:

- Using the `set*()` methods on MySQL implementations of `java.sql.DataSource` (which is the preferred method when using implementations of `java.sql.DataSource`):
  - `com.mysql.jdbc.jdbc2.optional.MysqlDataSource`
  - `com.mysql.jdbc.jdbc2.optional.MysqlConnectionPoolDataSource`
- As a key/value pair in the `java.util.Properties` instance passed to `DriverManager.getConnection()` or `Driver.connect()`
- As a JDBC URL parameter in the URL given to `java.sql.DriverManager.getConnection()`, `java.sql.Driver.connect()` or the MySQL implementations of the `javax.sql.DataSource.setURL()` method.

#### Note

If the mechanism you use to configure a JDBC URL is XML-based, you will need to use the XML character literal

& to separate configuration parameters, as the ampersand is a reserved character for XML.

The properties are listed in the following tables.

#### Connection/Authentication.

Property Name	Definition	Default Value	Since Version
user	The user to connect as		all versions
password	The password to use when connecting		all versions
socketFactory	The name of the class that the driver should use for creating socket connections to the server. This class must implement the interface 'com.mysql.jdbc.SocketFactory' and have public no-args constructor.	com.mysql.jdbc.StandardSocketFactory	3.0.3
connectTimeout	Timeout for socket connect (in milliseconds), with 0 being no timeout. Only works on JDK-1.4 or newer. Defaults to '0'.	0	3.0.1
socketTimeout	Timeout on network socket operations (0, the default means no timeout).	0	3.0.1
connectionLifecycleInterceptors	A comma-delimited list of classes that implement "com.mysql.jdbc.ConnectionLifecycleInterceptor" that should notified of connection lifecycle events (creation, destruction, commit, rollback, setCatalog and setAutoCommit) and potentially alter the execution of these commands. ConnectionLifecycleInterceptors are "stackable", more than one interceptor may be specified via the configuration property as a comma-delimited list, with the interceptors executed in order from left to right.		5.1.4
useConfigs	Load the comma-delimited list of configuration properties before parsing the URL or applying user-specified properties. These configurations are explained in the 'Configurations' of the documentation.		3.1.5
interactiveClient	Set the CLIENT_INTERACTIVE flag, which tells MySQL to timeout connections based on INTERACTIVE_TIMEOUT instead of WAIT_TIMEOUT	false	3.1.0
localSocketAddress	Host name or IP address given to explicitly configure the interface that the driver will bind the client side of the TCP/IP connection to when connecting.		5.0.5
mysqlIOFactory	The name of the class which implements "com.mysql.jdbc.MySQLIO" for communicating with mysqld. (default is "com.mysql.jdbc.MySQLIOprotocol")	com.mysql.jdbc.MySQLIOprotocol	6.0.0
propertiesTransform	An implementation of com.mysql.jdbc.ConnectionPropertiesTransform that the driver will use to modify URL properties passed to the driver before attempting a connection		3.1.4
useCompression	Use zlib compression when communicating with the server (true/false)? Defaults to 'false'.	false	3.0.17

#### Networking.

Property Name	Definition	Default Value	Since Version
tcpKeepAlive	If connecting using TCP/IP, should the driver set SO_KEEPALIVE?	true	5.0.7
tcpNoDelay	If connecting using TCP/IP, should the driver set SO_TCP_NODELAY (disabling the Nagle Algorithm)?	true	5.0.7
tcpRcvBuf	If connecting using TCP/IP, should the driver set SO_RCV_BUF to the given value? The default value of '0', means use the platform default value for this property)	0	5.0.7

tcpSndBuf	If connecting using TCP/IP, should the driver set SO_SND_BUF to the given value? The default value of '0', means use the platform default value for this property)	0	5.0.7
tcpTrafficClass	If connecting using TCP/IP, should the driver set traffic class or type-of-service fields ?See the documentation for java.net.Socket.setTrafficClass() for more information.	0	5.0.7

### High Availability and Clustering.

Property Name	Definition	Default Value	Since Version
autoReconnect	Should the driver try to re-establish stale and/or dead connections? If enabled the driver will throw an exception for a queries issued on a stale or dead connection, which belong to the current transaction, but will attempt reconnect before the next query issued on the connection in a new transaction. The use of this feature is not recommended, because it has side effects related to session state and data consistency when applications do not handle SQLExceptions properly, and is only designed to be used when you are unable to configure your application to handle SQLExceptions resulting from dead and stale connections properly. Alternatively, investigate setting the MySQL server variable "wait_timeout" to some high value rather than the default of 8 hours.	false	1.1
autoReconnectForPools	Use a reconnection strategy appropriate for connection pools (defaults to 'false')	false	3.1.3
failOverReadOnly	When failing over in autoReconnect mode, should the connection be set to 'read-only'?	true	3.0.12
maxReconnects	Maximum number of reconnects to attempt if autoReconnect is true, default is '3'.	3	1.1
reconnectAtTxEnd	If autoReconnect is set to true, should the driver attempt reconnects at the end of every transaction?	false	3.0.10
initialTimeout	If autoReconnect is enabled, the initial time to wait between reconnect attempts (in seconds, defaults to '2').	2	1.1
roundRobinLoadBalance	When autoReconnect is enabled, and failoverReadonly is false, should we pick hosts to connect to on a round-robin basis?	false	3.1.2
queriesBeforeRetryMaster	Number of queries to issue before falling back to master when failed over (when using multi-host failover). Whichever condition is met first, 'queriesBeforeRetryMaster' or 'secondsBeforeRetryMaster' will cause an attempt to be made to reconnect to the master. Defaults to 50.	50	3.0.2
secondsBeforeRetryMaster	How long should the driver wait, when failed over, before attempting	30	3.0.2
selfDestructOnPingMaxOperations	=If set to a nonzero value, the driver will report close the connection and report failure when Connection.ping() or Connection.isValid(int) is called if the connection's count of commands sent to the server exceeds this value.	0	5.1.6
selfDestructOnPingSecondsLifetime	If set to a nonzero value, the driver will report close the connection and report failure when Connection.ping() or Connection.isValid(int) is called if the connection's lifetime exceeds this value.	0	5.1.6
resourceId	A globally unique name that identifies the resource that this datasource or connection is connected to, used for XAResource.isSameRM() when the driver cannot determine this value based on host names used in the URL		5.0.1

### Security.

Property Name	Definition	Default Value	Since Version
allowMultiQueries	Allow the use of ';' to delimit multiple queries during one state-	false	3.1.1

	ment (true/false), defaults to 'false'		
useSSL	Use SSL when communicating with the server (true/false), defaults to 'false'	false	3.0.2
requireSSL	Require SSL connection if useSSL=true? (defaults to 'false').	false	3.1.0
verifyServerCertificate	If "useSSL" is set to "true", should the driver verify the server's certificate? When using this feature, the keystore parameters should be specified by the "clientCertificateKeyStore*" properties, rather than system properties.	true	5.1.6
clientCertificateKeyStoreUrl	URL to the client certificate KeyStore (if not specified, use defaults)		5.1.0
clientCertificateKeyStoreType	KeyStore type for client certificates (NULL or empty means use default, standard keystore types supported by the JVM are "JKS" and "PKCS12", your environment may have more available depending on what security products are installed and available to the JVM.		5.1.0
clientCertificateKeyStorePassword	Password for the client certificates KeyStore		5.1.0
trustCertificateKeyStoreUrl	URL to the trusted root certificate KeyStore (if not specified, use defaults)		5.1.0
trustCertificateKeyStoreType	KeyStore type for trusted root certificates (NULL or empty means use default, standard keystore types supported by the JVM are "JKS" and "PKCS12", your environment may have more available depending on what security products are installed and available to the JVM.		5.1.0
trustCertificateKeyStorePassword	Password for the trusted root certificates KeyStore		5.1.0
allowLoadLocalInfile	Should the driver allow use of 'LOAD DATA LOCAL INFILE...' (defaults to 'true').	true	3.0.3
allowUrlInLocalInfile	Should the driver allow URLs in 'LOAD DATA LOCAL INFILE' statements?	false	3.1.4
paranoid	Take measures to prevent exposure sensitive information in error messages and clear data structures holding sensitive data when possible? (defaults to 'false')	false	3.0.1

**Performance Extensions.**

Property Name	Definition	Default Value	Since Version
callableStmtCacheSize	If 'cacheCallableStmts' is enabled, how many callable statements should be cached?	100	3.1.2
metadataCacheSize	The number of queries to cache ResultSetMetadata for if cacheResultSetMetaData is set to 'true' (default 50)	50	3.1.1
prepStmtCacheSize	If prepared statement caching is enabled, how many prepared statements should be cached?	25	3.0.10
prepStmtCacheSqlLimit	If prepared statement caching is enabled, what is the largest SQL the driver will cache the parsing for?	256	3.0.10
alwaysSendSetIsolation	Should the driver always communicate with the database when Connection.setTransactionIsolation() is called? If set to false, the driver will only communicate with the database when the requested transaction isolation is different than the whichever is newer, the last value that was set via Connection.setTransactionIsolation(), or the value that was read from the server when the connection was established.	true	3.1.7
maintainTimeStats	Should the driver maintain various internal timers to enable idle time calculations as well as more verbose error messages when the connection to the server fails? Setting this property to false removes at least two calls to System.getCurrentTimeMillis() per query.	true	3.1.9
useCursorFetch	If connected to MySQL > 5.0.2, and setFetchSize() > 0 on a statement, should that statement use cursor-based fetching to retrieve rows?	false	5.0.0

blobSendChunkSize	Chunk to use when sending BLOB/CLOBs via ServerPrepared-Statements	1048576	3.1.9
cacheCallableStmts	Should the driver cache the parsing stage of CallableStatements	false	3.1.2
cachePrepStmts	Should the driver cache the parsing stage of PreparedStatements of client-side prepared statements, the "check" for suitability of server-side prepared and server-side prepared statements themselves?	false	3.0.10
cacheResultSetMetadata	Should the driver cache ResultSetMetaData for Statements and PreparedStatements? (Req. JDK-1.4+, true/false, default 'false')	false	3.1.1
cacheServerConfiguration	Should the driver cache the results of 'SHOW VARIABLES' and 'SHOW COLLATION' on a per-URL basis?	false	3.1.5
defaultFetchSize	The driver will call setFetchSize(n) with this value on all newly-created Statements	0	3.1.9
dontTrackOpenResources	The JDBC specification requires the driver to automatically track and close resources, however if your application doesn't do a good job of explicitly calling close() on statements or result sets, this can cause memory leakage. Setting this property to true relaxes this constraint, and can be more memory efficient for some applications.	false	3.1.7
dynamicCalendars	Should the driver retrieve the default calendar when required, or cache it per connection/session?	false	3.1.5
elideSetAutoCommits	If using MySQL-4.1 or newer, should the driver only issue 'set autocommit=n' queries when the server's state doesn't match the requested state by Connection.setAutoCommit(boolean)?	false	3.1.3
enableQueryTimeouts	When enabled, query timeouts set via Statement.setQueryTimeout() use a shared java.util.Timer instance for scheduling. Even if the timeout doesn't expire before the query is processed, there will be memory used by the TimerTask for the given timeout which will not be reclaimed until the time the timeout would have expired if it hadn't been cancelled by the driver. High-load environments might want to consider disabling this functionality.	true	5.0.6
holdResultsOpenOverStatementClose	Should the driver close result sets on Statement.close() as required by the JDBC specification?	false	3.1.7
largeRowSizeThreshold	What size result set row should the JDBC driver consider "large", and thus use a more memory-efficient way of representing the row internally?	2048	5.1.1
loadBalanceStrategy	If using a load-balanced connection to connect to SQL nodes in a MySQL Cluster/NDB configuration (by using the URL prefix "jdbc:mysql:loadbalance://"), which load balancing algorithm should the driver use: (1) "random" - the driver will pick a random host for each request. This tends to work better than round-robin, as the randomness will somewhat account for spreading loads where requests vary in response time, while round-robin can sometimes lead to overloaded nodes if there are variations in response times across the workload. (2) "bestResponseTime" - the driver will route the request to the host that had the best response time for the previous transaction.	random	5.0.6
locatorFetchBufferSize	If 'emulateLocators' is configured to 'true', what size buffer should be used when fetching BLOB data for getBinaryInputStream?	1048576	3.2.1
rewriteBatchedStatements	Should the driver use multiqueries (irregardless of the setting of "allowMultiQueries") as well as rewriting of prepared statements for INSERT into multi-value inserts when executeBatch() is called? Notice that this has the potential for SQL injection if using plain java.sql.Statements and your code doesn't sanitize input correctly. Notice that for prepared statements, server-side prepared statements can not currently take advantage of this rewrite option, and that if you do not specify stream lengths when using PreparedStatement.set*Stream(), the driver will not be able to determine the optimum number of parameters per batch and you might receive an error from the driver that the resultant packet is too large. Statement.getGeneratedKeys() for these re-	false	3.1.13

	written statements only works when the entire batch includes INSERT statements.		
useDirectRowUnpack	Use newer result set row unpacking code that skips a copy from network buffers to a MySQL packet instance and instead reads directly into the result set row data buffers.	true	5.1.1
useDynamicCharsetInfo	Should the driver use a per-connection cache of character set information queried from the server when necessary, or use a built-in static mapping that is more efficient, but isn't aware of custom character sets or character sets implemented after the release of the JDBC driver?	true	5.0.6
useFastDateParsing	Use internal String->Date/Time/Timestamp conversion routines to avoid excessive object creation?	true	5.0.5
useFastIntParsing	Use internal String->Integer conversion routines to avoid excessive object creation?	true	3.1.4
useJvmCharsetConverters	Always use the character encoding routines built into the JVM, rather than using lookup tables for single-byte character sets?	false	5.0.1
useLocalSessionState	Should the driver refer to the internal values of autocommit and transaction isolation that are set by Connection.setAutoCommit() and Connection.setTransactionIsolation() and transaction state as maintained by the protocol, rather than querying the database or blindly sending commands to the database for commit() or rollback() method calls?	false	3.1.7
useReadAheadInput	Use newer, optimized non-blocking, buffered input stream when reading from the server?	true	3.1.5

**Debugging/Profiling.**

Property Name	Definition	Default Value	Since Version
logger	The name of a class that implements "com.mysql.jdbc.log.Log" that will be used to log messages to. (default is "com.mysql.jdbc.log.StandardLogger", which logs to STDERR)	com.mysql.jdbc.log.StandardLogger	3.1.1
gatherPerfMetrics	Should the driver gather performance metrics, and report them via the configured logger every 'reportMetricsIntervalMillis' milliseconds?	false	3.1.2
profileSQL	Trace queries and their execution/fetch times to the configured logger (true/false) defaults to 'false'	false	3.1.0
profileSql	Deprecated, use 'profileSQL' instead. Trace queries and their execution/fetch times on STDERR (true/false) defaults to 'false'		2.0.14
reportMetricsIntervalMillis	If 'gatherPerfMetrics' is enabled, how often should they be logged (in ms)?	30000	3.1.2
maxQuerySizeToLog	Controls the maximum length/size of a query that will get logged when profiling or tracing	2048	3.1.3
packetDebugBufferSize	The maximum number of packets to retain when 'enablePacketDebug' is true	20	3.1.3
slowQueryThresholdMillis	If 'logSlowQueries' is enabled, how long should a query (in ms) before it is logged as 'slow'?	2000	3.1.2
slowQueryThresholdNanos	If 'useNanosForElapsedTime' is set to true, and this property is set to a nonzero value, the driver will use this threshold (in nanosecond units) to determine if a query was slow.	0	5.0.7
useUsageAdvisor	Should the driver issue 'usage' warnings advising proper and efficient usage of JDBC and MySQL Connector/J to the log (true/false, defaults to 'false')?	false	3.1.1
autoGenerateTestcaseScript	Should the driver dump the SQL it is executing, including server-side prepared statements to STDERR?	false	3.1.9
autoSlowLog	Instead of using slowQueryThreshold* to determine if a query is slow enough to be logged, maintain statistics that allow the driver to determine queries that are outside the 99th percentile?	true	5.1.4

clientInfoProvider	The name of a class that implements the com.mysql.jdbc.JDBC4ClientInfoProvider interface in order to support JDBC-4.0's Connection.getClientInfo() methods	com.mysql.jdbc.JDBC4ClientInfoProvider	5.1.0
dumpMetadataOnColumnNotFound	Should the driver dump the field-level metadata of a result set into the exception message when ResultSet.findColumn() fails?	false	3.1.13
dumpQueriesOnException	Should the driver dump the contents of the query sent to the server in the message for SQLExceptions?	false	3.1.3
enablePacketDebug	When enabled, a ring-buffer of 'packetDebugBufferSize' packets will be kept, and dumped when exceptions are thrown in key areas in the driver's code	false	3.1.3
explainSlowQueries	If 'logSlowQueries' is enabled, should the driver automatically issue an 'EXPLAIN' on the server and send the results to the configured log at a WARN level?	false	3.1.2
includeInnodbStatusInDeadlockExceptions	Include the output of "SHOW ENGINE INNODB STATUS" in exception messages when deadlock exceptions are detected?	false	5.0.7
logSlowQueries	Should queries that take longer than 'slowQueryThresholdMillis' be logged?	false	3.1.2
logXaCommands	Should the driver log XA commands sent by MySQLXaConnection to the server, at the DEBUG level of logging?	false	5.0.5
profilerEventHandler	Name of a class that implements the interface com.mysql.jdbc.profiler.ProfilerEventHandler that will be used to handle profiling/tracing events.	com.mysql.jdbc.profiler.LoggingProfilerEventHandler	5.1.6
resultSetSizeThreshold	If the usage advisor is enabled, how many rows should a result set contain before the driver warns that it is suspiciously large?	100	5.0.5
traceProtocol	Should trace-level network protocol be logged?	false	3.1.2
useNanosForElapsedTime	For profiling/debugging functionality that measures elapsed time, should the driver try to use nanoseconds resolution if available (JDK >= 1.5)?	false	5.0.7

**Miscellaneous.**

Property Name	Definition	Default Value	Since Version
useUnicode	Should the driver use Unicode character encodings when handling strings? Should only be used when the driver cannot determine the character set mapping, or you are trying to 'force' the driver to use a character set that MySQL either doesn't natively support (such as UTF-8), true/false, defaults to 'true'	true	1.1g
characterEncoding	If 'useUnicode' is set to true, what character encoding should the driver use when dealing with strings? (defaults is to 'autodetect')		1.1g
characterSetResults	Character set to tell the server to return results as.		3.0.13
connectionCollation	If set, tells the server to use this collation via 'set collation_connection'		3.0.13
useBlobToStoreUTF8OutsideBMP	Tells the driver to treat [MEDIUM/LONG]BLOB columns as [LONG]VARCHAR columns holding text encoded in UTF-8 that has characters outside the BMP (4-byte encodings), which MySQL server cannot handle natively.	false	5.1.3
utf8OutsideBmpExcludedColumnNamePattern	When "useBlobToStoreUTF8OutsideBMP" is set to "true", column names matching the given regex will still be treated as BLOBs unless they match the regex specified for "utf8OutsideBmpIncludedColumnNamePattern". The regex must follow the patterns used for the java.util.regex package.		5.1.3

utf8OutsideBmpIncludedColumnNamePattern	Used to specify exclusion rules to "utf8OutsideBmpExcludedColumnNamePattern". The regex must follow the patterns used for the java.util.regex package.		5.1.3
sessionVariables	A comma-separated list of name/value pairs to be sent as SET SESSION ... to the server when the driver connects.		3.1.8
allowNaNAndInf	Should the driver allow NaN or +/- INF values in PreparedStatement.setDouble()?	false	3.1.5
autoClosePstmtStreams	Should the driver automatically call .close() on streams/readers passed as arguments via set*() methods?	false	3.1.12
autoDeserialize	Should the driver automatically detect and de-serialize objects stored in BLOB fields?	false	3.1.5
blobsAreStrings	Should the driver always treat BLOBs as Strings - specifically to work around dubious metadata returned by the server for GROUP BY clauses?	false	5.0.8
capitalizeTypeNames	Capitalize type names in DatabaseMetaData? (usually only useful when using WebObjects, true/false, defaults to 'false')	true	2.0.7
clobCharacterEncoding	The character encoding to use for sending and retrieving TEXT, MEDIUMTEXT and LONGTEXT values instead of the configured connection characterEncoding		5.0.0
clobberStreamingResults	This will cause a 'streaming' ResultSet to be automatically closed, and any outstanding data still streaming from the server to be discarded if another query is executed before all the data has been read from the server.	false	3.0.9
continueBatchOnError	Should the driver continue processing batch commands if one statement fails. The JDBC spec allows either way (defaults to 'true').	true	3.0.3
createDatabaseIfNotExist	Creates the database given in the URL if it doesn't yet exist. Assumes the configured user has permissions to create databases.	false	3.1.9
emptyStringsConvertToZero	Should the driver allow conversions from empty string fields to numeric values of '0'?	true	3.1.8
emulateLocators	Should the driver emulate java.sql.Blobs with locators? With this feature enabled, the driver will delay loading the actual Blob data until the one of the retrieval methods (getInputStream(), getBytes(), and so forth) on the blob data stream has been accessed. For this to work, you must use a column alias with the value of the column to the actual name of the Blob. The feature also has the following restrictions: The SELECT that created the result set must reference only one table, the table must have a primary key; the SELECT must alias the original blob column name, specified as a string, to an alternate name; the SELECT must cover all columns that make up the primary key.	false	3.1.0
emulateUnsupportedPstmts	Should the driver detect prepared statements that are not supported by the server, and replace them with client-side emulated versions?	true	3.1.7
functionsNeverReturnBlobs	Should the driver always treat data from functions returning BLOBs as Strings - specifically to work around dubious metadata returned by the server for GROUP BY clauses?	false	5.0.8
generateSimpleParameterMetadata	Should the driver generate simplified parameter metadata for PreparedStatements when no metadata is available either because the server couldn't support preparing the statement, or server-side prepared statements are disabled?	false	5.0.5
ignoreNonTxTables	Ignore non-transactional table warning for rollback? (defaults to 'false').	false	3.0.9
jdbcCompliantTruncation	Should the driver throw java.sql.DataTruncation exceptions when data is truncated as is required by the JDBC specification when connected to a server that supports warnings (MySQL 4.1.0 and newer)? This property has no effect if the server sql-mode includes STRICT_TRANS_TABLES.	true	3.1.2
maxRows	The maximum number of rows to return (0, the default means return all rows).	-1	all versions

netTimeoutForStreamingResults	What value should the driver automatically set the server setting 'net_write_timeout' to when the streaming result sets feature is in use? (value has unit of seconds, the value '0' means the driver will not try and adjust this value)	600	5.1.0
noAccessToProcedureBodies	When determining procedure parameter types for CallableStatements, and the connected user cannot access procedure bodies through "SHOW CREATE PROCEDURE" or select on mysql.proc should the driver instead create basic metadata (all parameters reported as IN VARCHARs, but allowing registerOutParameter() to be called on them anyway) instead of throwing an exception?	false	5.0.3
noDatetimeStringSync	Do not ensure that ResultSet.getDateType().toString().equals(ResultSet.getString())	false	3.1.7
noTimezoneConversionForTimeType	Do not convert TIME values using the server timezone if 'useTimezone'='true'	false	5.0.0
nullCatalogMeansCurrent	When DatabaseMetadataMethods ask for a 'catalog' parameter, does the value null mean use the current catalog? (this is not JDBC-compliant, but follows legacy behavior from earlier versions of the driver)	true	3.1.8
nullNamePatternMatchesAll	Should DatabaseMetaMethods that accept *pattern parameters treat null the same as '%' (this is not JDBC-compliant, however older versions of the driver accepted this departure from the specification)	true	3.1.8
overrideSupportsIntegrityEnhancementFacility	Should the driver return "true" for DatabaseMetaMethods.supportsIntegrityEnhancementFacility() even if the database doesn't support it to workaround applications that require this method to return "true" to signal support of foreign keys, even though the SQL specification states that this facility contains much more than just foreign key support (one such application being OpenOffice)?	false	3.1.12
padCharsWithSpace	If a result set column has the CHAR type and the value does not fill the amount of characters specified in the DDL for the column, should the driver pad the remaining characters with space (for ANSI compliance)?	false	5.0.6
pedantic	Follow the JDBC spec to the letter.	false	3.0.0
pinGlobalTxToPhysicalConnection	When using XAConnections, should the driver ensure that operations on a given XID are always routed to the same physical connection? This allows the XAConnection to support "XA START ... JOIN" after "XA END" has been called	false	5.0.1
populateInsertRowWithDefaultValues	When using ResultSets that are CONCUR_UPDATABLE, should the driver pre-populate the "insert" row with default values from the DDL for the table used in the query so those values are immediately available for ResultSet accessors? This functionality requires a call to the database for metadata each time a result set of this type is created. If disabled (the default), the default values will be populated by the an internal call to refreshRow() which pulls back default values and/or values changed by triggers.	false	5.0.5
processEscapeCodesForPrepStmts	Should the driver process escape codes in queries that are prepared?	true	3.1.12
relaxAutoCommit	If the version of MySQL the driver connects to does not support transactions, still allow calls to commit(), rollback() and setAutoCommit() (true/false, defaults to 'false')?	false	2.0.13
retainStatementAfterResultSetClose	Should the driver retain the Statement reference in a ResultSet after ResultSet.close() has been called. This is not JDBC-compliant after JDBC-4.0.	false	3.1.11
rollbackOnPooledClose	Should the driver issue a rollback() when the logical connection in a pool is closed?	true	3.0.15
runningCTS13	Enables workarounds for bugs in Sun's JDBC compliance test-suite version 1.3	false	3.1.7
serverTimezone	Override detection/mapping of timezone. Used when timezone from server doesn't map to Java timezone		3.0.2

statementInterceptors	A comma-delimited list of classes that implement "com.mysql.jdbc.StatementInterceptor" that should be placed "in between" query execution to influence the results. StatementInterceptors are "chainable", the results returned by the "current" interceptor will be passed on to the next in the chain, from left-to-right order, as specified in this property.		5.1.1
strictFloatingPoint	Used only in older versions of compliance test	false	3.0.0
strictUpdates	Should the driver do strict checking (all primary keys selected) of updatable result sets (true, false, defaults to 'true')?	true	3.0.4
tinyIntIsBit	Should the driver treat the datatype TINYINT(1) as the BIT type (because the server silently converts BIT -> TINYINT(1) when creating tables)?	true	3.0.16
transformedBitIsBoolean	If the driver converts TINYINT(1) to a different type, should it use BOOLEAN instead of BIT for future compatibility with MySQL-5.0, as MySQL-5.0 has a BIT type?	false	3.1.9
treatUtilDateAsTimestamp	Should the driver treat java.util.Date as a TIMESTAMP for the purposes of PreparedStatement.setObject()?	true	5.0.5
ultraDevHack	Create PreparedStatements for prepareCall() when required, because UltraDev is broken and issues a prepareCall() for _all_ statements? (true/false, defaults to 'false')	false	2.0.3
useGmtMillisForDatetimes	Convert between session timezone and GMT before creating Date and Timestamp instances (value of "false" is legacy behavior, "true" leads to more JDBC-compliant behavior.	false	3.1.12
useHostsInPrivileges	Add '@hostname' to users in Database-MetaData.getColumn/TablePrivileges() (true/false), defaults to 'true'.	true	3.0.2
useInformationSchema	When connected to MySQL-5.0.7 or newer, should the driver use the INFORMATION_SCHEMA to derive information used by DatabaseMetaData?	false	5.0.0
useJDBCCompliantTimezoneShift	Should the driver use JDBC-compliant rules when converting TIME/TIMESTAMP/DATETIME values' timezone information for those JDBC arguments which take a java.util.Calendar argument? (Notice that this option is exclusive of the "use-Timezone=true" configuration option.)	false	5.0.0
useLegacyDatetimeCode	Use code for DATE/TIME/DATETIME/TIMESTAMP handling in result sets and statements that consistently handles timezone conversions from client to server and back again, or use the legacy code for these datatypes that has been in the driver for backwards-compatibility?	true	5.1.6
useOldAliasMetadataBehavior	Should the driver use the legacy behavior for "AS" clauses on columns and tables, and only return aliases (if any) for ResultSetMetaData.getColumn() or ResultSetMetaData.getTableName() rather than the original column/table name? In 5.0.x, the default value was true.	false	5.0.4
useOldUTF8Behavior	Use the UTF-8 behavior the driver did when communicating with 4.0 and older servers	false	3.1.6
useOnlyServerErrorMessages	Do not prepend 'standard' SQLState error messages to error messages returned by the server.	true	3.0.15
useSSPSCompatibleTimezoneShift	If migrating from an environment that was using server-side prepared statements, and the configuration property "useJDBCCompliantTimezoneShift" set to "true", use compatible behavior when not using server-side prepared statements when sending TIMESTAMP values to the MySQL server.	false	5.0.5
useServerPrepStmts	Use server-side prepared statements if the server supports them?	false	3.1.0
useSqlStateCodes	Use SQL Standard state codes instead of 'legacy' X/Open/SQL state codes (true/false), default is 'true'	true	3.1.3
useStreamLengthsInPrepStmts	Honor stream length parameter in PreparedStatement/ResultSet.setXXXStream() method calls (true/false, defaults to 'true')?	true	3.0.2
useTimezone	Convert time/date types between client and server timezones (true/false, defaults to 'false')?	false	3.0.2

useUnbufferedInput	Do not use BufferedInputStream for reading data from the server	true	3.0.11
yearIsDateType	Should the JDBC driver treat the MySQL type "YEAR" as a java.sql.Date, or as a SHORT?	true	3.1.9
zeroDateTimeBehavior	What should happen when the driver encounters DATETIME values that are composed entirely of zeroes (used by MySQL to represent invalid dates)? Valid values are "exception", "round" and "convertToNull".	exception	3.1.4

Connector/J also supports access to MySQL via named pipes on Windows NT/2000/XP using the NamedPipeSocketFactory as a plugin-socket factory via the socketFactory property. If you do not use a namedPipePath property, the default of '\\.\pipe\MySQL' will be used. If you use the [NamedPipeSocketFactory](#), the host name and port number values in the JDBC url will be ignored. You can enable this feature using:

```
socketFactory=com.mysql.jdbc.NamedPipeSocketFactory
```

Named pipes only work when connecting to a MySQL server on the same physical machine as the one the JDBC driver is being used on. In simple performance tests, it appears that named pipe access is between 30%-50% faster than the standard TCP/IP access. However, this varies per system, and named pipes are slower than TCP/IP in many Windows configurations.

You can create your own socket factories by following the example code in [com.mysql.jdbc.NamedPipeSocketFactory](#), or [com.mysql.jdbc.StandardSocketFactory](#).

#### 20.4.4.2. JDBC API Implementation Notes

MySQL Connector/J passes all of the tests in the publicly-available version of Sun's JDBC compliance test suite. However, in many places the JDBC specification is vague about how certain functionality should be implemented, or the specification allows leeway in implementation.

This section gives details on a interface-by-interface level about how certain implementation decisions may affect how you use MySQL Connector/J.

- **Blob**

Starting with Connector/J version 3.1.0, you can emulate Blobs with locators by adding the property 'emulateLocators=true' to your JDBC URL. Using this method, the driver will delay loading the actual Blob data until you retrieve the other data and then use retrieval methods ([getInputStream\(\)](#), [getBytes\(\)](#), and so forth) on the blob data stream.

For this to work, you must use a column alias with the value of the column to the actual name of the Blob, for example:

```
SELECT id, 'data' as blob_data from blobtable
```

For this to work, you must also follow these rules:

- The **SELECT** must also reference only one table, the table must have a primary key.
- The **SELECT** must alias the original blob column name, specified as a string, to an alternate name.
- The **SELECT** must cover all columns that make up the primary key.

The Blob implementation does not allow in-place modification (they are copies, as reported by the [DatabaseMetaData.locatorsUpdateCopies\(\)](#) method). Because of this, you should use the corresponding [PreparedStatement.setBlob\(\)](#) or [ResultSet.updateBlob\(\)](#) (in the case of updatable result sets) methods to save changes back to the database.

#### MySQL Enterprise

MySQL Enterprise subscribers will find more information about type conversion in the Knowledge Base article, [Type Conversions Supported by MySQL Connector/J](#). To subscribe to MySQL Enterprise see <http://www.mysql.com/products/enterprise/advisors.html>.

- **CallableStatement**

Starting with Connector/J 3.1.1, stored procedures are supported when connecting to MySQL version 5.0 or newer via the [CallableStatement](#) interface. Currently, the [getParameterMetaData\(\)](#) method of [CallableStatement](#) is not supported.

- **Clob**

The Clob implementation does not allow in-place modification (they are copies, as reported by the `DatabaseMetaData.locatorsUpdateCopies()` method). Because of this, you should use the `PreparedStatement.setClob()` method to save changes back to the database. The JDBC API does not have a `ResultSet.updateClob()` method.

- **Connection**

Unlike older versions of MM.MySQL the `isClosed()` method does not ping the server to determine if it is alive. In accordance with the JDBC specification, it only returns true if `closed()` has been called on the connection. If you need to determine if the connection is still valid, you should issue a simple query, such as `SELECT 1`. The driver will throw an exception if the connection is no longer valid.

- **DatabaseMetaData**

Foreign Key information (`getImportedKeys()/getExportedKeys()` and `getCrossReference()`) is only available from InnoDB tables. However, the driver uses `SHOW CREATE TABLE` to retrieve this information, so when other storage engines support foreign keys, the driver will transparently support them as well.

- **PreparedStatement**

PreparedStatements are implemented by the driver, as MySQL does not have a prepared statement feature. Because of this, the driver does not implement `getParameterMetaData()` or `getMetaData()` as it would require the driver to have a complete SQL parser in the client.

Starting with version 3.1.0 MySQL Connector/J, server-side prepared statements and binary-encoded result sets are used when the server supports them.

Take care when using a server-side prepared statement with **large** parameters that are set via `setBinaryStream()`, `setAsciiStream()`, `setUnicodeStream()`, `setBlob()`, or `setClob()`. If you want to re-execute the statement with any large parameter changed to a non-large parameter, it is necessary to call `clearParameters()` and set all parameters again. The reason for this is as follows:

- During both server-side prepared statements and client-side emulation, large data is exchanged only when `PreparedStatement.execute()` is called.
- Once that has been done, the stream used to read the data on the client side is closed (as per the JDBC spec), and cannot be read from again.
- If a parameter changes from large to non-large, the driver must reset the server-side state of the prepared statement to allow the parameter that is being changed to take the place of the prior large value. This removes all of the large data that has already been sent to the server, thus requiring the data to be re-sent, via the `setBinaryStream()`, `setAsciiStream()`, `setUnicodeStream()`, `setBlob()` or `setClob()` methods.

Consequently, if you want to change the type of a parameter to a non-large one, you must call `clearParameters()` and set all parameters of the prepared statement again before it can be re-executed.

- **ResultSet**

By default, ResultSets are completely retrieved and stored in memory. In most cases this is the most efficient way to operate, and due to the design of the MySQL network protocol is easier to implement. If you are working with ResultSets that have a large number of rows or large values, and can not allocate heap space in your JVM for the memory required, you can tell the driver to stream the results back one row at a time.

To enable this functionality, you need to create a Statement instance in the following manner:

```
stmt = conn.createStatement( java.sql.ResultSet.TYPE_FORWARD_ONLY,
                             java.sql.ResultSet.CONCUR_READ_ONLY );
stmt.setFetchSize( Integer.MIN_VALUE );
```

The combination of a forward-only, read-only result set, with a fetch size of `Integer.MIN_VALUE` serves as a signal to the driver to stream result sets row-by-row. After this any result sets created with the statement will be retrieved row-by-row.

There are some caveats with this approach. You will have to read all of the rows in the result set (or close it) before you can issue any other queries on the connection, or an exception will be thrown.

The earliest the locks these statements hold can be released (whether they be `MyISAM` table-level locks or row-level locks in some other storage engine such as `InnoDB`) is when the statement completes.

If the statement is within scope of a transaction, then locks are released when the transaction completes (which implies that the

statement needs to complete first). As with most other databases, statements are not complete until all the results pending on the statement are read or the active result set for the statement is closed.

Therefore, if using streaming results, you should process them as quickly as possible if you want to maintain concurrent access to the tables referenced by the statement producing the result set.

- **ResultSetMetaData**

The `isAutoIncrement()` method only works when using MySQL servers 4.0 and newer.

- **Statement**

When using versions of the JDBC driver earlier than 3.2.1, and connected to server versions earlier than 5.0.3, the `setFetchSize()` method has no effect, other than to toggle result set streaming as described above.

Connector/J 5.0.0 and later include support for both `Statement.cancel()` and `Statement.setQueryTimeout()`. Both require MySQL 5.0.0 or newer server, and require a separate connection to issue the `KILL QUERY` statement. In the case of `setQueryTimeout()`, the implementation creates an additional thread to handle the timeout functionality.

### Note

Failures to cancel the statement for `setQueryTimeout()` may manifest themselves as `RuntimeException` rather than failing silently, as there is currently no way to unblock the thread that is executing the query being cancelled due to timeout expiration and have it throw the exception instead.

MySQL does not support SQL cursors, and the JDBC driver doesn't emulate them, so "setCursorName()" has no effect.

Connector/J 5.1.3 and later include two additional methods:

- `setLocalInfileInputStream()` sets an `InputStream` instance that will be used to send data to the MySQL server for a `LOAD DATA LOCAL INFILE` statement rather than a `FileInputStream` or `URLInputStream` that represents the path given as an argument to the statement.

This stream will be read to completion upon execution of a `LOAD DATA LOCAL INFILE` statement, and will automatically be closed by the driver, so it needs to be reset before each call to `execute*()` that would cause the MySQL server to request data to fulfill the request for `LOAD DATA LOCAL INFILE`.

If this value is set to `NULL`, the driver will revert to using a `FileInputStream` or `URLInputStream` as required.

- `getLocalInfileInputStream()` returns the `InputStream` instance that will be used to send data in response to a `LOAD DATA LOCAL INFILE` statement.

This method returns `NULL` if no such stream has been set via `setLocalInfileInputStream()`.

### 20.4.4.3. Java, JDBC and MySQL Types

MySQL Connector/J is flexible in the way it handles conversions between MySQL data types and Java data types.

In general, any MySQL data type can be converted to a `java.lang.String`, and any numerical type can be converted to any of the Java numerical types, although round-off, overflow, or loss of precision may occur.

Starting with Connector/J 3.1.0, the JDBC driver will issue warnings or throw `DataTruncation` exceptions as is required by the JDBC specification unless the connection was configured not to do so by using the property `jdbcCompliantTruncation` and setting it to `false`.

The conversions that are always guaranteed to work are listed in the following table:

#### Connection Properties - Miscellaneous.

These MySQL Data Types	Can always be converted to these Java types
CHAR, VARCHAR, BLOB, TEXT, ENUM, and SET	<code>java.lang.String</code> , <code>java.io.InputStream</code> , <code>java.io.Reader</code> , <code>java.sql.Blob</code> , <code>java.sql.Clob</code>
FLOAT, REAL, DOUBLE PRECISION, NUMERIC, DECIMAL, TINYINT, SMALLINT, MEDIUMINT, INTEGER, BIGINT	<code>java.lang.String</code> , <code>java.lang.Short</code> , <code>java.lang.Integer</code> , <code>java.lang.Long</code> , <code>java.lang.Double</code> , <code>java.math.BigDecimal</code>
DATE, TIME, DATETIME, TIMESTAMP	<code>java.lang.String</code> , <code>java.sql.Date</code> ,

	<code>java.sql.Timestamp</code>
--	---------------------------------

**Note**

Round-off, overflow or loss of precision may occur if you choose a Java numeric data type that has less precision or capacity than the MySQL data type you are converting to/from.

The `ResultSet.getObject()` method uses the type conversions between MySQL and Java types, following the JDBC specification where appropriate. The value returned by `ResultSetMetaData.getColumnClassName()` is also shown below. For more information on the `java.sql.Types` classes see [Java 2 Platform Types](#).

**MySQL Types to Java Types for `ResultSet.getObject()`.**

MySQL Type Name	Return value of <code>getColumnClassName</code>	Returned as Java Class
BIT(1) (new in MySQL-5.0)	BIT	<code>java.lang.Boolean</code>
BIT(> 1) (new in MySQL-5.0)	BIT	<code>byte[]</code>
TINYINT	TINYINT	<code>java.lang.Boolean</code> if the configuration property <code>tinyIntIsBit</code> is set to <code>true</code> (the default) and the storage size is 1, or <code>java.lang.Integer</code> if not.
BOOL, BOOLEAN	TINYINT	See TINYINT, above as these are aliases for TINYINT(1), currently.
SMALLINT[(M)] [UNSIGNED]	SMALLINT [UNSIGNED]	<code>java.lang.Integer</code> (regardless if UNSIGNED or not)
MEDIUMINT[(M)] [UNSIGNED]	MEDIUMINT [UNSIGNED]	<code>java.lang.Integer</code> , if UNSIGNED <code>java.lang.Long</code> (C/J 3.1 and earlier), or <code>java.lang.Integer</code> for C/J 5.0 and later
INT,INTEGER[(M)] [UNSIGNED]	INTEGER [UNSIGNED]	<code>java.lang.Integer</code> , if UNSIGNED <code>java.lang.Long</code>
BIGINT[(M)] [UNSIGNED]	BIGINT [UNSIGNED]	<code>java.lang.Long</code> , if UNSIGNED <code>java.math.BigInteger</code>
FLOAT[(M,D)]	FLOAT	<code>java.lang.Float</code>
DOUBLE[(M,B)]	DOUBLE	<code>java.lang.Double</code>
DECIMAL[(M,D)]	DECIMAL	<code>java.math.BigDecimal</code>
DATE	DATE	<code>java.sql.Date</code>
DATETIME	DATETIME	<code>java.sql.Timestamp</code>
TIMESTAMP[(M)]	TIMESTAMP	<code>java.sql.Timestamp</code>
TIME	TIME	<code>java.sql.Time</code>
YEAR[(2 4)]	YEAR	If <code>yearIsDateType</code> configuration property is set to false, then the returned object type is <code>java.sql.Short</code> . If set to true (the default) then an object of type <code>java.sql.Date</code> (with the date set to January 1st, at midnight).
CHAR(M)	CHAR	<code>java.lang.String</code> (unless the character set for the column is BINARY, then <code>byte[]</code> is returned).
VARCHAR(M) [BINARY]	VARCHAR	<code>java.lang.String</code> (unless the character set for the column is BINARY, then <code>byte[]</code> is returned).
BINARY(M)	BINARY	<code>byte[]</code>
VARBINARY(M)	VARBINARY	<code>byte[]</code>
TINYBLOB	TINYBLOB	<code>byte[]</code>
TINYTEXT	VARCHAR	<code>java.lang.String</code>
BLOB	BLOB	<code>byte[]</code>
TEXT	VARCHAR	<code>java.lang.String</code>
MEDIUMBLOB	MEDIUMBLOB	<code>byte[]</code>
MEDIUMTEXT	VARCHAR	<code>java.lang.String</code>
LOBLOB	LOBLOB	<code>byte[]</code>
LONGTEXT	VARCHAR	<code>java.lang.String</code>

ENUM('value1','value2',...)	CHAR	<code>java.lang.String</code>
SET('value1','value2',...)	CHAR	<code>java.lang.String</code>

#### 20.4.4.4. Using Character Sets and Unicode

All strings sent from the JDBC driver to the server are converted automatically from native Java Unicode form to the client character encoding, including all queries sent via `Statement.execute()`, `Statement.executeUpdate()`, `Statement.executeQuery()` as well as all `PreparedStatement` and `CallableStatement` parameters with the exclusion of parameters set using `setBytes()`, `setBinaryStream()`, `setAsciiStream()`, `setUnicodeStream()` and `setBlob()`.

Prior to MySQL Server 4.1, Connector/J supported a single character encoding per connection, which could either be automatically detected from the server configuration, or could be configured by the user through the `useUnicode` and `characterEncoding` properties.

Starting with MySQL Server 4.1, Connector/J supports a single character encoding between client and server, and any number of character encodings for data returned by the server to the client in `ResultSets`.

The character encoding between client and server is automatically detected upon connection. The encoding used by the driver is specified on the server via the `character_set` system variable for server versions older than 4.1.0 and `character_set_server` for server versions 4.1.0 and newer. For more information, see [Section 9.1.3.1, “Server Character Set and Collation”](#).

To override the automatically-detected encoding on the client side, use the `characterEncoding` property in the URL used to connect to the server.

When specifying character encodings on the client side, Java-style names should be used. The following table lists Java-style names for MySQL character sets:

##### MySQL to Java Encoding Name Translations.

MySQL Character Set Name	Java-Style Character Encoding Name
ascii	US-ASCII
big5	Big5
gbk	GBK
sjis	SJIS (or Cp932 or MS932 for MySQL Server < 4.1.11)
cp932	Cp932 or MS932 (MySQL Server > 4.1.11)
gb2312	EUC_CN
ujis	EUC_JP
euckr	EUC_KR
latin1	ISO8859_1
latin2	ISO8859_2
greek	ISO8859_7
hebrew	ISO8859_8
cp866	Cp866
tis620	TIS620
cp1250	Cp1250
cp1251	Cp1251
cp1257	Cp1257
macroman	MacRoman
macce	MacCentralEurope
utf8	UTF-8
ucs2	UnicodeBig

#### Warning

Do not issue the query 'set names' with Connector/J, as the driver will not detect that the character set has changed,

and will continue to use the character set detected during the initial connection setup.

To allow multiple character sets to be sent from the client, the UTF-8 encoding should be used, either by configuring `utf8` as the default server character set, or by configuring the JDBC driver to use UTF-8 through the `characterEncoding` property.

### 20.4.4.5. Connecting Securely Using SSL

SSL in MySQL Connector/J encrypts all data (other than the initial handshake) between the JDBC driver and the server. The performance penalty for enabling SSL is an increase in query processing time between 35% and 50%, depending on the size of the query, and the amount of data it returns.

For SSL Support to work, you must have the following:

- A JDK that includes JSSE (Java Secure Sockets Extension), like JDK-1.4.1 or newer. SSL does not currently work with a JDK that you can add JSSE to, like JDK-1.2.x or JDK-1.3.x due to the following JSSE bug: <http://developer.java.sun.com/developer/bugParade/bugs/4273544.html>
- A MySQL server that supports SSL and has been compiled and configured to do so, which is MySQL-4.0.4 or later, see [Section 5.5.7, “Using SSL for Secure Connections”](#), for more information.
- A client certificate (covered later in this section)

The system works through two Java truststore files, one file contains the certificate information for the server (`truststore` in the examples below). The other file contains the certificate for the client (`keystore` in the examples below). All Java truststore files are password protected by supplying a suitable password to the `keytool` when you create the files. You need the file names and associated passwords to create an SSL connection.

You will first need to import the MySQL server CA Certificate into a Java truststore. A sample MySQL server CA Certificate is located in the `SSL` subdirectory of the MySQL source distribution. This is what SSL will use to determine if you are communicating with a secure MySQL server. Alternatively, use the CA Certificate that you have generated or been provided with by your SSL provider.

To use Java's `keytool` to create a truststore in the current directory, and import the server's CA certificate (`cacert.pem`), you can do the following (assuming that `keytool` is in your path. The `keytool` should be located in the `bin` subdirectory of your JDK or JRE):

```
shell> keytool -import -alias mysqlServerCACert \
               -file cacert.pem -keystore truststore
```

You will need to enter the password when prompted for the keystore file. Interaction with `keytool` will look like this:

```
Enter keystore password: *****
Owner: EMAILADDRESS=walrus@example.com, CN=Walrus,
O=MySQL AB, L=Orenburg, ST=Some-State, C=RU
Issuer: EMAILADDRESS=walrus@example.com, CN=Walrus,
O=MySQL AB, L=Orenburg, ST=Some-State, C=RU
Serial number: 0
Valid from:
  Fri Aug 02 16:55:53 CDT 2002 until: Sat Aug 02 16:55:53 CDT 2003
Certificate fingerprints:
  MD5: 61:91:A0:F2:03:07:61:7A:81:38:66:DA:19:C4:8D:AB
  SHA1: 25:77:41:05:D5:AD:99:8C:14:8C:CA:68:9C:2F:B8:89:C3:34:4D:6C
Trust this certificate? [no]: yes
Certificate was added to keystore
```

You then have two options, you can either import the client certificate that matches the CA certificate you just imported, or you can create a new client certificate.

To import an existing certificate, the certificate should be in DER format. You can use `openssl` to convert an existing certificate into the new format. For example:

```
shell> openssl x509 -outform DER -in client-cert.pem -out client.cert
```

You now need to import the converted certificate into your keystore using `keytool`:

```
shell> keytool -import -file client.cert -keystore keystore -alias mysqlClientCertificate
```

To generate your own client certificate, use `keytool` to create a suitable certificate and add it to the `keystore` file:

```
shell> keytool -genkey -keyalg rsa \
```

```
-alias mysqlClientCertificate -keystore keystore
```

Keytool will prompt you for the following information, and create a keystore named `keystore` in the current directory.

You should respond with information that is appropriate for your situation:

```
Enter keystore password: *****
What is your first and last name?
[Unknown]: Matthews
What is the name of your organizational unit?
[Unknown]: Software Development
What is the name of your organization?
[Unknown]: MySQL AB
What is the name of your City or Locality?
[Unknown]: Flossmoor
What is the name of your State or Province?
[Unknown]: IL
What is the two-letter country code for this unit?
[Unknown]: US
Is <CN=Matthews, OU=Software Development, O=MySQL AB,
L=Flossmoor, ST=IL, C=US> correct?
[no]: y

Enter key password for <mysqlClientCertificate>
(RETURN if same as keystore password):
```

Finally, to get JSSE to use the keystore and truststore that you have generated, you need to set the following system properties when you start your JVM, replacing `path_to_keystore_file` with the full path to the keystore file you created, `path_to_truststore_file` with the path to the truststore file you created, and using the appropriate password values for each property. You can do this either on the command line:

```
-Djavax.net.ssl.keyStore=path_to_keystore_file
-Djavax.net.ssl.keyStorePassword=password
-Djavax.net.ssl.trustStore=path_to_truststore_file
-Djavax.net.ssl.trustStorePassword=password
```

Or you can set the values directly within the application:

```
System.setProperty("javax.net.ssl.keyStore","path_to_keystore_file");
System.setProperty("javax.net.ssl.keyStorePassword","password");
System.setProperty("javax.net.ssl.trustStore","path_to_truststore_file");
System.setProperty("javax.net.ssl.trustStorePassword","password");
```

You will also need to set `useSSL` to `true` in your connection parameters for MySQL Connector/J, either by adding `useSSL=true` to your URL, or by setting the property `useSSL` to `true` in the `java.util.Properties` instance you pass to `DriverManager.getConnection()`.

You can test that SSL is working by turning on JSSE debugging (as detailed below), and look for the following key events:

```

main, READ: SSL v3.1 Handshake, length = 1712
...

```

JSSSE provides debugging (to STDOUT) when you set the following system property: `-Djavax.net.debug=all`. This will tell you what keystores and truststores are being used, as well as what is going on during the SSL handshake and certificate exchange. It will be helpful when trying to determine what is not working when trying to get an SSL connection to happen.

#### 20.4.4.6. Using Master/Slave Replication with ReplicationConnection

Starting with Connector/J 3.1.7, we've made available a variant of the driver that will automatically send queries to a read/write master, or a failover or round-robin loadbalanced set of slaves based on the state of `Connection.getReadOnly()`.

An application signals that it wants a transaction to be read-only by calling `Connection.setReadOnly(true)`, this replication-aware connection will use one of the slave connections, which are load-balanced per-vm using a round-robin scheme (a given connection is sticky to a slave unless that slave is removed from service). If you have a write transaction, or if you have a read that is time-sensitive (remember, replication in MySQL is asynchronous), set the connection to be not read-only, by calling `Connection.setReadOnly(false)` and the driver will ensure that further calls are sent to the master MySQL server. The driver takes care of propagating the current state of autocommit, isolation level, and catalog between all of the connections that it uses to accomplish this load balancing functionality.

To enable this functionality, use the "`com.mysql.jdbc.ReplicationDriver`" class when configuring your application server's connection pool or when creating an instance of a JDBC driver for your standalone application. Because it accepts the same URL format as the standard MySQL JDBC driver, `ReplicationDriver` does not currently work with `java.sql.DriverManager`-based connection creation unless it is the only MySQL JDBC driver registered with the `DriverManager`.

Here is a short, simple example of how `ReplicationDriver` might be used in a standalone application.

```
import java.sql.Connection;
import java.sql.ResultSet;
import java.util.Properties;

import com.mysql.jdbc.ReplicationDriver;

public class ReplicationDriverDemo {

    public static void main(String[] args) throws Exception {
        ReplicationDriver driver = new ReplicationDriver();

        Properties props = new Properties();

        // We want this for failover on the slaves
        props.put("autoReconnect", "true");

        // We want to load balance between the slaves
        props.put("roundRobinLoadBalance", "true");

        props.put("user", "foo");
        props.put("password", "bar");

        //
        // Looks like a normal MySQL JDBC url, with a
        // comma-separated list of hosts, the first
        // being the 'master', the rest being any number
        // of slaves that the driver will load balance against
        //
        Connection conn =
            driver.connect("jdbc:mysql://master,slave1,slave2,slave3/test",
                props);

        //
        // Perform read/write work on the master
        // by setting the read-only flag to "false"
        //
        conn.setReadOnly(false);
        conn.setAutoCommit(false);
        conn.createStatement().executeUpdate("UPDATE some_table ...");
        conn.commit();

        //
        // Now, do a query from a slave, the driver automatically picks one
        // from the list
        //
        conn.setReadOnly(true);

        ResultSet rs =
            conn.createStatement().executeQuery("SELECT a,b FROM alt_table");

        .....
    }
}
```

You may also want to investigate the Load Balancing JDBC Pool (lbpool) tool, which provides a wrapper around the standard JDBC driver and allows you to use DB connection pools that includes checks for system failures and uneven load distribution. For more

information, see [Load Balancing JDBC Pool \(lbpool\)](#).

### 20.4.4.7. Mapping MySQL Error Numbers to SQLStates

The table below provides a mapping of the MySQL Error Numbers to [SQL States](#)

**Table 20.3. Mapping of MySQL Error Numbers to SQLStates**

MySQL Error Number	MySQL Error Name	Legacy (X/Open) SQLState	SQL Standard SQLState
1022	ER_DUP_KEY	S1000	23000
1037	ER_OUT_OFMEMORY	S1001	HY001
1038	ER_OUT_OF_SORTMEMORY	S1001	HY001

## 20.4.5. Connector/J Notes and Tips

### 20.4.5.1. Basic JDBC Concepts

This section provides some general JDBC background.

#### 20.4.5.1.1. Connecting to MySQL Using the `DriverManager` Interface

When you are using JDBC outside of an application server, the `DriverManager` class manages the establishment of Connections.

The `DriverManager` needs to be told which JDBC drivers it should try to make Connections with. The easiest way to do this is to use `Class.forName()` on the class that implements the `java.sql.Driver` interface. With MySQL Connector/J, the name of this class is `com.mysql.jdbc.Driver`. With this method, you could use an external configuration file to supply the driver class name and driver parameters to use when connecting to a database.

The following section of Java code shows how you might register MySQL Connector/J from the `main()` method of your application:

```
import java.sql.Connection;
import java.sql.DriverManager;
import java.sql.SQLException;

// Notice, do not import com.mysql.jdbc.*
// or you will have problems!

public class LoadDriver {
    public static void main(String[] args) {
        try {
            // The newInstance() call is a work around for some
            // broken Java implementations

            Class.forName("com.mysql.jdbc.Driver").newInstance();
        } catch (Exception ex) {
            // handle the error
        }
    }
}
```

After the driver has been registered with the `DriverManager`, you can obtain a `Connection` instance that is connected to a particular database by calling `DriverManager.getConnection()`:

#### Example 20.1. Connector/J: Obtaining a connection from the `DriverManager`

This example shows how you can obtain a `Connection` instance from the `DriverManager`. There are a few different signatures for the `getConnection()` method. You should see the API documentation that comes with your JDK for more specific in-

formation on how to use them.

```
import java.sql.Connection;
import java.sql.DriverManager;
import java.sql.SQLException;

Connection conn = null;
...
try {
    conn =
        DriverManager.getConnection("jdbc:mysql://localhost/test?" +
                                   "user=monty&password=greatsqladb");

    // Do something with the Connection

    ...
} catch (SQLException ex) {
    // handle any errors
    System.out.println("SQLException: " + ex.getMessage());
    System.out.println("SQLState: " + ex.getSQLState());
    System.out.println("VendorError: " + ex.getErrorCode());
}
```

Once a `Connection` is established, it can be used to create `Statement` and `PreparedStatement` objects, as well as retrieve metadata about the database. This is explained in the following sections.

### 20.4.5.1.2. Using Statements to Execute SQL

`Statement` objects allow you to execute basic SQL queries and retrieve the results through the `ResultSet` class which is described later.

To create a `Statement` instance, you call the `createStatement()` method on the `Connection` object you have retrieved via one of the `DriverManager.getConnection()` or `DataSource.getConnection()` methods described earlier.

Once you have a `Statement` instance, you can execute a `SELECT` query by calling the `executeQuery(String)` method with the SQL you want to use.

To update data in the database, use the `executeUpdate(String SQL)` method. This method returns the number of rows affected by the update statement.

If you do not know ahead of time whether the SQL statement will be a `SELECT` or an `UPDATE/INSERT`, then you can use the `execute(String SQL)` method. This method will return true if the SQL query was a `SELECT`, or false if it was an `UPDATE`, `INSERT`, or `DELETE` statement. If the statement was a `SELECT` query, you can retrieve the results by calling the `getResultSet()` method. If the statement was an `UPDATE`, `INSERT`, or `DELETE` statement, you can retrieve the affected rows count by calling `getUpdateCount()` on the `Statement` instance.

#### Example 20.2. Connector/J: Using `java.sql.Statement` to execute a `SELECT` query

```
import java.sql.Connection;
import java.sql.DriverManager;
import java.sql.SQLException;
import java.sql.Statement;
import java.sql.ResultSet;

// assume that conn is an already created JDBC connection (see previous examples)

Statement stmt = null;
ResultSet rs = null;

try {
    stmt = conn.createStatement();
    rs = stmt.executeQuery("SELECT foo FROM bar");

    // or alternatively, if you don't know ahead of time that
    // the query will be a SELECT...

    if (stmt.execute("SELECT foo FROM bar")) {
        rs = stmt.getResultSet();
    }

    // Now do something with the ResultSet ....
}
catch (SQLException ex){
    // handle any errors
    System.out.println("SQLException: " + ex.getMessage());
    System.out.println("SQLState: " + ex.getSQLState());
    System.out.println("VendorError: " + ex.getErrorCode());
}
finally {
    // it is a good idea to release
    // resources in a finally{} block
    // in reverse-order of their creation
    // if they are no-longer needed
}
```

```

if (rs != null) {
    try {
        rs.close();
    } catch (SQLException sqlEx) { } // ignore
    rs = null;
}

if (stmt != null) {
    try {
        stmt.close();
    } catch (SQLException sqlEx) { } // ignore
    stmt = null;
}
}

```

### 20.4.5.1.3. Using `CallableStatements` to Execute Stored Procedures

Starting with MySQL server version 5.0 when used with Connector/J 3.1.1 or newer, the `java.sql.CallableStatement` interface is fully implemented with the exception of the `getParameterMetaData()` method.

For more information on MySQL stored procedures, please refer to <http://dev.mysql.com/doc/mysql/en/stored-routines.html>.

Connector/J exposes stored procedure functionality through JDBC's `CallableStatement` interface.

#### Note

Current versions of MySQL server do not return enough information for the JDBC driver to provide result set metadata for callable statements. This means that when using `CallableStatement`, `ResultSetMetaData` may return `NULL`.

The following example shows a stored procedure that returns the value of `inOutParam` incremented by 1, and the string passed in via `inputParam` as a `ResultSet`:

#### Example 20.3. Connector/J: Calling Stored Procedures

```

CREATE PROCEDURE demoSp(IN inputParam VARCHAR(255), \
                        INOUT inOutParam INT)
BEGIN
    DECLARE z INT;
    SET z = inOutParam + 1;
    SET inOutParam = z;

    SELECT inputParam;

    SELECT CONCAT('zyxw', inputParam);
END

```

To use the `demoSp` procedure with Connector/J, follow these steps:

1. Prepare the callable statement by using `Connection.prepareCall()`.

Notice that you have to use JDBC escape syntax, and that the parentheses surrounding the parameter placeholders are not optional:

#### Example 20.4. Connector/J: Using `Connection.prepareCall()`

```

import java.sql.CallableStatement;
...

//
// Prepare a call to the stored procedure 'demoSp'
// with two parameters
//
// Notice the use of JDBC-escape syntax ({call ...})
//

CallableStatement cStmt = conn.prepareCall("{call demoSp(?, ?)}");

cStmt.setString(1, "abcdefg");

```

**Note**

`Connection.prepareStatement()` is an expensive method, due to the metadata retrieval that the driver performs to support output parameters. For performance reasons, you should try to minimize unnecessary calls to `Connection.prepareStatement()` by reusing `CallableStatement` instances in your code.

2. Register the output parameters (if any exist)

To retrieve the values of output parameters (parameters specified as `OUT` or `INOUT` when you created the stored procedure), JDBC requires that they be specified before statement execution using the various `registerOutputParameter()` methods in the `CallableStatement` interface:

**Example 20.5. Connector/J: Registering output parameters**

```
import java.sql.Types;
...
//
// Connector/J supports both named and indexed
// output parameters. You can register output
// parameters using either method, as well
// as retrieve output parameters using either
// method, regardless of what method was
// used to register them.
//
// The following examples show how to use
// the various methods of registering
// output parameters (you should of course
// use only one registration per parameter).
//
//
// Registers the second parameter as output, and
// uses the type 'INTEGER' for values returned from
// getObject()
//
cStmt.registerOutParameter(2, Types.INTEGER);
//
// Registers the named parameter 'inOutParam', and
// uses the type 'INTEGER' for values returned from
// getObject()
//
cStmt.registerOutParameter("inOutParam", Types.INTEGER);
...
```

3. Set the input parameters (if any exist)

Input and in/out parameters are set as for `PreparedStatement` objects. However, `CallableStatement` also supports setting parameters by name:

**Example 20.6. Connector/J: Setting `CallableStatement` input parameters**

```
...
//
// Set a parameter by index
//
cStmt.setString(1, "abcdefg");
//
// Alternatively, set a parameter using
// the parameter name
//
cStmt.setString("inputParameter", "abcdefg");
//
// Set the 'in/out' parameter using an index
//
cStmt.setInt(2, 1);
//
// Alternatively, set the 'in/out' parameter
// by name
//
cStmt.setInt("inOutParam", 1);
```

...

4. Execute the `CallableStatement`, and retrieve any result sets or output parameters.

Although `CallableStatement` supports calling any of the `Statement` execute methods (`executeUpdate()`, `executeQuery()` or `execute()`), the most flexible method to call is `execute()`, as you do not need to know ahead of time if the stored procedure returns result sets:

### Example 20.7. Connector/J: Retrieving results and output parameter values

```
...
boolean hadResults = cStmt.execute();
//
// Process all returned result sets
//
while (hadResults) {
    ResultSet rs = cStmt.getResultSet();

    // process result set
    ...

    hadResults = cStmt.getMoreResults();
}

//
// Retrieve output parameters
//
// Connector/J supports both index-based and
// name-based retrieval
//
int outputValue = cStmt.getInt(2); // index-based
outputValue = cStmt.getInt("inOutParam"); // name-based
...
```

#### 20.4.5.1.4. Retrieving `AUTO_INCREMENT` Column Values

Before version 3.0 of the JDBC API, there was no standard way of retrieving key values from databases that supported auto increment or identity columns. With older JDBC drivers for MySQL, you could always use a MySQL-specific method on the `Statement` interface, or issue the query `SELECT LAST_INSERT_ID()` after issuing an `INSERT` to a table that had an `AUTO_INCREMENT` key. Using the MySQL-specific method call isn't portable, and issuing a `SELECT` to get the `AUTO_INCREMENT` key's value requires another round-trip to the database, which isn't as efficient as possible. The following code snippets demonstrate the three different ways to retrieve `AUTO_INCREMENT` values. First, we demonstrate the use of the new JDBC-3.0 method `getGeneratedKeys()` which is now the preferred method to use if you need to retrieve `AUTO_INCREMENT` keys and have access to JDBC-3.0. The second example shows how you can retrieve the same value using a standard `SELECT LAST_INSERT_ID()` query. The final example shows how updatable result sets can retrieve the `AUTO_INCREMENT` value when using the `insertRow()` method.

### Example 20.8. Connector/J: Retrieving `AUTO_INCREMENT` column values using `Statement.getGeneratedKeys()`

```
Statement stmt = null;
ResultSet rs = null;

try {
    //
    // Create a Statement instance that we can use for
    // 'normal' result sets assuming you have a
    // Connection 'conn' to a MySQL database already
    // available
    stmt = conn.createStatement(java.sql.ResultSet.TYPE_FORWARD_ONLY,
                               java.sql.ResultSet.CONCUR_UPDATABLE);

    //
    // Issue the DDL queries for the table for this example
    //
    stmt.executeUpdate("DROP TABLE IF EXISTS autoIncTutorial");
    stmt.executeUpdate(
```

```

        "CREATE TABLE autoIncTutorial ( "
        + "priKey INT NOT NULL AUTO_INCREMENT, "
        + "dataField VARCHAR(64), PRIMARY KEY (priKey))");

//
// Insert one row that will generate an AUTO INCREMENT
// key in the 'priKey' field
//
stmt.executeUpdate(
    "INSERT INTO autoIncTutorial (dataField) "
    + "values ('Can I Get the Auto Increment Field?')",
    Statement.RETURN_GENERATED_KEYS);

//
// Example of using Statement.getGeneratedKeys()
// to retrieve the value of an auto-increment
// value
//
int autoIncKeyFromApi = -1;

rs = stmt.getGeneratedKeys();

if (rs.next()) {
    autoIncKeyFromApi = rs.getInt(1);
} else {
    // throw an exception from here
}

rs.close();

rs = null;

System.out.println("Key returned from getGeneratedKeys():"
    + autoIncKeyFromApi);
} finally {
    if (rs != null) {
        try {
            rs.close();
        } catch (SQLException ex) {
            // ignore
        }
    }

    if (stmt != null) {
        try {
            stmt.close();
        } catch (SQLException ex) {
            // ignore
        }
    }
}
}

```

### Example 20.9. Connector/J: Retrieving `AUTO_INCREMENT` column values using `SELECT LAST_INSERT_ID()`

```

Statement stmt = null;
ResultSet rs = null;

try {
    //
    // Create a Statement instance that we can use for
    // 'normal' result sets.

    stmt = conn.createStatement();

    //
    // Issue the DDL queries for the table for this example
    //

    stmt.executeUpdate("DROP TABLE IF EXISTS autoIncTutorial");
    stmt.executeUpdate(
        "CREATE TABLE autoIncTutorial ( "
        + "priKey INT NOT NULL AUTO_INCREMENT, "
        + "dataField VARCHAR(64), PRIMARY KEY (priKey))");

    //
    // Insert one row that will generate an AUTO INCREMENT
    // key in the 'priKey' field
    //

    stmt.executeUpdate(
        "INSERT INTO autoIncTutorial (dataField) "
        + "values ('Can I Get the Auto Increment Field?')");

    //
    // Use the MySQL LAST_INSERT_ID()

```

```

// function to do the same thing as getGeneratedKeys()
//
int autoIncKeyFromFunc = -1;
rs = stmt.executeQuery("SELECT LAST_INSERT_ID()");

if (rs.next()) {
    autoIncKeyFromFunc = rs.getInt(1);
} else {
    // throw an exception from here
}

rs.close();

System.out.println("Key returned from " +
    "'SELECT LAST_INSERT_ID()': " +
    autoIncKeyFromFunc);
} finally {
    if (rs != null) {
        try {
            rs.close();
        } catch (SQLException ex) {
            // ignore
        }
    }

    if (stmt != null) {
        try {
            stmt.close();
        } catch (SQLException ex) {
            // ignore
        }
    }
}
}

```

### Example 20.10. Connector/J: Retrieving `AUTO_INCREMENT` column values in `Updatable ResultSets`

```

Statement stmt = null;
ResultSet rs = null;

try {
    //
    // Create a Statement instance that we can use for
    // 'normal' result sets as well as an 'updatable'
    // one, assuming you have a Connection 'conn' to
    // a MySQL database already available
    //
    stmt = conn.createStatement(java.sql.ResultSet.TYPE_FORWARD_ONLY,
        java.sql.ResultSet.CONCUR_UPDATABLE);

    //
    // Issue the DDL queries for the table for this example
    //
    stmt.executeUpdate("DROP TABLE IF EXISTS autoIncTutorial");
    stmt.executeUpdate(
        "CREATE TABLE autoIncTutorial ("
        + "priKey INT NOT NULL AUTO_INCREMENT, "
        + "dataField VARCHAR(64), PRIMARY KEY (priKey))");

    //
    // Example of retrieving an AUTO INCREMENT key
    // from an updatable result set
    //
    rs = stmt.executeQuery("SELECT priKey, dataField "
        + "FROM autoIncTutorial");

    rs.moveToInsertRow();

    rs.updateString("dataField", "AUTO INCREMENT here?");
    rs.insertRow();

    //
    // the driver adds rows at the end
    //
    rs.last();

    //
    // We should now be on the row we just inserted
    //
    int autoIncKeyFromRS = rs.getInt("priKey");
}

```

```

rs.close();

rs = null;

System.out.println("Key returned for inserted row: "
    + autoIncKeyFromRS);
} finally {
    if (rs != null) {
        try {
            rs.close();
        } catch (SQLException ex) {
            // ignore
        }
    }

    if (stmt != null) {
        try {
            stmt.close();
        } catch (SQLException ex) {
            // ignore
        }
    }
}
}

```

When you run the preceding example code, you should get the following output: Key returned from `getGeneratedKeys()`: 1 Key returned from `SELECT LAST_INSERT_ID()`: 1 Key returned for inserted row: 2 You should be aware, that at times, it can be tricky to use the `SELECT LAST_INSERT_ID()` query, as that function's value is scoped to a connection. So, if some other query happens on the same connection, the value will be overwritten. On the other hand, the `getGeneratedKeys()` method is scoped by the `Statement` instance, so it can be used even if other queries happen on the same connection, but not on the same `Statement` instance.

## 20.4.5.2. Using Connector/J with J2EE and Other Java Frameworks

This section describes how to use Connector/J in several contexts.

### 20.4.5.2.1. General J2EE Concepts

This section provides general background on J2EE concepts that pertain to use of Connector/J.

#### 20.4.5.2.1.1. Understanding Connection Pooling

Connection pooling is a technique of creating and managing a pool of connections that are ready for use by any thread that needs them.

This technique of pooling connections is based on the fact that most applications only need a thread to have access to a JDBC connection when they are actively processing a transaction, which usually take only milliseconds to complete. When not processing a transaction, the connection would otherwise sit idle. Instead, connection pooling allows the idle connection to be used by some other thread to do useful work.

In practice, when a thread needs to do work against a MySQL or other database with JDBC, it requests a connection from the pool. When the thread is finished using the connection, it returns it to the pool, so that it may be used by any other threads that want to use it.

When the connection is loaned out from the pool, it is used exclusively by the thread that requested it. From a programming point of view, it is the same as if your thread called `DriverManager.getConnection()` every time it needed a JDBC connection, however with connection pooling, your thread may end up using either a new, or already-existing connection.

Connection pooling can greatly increase the performance of your Java application, while reducing overall resource usage. The main benefits to connection pooling are:

- Reduced connection creation time

Although this is not usually an issue with the quick connection setup that MySQL offers compared to other databases, creating new JDBC connections still incurs networking and JDBC driver overhead that will be avoided if connections are recycled.

- Simplified programming model

When using connection pooling, each individual thread can act as though it has created its own JDBC connection, allowing you to use straight-forward JDBC programming techniques.

- Controlled resource usage

If you do not use connection pooling, and instead create a new connection every time a thread needs one, your application's resource usage can be quite wasteful and lead to unpredictable behavior under load.

Remember that each connection to MySQL has overhead (memory, CPU, context switches, and so forth) on both the client and server side. Every connection limits how many resources there are available to your application as well as the MySQL server. Many of these resources will be used whether or not the connection is actually doing any useful work!

Connection pools can be tuned to maximize performance, while keeping resource utilization below the point where your application will start to fail rather than just run slower.

Luckily, Sun has standardized the concept of connection pooling in JDBC through the JDBC-2.0 Optional interfaces, and all major application servers have implementations of these APIs that work fine with MySQL Connector/J.

Generally, you configure a connection pool in your application server configuration files, and access it via the Java Naming and Directory Interface (JNDI). The following code shows how you might use a connection pool from an application deployed in a J2EE application server:

### Example 20.11. Connector/J: Using a connection pool with a J2EE application server

```
import java.sql.Connection;
import java.sql.SQLException;
import java.sql.Statement;

import javax.naming.InitialContext;
import javax.sql.DataSource;

public class MyServletJspOrEjb {

    public void doSomething() throws Exception {
        /*
         * Create a JNDI Initial context to be able to
         * lookup the DataSource
         *
         * In production-level code, this should be cached as
         * an instance or static variable, as it can
         * be quite expensive to create a JNDI context.
         *
         * Note: This code only works when you are using servlets
         * or EJBs in a J2EE application server. If you are
         * using connection pooling in standalone Java code, you
         * will have to create/configure datasources using whatever
         * mechanisms your particular connection pooling library
         * provides.
         */

        InitialContext ctx = new InitialContext();

        /*
         * Lookup the DataSource, which will be backed by a pool
         * that the application server provides. DataSource instances
         * are also a good candidate for caching as an instance
         * variable, as JNDI lookups can be expensive as well.
         */

        DataSource ds =
            (DataSource)ctx.lookup("java:comp/env/jdbc/MySQLDB");

        /*
         * The following code is what would actually be in your
         * Servlet, JSP or EJB 'service' method...where you need
         * to work with a JDBC connection.
         */

        Connection conn = null;
        Statement stmt = null;

        try {
            conn = ds.getConnection();

            /*
             * Now, use normal JDBC programming to work with
             * MySQL, making sure to close each resource when you're
             * finished with it, which allows the connection pool
             * resources to be recovered as quickly as possible
             */

            stmt = conn.createStatement();
            stmt.execute("SOME SQL QUERY");

            stmt.close();
            stmt = null;

            conn.close();
            conn = null;
        }
    }
}
```

```

    } finally {
        /*
         * close any jdbc instances here that weren't
         * explicitly closed during normal code path, so
         * that we don't 'leak' resources...
         */

        if (stmt != null) {
            try {
                stmt.close();
            } catch (SQLException sqlex) {
                // ignore -- as we can't do anything about it here
            }

            stmt = null;
        }

        if (conn != null) {
            try {
                conn.close();
            } catch (SQLException sqlex) {
                // ignore -- as we can't do anything about it here
            }

            conn = null;
        }
    }
}

```

As shown in the example above, after obtaining the JNDI InitialContext, and looking up the DataSource, the rest of the code should look familiar to anyone who has done JDBC programming in the past.

The most important thing to remember when using connection pooling is to make sure that no matter what happens in your code (exceptions, flow-of-control, and so forth), connections, and anything created by them (such as statements or result sets) are closed, so that they may be re-used, otherwise they will be stranded, which in the best case means that the MySQL server resources they represent (such as buffers, locks, or sockets) may be tied up for some time, or worst case, may be tied up forever.

#### What Is the Best Size for my Connection Pool?

As with all other configuration rules-of-thumb, the answer is: it depends. Although the optimal size depends on anticipated load and average database transaction time, the optimum connection pool size is smaller than you might expect. If you take Sun's Java Petstore blueprint application for example, a connection pool of 15-20 connections can serve a relatively moderate load (600 concurrent users) using MySQL and Tomcat with response times that are acceptable.

To correctly size a connection pool for your application, you should create load test scripts with tools such as Apache JMeter or The Grinder, and load test your application.

An easy way to determine a starting point is to configure your connection pool's maximum number of connections to be unbounded, run a load test, and measure the largest amount of concurrently used connections. You can then work backward from there to determine what values of minimum and maximum pooled connections give the best performance for your particular application.

### 20.4.5.2.2. Using Connector/J with Tomcat

The following instructions are based on the instructions for Tomcat-5.x, available at <http://tomcat.apache.org/tomcat-5.5-doc/jndi-datasource-examples-howto.html> which is current at the time this document was written.

First, install the .jar file that comes with Connector/J in `$(CATALINA_HOME)/common/lib` so that it is available to all applications installed in the container.

Next, Configure the JNDI DataSource by adding a declaration resource to `$(CATALINA_HOME)/conf/server.xml` in the context that defines your web application:

```

<Context ...>
    ...
    <Resource name="jdbc/MySQLDB"
              auth="Container"
              type="javax.sql.DataSource"/>

    <!-- The name you used above, must match _exactly_ here!

         The connection pool will be bound into JNDI with the name
         "java:/comp/env/jdbc/MySQLDB"
    -->

    <ResourceParams name="jdbc/MySQLDB">
        <parameter>
            <name>factory</name>
            <value>org.apache.commons.dbcp.BasicDataSourceFactory</value>
        </parameter>
    </ResourceParams>

```

```

<!-- Don't set this any higher than max_connections on your
MySQL server, usually this should be a 10 or a few 10's
of connections, not hundreds or thousands -->

<parameter>
  <name>maxActive</name>
  <value>10</value>
</parameter>

<!-- You don't want too many idle connections hanging around
if you can avoid it, only enough to soak up a spike in
the load -->

<parameter>
  <name>maxIdle</name>
  <value>5</value>
</parameter>

<!-- Don't use autoReconnect=true, it's going away eventually
and it's a crutch for older connection pools that couldn't
test connections. You need to decide whether your application
is supposed to deal with SQLExceptions (hint, it should), and
how much of a performance penalty you're willing to pay
to ensure 'freshness' of the connection -->

<parameter>
  <name>validationQuery</name>
  <value>SELECT 1</value>
</parameter>

<!-- The most conservative approach is to test connections
before they're given to your application. For most applications
this is okay, the query used above is very small and takes
no real server resources to process, other than the time used
to traverse the network.

If you have a high-load application you'll need to rely on
something else. -->

<parameter>
  <name>testOnBorrow</name>
  <value>true</value>
</parameter>

<!-- Otherwise, or in addition to testOnBorrow, you can test
while connections are sitting idle -->

<parameter>
  <name>testWhileIdle</name>
  <value>true</value>
</parameter>

<!-- You have to set this value, otherwise even though
you've asked connections to be tested while idle,
the idle evictor thread will never run -->

<parameter>
  <name>timeBetweenEvictionRunsMillis</name>
  <value>10000</value>
</parameter>

<!-- Don't allow connections to hang out idle too long,
never longer than what wait_timeout is set to on the
server...A few minutes or even fraction of a minute
is sometimes okay here, it depends on your application
and how much spikey load it will see -->

<parameter>
  <name>minEvictableIdleTimeMillis</name>
  <value>60000</value>
</parameter>

<!-- Username and password used when connecting to MySQL -->

<parameter>
  <name>username</name>
  <value>someuser</value>
</parameter>

<parameter>
  <name>password</name>
  <value>somepass</value>
</parameter>

<!-- Class name for the Connector/J driver -->

<parameter>
  <name>driverClassName</name>
  <value>com.mysql.jdbc.Driver</value>
</parameter>

<!-- The JDBC connection url for connecting to MySQL, notice
that if you want to pass any other MySQL-specific parameters
you should pass them here in the URL, setting them using the
parameter tags above will have no effect, you will also
need to use &amp; to separate parameter values as the

```

```

    ampersand is a reserved character in XML -->
    <parameter>
      <name>url</name>
      <value>jdbc:mysql://localhost:3306/test</value>
    </parameter>
  </ResourceParams>
</Context>

```

In general, you should follow the installation instructions that come with your version of Tomcat, as the way you configure data-sources in Tomcat changes from time-to-time, and unfortunately if you use the wrong syntax in your XML file, you will most likely end up with an exception similar to the following:

```

Error: java.sql.SQLException: Cannot load JDBC driver class 'null ' SQL
state: null

```

### 20.4.5.2.3. Using Connector/J with JBoss

These instructions cover JBoss-4.x. To make the JDBC driver classes available to the application server, copy the .jar file that comes with Connector/J to the `lib` directory for your server configuration (which is usually called `default`). Then, in the same configuration directory, in the subdirectory named `deploy`, create a datasource configuration file that ends with `-ds.xml`, which tells JBoss to deploy this file as a JDBC Datasource. The file should have the following contents:

```

<datasources>
  <local-tx-datasource>
    <!-- This connection pool will be bound into JNDI with the name
         "java/MySQLDB" -->
    <jndi-name>MySQLDB</jndi-name>
    <connection-url>jdbc:mysql://localhost:3306/dbname</connection-url>
    <driver-class>com.mysql.jdbc.Driver</driver-class>
    <user-name>user</user-name>
    <password>pass</password>

    <min-pool-size>5</min-pool-size>

    <!-- Don't set this any higher than max_connections on your
         MySQL server, usually this should be a 10 or a few 10's
         of connections, not hundreds or thousands -->
    <max-pool-size>20</max-pool-size>

    <!-- Don't allow connections to hang out idle too long,
         never longer than what wait_timeout is set to on the
         server...A few minutes is usually okay here,
         it depends on your application
         and how much spikey load it will see -->
    <idle-timeout-minutes>5</idle-timeout-minutes>

    <!-- If you're using Connector/J 3.1.8 or newer, you can use
         our implementation of these to increase the robustness
         of the connection pool. -->
    <exception-sorter-class-name>
      com.mysql.jdbc.integration.jboss.ExtendedMysqlExceptionSorter
    </exception-sorter-class-name>
    <valid-connection-checker-class-name>
      com.mysql.jdbc.integration.jboss.MysqlValidConnectionChecker
    </valid-connection-checker-class-name>

  </local-tx-datasource>
</datasources>

```

### 20.4.5.2.4. Using Connector/J with Spring

The Spring Framework is a Java-based application framework designed for assisting in application design by providing a way to configure components. The technique used by Spring is a well known design pattern called Dependency Injection (see [Inversion of Control Containers and the Dependency Injection pattern](#)). This article will focus on Java-oriented access to MySQL databases with Spring 2.0. For those wondering, there is a .NET port of Spring appropriately named Spring.NET.

Spring is not only a system for configuring components, but also includes support for aspect oriented programming (AOP). This is one of the main benefits and the foundation for Spring's resource and transaction management. Spring also provides utilities for integrating resource management with JDBC and Hibernate.

For the examples in this section the MySQL world sample database will be used. The first task is to set up a MySQL data source through Spring. Components within Spring use the "bean" terminology. For example, to configure a connection to a MySQL server supporting the world sample database you might use:

```

<util:map id="dbProps">
  <entry key="db.driver" value="com.mysql.jdbc.Driver"/>
  <entry key="db.jdbcurl" value="jdbc:mysql://localhost/world"/>

```

```
<entry key="db.username" value="myuser" />
<entry key="db.password" value="mypass" />
</util:map>
```

In the above example we are assigning values to properties that will be used in the configuration. For the datasource configuration:

```
<bean id="dataSource"
      class="org.springframework.jdbc.datasource.DriverManagerDataSource">
  <property name="driverClassName" value="${db.driver}" />
  <property name="url" value="${db.jdbcurl}" />
  <property name="username" value="${db.username}" />
  <property name="password" value="${db.password}" />
</bean>
```

The placeholders are used to provide values for properties of this bean. This means that you can specify all the properties of the configuration in one place instead of entering the values for each property on each bean. We do, however, need one more bean to pull this all together. The last bean is responsible for actually replacing the placeholders with the property values.

```
<bean
  class="org.springframework.beans.factory.config.PropertyPlaceholderConfigurer">
  <property name="properties" ref="dbProps" />
</bean>
```

Now that we have our MySQL data source configured and ready to go, we write some Java code to access it. The example below will retrieve three random cities and their corresponding country using the data source we configured with Spring.

```
// Create a new application context. this processes the Spring config
ApplicationContext ctx =
  new ClassPathXmlApplicationContext("ex1appContext.xml");
// Retrieve the data source from the application context
DataSource ds = (DataSource) ctx.getBean("dataSource");
// Open a database connection using Spring's DataSourceUtils
Connection c = DataSourceUtils.getConnection(ds);
try {
  // retrieve a list of three random cities
  PreparedStatement ps = c.prepareStatement(
    "select City.Name as 'City', Country.Name as 'Country' " +
    "from City inner join Country on City.CountryCode = Country.Code " +
    "order by rand() limit 3");
  ResultSet rs = ps.executeQuery();
  while(rs.next()) {
    String city = rs.getString("City");
    String country = rs.getString("Country");
    System.out.printf("The city %s is in %s\n", city, country);
  }
} catch (SQLException ex) {
  // something has failed and we print a stack trace to analyse the error
  ex.printStackTrace();
  // ignore failure closing connection
  try { c.close(); } catch (SQLException e) { }
} finally {
  // properly release our connection
  DataSourceUtils.releaseConnection(c, ds);
}
```

This is very similar to normal JDBC access to MySQL with the main difference being that we are using `DataSourceUtils` instead of the `DriverManager` to create the connection.

While it may seem like a small difference, the implications are somewhat far reaching. Spring manages this resource in a way similar to a container managed data source in a J2EE application server. When a connection is opened, it can be subsequently accessed in other parts of the code if it is synchronized with a transaction. This makes it possible to treat different parts of your application as transactional instead of passing around a database connection.

#### 20.4.5.2.4.1. Using `JdbcTemplate`

Spring makes extensive use of the Template method design pattern (see [Template Method Pattern](#)). Our immediate focus will be on the `JdbcTemplate` and related classes, specifically `NamedParameterJdbcTemplate`. The template classes handle obtaining and releasing a connection for data access when one is needed.

The next example shows how to use `NamedParameterJdbcTemplate` inside of a DAO (Data Access Object) class to retrieve a random city given a country code.

```
public class Ex2JdbcDao {
  /**
   * Data source reference which will be provided by Spring.
   */
  private DataSource dataSource;
```

```

/**
 * Our query to find a random city given a country code. Notice
 * the ":country" parameter towards the end. This is called a
 * named parameter.
 */
private String queryString = "select Name from City " +
    "where CountryCode = :country order by rand() limit 1";

/**
 * Retrieve a random city using Spring JDBC access classes.
 */
public String getRandomCityByCountryCode(String cntryCode) {
    // A template that allows using queries with named parameters
    NamedParameterJdbcTemplate template =
        new NamedParameterJdbcTemplate(dataSource);
    // A java.util.Map is used to provide values for the parameters
    Map params = new HashMap();
    params.put("country", cntryCode);
    // We query for an Object and specify what class we are expecting
    return (String)template.queryForObject(queryString, params, String.class);
}

/**
 * A JavaBean setter-style method to allow Spring to inject the data source.
 * @param dataSource
 */
public void setDataSource(DataSource dataSource) {
    this.dataSource = dataSource;
}
}

```

The focus in the above code is on the `getRandomCityByCountryCode()` method. We pass a country code and use the `NamedParameterJdbcTemplate` to query for a city. The country code is placed in a Map with the key "country", which is the parameter is named in the SQL query.

To access this code, you need to configure it with Spring by providing a reference to the data source.

```

<bean id="dao" class="code.Ex2JdbcDao">
  <property name="dataSource" ref="dataSource"/>
</bean>

```

At this point, we can just grab a reference to the DAO from Spring and call `getRandomCityByCountryCode()`.

```

// Create the application context
ApplicationContext ctx =
    new ClassPathXmlApplicationContext("ex2appContext.xml");
// Obtain a reference to our DAO
Ex2JdbcDao dao = (Ex2JdbcDao) ctx.getBean("dao");

String countryCode = "USA";

// Find a few random cities in the US
for(int i = 0; i < 4; ++i)
    System.out.printf("A random city in %s is %s%n", countryCode,
        dao.getRandomCityByCountryCode(countryCode));

```

This example shows how to use Spring's JDBC classes to completely abstract away the use of traditional JDBC classes including `Connection` and `PreparedStatement`.

#### 20.4.5.2.4.2. Transactional JDBC Access

You might be wondering how we can add transactions into our code if we do not deal directly with the JDBC classes. Spring provides a transaction management package that not only replaces JDBC transaction management, but also allows declarative transaction management (configuration instead of code).

In order to use transactional database access, we will need to change the storage engine of the tables in the world database. The downloaded script explicitly creates MyISAM tables which do not support transactional semantics. The InnoDB storage engine does support transactions and this is what we will be using. We can change the storage engine with the following statements.

```

ALTER TABLE City ENGINE=InnoDB;
ALTER TABLE Country ENGINE=InnoDB;
ALTER TABLE CountryLanguage ENGINE=InnoDB;

```

A good programming practice emphasized by Spring is separating interfaces and implementations. What this means is that we can create a Java interface and only use the operations on this interface without any internal knowledge of what the actual implementation is. We will let Spring manage the implementation and with this it will manage the transactions for our implementation.

First you create a simple interface:

```

public interface Ex3Dao {
    Integer createCity(String name, String countryCode,

```

```
String district, Integer population);
}
```

This interface contains one method that will create a new city record in the database and return the id of the new record. Next you need to create an implementation of this interface.

```
public class Ex3DaoImpl implements Ex3Dao {
    protected DataSource dataSource;
    protected SqlUpdate updateQuery;
    protected SqlFunction idQuery;

    public Integer createCity(String name, String countryCode,
        String district, Integer population) {
        updateQuery.update(new Object[] { name, countryCode,
            district, population });
        return getLastId();
    }

    protected Integer getLastId() {
        return idQuery.run();
    }
}
```

You can see that we only operate on abstract query objects here and do not deal directly with the JDBC API. Also, this is the complete implementation. All of our transaction management will be dealt with in the configuration. To get the configuration started, we need to create the DAO.

```
<bean id="dao" class="code.Ex3DaoImpl">
    <property name="dataSource" ref="dataSource"/>
    <property name="updateQuery">...</property>
    <property name="idQuery">...</property>
</bean>
```

Now you need to set up the transaction configuration. The first thing you must do is create transaction manager to manage the data source and a specification of what transaction properties are required for the `dao` methods.

```
<bean id="transactionManager"
    class="org.springframework.jdbc.datasource.DataSourceTransactionManager">
    <property name="dataSource" ref="dataSource"/>
</bean>

<tx:advice id="txAdvice" transaction-manager="transactionManager">
    <tx:attributes>
        <tx:method name="*" />
    </tx:attributes>
</tx:advice>
```

The preceding code creates a transaction manager that handles transactions for the data source provided to it. The `txAdvice` uses this transaction manager and the attributes specify to create a transaction for all methods. Finally you need to apply this advice with an AOP pointcut.

```
<aop:config>
    <aop:pointcut id="daoMethods"
        expression="execution(* code.Ex3Dao.*(..))"/>
    <aop:advisor advice-ref="txAdvice" pointcut-ref="daoMethods"/>
</aop:config>
```

This basically says that all methods called on the `Ex3Dao` interface will be wrapped in a transaction. To make use of this, you only have to retrieve the `dao` from the application context and call a method on the `dao` instance.

```
Ex3Dao dao = (Ex3Dao) ctx.getBean("dao");
Integer id = dao.createCity(name, countryCode, district, pop);
```

We can verify from this that there is no transaction management happening in our Java code and it is all configured with Spring. This is a very powerful notion and regarded as one of the most beneficial features of Spring.

#### 20.4.5.2.4.3. Connection Pooling

In many situations, such as web applications, there will be a large number of small database transactions. When this is the case, it usually makes sense to create a pool of database connections available for web requests as needed. Although MySQL does not spawn an extra process when a connection is made, there is still a small amount of overhead to create and set up the connection. Pooling of connections also alleviates problems such as collecting large amounts of sockets in the `TIME_WAIT` state.

Setting up pooling of MySQL connections with Spring is as simple as changing the data source configuration in the application context. There are a number of configurations that we can use. The first example is based on the [Jakarta Commons DBCP library](#). The example below replaces the source configuration that was based on `DriverManagerDataSource` with DBCP's `BasicDataSource`.

```
<bean id="dataSource" destroy-method="close"
  class="org.apache.commons.dbcp.BasicDataSource">
  <property name="driverClassName" value="{db.driver}"/>
  <property name="url" value="{db.jdbcurl}"/>
  <property name="username" value="{db.username}"/>
  <property name="password" value="{db.password}"/>
  <property name="initialSize" value="3"/>
</bean>
```

The configuration of the two solutions is very similar. The difference is that DBCP will pool connections to the database instead of creating a new connection every time one is requested. We have also set a parameter here called `initialSize`. This tells DBCP that we want three connections in the pool when it is created.

Another way to configure connection pooling is to configure a data source in our J2EE application server. Using JBoss as an example, you can set up the MySQL connection pool by creating a file called `mysql-local-ds.xml` and placing it in the server/default/deploy directory in JBoss. Once we have this setup, we can use JNDI to look it up. With Spring, this lookup is very simple. The data source configuration looks like this.

```
<jee:jndi-lookup id="dataSource" jndi-name="java:MySQL_DS"/>
```

### 20.4.5.2.5. Using Connector/J with GlassFish

## 20.4.5.3. Common Problems and Solutions

There are a few issues that seem to be commonly encountered often by users of MySQL Connector/J. This section deals with their symptoms, and their resolutions.

### Questions

- [20.4.5.3.1](#): When I try to connect to the database with MySQL Connector/J, I get the following exception:

```
SQLException: Server configuration denies access to data source
SQLState: 08001
VendorError: 0
```

What is going on? I can connect just fine with the MySQL command-line client.

- [20.4.5.3.2](#): My application throws an SQLException 'No Suitable Driver'. Why is this happening?
- [20.4.5.3.3](#): I'm trying to use MySQL Connector/J in an applet or application and I get an exception similar to:

```
SQLException: Cannot connect to MySQL server on host:3306.
Is there a MySQL server running on the machine/port you
are trying to connect to?

(java.security.AccessControlException)
SQLState: 08S01
VendorError: 0
```

- [20.4.5.3.4](#): I have a servlet/application that works fine for a day, and then stops working overnight
- [20.4.5.3.5](#): I'm trying to use JDBC-2.0 updatable result sets, and I get an exception saying my result set is not updatable.
- [20.4.5.3.6](#): I cannot connect to the MySQL server using Connector/J, and I'm sure the connection parameters are correct.
- [20.4.5.3.7](#): I am trying to connect to my MySQL server within my application, but I get the following error and stack trace:

```
java.net.SocketException
MESSAGE: Software caused connection abort: recv failed

STACKTRACE:

java.net.SocketException: Software caused connection abort: recv failed
at java.net.SocketInputStream.socketRead0(Native Method)
at java.net.SocketInputStream.read(Unknown Source)
at com.mysql.jdbc.MysqlIO.readFully(MysqlIO.java:1392)
at com.mysql.jdbc.MysqlIO.readPacket(MysqlIO.java:1414)
at com.mysql.jdbc.MysqlIO.doHandshake(MysqlIO.java:625)
at com.mysql.jdbc.Connection.createNewIO(Connection.java:1926)
at com.mysql.jdbc.Connection.<init>(Connection.java:452)
at com.mysql.jdbc.NonRegisteringDriver.connect(NonRegisteringDriver.java:411)
```

- [20.4.5.3.8](#): My application is deployed through JBoss and I am using transactions to handle the statements on the MySQL database. Under heavy loads I am getting an error and stack trace, but these only occur after a fixed period of heavy activity.

- [20.4.5.3.9](#): When using `gcj` an `java.io.CharConversionException` is raised when working with certain character sequences.
- [20.4.5.3.10](#): Updating a table that contains a primary key that is either `FLOAT` or compound primary key that uses `FLOAT` fails to update the table and raises an exception.
- [20.4.5.3.11](#): You get an `ER_NET_PACKET_TOO_LARGE` exception, even though the binary blob size you want to insert via JDBC is safely below the `max_allowed_packet` size.

## Questions and Answers

### 20.4.5.3.1: When I try to connect to the database with MySQL Connector/J, I get the following exception:

```
SQLException: Server configuration denies access to data source
SQLState: 08001
VendorError: 0
```

#### What is going on? I can connect just fine with the MySQL command-line client.

MySQL Connector/J must use TCP/IP sockets to connect to MySQL, as Java does not support Unix Domain Sockets. Therefore, when MySQL Connector/J connects to MySQL, the security manager in MySQL server will use its grant tables to determine whether the connection should be allowed.

You must add the necessary security credentials to the MySQL server for this to happen, using the `GRANT` statement to your MySQL Server. See [Section 12.5.1.3, “GRANT Syntax”](#), for more information.

#### Note

Testing your connectivity with the `mysql` command-line client will not work unless you add the `--host` flag, and use something other than `localhost` for the host. The `mysql` command-line client will use Unix domain sockets if you use the special host name `localhost`. If you are testing connectivity to `localhost`, use `127.0.0.1` as the host name instead.

#### Warning

Changing privileges and permissions improperly in MySQL can potentially cause your server installation to not have optimal security properties.

### 20.4.5.3.2: My application throws an SQLException 'No Suitable Driver'. Why is this happening?

There are three possible causes for this error:

- The Connector/J driver is not in your `CLASSPATH`, see [Section 20.4.2, “Connector/J Installation”](#).
- The format of your connection URL is incorrect, or you are referencing the wrong JDBC driver.
- When using `DriverManager`, the `jdbc.drivers` system property has not been populated with the location of the Connector/J driver.

### 20.4.5.3.3: I'm trying to use MySQL Connector/J in an applet or application and I get an exception similar to:

```
SQLException: Cannot connect to MySQL server on host:3306.
Is there a MySQL server running on the machine/port you
are trying to connect to?

(java.security.AccessControlException)
SQLState: 08S01
VendorError: 0
```

Either you're running an Applet, your MySQL server has been installed with the `--skip-networking` option set, or your MySQL server has a firewall sitting in front of it.

Applets can only make network connections back to the machine that runs the web server that served the `.class` files for the applet. This means that MySQL must run on the same machine (or you must have some sort of port re-direction) for this to work. This also means that you will not be able to test applets from your local file system, you must always deploy them to a web server.

MySQL Connector/J can only communicate with MySQL using TCP/IP, as Java does not support Unix domain sockets. TCP/IP communication with MySQL might be affected if MySQL was started with the `--skip-networking` flag, or if it is firewalled.

If MySQL has been started with the `--skip-networking` option set (the Debian Linux package of MySQL server does this for ex-

ample), you need to comment it out in the file `/etc/mysql/my.cnf` or `/etc/my.cnf`. Of course your `my.cnf` file might also exist in the `data` directory of your MySQL server, or anywhere else (depending on how MySQL was compiled for your system). Binaries created by us always look in `/etc/my.cnf` and `[datadir]/my.cnf`. If your MySQL server has been firewalled, you will need to have the firewall configured to allow TCP/IP connections from the host where your Java code is running to the MySQL server on the port that MySQL is listening to (by default, 3306).

#### 20.4.5.3.4: I have a servlet/application that works fine for a day, and then stops working overnight

MySQL closes connections after 8 hours of inactivity. You either need to use a connection pool that handles stale connections or use the `"autoReconnect"` parameter (see [Section 20.4.4.1, "Driver/Datasource Class Names, URL Syntax and Configuration Properties for Connector/J"](#)).

Also, you should be catching `SQLExceptions` in your application and dealing with them, rather than propagating them all the way until your application exits, this is just good programming practice. MySQL Connector/J will set the `SQLState` (see [`java.sql.SQLException.getSQLState\(\)`](#) in your APIDocs) to `"08S01"` when it encounters network-connectivity issues during the processing of a query. Your application code should then attempt to re-connect to MySQL at this point.

The following (simplistic) example shows what code that can handle these exceptions might look like:

#### Example 20.12. Connector/J: Example of transaction with retry logic

```
public void doBusinessOp() throws SQLException {
    Connection conn = null;
    Statement stmt = null;
    ResultSet rs = null;

    //
    // How many times do you want to retry the transaction
    // (or at least _getting_ a connection)?
    //
    int retryCount = 5;

    boolean transactionCompleted = false;

    do {
        try {
            conn = getConnection(); // assume getting this from a
                                   // javax.sql.DataSource, or the
                                   // java.sql.DriverManager

            conn.setAutoCommit(false);

            //
            // Okay, at this point, the 'retry-ability' of the
            // transaction really depends on your application logic,
            // whether or not you're using autocommit (in this case
            // not), and whether you're using transaccational storage
            // engines
            //
            // For this example, we'll assume that it's _not_ safe
            // to retry the entire transaction, so we set retry
            // count to 0 at this point
            //
            // If you were using exclusively transaction-safe tables,
            // or your application could recover from a connection going
            // bad in the middle of an operation, then you would not
            // touch 'retryCount' here, and just let the loop repeat
            // until retryCount == 0.
            //
            retryCount = 0;

            stmt = conn.createStatement();

            String query = "SELECT foo FROM bar ORDER BY baz";

            rs = stmt.executeQuery(query);

            while (rs.next()) {
            }

            rs.close();
            rs = null;

            stmt.close();
            stmt = null;

            conn.commit();
            conn.close();
            conn = null;

            transactionCompleted = true;
        } catch (SQLException sqlEx) {

            //
            // The two SQL states that are 'retry-able' are 08S01
            // for a communications error, and 40001 for deadlock.

```

```

//
// Only retry if the error was due to a stale connection,
// communications problem or deadlock
//

String sqlState = sqlEx.getSQLState();

if ("08S01".equals(sqlState) || "40001".equals(sqlState)) {
    retryCount--;
} else {
    retryCount = 0;
}
} finally {
    if (rs != null) {
        try {
            rs.close();
        } catch (SQLException sqlEx) {
            // You'd probably want to log this . . .
        }
    }

    if (stmt != null) {
        try {
            stmt.close();
        } catch (SQLException sqlEx) {
            // You'd probably want to log this as well . . .
        }
    }

    if (conn != null) {
        try {
            //
            // If we got here, and conn is not null, the
            // transaction should be rolled back, as not
            // all work has been done

            try {
                conn.rollback();
            } finally {
                conn.close();
            }
        } catch (SQLException sqlEx) {
            //
            // If we got an exception here, something
            // pretty serious is going on, so we better
            // pass it up the stack, rather than just
            // logging it. . .
            throw sqlEx;
        }
    }
}
} while (!transactionCompleted && (retryCount > 0));
}

```

## Note

Use of the `autoReconnect` option is not recommended because there is no safe method of reconnecting to the MySQL server without risking some corruption of the connection state or database state information. Instead, you should use a connection pool which will enable your application to connect to the MySQL server using an available connection from the pool. The `autoReconnect` facility is deprecated, and may be removed in a future release.

### 20.4.5.3.5: I'm trying to use JDBC-2.0 updatable result sets, and I get an exception saying my result set is not updatable.

Because MySQL does not have row identifiers, MySQL Connector/J can only update result sets that have come from queries on tables that have at least one primary key, the query must select every primary key and the query can only span one table (that is, no joins). This is outlined in the JDBC specification.

Note that this issue only occurs when using updatable result sets, and is caused because Connector/J is unable to guarantee that it can identify the correct rows within the result set to be updated without having a unique reference to each row. There is no requirement to have a unique field on a table if you are using `UPDATE` or `DELETE` statements on a table where you can individually specify the criteria to be matched using a `WHERE` clause.

### 20.4.5.3.6: I cannot connect to the MySQL server using Connector/J, and I'm sure the connection parameters are correct.

Make sure that the `skip-networking` option has not been enabled on your server. Connector/J must be able to communicate with your server over TCP/IP, named sockets are not supported. Also ensure that you are not filtering connections through a Firewall or other network security system. For more information, see [Section B.1.2.2, "Can't connect to \[local\] MySQL server"](#).

### 20.4.5.3.7: I am trying to connect to my MySQL server within my application, but I get the following error and stack trace:

```

java.net.SocketException
MESSAGE: Software caused connection abort: recv failed

```

## STACKTRACE:

```

java.net.SocketException: Software caused connection abort: recv failed
at java.net.SocketInputStream.socketRead0(Native Method)
at java.net.SocketInputStream.read(Unknown Source)
at com.mysql.jdbc.MysqlIO.readFully(MysqlIO.java:1392)
at com.mysql.jdbc.MysqlIO.readPacket(MysqlIO.java:1414)
at com.mysql.jdbc.MysqlIO.doHandshake(MysqlIO.java:625)
at com.mysql.jdbc.Connection.createNewIO(Connection.java:1926)
at com.mysql.jdbc.Connection.<init>(Connection.java:452)
at com.mysql.jdbc.NonRegisteringDriver.connect(NonRegisteringDriver.java:411)

```

The error probably indicates that you are using an older version of the Connector/J JDBC driver (2.0.14 or 3.0.x) and you are trying to connect to a MySQL server with version 4.1x or newer. The older drivers are not compatible with 4.1 or newer of MySQL as they do not support the newer authentication mechanisms.

It is likely that the older version of the Connector/J driver exists within your application directory or your `CLASSPATH` includes the older Connector/J package.

#### 20.4.5.3.8: My application is deployed through JBoss and I am using transactions to handle the statements on the MySQL database. Under heavy loads I am getting an error and stack trace, but these only occur after a fixed period of heavy activity.

This is a JBoss, not Connector/J, issue and is connected to the use of transactions. Under heavy loads the time taken for transactions to complete can increase, and the error is caused because you have exceeded the predefined timeout.

You can increase the timeout value by setting the `TransactionTimeout` attribute to the `TransactionManagerService` within the `/conf/jboss-service.xml` file (pre-4.0.3) or `/deploy/jta-service.xml` for JBoss 4.0.3 or later. See `TransactionTimeout` within the JBoss wiki for more information.

#### 20.4.5.3.9: When using gcj an java.io.CharConversionException is raised when working with certain character sequences.

This is a known issue with `gcj` which raises an exception when it reaches an unknown character or one it cannot convert. You should add `useJvmCharsetConverters=true` to your connection string to force character conversion outside of the `gcj` libraries, or try a different JDK.

#### 20.4.5.3.10: Updating a table that contains a primary key that is either FLOAT or compound primary key that uses FLOAT fails to update the table and raises an exception.

Connector/J adds conditions to the `WHERE` clause during an `UPDATE` to check the old values of the primary key. If there is no match then Connector/J considers this a failure condition and raises an exception.

The problem is that rounding differences between supplied values and the values stored in the database may mean that the values never match, and hence the update fails. The issue will affect all queries, not just those from Connector/J.

To prevent this issue, use a primary key that does not use `FLOAT`. If you have to use a floating point column in your primary key use `DOUBLE` or `DECIMAL` types in place of `FLOAT`.

#### 20.4.5.3.11: You get an ER\_NET\_PACKET\_TOO\_LARGE exception, even though the binary blob size you want to insert via JDBC is safely below the max\_allowed\_packet size.

This is because the `hexEscapeBlock()` method in `com.mysql.jdbc.PreparedStatement.streamToBytes()` may almost double the size of your data.

## 20.4.6. Connector/J Support

### 20.4.6.1. Connector/J Community Support

Sun Microsystems, Inc. provides assistance to the user community by means of its mailing lists. For Connector/J related issues, you can get help from experienced users by using the MySQL and Java mailing list. Archives and subscription information is available online at <http://lists.mysql.com/java>.

For information about subscribing to MySQL mailing lists or to browse list archives, visit <http://lists.mysql.com/>. See [Section 1.5.1, “MySQL Mailing Lists”](#).

Community support from experienced users is also available through the [JDBC Forum](#). You may also find help from other users in the other MySQL Forums, located at <http://forums.mysql.com>. See [Section 1.5.2, “MySQL Community Support at the MySQL Forums”](#).

### 20.4.6.2. How to Report Connector/J Bugs or Problems

The normal place to report bugs is <http://bugs.mysql.com/>, which is the address for our bugs database. This database is public, and can be browsed and searched by anyone. If you log in to the system, you will also be able to enter new reports.

If you have found a sensitive security bug in MySQL, you can send email to [<security@mysql.com>](mailto:security@mysql.com).

Writing a good bug report takes patience, but doing it right the first time saves time both for us and for yourself. A good bug report, containing a full test case for the bug, makes it very likely that we will fix the bug in the next release.

This section will help you write your report correctly so that you do not waste your time doing things that may not help us much or at all.

If you have a repeatable bug report, please report it to the bugs database at <http://bugs.mysql.com/>. Any bug that we are able to repeat has a high chance of being fixed in the next MySQL release.

To report other problems, you can use one of the MySQL mailing lists.

Remember that it is possible for us to respond to a message containing too much information, but not to one containing too little. People often omit facts because they think they know the cause of a problem and assume that some details do not matter.

A good principle is this: If you are in doubt about stating something, state it. It is faster and less troublesome to write a couple more lines in your report than to wait longer for the answer if we must ask you to provide information that was missing from the initial report.

The most common errors made in bug reports are (a) not including the version number of Connector/J or MySQL used, and (b) not fully describing the platform on which Connector/J is installed (including the JVM version, and the platform type and version number that MySQL itself is installed on).

This is highly relevant information, and in 99 cases out of 100, the bug report is useless without it. Very often we get questions like, “Why doesn't this work for me?” Then we find that the feature requested wasn't implemented in that MySQL version, or that a bug described in a report has already been fixed in newer MySQL versions.

Sometimes the error is platform-dependent; in such cases, it is next to impossible for us to fix anything without knowing the operating system and the version number of the platform.

If at all possible, you should create a repeatable, standalone testcase that doesn't involve any third-party classes.

To streamline this process, we ship a base class for testcases with Connector/J, named `'com.mysql.jdbc.util.BaseBugReport'`. To create a testcase for Connector/J using this class, create your own class that inherits from `com.mysql.jdbc.util.BaseBugReport` and override the methods `setUp()`, `tearDown()` and `runTest()`.

In the `setUp()` method, create code that creates your tables, and populates them with any data needed to demonstrate the bug.

In the `runTest()` method, create code that demonstrates the bug using the tables and data you created in the `setUp` method.

In the `tearDown()` method, drop any tables you created in the `setUp()` method.

In any of the above three methods, you should use one of the variants of the `getConnection()` method to create a JDBC connection to MySQL:

- `getConnection()` - Provides a connection to the JDBC URL specified in `getUrl()`. If a connection already exists, that connection is returned, otherwise a new connection is created.
- `getNewConnection()` - Use this if you need to get a new connection for your bug report (that is, there is more than one connection involved).
- `getConnection(String url)` - Returns a connection using the given URL.
- `getConnection(String url, Properties props)` - Returns a connection using the given URL and properties.

If you need to use a JDBC URL that is different from `'jdbc:mysql:///test'`, override the method `getUrl()` as well.

Use the `assertTrue(boolean expression)` and `assertTrue(String failureMessage, boolean expression)` methods to create conditions that must be met in your testcase demonstrating the behavior you are expecting (vs. the behavior you are observing, which is why you are most likely filing a bug report).

Finally, create a `main()` method that creates a new instance of your testcase, and calls the `run` method:

```
public static void main(String[] args) throws Exception {
    new MyBugReport().run();
}
```

}

Once you have finished your testcase, and have verified that it demonstrates the bug you are reporting, upload it with your bug report to <http://bugs.mysql.com/>.

### 20.4.6.3. Connector/J Change History

The Connector/J Change History (Changelog) is located with the main Changelog for MySQL. See [Section E.7, “MySQL Connector/J Change History”](#).

## 20.5. MySQL Connector/MXJ

MySQL Connector/MXJ is a Java Utility package for deploying and managing a MySQL database. Deploying and using MySQL can be as easy as adding an additional parameter to the JDBC connection url, which will result in the database being started when the first connection is made. This makes it easy for Java developers to deploy applications which require a database by reducing installation barriers for their end-users.

MySQL Connector/MXJ makes the MySQL database appear to be a java-based component. It does this by determining what platform the system is running on, selecting the appropriate binary, and launching the executable. It will also optionally deploy an initial database, with any specified parameters.

Included are instructions for use with a JDBC driver and deploying as a JMX MBean to JBoss.

You can download sources and binaries from: <http://dev.mysql.com/downloads/connector/mxj/>

This is a beta release and feedback is welcome and encouraged.

Please send questions or comments to the [MySQL and Java mailing list](#).

### 20.5.1. Connector/MXJ Overview

Connector/MXJ consists of a Java class, a copy of the `mysqld` binary for a specific list of platforms, and associated files and support utilities. The Java class controls the initialization of an instance of the embedded `mysqld` binary, and the ongoing management of the `mysqld` process. The entire sequence and management can be controlled entirely from within Java using the Connector/MXJ Java classes. You can see an overview of the contents of the Connector/MXJ package in the figure below.

It is important to note that Connector/MXJ is not an embedded version of MySQL, or a version of MySQL written as part of a Java class. Connector/MXJ works through the use of an embedded, compiled binary of `mysqld` as would normally be used when deploying a standard MySQL installation.

It is the Connector/MXJ wrapper, support classes and tools, that enable Connector/MXJ to appear as a MySQL instance.

When Connector/MXJ is initialized, the corresponding `mysqld` binary for the current platform is extracted, along with a pre-

configured data directed. Both are contained within the Connector/MXJ JAR file. The `mysqld` instance is then started, with any additional options as specified during the initialization, and the MySQL database becomes accessible.

Because Connector/MXJ works in combination with Connector/J, you can access and integrate with the MySQL instance through a JDBC connection. When you have finished with the server, the instance is terminated, and, by default, any data created during the session is retained within the temporary directory created when the instance was started.

Connector/MXJ and the embedded `mysqld` instance can be deployed in a number of environments where relying on an existing database, or installing a MySQL instance would be impossible, including CD-ROM embedded database applications and temporary database requirements within a Java-based application environment.

## 20.5.2. Connector/MXJ Versions

- Connector/MXJ 5.x, currently in beta status, includes `mysqld` version 5.x and includes binaries for Linux x86, Mac OS X PPC, Windows XP/NT/2000 x86 and Solaris SPARC. Connector/MXJ 5.x requires the Connector/J 5.x package.

The exact version of `mysqld` included depends on the version of Connector/MXJ

- Connector/MXJ v5.0.3 included MySQL v5.0.22
  - Connector/MXJ v5.0.4 includes MySQL v5.0.27 (Community) or MySQL v5.0.32 (Enterprise)
  - Connector/MXJ v5.0.6 includes MySQL 5.0.37 (Community)
  - Connector/MXJ v5.0.7 includes MySQL 5.0.41 (Community) or MySQL 5.0.42 (Enterprise)
  - Connector/MXJ v5.0.8 includes MySQL 5.0.45 (Community) or MySQL 5.0.46 (Enterprise)
  - Connector/MXJ v5.0.9 includes MySQL 5.0.51a (Community) or MySQL 5.0.54 (Enterprise)
- Connector/MXJ 1.x includes `mysqld` version 4.1.13 and includes binaries for Linux x86, Windows XP/NT/2000 x86 and Solaris SPARC. Connector/MXJ 1.x requires the Connector/J 3.x package.

A summary of the different MySQL versions supplied with each Connector/MXJ release are shown in the table.

Connector/MXJ Version	MySQL Version(s)
5.0.8	5.0.45 (CS), 5.0.46 (ES)
5.0.7	5.0.41 (CS), 5.0.42 (ES)
5.0.6	5.0.37 (CS), 5.0.40 (ES)
5.0.5	5.0.37 (CS), 5.0.36 (ES)
5.0.4	5.0.27 (CS), 5.0.32 (ES)
5.0.3	5.0.22
5.0.2	5.0.19

This guide provides information on the Connector/MXJ 5.x release. For information on using the older releases, please see the documentation included with the appropriate distribution.

## 20.5.3. Connector/MXJ Installation

Connector/MXJ does not have a installation application or process, but there are some steps you can follow to make the installation and deployment of Connector/MXJ easier.

Before you start, there are some baseline requirements for

- Java Runtime Environment (v1.4.0 or newer) if you are only going to deploy the package.
- Java Development Kit (v1.4.0 or newer) if you want to build Connector/MXJ from source.
- Connector/J 5.0 or newer.

Depending on your target installation/deployment environment you may also require:

- JBoss - 4.0rc1 or newer
- Apache Tomcat - 5.0 or newer
- Sun's JMX reference implementation version 1.2.1 (from <http://java.sun.com/products/JavaManagement/>)

### 20.5.3.1. Supported Platforms

Connector/MXJ is compatible with any platform supporting Java and MySQL. By default, Connector/MXJ incorporates the `mysqld` binary for a select number of platforms which differs by version. The following platforms have been tested and working as deployment platforms. Support for all the platforms listed below is not included by default.

- Linux (i386)
- FreeBSD (i386)
- Windows NT (x86), Windows 2000 (x86), Windows XP (x86), Windows Vista (x86)
- Solaris 8, SPARC 32-bit (compatible with Solaris 8, Solaris 9 and Solaris 10 on SPARC 32-bit and 64-bit platforms)
- Mac OS X (PowerPC and Intel)

The Connector/MXJ 5.0.8 release includes `mysqld` binaries for the following platforms by as standard:

- Linux (i386)
- Windows (x86), compatible with Windows NT, Windows 2000, Windows XP , Windows Vista
- Solaris 8, SPARC 32-bit (compatible with Solaris 8, Solaris 9 and Solaris 10 on SPARC 32-bit and 64-bit platforms)
- Mac OS X (PowerPC and Intel)

For more information on packaging your own Connector/MXJ with the platforms you require, see [Section 20.5.6.1, “Creating your own Connector/MXJ Package”](#)

### 20.5.3.2. Connector/MXJ Base Installation

Because there is no formal installation process, the method, installation directory, and access methods you use for Connector/MXJ are entirely up to your individual requirements.

To perform a basic installation, choose a target directory for the files included in the Connector/MXJ package. On Unix/Linux systems you may opt to use a directory such as `/usr/local/connector-mxj`; On Windows, you may want to install the files in the base directory, `C:\Connector-MXJ`, or within the `Program Files` directory.

To install the files, for a Connector/MXJ 5.0.4 installation:

1. Download the Connector/MXJ package, either in Tar/Gzip format (ideal for Unix/Linux systems) or Zip format (Windows).
2. Extract the files from the package. This will create a directory `mysql-connector-mxj-gpl-[ver]`. Copy and optionally rename this directory to your desired location.
3. For best results, you should update your global `CLASSPATH` variable with the location of the required `jar` files.

Within Unix/Linux you can do this globally by editing the global shell profile, or on a user by user basis by editing their individual shell profile.

On Windows 2000, Windows NT and Windows XP, you can edit the global `CLASSPATH` by editing the `Environment Variables` configured through the `System` control panel.

For Connector/MXJ 5.0.6 and later you need the following JAR files in your `CLASSPATH`:

1. `mysql-connector-mxj-gpl-[ver].jar` — contains the main Connector/MXJ classes.

2. `mysql-connector-mxj-gpl-[ver]-db-files.jar` — contains the embedded `mysqld` and database files.
3. `aspectjrt.jar` — the AspectJ runtime library, located in `lib/aspectjrt.jar` in the Connector/MXJ package.
4. `mysql-connector-java-[ver]-bin.jar` — Connector/J, see [Section 20.4, “MySQL Connector/J”](#).

For Connector/MXJ 5.0.4 and later you need the following JAR files in your `CLASSPATH`:

1. `connector-mxj.jar` — contains the main Connector/MXJ classes.
2. `connector-mxj-db-files.jar` — contains the embedded `mysqld` and database files.
3. `aspectjrt.jar` — the AspectJ runtime library, located in `lib/aspectjrt.jar` in the Connector/MXJ package.
4. `mysql-connector-mxj-gpl-[ver].jar` — Connector/J, see [Section 20.4, “MySQL Connector/J”](#).

For Connector/MXJ 5.0.3 and earlier, you need the following JAR files:

1. `connector-mxj.jar`
2. `aspectjrt.jar` — the AspectJ runtime library, located in `lib/aspectjrt.jar` in the Connector/MXJ package.
3. `mysql-connector-mxj-gpl-[ver].jar` — Connector/J, see [Section 20.4, “MySQL Connector/J”](#).

### 20.5.3.3. Connector/MXJ Quick Start Guide

Once you have extracted the Connector/MXJ and Connector/J components you can run one of the sample applications that initiates a MySQL instance. You can test the installation by running the `ConnectorMXJUrlTestExample`:

```
shell> java ConnectorMXJUrlTestExample
jdbc:mysql:mxj://localhost:3336/our_test_app?server.basedir»
=/var/tmp/test-mxj&createDatabaseIfNotExist=true&server.initialize-user=true
[/var/tmp/test-mxj/bin/mysqld][--no-defaults][--port=3336][--socket=mysql.sock]»
[--basedir=/var/tmp/test-mxj][--datadir=/var/tmp/test-mxj/data]»
[--pid-file=/var/tmp/test-mxj/data/MysqldResource.pid]
[MysqldResource] launching mysqld (driver_launched_mysqld_1)
InnoDB: The first specified data file ./ibdata1 did not exist:
InnoDB: a new database to be created!
080220 9:40:20 InnoDB: Setting file ./ibdata1 size to 10 MB
InnoDB: Database physically writes the file full: wait...
080220 9:40:20 InnoDB: Log file ./ib_logfile0 did not exist: new to be created
InnoDB: Setting log file ./ib_logfile0 size to 5 MB
InnoDB: Database physically writes the file full: wait...
080220 9:40:20 InnoDB: Log file ./ib_logfile1 did not exist: new to be created
InnoDB: Setting log file ./ib_logfile1 size to 5 MB
InnoDB: Database physically writes the file full: wait...
InnoDB: Doublewrite buffer not found: creating new
InnoDB: Doublewrite buffer created
InnoDB: Creating foreign key constraint system tables
InnoDB: Foreign key constraint system tables created
080220 9:40:21 InnoDB: Started; log sequence number 0 0
080220 9:40:21 [Note] /var/tmp/test-mxj/bin/mysqld: ready for connections.
Version: '5.0.51a' socket: 'mysql.sock' port: 3336 MySQL Community Server (GPL)
[MysqldResource] mysqld running as process: 2238

-----
SELECT VERSION()
-----
5.0.51a
-----
[MysqldResource] stopping mysqld (process: 2238)
080220 9:40:27 [Note] /var/tmp/test-mxj/bin/mysqld: Normal shutdown

080220 9:40:27 InnoDB: Starting shutdown...
080220 9:40:29 InnoDB: Shutdown completed; log sequence number 0 43655
080220 9:40:29 [Note] /var/tmp/test-mxj/bin/mysqld: Shutdown complete

[MysqldResource] shutdown complete
```

The above output shows an instance of MySQL starting, the necessary files being created (log files, InnoDB data files) and the MySQL database entering the running state. The instance is then shutdown by Connector/MXJ before the example terminates.

#### Warning

You should avoid running your Connector/MXJ application as the `root` user, because this will cause the `mysqld` to also be executed with root privileges. For more information, see [Section 5.3.5, “How to Run MySQL as a Normal User”](#).

### 20.5.3.4. Deploying Connector/MXJ using Driver Launch

Connector/MXJ and Connector/J work together to enable you to launch an instance of the `mysqld` server through the use of a keyword in the JDBC connection string. Deploying Connector/MXJ within a Java application can be automated through this method, making the deployment of Connector/MXJ a simple process:

1. Download and unzip Connector/MXJ, add `mysql-connector-mxj-gpl-[ver].jar` to the `CLASSPATH`.  
If you are using Connector/MXJ v5.0.4 or later you will also need to add the `mysql-connector-mxj-gpl-[ver]-db-files.jar` file to your `CLASSPATH`.
2. To the JDBC connection string, embed the `mxj` keyword, for example: `jdbc:mysql:mxj://localhost:PORT/DB-NAME`.

For more details, see [Section 20.5.4, “Connector/MXJ Configuration”](#).

### 20.5.3.5. Deploying Connector/MXJ within JBoss

For deployment within a JBoss environment, you must configure the JBoss environment to use the Connector/MXJ component within the JDBC parameters:

1. Download Connector/MXJ and copy the `mysql-connector-mxj-gpl-[ver].jar` file to the `$JBOSS_HOME/server/default/lib` directory.  
If you are using Connector/MXJ v5.0.4 or later you will also need to copy the `mysql-connector-mxj-gpl-[ver]-db-files.jar` file to `$JBOSS_HOME/server/default/lib`.
2. Download Connector/J and copy the `mysql-connector-java-5.1.5-bin.jar` file to the `$JBOSS_HOME/server/default/lib` directory.
3. Create an MBean service xml file in the `$JBOSS_HOME/server/default/deploy` directory with any attributes set, for instance the `datadir` and `autostart`.
4. Set the JDBC parameters of your web application to use:

```
String driver = "com.mysql.jdbc.Driver";
String url = "jdbc:mysql:///test?propertiesTransform="+
    "com.mysql.management.jmx.ConnectorMXJPropertiesTransform";
String user = "root";
String password = "";
Class.forName(driver);
Connection conn = DriverManager.getConnection(url, user, password);
```

You may wish to create a separate users and database table spaces for each application, rather than using "root and test".

We highly suggest having a routine backup procedure for backing up the database files in the `datadir`.

### 20.5.3.6. Verifying Installation using JUnit

The best way to ensure that your platform is supported is to run the JUnit tests. These will test the Connector/MXJ classes and the associated components.

#### 20.5.3.6.1. JUnit Test Requirements

The first thing to do is make sure that the components will work on the platform. The `MysqldResource` class is really a wrapper for a native version of MySQL, so not all platforms are supported. At the time of this writing, Linux on the i386 architecture has been tested and seems to work quite well, as does OS X v10.3. There has been limited testing on Windows and Solaris.

Requirements:

1. JDK-1.4 or newer (or the JRE if you aren't going to be compiling the source or JSPs).
2. MySQL Connector/J version 5.0 or newer (from <http://dev.mysql.com/downloads/connector/j/>) installed and available via your `CLASSPATH`.
3. The `javax.management` classes for JMX version 1.2.1, these are present in the following application servers:

- JBoss - 4.0rc1 or newer.
  - Apache Tomcat - 5.0 or newer.
  - Sun's JMX reference implementation version 1.2.1 (from <http://java.sun.com/products/JavaManagement/>).
4. JUnit 3.8.1 (from <http://www.junit.org/>).

If building from source, All of the requirements from above, plus:

1. Ant version 1.5 or newer (download from <http://ant.apache.org/>).

### 20.5.3.6.2. Running the JUnit Tests

1. The tests attempt to launch MySQL on the port 3336. If you have a MySQL running, it may conflict, but this isn't very likely because the default port for MySQL is 3306. However, You may set the "c-mxj\_test\_port" Java property to a port of your choosing. Alternatively, you may wish to start by shutting down any instances of MySQL you have running on the target machine.

The tests suppress output to the console by default. For verbose output, you may set the "c-mxj\_test\_silent" Java property to "false".

2. To run the JUnit test suite, the \$CLASSPATH must include the following:

- JUnit
- JMX
- Connector/J
- MySQL Connector/MXJ

3. If `connector-mxj.jar` is not present in your download, unzip MySQL Connector/MXJ source archive.

```
cd mysqljmx
ant dist
```

Then add `$TEMP/cmxj/stage/connector-mxj/connector-mxj.jar` to the CLASSPATH.

4. if you have `junit`, execute the unit tests. From the command line, type:

```
java com.mysql.management.AllTestsSuite
```

The output should look something like this:

```
.....
.....
.....
Time: 259.438
OK (101 tests)
```

Note that the tests are a bit slow near the end, so please be patient.

## 20.5.4. Connector/MXJ Configuration

### 20.5.4.1. Running as part of the JDBC Driver

A feature of the MySQL Connector/J JDBC driver is the ability to specify a connection to an embedded Connector/MXJ instance through the use of the `mxj` keyword in the JDBC connection string.

In the following example, we have a program which creates a connection, executes a query, and prints the result to the `System.out`. The MySQL database will be deployed and started as part of the connection process, and shutdown as part of the finally block.

You can find this file in the Connector/MXJ package as [src/ConnectorMXJUrlTestExample.java](#).

```
import java.io.File;
import java.sql.Connection;
import java.sql.DriverManager;

import com.mysql.management.driverlaunched.ServerLauncherSocketFactory;
import com.mysql.management.util.QueryUtil;

public class ConnectorMXJUrlTestExample {
    public static String DRIVER = "com.mysql.jdbc.Driver";

    public static String JAVA_IO_TMPDIR = "java.io.tmpdir";

    public static void main(String[] args) throws Exception {
        File ourAppDir = new File(System.getProperty(JAVA_IO_TMPDIR));
        File databaseDir = new File(ourAppDir, "test-mxj");
        int port = Integer.parseInt(System.getProperty("c-mxj_test_port", "3336"));
        String dbName = "our_test_app";

        String url = "jdbc:mysql:mxj://localhost:" + port + "/" + dbName //
            + "?" + "serverbasedir=" + databaseDir //
            + "&" + "createDatabaseIfNotExist=true" //
            + "&" + "server.initialize-user=true" //
        ;

        System.out.println(url);

        String userName = "alice";
        String password = "q93uti0opwhkd";

        Class.forName(DRIVER);
        Connection conn = null;
        try {
            conn = DriverManager.getConnection(url, userName, password);
            String sql = "SELECT VERSION()";
            String queryForString = new QueryUtil(conn).queryForString(sql);

            System.out.println("-----");
            System.out.println(sql);
            System.out.println("-----");
            System.out.println(queryForString);
            System.out.println("-----");
            System.out.flush();
            Thread.sleep(100); // wait for System.out to finish flush
        } finally {
            try {
                if (conn != null)
                    conn.close();
            } catch (Exception e) {
                e.printStackTrace();
            }
        }

        ServerLauncherSocketFactory.shutdown(databaseDir, null);
    }
}
```

To run the above program, be sure to have connector-mxj.jar and Connector/J in the CLASSPATH. Then type:

```
java ConnectorMXJTestExample
```

### 20.5.4.2. Running within a Java Object

If you have a java application and wish to “embed” a MySQL database, make use of the [com.mysql.management.MysqldResource](#) class directly. This class may be instantiated with the default (no argument) constructor, or by passing in a [java.io.File](#) object representing the directory you wish the server to be “unzipped” into. It may also be instantiated with printstreams for “stdout” and “stderr” for logging.

Once instantiated, a [java.util.Map](#), the object will be able to provide a [java.util.Map](#) of server options appropriate for the platform and version of MySQL which you will be using.

The [MysqldResource](#) enables you to “start” MySQL with a [java.util.Map](#) of server options which you provide, as well as “shutdown” the database. The following example shows a simplistic way to embed MySQL in an application using plain java objects.

You can find this file in the Connector/MXJ package as [src/ConnectorMXJObjectTestExample.java](#).

```
import java.io.File;
import java.sql.Connection;
import java.sql.DriverManager;
import java.util.HashMap;
import java.util.Map;

import com.mysql.management.MysqldResource;
```

```

import com.mysql.management.MysqldResourceI;
import com.mysql.management.util.QueryUtil;

public class ConnectorMXJObjectTestExample {
    public static final String DRIVER = "com.mysql.jdbc.Driver";

    public static final String JAVA_IO_TMPDIR = "java.io.tmpdir";

    public static void main(String[] args) throws Exception {
        File ourAppDir = new File(System.getProperty(JAVA_IO_TMPDIR));
        File databaseDir = new File(ourAppDir, "mysql-mxj");
        int port = Integer.parseInt(System.getProperty("c-mxj_test_port",
            "3336"));
        String userName = "alice";
        String password = "q93uti0opwhkd";

        MysqldResource mysqldResource = startDatabase(databaseDir, port,
            userName, password);

        Class.forName(DRIVER);
        Connection conn = null;
        try {
            String dbName = "our_test_app";
            String url = "jdbc:mysql://localhost:" + port + "/" + dbName //
                + "?" + "createDatabaseIfNotExist=true"//
            ;
            conn = DriverManager.getConnection(url, userName, password);
            String sql = "SELECT VERSION()";
            String queryForString = new QueryUtil(conn).queryForString(sql);

            System.out.println("-----");
            System.out.println(sql);
            System.out.println("-----");
            System.out.println(queryForString);
            System.out.println("-----");
            System.out.flush();
            Thread.sleep(100); // wait for System.out to finish flush
        } finally {
            try {
                if (conn != null) {
                    conn.close();
                }
            } catch (Exception e) {
                e.printStackTrace();
            }
            try {
                mysqldResource.shutdown();
            } catch (Exception e) {
                e.printStackTrace();
            }
        }
    }

    public static MysqldResource startDatabase(File databaseDir, int port,
        String userName, String password) {
        MysqldResource mysqldResource = new MysqldResource(databaseDir);

        Map database_options = new HashMap();
        database_options.put(MysqldResourceI.PORT, Integer.toString(port));
        database_options.put(MysqldResourceI.INITIALIZE_USER, "true");
        database_options.put(MysqldResourceI.INITIALIZE_USER_NAME, userName);
        database_options.put(MysqldResourceI.INITIALIZE_PASSWORD, password);

        mysqldResource.start("test-mysqld-thread", database_options);

        if (!mysqldResource.isRunning()) {
            throw new RuntimeException("MySQL did not start.");
        }

        System.out.println("MySQL is running.");

        return mysqldResource;
    }
}

```

### 20.5.4.3. Setting server options

Of course there are many options we may wish to set for a MySQL database. These options may be specified as part of the JDBC connection string simply by prefixing each server option with `server..` In the following example we set two driver parameters and two server parameters:

```

String url = "jdbc:mysql://" + hostColonPort + "/"
    + "?"
    + "cacheServerConfiguration=true"
    + "&"
    + "useLocalSessionState=true"
    + "&"
    + "server.basedir=/opt/myapp/db"
    + "&"
    + "server.datadir=/mnt/bigdisk/myapp/data";

```

Starting with Connector/MXJ 5.0.6 you can use the `initializer-user` property to a connection string. If set to true, the default anonymous and root users will be removed and the user/password combination from the connection URL will be used to create a new user. For example:

```
String url = "jdbc:mysql:mxj://localhost:" + port
+ "/alice_db"
+ "?server.dataDir=" + dataDir.getPath()
+ "&server.initialize-user=true"
+ "&createDatabaseIfNotExist=true"
;
```

## 20.5.5. Connector/MXJ Reference

The following sections include detailed information on the different API interfaces to Connector/MXJ.

### 20.5.5.1. MysqlResource Constructors

The `MysqlResource` class supports three different constructor forms:

- `public MysqlResource(File baseDir, File dataDir, String mysqlVersionString, PrintStream out, PrintStream err)`  
Enables you to set the base directory, data directory, select a server by its version string, standard out and standard error.
- `public MysqlResource(File baseDir, File dataDir, String mysqlVersionString)`  
Enables you to set the base directory, data directory and select a server by its version string. Output for standard out and standard err are directed to `System.out` and `System.err`.
- `public MysqlResource(File baseDir, File dataDir)`  
Enables you to set the base directory and data directory. The default MySQL version is selected, and output for standard out and standard err are directed to `System.out` and `System.err`.
- `public MysqlResource(File baseDir);`  
Allows the setting of the "basedir" to deploy the MySQL files to. Output for standard out and standard err are directed to `System.out` and `System.err`.
- `public MysqlResource();`  
The basedir is defaulted to a subdirectory of the `java.io.tmpdir`. Output for standard out and standard err are directed to `System.out` and `System.err`;

### 20.5.5.2. MysqlResource Methods

`MysqlResource` API includes the following methods:

- `void start(String threadName, Map mysqlArgs);`  
Deploys and starts MySQL. The "threadName" string is used to name the thread which actually performs the execution of the MySQL command line. The map is the set of arguments and their values to be passed to the command line.
- `void shutdown();`  
Shuts down the MySQL instance managed by the `MysqlResource` object.
- `Map getServerOptions();`  
Returns a map of all the options and their current (or default, if not running) options available for the MySQL database.
- `boolean isRunning();`  
Returns true if the MySQL database is running.
- `boolean isReadyForConnections();`  
Returns true once the database reports that is ready for connections.

- `void setKillDelay(int millis);`

The default “Kill Delay” is 30 seconds. This represents the amount of time to wait between the initial request to shutdown and issuing a “force kill” if the database has not shutdown by itself.

- `void addCompletionListener(Runnable listener);`

Allows for applications to be notified when the server process completes. Each "listener" will be fired off in its own thread.

- `String getVersion();`

Returns the version of MySQL.

- `void setVersion(int MajorVersion, int minorVersion, int patchLevel);`

The standard distribution comes with only one version of MySQL packaged. However, it is possible to package multiple versions, and specify which version to use.

## 20.5.6. Connector/MXJ Notes and Tips

This section contains notes and tips on using the Connector/MXJ component within your applications.

### 20.5.6.1. Creating your own Connector/MXJ Package

If you want to create a custom Connector/MXJ package that includes a specific `mysqld` version or platform then you must extract and rebuild the `mysql-connector-mxj.jar` (Connector/MXJ v5.0.3 or earlier) or `mysql-connector-mxj-gpl-[ver]-db-files.jar` (Connector/MXJ v5.0.4 or later) file.

First, you should create a new directory into which you can extract the current `connector-mxj.jar`:

```
shell> mkdir custom-mxj
shell> cd custom-mxj
shell> jar -xf connector-mxj.jar
shell> ls
5-0-22/
ConnectorMXJObjectTestExample.class
ConnectorMXJUrlTestExample.class
META-INF/
TestDb.class
com/
kill.exe
```

If you are using Connector/MXJ v5.0.4 or later, you should unpack the `connector-mxj-db-files.jar`:

```
shell> mkdir custom-mxj
shell> cd custom-mxj
shell> jar -xf connector-mxj-db-files.jar
shell> ls
5-0-51a/
META-INF/
connector-mxj.properties
```

The MySQL version directory, `5-0-22` or `5-0-51a` in the preceding examples, contains all of the files used to create an instance of MySQL when Connector/MXJ is executed. All of the files in this directory are required for each version of MySQL that you want to embed. Note as well the format of the version number, which uses hyphens instead of periods to separate the version number components.

Within the version specific directory are the platform specific directories, and archives of the `data` and `share` directory required by MySQL for the various platforms. For example, here is the listing for the default Connector/MXJ package:

```
shell>> ls
Linux-i386/
META-INF/
Mac_OS_X-ppc/
SunOS-sparc/
Win-x86/
com/
data_dir.jar
share_dir.jar
win_share_dir.jar
```

Platform specific directories are listed by their OS and platform - for example the `mysqld` for Mac OS X PowerPC is located within the `Mac_OS_X-ppc` directory. You can delete directories from this location that you do not require, and add new directories for additional platforms that you want to support.

To add a platform specific `mysqld`, create a new directory with the corresponding name for your operating system/platform. For example, you could add a directory for Mac OS X/Intel using the directory `Mac_OS_X-i386`.

On Unix systems, you can determine the platform using `uname`:

```
shell> uname -p
i386
```

In Connector/MXJ v5.0.9 and later, an additional `platform-map.properties` file is used to associate a specific platform and operating system combination with the directory in which the `mysqld` for that combination is located. The determined operating system and platform are on the left, and the directory name where the appropriate `mysqld` is located is on the right. You can see a sample of the file below:

```
Linux-i386=Linux-i386
Linux-x86=Linux-i386
Linux-i686=Linux-i386
Linux-x86_64=Linux-i386
Linux-ia64=Linux-i386

#Linux-ppc=Linux-ppc
#Linux-ppc64=Linux-ppc

Mac_OS_X-i386=Mac_OS_X-i386
Mac_OS_X-ppc=Mac_OS_X-ppc
Rhapsody-PowerPC=Mac_OS_X-ppc
#Mac_OS-PowerPC=
#macos-PowerPC=
#MacOS-PowerPC=

SunOS-sparc=SunOS-sparc
Solaris-sparc=SunOS-sparc
SunOS-x86=SunOS-x86
Solaris-x86=SunOS-x86

FreeBSD-x86=FreeBSD-x86

Windows_Vista-x86=Win-x86
Windows_2003-x86=Win-x86
Windows_XP-x86=Win-x86
Windows_2000-x86=Win-x86
Windows_NT-x86=Win-x86
Windows_NT_(unknown)-x86=Win-x86
```

Now you need to download or compile `mysqld` for the MySQL version and platform you want to include in your custom `connector-mxj.jar` package into the new directory.

Create a file called `version.txt` in the OS/platform directory you have just created that contains the version string/path of the `mysqld` binary. For example:

```
mysql-5.0.22-osx10.3-i386/bin/mysqld
```

You can now recreate the `connector-mxj.jar` file with the added `mysqld`:

```
shell> cd custom-mxj
shell> jar -cf ../connector-mxj.jar *
```

For Connector/MXJ v5.0.4 and later, you should repackage to the `connector-mxj-db-files.jar`:

```
shell> cd custom-mxj
shell> jar -cf ../mysql-connector-mxj-gpl-[ver]-db-files.jar *
```

You should test this package using the steps outlined in [Section 20.5.3.3, “Connector/MXJ Quick Start Guide”](#).

### Note

Because the `mysql-connector-mxj-gpl-[ver]-db-files.jar` file is separate from the main Connector/MXJ classes you can distribute different `mysql-connector-mxj-gpl-[ver]-db-files.jar` files to different hosts or for different projects without having to create a completely new main `mysql-connector-mxj-gpl-[ver].jar` file for each one.

## 20.5.6.2. Deploying Connector/MXJ with a pre-configured database

To include a pre-configured/populated database within your Connector/MXJ JAR file you must create a custom `data_dir.jar` file, as included within the main `connector-mxj.jar` (Connector/MXJ 5.0.3 or earlier) or `mysql-connector-mxj-gpl-[ver]-db-files.jar` (Connector/MXJ 5.0.4 or later) file:

1. First extract the `connector-mxj.jar` or `mysql-connector-gpl-[ver]-db-files.jar` file, as outlined in the previous section (see [Section 20.5.6.1](#), “Creating your own Connector/MXJ Package”).
2. First, create your database and populate the database with the information you require in an existing instance of MySQL - including Connector/MXJ instances. Data file formats are compatible across platforms.
3. Shutdown the instance of MySQL.
4. Create a JAR file of the data directory and databases that you want to include your Connector/MXJ package. You should include the `mysql` database, which includes user authentication information, in addition to the specific databases you want to include. For example, to create a JAR of the `mysql` and `mxjtest` databases:

```
shell> jar -cf ../data_dir.jar mysql mxjtest
```

5. For Connector/MXJ 5.0.3 or earlier, copy the `data_dir.jar` file into the extracted `connector-mxj.jar` directory, and then create an archive for `connector-mxj.jar`.

For Connector/MXJ 5.0.4 or later, copy the `data_dir.jar` file into the extracted `mysql-connector-mxj-gpl-[ver]-db-files.jar` directory, and then create an archive for `mysql-connector-mxj-gpl-[ver]-db-files.jar`.

Note that if you are create databases using the InnoDB engine, you must include the `ibdata.*` and `ib_logfile*` files within the `data_dir.jar` archive.

### 20.5.6.3. Running within a JMX Agent (custom)

As a JMX MBean, MySQL Connector/MXJ requires a JMX v1.2 compliant MBean container, such as JBoss version 4. The MBean will use the standard JMX management APIs to present (and allow the setting of) parameters which are appropriate for that platform.

If you are not using the SUN Reference implementation of the JMX libraries, you should skip this section. Or, if you are deploying to JBoss, you also may wish to skip to the next section.

We want to see the `MysqldDynamicMBean` in action inside of a JMX agent. In the `com.mysql.management.jmx.sunri` package is a custom JMX agent with two MBeans:

1. the `MysqldDynamicMBean`, and
2. a `com.sun.jdmk.comm.HtmlAdaptorServer`, which provides a web interface for manipulating the beans inside of a JMX agent.

When this very simple agent is started, it will allow a MySQL database to be started and stopped with a web browser.

1. Complete the testing of the platform as above.
  - current JDK, JUnit, Connector/J, MySQL Connector/MXJ
  - this section *requires* the SUN reference implementation of JMX
  - `PATH`, `JAVA_HOME`, `ANT_HOME`, `CLASSPATH`
2. If not building from source, skip to next step

rebuild with the "sunri.present"

```
ant -Dsunri.present=true dist
re-run tests:
java junit.textui.TestRunner com.mysql.management.AllTestsSuite
```

3. launch the test agent from the command line:

```
java com.mysql.management.jmx.sunri.MysqldTestAgentSunHtmlAdaptor &
```

4. from a browser:

```
http://localhost:9092/
```

5. under MysqlAgent,

```
select "name=mysqlid"
```

6. Observe the MBean View
7. scroll to the bottom of the screen press the STARTMYSQLD button
8. click [Back to MBean View](#)
9. scroll to the bottom of the screen press STOPMYSQLD button
10. kill the java process running the Test Agent (jmx server)

#### 20.5.6.4. Deployment in a standard JMX Agent environment (JBoss)

Once there is confidence that the MBean will function on the platform, deploying the MBean inside of a standard JMX Agent is the next step. Included are instructions for deploying to JBoss.

1. Ensure a current version of java development kit (v1.4.x), see above.
  - Ensure `JAVA_HOME` is set (JBoss requires `JAVA_HOME`)
  - Ensure `JAVA_HOME/bin` is in the `PATH` (You will NOT need to set your `CLASSPATH`, nor will you need any of the jars used in the previous tests).
2. Ensure a current version of JBoss (v4.0RC1 or better)

```
http://www.jboss.org/index.html
select "Downloads"
select "jboss-4.0.zip"
pick a mirror
unzip ~/dload/jboss-4.0.zip
create a JBOSS_HOME environment variable set to the unzipped directory
unix only:
cd $JBOSS_HOME/bin
chmod +x *.sh
```

3. Deploy (copy) the `connector-mxj.jar` to `$JBOSS_HOME/server/default/lib`.
4. Deploy (copy) `mysql-connector-java-3.1.4-beta-bin.jar` to `$JBOSS_HOME/server/default/lib`.
5. Create a `mxjtest.war` directory in `$JBOSS_HOME/server/default/deploy`.
6. Deploy (copy) `index.jsp` to `$JBOSS_HOME/server/default/deploy/mxjtest.war`.
7. Create a `mysqlid-service.xml` file in `$JBOSS_HOME/server/default/deploy`.

```
<?xml version="1.0" encoding="UTF-8"?>
<server>
  <mbean code="com.mysql.management.jmx.jboss.JBossMysqlidDynamicMBean"
    name="mysql:type=service,name=mysqlid">
    <attribute name="datadir">/tmp/xxx_data_xxx</attribute>
    <attribute name="autostart">true</attribute>
  </mbean>
</server>
```

8. Start jboss:
  - on unix: `$JBOSS_HOME/bin/run.sh`
  - on windows: `%JBOSS_HOME%\bin\run.bat`

Be ready: JBoss sends a lot of output to the screen.

9. When JBoss seems to have stopped sending output to the screen, open a web browser to: <http://localhost:8080/jmx-console>
10. Scroll down to the bottom of the page in the `mysql` section, select the bulleted `mysqlid` link.
11. Observe the JMX MBean View page. MySQL should already be running.

12. (If "autostart=true" was set, you may skip this step.) Scroll to the bottom of the screen. You may press the INVOKE button to stop (or start) MySQL observe `Operation completed successfully without a return value`. Click `Back to MBean View`
13. To confirm MySQL is running, open a web browser to `http://localhost:8080/mxjtest/` and you should see that

```
SELECT 1
```

returned with a result of

```
1
```

14. Guided by the `$JBOSS_HOME/server/default/deploy/mxjtest.war/index.jsp` you will be able to use MySQL in your Web Application. There is a `test` database and a `root` user (no password) ready to experiment with. Try creating a table, inserting some rows, and doing some selects.
15. Shut down MySQL. MySQL will be stopped automatically when JBoss is stopped, or: from the browser, scroll down to the bottom of the MBean View press the stop service INVOKE button to halt the service. Observe `Operation completed successfully without a return value`. Using `ps` or `task manager` see that MySQL is no longer running

As of 1.0.6-beta version is the ability to have the MBean start the MySQL database upon start up. Also, we've taken advantage of the JBoss life-cycle extension methods so that the database will gracefully shut down when JBoss is shutdown.

## 20.5.7. Connector/MXJ Support

There are a wide variety of options available for obtaining support for using Connector/MXJ. You should contact the Connector/MXJ community for help before reporting a potential bug or problem. See [Section 20.5.7.1, "Connector/MXJ Community Support"](#).

### 20.5.7.1. Connector/MXJ Community Support

Sun Microsystems, Inc. provides assistance to the user community by means of a number of mailing lists and web based forums.

You can find help and support through the [MySQL and Java](#) mailing list.

For information about subscribing to MySQL mailing lists or to browse list archives, visit <http://lists.mysql.com/>. See [Section 1.5.1, "MySQL Mailing Lists"](#).

Community support from experienced users is also available through the [MyODBC Forum](#). You may also find help from other users in the other MySQL Forums, located at <http://forums.mysql.com>. See [Section 1.5.2, "MySQL Community Support at the MySQL Forums"](#).

### 20.5.7.2. How to Report Connector/MXJ Problems

If you encounter difficulties or problems with Connector/MXJ, contact the Connector/MXJ community [Section 20.5.7.1, "Connector/MXJ Community Support"](#).

If reporting a problem, you should ideally include the following information with the email:

- Operating system and version
- Connector/MXJ version
- MySQL server version
- Copies of error messages or other unexpected output
- Simple reproducible sample

Remember that the more information you can supply to us, the more likely it is that we can fix the problem.

If you believe the problem to be a bug, then you must report the bug through <http://bugs.mysql.com/>.

### 20.5.7.3. Connector/MXJ Change History

The Connector/MXJ Change History (Changelog) is located with the main Changelog for MySQL. See [Section E.8, "MySQL Con-](#)

[nector/MXJ Change History](#)".

## 20.6. MySQL Connector/C

### What is MySQL Connector/C?

MySQL Connector/C is a C client library for client-server communication. It is a standalone replacement for the MySQL Client Library shipped with the MySQL Server.

### Why have a replacement for MySQL Client Library?

There is no need to compile or install the MySQL Server package if you only need the client library.

MySQL Connector/C does not rely on the MySQL Server release cycle, so bug fixes and new features are released more often.

MySQL Connector/C API documentation is available [online](#).

Supported platforms include:

- Windows
- Windows x64
- Linux
- Solaris
- FreeBSD
- Mac OS X
- HP-UX
- IBM AIX
- IBM i5/OS

### 20.6.1. Building MySQL Connector/C from the Source Code

#### Obtaining the Source Code

The source can be downloaded as a Zip file or tar-ball from the source repository on [Launchpad](#).

#### • Building on Unix

Examples of supported Unix or Unix-like operating systems include:

- Solaris
- Linux
- HP-UX
- AIX
- OS X

#### Compiler Tools

Ideally, the native compiler tool set for the target platform is used for compilation. This would be SunStudio for Solaris and aCC for HP-UX for example. However, the GNU tool-chain can be used across all platforms.

You also need CMake 2.6 or newer, which is available [online](#).

#### To Build

If using GNU AutoTools change to the MySQL Connector/C source directory and follow the procedure below.

1. To generate the makefile enter:

```
shell> cmake -G "Unix Makefiles"
```

or for a Debug build enter:

```
shell> cmake -G "Unix Makefiles" -DCMAKE_BUILD_TYPE=Debug
```

2. Then build the project using:

```
shell> make
```

### To Install

By default make install will install the MySQL Connector/C files in the `/usr/local` directory. You can change this behavior by specifying another directory when generating the `makefile`:

```
shell> cmake -G "Unix Makefiles" -DCMAKE_INSTALL_PREFIX=/mypath
```

Now, in the root shell, enter the following to install the MySQL Connector/C libraries and tools:

```
root-shell> make install
```

At this point all of the MySQL Connector/C files will be in place.

- **Building on Microsoft Windows**

Older versions of Microsoft Windows are not supported. Supported versions are Windows 2000, Windows XP, Windows Vista, Windows Server 2003, or Windows Server 2008.

### Compiler Tools

Microsoft Visual Studio 8 and 9 are recommended. The Express Edition of Visual Studio and other compilers may work, but are untested.

You also need CMake 2.6 or newer, available at <http://www.cmake.org>

### To Build

You need to have the environment variables set for the Visual Studio toolchain. Visual Studio includes a batch file to set these for you, and installs a shortcut into the **START** menu to open a command prompt with these variables set.

Build MySQL Connector/C using the CMake command-line tool by entering the following from the source root directory in a command prompt window:

```
shell> cmake -G "Visual Studio 9 2008"
```

This produces a project file that you can open with Visual Studio or build from the command line with either of:

```
shell> devenv.com libmysql.sln /build Release
```

```
shell> devenv.com libmysql.sln /build RelWithDebInfo
```

For other versions of Visual Studio or `nmake` based build, run the following command:

```
shell> cmake --help
```

to check the supported generators.

To compile the Debug build, you must run set the CMake build type so the correct version of external libraries are used:

```
shell> cmake -G "Visual Studio 8 2005" -DCMAKE_BUILD_TYPE=Debug
```

Followed by:

```
shell> devenv.com libmysql.sln /build Debug
```

**To Install**

To create a install package you can choose between two variants:

1. Creating a Zip package
2. Creating an MSI install package

- **Zip package**

To create a Zip package, run the `cpack` command from the root of your MySQL Connector/C source directory.

- **MSI Install package**

The required tools include Windows XML Installer toolset (WIX), which is available [online](#).

To create the MSI install package change to the subdirectory `win` and generate the `makefile`:

```
shell> cmake -G "NMake Makefiles"
```

Create the MSI install package by calling `nmake`:

```
shell> nmake
```

## 20.6.2. Testing MySQL Connector/C

For testing MySQL Connector/C you will need a running MySQL server instance. Before you run the test suite you need to specify the following environment variables:

- `MYSQL_TEST_HOST` (default localhost)
- `MYSQL_TEST_USER`
- `MYSQL_TEST_PASSWD`
- `MYSQL_TEST_PORT`
- `MYSQL_TEST_SOCKET`
- `MYSQL_TEST_DB` (default test)

To run the test suite, execute `ctest` from the command line:

```
shell> ctest
```

## 20.6.3. MySQL Connector/C FAQ

**Questions**

- [20.6.3.1](#): What is “libmysqld”?
- [20.6.3.2](#): What is “MySQL Connector/C”?
- [20.6.3.3](#): What is the “MySQL Native C API”? What are its typical benefits and use cases?
- [20.6.3.4](#): What is the difference between “Native C API”, “libmysql”, “libmysqld” and “MySQL Connector/C”?
- [20.6.3.5](#): Does MySQL Connector/C replace any of “Native C API”, “libmysql” and “libmysqld”?
- [20.6.3.6](#): What is “libmysql”?

**Questions and Answers****20.6.3.1: What is “libmysqld”?**

`libmysqld` is an embedded database server with the same API as MySQL Connector/C. It is included with the MySQL Server distribution.

#### 20.6.3.2: What is “MySQL Connector/C”?

MySQL Connector/C is a standalone distribution of the `libmysql` library, which was previously only available as part of the MySQL Server distribution. The version of `libmysql` included with MySQL Connector/C and the version bundled with the server are functionally equivalent, but the cross-platform build system for MySQL Connector/C uses CMake.

#### 20.6.3.3: What is the “MySQL Native C API”? What are its typical benefits and use cases?

MySQL Connector/C, also known as `libmysql`, or MySQL Native C API, is a standalone, C-based API and library that you can use in C applications to connect with the MySQL Server. It implements the same MySQL client API that has been in use for a decade.

It is also used as the foundation for drivers for standard database APIs such as ODBC, Perl's DBI, and Python's DB API.

#### 20.6.3.4: What is the difference between “Native C API”, “libmysql”, “libmysqld” and “MySQL Connector/C”?

MySQL Connector/C and `libmysql` are the “native C API for MySQL”, and all three terms can be used interchangeably. “libmysqld” is the embedded version of the MySQL Server, and is included in the server distribution.

#### 20.6.3.5: Does MySQL Connector/C replace any of “Native C API”, “libmysql” and “libmysqld”?

MySQL Connector/C contains `libmysql`, and implements a native C API. It does not include `libmysqld`, which can be found with the MySQL server distribution.

#### 20.6.3.6: What is “libmysql”?

`libmysql` is the name of the library that MySQL Connector/C provides.

## 20.7. MySQL Connector/OpenOffice.org

MySQL Connector/OpenOffice.org is a native MySQL database connector for OpenOffice.org. Currently, it is in preview status and supports OpenOffice.org 2.4 only. It can be used to connect OpenOffice.org applications to a MySQL server.

Before MySQL Connector/OpenOffice.org became available you would have to use MySQL Connector/J (JDBC) or MySQL Connector/ODBC to connect to a MySQL server.

Connector/OpenOffice.org is a community project, although Sun Microsystems actively contributes code. The source code for Connector/OpenOffice.org is available under GPL with the FLOSS License Exception.

In the future a closed-source StarOffice version of Connector/OpenOffice.org will be made available.

### Advantages

Using MySQL Connector/OpenOffice.org has the following advantages:

- Easy installation through the OpenOffice.org Extension Manager.
- Seamless integration into OpenOffice.org.
- No need to go through an additional Connector installation routine (ODBC/JDBC)
- No need to configure or register an additional Connector (ODBC)
- No need to install or configure a driver manager (ODBC)

### Status

MySQL Connector/OpenOffice.org is available as a development preview version. We kindly ask users and developers to try it out and provide us with feedback. We do not encourage you to use it in production environments, though.

#### Note

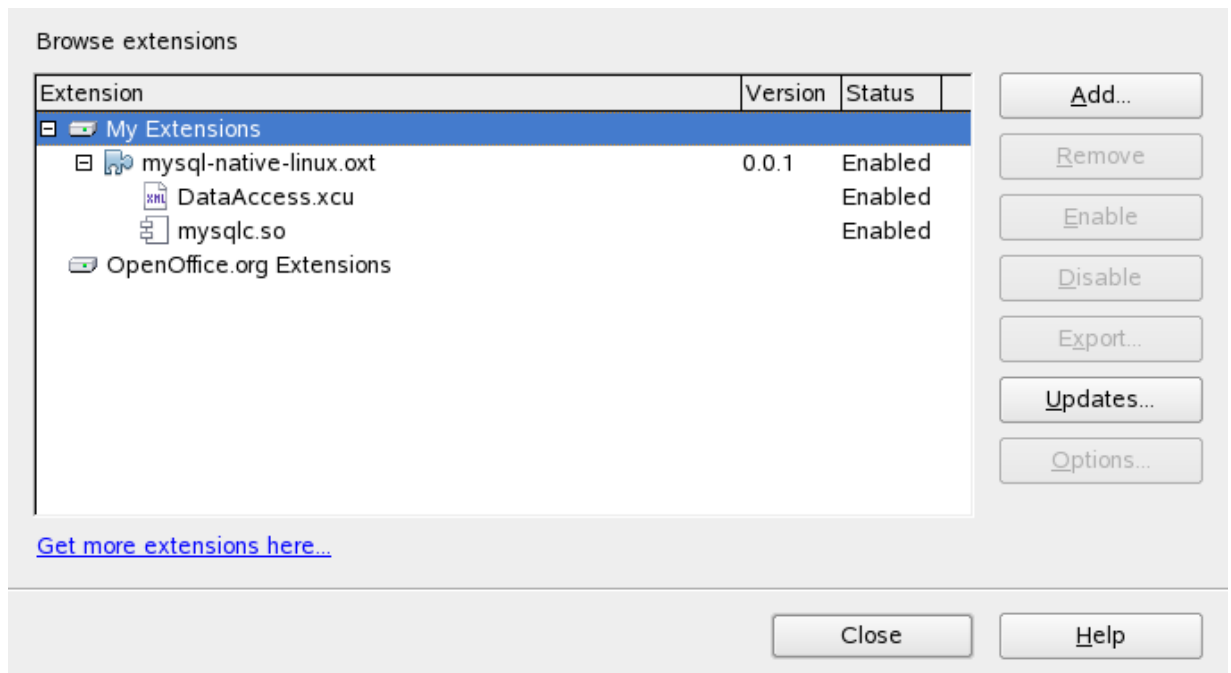

Sun Microsystems does not provide formal support for Connector/OpenOffice.org.

If you have any queries please contact us through our mailing list at [<users@dba.openoffice.org>](mailto:users@dba.openoffice.org)

## 20.7.1. Installation

1. Install or upgrade to OpenOffice.org 2.4.
2. Download MySQL Connector/OpenOffice.org from [The OpenOffice.org download site](#). Save the file, `mysql-native-win32.oxt` or `mysql-native-linux.oxt`, respectively, to a location of your choice, for example `My Documents` or `~/Documents`.
3. Add the `.oxt` extension through the Extension Manager of OpenOffice.org. In OpenOffice.org, select **TOOLS**, **EXTENSION MANAGER...** and specify the `.oxt` file as a new extension. When done, MySQL Connector/OpenOffice.org will show up as a new extension under **MY EXTENSIONS**.

**Figure 20.40. Adding an extension**

4. Restart OpenOffice.org.

## 20.7.2. Getting Started: Connecting to MySQL

MySQL Connector/OpenOffice.org allows you to access the MySQL Server and its schemata from the OpenOffice.org suite. Currently the connector is in preview status, and only OpenOffice.org 2.4 is supported.

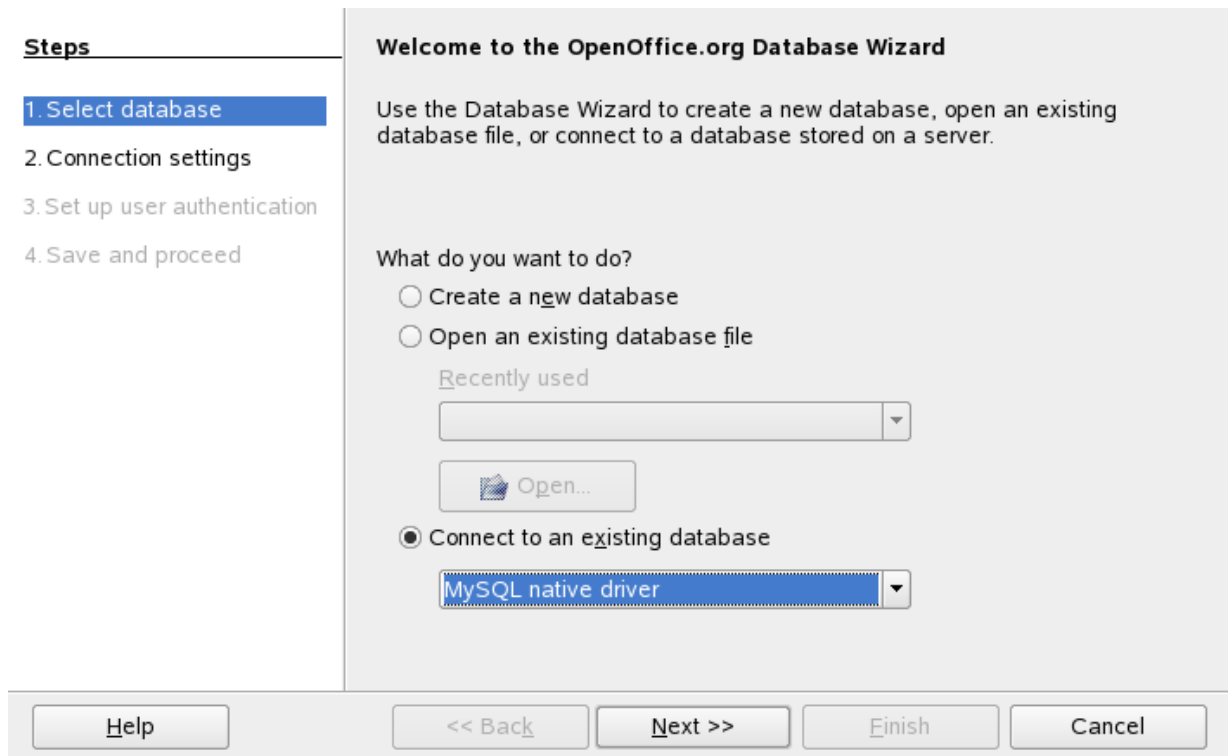

The following example demonstrates the creation of a new OpenOffice.org Base database which uses a local MySQL Server for storage and the new connector for connecting.

1. Select the database

Create a new database by selecting **FILE**, **NEW**, **DATABASE**. This starts a wizard that allows you to create a new, open an existing, or connect to existing database. Select the latter option. From the drop-down list, select MySQL native driver. Click **NEXT >>**.

**Figure 20.41. Selecting the database**

2. Fill in the connection settings

Under **MYSQL NATIVE DRIVER**, fill in the host name, and optionally a database name, and port name, for example:

**localhost/test**

This will connect to a MySQL server running on the local host and select the test database. Note that if you do not specify a database the process below will still work, and all databases will be available for selection.

On Linux, you may have to specify an IP number and a port number instead, due to a limitation in Connector/OpenOffice.org. You have to do so if your MySQL socket file is not `/tmp/mysql.sock`. Enter your data using the format illustrated in the following example:

**127.0.0.1:3306/test**

This will connect to a MySQL server running on the local host, but do so via TCP/IP using 3306 as the port number. Click **NEXT >>**.

**Figure 20.42. Entering connection settings**

The screenshot shows a configuration dialog for a MySQL native driver. On the left, a 'Steps' list includes: 1. Select database, 2. Connection settings (highlighted in blue), 3. Set up user authentication, and 4. Save and proceed. The main area is titled 'MySQL native driver' and contains a text input field with the value 'localhost:3306/test'. At the bottom, there are five buttons: 'Help', '<< Back', 'Next >>', 'Finish', and 'Cancel'.

3. Fill in credentials

If you are using MySQL server's anonymous account without a password, you do not have to fill in anything in this step. Otherwise, fill in your MySQL user name and check the password checkbox. Note, for security reasons, you should not normally use the anonymous account without a password.

**Figure 20.43. Setting up user authentication**

The screenshot shows a dialog titled 'Set up the user authentication'. It contains the text: 'Some databases require you to enter a user name.' Below this, there is a 'User name' label followed by a text input field containing 'your\_user\_name'. Underneath the input field is a checkbox labeled 'Password required', which is checked. At the bottom right of the main area is a 'Test Connection' button. The bottom of the dialog features five buttons: 'Help', '<< Back', 'Next >>', 'Finish', and 'Cancel'.

You can now test your connection to the MySQL database server by clicking the **TEST CONNECTION** button. Check the checkbox if you do not want OpenOffice.org to ask you for your password again in the current session. Testing the connection is optional, although recommended.

**Figure 20.44. Entering user credentials**

Log in

A password is needed to connect to the data source "New Database".

User name

Password

Remember password until end of session

OK

Cancel

Help

Click **NEXT >>**.

4. Finish the wizard

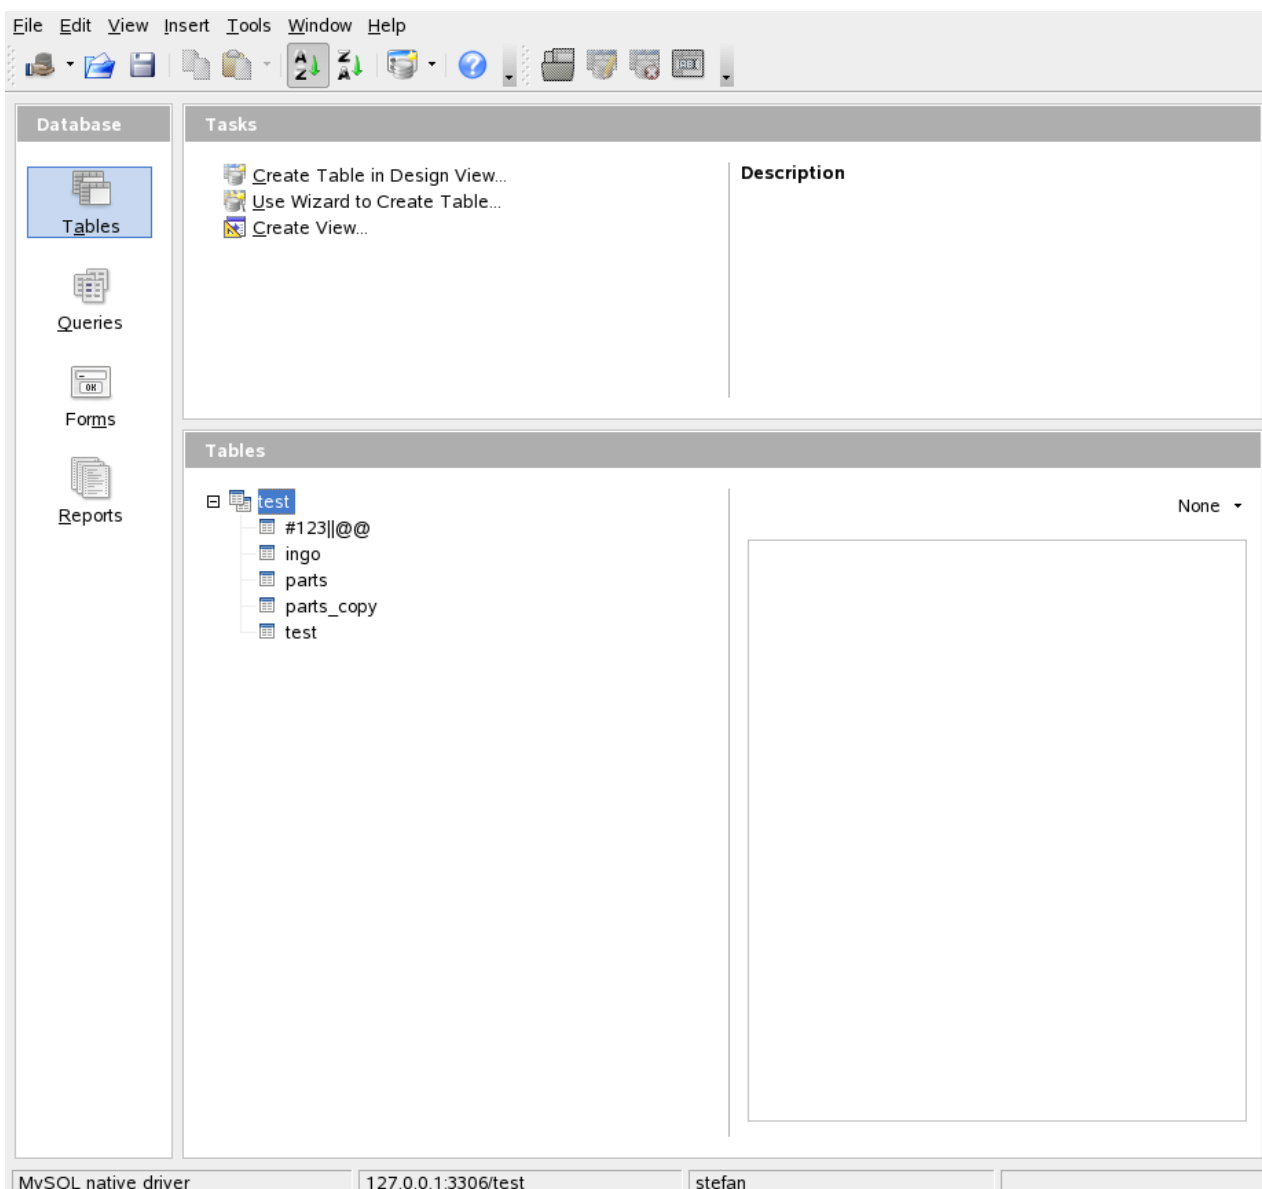

Leave the default settings and click **FINISH**. You will be forwarded to the OpenOffice.org Base main window. Note that you can invoke the wizard again at any point by right-clicking in the **TABLES** section of the **BASE** main window and selecting **DATABASE, CONNECTION TYPE**.

### 20.7.3. Getting Started: Usage Examples

#### Listing Tables

In the **DATABASE** area of the **BASE** main window, select **TABLES**. If this is the first time you are accessing the database you will be prompted for your credentials (user name and password); you can store these settings for your current Base session.

**Figure 20.45. Listing tables**

Depending on your connection settings you will now see all databases with all their tables, or just the database you have specified in the connection settings.

## 20.7.4. References

See the [OpenOffice.org website](http://OpenOffice.org) for documentation of the office suite and its Extension Manager.

## 20.7.5. Known Bugs

If you discover a bug in Connector/OpenOffice.org please [add it to this list](#) and send an email to [<users@dba.openoffice.org>](mailto:users@dba.openoffice.org). You need to be logged in with an OpenOffice.org account for both; see the [project mailing list](#) for details.

## 20.7.6. Contact

To discuss the new MySQL Connector/OpenOffice.org, please subscribe to the mailing list [<users@dba.openoffice.org>](mailto:users@dba.openoffice.org). It is a low-volume list with less than 10 mails per day.

## 20.8. libmysqld, the Embedded MySQL Server Library

The embedded MySQL server library is NOT part of MySQL 5.0. It is part of previous editions and will be included in fu-

ture versions, starting with MySQL 5.1. You can find appropriate documentation in the corresponding manuals for these versions. In this manual, only an overview of the embedded library is provided.

The embedded MySQL server library makes it possible to run a full-featured MySQL server inside a client application. The main benefits are increased speed and more simple management for embedded applications.

The embedded server library is based on the client/server version of MySQL, which is written in C/C++. Consequently, the embedded server also is written in C/C++. There is no embedded server available in other languages.

The API is identical for the embedded MySQL version and the client/server version. To change an old threaded application to use the embedded library, you normally only have to add calls to the following functions.

Function	When to Call
<code>mysql_library_init()</code>	Should be called before any other MySQL function is called, preferably early in the <code>main()</code> function.
<code>mysql_library_end()</code>	Should be called before your program exits.
<code>mysql_thread_init()</code>	Should be called in each thread you create that accesses MySQL.
<code>mysql_thread_end()</code>	Should be called before calling <code>pthread_exit()</code>

Then you must link your code with `libmysqld.a` instead of `libmysqlclient.a`. To ensure binary compatibility between your application and the server library, be sure to compile your application against headers for the same series of MySQL that was used to compile the server library. For example, if `libmysqld` was compiled against MySQL 4.1 headers, do not compile your application against MySQL 5.1 headers, or vice versa.

The `mysql_library_xxx()` functions are also included in `libmysqlclient.a` to allow you to change between the embedded and the client/server version by just linking your application with the right library. See [Section 20.9.3.40](#), “`mysql_library_init()`”.

One difference between the embedded server and the standalone server is that for the embedded server, authentication for connections is disabled by default. To use authentication for the embedded server, specify the `-with-embedded-privilege-control` option when you invoke `configure` to configure your MySQL distribution.

## 20.9. MySQL C API

The C API code is distributed with MySQL. It is included in the `mysqlclient` library and allows C programs to access a database.

Many of the clients in the MySQL source distribution are written in C. If you are looking for examples that demonstrate how to use the C API, take a look at these clients. You can find these in the `client` directory in the MySQL source distribution.

Most of the other client APIs (all except Connector/J and Connector/NET) use the `mysqlclient` library to communicate with the MySQL server. This means that, for example, you can take advantage of many of the same environment variables that are used by other client programs, because they are referenced from the library. See [Chapter 4, MySQL Programs](#), for a list of these variables.

The client has a maximum communication buffer size. The size of the buffer that is allocated initially (16KB) is automatically increased up to the maximum size (the maximum is 16MB). Because buffer sizes are increased only as demand warrants, simply increasing the default maximum limit does not in itself cause more resources to be used. This size check is mostly a check for erroneous statements and communication packets.

The communication buffer must be large enough to contain a single SQL statement (for client-to-server traffic) and one row of returned data (for server-to-client traffic). Each thread's communication buffer is dynamically enlarged to handle any query or row up to the maximum limit. For example, if you have `BLOB` values that contain up to 16MB of data, you must have a communication buffer limit of at least 16MB (in both server and client). The client's default maximum is 16MB, but the default maximum in the server is 1MB. You can increase this by changing the value of the `max_allowed_packet` parameter when the server is started. See [Section 7.5.3](#), “Tuning Server Parameters”.

The MySQL server shrinks each communication buffer to `net_buffer_length` bytes after each query. For clients, the size of the buffer associated with a connection is not decreased until the connection is closed, at which time client memory is reclaimed.

For programming with threads, see [Section 20.9.17](#), “How to Make a Threaded Client”. For creating a standalone application which includes the “server” and “client” in the same program (and does not communicate with an external MySQL server), see [Section 20.8](#), “`libmysqld`, the Embedded MySQL Server Library”.

### MySQL Enterprise

MySQL Enterprise subscribers will find more information about using the C API in the Knowledge Base articles, [The C API](#). Access to the MySQL Knowledge Base collection of articles is one of the advantages of

subscribing to MySQL Enterprise. For more information, see <http://www.mysql.com/products/enterprise/advisors.html>.

## 20.9.1. C API Data Types

This section describes C API data types other than those used for prepared statements. For information about the latter, see [Section 20.9.5, “C API Prepared Statement Data types”](#).

- `MYSQL`

This structure represents a handle to one database connection. It is used for almost all MySQL functions. You should not try to make a copy of a `MYSQL` structure. There is no guarantee that such a copy will be usable.

- `MYSQL_RES`

This structure represents the result of a query that returns rows (`SELECT`, `SHOW`, `DESCRIBE`, `EXPLAIN`). The information returned from a query is called the *result set* in the remainder of this section.

- `MYSQL_ROW`

This is a type-safe representation of one row of data. It is currently implemented as an array of counted byte strings. (You cannot treat these as null-terminated strings if field values may contain binary data, because such values may contain null bytes internally.) Rows are obtained by calling `mysql_fetch_row()`.

- `MYSQL_FIELD`

This structure contains information about a field, such as the field's name, type, and size. Its members are described in more detail here. You may obtain the `MYSQL_FIELD` structures for each field by calling `mysql_fetch_field()` repeatedly. Field values are not part of this structure; they are contained in a `MYSQL_ROW` structure.

- `MYSQL_FIELD_OFFSET`

This is a type-safe representation of an offset into a MySQL field list. (Used by `mysql_field_seek()`.) Offsets are field numbers within a row, beginning at zero.

- `my_ulonglong`

The type used for the number of rows and for `mysql_affected_rows()`, `mysql_num_rows()`, and `mysql_insert_id()`. This type provides a range of 0 to 1.84e19.

On some systems, attempting to print a value of type `my_ulonglong` does not work. To print such a value, convert it to `unsigned long` and use a `%lu` print format. Example:

```
printf ("Number of rows: %lu\n",
        (unsigned long) mysql_num_rows(result));
```

- `my_bool`

A boolean type, for values that are true (nonzero) or false (zero).

The `MYSQL_FIELD` structure contains the members described in the following list:

- `char * name`

The name of the field, as a null-terminated string. If the field was given an alias with an `AS` clause, the value of `name` is the alias.

- `char * org_name`

The name of the field, as a null-terminated string. Aliases are ignored.

- `char * table`

The name of the table containing this field, if it isn't a calculated field. For calculated fields, the `table` value is an empty string. If the column is selected from a view, `table` names the view. If the table or view was given an alias with an `AS` clause, the value of `table` is the alias. For a `UNION`, the value is the empty string.

- `char * org_table`

The name of the table, as a null-terminated string. Aliases are ignored. If the column is selected from a view, `org_table` names the underlying table. For a `UNION`, the value is the empty string.

- `char * db`

The name of the database that the field comes from, as a null-terminated string. If the field is a calculated field, `db` is an empty string. For a `UNION`, the value is the empty string.

- `char * catalog`

The catalog name. This value is always `"def"`.

- `char * def`

The default value of this field, as a null-terminated string. This is set only if you use `mysql_list_fields()`.

- `unsigned long length`

The width of the field. This corresponds to the display length, in bytes.

- `unsigned long max_length`

The maximum width of the field for the result set (the length in bytes of the longest field value for the rows actually in the result set). If you use `mysql_store_result()` or `mysql_list_fields()`, this contains the maximum length for the field. If you use `mysql_use_result()`, the value of this variable is zero.

The value of `max_length` is the length of the string representation of the values in the result set. For example, if you retrieve a `FLOAT` column and the “widest” value is `-12.345`, `max_length` is 7 (the length of `'-12.345'`).

If you are using prepared statements, `max_length` is not set by default because for the binary protocol the lengths of the values depend on the types of the values in the result set. (See [Section 20.9.5, “C API Prepared Statement Data types”](#).) If you want the `max_length` values anyway, enable the `STMT_ATTR_UPDATE_MAX_LENGTH` option with `mysql_stmt_attr_set()` and the lengths will be set when you call `mysql_stmt_store_result()`. (See [Section 20.9.7.3, “mysql\\_stmt\\_attr\\_set\(\)”](#), and [Section 20.9.7.27, “mysql\\_stmt\\_store\\_result\(\)”](#).)

- `unsigned int name_length`

The length of `name`.

- `unsigned int org_name_length`

The length of `org_name`.

- `unsigned int table_length`

The length of `table`.

- `unsigned int org_table_length`

The length of `org_table`.

- `unsigned int db_length`

The length of `db`.

- `unsigned int catalog_length`

The length of `catalog`.

- `unsigned int def_length`

The length of `def`.

- `unsigned int flags`

Different bit-flags for the field. The `flags` value may have zero or more of the following bits set.

Flag Value	Flag Description
<code>NOT_NULL_FLAG</code>	Field can't be <code>NULL</code>
<code>PRI_KEY_FLAG</code>	Field is part of a primary key

<code>UNIQUE_KEY_FLAG</code>	Field is part of a unique key
<code>MULTIPLE_KEY_FLAG</code>	Field is part of a non-unique key
<code>UNSIGNED_FLAG</code>	Field has the <code>UNSIGNED</code> attribute
<code>ZEROFILL_FLAG</code>	Field has the <code>ZEROFILL</code> attribute
<code>BINARY_FLAG</code>	Field has the <code>BINARY</code> attribute
<code>AUTO_INCREMENT_FLAG</code>	Field has the <code>AUTO_INCREMENT</code> attribute
<code>ENUM_FLAG</code>	Field is an <code>ENUM</code> (deprecated)
<code>SET_FLAG</code>	Field is a <code>SET</code> (deprecated)
<code>BLOB_FLAG</code>	Field is a <code>BLOB</code> or <code>TEXT</code> (deprecated)
<code>TIMESTAMP_FLAG</code>	Field is a <code>TIMESTAMP</code> (deprecated)
<code>NUM_FLAG</code>	Field is numeric; see additional notes following table
<code>NO_DEFAULT_VALUE_FLAG</code>	Field has no default value; see additional notes following table

Use of the `BLOB_FLAG`, `ENUM_FLAG`, `SET_FLAG`, and `TIMESTAMP_FLAG` flags is deprecated because they indicate the type of a field rather than an attribute of its type. It is preferable to test `field->type` against `MYSQL_TYPE_BLOB`, `MYSQL_TYPE_ENUM`, `MYSQL_TYPE_SET`, or `MYSQL_TYPE_TIMESTAMP` instead.

`NUM_FLAG` indicates that a column is numeric. This includes columns with a type of `MYSQL_TYPE_DECIMAL`, `MYSQL_TYPE_TINY`, `MYSQL_TYPE_SHORT`, `MYSQL_TYPE_LONG`, `MYSQL_TYPE_FLOAT`, `MYSQL_TYPE_DOUBLE`, `MYSQL_TYPE_NULL`, `MYSQL_TYPE_TIMESTAMP`, `MYSQL_TYPE_LONGLONG`, `MYSQL_TYPE_INT24`, and `MYSQL_TYPE_YEAR`.

`NO_DEFAULT_VALUE_FLAG` indicates that a column has no `DEFAULT` clause in its definition. This does not apply to `NULL` columns (because such columns have a default of `NULL`), or to `AUTO_INCREMENT` columns (which have an implied default value). `NO_DEFAULT_VALUE_FLAG` was added in MySQL 5.0.2.

The following example illustrates a typical use of the `flags` value:

```
if (field->flags & NOT_NULL_FLAG)
    printf("Field can't be null\n");
```

You may use the following convenience macros to determine the boolean status of the `flags` value.

Flag Status	Description
<code>IS_NOT_NULL(flags)</code>	True if this field is defined as <code>NOT NULL</code>
<code>IS_PRI_KEY(flags)</code>	True if this field is a primary key
<code>IS_BLOB(flags)</code>	True if this field is a <code>BLOB</code> or <code>TEXT</code> (deprecated; test <code>field-&gt;type</code> instead)

- `unsigned int decimals`

The number of decimals for numeric fields.

- `unsigned int charsetnr`

An ID number that indicates the character set/collation pair for the field.

To distinguish between binary and nonbinary data for string data types, check whether the `charsetnr` value is 63. If so, the character set is `binary`, which indicates binary rather than nonbinary data. This enables you to distinguish `BINARY` from `CHAR`, `VARBINARY` from `VARCHAR`, and the `BLOB` types from the `TEXT` types.

`charsetnr` values are the same as those displayed in the `Id` column of the `SHOW COLLATION` statement or the `ID` column of the `INFORMATION_SCHEMA_COLLATIONS` table. You can use those information sources to see which character set and collation specific `charsetnr` values indicate:

```
mysql> SHOW COLLATION WHERE Id = 63;
+-----+-----+-----+-----+-----+-----+
| Collation | Charset | Id | Default | Compiled | Sortlen |
+-----+-----+-----+-----+-----+-----+
| binary   | binary  | 63 | Yes     | Yes      | 1       |
+-----+-----+-----+-----+-----+-----+

mysql> SELECT COLLATION_NAME, CHARACTER_SET_NAME
```

```
-> FROM INFORMATION_SCHEMA.COLLATIONS WHERE ID = 33;
```

COLLATION_NAME	CHARACTER_SET_NAME
utf8_general_ci	utf8

- `enum enum_field_types type`

The type of the field. The `type` value may be one of the `MYSQL_TYPE_` symbols shown in the following table.

Type Value	Type Description
<code>MYSQL_TYPE_TINY</code>	TINYINT field
<code>MYSQL_TYPE_SHORT</code>	SMALLINT field
<code>MYSQL_TYPE_LONG</code>	INTEGER field
<code>MYSQL_TYPE_INT24</code>	MEDIUMINT field
<code>MYSQL_TYPE_LONGLONG</code>	BIGINT field
<code>MYSQL_TYPE_DECIMAL</code>	DECIMAL or NUMERIC field
<code>MYSQL_TYPE_NEWDECIMAL</code>	Precision math DECIMAL or NUMERIC field (MySQL 5.0.3 and up)
<code>MYSQL_TYPE_FLOAT</code>	FLOAT field
<code>MYSQL_TYPE_DOUBLE</code>	DOUBLE or REAL field
<code>MYSQL_TYPE_BIT</code>	BIT field (MySQL 5.0.3 and up)
<code>MYSQL_TYPE_TIMESTAMP</code>	TIMESTAMP field
<code>MYSQL_TYPE_DATE</code>	DATE field
<code>MYSQL_TYPE_TIME</code>	TIME field
<code>MYSQL_TYPE_DATETIME</code>	DATETIME field
<code>MYSQL_TYPE_YEAR</code>	YEAR field
<code>MYSQL_TYPE_STRING</code>	CHAR or BINARY field
<code>MYSQL_TYPE_VAR_STRING</code>	VARCHAR or VARBINARY field
<code>MYSQL_TYPE_BLOB</code>	BLOB or TEXT field (use <code>max_length</code> to determine the maximum length)
<code>MYSQL_TYPE_SET</code>	SET field
<code>MYSQL_TYPE_ENUM</code>	ENUM field
<code>MYSQL_TYPE_GEOMETRY</code>	Spatial field
<code>MYSQL_TYPE_NULL</code>	NULL-type field

You can use the `IS_NUM()` macro to test whether a field has a numeric type. Pass the `type` value to `IS_NUM()` and it evaluates to TRUE if the field is numeric:

```
if (IS_NUM(field->type))
    printf("Field is numeric\n");
```

## 20.9.2. C API Function Overview

The functions available in the C API are summarized here and described in greater detail in a later section. See [Section 20.9.3, “C API Function Descriptions”](#).

Function	Description
<code>my_init()</code>	Initialize global variables, and thread handler in thread-safe programs
<code>mysql_affected_rows()</code>	Returns the number of rows changed/deleted/inserted by the last <code>UPDATE</code> , <code>DELETE</code> , or <code>INSERT</code> query
<code>mysql_autocommit()</code>	Toggles autocommit mode on/off
<code>mysql_change_user()</code>	Changes user and database on an open connection
<code>mysql_character_set_name()</code>	Return default character set name for current connection
<code>mysql_close()</code>	Closes a server connection
<code>mysql_commit()</code>	Commits the transaction

<code>mysql_connect()</code>	Connects to a MySQL server (this function is deprecated; use <code>mysql_real_connect()</code> instead)
<code>mysql_create_db()</code>	Creates a database (this function is deprecated; use the SQL statement <code>CREATE DATABASE</code> instead)
<code>mysql_data_seek()</code>	Seeks to an arbitrary row number in a query result set
<code>mysql_debug()</code>	Does a <code>DEBUG_PUSH</code> with the given string
<code>mysql_drop_db()</code>	Drops a database (this function is deprecated; use the SQL statement <code>DROP DATABASE</code> instead)
<code>mysql_dump_debug_info()</code>	Makes the server write debug information to the log
<code>mysql_eof()</code>	Determines whether the last row of a result set has been read (this function is deprecated; <code>mysql_errno()</code> or <code>mysql_error()</code> may be used instead)
<code>mysql_errno()</code>	Returns the error number for the most recently invoked MySQL function
<code>mysql_error()</code>	Returns the error message for the most recently invoked MySQL function
<code>mysql_escape_string()</code>	Escapes special characters in a string for use in an SQL statement
<code>mysql_fetch_field()</code>	Returns the type of the next table field
<code>mysql_fetch_field_direct()</code>	Returns the type of a table field, given a field number
<code>mysql_fetch_fields()</code>	Returns an array of all field structures
<code>mysql_fetch_lengths()</code>	Returns the lengths of all columns in the current row
<code>mysql_fetch_row()</code>	Fetches the next row from the result set
<code>mysql_field_count()</code>	Returns the number of result columns for the most recent statement
<code>mysql_field_seek()</code>	Puts the column cursor on a specified column
<code>mysql_field_tell()</code>	Returns the position of the field cursor used for the last <code>mysql_fetch_field()</code>
<code>mysql_free_result()</code>	Frees memory used by a result set
<code>mysql_get_character_set_info()</code>	Return information about default character set
<code>mysql_get_client_info()</code>	Returns client version information as a string
<code>mysql_get_client_version()</code>	Returns client version information as an integer
<code>mysql_get_host_info()</code>	Returns a string describing the connection
<code>mysql_get_proto_info()</code>	Returns the protocol version used by the connection
<code>mysql_get_server_info()</code>	Returns the server version number
<code>mysql_get_server_version()</code>	Returns version number of server as an integer
<code>mysql_get_ssl_cipher()</code>	Return current SSL cipher
<code>mysql_hex_string()</code>	Encode string in hexadecimal format
<code>mysql_info()</code>	Returns information about the most recently executed query
<code>mysql_init()</code>	Gets or initializes a <code>MYSQL</code> structure
<code>mysql_insert_id()</code>	Returns the ID generated for an <code>AUTO_INCREMENT</code> column by the previous query
<code>mysql_kill()</code>	Kills a given thread
<code>mysql_library_end()</code>	Finalize the MySQL C API library
<code>mysql_library_init()</code>	Initialize the MySQL C API library
<code>mysql_list_dbs()</code>	Returns database names matching a simple regular expression
<code>mysql_list_fields()</code>	Returns field names matching a simple regular expression
<code>mysql_list_processes()</code>	Returns a list of the current server threads
<code>mysql_list_tables()</code>	Returns table names matching a simple regular expression
<code>mysql_more_results()</code>	Checks whether any more results exist
<code>mysql_next_result()</code>	Returns/initiates the next result in multiple-statement executions
<code>mysql_num_fields()</code>	Returns the number of columns in a result set
<code>mysql_num_rows()</code>	Returns the number of rows in a result set
<code>mysql_options()</code>	Sets connect options for <code>mysql_real_connect()</code>
<code>mysql_ping()</code>	Checks whether the connection to the server is working, reconnecting as necessary
<code>mysql_query()</code>	Executes an SQL query specified as a null-terminated string

<code>mysql_real_connect()</code>	Connects to a MySQL server
<code>mysql_real_escape_string()</code>	Escapes special characters in a string for use in an SQL statement, taking into account the current character set of the connection
<code>mysql_real_query()</code>	Executes an SQL query specified as a counted string
<code>mysql_refresh()</code>	Flush or reset tables and caches
<code>mysql_reload()</code>	Tells the server to reload the grant tables
<code>mysql_rollback()</code>	Rolls back the transaction
<code>mysql_row_seek()</code>	Seeks to a row offset in a result set, using value returned from <code>mysql_row_tell()</code>
<code>mysql_row_tell()</code>	Returns the row cursor position
<code>mysql_select_db()</code>	Selects a database
<code>mysql_server_end()</code>	Finalize the MySQL C API library
<code>mysql_server_init()</code>	Initialize the MySQL C API library
<code>mysql_set_character_set()</code>	Set default character set for current connection
<code>mysql_set_local_infile_default()</code>	Set the <code>LOAD DATA LOCAL INFILE</code> handler callbacks to their default values
<code>mysql_set_local_infile_handler()</code>	Install application-specific <code>LOAD DATA LOCAL INFILE</code> handler callbacks
<code>mysql_set_server_option()</code>	Sets an option for the connection (like <code>multi-statements</code> )
<code>mysql_sqlstate()</code>	Returns the <code>SQLSTATE</code> error code for the last error
<code>mysql_shutdown()</code>	Shuts down the database server
<code>mysql_ssl_set()</code>	Prepare to establish SSL connection to server
<code>mysql_stat()</code>	Returns the server status as a string
<code>mysql_store_result()</code>	Retrieves a complete result set to the client
<code>mysql_thread_end()</code>	Finalize thread handler
<code>mysql_thread_id()</code>	Returns the current thread ID
<code>mysql_thread_init()</code>	Initialize thread handler
<code>mysql_thread_safe()</code>	Returns 1 if the clients are compiled as thread-safe
<code>mysql_use_result()</code>	Initiates a row-by-row result set retrieval
<code>mysql_warning_count()</code>	Returns the warning count for the previous SQL statement

Application programs should use this general outline for interacting with MySQL:

1. Initialize the MySQL library by calling `mysql_library_init()`. This function exists in both the `mysqlclient` C client library and the `mysqld` embedded server library, so it is used whether you build a regular client program by linking with the `-libmysqlclient` flag, or an embedded server application by linking with the `-libmysqld` flag.
2. Initialize a connection handler by calling `mysql_init()` and connect to the server by calling `mysql_real_connect()`.
3. Issue SQL statements and process their results. (The following discussion provides more information about how to do this.)
4. Close the connection to the MySQL server by calling `mysql_close()`.
5. End use of the MySQL library by calling `mysql_library_end()`.

The purpose of calling `mysql_library_init()` and `mysql_library_end()` is to provide proper initialization and finalization of the MySQL library. For applications that are linked with the client library, they provide improved memory management. If you don't call `mysql_library_end()`, a block of memory remains allocated. (This does not increase the amount of memory used by the application, but some memory leak detectors will complain about it.) For applications that are linked with the embedded server, these calls start and stop the server.

`mysql_library_init()` and `mysql_library_end()` are available as of MySQL 5.0.3. For older versions of MySQL, you can call `mysql_server_init()` and `mysql_server_end()` instead.

In a non-multi-threaded environment, the call to `mysql_library_init()` may be omitted, because `mysql_init()` will invoke it automatically as necessary. However, `mysql_library_init()` is not thread-safe in a multi-threaded environment, and thus neither is `mysql_init()`, which calls `mysql_library_init()`. You must either call `mysql_library_init()`

prior to spawning any threads, or else use a mutex to protect the call, whether you invoke `mysql_library_init()` or indirectly via `mysql_init()`. This should be done prior to any other client library call.

To connect to the server, call `mysql_init()` to initialize a connection handler, then call `mysql_real_connect()` with that handler (along with other information such as the host name, user name, and password). Upon connection, `mysql_real_connect()` sets the `reconnect` flag (part of the `MYSQL` structure) to a value of `1` in versions of the API older than 5.0.3, or `0` in newer versions. A value of `1` for this flag indicates that if a statement cannot be performed because of a lost connection, to try reconnecting to the server before giving up. As of MySQL 5.0.13, you can use the `MYSQL_OPT_RECONNECT` option to `mysql_options()` to control reconnection behavior. When you are done with the connection, call `mysql_close()` to terminate it.

While a connection is active, the client may send SQL statements to the server using `mysql_query()` or `mysql_real_query()`. The difference between the two is that `mysql_query()` expects the query to be specified as a null-terminated string whereas `mysql_real_query()` expects a counted string. If the string contains binary data (which may include null bytes), you must use `mysql_real_query()`.

For each non-`SELECT` query (for example, `INSERT`, `UPDATE`, `DELETE`), you can find out how many rows were changed (affected) by calling `mysql_affected_rows()`.

For `SELECT` queries, you retrieve the selected rows as a result set. (Note that some statements are `SELECT`-like in that they return rows. These include `SHOW`, `DESCRIBE`, and `EXPLAIN`. They should be treated the same way as `SELECT` statements.)

There are two ways for a client to process result sets. One way is to retrieve the entire result set all at once by calling `mysql_store_result()`. This function acquires from the server all the rows returned by the query and stores them in the client. The second way is for the client to initiate a row-by-row result set retrieval by calling `mysql_use_result()`. This function initializes the retrieval, but does not actually get any rows from the server.

In both cases, you access rows by calling `mysql_fetch_row()`. With `mysql_store_result()`, `mysql_fetch_row()` accesses rows that have previously been fetched from the server. With `mysql_use_result()`, `mysql_fetch_row()` actually retrieves the row from the server. Information about the size of the data in each row is available by calling `mysql_fetch_lengths()`.

After you are done with a result set, call `mysql_free_result()` to free the memory used for it.

The two retrieval mechanisms are complementary. Client programs should choose the approach that is most appropriate for their requirements. In practice, clients tend to use `mysql_store_result()` more commonly.

An advantage of `mysql_store_result()` is that because the rows have all been fetched to the client, you not only can access rows sequentially, you can move back and forth in the result set using `mysql_data_seek()` or `mysql_row_seek()` to change the current row position within the result set. You can also find out how many rows there are by calling `mysql_num_rows()`. On the other hand, the memory requirements for `mysql_store_result()` may be very high for large result sets and you are more likely to encounter out-of-memory conditions.

An advantage of `mysql_use_result()` is that the client requires less memory for the result set because it maintains only one row at a time (and because there is less allocation overhead, `mysql_use_result()` can be faster). Disadvantages are that you must process each row quickly to avoid tying up the server, you don't have random access to rows within the result set (you can only access rows sequentially), and you don't know how many rows are in the result set until you have retrieved them all. Furthermore, you **must** retrieve all the rows even if you determine in mid-retrieval that you've found the information you were looking for.

The API makes it possible for clients to respond appropriately to statements (retrieving rows only as necessary) without knowing whether the statement is a `SELECT`. You can do this by calling `mysql_store_result()` after each `mysql_query()` (or `mysql_real_query()`). If the result set call succeeds, the statement was a `SELECT` and you can read the rows. If the result set call fails, call `mysql_field_count()` to determine whether a result was actually to be expected. If `mysql_field_count()` returns zero, the statement returned no data (indicating that it was an `INSERT`, `UPDATE`, `DELETE`, and so forth), and was not expected to return rows. If `mysql_field_count()` is nonzero, the statement should have returned rows, but didn't. This indicates that the statement was a `SELECT` that failed. See the description for `mysql_field_count()` for an example of how this can be done.

Both `mysql_store_result()` and `mysql_use_result()` allow you to obtain information about the fields that make up the result set (the number of fields, their names and types, and so forth). You can access field information sequentially within the row by calling `mysql_fetch_field()` repeatedly, or by field number within the row by calling `mysql_fetch_field_direct()`. The current field cursor position may be changed by calling `mysql_field_seek()`. Setting the field cursor affects subsequent calls to `mysql_fetch_field()`. You can also get information for fields all at once by calling `mysql_fetch_fields()`.

For detecting and reporting errors, MySQL provides access to error information by means of the `mysql_errno()` and `mysql_error()` functions. These return the error code or error message for the most recently invoked function that can succeed or fail, allowing you to determine when an error occurred and what it was.

### 20.9.3. C API Function Descriptions

In the descriptions here, a parameter or return value of `NULL` means `NULL` in the sense of the C programming language, not a MySQL `NULL` value.

Functions that return a value generally return a pointer or an integer. Unless specified otherwise, functions returning a pointer return a non-`NULL` value to indicate success or a `NULL` value to indicate an error, and functions returning an integer return zero to indicate success or nonzero to indicate an error. Note that “nonzero” means just that. Unless the function description says otherwise, do not test against a value other than zero:

```
if (result)                /* correct */
    ... error ...

if (result < 0)            /* incorrect */
    ... error ...

if (result == -1)         /* incorrect */
    ... error ...
```

When a function returns an error, the **Errors** subsection of the function description lists the possible types of errors. You can find out which of these occurred by calling `mysql_errno()`. A string representation of the error may be obtained by calling `mysql_error()`.

#### MySQL Enterprise

MySQL Enterprise subscribers will find more information about the C API functions in the Knowledge Base articles, [The C API](#). Access to the MySQL Knowledge Base collection of articles is one of the advantages of subscribing to MySQL Enterprise. For more information, see <http://www.mysql.com/products/enterprise/advisors.html>.

### 20.9.3.1. `mysql_affected_rows()`

```
my_ulonglong mysql_affected_rows(MYSQL *mysql)
```

#### Description

After executing a statement with `mysql_query()` or `mysql_real_query()`, returns the number of rows changed (for `UPDATE`), deleted (for `DELETE`), or inserted (for `INSERT`). For `SELECT` statements, `mysql_affected_rows()` works like `mysql_num_rows()`.

#### Return Values

An integer greater than zero indicates the number of rows affected or retrieved. Zero indicates that no records were updated for an `UPDATE` statement, no rows matched the `WHERE` clause in the query or that no query has yet been executed. -1 indicates that the query returned an error or that, for a `SELECT` query, `mysql_affected_rows()` was called prior to calling `mysql_store_result()`. Because `mysql_affected_rows()` returns an unsigned value, you can check for -1 by comparing the return value to `(my_ulonglong)-1` (or to `(my_ulonglong)~0`, which is equivalent).

#### Errors

None.

#### Example

```
char *stmt = "UPDATE products SET cost=cost*1.25 WHERE group=10";
mysql_query(&mysql, stmt);
printf("%ld products updated",
       (long) mysql_affected_rows(&mysql));
```

For `UPDATE` statements, if you specify the `CLIENT_FOUND_ROWS` flag when connecting to `mysqld`, `mysql_affected_rows()` returns the number of rows matched by the `WHERE` clause. Otherwise, the default behavior is to return the number of rows actually changed.

Note that when you use a `REPLACE` command, `mysql_affected_rows()` returns 2 if the new row replaced an old row, because in this case, one row was inserted after the duplicate was deleted.

If you use `INSERT ... ON DUPLICATE KEY UPDATE` to insert a row, `mysql_affected_rows()` returns 1 if the row is inserted as a new row and 2 if an existing row is updated.

`mysql_affected_rows()` returns 0 following a `CALL` statement for a stored procedure that contains a statement that modifies rows because in this case `mysql_insert_id()` applies to `CALL` and not the statement within the procedure. Within the procedure, you can use `ROW_COUNT()` at the SQL level to obtain the `AUTO_INCREMENT` value.

### 20.9.3.2. `mysql_autocommit()`

```
my_bool mysql_autocommit(MYSQL *mysql, my_bool mode)
```

**Description**

Sets autocommit mode on if `mode` is 1, off if `mode` is 0.

**Return Values**

Zero if successful. Nonzero if an error occurred.

**Errors**

None.

### 20.9.3.3. `mysql_change_user()`

```
my_bool mysql_change_user(MYSQL *mysql, const char *user, const char *password, const char *db)
```

**Description**

Changes the user and causes the database specified by `db` to become the default (current) database on the connection specified by `mysql`. In subsequent queries, this database is the default for table references that do not include an explicit database specifier.

`mysql_change_user()` fails if the connected user cannot be authenticated or doesn't have permission to use the database. In this case, the user and database are not changed.

The `db` parameter may be set to `NULL` if you don't want to have a default database.

This command resets the state as if one had done a new connect. (See [Section 20.9.11, “Controlling Automatic Reconnection Behavior”](#).) It always performs a `ROLLBACK` of any active transactions, closes and drops all temporary tables, and unlocks all locked tables. Session system variables are reset to the values of the corresponding global system variables. Prepared statements are released and `HANDLER` variables are closed. Locks acquired with `GET_LOCK()` are released. These effects occur even if the user didn't change.

**Return Values**

Zero for success. Nonzero if an error occurred.

**Errors**

The same that you can get from `mysql_real_connect()`.

- `CR_COMMANDS_OUT_OF_SYNC`  
Commands were executed in an improper order.
- `CR_SERVER_GONE_ERROR`  
The MySQL server has gone away.
- `CR_SERVER_LOST`  
The connection to the server was lost during the query.
- `CR_UNKNOWN_ERROR`  
An unknown error occurred.
- `ER_UNKNOWN_COM_ERROR`  
The MySQL server doesn't implement this command (probably an old server).
- `ER_ACCESS_DENIED_ERROR`  
The user or password was wrong.
- `ER_BAD_DB_ERROR`  
The database didn't exist.

- [ER\\_DBACCESS\\_DENIED\\_ERROR](#)

The user did not have access rights to the database.

- [ER\\_WRONG\\_DB\\_NAME](#)

The database name was too long.

#### Example

```
if (mysql_change_user(&mysql, "user", "password", "new_database"))
{
    fprintf(stderr, "Failed to change user. Error: %s\n",
            mysql_error(&mysql));
}
```

### 20.9.3.4. [mysql\\_character\\_set\\_name\(\)](#)

```
const char *mysql_character_set_name(MYSQL *mysql)
```

#### Description

Returns the default character set name for the current connection.

#### Return Values

The default character set name

#### Errors

None.

### 20.9.3.5. [mysql\\_close\(\)](#)

```
void mysql_close(MYSQL *mysql)
```

#### Description

Closes a previously opened connection. [mysql\\_close\(\)](#) also deallocates the connection handle pointed to by [mysql](#) if the handle was allocated automatically by [mysql\\_init\(\)](#) or [mysql\\_connect\(\)](#).

#### Return Values

None.

#### Errors

None.

### 20.9.3.6. [mysql\\_commit\(\)](#)

```
my_bool mysql_commit(MYSQL *mysql)
```

#### Description

Commits the current transaction.

As of MySQL 5.0.3, the action of this function is subject to the value of the [completion\\_type](#) system variable. In particular, if the value of [completion\\_type](#) is 2, the server performs a release after terminating a transaction and closes the client connection. The client program should call [mysql\\_close\(\)](#) to close the connection from the client side.

#### Return Values

Zero if successful. Nonzero if an error occurred.

#### Errors

None.

### 20.9.3.7. [mysql\\_connect\(\)](#)

```
MYSQL *mysql_connect(MYSQL *mysql, const char *host, const char *user, const char *passwd)
```

**Description**

This function is deprecated. Use `mysql_real_connect()` instead.

`mysql_connect()` attempts to establish a connection to a MySQL database engine running on `host`. `mysql_connect()` must complete successfully before you can execute any of the other API functions, with the exception of `mysql_get_client_info()`.

The meanings of the parameters are the same as for the corresponding parameters for `mysql_real_connect()` with the difference that the connection parameter may be `NULL`. In this case, the C API allocates memory for the connection structure automatically and frees it when you call `mysql_close()`. The disadvantage of this approach is that you can't retrieve an error message if the connection fails. (To get error information from `mysql_errno()` or `mysql_error()`, you must provide a valid `MYSQL` pointer.)

**Return Values**

Same as for `mysql_real_connect()`.

**Errors**

Same as for `mysql_real_connect()`.

### 20.9.3.8. `mysql_create_db()`

```
int mysql_create_db(MYSQL *mysql, const char *db)
```

**Description**

Creates the database named by the `db` parameter.

This function is deprecated. It is preferable to use `mysql_query()` to issue an SQL `CREATE DATABASE` statement instead.

**Return Values**

Zero if the database was created successfully. Nonzero if an error occurred.

**Errors**

- `CR_COMMANDS_OUT_OF_SYNC`  
Commands were executed in an improper order.
- `CR_SERVER_GONE_ERROR`  
The MySQL server has gone away.
- `CR_SERVER_LOST`  
The connection to the server was lost during the query.
- `CR_UNKNOWN_ERROR`  
An unknown error occurred.

**Example**

```
if(mysql_create_db(&mysql, "my_database"))
{
    fprintf(stderr, "Failed to create new database. Error: %s\n",
            mysql_error(&mysql));
}
```

### 20.9.3.9. `mysql_data_seek()`

```
void mysql_data_seek(MYSQL_RES *result, my_ulonglong offset)
```

**Description**

---

Seeks to an arbitrary row in a query result set. The `offset` value is a row number and should be in the range from 0 to `mysql_num_rows(result)-1`.

This function requires that the result set structure contains the entire result of the query, so `mysql_data_seek()` may be used only in conjunction with `mysql_store_result()`, not with `mysql_use_result()`.

**Return Values**

None.

**Errors**

None.

### 20.9.3.10. `mysql_debug()`

```
void mysql_debug(const char *debug)
```

**Description**

Does a `DEBUG_PUSH` with the given string. `mysql_debug()` uses the Fred Fish debug library. To use this function, you must compile the client library to support debugging. See [MySQL Internals: Porting](#).

**Return Values**

None.

**Errors**

None.

**Example**

The call shown here causes the client library to generate a trace file in `/tmp/client.trace` on the client machine:

```
mysql_debug("d:t:0,/tmp/client.trace");
```

### 20.9.3.11. `mysql_drop_db()`

```
int mysql_drop_db(MYSQL *mysql, const char *db)
```

**Description**

Drops the database named by the `db` parameter.

This function is deprecated. It is preferable to use `mysql_query()` to issue an SQL `DROP DATABASE` statement instead.

**Return Values**

Zero if the database was dropped successfully. Nonzero if an error occurred.

**Errors**

- `CR_COMMANDS_OUT_OF_SYNC`  
Commands were executed in an improper order.
- `CR_SERVER_GONE_ERROR`  
The MySQL server has gone away.
- `CR_SERVER_LOST`  
The connection to the server was lost during the query.
- `CR_UNKNOWN_ERROR`  
An unknown error occurred.

**Example**

```
if(mysql_drop_db(&mysql, "my_database"))
    fprintf(stderr, "Failed to drop the database: Error: %s\n",
            mysql_error(&mysql));
```

**20.9.3.12. `mysql_dump_debug_info()`**

```
int mysql_dump_debug_info(MYSQL *mysql)
```

**Description**

Instructs the server to write some debug information to the log. For this to work, the connected user must have the `SUPER` privilege.

**Return Values**

Zero if the command was successful. Nonzero if an error occurred.

**Errors**

- `CR_COMMANDS_OUT_OF_SYNC`  
Commands were executed in an improper order.
- `CR_SERVER_GONE_ERROR`  
The MySQL server has gone away.
- `CR_SERVER_LOST`  
The connection to the server was lost during the query.
- `CR_UNKNOWN_ERROR`  
An unknown error occurred.

**20.9.3.13. `mysql_eof()`**

```
my_bool mysql_eof(MYSQL_RES *result)
```

**Description**

This function is deprecated. `mysql_errno()` or `mysql_error()` may be used instead.

`mysql_eof()` determines whether the last row of a result set has been read.

If you acquire a result set from a successful call to `mysql_store_result()`, the client receives the entire set in one operation. In this case, a `NULL` return from `mysql_fetch_row()` always means the end of the result set has been reached and it is unnecessary to call `mysql_eof()`. When used with `mysql_store_result()`, `mysql_eof()` always returns true.

On the other hand, if you use `mysql_use_result()` to initiate a result set retrieval, the rows of the set are obtained from the server one by one as you call `mysql_fetch_row()` repeatedly. Because an error may occur on the connection during this process, a `NULL` return value from `mysql_fetch_row()` does not necessarily mean the end of the result set was reached normally. In this case, you can use `mysql_eof()` to determine what happened. `mysql_eof()` returns a nonzero value if the end of the result set was reached and zero if an error occurred.

Historically, `mysql_eof()` predates the standard MySQL error functions `mysql_errno()` and `mysql_error()`. Because those error functions provide the same information, their use is preferred over `mysql_eof()`, which is deprecated. (In fact, they provide more information, because `mysql_eof()` returns only a boolean value whereas the error functions indicate a reason for the error when one occurs.)

**Return Values**

Zero if no error occurred. Nonzero if the end of the result set has been reached.

**Errors**

None.

## Example

The following example shows how you might use `mysql_eof()`:

```
mysql_query(&mysql,"SELECT * FROM some_table");
result = mysql_use_result(&mysql);
while((row = mysql_fetch_row(result)))
{
    // do something with data
}
if(!mysql_eof(result)) // mysql_fetch_row() failed due to an error
{
    fprintf(stderr, "Error: %s\n", mysql_error(&mysql));
}
```

However, you can achieve the same effect with the standard MySQL error functions:

```
mysql_query(&mysql,"SELECT * FROM some_table");
result = mysql_use_result(&mysql);
while((row = mysql_fetch_row(result)))
{
    // do something with data
}
if(mysql_errno(&mysql)) // mysql_fetch_row() failed due to an error
{
    fprintf(stderr, "Error: %s\n", mysql_error(&mysql));
}
```

### 20.9.3.14. `mysql_errno()`

```
unsigned int mysql_errno(MYSQL *mysql)
```

#### Description

For the connection specified by `mysql`, `mysql_errno()` returns the error code for the most recently invoked API function that can succeed or fail. A return value of zero means that no error occurred. Client error message numbers are listed in the MySQL `errmsg.h` header file. Server error message numbers are listed in `mysqld_error.h`. Errors also are listed at [Appendix B, Errors, Error Codes, and Common Problems](#).

Note that some functions like `mysql_fetch_row()` don't set `mysql_errno()` if they succeed.

A rule of thumb is that all functions that have to ask the server for information reset `mysql_errno()` if they succeed.

MySQL-specific error numbers returned by `mysql_errno()` differ from SQLSTATE values returned by `mysql_sqlstate()`. For example, the `mysql` client program displays errors using the following format, where `1146` is the `mysql_errno()` value and `'42S02'` is the corresponding `mysql_sqlstate()` value:

```
shell> SELECT * FROM no_such_table;
ERROR 1146 (42S02): Table 'test.no_such_table' doesn't exist
```

#### Return Values

An error code value for the last `mysql_xxx()` call, if it failed. zero means no error occurred.

#### Errors

None.

### 20.9.3.15. `mysql_error()`

```
const char *mysql_error(MYSQL *mysql)
```

#### Description

For the connection specified by `mysql`, `mysql_error()` returns a null-terminated string containing the error message for the most recently invoked API function that failed. If a function didn't fail, the return value of `mysql_error()` may be the previous error or an empty string to indicate no error.

A rule of thumb is that all functions that have to ask the server for information reset `mysql_error()` if they succeed.

For functions that reset `mysql_error()`, the following two tests are equivalent:

```
if(*mysql_error(&mysql))
{
    // an error occurred
}
```

```
if(mysql_error(&mysql)[0])
{
    // an error occurred
}
```

The language of the client error messages may be changed by recompiling the MySQL client library. Currently, you can choose error messages in several different languages. See [Section 9.3, “Setting the Error Message Language”](#).

#### Return Values

A null-terminated character string that describes the error. An empty string if no error occurred.

#### Errors

None.

### 20.9.3.16. `mysql_escape_string()`

You should use `mysql_real_escape_string()` instead!

This function is identical to `mysql_real_escape_string()` except that `mysql_real_escape_string()` takes a connection handler as its first argument and escapes the string according to the current character set. `mysql_escape_string()` does not take a connection argument and does not respect the current character set.

### 20.9.3.17. `mysql_fetch_field()`

```
MYSQL_FIELD *mysql_fetch_field(MYSQL_RES *result)
```

#### Description

Returns the definition of one column of a result set as a `MYSQL_FIELD` structure. Call this function repeatedly to retrieve information about all columns in the result set. `mysql_fetch_field()` returns `NULL` when no more fields are left.

`mysql_fetch_field()` is reset to return information about the first field each time you execute a new `SELECT` query. The field returned by `mysql_fetch_field()` is also affected by calls to `mysql_field_seek()`.

If you've called `mysql_query()` to perform a `SELECT` on a table but have not called `mysql_store_result()`, MySQL returns the default blob length (8KB) if you call `mysql_fetch_field()` to ask for the length of a `BLOB` field. (The 8KB size is chosen because MySQL doesn't know the maximum length for the `BLOB`. This should be made configurable sometime.) Once you've retrieved the result set, `field->max_length` contains the length of the largest value for this column in the specific query.

#### Return Values

The `MYSQL_FIELD` structure for the current column. `NULL` if no columns are left.

#### Errors

None.

#### Example

```
MYSQL_FIELD *field;
while((field = mysql_fetch_field(result)))
{
    printf("field name %s\n", field->name);
}
```

### 20.9.3.18. `mysql_fetch_field_direct()`

```
MYSQL_FIELD *mysql_fetch_field_direct(MYSQL_RES *result, unsigned int fieldnr)
```

#### Description

Given a field number `fieldnr` for a column within a result set, returns that column's field definition as a `MYSQL_FIELD` structure. You may use this function to retrieve the definition for an arbitrary column. The value of `fieldnr` should be in the range from 0 to `mysql_num_fields(result)-1`.

#### Return Values

The `MYSQL_FIELD` structure for the specified column.

#### Errors

None.

#### Example

```
unsigned int num_fields;
unsigned int i;
MYSQL_FIELD *field;

num_fields = mysql_num_fields(result);
for(i = 0; i < num_fields; i++)
{
    field = mysql_fetch_field_direct(result, i);
    printf("Field %u is %s\n", i, field->name);
}
```

### 20.9.3.19. `mysql_fetch_fields()`

```
MYSQL_FIELD *mysql_fetch_fields(MYSQL_RES *result)
```

#### Description

Returns an array of all `MYSQL_FIELD` structures for a result set. Each structure provides the field definition for one column of the result set.

#### Return Values

An array of `MYSQL_FIELD` structures for all columns of a result set.

#### Errors

None.

#### Example

```
unsigned int num_fields;
unsigned int i;
MYSQL_FIELD *fields;

num_fields = mysql_num_fields(result);
fields = mysql_fetch_fields(result);
for(i = 0; i < num_fields; i++)
{
    printf("Field %u is %s\n", i, fields[i].name);
}
```

### 20.9.3.20. `mysql_fetch_lengths()`

```
unsigned long *mysql_fetch_lengths(MYSQL_RES *result)
```

#### Description

Returns the lengths of the columns of the current row within a result set. If you plan to copy field values, this length information is also useful for optimization, because you can avoid calling `strlen()`. In addition, if the result set contains binary data, you **must** use this function to determine the size of the data, because `strlen()` returns incorrect results for any field containing null characters.

The length for empty columns and for columns containing `NULL` values is zero. To see how to distinguish these two cases, see the description for `mysql_fetch_row()`.

#### Return Values

An array of unsigned long integers representing the size of each column (not including any terminating null characters). `NULL` if an error occurred.

#### Errors

`mysql_fetch_lengths()` is valid only for the current row of the result set. It returns `NULL` if you call it before calling `mysql_fetch_row()` or after retrieving all rows in the result.

#### Example

```

MYSQL_ROW row;
unsigned long *lengths;
unsigned int num_fields;
unsigned int i;

row = mysql_fetch_row(result);
if (row)
{
    num_fields = mysql_num_fields(result);
    lengths = mysql_fetch_lengths(result);
    for(i = 0; i < num_fields; i++)
    {
        printf("Column %u is %lu bytes in length.\n",
            i, lengths[i]);
    }
}

```

### 20.9.3.21. `mysql_fetch_row()`

```
MYSQL_ROW mysql_fetch_row(MYSQL_RES *result)
```

#### Description

Retrieves the next row of a result set. When used after `mysql_store_result()`, `mysql_fetch_row()` returns `NULL` when there are no more rows to retrieve. When used after `mysql_use_result()`, `mysql_fetch_row()` returns `NULL` when there are no more rows to retrieve or if an error occurred.

The number of values in the row is given by `mysql_num_fields(result)`. If `row` holds the return value from a call to `mysql_fetch_row()`, pointers to the values are accessed as `row[0]` to `row[mysql_num_fields(result)-1]`. `NULL` values in the row are indicated by `NULL` pointers.

The lengths of the field values in the row may be obtained by calling `mysql_fetch_lengths()`. Empty fields and fields containing `NULL` both have length 0; you can distinguish these by checking the pointer for the field value. If the pointer is `NULL`, the field is `NULL`; otherwise, the field is empty.

#### Return Values

A `MYSQL_ROW` structure for the next row. `NULL` if there are no more rows to retrieve or if an error occurred.

#### Errors

Note that error is not reset between calls to `mysql_fetch_row()`

- `CR_SERVER_LOST`

The connection to the server was lost during the query.

- `CR_UNKNOWN_ERROR`

An unknown error occurred.

#### Example

```

MYSQL_ROW row;
unsigned int num_fields;
unsigned int i;

num_fields = mysql_num_fields(result);
while ((row = mysql_fetch_row(result)))
{
    unsigned long *lengths;
    lengths = mysql_fetch_lengths(result);
    for(i = 0; i < num_fields; i++)
    {
        printf("[%.*s] ", (int) lengths[i],
            row[i] ? row[i] : "NULL");
    }
    printf("\n");
}

```

### 20.9.3.22. `mysql_field_count()`

```
unsigned int mysql_field_count(MYSQL *mysql)
```

#### Description

Returns the number of columns for the most recent query on the connection.

The normal use of this function is when `mysql_store_result()` returned `NULL` (and thus you have no result set pointer). In this case, you can call `mysql_field_count()` to determine whether `mysql_store_result()` should have produced a non-empty result. This allows the client program to take proper action without knowing whether the query was a `SELECT` (or `SELECT`-like) statement. The example shown here illustrates how this may be done.

See [Section 20.9.10.1, “Why `mysql\_store\_result\(\)` Sometimes Returns `NULL` After `mysql\_query\(\)` Returns Success”](#).

### Return Values

An unsigned integer representing the number of columns in a result set.

### Errors

None.

### Example

```
MYSQL_RES *result;
unsigned int num_fields;
unsigned int num_rows;

if (mysql_query(&mysql, query_string))
{
    // error
}
else // query succeeded, process any data returned by it
{
    result = mysql_store_result(&mysql);
    if (result) // there are rows
    {
        num_fields = mysql_num_fields(result);
        // retrieve rows, then call mysql_free_result(result)
    }
    else // mysql_store_result() returned nothing; should it have?
    {
        if(mysql_field_count(&mysql) == 0)
        {
            // query does not return data
            // (it was not a SELECT)
            num_rows = mysql_affected_rows(&mysql);
        }
        else // mysql_store_result() should have returned data
        {
            fprintf(stderr, "Error: %s\n", mysql_error(&mysql));
        }
    }
}
```

An alternative is to replace the `mysql_field_count(&mysql)` call with `mysql_errno(&mysql)`. In this case, you are checking directly for an error from `mysql_store_result()` rather than inferring from the value of `mysql_field_count()` whether the statement was a `SELECT`.

### 20.9.3.23. `mysql_field_seek()`

```
MYSQL_FIELD_OFFSET mysql_field_seek(MYSQL_RES *result, MYSQL_FIELD_OFFSET offset)
```

#### Description

Sets the field cursor to the given offset. The next call to `mysql_fetch_field()` retrieves the field definition of the column associated with that offset.

To seek to the beginning of a row, pass an `offset` value of zero.

#### Return Values

The previous value of the field cursor.

#### Errors

None.

### 20.9.3.24. `mysql_field_tell()`

```
MYSQL_FIELD_OFFSET mysql_field_tell(MYSQL_RES *result)
```

#### Description

Returns the position of the field cursor used for the last `mysql_fetch_field()`. This value can be used as an argument to `mysql_field_seek()`.

**Return Values**

The current offset of the field cursor.

**Errors**

None.

### 20.9.3.25. `mysql_free_result()`

```
void mysql_free_result(MYSQL_RES *result)
```

**Description**

Frees the memory allocated for a result set by `mysql_store_result()`, `mysql_use_result()`, `mysql_list_dbs()`, and so forth. When you are done with a result set, you must free the memory it uses by calling `mysql_free_result()`.

Do not attempt to access a result set after freeing it.

**Return Values**

None.

**Errors**

None.

### 20.9.3.26. `mysql_get_character_set_info()`

```
void mysql_get_character_set_info(MYSQL *mysql, MY_CHARSET_INFO *cs)
```

**Description**

This function provides information about the default client character set. The default character set may be changed with the `mysql_set_character_set()` function.

This function was added in MySQL 5.0.10.

**Example**

This example shows the fields that are available in the `MY_CHARSET_INFO` structure:

```
if (!mysql_set_character_set(&mysql, "utf8"))
{
    MY_CHARSET_INFO cs;
    mysql_get_character_set_info(&mysql, &cs);
    printf("character set information:\n");
    printf("character set+collation number: %d\n", cs.number);
    printf("character set name: %s\n", cs.name);
    printf("collation name: %s\n", cs.csname);
    printf("comment: %s\n", cs.comment);
    printf("directory: %s\n", cs.dir);
    printf("multi byte character min. length: %d\n", cs.mbminlen);
    printf("multi byte character max. length: %d\n", cs.mbmaxlen);
}
```

### 20.9.3.27. `mysql_get_client_info()`

```
const char *mysql_get_client_info(void)
```

**Description**

Returns a string that represents the client library version.

**Return Values**

A character string that represents the MySQL client library version.

**Errors**

None.

### 20.9.3.28. `mysql_get_client_version()`

```
unsigned long mysql_get_client_version(void)
```

#### Description

Returns an integer that represents the client library version. The value has the format `XYZZ` where `X` is the major version, `YY` is the release level, and `ZZ` is the version number within the release level. For example, a value of `40102` represents a client library version of `4.1.2`.

#### Return Values

An integer that represents the MySQL client library version.

#### Errors

None.

### 20.9.3.29. `mysql_get_host_info()`

```
const char *mysql_get_host_info(MYSQL *mysql)
```

#### Description

Returns a string describing the type of connection in use, including the server host name.

#### Return Values

A character string representing the server host name and the connection type.

#### Errors

None.

### 20.9.3.30. `mysql_get_proto_info()`

```
unsigned int mysql_get_proto_info(MYSQL *mysql)
```

#### Description

Returns the protocol version used by current connection.

#### Return Values

An unsigned integer representing the protocol version used by the current connection.

#### Errors

None.

### 20.9.3.31. `mysql_get_server_info()`

```
const char *mysql_get_server_info(MYSQL *mysql)
```

#### Description

Returns a string that represents the server version number.

#### Return Values

A character string that represents the server version number.

#### Errors

None.

### 20.9.3.32. `mysql_get_server_version()`

```
unsigned long mysql_get_server_version(MYSQL *mysql)
```

**Description**

Returns the version number of the server as an integer.

**Return Values**

A number that represents the MySQL server version in this format:

```
major_version*10000 + minor_version *100 + sub_version
```

For example, 5.0.12 is returned as 50012.

This function is useful in client programs for quickly determining whether some version-specific server capability exists.

**Errors**

None.

**20.9.3.33. `mysql_get_ssl_cipher()`**

```
const char *mysql_get_ssl_cipher(MYSQL *mysql)
```

**Description**

`mysql_get_ssl_cipher()` returns the SSL cipher used for the given connection to the server. `mysql` is the connection handler returned from `mysql_init()`.

This function was added in MySQL 5.0.23.

**Return Values**

A string naming the SSL cipher used for the connection, or `NULL` if no cipher is being used.

**20.9.3.34. `mysql_hex_string()`**

```
unsigned long mysql_hex_string(char *to, const char *from, unsigned long length)
```

**Description**

This function is used to create a legal SQL string that you can use in an SQL statement. See [Section 8.1.1, “Strings”](#).

The string in `from` is encoded to hexadecimal format, with each character encoded as two hexadecimal digits. The result is placed in `to` and a terminating null byte is appended.

The string pointed to by `from` must be `length` bytes long. You must allocate the `to` buffer to be at least `length*2+1` bytes long. When `mysql_hex_string()` returns, the contents of `to` is a null-terminated string. The return value is the length of the encoded string, not including the terminating null character.

The return value can be placed into an SQL statement using either `0xvalue` or `X'value'` format. However, the return value does not include the `0x` or `X'...`. The caller must supply whichever of those is desired.

**Example**

```
char query[1000],*end;

end = strmov(query,"INSERT INTO test_table values(");
end = strmov(end,"0x");
end += mysql_hex_string(end,"What is this",12);
end = strmov(end,",0x");
end += mysql_hex_string(end,"binary data: \0\r\n",16);
*end++ = ')';

if (mysql_real_query(&mysql,query,(unsigned int) (end - query)))
{
    fprintf(stderr, "Failed to insert row, Error: %s\n",
            mysql_error(&mysql));
}
```

The `strmov()` function used in the example is included in the `mysqlclient` library and works like `strcpy()` but returns a pointer to the terminating null of the first parameter.

**Return Values**

The length of the value placed into `to`, not including the terminating null character.

**Errors**

None.

**20.9.3.35. `mysql_info()`**

```
const char *mysql_info(MYSQL *mysql)
```

**Description**

Retrieves a string providing information about the most recently executed statement, but only for the statements listed here. For other statements, `mysql_info()` returns `NULL`. The format of the string varies depending on the type of statement, as described here. The numbers are illustrative only; the string contains values appropriate for the statement.

- `INSERT INTO ... SELECT ...`  
String format: `Records: 100 Duplicates: 0 Warnings: 0`
- `INSERT INTO ... VALUES (...),(...),(...)...`  
String format: `Records: 3 Duplicates: 0 Warnings: 0`
- `LOAD DATA INFILE ...`  
String format: `Records: 1 Deleted: 0 Skipped: 0 Warnings: 0`
- `ALTER TABLE`  
String format: `Records: 3 Duplicates: 0 Warnings: 0`
- `UPDATE`  
String format: `Rows matched: 40 Changed: 40 Warnings: 0`

Note that `mysql_info()` returns a non-`NULL` value for `INSERT ... VALUES` only for the multiple-row form of the statement (that is, only if multiple value lists are specified).

**Return Values**

A character string representing additional information about the most recently executed statement. `NULL` if no information is available for the statement.

**Errors**

None.

**20.9.3.36. `mysql_init()`**

```
MYSQL *mysql_init(MYSQL *mysql)
```

**Description**

Allocates or initializes a `MYSQL` object suitable for `mysql_real_connect()`. If `mysql` is a `NULL` pointer, the function allocates, initializes, and returns a new object. Otherwise, the object is initialized and the address of the object is returned. If `mysql_init()` allocates a new object, it is freed when `mysql_close()` is called to close the connection.

**Return Values**

An initialized `MYSQL*` handle. `NULL` if there was insufficient memory to allocate a new object.

**Errors**

In case of insufficient memory, `NULL` is returned.

**20.9.3.37. `mysql_insert_id()`**

```
my_ulonglong mysql_insert_id(MYSQL *mysql)
```

### Description

Returns the value generated for an `AUTO_INCREMENT` column by the previous `INSERT` or `UPDATE` statement. Use this function after you have performed an `INSERT` statement into a table that contains an `AUTO_INCREMENT` field, or have used `INSERT` or `UPDATE` to set a column value with `LAST_INSERT_ID(expr)`.

More precisely, `mysql_insert_id()` is updated under these conditions:

- `INSERT` statements that store a value into an `AUTO_INCREMENT` column. This is true whether the value is automatically generated by storing the special values `NULL` or `0` into the column, or is an explicit non-special value.
- In the case of a multiple-row `INSERT` statement, `mysql_insert_id()` returns the *first* automatically generated `AUTO_INCREMENT` value; if no such value is generated, it returns the *last* explicit value inserted into the `AUTO_INCREMENT` column.  
  
If no rows are successfully inserted, `mysql_insert_id()` returns 0.
- Starting in MySQL 5.0.54, if an `INSERT ... SELECT` statement is executed, and no automatically generated value is successfully inserted, `mysql_insert_id()` returns the ID of the last inserted row.
- `INSERT` statements that generate an `AUTO_INCREMENT` value by inserting `LAST_INSERT_ID(expr)` into any column or by updating any column to `LAST_INSERT_ID(expr)`.
- If the previous statement returned an error, the value of `mysql_insert_id()` is undefined.

`mysql_insert_id()` returns 0 if the previous statement does not use an `AUTO_INCREMENT` value. If you need to save the value for later, be sure to call `mysql_insert_id()` immediately after the statement that generates the value.

The value of `mysql_insert_id()` is not affected by statements such as `SELECT` that return a result set.

The value of `mysql_insert_id()` is affected only by statements issued within the current client connection. It is not affected by statements issued by other clients.

The `LAST_INSERT_ID()` SQL function returns the most recently generated `AUTO_INCREMENT` value, and is not reset between statements because the value of that function is maintained in the server. Another difference from `mysql_insert_id()` is that `LAST_INSERT_ID()` is not updated if you set an `AUTO_INCREMENT` column to a specific non-special value. See [Section 11.10.3, “Information Functions”](#).

`mysql_insert_id()` returns 0 following a `CALL` statement for a stored procedure that generates an `AUTO_INCREMENT` value because in this case `mysql_insert_id()` applies to `CALL` and not the statement within the procedure. Within the procedure, you can use `LAST_INSERT_ID()` at the SQL level to obtain the `AUTO_INCREMENT` value.

The reason for the differences between `LAST_INSERT_ID()` and `mysql_insert_id()` is that `LAST_INSERT_ID()` is made easy to use in scripts while `mysql_insert_id()` tries to provide more exact information about what happens to the `AUTO_INCREMENT` column.

### Return Values

Described in the preceding discussion.

### Errors

None.

## 20.9.3.38. `mysql_kill()`

```
int mysql_kill(MYSQL *mysql, unsigned long pid)
```

### Description

Asks the server to kill the thread specified by `pid`.

This function is deprecated. It is preferable to use `mysql_query()` to issue an SQL `KILL` statement instead.

### Return Values

Zero for success. Nonzero if an error occurred.

**Errors**

- `CR_COMMANDS_OUT_OF_SYNC`  
Commands were executed in an improper order.
- `CR_SERVER_GONE_ERROR`  
The MySQL server has gone away.
- `CR_SERVER_LOST`  
The connection to the server was lost during the query.
- `CR_UNKNOWN_ERROR`  
An unknown error occurred.

**20.9.3.39. `mysql_library_end()`**

```
void mysql_library_end(void)
```

**Description**

This function finalizes the MySQL library. You should call it when you are done using the library (for example, after disconnecting from the server). The action taken by the call depends on whether your application is linked to the MySQL client library or the MySQL embedded server library. For a client program linked against the `libmysqlclient` library by using the `-lmysqlclient` flag, `mysql_library_end()` performs some memory management to clean up. For an embedded server application linked against the `libmysqld` library by using the `-lmysqld` flag, `mysql_library_end()` shuts down the embedded server and then cleans up.

For usage information, see [Section 20.9.2, “C API Function Overview”](#), and [Section 20.9.3.40, “mysql\\_library\\_init\(\)”](#).

`mysql_library_end()` was added in MySQL 5.0.3. For older versions of MySQL, call `mysql_server_end()` instead.

**20.9.3.40. `mysql_library_init()`**

```
int mysql_library_init(int argc, char **argv, char **groups)
```

**Description**

This function should be called to initialize the MySQL library before you call any other MySQL function, whether your application is a regular client program or uses the embedded server. If the application uses the embedded server, this call starts the server and initializes any subsystems (`mysys`, `InnoDB`, and so forth) that the server uses.

After your application is done using the MySQL library, call `mysql_library_end()` to clean up. See [Section 20.9.3.39, “mysql\\_library\\_end\(\)”](#).

The choice of whether the application operates as a regular client or uses the embedded server depends on whether you use the `libmysqlclient` or `libmysqld` library at link time to produce the final executable. For additional information, see [Section 20.9.2, “C API Function Overview”](#).

In a non-multi-threaded environment, the call to `mysql_library_init()` may be omitted, because `mysql_init()` will invoke it automatically as necessary. However, `mysql_library_init()` is not thread-safe in a multi-threaded environment, and thus neither is `mysql_init()`, which calls `mysql_library_init()`. You must either call `mysql_library_init()` prior to spawning any threads, or else use a mutex to protect the call, whether you invoke `mysql_library_init()` or indirectly via `mysql_init()`. This should be done prior to any other client library call.

The `argc` and `argv` arguments are analogous to the arguments to `main()`, and enable passing of options to the embedded server. For convenience, `argc` may be 0 (zero) if there are no command-line arguments for the server. This is the usual case for applications intended for use only as regular (non-embedded) clients, and the call typically is written as `mysql_library_init(0, NULL, NULL)`.

```
#include <mysql.h>
#include <stdlib.h>

int main(void) {
    if (mysql_library_init(0, NULL, NULL)) {
        fprintf(stderr, "could not initialize MySQL library\n");
        exit(1);
    }
}
```

```

/* Use any MySQL API functions here */
mysql_library_end();
return EXIT_SUCCESS;
}

```

When arguments are to be passed (*argc* is greater than 0), the first element of *argv* is ignored (it typically contains the program name). `mysql_library_init()` makes a copy of the arguments so it is safe to destroy *argv* or *groups* after the call.

For embedded applications, if you want to connect to an external server without starting the embedded server, you have to specify a negative value for *argc*.

The *groups* argument should be an array of strings that indicate the groups in option files from which options should be read. See [Section 4.2.3.2, “Using Option Files”](#). The final entry in the array should be `NULL`. For convenience, if the *groups* argument itself is `NULL`, the `[server]` and `[embedded]` groups are used by default.

```

#include <mysql.h>
#include <stdlib.h>

static char *server_args[] = {
    "this_program", /* this string is not used */
    "--datadir=",
    "--key_buffer_size=32M"
};
static char *server_groups[] = {
    "embedded",
    "server",
    "this_program_SERVER",
    (char *)NULL
};

int main(void) {
    if (mysql_library_init(sizeof(server_args) / sizeof(char *),
                          server_args, server_groups)) {
        fprintf(stderr, "could not initialize MySQL library\n");
        exit(1);
    }

    /* Use any MySQL API functions here */

    mysql_library_end();

    return EXIT_SUCCESS;
}

```

`mysql_library_init()` was added in MySQL 5.0.3. For older versions of MySQL, call `mysql_server_init()` instead.

### Return Values

Zero if successful. Nonzero if an error occurred.

## 20.9.3.41. `mysql_list_dbs()`

```
MYSQL_RES *mysql_list_dbs(MYSQL *mysql, const char *wild)
```

### Description

Returns a result set consisting of database names on the server that match the simple regular expression specified by the *wild* parameter. *wild* may contain the wildcard characters “%” or “\_”, or may be a `NULL` pointer to match all databases. Calling `mysql_list_dbs()` is similar to executing the query `SHOW DATABASES [LIKE wild]`.

You must free the result set with `mysql_free_result()`.

### Return Values

A `MYSQL_RES` result set for success. `NULL` if an error occurred.

### Errors

- `CR_COMMANDS_OUT_OF_SYNC`  
Commands were executed in an improper order.
- `CR_OUT_OF_MEMORY`  
Out of memory.

- `CR_SERVER_GONE_ERROR`

The MySQL server has gone away.

- `CR_SERVER_LOST`

The connection to the server was lost during the query.

- `CR_UNKNOWN_ERROR`

An unknown error occurred.

### 20.9.3.42. `mysql_list_fields()`

```
MYSQL_RES *mysql_list_fields(MYSQL *mysql, const char *table, const char *wild)
```

#### Description

Returns a result set consisting of field names in the given table that match the simple regular expression specified by the `wild` parameter. `wild` may contain the wildcard characters “%” or “\_”, or may be a `NULL` pointer to match all fields. Calling `mysql_list_fields()` is similar to executing the query `SHOW COLUMNS FROM tbl_name [LIKE wild]`.

It is recommended that you use `SHOW COLUMNS FROM tbl_name` instead of `mysql_list_fields()`.

You must free the result set with `mysql_free_result()`.

#### Return Values

A `MYSQL_RES` result set for success. `NULL` if an error occurred.

#### Errors

- `CR_COMMANDS_OUT_OF_SYNC`

Commands were executed in an improper order.

- `CR_SERVER_GONE_ERROR`

The MySQL server has gone away.

- `CR_SERVER_LOST`

The connection to the server was lost during the query.

- `CR_UNKNOWN_ERROR`

An unknown error occurred.

### 20.9.3.43. `mysql_list_processes()`

```
MYSQL_RES *mysql_list_processes(MYSQL *mysql)
```

#### Description

Returns a result set describing the current server threads. This is the same kind of information as that reported by `mysqladmin processlist` or a `SHOW PROCESSLIST` query.

You must free the result set with `mysql_free_result()`.

#### Return Values

A `MYSQL_RES` result set for success. `NULL` if an error occurred.

#### Errors

- `CR_COMMANDS_OUT_OF_SYNC`

Commands were executed in an improper order.

- [CR\\_SERVER\\_GONE\\_ERROR](#)

The MySQL server has gone away.

- [CR\\_SERVER\\_LOST](#)

The connection to the server was lost during the query.

- [CR\\_UNKNOWN\\_ERROR](#)

An unknown error occurred.

### 20.9.3.44. `mysql_list_tables()`

```
MYSQL_RES *mysql_list_tables(MYSQL *mysql, const char *wild)
```

#### Description

Returns a result set consisting of table names in the current database that match the simple regular expression specified by the `wild` parameter. `wild` may contain the wildcard characters “%” or “\_”, or may be a `NULL` pointer to match all tables. Calling `mysql_list_tables()` is similar to executing the query `SHOW TABLES [LIKE wild]`.

You must free the result set with `mysql_free_result()`.

#### Return Values

A `MYSQL_RES` result set for success. `NULL` if an error occurred.

#### Errors

- [CR\\_COMMANDS\\_OUT\\_OF\\_SYNC](#)

Commands were executed in an improper order.

- [CR\\_SERVER\\_GONE\\_ERROR](#)

The MySQL server has gone away.

- [CR\\_SERVER\\_LOST](#)

The connection to the server was lost during the query.

- [CR\\_UNKNOWN\\_ERROR](#)

An unknown error occurred.

### 20.9.3.45. `mysql_more_results()`

```
my_bool mysql_more_results(MYSQL *mysql)
```

#### Description

This function is used when you execute multiple statements specified as a single statement string, or when you execute `CALL` statements, which can return multiple result sets.

`mysql_more_results()` true if more results exist from the currently executed statement, in which case the application must call `mysql_next_result()` to fetch the results.

#### Return Values

`TRUE` (1) if more results exist. `FALSE` (0) if no more results exist.

In most cases, you can call `mysql_next_result()` instead to test whether more results exist and initiate retrieval if so.

See [Section 20.9.12, “C API Support for Multiple Statement Execution”](#), and [Section 20.9.3.46, “mysql\\_next\\_result\(\)”](#).

#### Errors

None.

### 20.9.3.46. `mysql_next_result()`

```
int mysql_next_result(MYSQL *mysql)
```

#### Description

This function is used when you execute multiple statements specified as a single statement string, or when you use `CALL` statements to execute stored procedures, which can return multiple result sets.

`mysql_next_result()` reads the next statement result and returns a status to indicate whether more results exist. If `mysql_next_result()` returns an error, there are no more results.

Before each call to `mysql_next_result()`, you must call `mysql_free_result()` for the current statement if it is a statement that returned a result set (rather than just a result status).

After calling `mysql_next_result()` the state of the connection is as if you had called `mysql_real_query()` or `mysql_query()` for the next statement. This means that you can call `mysql_store_result()`, `mysql_warning_count()`, `mysql_affected_rows()`, and so forth.

If your program uses `CALL` statements to execute stored procedures, the `CLIENT_MULTI_RESULTS` flag must be enabled. This is because each `CALL` returns a result to indicate the call status, in addition to any result sets that might be returned by statements executed within the procedure. Because `CALL` can return multiple results, you should process them using a loop that calls `mysql_next_result()` to determine whether there are more results.

`CLIENT_MULTI_RESULTS` can be enabled when you call `mysql_real_connect()`, either explicitly by passing the `CLIENT_MULTI_RESULTS` flag itself, or implicitly by passing `CLIENT_MULTI_STATEMENTS` (which also enables `CLIENT_MULTI_RESULTS`).

It is also possible to test whether there are more results by calling `mysql_more_results()`. However, this function does not change the connection state, so if it returns true, you must still call `mysql_next_result()` to advance to the next result.

For an example that shows how to use `mysql_next_result()`, see [Section 20.9.12, “C API Support for Multiple Statement Execution”](#).

#### Return Values

Return Value	Description
0	Successful and there are more results
-1	Successful and there are no more results
>0	An error occurred

#### Errors

- `CR_COMMANDS_OUT_OF_SYNC`**  
 Commands were executed in an improper order. For example if you didn't call `mysql_use_result()` for a previous result set.
- `CR_SERVER_GONE_ERROR`**  
 The MySQL server has gone away.
- `CR_SERVER_LOST`**  
 The connection to the server was lost during the query.
- `CR_UNKNOWN_ERROR`**  
 An unknown error occurred.

### 20.9.3.47. `mysql_num_fields()`

```
unsigned int mysql_num_fields(MYSQL_RES *result)
```

To pass a `MYSQL*` argument instead, use `unsigned int mysql_field_count(MYSQL *mysql)`.

### Description

Returns the number of columns in a result set.

Note that you can get the number of columns either from a pointer to a result set or to a connection handle. You would use the connection handle if `mysql_store_result()` or `mysql_use_result()` returned `NULL` (and thus you have no result set pointer). In this case, you can call `mysql_field_count()` to determine whether `mysql_store_result()` should have produced a non-empty result. This allows the client program to take proper action without knowing whether the query was a `SELECT` (or `SELECT`-like) statement. The example shown here illustrates how this may be done.

See [Section 20.9.10.1, “Why `mysql\_store\_result\(\)` Sometimes Returns `NULL` After `mysql\_query\(\)` Returns Success”](#).

### Return Values

An unsigned integer representing the number of columns in a result set.

### Errors

None.

### Example

```
MYSQL_RES *result;
unsigned int num_fields;
unsigned int num_rows;

if (mysql_query(&mysql, query_string))
{
    // error
}
else // query succeeded, process any data returned by it
{
    result = mysql_store_result(&mysql);
    if (result) // there are rows
    {
        num_fields = mysql_num_fields(result);
        // retrieve rows, then call mysql_free_result(result)
    }
    else // mysql_store_result() returned nothing; should it have?
    {
        if (mysql_errno(&mysql))
        {
            fprintf(stderr, "Error: %s\n", mysql_error(&mysql));
        }
        else if (mysql_field_count(&mysql) == 0)
        {
            // query does not return data
            // (it was not a SELECT)
            num_rows = mysql_affected_rows(&mysql);
        }
    }
}
```

An alternative (if you know that your query should have returned a result set) is to replace the `mysql_errno(&mysql)` call with a check whether `mysql_field_count(&mysql)` returns 0. This happens only if something went wrong.

## 20.9.3.48. `mysql_num_rows()`

```
my_ulonglong mysql_num_rows(MYSQL_RES *result)
```

### Description

Returns the number of rows in the result set.

The use of `mysql_num_rows()` depends on whether you use `mysql_store_result()` or `mysql_use_result()` to return the result set. If you use `mysql_store_result()`, `mysql_num_rows()` may be called immediately. If you use `mysql_use_result()`, `mysql_num_rows()` does not return the correct value until all the rows in the result set have been retrieved.

`mysql_num_rows()` is intended for use with statements that return a result set, such as `SELECT`. For statements such as `INSERT`, `UPDATE`, or `DELETE`, the number of affected rows can be obtained with `mysql_affected_rows()`.

### Return Values

The number of rows in the result set.

**Errors**

None.

**20.9.3.49. `mysql_options()`**

```
int mysql_options(MYSQL *mysql, enum mysql_option option, const char *arg)
```

**Description**

Can be used to set extra connect options and affect behavior for a connection. This function may be called multiple times to set several options.

`mysql_options()` should be called after `mysql_init()` and before `mysql_connect()` or `mysql_real_connect()`.

The `option` argument is the option that you want to set; the `arg` argument is the value for the option. If the option is an integer, `arg` should point to the value of the integer.

The following list describes the possible options, their effect, and how `arg` is used for each option. Several of the options apply only when the application is linked against the `libmysqld` embedded server library and are unused for applications linked against the `libmysql` client library. For option descriptions that indicate `arg` is unused, its value is irrelevant; it is conventional to pass 0.

- `MYSQL_INIT_COMMAND` (argument type: `char *`)  
SQL statement to execute when connecting to the MySQL server. Automatically re-executed if reconnection occurs.
- `MYSQL_OPT_COMPRESS` (argument: not used)  
Use the compressed client/server protocol.
- `MYSQL_OPT_CONNECT_TIMEOUT` (argument type: `unsigned int *`)  
Connect timeout in seconds.
- `MYSQL_OPT_GUESS_CONNECTION` (argument: not used)  
For an application linked against the `libmysqld` embedded server library, this allows the library to guess whether to use the embedded server or a remote server. “Guess” means that if the host name is set and is not `localhost`, it uses a remote server. This behavior is the default. `MYSQL_OPT_USE_EMBEDDED_CONNECTION` and `MYSQL_OPT_USE_REMOTE_CONNECTION` can be used to override it. This option is ignored for applications linked against the `libmysqlclient` client library.
- `MYSQL_OPT_LOCAL_INFILE` (argument type: optional pointer to `unsigned int`)  
If no pointer is given or if pointer points to an `unsigned int` that has a nonzero value, the `LOAD LOCAL INFILE` statement is enabled.
- `MYSQL_OPT_NAMED_PIPE` (argument: not used)  
Use named pipes to connect to a MySQL server on Windows, if the server allows named-pipe connections.
- `MYSQL_OPT_PROTOCOL` (argument type: `unsigned int *`)  
Type of protocol to use. Should be one of the enum values of `mysql_protocol_type` defined in `mysql.h`.
- `MYSQL_OPT_READ_TIMEOUT` (argument type: `unsigned int *`)  
The timeout in seconds for attempts to read from the server. Each attempt uses this timeout value and there are retries if necessary, so the total effective timeout value is three times the option value. You can set the value so that a lost connection can be detected earlier than the TCP/IP `Close_Wait_Timeout` value of 10 minutes. This option works only for TCP/IP connections and, prior to MySQL 5.0.25, only for Windows.
- `MYSQL_OPT_RECONNECT` (argument type: `my_bool *`)  
Enable or disable automatic reconnection to the server if the connection is found to have been lost. Reconnect has been off by default since MySQL 5.0.3; this option is new in 5.0.13 and provides a way to set reconnection behavior explicitly.

Note: `mysql_real_connect()` incorrectly reset the `MYSQL_OPT_RECONNECT` option to its default value before MySQL 5.0.19. Therefore, prior to that version, if you want reconnect to be enabled for each connection, you must call

`mysql_options()` with the `MYSQL_OPT_RECONNECT` option after each call to `mysql_real_connect()`. This is not necessary as of 5.0.19: Call `mysql_options()` only before `mysql_real_connect()` as usual.

- `MYSQL_SET_CLIENT_IP` (argument type: `char *`)

For an application linked against the `libmysqld` embedded server library (when `libmysqld` is compiled with authentication support), this means that the user is considered to have connected from the specified IP address (specified as a string) for authentication purposes. This option is ignored for applications linked against the `libmysqlclient` client library.

- `MYSQL_OPT_SSL_VERIFY_SERVER_CERT` (argument type: `my_bool *`)

Enable or disable verification of the server's Common Name value in its certificate against the host name used when connecting to the server. The connection is rejected if there is a mismatch. This feature can be used to prevent man-in-the-middle attacks. Verification is disabled by default. Added in MySQL 5.0.23.

- `MYSQL_OPT_USE_EMBEDDED_CONNECTION` (argument: not used)

For an application linked against the `libmysqld` embedded server library, this forces the use of the embedded server for the connection. This option is ignored for applications linked against the `libmysqlclient` client library.

- `MYSQL_OPT_USE_REMOTE_CONNECTION` (argument: not used)

For an application linked against the `libmysqld` embedded server library, this forces the use of a remote server for the connection. This option is ignored for applications linked against the `libmysqlclient` client library.

- `MYSQL_OPT_USE_RESULT` (argument: not used)

This option is unused.

- `MYSQL_OPT_WRITE_TIMEOUT` (argument type: `unsigned int *`)

The timeout in seconds for attempts to write to the server. Each attempt uses this timeout value and there are `net_retry_count` retries if necessary, so the total effective timeout value is `net_retry_count` times the option value. This option works only for TCP/IP connections and, prior to MySQL 5.0.25, only for Windows.

- `MYSQL_READ_DEFAULT_FILE` (argument type: `char *`)

Read options from the named option file instead of from `my.cnf`.

- `MYSQL_READ_DEFAULT_GROUP` (argument type: `char *`)

Read options from the named group from `my.cnf` or the file specified with `MYSQL_READ_DEFAULT_FILE`.

- `MYSQL_REPORT_DATA_TRUNCATION` (argument type: `my_bool *`)

Enable or disable reporting of data truncation errors for prepared statements via the `error` member of `MYSQL_BIND` structures. (Default: enabled) Added in 5.0.3.

- `MYSQL_SECURE_AUTH` (argument type: `my_bool *`)

Whether to connect to a server that does not support the password hashing used in MySQL 4.1.1 and later.

- `MYSQL_SET_CHARSET_DIR` (argument type: `char *`)

The path name to the directory that contains character set definition files.

- `MYSQL_SET_CHARSET_NAME` (argument type: `char *`)

The name of the character set to use as the default character set.

- `MYSQL_SHARED_MEMORY_BASE_NAME` (argument type: `char *`)

The name of the shared-memory object for communication to the server on Windows, if the server supports shared-memory connections. Should have the same value as the `--shared-memory-base-name` option used for the `mysqld` server you want to connect to.

The `client` group is always read if you use `MYSQL_READ_DEFAULT_FILE` or `MYSQL_READ_DEFAULT_GROUP`.

The specified group in the option file may contain the following options.

Option	Description
--------	-------------

<code>character-sets-dir=path</code>	The directory where character sets are installed.
<code>compress</code>	Use the compressed client/server protocol.
<code>connect-timeout=seconds</code>	Connect timeout in seconds. On Linux this timeout is also used for waiting for the first answer from the server.
<code>database=db_name</code>	Connect to this database if no database was specified in the connect command.
<code>debug</code>	Debug options.
<code>default-character-set=char-set_name</code>	The default character set to use.
<code>disable-local-infile</code>	Disable use of <code>LOAD DATA LOCAL</code> .
<code>host=host_name</code>	Default host name.
<code>init-command=stmt</code>	Statement to execute when connecting to MySQL server. Automatically re-executed if reconnection occurs.
<code>interactive-timeout=seconds</code>	Same as specifying <code>CLIENT_INTERACTIVE</code> to <code>mysql_real_connect()</code> . See <a href="#">Section 20.9.3.52</a> , “ <code>mysql_real_connect()</code> ”.
<code>local-infile[={0 1}]</code>	If no argument or nonzero argument, enable use of <code>LOAD DATA LOCAL</code> ; otherwise disable.
<code>max_allowed_packet=bytes</code>	Maximum size of packet that client can read from server.
<code>multi-queries, multi-results</code>	Allow multiple result sets from multiple-statement executions or stored procedures.
<code>multi-statements</code>	Allow the client to send multiple statements in a single string (separated by “;”).
<code>password=password</code>	Default password.
<code>pipe</code>	Use named pipes to connect to a MySQL server on Windows.
<code>port=port_num</code>	Default port number.
<code>protocol={TCP SOCKET PIPE MEMORY}</code>	The protocol to use when connecting to the server.
<code>return-found-rows</code>	Tell <code>mysql_info()</code> to return found rows instead of updated rows when using <code>UPDATE</code> .
<code>shared-memory-base-name=name</code>	Shared-memory name to use to connect to server.
<code>socket=path</code>	Default socket file.
<code>ssl-ca=file_name</code>	Certificate Authority file.
<code>ssl-capath=path</code>	Certificate Authority directory.
<code>ssl-cert=file_name</code>	Certificate file.
<code>ssl-cipher=cipher_list</code>	Allowable SSL ciphers.
<code>ssl-key=file_name</code>	Key file.
<code>timeout=seconds</code>	Like <code>connect-timeout</code> .
<code>user</code>	Default user.

`timeout` has been replaced by `connect-timeout`, but `timeout` is still supported in MySQL 5.0 for backward compatibility.

For more information about option files, see [Section 4.2.3.2](#), “Using Option Files”.

### Return Values

Zero for success. Nonzero if you specify an unknown option.

### Example

The following `mysql_options()` calls request the use of compression in the client/server protocol, cause options to be read from the `[odbc]` group of option files, and disable transaction autocommit mode:

```
MYSQL mysql;

mysql_init(&mysql);
mysql_options(&mysql, MYSQL_OPT_COMPRESS, 0);
mysql_options(&mysql, MYSQL_READ_DEFAULT_GROUP, "odbc");
mysql_options(&mysql, MYSQL_INIT_COMMAND, "SET autocommit=0");
if (!mysql_real_connect(&mysql, "host", "user", "passwd", "database", 0, NULL, 0))
{
    fprintf(stderr, "Failed to connect to database: Error: %s\n",
            mysql_error(&mysql));
}
```

This code requests that the client use the compressed client/server protocol and read the additional options from the `odbc` section in the `my.cnf` file.

### 20.9.3.50. `mysql_ping()`

```
int mysql_ping(MYSQL *mysql)
```

#### Description

Checks whether the connection to the server is working. If the connection has gone down and auto-reconnect is enabled an attempt to reconnect is made. If the connection is down and auto-reconnect is disabled, `mysql_ping()` returns an error.

Auto-reconnect is enabled by default before MySQL 5.0.3 and enabled from 5.0.3 on. To enable auto-connect, call `mysql_options()` with the `MYSQL_OPT_RECONNECT` option. For details, see [Section 20.9.3.49](#), “`mysql_options()`”.

`mysql_ping()` can be used by clients that remain idle for a long while, to check whether the server has closed the connection and reconnect if necessary.

If `mysql_ping()` does cause a reconnect, there is no explicit indication of it. To determine whether a reconnect occurs, call `mysql_thread_id()` to get the original connection identifier before calling `mysql_ping()`, and then call `mysql_thread_id()` again to see whether the identifier has changed.

If reconnect occurs, some characteristics of the connection will have been reset. For details about these characteristics, see [Section 20.9.11](#), “Controlling Automatic Reconnection Behavior”.

#### Return Values

Zero if the connection to the server is alive. Nonzero if an error occurred. A nonzero return does not indicate whether the MySQL server itself is down; the connection might be broken for other reasons such as network problems.

#### Errors

- `CR_COMMANDS_OUT_OF_SYNC`  
Commands were executed in an improper order.
- `CR_SERVER_GONE_ERROR`  
The MySQL server has gone away.
- `CR_UNKNOWN_ERROR`  
An unknown error occurred.

### 20.9.3.51. `mysql_query()`

```
int mysql_query(MYSQL *mysql, const char *stmt_str)
```

#### Description

Executes the SQL statement pointed to by the null-terminated string `stmt_str`. Normally, the string must consist of a single SQL statement and you should not add a terminating semicolon (“;”) or `\g` to the statement. If multiple-statement execution has been enabled, the string can contain several statements separated by semicolons. See [Section 20.9.12](#), “C API Support for Multiple Statement Execution”.

`mysql_query()` cannot be used for statements that contain binary data; you must use `mysql_real_query()` instead. (Binary data may contain the “\0” character, which `mysql_query()` interprets as the end of the statement string.)

If you want to know whether the statement should return a result set, you can use `mysql_field_count()` to check for this. See [Section 20.9.3.22](#), “`mysql_field_count()`”.

#### Return Values

Zero if the statement was successful. Nonzero if an error occurred.

#### Errors

- `CR_COMMANDS_OUT_OF_SYNC`

Commands were executed in an improper order.

- `CR_SERVER_GONE_ERROR`

The MySQL server has gone away.

- `CR_SERVER_LOST`

The connection to the server was lost during the query.

- `CR_UNKNOWN_ERROR`

An unknown error occurred.

### 20.9.3.52. `mysql_real_connect()`

```
MYSQL *mysql_real_connect(MYSQL *mysql, const char *host, const char *user, const char *passwd, const char *db, unsigned int port, const char *unix_socket, unsigned long client_flag)
```

#### Description

`mysql_real_connect()` attempts to establish a connection to a MySQL database engine running on `host`.

`mysql_real_connect()` must complete successfully before you can execute any other API functions that require a valid `MYSQL` connection handle structure.

The parameters are specified as follows:

- The first parameter should be the address of an existing `MYSQL` structure. Before calling `mysql_real_connect()` you must call `mysql_init()` to initialize the `MYSQL` structure. You can change a lot of connect options with the `mysql_options()` call. See [Section 20.9.3.49, “mysql\\_options\(\)”](#).
- The value of `host` may be either a host name or an IP address. If `host` is `NULL` or the string `"localhost"`, a connection to the local host is assumed. For Windows, the client connects using a shared-memory connection, if the server has shared-memory connections enabled. Otherwise, TCP/IP is used. For Unix, the client connects using a Unix socket file. For local connections, you can also influence the type of connection to use with the `MYSQL_OPT_PROTOCOL` or `MYSQL_OPT_NAMED_PIPE` options to `mysql_options()`. The type of connection must be supported by the server. For a `host` value of `."` on Windows, the client connects using a named pipe, if the server has named-pipe connections enabled. If named-pipe connections are not enabled, an error occurs.
- The `user` parameter contains the user's MySQL login ID. If `user` is `NULL` or the empty string `" "`, the current user is assumed. Under Unix, this is the current login name. Under Windows ODBC, the current user name must be specified explicitly. See the MyODBC section of [Chapter 20, Connectors and APIs](#).
- The `passwd` parameter contains the password for `user`. If `passwd` is `NULL`, only entries in the `user` table for the user that have a blank (empty) password field are checked for a match. This allows the database administrator to set up the MySQL privilege system in such a way that users get different privileges depending on whether they have specified a password.

#### Note

Do not attempt to encrypt the password before calling `mysql_real_connect()`; password encryption is handled automatically by the client API.

- The `user` and `passwd` parameters use whatever character set has been configured for the `MYSQL` object. By default, this is `latin1`, but can be changed by calling `mysql_options(mysql, MYSQL_SET_CHARSET_NAME, "charset_name")` prior to connecting.
- `db` is the database name. If `db` is not `NULL`, the connection sets the default database to this value.
- If `port` is not 0, the value is used as the port number for the TCP/IP connection. Note that the `host` parameter determines the type of the connection.
- If `unix_socket` is not `NULL`, the string specifies the socket or named pipe that should be used. Note that the `host` parameter determines the type of the connection.
- The value of `client_flag` is usually 0, but can be set to a combination of the following flags to enable certain features.

Flag Name	Flag Description
<code>CLIENT_COMPRESS</code>	Use compression protocol.
<code>CLIENT_FOUND_ROWS</code>	Return the number of found (matched) rows, not the number of changed rows.
<code>CLIENT_IGNORE_SIGPIPE</code>	Prevents the client library from installing a <code>SIGPIPE</code> signal handler. This can be used to avoid conflicts with a handler that the application has already installed.
<code>CLIENT_IGNORE_SPACE</code>	Allow spaces after function names. Makes all functions names reserved words.
<code>CLIENT_INTERACTIVE</code>	Allow <code>interactive_timeout</code> seconds (instead of <code>wait_timeout</code> seconds) of inactivity before closing the connection. The client's session <code>wait_timeout</code> variable is set to the value of the session <code>interactive_timeout</code> variable.
<code>CLIENT_LOCAL_FILES</code>	Enable <code>LOAD DATA LOCAL</code> handling.
<code>CLIENT_MULTI_RESULTS</code>	Tell the server that the client can handle multiple result sets from multiple-statement executions or stored procedures. This flag is automatically enabled if <code>CLIENT_MULTI_STATEMENTS</code> is enabled. See the note following this table for more information about this flag.
<code>CLIENT_MULTI_STATEMENTS</code>	Tell the server that the client may send multiple statements in a single string (separated by “;”). If this flag is not set, multiple-statement execution is disabled. See the note following this table for more information about this flag.
<code>CLIENT_NO_SCHEMA</code>	Don't allow the <code>db_name.tbl_name.col_name</code> syntax. This is for ODBC. It causes the parser to generate an error if you use that syntax, which is useful for trapping bugs in some ODBC programs.
<code>CLIENT_ODBC</code>	Unused.
<code>CLIENT_SSL</code>	Use SSL (encrypted protocol). This option should not be set by application programs; it is set internally in the client library. Instead, use <code>mysql_ssl_set()</code> before calling <code>mysql_real_connect()</code> .
<code>CLIENT_REMEMBER_OPTIONS</code>	Remember options specified by calls to <code>mysql_options()</code> . Without this option, if <code>mysql_real_connect()</code> fails, you must repeat the <code>mysql_options()</code> calls before trying to connect again. With this option, the <code>mysql_options()</code> calls need not be repeated.

If your program uses `CALL` statements to execute stored procedures, the `CLIENT_MULTI_RESULTS` flag must be enabled. This is because each `CALL` returns a result to indicate the call status, in addition to any result sets that might be returned by statements executed within the procedure. Because `CALL` can return multiple results, you should process them using a loop that calls `mysql_next_result()` to determine whether there are more results.

`CLIENT_MULTI_RESULTS` can be enabled when you call `mysql_real_connect()`, either explicitly by passing the `CLIENT_MULTI_RESULTS` flag itself, or implicitly by passing `CLIENT_MULTI_STATEMENTS` (which also enables `CLIENT_MULTI_RESULTS`).

If you enable `CLIENT_MULTI_STATEMENTS` or `CLIENT_MULTI_RESULTS`, you should process the result for every call to `mysql_query()` or `mysql_real_query()` by using a loop that calls `mysql_next_result()` to determine whether there are more results. For an example, see [Section 20.9.12, “C API Support for Multiple Statement Execution”](#).

For some parameters, it is possible to have the value taken from an option file rather than from an explicit value in the `mysql_real_connect()` call. To do this, call `mysql_options()` with the `MYSQL_READ_DEFAULT_FILE` or `MYSQL_READ_DEFAULT_GROUP` option before calling `mysql_real_connect()`. Then, in the `mysql_real_connect()` call, specify the “no-value” value for each parameter to be read from an option file:

- For `host`, specify a value of `NULL` or the empty string (“”).
- For `user`, specify a value of `NULL` or the empty string.
- For `passwd`, specify a value of `NULL`. (For the password, a value of the empty string in the `mysql_real_connect()` call cannot be overridden in an option file, because the empty string indicates explicitly that the MySQL account must have an empty password.)
- For `db`, specify a value of `NULL` or the empty string.
- For `port`, specify a value of 0.
- For `unix_socket`, specify a value of `NULL`.

If no value is found in an option file for a parameter, its default value is used as indicated in the descriptions given earlier in this section.

### Return Values

A `MYSQL*` connection handle if the connection was successful, `NULL` if the connection was unsuccessful. For a successful connection, the return value is the same as the value of the first parameter.

### Errors

- `CR_CONN_HOST_ERROR`  
Failed to connect to the MySQL server.
- `CR_CONNECTION_ERROR`  
Failed to connect to the local MySQL server.
- `CR_IPSOCK_ERROR`  
Failed to create an IP socket.
- `CR_OUT_OF_MEMORY`  
Out of memory.
- `CR_SOCKET_CREATE_ERROR`  
Failed to create a Unix socket.
- `CR_UNKNOWN_HOST`  
Failed to find the IP address for the host name.
- `CR_VERSION_ERROR`  
A protocol mismatch resulted from attempting to connect to a server with a client library that uses a different protocol version.
- `CR_NAMEDPIPEOPEN_ERROR`  
Failed to create a named pipe on Windows.
- `CR_NAMEDPIPEWAIT_ERROR`  
Failed to wait for a named pipe on Windows.
- `CR_NAMEDPIPESETSTATE_ERROR`  
Failed to get a pipe handler on Windows.
- `CR_SERVER_LOST`  
If `connect_timeout > 0` and it took longer than `connect_timeout` seconds to connect to the server or if the server died while executing the `init-command`.

### Example

```
MYSQL mysql;  
  
mysql_init(&mysql);  
mysql_options(&mysql, MYSQL_READ_DEFAULT_GROUP, "your_prog_name");  
if (!mysql_real_connect(&mysql, "host", "user", "passwd", "database", 0, NULL, 0))  
{  
    fprintf(stderr, "Failed to connect to database: Error: %s\n",  
            mysql_error(&mysql));  
}
```

By using `mysql_options()` the MySQL library reads the `[client]` and `[your_prog_name]` sections in the `my.cnf` file which ensures that your program works, even if someone has set up MySQL in some non-standard way.

Note that upon connection, `mysql_real_connect()` sets the `reconnect` flag (part of the `MYSQL` structure) to a value of `1` in versions of the API older than 5.0.3, or `0` in newer versions. A value of `1` for this flag indicates that if a statement cannot be per-

formed because of a lost connection, to try reconnecting to the server before giving up. As of MySQL 5.0.13, you can use the `MYSQL_OPT_RECONNECT` option to `mysql_options()` to control reconnection behavior.

### 20.9.3.53. `mysql_real_escape_string()`

```
unsigned long mysql_real_escape_string(MYSQL *mysql, char *to, const char *from, unsigned long length)
```

Note that `mysql` must be a valid, open connection. This is needed because the escaping depends on the character set in use by the server.

#### Description

This function is used to create a legal SQL string that you can use in an SQL statement. See [Section 8.1.1, “Strings”](#).

The string in `from` is encoded to an escaped SQL string, taking into account the current character set of the connection. The result is placed in `to` and a terminating null byte is appended. Characters encoded are `NUL` (ASCII 0), “`\n`”, “`\r`”, “`\`”, “`'`”, “`”`”, and Control-Z (see [Section 8.1, “Literal Values”](#)). (Strictly speaking, MySQL requires only that backslash and the quote character used to quote the string in the query be escaped. This function quotes the other characters to make them easier to read in log files.)

The string pointed to by `from` must be `length` bytes long. You must allocate the `to` buffer to be at least `length*2+1` bytes long. (In the worst case, each character may need to be encoded as using two bytes, and you need room for the terminating null byte.) When `mysql_real_escape_string()` returns, the contents of `to` is a null-terminated string. The return value is the length of the encoded string, not including the terminating null character.

If you need to change the character set of the connection, you should use the `mysql_set_character_set()` function rather than executing a `SET NAMES` (or `SET CHARACTER SET`) statement. `mysql_set_character_set()` works like `SET NAMES` but also affects the character set used by `mysql_real_escape_string()`, which `SET NAMES` does not.

#### Example

```
char query[1000],*end;

end = strmov(query,"INSERT INTO test_table values(");
*end++ = '\\';
end += mysql_real_escape_string(&mysql, end,"What is this",12);
*end++ = '\\';
*end++ = ',';
*end++ = '\\';
end += mysql_real_escape_string(&mysql, end,"binary data: \\0\\r\\n",16);
*end++ = '\\';
*end++ = ')';

if (mysql_real_query(&mysql,query,(unsigned int) (end - query)))
{
    fprintf(stderr, "Failed to insert row, Error: %s\\n",
            mysql_error(&mysql));
}
```

The `strmov()` function used in the example is included in the `mysqlclient` library and works like `strcpy()` but returns a pointer to the terminating null of the first parameter.

#### Return Values

The length of the value placed into `to`, not including the terminating null character.

#### Errors

None.

### 20.9.3.54. `mysql_real_query()`

```
int mysql_real_query(MYSQL *mysql, const char *stmt_str, unsigned long length)
```

#### Description

Executes the SQL statement pointed to by `stmt_str`, which should be a string `length` bytes long. Normally, the string must consist of a single SQL statement and you should not add a terminating semicolon (“`;`”) or `\g` to the statement. If multiple-statement execution has been enabled, the string can contain several statements separated by semicolons. See [Section 20.9.12, “C API Support for Multiple Statement Execution”](#).

`mysql_query()` cannot be used for statements that contain binary data; you must use `mysql_real_query()` instead. (Binary data may contain the “`\0`” character, which `mysql_query()` interprets as the end of the statement string.) In addition, `mysql_real_query()` is faster than `mysql_query()` because it does not call `strlen()` on the statement string.

If you want to know whether the statement should return a result set, you can use `mysql_field_count()` to check for this. See [Section 20.9.3.22, “mysql\\_field\\_count\(\)”](#).

### Return Values

Zero if the statement was successful. Nonzero if an error occurred.

### Errors

- `CR_COMMANDS_OUT_OF_SYNC`  
Commands were executed in an improper order.
- `CR_SERVER_GONE_ERROR`  
The MySQL server has gone away.
- `CR_SERVER_LOST`  
The connection to the server was lost during the query.
- `CR_UNKNOWN_ERROR`  
An unknown error occurred.

## 20.9.3.55. `mysql_refresh()`

```
int mysql_refresh(MYSQL *mysql, unsigned int options)
```

### Description

This function flushes tables or caches, or resets replication server information. The connected user must have the `RELOAD` privilege.

The `options` argument is a bit mask composed from any combination of the following values. Multiple values can be OR'ed together to perform multiple operations with a single call.

- `REFRESH_GRANT`  
Refresh the grant tables, like `FLUSH PRIVILEGES`.
- `REFRESH_LOG`  
Flush the logs, like `FLUSH LOGS`.
- `REFRESH_TABLES`  
Flush the table cache, like `FLUSH TABLES`.
- `REFRESH_HOSTS`  
Flush the host cache, like `FLUSH HOSTS`.
- `REFRESH_STATUS`  
Reset status variables, like `FLUSH STATUS`.
- `REFRESH_THREADS`  
Flush the thread cache.
- `REFRESH_SLAVE`  
On a slave replication server, reset the master server information and restart the slave, like `RESET SLAVE`.
- `REFRESH_MASTER`  
On a master replication server, remove the binary log files listed in the binary log index and truncate the index file, like `RESET MASTER`.

**Return Values**

Zero for success. Nonzero if an error occurred.

**Errors**

- [CR\\_COMMANDS\\_OUT\\_OF\\_SYNC](#)  
Commands were executed in an improper order.
- [CR\\_SERVER\\_GONE\\_ERROR](#)  
The MySQL server has gone away.
- [CR\\_SERVER\\_LOST](#)  
The connection to the server was lost during the query.
- [CR\\_UNKNOWN\\_ERROR](#)  
An unknown error occurred.

**20.9.3.56. `mysql_reload()`**

```
int mysql_reload(MYSQL *mysql)
```

**Description**

Asks the MySQL server to reload the grant tables. The connected user must have the [RELOAD](#) privilege.

This function is deprecated. It is preferable to use [mysql\\_query\(\)](#) to issue an SQL [FLUSH PRIVILEGES](#) statement instead.

**Return Values**

Zero for success. Nonzero if an error occurred.

**Errors**

- [CR\\_COMMANDS\\_OUT\\_OF\\_SYNC](#)  
Commands were executed in an improper order.
- [CR\\_SERVER\\_GONE\\_ERROR](#)  
The MySQL server has gone away.
- [CR\\_SERVER\\_LOST](#)  
The connection to the server was lost during the query.
- [CR\\_UNKNOWN\\_ERROR](#)  
An unknown error occurred.

**20.9.3.57. `mysql_rollback()`**

```
my_bool mysql_rollback(MYSQL *mysql)
```

**Description**

Rolls back the current transaction.

As of MySQL 5.0.3, the action of this function is subject to the value of the [completion\\_type](#) system variable. In particular, if the value of [completion\\_type](#) is 2, the server performs a release after terminating a transaction and closes the client connection. The client program should call [mysql\\_close\(\)](#) to close the connection from the client side.

**Return Values**

Zero if successful. Nonzero if an error occurred.

**Errors**

None.

### 20.9.3.58. `mysql_row_seek()`

```
MYSQL_ROW_OFFSET mysql_row_seek(MYSQL_RES *result, MYSQL_ROW_OFFSET offset)
```

**Description**

Sets the row cursor to an arbitrary row in a query result set. The `offset` value is a row offset that should be a value returned from `mysql_row_tell()` or from `mysql_row_seek()`. This value is not a row number; if you want to seek to a row within a result set by number, use `mysql_data_seek()` instead.

This function requires that the result set structure contains the entire result of the query, so `mysql_row_seek()` may be used only in conjunction with `mysql_store_result()`, not with `mysql_use_result()`.

**Return Values**

The previous value of the row cursor. This value may be passed to a subsequent call to `mysql_row_seek()`.

**Errors**

None.

### 20.9.3.59. `mysql_row_tell()`

```
MYSQL_ROW_OFFSET mysql_row_tell(MYSQL_RES *result)
```

**Description**

Returns the current position of the row cursor for the last `mysql_fetch_row()`. This value can be used as an argument to `mysql_row_seek()`.

You should use `mysql_row_tell()` only after `mysql_store_result()`, not after `mysql_use_result()`.

**Return Values**

The current offset of the row cursor.

**Errors**

None.

### 20.9.3.60. `mysql_select_db()`

```
int mysql_select_db(MYSQL *mysql, const char *db)
```

**Description**

Causes the database specified by `db` to become the default (current) database on the connection specified by `mysql`. In subsequent queries, this database is the default for table references that do not include an explicit database specifier.

`mysql_select_db()` fails unless the connected user can be authenticated as having permission to use the database.

**Return Values**

Zero for success. Nonzero if an error occurred.

**Errors**

- `CR_COMMANDS_OUT_OF_SYNC`  
Commands were executed in an improper order.
- `CR_SERVER_GONE_ERROR`  
The MySQL server has gone away.

- `CR_SERVER_LOST`

The connection to the server was lost during the query.

- `CR_UNKNOWN_ERROR`

An unknown error occurred.

### 20.9.3.61. `mysql_set_character_set()`

```
int mysql_set_character_set(MYSQL *mysql, const char *csname)
```

#### Description

This function is used to set the default character set for the current connection. The string `csname` specifies a valid character set name. The connection collation becomes the default collation of the character set. This function works like the `SET NAMES` statement, but also sets the value of `mysql->charset`, and thus affects the character set used by `mysql_real_escape_string()`

This function was added in MySQL 5.0.7.

#### Return Values

Zero for success. Nonzero if an error occurred.

#### Example

```
MYSQL mysql;

mysql_init(&mysql);
if (!mysql_real_connect(&mysql, "host", "user", "passwd", "database", 0, NULL, 0))
{
    fprintf(stderr, "Failed to connect to database: Error: %s\n",
            mysql_error(&mysql));
}

if (!mysql_set_character_set(&mysql, "utf8"))
{
    printf("New client character set: %s\n",
          mysql_character_set_name(&mysql));
}
```

### 20.9.3.62. `mysql_set_local_infile_default()`

```
void mysql_set_local_infile_default(MYSQL *mysql);
```

#### Description

Sets the `LOAD LOCAL DATA INFILE` handler callback functions to the defaults used internally by the C client library. The library calls this function automatically if `mysql_set_local_infile_handler()` has not been called or does not supply valid functions for each of its callbacks.

The `mysql_set_local_infile_default()` function was added in MySQL 4.1.2.

#### Return Values

None.

#### Errors

None.

### 20.9.3.63. `mysql_set_local_infile_handler()`

```
void mysql_set_local_infile_handler(MYSQL *mysql, int (*local_infile_init)(void **,
const char *, void *), int (*local_infile_read)(void *, char *, unsigned int), void
(*local_infile_end)(void *), int (*local_infile_error)(void *, char*, unsigned int),
void *userdata);
```

#### Description

This function installs callbacks to be used during the execution of `LOAD DATA LOCAL INFILE` statements. It enables applica-

tion programs to exert control over local (client-side) data file reading. The arguments are the connection handler, a set of pointers to callback functions, and a pointer to a data area that the callbacks can use to share information.

To use `mysql_set_local_infile_handler()`, you must write the following callback functions:

```
int
local_infile_init(void **ptr, const char *filename, void *userdata);
```

The initialization function. This is called once to do any setup necessary, open the data file, allocate data structures, and so forth. The first `void**` argument is a pointer to a pointer. You can set the pointer (that is, `*ptr`) to a value that will be passed to each of the other callbacks (as a `void*`). The callbacks can use this pointed-to value to maintain state information. The `userdata` argument is the same value that is passed to `mysql_set_local_infile_handler()`.

The initialization function should return zero for success, nonzero for an error.

```
int
local_infile_read(void *ptr, char *buf, unsigned int buf_len);
```

The data-reading function. This is called repeatedly to read the data file. `buf` points to the buffer where the read data should be stored, and `buf_len` is the maximum number of bytes that the callback can read and store in the buffer. (It can read fewer bytes, but should not read more.)

The return value is the number of bytes read, or zero when no more data could be read (this indicates EOF). Return a value less than zero if an error occurs.

```
void
local_infile_end(void *ptr)
```

The termination function. This is called once after `local_infile_read()` has returned zero (EOF) or an error. This function should deallocate any memory allocated by `local_infile_init()` and perform any other cleanup necessary. It is invoked even if the initialization function returns an error.

```
int
local_infile_error(void *ptr,
                  char *error_msg,
                  unsigned int error_msg_len);
```

The error-handling function. This is called to get a textual error message to return to the user in case any of your other functions returns an error. `error_msg` points to the buffer into which the message should be written, and `error_msg_len` is the length of the buffer. The message should be written as a null-terminated string, so the message can be at most `error_msg_len-1` bytes long.

The return value is the error number.

Typically, the other callbacks store the error message in the data structure pointed to by `ptr`, so that `local_infile_error()` can copy the message from there into `error_msg`.

After calling `mysql_set_local_infile_handler()` in your C code and passing pointers to your callback functions, you can then issue a `LOAD DATA LOCAL INFILE` statement (for example, by using `mysql_query()`). The client library automatically invokes your callbacks. The file name specified in `LOAD DATA LOCAL INFILE` will be passed as the second parameter to the `local_infile_init()` callback.

The `mysql_set_local_infile_handler()` function was added in MySQL 4.1.2.

#### Return Values

None.

#### Errors

None.

### 20.9.3.64. `mysql_set_server_option()`

```
int mysql_set_server_option(MYSQL *mysql, enum enum_mysql_set_option option)
```

#### Description

Enables or disables an option for the connection. `option` can have one of the following values.

<code>MYSQL_OPTION_MULTI_STATEMENTS_ON</code>	Enable multiple-statement support
---	-----------------------------------

<code>MYSQL_OPTION_MULTI_STATEMENTS_OFF</code>	Disable multiple-statement support
--	------------------------------------

If you enable multiple-statement support, you should retrieve results from calls to `mysql_query()` or `mysql_real_query()` by using a loop that calls `mysql_next_result()` to determine whether there are more results. For an example, see [Section 20.9.12, “C API Support for Multiple Statement Execution”](#).

Enabling multiple-statement support with `MYSQL_OPTION_MULTI_STATEMENTS_ON` does not have quite the same effect as enabling it by passing the `CLIENT_MULTI_STATEMENTS` flag to `mysql_real_connect()`; `CLIENT_MULTI_STATEMENTS` also enables `CLIENT_MULTI_RESULTS`. If you are using the `CALL SQL` statement in your programs, multiple-result support must be enabled; this means that `MYSQL_OPTION_MULTI_STATEMENTS_ON` by itself is insufficient to allow the use of `CALL`.

### Return Values

Zero for success. Nonzero if an error occurred.

### Errors

- `CR_COMMANDS_OUT_OF_SYNC`  
Commands were executed in an improper order.
- `CR_SERVER_GONE_ERROR`  
The MySQL server has gone away.
- `CR_SERVER_LOST`  
The connection to the server was lost during the query.
- `ER_UNKNOWN_COM_ERROR`  
The server didn't support `mysql_set_server_option()` (which is the case that the server is older than 4.1.1) or the server didn't support the option one tried to set.

## 20.9.3.65. `mysql_shutdown()`

```
int mysql_shutdown(MYSQL *mysql, enum mysql_enum_shutdown_level shutdown_level)
```

### Description

Asks the database server to shut down. The connected user must have the `SHUTDOWN` privilege. The `shutdown_level` argument was added in MySQL 5.0.1. MySQL 5.0 servers support only one type of shutdown; `shutdown_level` must be equal to `SHUTDOWN_DEFAULT`. Additional shutdown levels are planned to make it possible to choose the desired level. Dynamically linked executables which have been compiled with older versions of the `libmysqlclient` headers and call `mysql_shutdown()` need to be used with the old `libmysqlclient` dynamic library.

The shutdown process is described in [Section 5.1.10, “The Shutdown Process”](#).

### Return Values

Zero for success. Nonzero if an error occurred.

### Errors

- `CR_COMMANDS_OUT_OF_SYNC`  
Commands were executed in an improper order.
- `CR_SERVER_GONE_ERROR`  
The MySQL server has gone away.
- `CR_SERVER_LOST`  
The connection to the server was lost during the query.

- `CR_UNKNOWN_ERROR`

An unknown error occurred.

### 20.9.3.66. `mysql_sqlstate()`

```
const char *mysql_sqlstate(MYSQL *mysql)
```

#### Description

Returns a null-terminated string containing the SQLSTATE error code for the most recently executed SQL statement. The error code consists of five characters. '00000' means "no error." The values are specified by ANSI SQL and ODBC. For a list of possible values, see [Appendix B, Errors, Error Codes, and Common Problems](#).

SQLSTATE values returned by `mysql_sqlstate()` differ from MySQL-specific error numbers returned by `mysql_errno()`. For example, the `mysql` client program displays errors using the following format, where 1146 is the `mysql_errno()` value and '42S02' is the corresponding `mysql_sqlstate()` value:

```
shell> SELECT * FROM no_such_table;
ERROR 1146 (42S02): Table 'test.no_such_table' doesn't exist
```

Not all MySQL error numbers are mapped to SQLSTATE error codes. The value 'HY000' (general error) is used for unmapped error numbers.

If you call `mysql_sqlstate()` after `mysql_real_connect()` fails, `mysql_sqlstate()` might not return a useful value. For example, this happens if a host is blocked by the server and the connection is closed without any SQLSTATE value being sent to the client.

#### Return Values

A null-terminated character string containing the SQLSTATE error code.

#### See Also

See [Section 20.9.3.14, "mysql\\_errno\(\)"](#), [Section 20.9.3.15, "mysql\\_error\(\)"](#), and [Section 20.9.7.26, "mysql\\_stmt\\_sqlstate\(\)"](#).

### 20.9.3.67. `mysql_ssl_set()`

```
my_bool mysql_ssl_set(MYSQL *mysql, const char *key, const char *cert, const char *ca,
const char *capath, const char *cipher)
```

#### Description

`mysql_ssl_set()` is used for establishing secure connections using SSL. It must be called before `mysql_real_connect()`.

`mysql_ssl_set()` does nothing unless SSL support is enabled in the client library.

`mysql` is the connection handler returned from `mysql_init()`. The other parameters are specified as follows:

- `key` is the path name to the key file.
- `cert` is the path name to the certificate file.
- `ca` is the path name to the certificate authority file.
- `capath` is the path name to a directory that contains trusted SSL CA certificates in pem format.
- `cipher` is a list of allowable ciphers to use for SSL encryption.

Any unused SSL parameters may be given as `NULL`.

#### Return Values

This function always returns 0. If SSL setup is incorrect, `mysql_real_connect()` returns an error when you attempt to connect.

### 20.9.3.68. `mysql_stat()`

```
const char *mysql_stat(MYSQL *mysql)
```

#### Description

Returns a character string containing information similar to that provided by the `mysqladmin status` command. This includes uptime in seconds and the number of running threads, questions, reloads, and open tables.

#### Return Values

A character string describing the server status. `NULL` if an error occurred.

#### Errors

- `CR_COMMANDS_OUT_OF_SYNC`  
Commands were executed in an improper order.
- `CR_SERVER_GONE_ERROR`  
The MySQL server has gone away.
- `CR_SERVER_LOST`  
The connection to the server was lost during the query.
- `CR_UNKNOWN_ERROR`  
An unknown error occurred.

### 20.9.3.69. `mysql_store_result()`

```
MYSQL_RES *mysql_store_result(MYSQL *mysql)
```

#### Description

After invoking `mysql_query()` or `mysql_real_query()`, you must call `mysql_store_result()` or `mysql_use_result()` for every statement that successfully produces a result set (`SELECT`, `SHOW`, `DESCRIBE`, `EXPLAIN`, `CHECK TABLE`, and so forth). You must also call `mysql_free_result()` after you are done with the result set.

You don't have to call `mysql_store_result()` or `mysql_use_result()` for other statements, but it does not do any harm or cause any notable performance degradation if you call `mysql_store_result()` in all cases. You can detect whether the statement has a result set by checking whether `mysql_store_result()` returns a nonzero value (more about this later on).

If you enable multiple-statement support, you should retrieve results from calls to `mysql_query()` or `mysql_real_query()` by using a loop that calls `mysql_next_result()` to determine whether there are more results. For an example, see [Section 20.9.12, “C API Support for Multiple Statement Execution”](#).

If you want to know whether a statement should return a result set, you can use `mysql_field_count()` to check for this. See [Section 20.9.3.22, “mysql\\_field\\_count\(\)”](#).

`mysql_store_result()` reads the entire result of a query to the client, allocates a `MYSQL_RES` structure, and places the result into this structure.

`mysql_store_result()` returns a null pointer if the statement didn't return a result set (for example, if it was an `INSERT` statement).

`mysql_store_result()` also returns a null pointer if reading of the result set failed. You can check whether an error occurred by checking whether `mysql_error()` returns a non-empty string, `mysql_errno()` returns nonzero, or `mysql_field_count()` returns zero.

An empty result set is returned if there are no rows returned. (An empty result set differs from a null pointer as a return value.)

After you have called `mysql_store_result()` and gotten back a result that isn't a null pointer, you can call `mysql_num_rows()` to find out how many rows are in the result set.

You can call `mysql_fetch_row()` to fetch rows from the result set, or `mysql_row_seek()` and `mysql_row_tell()` to obtain or set the current row position within the result set.

See [Section 20.9.10.1, “Why `mysql\_store\_result\(\)` Sometimes Returns `NULL` After `mysql\_query\(\)` Returns Success”](#).

### Return Values

A `MYSQL_RES` result structure with the results. `NULL` (0) if an error occurred.

### Errors

`mysql_store_result()` resets `mysql_error()` and `mysql_errno()` if it succeeds.

- `CR_COMMANDS_OUT_OF_SYNC`  
Commands were executed in an improper order.
- `CR_OUT_OF_MEMORY`  
Out of memory.
- `CR_SERVER_GONE_ERROR`  
The MySQL server has gone away.
- `CR_SERVER_LOST`  
The connection to the server was lost during the query.
- `CR_UNKNOWN_ERROR`  
An unknown error occurred.

## 20.9.3.70. `mysql_thread_id()`

```
unsigned long mysql_thread_id(MYSQL *mysql)
```

### Description

Returns the thread ID of the current connection. This value can be used as an argument to `mysql_kill()` to kill the thread.

If the connection is lost and you reconnect with `mysql_ping()`, the thread ID changes. This means you should not get the thread ID and store it for later. You should get it when you need it.

### Return Values

The thread ID of the current connection.

### Errors

None.

## 20.9.3.71. `mysql_use_result()`

```
MYSQL_RES *mysql_use_result(MYSQL *mysql)
```

### Description

After invoking `mysql_query()` or `mysql_real_query()`, you must call `mysql_store_result()` or `mysql_use_result()` for every statement that successfully produces a result set (`SELECT`, `SHOW`, `DESCRIBE`, `EXPLAIN`, `CHECK TABLE`, and so forth). You must also call `mysql_free_result()` after you are done with the result set.

`mysql_use_result()` initiates a result set retrieval but does not actually read the result set into the client like `mysql_store_result()` does. Instead, each row must be retrieved individually by making calls to `mysql_fetch_row()`. This reads the result of a query directly from the server without storing it in a temporary table or local buffer, which is somewhat faster and uses much less memory than `mysql_store_result()`. The client allocates memory only for the current row and a communication buffer that may grow up to `max_allowed_packet` bytes.

On the other hand, you shouldn't use `mysql_use_result()` if you are doing a lot of processing for each row on the client side, or if the output is sent to a screen on which the user may type a `^S` (stop scroll). This ties up the server and prevent other threads from updating any tables from which the data is being fetched.

When using `mysql_use_result()`, you must execute `mysql_fetch_row()` until a `NULL` value is returned, otherwise, the unfetched rows are returned as part of the result set for your next query. The C API gives the error `Commands out of sync; you can't run this command now` if you forget to do this!

You may not use `mysql_data_seek()`, `mysql_row_seek()`, `mysql_row_tell()`, `mysql_num_rows()`, or `mysql_affected_rows()` with a result returned from `mysql_use_result()`, nor may you issue other queries until `mysql_use_result()` has finished. (However, after you have fetched all the rows, `mysql_num_rows()` accurately returns the number of rows fetched.)

You must call `mysql_free_result()` once you are done with the result set.

When using the `libmysqld` embedded server, the memory benefits are essentially lost because memory usage incrementally increases with each row retrieved until `mysql_free_result()` is called.

### Return Values

A `MYSQL_RES` result structure. `NULL` if an error occurred.

### Errors

`mysql_use_result()` resets `mysql_error()` and `mysql_errno()` if it succeeds.

- `CR_COMMANDS_OUT_OF_SYNC`  
Commands were executed in an improper order.
- `CR_OUT_OF_MEMORY`  
Out of memory.
- `CR_SERVER_GONE_ERROR`  
The MySQL server has gone away.
- `CR_SERVER_LOST`  
The connection to the server was lost during the query.
- `CR_UNKNOWN_ERROR`  
An unknown error occurred.

### 20.9.3.72. `mysql_warning_count()`

```
unsigned int mysql_warning_count(MYSQL *mysql)
```

#### Description

Returns the number of warnings generated during execution of the previous SQL statement.

#### Return Values

The warning count.

#### Errors

None.

## 20.9.4. C API Prepared Statements

The MySQL client/server protocol provides for the use of prepared statements. This capability uses the `MYSQL_STMT` statement handler data structure returned by the `mysql_stmt_init()` initialization function. Prepared execution is an efficient way to execute a statement more than once. The statement is first parsed to prepare it for execution. Then it is executed one or more times at a later time, using the statement handle returned by the initialization function.

Prepared execution is faster than direct execution for statements executed more than once, primarily because the query is parsed only once. In the case of direct execution, the query is parsed every time it is executed. Prepared execution also can provide a reduction of network traffic because for each execution of the prepared statement, it is necessary only to send the data for the parameters.

Prepared statements might not provide a performance increase in some situations. For best results, test your application both with prepared and non-prepared statements and choose whichever yields best performance.

Another advantage of prepared statements is that it uses a binary protocol that makes data transfer between client and server more efficient.

The following statements can be used as prepared statements: `CALL`, `CREATE TABLE`, `DELETE`, `DO`, `INSERT`, `REPLACE`, `SELECT`, `SET`, `UPDATE`, and most `SHOW` statements. Other statements are not supported in MySQL 5.0.

#### MySQL Enterprise

MySQL Enterprise subscribers will find more information about using prepared statements in the Knowledge Base article, [How can I create server-side prepared statements?](#). Access to the MySQL Knowledge Base collection of articles is one of the advantages of subscribing to MySQL Enterprise. For more information, see <http://www.mysql.com/products/enterprise/advisors.html>.

## 20.9.5. C API Prepared Statement Data types

Prepared statements use several data structures:

- To prepare a statement, pass the statement string to `mysql_stmt_init()`, which returns a pointer to a `MYSQL_STMT` data structure.
- To provide input parameters for a prepared statement, set up `MYSQL_BIND` structures and pass them to `mysql_stmt_bind_param()`. To receive output column values, set up `MYSQL_BIND` structures and pass them to `mysql_stmt_bind_result()`.
- The `MYSQL_TIME` structure is used to transfer temporal data in both directions.

The following discussion describes the prepared statement data types in detail.

- `MYSQL_STMT`

This structure represents a prepared statement. A statement is created by calling `mysql_stmt_init()`, which returns a statement handle (that is, a pointer to a `MYSQL_STMT`). The handle is used for all subsequent operations with the statement until you close it with `mysql_stmt_close()`, at which point the handle becomes invalid.

The `MYSQL_STMT` structure has no members that are intended for application use. Also, you should not try to make a copy of a `MYSQL_STMT` structure. There is no guarantee that such a copy will be usable.

Multiple statement handles can be associated with a single connection. The limit on the number of handles depends on the available system resources.

- `MYSQL_BIND`

This structure is used both for statement input (data values sent to the server) and output (result values returned from the server):

- For input, `MYSQL_BIND` is used with `mysql_stmt_bind_param()` to bind parameter data values to buffers for use by `mysql_stmt_execute()`.
- For output, `MYSQL_BIND` is used with `mysql_stmt_bind_result()` to bind result set buffers for use in fetching rows with `mysql_stmt_fetch()`.

To use a `MYSQL_BIND` structure, you should zero its contents to initialize it, and then set its members appropriately. For example, to declare and initialize an array of three `MYSQL_BIND` structures, use this code:

```
MYSQL_BIND bind[3];
memset(bind, 0, sizeof(bind));
```

The `MYSQL_BIND` structure contains the following members for use by application programs. For several of the members, the manner of use depends on whether the structure is used for input or output.

- `enum enum_field_types buffer_type`

The type of the buffer. This member indicates the data type of the C language variable that you are binding to the statement parameter. The allowable `buffer_type` values are listed later in this section. For input, `buffer_type` indicates the type of the variable containing the value that you will send to the server. For output, it indicates the type of the variable into

which you want a value received from the server to be stored.

- `void *buffer`

A pointer to the buffer to be used for data transfer. This is the address of a variable.

For input, `buffer` is a pointer to the variable in which a statement parameter's data value is stored. When you call `mysql_stmt_execute()`, MySQL takes the value that you have stored in the variable and uses it in place of the corresponding parameter marker in the statement.

For output, `buffer` is a pointer to the variable in which to return a result set column value. When you call `mysql_stmt_fetch()`, MySQL returns a column value and stores it in this variable. You can access the value when the call returns.

To minimize the need for MySQL to perform type conversions between C language values on the client side and SQL values on the server side, use variables that have types similar to those of the corresponding SQL values. For numeric data types, `buffer` should point to a variable of the proper numeric C type. (For `char` or integer variables, you should also indicate whether the variable has the `unsigned` attribute by setting the `is_unsigned` member, described later in this list.) For character (nonbinary) and binary string data types, `buffer` should point to a character buffer. For date and time data types, `buffer` should point to a `MYSQL_TIME` structure.

See the notes about type conversions later in the section.

- `unsigned long buffer_length`

The actual size of `*buffer` in bytes. This indicates the maximum amount of data that can be stored in the buffer. For character and binary C data, the `buffer_length` value specifies the length of `*buffer` when used with `mysql_stmt_bind_param()` to specify input values, or the maximum number of output data bytes that can be fetched into the buffer when used with `mysql_stmt_bind_result()`.

- `unsigned long *length`

A pointer to an `unsigned long` variable that indicates the actual number of bytes of data stored in `*buffer`. `length` is used for character or binary C data.

For input parameter data binding, `length` points to an `unsigned long` variable that indicates the actual length of the parameter value stored in `*buffer`; this is used by `mysql_stmt_execute()`.

For output value binding, the return value of `mysql_stmt_fetch()` determines the interpretation of the length:

- If `mysql_stmt_fetch()` returns 0, `*length` indicates the actual length of the parameter value.
- If `mysql_stmt_fetch()` returns `MYSQL_DATA_TRUNCATED`, `*length` indicates the non-truncated length of the parameter value. In this case, the minimum of `*length` and `buffer_length` indicates the actual length of the value.

`length` is ignored for numeric and temporal data types because the length of the data value is determined by the `buffer_type` value.

If you need to be able to determine the length of a returned value before fetching it with `mysql_stmt_fetch()`, see [Section 20.9.7.11, “mysql\\_stmt\\_fetch\(\)”](#), for some strategies.

- `my_bool *is_null`

This member points to a `my_bool` variable that is true if a value is `NULL`, false if it is not `NULL`. For input, set `*is_null` to true to indicate that you are passing a `NULL` value as a statement parameter.

The reason that `is_null` is not a boolean scalar but is instead a *pointer* to a boolean scalar is to provide flexibility in how you specify `NULL` values:

- If your data values are always `NULL`, use `MYSQL_TYPE_NULL` as the `buffer_type` value when you bind the column. The other members do not matter.
- If your data values are always `NOT NULL`, set the other members appropriately for the variable you are binding, and set `is_null = (my_bool*) 0`.
- In all other cases, set the other members appropriately, and set `is_null` to the address of a `my_bool` variable. Set that variable's value to true or false appropriately between executions to indicate whether data values are `NULL` or `NOT NULL`, respectively.

For output, the value pointed to by `is_null` is set to true after you fetch a row if the result set column value returned from the statement is `NULL`.

- `my_bool is_unsigned`

This member is used for C variables with data types that can be `unsigned` (`char`, `short int`, `int`, `long long int`). Set `is_unsigned` to true if the variable pointed to by `buffer` is `unsigned` and false otherwise. For example, if you bind a `signed char` variable to `buffer`, specify a type code of `MYSQL_TYPE_TINY` and set `is_unsigned` to false. If you bind an `unsigned char` instead, the type code is the same but `is_unsigned` should be true. (For `char`, it is not defined whether it is signed or unsigned, so it is best to be explicit about signedness by using `signed char` or `unsigned char`.)

`is_unsigned` applies only to the C language variable on the client side. It indicates nothing about the signedness of the corresponding SQL value on the server side. For example, if you use an `int` variable to supply a value for a `BIGINT UNSIGNED` column, `is_unsigned` should be false because `int` is a signed type. If you use an `unsigned int` variable to supply a value for a `BIGINT` column, `is_unsigned` should be true because `unsigned int` is an unsigned type. MySQL performs the proper conversion between signed and unsigned values in both directions, although a warning occurs if truncation results.

- `my_bool *error`

For output, set this member to point to a `my_bool` variable to have truncation information for the parameter stored there after a row fetching operation. (Truncation reporting is enabled by default, but can be controlled by calling `mysql_options()` with the `MYSQL_REPORT_DATA_TRUNCATION` option.) When truncation reporting is enabled, `mysql_stmt_fetch()` returns `MYSQL_DATA_TRUNCATED` and `*error` is true in the `MYSQL_BIND` structures for parameters in which truncation occurred. Truncation indicates loss of sign or significant digits, or that a string was too long to fit in a column. The `error` member was added in MySQL 5.0.3.

- `MYSQL_TIME`

This structure is used to send and receive `DATE`, `TIME`, `DATETIME`, and `TIMESTAMP` data directly to and from the server. Set the `buffer_type` member of a `MYSQL_BIND` structure to one of the temporal types (`MYSQL_TYPE_TIME`, `MYSQL_TYPE_DATE`, `MYSQL_TYPE_DATETIME`, `MYSQL_TYPE_TIMESTAMP`), and set the `buffer` member to point to a `MYSQL_TIME` structure.

The `MYSQL_TIME` structure contains the members listed in the following table.

Member	Description
<code>unsigned int year</code>	The year
<code>unsigned int month</code>	The month of the year
<code>unsigned int day</code>	The day of the month
<code>unsigned int hour</code>	The hour of the day
<code>unsigned int minute</code>	The minute of the hour
<code>unsigned int second</code>	The second of the minute
<code>my_bool neg</code>	A boolean flag to indicate whether the time is negative
<code>unsigned long second_part</code>	The fractional part of the second in microseconds; currently unused

Only those parts of a `MYSQL_TIME` structure that apply to a given type of temporal value are used. The `year`, `month`, and `day` elements are used for `DATE`, `DATETIME`, and `TIMESTAMP` values. The `hour`, `minute`, and `second` elements are used for `TIME`, `DATETIME`, and `TIMESTAMP` values. See [Section 20.9.14, “C API Prepared Statement Handling of Date and Time Values”](#).

The following table shows the allowable values that may be specified in the `buffer_type` member of `MYSQL_BIND` structures for input values. The value should be chosen according to the data type of the C language variable that you are binding. If the variable is `unsigned`, you should also set the `is_unsigned` member to true. The table shows the C variable types that you can use, the corresponding type codes, and the SQL data types for which the supplied value can be used without conversion.

Input Variable C Type	<code>buffer_type</code> Value	SQL Type of Destination Value
<code>signed char</code>	<code>MYSQL_TYPE_TINY</code>	<code>TINYINT</code>
<code>short int</code>	<code>MYSQL_TYPE_SHORT</code>	<code>SMALLINT</code>
<code>int</code>	<code>MYSQL_TYPE_LONG</code>	<code>INT</code>

long long int	MYSQL_TYPE_LONGLONG	BIGINT
float	MYSQL_TYPE_FLOAT	FLOAT
double	MYSQL_TYPE_DOUBLE	DOUBLE
MYSQL_TIME	MYSQL_TYPE_TIME	TIME
MYSQL_TIME	MYSQL_TYPE_DATE	DATE
MYSQL_TIME	MYSQL_TYPE_DATETIME	DATETIME
MYSQL_TIME	MYSQL_TYPE_TIMESTAMP	TIMESTAMP
char[]	MYSQL_TYPE_STRING (for nonbinary data)	TEXT, CHAR, VARCHAR
char[]	MYSQL_TYPE_BLOB (for binary data)	BLOB, BINARY, VARBINARY
	MYSQL_TYPE_NULL	NULL

The use of `MYSQL_TYPE_NULL` is described earlier in connection with the `is_null` member.

The following table shows the allowable values that may be specified in the `buffer_type` member of `MYSQL_BIND` structures for output values. The value should be chosen according to the data type of the C language variable that you are binding. If the variable is `unsigned`, you should also set the `is_unsigned` member to true. The table shows the SQL types of received values, the corresponding type code that such values have in result set metadata, and the recommended C language data types to bind to the `MYSQL_BIND` structure to receive the SQL values without conversion.

If there is a mismatch between the C variable type on the client side and the corresponding SQL value on the server side, MySQL performs implicit type conversions in both directions.

SQL Type of Received Value	buffer_type Value	Output Variable C Type
TINYINT	MYSQL_TYPE_TINY	signed char
SMALLINT	MYSQL_TYPE_SHORT	short int
MEDIUMINT	MYSQL_TYPE_INT24	int
INT	MYSQL_TYPE_LONG	int
BIGINT	MYSQL_TYPE_LONGLONG	long long int
FLOAT	MYSQL_TYPE_FLOAT	float
DOUBLE	MYSQL_TYPE_DOUBLE	double
DECIMAL	MYSQL_TYPE_NEWDECIMAL	char[]
YEAR	MYSQL_TYPE_SHORT	short int
TIME	MYSQL_TYPE_TIME	MYSQL_TIME
DATE	MYSQL_TYPE_DATE	MYSQL_TIME
DATETIME	MYSQL_TYPE_DATETIME	MYSQL_TIME
TIMESTAMP	MYSQL_TYPE_TIMESTAMP	MYSQL_TIME
CHAR, BINARY	MYSQL_TYPE_STRING	char[]
VARCHAR, VARBINARY	MYSQL_TYPE_VAR_STRING	char[]
TINYBLOB, TINYTEXT	MYSQL_TYPE_TINY_BLOB	char[]
BLOB, TEXT	MYSQL_TYPE_BLOB	char[]
MEDIUMBLOB, MEDIUMTEXT	MYSQL_TYPE_MEDIUM_BLOB	char[]
LOBLOB, LONGTEXT	MYSQL_TYPE_LONG_BLOB	char[]
BIT	MYSQL_TYPE_BIT	char[]

MySQL knows the type code for the SQL value on the server side. The `buffer_type` value indicates the MySQL the type code of the C variable that holds the value on the client side. The two codes together tell MySQL what conversion must be performed, if any. Here are some examples:

- If you use `MYSQL_TYPE_LONG` with an `int` variable to pass an integer value to the server that is to be stored into a `FLOAT` column, MySQL converts the value to floating-point format before storing it.
- If you fetch an SQL `MEDIUMINT` column value, but specify a `buffer_type` value of `MYSQL_TYPE_LONGLONG` and use a

C variable of type `long long int` as the destination buffer, MySQL will convert the `MEDIUMINT` value (which requires less than 8 bytes) for storage into the `long long int` (an 8-byte variable).

- If you fetch a numeric column with a value of 255 into a `char[4]` character array and specify a `buffer_type` value of `MYSQL_TYPE_STRING`, the resulting value in the array will be a 4-byte string containing `'255\0'`.
- `DECIMAL` values are returned as strings, which is why the corresponding C type is `char[]`. `DECIMAL` values returned by the server correspond to the string representation of the original server-side value. For example, `12.345` is returned to the client as `'12.345'`. If you specify `MYSQL_TYPE_NEWDECIMAL` and bind a string buffer to the `MYSQL_BIND` structure, `mysql_stmt_fetch()` stores the value in the buffer without conversion. If instead you specify a numeric variable and type code, `mysql_stmt_fetch()` converts the string-format `DECIMAL` value to numeric form.
- For the `MYSQL_TYPE_BIT` type code, `BIT` values are returned into a string buffer (thus, the corresponding C type is `char[]` here, too). The value represents a bit string that requires interpretation on the client side. To return the value as a type that is easier to deal with, you can cause the value to be cast to integer using either of the following types of expressions:

```
SELECT bit_col + 0 FROM t
SELECT CAST(bit_col AS UNSIGNED) FROM t
```

To retrieve the value, bind an integer variable large enough to hold the value and specify the appropriate corresponding integer type code.

Before binding variables to the `MYSQL_BIND` structures that are to be used for fetching column values, you can check the type codes for each column of the result set. This might be desirable if you want to determine which variable types would be best to use to avoid type conversions. To get the type codes, call `mysql_stmt_result_metadata()` after executing the prepared statement with `mysql_stmt_execute()`. The metadata provides access to the type codes for the result set as described in [Section 20.9.7.22, “mysql\\_stmt\\_result\\_metadata\(\)”](#), and [Section 20.9.1, “C API Data Types”](#).

If you cause the `max_length` member of the `MYSQL_FIELD` column metadata structures to be set (by calling `mysql_stmt_attr_set()`), be aware that the `max_length` values for the result set indicate the lengths of the longest string representation of the result values, not the lengths of the binary representation. That is, `max_length` does not necessarily correspond to the size of the buffers needed to fetch the values with the binary protocol used for prepared statements. The size of the buffers should be chosen according to the types of the variables into which you fetch the values.

For input character (nonbinary) string data (indicated by `MYSQL_TYPE_STRING`), the value is assumed to be in the character set indicated by the `character_set_client` system variable. If the value is stored into a column with a different character set, the appropriate conversion to that character set occurs. For input binary string data (indicated by `MYSQL_TYPE_BLOB`), the value is treated as having the `binary` character set; that is, it is treated as a byte string and no conversion occurs.

To determine whether output string values in a result set returned from the server contain binary or nonbinary data, check whether the `charsetnr` value of the result set metadata is 63 (see [Section 20.9.1, “C API Data Types”](#)). If so, the character set is `binary`, which indicates binary rather than nonbinary data. This enables you to distinguish `BINARY` from `CHAR`, `VARBINARY` from `VARCHAR`, and the `BLOB` types from the `TEXT` types.

## 20.9.6. C API Prepared Statement Function Overview

The functions available for prepared statement processing are summarized here and described in greater detail in a later section. See [Section 20.9.7, “C API Prepared Statement Function Descriptions”](#).

Function	Description
<code>mysql_stmt_affected_rows()</code>	Returns the number of rows changed, deleted, or inserted by prepared <code>UPDATE</code> , <code>DELETE</code> , or <code>INSERT</code> statement
<code>mysql_stmt_attr_get()</code>	Get value of an attribute for a prepared statement
<code>mysql_stmt_attr_set()</code>	Sets an attribute for a prepared statement
<code>mysql_stmt_bind_param()</code>	Associates application data buffers with the parameter markers in a prepared SQL statement
<code>mysql_stmt_bind_result()</code>	Associates application data buffers with columns in the result set
<code>mysql_stmt_close()</code>	Frees memory used by prepared statement
<code>mysql_stmt_data_seek()</code>	Seeks to an arbitrary row number in a statement result set
<code>mysql_stmt_errno()</code>	Returns the error number for the last statement execution
<code>mysql_stmt_error()</code>	Returns the error message for the last statement execution
<code>mysql_stmt_execute()</code>	Executes the prepared statement
<code>mysql_stmt_fetch()</code>	Fetches the next row of data from the result set and returns data for all bound columns

<code>mysql_stmt_fetch_column()</code>	Fetch data for one column of the current row of the result set
<code>mysql_stmt_field_count()</code>	Returns the number of result columns for the most recent statement
<code>mysql_stmt_free_result()</code>	Free the resources allocated to the statement handle
<code>mysql_stmt_init()</code>	Allocates memory for <code>MYSQL_STMT</code> structure and initializes it
<code>mysql_stmt_insert_id()</code>	Returns the ID generated for an <code>AUTO_INCREMENT</code> column by prepared statement
<code>mysql_stmt_num_rows()</code>	Returns total row count from the buffered statement result set
<code>mysql_stmt_param_count()</code>	Returns the number of parameters in a prepared SQL statement
<code>mysql_stmt_param_metadata()</code>	(Return parameter metadata in the form of a result set.) Currently, this function does nothing
<code>mysql_stmt_prepare()</code>	Prepares an SQL string for execution
<code>mysql_stmt_reset()</code>	Reset the statement buffers in the server
<code>mysql_stmt_result_metadata()</code>	Returns prepared statement metadata in the form of a result set
<code>mysql_stmt_row_seek()</code>	Seeks to a row offset in a statement result set, using value returned from <code>mysql_stmt_row_tell()</code>
<code>mysql_stmt_row_tell()</code>	Returns the statement row cursor position
<code>mysql_stmt_send_long_data()</code>	Sends long data in chunks to server
<code>mysql_stmt_sqlstate()</code>	Returns the <code>SQLSTATE</code> error code for the last statement execution
<code>mysql_stmt_store_result()</code>	Retrieves the complete result set to the client

Call `mysql_stmt_init()` to create a statement handle, then `mysql_stmt_prepare()` to prepare it, `mysql_stmt_bind_param()` to supply the parameter data, and `mysql_stmt_execute()` to execute the statement. You can repeat the `mysql_stmt_execute()` by changing parameter values in the respective buffers supplied through `mysql_stmt_bind_param()`.

If the statement is a `SELECT` or any other statement that produces a result set, `mysql_stmt_prepare()` also returns the result set metadata information in the form of a `MYSQL_RES` result set through `mysql_stmt_result_metadata()`.

You can supply the result buffers using `mysql_stmt_bind_result()`, so that the `mysql_stmt_fetch()` automatically returns data to these buffers. This is row-by-row fetching.

You can also send the text or binary data in chunks to server using `mysql_stmt_send_long_data()`. See [Section 20.9.7.25](#), “`mysql_stmt_send_long_data()`”.

When statement execution has been completed, the statement handle must be closed using `mysql_stmt_close()` so that all resources associated with it can be freed.

If you obtained a `SELECT` statement's result set metadata by calling `mysql_stmt_result_metadata()`, you should also free the metadata using `mysql_free_result()`.

### Execution Steps

To prepare and execute a statement, an application follows these steps:

1. Create a prepared statement handle with `mysql_stmt_init()`. To prepare the statement on the server, call `mysql_stmt_prepare()` and pass it a string containing the SQL statement.
2. If the statement produces a result set, call `mysql_stmt_result_metadata()` to obtain the result set metadata. This metadata is itself in the form of result set, albeit a separate one from the one that contains the rows returned by the query. The metadata result set indicates how many columns are in the result and contains information about each column.
3. Set the values of any parameters using `mysql_stmt_bind_param()`. All parameters must be set. Otherwise, statement execution returns an error or produces unexpected results.
4. Call `mysql_stmt_execute()` to execute the statement.
5. If the statement produces a result set, bind the data buffers to use for retrieving the row values by calling `mysql_stmt_bind_result()`.
6. Fetch the data into the buffers row by row by calling `mysql_stmt_fetch()` repeatedly until no more rows are found.
7. Repeat steps 3 through 6 as necessary, by changing the parameter values and re-executing the statement.

When `mysql_stmt_prepare()` is called, the MySQL client/server protocol performs these actions:

- The server parses the statement and sends the okay status back to the client by assigning a statement ID. It also sends total number of parameters, a column count, and its metadata if it is a result set oriented statement. All syntax and semantics of the statement are checked by the server during this call.
- The client uses this statement ID for the further operations, so that the server can identify the statement from among its pool of statements.

When `mysql_stmt_execute()` is called, the MySQL client/server protocol performs these actions:

- The client uses the statement handle and sends the parameter data to the server.
- The server identifies the statement using the ID provided by the client, replaces the parameter markers with the newly supplied data, and executes the statement. If the statement produces a result set, the server sends the data back to the client. Otherwise, it sends an okay status and total number of rows changed, deleted, or inserted.

When `mysql_stmt_fetch()` is called, the MySQL client/server protocol performs these actions:

- The client reads the data from the packet row by row and places it into the application data buffers by doing the necessary conversions. If the application buffer type is same as that of the field type returned from the server, the conversions are straightforward.

If an error occurs, you can get the statement error code, error message, and SQLSTATE value using `mysql_stmt_errno()`, `mysql_stmt_error()`, and `mysql_stmt_sqlstate()`, respectively.

### Prepared Statement Logging

For prepared statements that are executed with the `mysql_stmt_prepare()` and `mysql_stmt_execute()` C API functions, the server writes `Prepare` and `Execute` lines to the general query log so that you can tell when statements are prepared and executed.

Suppose that you prepare and execute a statement as follows:

1. Call `mysql_stmt_prepare()` to prepare the statement string "SELECT ?".
2. Call `mysql_stmt_bind_param()` to bind the value 3 to the parameter in the prepared statement.
3. Call `mysql_stmt_execute()` to execute the prepared statement.

As a result of the preceding calls, the server writes the following lines to the general query log:

```
Prepare [1] SELECT ?
Execute [1] SELECT 3
```

Each `Prepare` and `Execute` line in the log is tagged with a `[N]` statement identifier so that you can keep track of which prepared statement is being logged. `N` is a positive integer. If there are multiple prepared statements active simultaneously for the client, `N` may be greater than 1. Each `Execute` lines shows a prepared statement after substitution of data values for `?` parameters.

Version notes: `Prepare` lines are displayed without `[N]` before MySQL 4.1.10. `Execute` lines are not displayed at all before MySQL 4.1.10.

## 20.9.7. C API Prepared Statement Function Descriptions

To prepare and execute queries, use the functions described in detail in the following sections.

All functions that operate with a `MYSQL_STMT` structure begin with the prefix `mysql_stmt_`.

To create a `MYSQL_STMT` handle, use the `mysql_stmt_init()` function.

### 20.9.7.1. `mysql_stmt_affected_rows()`

```
my_ulonglong mysql_stmt_affected_rows(MYSQL_STMT *stmt)
```

**Description**

Returns the total number of rows changed, deleted, or inserted by the last executed statement. May be called immediately after `mysql_stmt_execute()` for `UPDATE`, `DELETE`, or `INSERT` statements. For `SELECT` statements, `mysql_stmt_affected_rows()` works like `mysql_num_rows()`.

**Return Values**

An integer greater than zero indicates the number of rows affected or retrieved. Zero indicates that no records were updated for an `UPDATE` statement, no rows matched the `WHERE` clause in the query, or that no query has yet been executed. -1 indicates that the query returned an error or that, for a `SELECT` query, `mysql_stmt_affected_rows()` was called prior to calling `mysql_stmt_store_result()`. Because `mysql_stmt_affected_rows()` returns an unsigned value, you can check for -1 by comparing the return value to `(my_ulonglong)-1` (or to `(my_ulonglong)~0`, which is equivalent).

See [Section 20.9.3.1](#), “`mysql_affected_rows()`”, for additional information on the return value.

**Errors**

None.

**Example**

For the usage of `mysql_stmt_affected_rows()`, refer to the Example from [Section 20.9.7.10](#), “`mysql_stmt_execute()`”.

**20.9.7.2. `mysql_stmt_attr_get()`**

```
my_bool mysql_stmt_attr_get(MYSQL_STMT *stmt, enum enum_stmt_attr_type option, void *arg)
```

**Description**

Can be used to get the current value for a statement attribute.

The `option` argument is the option that you want to get; the `arg` should point to a variable that should contain the option value. If the option is an integer, then `arg` should point to the value of the integer.

See [Section 20.9.7.3](#), “`mysql_stmt_attr_set()`”, for a list of options and option types.

**Note**

In MySQL 5.0, `mysql_stmt_attr_get()` uses `unsigned int *`, not `my_bool *`, for `STMT_ATTR_UPDATE_MAX_LENGTH`. This was corrected in MySQL 5.1.7.

**Return Values**

Zero if successful. Nonzero if `option` is unknown.

**Errors**

None.

**20.9.7.3. `mysql_stmt_attr_set()`**

```
my_bool mysql_stmt_attr_set(MYSQL_STMT *stmt, enum enum_stmt_attr_type option, const void *arg)
```

**Description**

Can be used to affect behavior for a prepared statement. This function may be called multiple times to set several options.

The `option` argument is the option that you want to set. The `arg` argument is the value for the option. `arg` should point to a variable that is set to the desired attribute value. The variable type is as indicated in the following table.

The following table shows the possible `option` values.

Option	Argument Type	Function
<code>STMT_ATTR_UPDATE_MAX_LENGTH</code>	<code>my_bool *</code>	If set to 1, causes <code>mysql_stmt_store_result()</code> to update the metadata <code>MYSQL_FIELD-&gt;max_length</code>

		value.
<code>STMT_ATTR_CURSOR_TYPE</code>	<code>unsigned long *</code>	Type of cursor to open for statement when <code>mysql_stmt_execute()</code> is invoked. <code>*arg</code> can be <code>CURSOR_TYPE_NO_CURSOR</code> (the default) or <code>CURSOR_TYPE_READ_ONLY</code> .
<code>STMT_ATTR_PREFETCH_ROWS</code>	<code>unsigned long *</code>	Number of rows to fetch from server at a time when using a cursor. <code>*arg</code> can be in the range from 1 to the maximum value of <code>unsigned long</code> . The default is 1.

**Note**

In MySQL 5.0, `mysql_stmt_attr_get()` uses `unsigned int *`, not `my_bool *`, for `STMT_ATTR_UPDATE_MAX_LENGTH`. This is corrected in MySQL 5.1.7.

If you use the `STMT_ATTR_CURSOR_TYPE` option with `CURSOR_TYPE_READ_ONLY`, a cursor is opened for the statement when you invoke `mysql_stmt_execute()`. If there is already an open cursor from a previous `mysql_stmt_execute()` call, it closes the cursor before opening a new one. `mysql_stmt_reset()` also closes any open cursor before preparing the statement for re-execution. `mysql_stmt_free_result()` closes any open cursor.

If you open a cursor for a prepared statement, `mysql_stmt_store_result()` is unnecessary, because that function causes the result set to be buffered on the client side.

The `STMT_ATTR_CURSOR_TYPE` option was added in MySQL 5.0.2. The `STMT_ATTR_PREFETCH_ROWS` option was added in MySQL 5.0.6.

**Return Values**

Zero if successful. Nonzero if `option` is unknown.

**Errors**

None.

**Example**

The following example opens a cursor for a prepared statement and sets the number of rows to fetch at a time to 5:

```
MYSQL_STMT *stmt;
int rc;
unsigned long type;
unsigned long prefetch_rows = 5;

stmt = mysql_stmt_init(mysql);
type = (unsigned long) CURSOR_TYPE_READ_ONLY;
rc = mysql_stmt_attr_set(stmt, STMT_ATTR_CURSOR_TYPE, (void*) &type);
/* ... check return value ... */
rc = mysql_stmt_attr_set(stmt, STMT_ATTR_PREFETCH_ROWS,
                        (void*) &prefetch_rows);
/* ... check return value ... */
```

**20.9.7.4. `mysql_stmt_bind_param()`**

```
my_bool mysql_stmt_bind_param(MYSQL_STMT *stmt, MYSQL_BIND *bind)
```

**Description**

`mysql_stmt_bind_param()` is used to bind input data for the parameter markers in the SQL statement that was passed to `mysql_stmt_prepare()`. It uses `MYSQL_BIND` structures to supply the data. `bind` is the address of an array of `MYSQL_BIND` structures. The client library expects the array to contain one element for each “?” parameter marker that is present in the query.

Suppose that you prepare the following statement:

```
INSERT INTO mytbl VALUES(?,?,?)
```

When you bind the parameters, the array of `MYSQL_BIND` structures must contain three elements, and can be declared like this:

```
MYSQL_BIND bind[3];
```

Section 20.9.5, “C API Prepared Statement Data types”, describes the members of each `MYSQL_BIND` element and how they should be set to provide input values.

#### Return Values

Zero if the bind operation was successful. Nonzero if an error occurred.

#### Errors

- `CR_UNSUPPORTED_PARAM_TYPE`  
The conversion is not supported. Possibly the `buffer_type` value is illegal or is not one of the supported types.
- `CR_OUT_OF_MEMORY`  
Out of memory.
- `CR_UNKNOWN_ERROR`  
An unknown error occurred.

#### Example

For the usage of `mysql_stmt_bind_param()`, refer to the Example from Section 20.9.7.10, “`mysql_stmt_execute()`”.

### 20.9.7.5. `mysql_stmt_bind_result()`

```
my_bool mysql_stmt_bind_result(MYSQL_STMT *stmt, MYSQL_BIND *bind)
```

#### Description

`mysql_stmt_bind_result()` is used to associate (that is, bind) output columns in the result set to data buffers and length buffers. When `mysql_stmt_fetch()` is called to fetch data, the MySQL client/server protocol places the data for the bound columns into the specified buffers.

All columns must be bound to buffers prior to calling `mysql_stmt_fetch()`. `bind` is the address of an array of `MYSQL_BIND` structures. The client library expects the array to contain one element for each column of the result set. If you do not bind columns to `MYSQL_BIND` structures, `mysql_stmt_fetch()` simply ignores the data fetch. The buffers should be large enough to hold the data values, because the protocol doesn't return data values in chunks.

A column can be bound or rebound at any time, even after a result set has been partially retrieved. The new binding takes effect the next time `mysql_stmt_fetch()` is called. Suppose that an application binds the columns in a result set and calls `mysql_stmt_fetch()`. The client/server protocol returns data in the bound buffers. Then suppose that the application binds the columns to a different set of buffers. The protocol places data into the newly bound buffers when the next call to `mysql_stmt_fetch()` occurs.

To bind a column, an application calls `mysql_stmt_bind_result()` and passes the type, address, and length of the output buffer into which the value should be stored. Section 20.9.5, “C API Prepared Statement Data types”, describes the members of each `MYSQL_BIND` element and how they should be set to receive output values.

#### Return Values

Zero if the bind operation was successful. Nonzero if an error occurred.

#### Errors

- `CR_UNSUPPORTED_PARAM_TYPE`  
The conversion is not supported. Possibly the `buffer_type` value is illegal or is not one of the supported types.
- `CR_OUT_OF_MEMORY`  
Out of memory.
- `CR_UNKNOWN_ERROR`  
An unknown error occurred.

**Example**

For the usage of `mysql_stmt_bind_result()`, refer to the Example from [Section 20.9.7.11](#), “`mysql_stmt_fetch()`”.

**20.9.7.6. `mysql_stmt_close()`**

```
my_bool mysql_stmt_close(MYSQL_STMT *)
```

**Description**

Closes the prepared statement. `mysql_stmt_close()` also deallocates the statement handle pointed to by `stmt`.

If the current statement has pending or unread results, this function cancels them so that the next query can be executed.

**Return Values**

Zero if the statement was freed successfully. Nonzero if an error occurred.

**Errors**

- `CR_SERVER_GONE_ERROR`  
The MySQL server has gone away.
- `CR_UNKNOWN_ERROR`  
An unknown error occurred.

**Example**

For the usage of `mysql_stmt_close()`, refer to the Example from [Section 20.9.7.10](#), “`mysql_stmt_execute()`”.

**20.9.7.7. `mysql_stmt_data_seek()`**

```
void mysql_stmt_data_seek(MYSQL_STMT *stmt, my_ulonglong offset)
```

**Description**

Seeks to an arbitrary row in a statement result set. The `offset` value is a row number and should be in the range from 0 to `mysql_stmt_num_rows(stmt)-1`.

This function requires that the statement result set structure contains the entire result of the last executed query, so `mysql_stmt_data_seek()` may be used only in conjunction with `mysql_stmt_store_result()`.

**Return Values**

None.

**Errors**

None.

**20.9.7.8. `mysql_stmt_errno()`**

```
unsigned int mysql_stmt_errno(MYSQL_STMT *stmt)
```

**Description**

For the statement specified by `stmt`, `mysql_stmt_errno()` returns the error code for the most recently invoked statement API function that can succeed or fail. A return value of zero means that no error occurred. Client error message numbers are listed in the MySQL `errmsg.h` header file. Server error message numbers are listed in `mysqld_error.h`. Errors also are listed at [Appendix B, Errors, Error Codes, and Common Problems](#).

**Return Values**

An error code value. Zero if no error occurred.

**Errors**

None.

### 20.9.7.9. `mysql_stmt_error()`

```
const char *mysql_stmt_error(MYSQL_STMT *stmt)
```

#### Description

For the statement specified by `stmt`, `mysql_stmt_error()` returns a null-terminated string containing the error message for the most recently invoked statement API function that can succeed or fail. An empty string ("" ) is returned if no error occurred. This means the following two tests are equivalent:

```
if (*mysql_stmt_errno(stmt))
{
    // an error occurred
}

if (mysql_stmt_error(stmt)[0])
{
    // an error occurred
}
```

The language of the client error messages may be changed by recompiling the MySQL client library. Currently, you can choose error messages in several different languages.

#### Return Values

A character string that describes the error. An empty string if no error occurred.

#### Errors

None.

### 20.9.7.10. `mysql_stmt_execute()`

```
int mysql_stmt_execute(MYSQL_STMT *stmt)
```

#### Description

`mysql_stmt_execute()` executes the prepared query associated with the statement handle. The currently bound parameter marker values are sent to server during this call, and the server replaces the markers with this newly supplied data.

If the statement is an `UPDATE`, `DELETE`, or `INSERT`, the total number of changed, deleted, or inserted rows can be found by calling `mysql_stmt_affected_rows()`. If this is a statement such as `SELECT` that generates a result set, you must call `mysql_stmt_fetch()` to fetch the data prior to calling any other functions that result in query processing. For more information on how to fetch the results, refer to [Section 20.9.7.11](#), “`mysql_stmt_fetch()`”.

For statements that generate a result set, you can request that `mysql_stmt_execute()` open a cursor for the statement by calling `mysql_stmt_attr_set()` before executing the statement. If you execute a statement multiple times, `mysql_stmt_execute()` closes any open cursor before opening a new one.

#### Return Values

Zero if execution was successful. Nonzero if an error occurred.

#### Errors

- `CR_COMMANDS_OUT_OF_SYNC`  
Commands were executed in an improper order.
- `CR_OUT_OF_MEMORY`  
Out of memory.
- `CR_SERVER_GONE_ERROR`  
The MySQL server has gone away.
- `CR_SERVER_LOST`  
The connection to the server was lost during the query.

- [CR\\_UNKNOWN\\_ERROR](#)

An unknown error occurred.

### Example

The following example demonstrates how to create and populate a table using `mysql_stmt_init()`, `mysql_stmt_prepare()`, `mysql_stmt_param_count()`, `mysql_stmt_bind_param()`, `mysql_stmt_execute()`, and `mysql_stmt_affected_rows()`. The `mysql` variable is assumed to be a valid connection handle.

```
#define STRING_SIZE 50

#define DROP_SAMPLE_TABLE "DROP TABLE IF EXISTS test_table"
#define CREATE_SAMPLE_TABLE "CREATE TABLE test_table(col1 INT,\
                                                    col2 VARCHAR(40),\
                                                    col3 SMALLINT,\
                                                    col4 TIMESTAMP)"

#define INSERT_SAMPLE "INSERT INTO \
test_table(col1,col2,col3) \
VALUES(?,?,?)"

MYSQL_STMT      *stmt;
MYSQL_BIND      bind[3];
my_ulonglong    affected_rows;

fprintf(stdout, " total affected rows(insert 2): %lu\n",
        (unsigned long) affected_rows);

if (affected_rows != 1) /* validate affected rows */
{
    fprintf(stderr, " invalid affected rows by MySQL\n");
    exit(0);
}

/* Close the statement */
if (mysql_stmt_close(stmt))
{
    fprintf(stderr, " failed while closing the statement\n");
    fprintf(stderr, " %s\n", mysql_stmt_error(stmt));
    exit(0);
}

```

**Note**

For complete examples on the use of prepared statement functions, refer to the file [tests/mysql\\_client\\_test.c](#). This file can be obtained from a MySQL source distribution or from the Bazaar source repository.

**20.9.7.11. `mysql_stmt_fetch()`**

```
int mysql_stmt_fetch(MYSQL_STMT *stmt)
```

**Description**

`mysql_stmt_fetch()` returns the next row in the result set. It can be called only while the result set exists; that is, after a call to `mysql_stmt_execute()` for a statement such as `SELECT` that creates a result set.

`mysql_stmt_fetch()` returns row data using the buffers bound by `mysql_stmt_bind_result()`. It returns the data in those buffers for all the columns in the current row set and the lengths are returned to the `length` pointer. All columns must be bound by the application before it calls `mysql_stmt_fetch()`.

By default, result sets are fetched unbuffered a row at a time from the server. To buffer the entire result set on the client, call `mysql_stmt_store_result()` after binding the data buffers and before calling `mysql_stmt_fetch()`.

If a fetched data value is a `NULL` value, the `*is_null` value of the corresponding `MYSQL_BIND` structure contains `TRUE` (1). Otherwise, the data and its length are returned in the `*buffer` and `*length` elements based on the buffer type specified by the application. Each numeric and temporal type has a fixed length, as listed in the following table. The length of the string types depends on the length of the actual data value, as indicated by `data_length`.

Type	Length
<code>MYSQL_TYPE_TINY</code>	1
<code>MYSQL_TYPE_SHORT</code>	2
<code>MYSQL_TYPE_LONG</code>	4
<code>MYSQL_TYPE_LONGLONG</code>	8
<code>MYSQL_TYPE_FLOAT</code>	4
<code>MYSQL_TYPE_DOUBLE</code>	8
<code>MYSQL_TYPE_TIME</code>	<code>sizeof(MYSQL_TIME)</code>
<code>MYSQL_TYPE_DATE</code>	<code>sizeof(MYSQL_TIME)</code>
<code>MYSQL_TYPE_DATETIME</code>	<code>sizeof(MYSQL_TIME)</code>
<code>MYSQL_TYPE_STRING</code>	<code>data_length</code>
<code>MYSQL_TYPE_BLOB</code>	<code>data_length</code>

### Return Values

Return Value	Description
0	Successful, the data has been fetched to application data buffers.
1	Error occurred. Error code and message can be obtained by calling <code>mysql_stmt_errno()</code> and <code>mysql_stmt_error()</code> .
<code>MYSQL_NO_DATA</code>	No more rows/data exists
<code>MYSQL_DATA_TRUNCATED</code>	Data truncation occurred

`MYSQL_DATA_TRUNCATED` is returned when truncation reporting is enabled. (Reporting is enabled by default, but can be controlled with `mysql_options()`.) To determine which parameters were truncated when this value is returned, check the `error` members of the `MYSQL_BIND` parameter structures.

### Errors

- `CR_COMMANDS_OUT_OF_SYNC`  
Commands were executed in an improper order.
- `CR_OUT_OF_MEMORY`  
Out of memory.
- `CR_SERVER_GONE_ERROR`  
The MySQL server has gone away.
- `CR_SERVER_LOST`  
The connection to the server was lost during the query.
- `CR_UNKNOWN_ERROR`

An unknown error occurred.

- `CR_UNSUPPORTED_PARAM_TYPE`

The buffer type is `MYSQL_TYPE_DATE`, `MYSQL_TYPE_TIME`, `MYSQL_TYPE_DATETIME`, or `MYSQL_TYPE_TIMESTAMP`, but the data type is not `DATE`, `TIME`, `DATETIME`, or `TIMESTAMP`.

- All other unsupported conversion errors are returned from `mysql_stmt_bind_result()`.

### Example

The following example demonstrates how to fetch data from a table using `mysql_stmt_result_metadata()`, `mysql_stmt_bind_result()`, and `mysql_stmt_fetch()`. (This example expects to retrieve the two rows inserted by the example shown in [Section 20.9.7.10](#), “`mysql_stmt_execute()`”). The `mysql` variable is assumed to be a valid connection handle.

```
#define STRING_SIZE 50

#define SELECT_SAMPLE "SELECT col1, col2, col3, col4 \
                      FROM test_table"

MYSQL_STMT      *stmt;
MYSQL_BIND      bind[4];
MYSQL_RES       *prepare_meta_result;

if (row_count != 2)
{
    fprintf(stderr, " MySQL failed to return all rows\n");
    exit(0);
}

```

```

}
/* Free the prepared result metadata */
mysql_free_result(prepare_meta_result);

/* Close the statement */
if (mysql_stmt_close(stmt))
{
    fprintf(stderr, " failed while closing the statement\n");
    fprintf(stderr, " %s\n", mysql_stmt_error(stmt));
    exit(0);
}

```

In some cases you might want to determine the length of a column value before fetching it with `mysql_stmt_fetch()`. For example, the value might be a long string or `BLOB` value for which you want to know how much space must be allocated. To accomplish this, you can use these strategies:

- Before invoking `mysql_stmt_fetch()` to retrieve individual rows, invoke `mysql_stmt_store_result()` to buffer the entire result on the client side. Then the maximal length of column values will be indicated by the `max_length` member of the result set metadata returned by `mysql_stmt_result_metadata()`. This strategy requires that you pass `STMT_ATTR_UPDATE_MAX_LENGTH` to `mysql_stmt_attr_set()` or the `max_length` values will not be calculated.
- Invoke `mysql_stmt_fetch()` with a zero-length buffer for the column in question and a pointer in which the real length can be stored. Then use the real length with `mysql_stmt_fetch_column()`.

```

real_length= 0;

bind[0].buffer= 0;
bind[0].buffer_length= 0;
bind[0].length= &real_length;
mysql_stmt_bind_result(stmt, bind);

mysql_stmt_fetch(stmt);
if (real_length > 0)
{
    data= malloc(real_length);
    bind[0].buffer= data;
    bind[0].buffer_length= real_length;
    mysql_stmt_fetch_column(stmt, bind, 0, 0);
}

```

### 20.9.7.12. `mysql_stmt_fetch_column()`

```
int mysql_stmt_fetch_column(MYSQL_STMT *stmt, MYSQL_BIND *bind, unsigned int column, unsigned long offset)
```

#### Description

Fetch one column from the current result set row. `bind` provides the buffer where data should be placed. It should be set up the same way as for `mysql_stmt_bind_result()`. `column` indicates which column to fetch. The first column is numbered 0. `offset` is the offset within the data value at which to begin retrieving data. This can be used for fetching the data value in pieces. The beginning of the value is offset 0.

#### Return Values

Zero if the value was fetched successfully. Nonzero if an error occurred.

#### Errors

- `CR_INVALID_PARAMETER_NO`  
Invalid column number.
- `CR_NO_DATA`  
The end of the result set has already been reached.

### 20.9.7.13. `mysql_stmt_field_count()`

```
unsigned int mysql_stmt_field_count(MYSQL_STMT *stmt)
```

#### Description

Returns the number of columns for the most recent statement for the statement handler. This value is zero for statements such as `INSERT` or `DELETE` that do not produce result sets.

`mysql_stmt_field_count()` can be called after you have prepared a statement by invoking `mysql_stmt_prepare()`.

#### Return Values

An unsigned integer representing the number of columns in a result set.

#### Errors

None.

### 20.9.7.14. `mysql_stmt_free_result()`

```
my_bool mysql_stmt_free_result(MYSQL_STMT *stmt)
```

#### Description

Releases memory associated with the result set produced by execution of the prepared statement. If there is a cursor open for the statement, `mysql_stmt_free_result()` closes it.

#### Return Values

Zero if the result set was freed successfully. Nonzero if an error occurred.

#### Errors

### 20.9.7.15. `mysql_stmt_init()`

```
MYSQL_STMT *mysql_stmt_init(MYSQL *mysql)
```

#### Description

Create a `MYSQL_STMT` handle. The handle should be freed with `mysql_stmt_close(MYSQL_STMT *)`.

#### Return values

A pointer to a `MYSQL_STMT` structure in case of success. `NULL` if out of memory.

#### Errors

- `CR_OUT_OF_MEMORY`

Out of memory.

### 20.9.7.16. `mysql_stmt_insert_id()`

```
my_ulonglong mysql_stmt_insert_id(MYSQL_STMT *stmt)
```

#### Description

Returns the value generated for an `AUTO_INCREMENT` column by the prepared `INSERT` or `UPDATE` statement. Use this function after you have executed a prepared `INSERT` statement on a table which contains an `AUTO_INCREMENT` field.

See [Section 20.9.3.37](#), “`mysql_insert_id()`”, for more information.

#### Return Values

Value for `AUTO_INCREMENT` column which was automatically generated or explicitly set during execution of prepared statement, or value generated by `LAST_INSERT_ID(expr)` function. Return value is undefined if statement does not set `AUTO_INCREMENT` value.

#### Errors

None.

### 20.9.7.17. `mysql_stmt_num_rows()`

```
my_ulonglong mysql_stmt_num_rows(MYSQL_STMT *stmt)
```

**Description**

Returns the number of rows in the result set.

The use of `mysql_stmt_num_rows()` depends on whether you used `mysql_stmt_store_result()` to buffer the entire result set in the statement handle.

If you use `mysql_stmt_store_result()`, `mysql_stmt_num_rows()` may be called immediately. Otherwise, the row count is unavailable unless you count the rows as you fetch them.

`mysql_stmt_num_rows()` is intended for use with statements that return a result set, such as `SELECT`. For statements such as `INSERT`, `UPDATE`, or `DELETE`, the number of affected rows can be obtained with `mysql_stmt_affected_rows()`.

**Return Values**

The number of rows in the result set.

**Errors**

None.

**20.9.7.18. `mysql_stmt_param_count()`**

```
unsigned long mysql_stmt_param_count(MYSQL_STMT *stmt)
```

**Description**

Returns the number of parameter markers present in the prepared statement.

**Return Values**

An unsigned long integer representing the number of parameters in a statement.

**Errors**

None.

**Example**

For the usage of `mysql_stmt_param_count()`, refer to the Example from [Section 20.9.7.10](#), “`mysql_stmt_execute()`”.

**20.9.7.19. `mysql_stmt_param_metadata()`**

```
MYSQL_RES *mysql_stmt_param_metadata(MYSQL_STMT *stmt)
```

This function currently does nothing.

**Description****Return Values****Errors****20.9.7.20. `mysql_stmt_prepare()`**

```
int mysql_stmt_prepare(MYSQL_STMT *stmt, const char *stmt_str, unsigned long length)
```

**Description**

Given the statement handle returned by `mysql_stmt_init()`, prepares the SQL statement pointed to by the string `stmt_str` and returns a status value. The string length should be given by the `length` argument. The string must consist of a single SQL statement. You should not add a terminating semicolon (“;”) or `\g` to the statement.

The application can include one or more parameter markers in the SQL statement by embedding question mark (“?”) characters into the SQL string at the appropriate positions.

The markers are legal only in certain places in SQL statements. For example, they are allowed in the `VALUES()` list of an `INSERT` statement (to specify column values for a row), or in a comparison with a column in a `WHERE` clause to specify a comparison

value. However, they are not allowed for identifiers (such as table or column names), or to specify both operands of a binary operator such as the = equal sign. The latter restriction is necessary because it would be impossible to determine the parameter type. In general, parameters are legal only in Data Manipulation Language (DML) statements, and not in Data Definition Language (DDL) statements.

The parameter markers must be bound to application variables using `mysql_stmt_bind_param()` before executing the statement.

### Return Values

Zero if the statement was prepared successfully. Nonzero if an error occurred.

### Errors

- `CR_COMMANDS_OUT_OF_SYNC`  
Commands were executed in an improper order.
- `CR_OUT_OF_MEMORY`  
Out of memory.
- `CR_SERVER_GONE_ERROR`  
The MySQL server has gone away.
- `CR_SERVER_LOST`  
The connection to the server was lost during the query
- `CR_UNKNOWN_ERROR`  
An unknown error occurred.

If the prepare operation was unsuccessful (that is, `mysql_stmt_prepare()` returns nonzero), the error message can be obtained by calling `mysql_stmt_error()`.

### Example

For the usage of `mysql_stmt_prepare()`, refer to the Example from [Section 20.9.7.10](#), “`mysql_stmt_execute()`”.

## 20.9.7.21. `mysql_stmt_reset()`

```
my_bool mysql_stmt_reset(MYSQL_STMT *stmt)
```

### Description

Reset the prepared statement on the client and server to state after prepare. This is mainly used to reset data sent with `mysql_stmt_send_long_data()`. Any open cursor for the statement is closed.

To re-prepare the statement with another query, use `mysql_stmt_prepare()`.

### Return Values

Zero if the statement was reset successfully. Nonzero if an error occurred.

### Errors

- `CR_COMMANDS_OUT_OF_SYNC`  
Commands were executed in an improper order.
- `CR_SERVER_GONE_ERROR`  
The MySQL server has gone away.
- `CR_SERVER_LOST`  
The connection to the server was lost during the query

- `CR_UNKNOWN_ERROR`

An unknown error occurred.

### 20.9.7.22. `mysql_stmt_result_metadata()`

```
MYSQL_RES *mysql_stmt_result_metadata(MYSQL_STMT *stmt)
```

#### Description

If a statement passed to `mysql_stmt_prepare()` is one that produces a result set, `mysql_stmt_result_metadata()` returns the result set metadata in the form of a pointer to a `MYSQL_RES` structure that can be used to process the meta information such as total number of fields and individual field information. This result set pointer can be passed as an argument to any of the field-based API functions that process result set metadata, such as:

- `mysql_num_fields()`
- `mysql_fetch_field()`
- `mysql_fetch_field_direct()`
- `mysql_fetch_fields()`
- `mysql_field_count()`
- `mysql_field_seek()`
- `mysql_field_tell()`
- `mysql_free_result()`

The result set structure should be freed when you are done with it, which you can do by passing it to `mysql_free_result()`. This is similar to the way you free a result set obtained from a call to `mysql_store_result()`.

The result set returned by `mysql_stmt_result_metadata()` contains only metadata. It does not contain any row results. The rows are obtained by using the statement handle with `mysql_stmt_fetch()`.

#### Return Values

A `MYSQL_RES` result structure. `NULL` if no meta information exists for the prepared query.

#### Errors

- `CR_OUT_OF_MEMORY`

Out of memory.

- `CR_UNKNOWN_ERROR`

An unknown error occurred.

#### Example

For the usage of `mysql_stmt_result_metadata()`, refer to the Example from [Section 20.9.7.11](#), “`mysql_stmt_fetch()`”.

### 20.9.7.23. `mysql_stmt_row_seek()`

```
MYSQL_ROW_OFFSET mysql_stmt_row_seek(MYSQL_STMT *stmt, MYSQL_ROW_OFFSET offset)
```

#### Description

Sets the row cursor to an arbitrary row in a statement result set. The `offset` value is a row offset that should be a value returned from `mysql_stmt_row_tell()` or from `mysql_stmt_row_seek()`. This value is not a row number; if you want to seek to a row within a result set by number, use `mysql_stmt_data_seek()` instead.

This function requires that the result set structure contains the entire result of the query, so `mysql_stmt_row_seek()` may be used only in conjunction with `mysql_stmt_store_result()`.

**Return Values**

The previous value of the row cursor. This value may be passed to a subsequent call to `mysql_stmt_row_seek()`.

**Errors**

None.

### 20.9.7.24. `mysql_stmt_row_tell()`

```
MYSQL_ROW_OFFSET mysql_stmt_row_tell(MYSQL_STMT *stmt)
```

**Description**

Returns the current position of the row cursor for the last `mysql_stmt_fetch()`. This value can be used as an argument to `mysql_stmt_row_seek()`.

You should use `mysql_stmt_row_tell()` only after `mysql_stmt_store_result()`.

**Return Values**

The current offset of the row cursor.

**Errors**

None.

### 20.9.7.25. `mysql_stmt_send_long_data()`

```
my_bool mysql_stmt_send_long_data(MYSQL_STMT *stmt, unsigned int parameter_number, const char *data, unsigned long length)
```

**Description**

Allows an application to send parameter data to the server in pieces (or “chunks”). Call this function after `mysql_stmt_bind_param()` and before `mysql_stmt_execute()`. It can be called multiple times to send the parts of a character or binary data value for a column, which must be one of the `TEXT` or `BLOB` data types.

`parameter_number` indicates which parameter to associate the data with. Parameters are numbered beginning with 0. `data` is a pointer to a buffer containing data to be sent, and `length` indicates the number of bytes in the buffer.

**Note**

The next `mysql_stmt_execute()` call ignores the bind buffer for all parameters that have been used with `mysql_stmt_send_long_data()` since last `mysql_stmt_execute()` or `mysql_stmt_reset()`.

If you want to reset/forget the sent data, you can do it with `mysql_stmt_reset()`. See [Section 20.9.7.21](#), “`mysql_stmt_reset()`”.

**Return Values**

Zero if the data is sent successfully to server. Nonzero if an error occurred.

**Errors**

- `CR_INVALID_BUFFER_USE`  
The parameter does not have a string or binary type.
- `CR_COMMANDS_OUT_OF_SYNC`  
Commands were executed in an improper order.
- `CR_SERVER_GONE_ERROR`  
The MySQL server has gone away.

- `CR_OUT_OF_MEMORY`

Out of memory.

- `CR_UNKNOWN_ERROR`

An unknown error occurred.

### Example

The following example demonstrates how to send the data for a `TEXT` column in chunks. It inserts the data value `'MySQL - The most popular Open Source database'` into the `text_column` column. The `mysql` variable is assumed to be a valid connection handle.

```
#define INSERT_QUERY "INSERT INTO \
                    test_long_data(text_column) VALUES(?)"

MYSQL_BIND bind[1];
long        length;

stmt = mysql_stmt_init(mysql);
if (!stmt)
{
    fprintf(stderr, "mysql_stmt_init(), out of memory\n");
    exit(0);
}
if (mysql_stmt_prepare(stmt, INSERT_QUERY, strlen(INSERT_QUERY))
{
    fprintf(stderr, "\n mysql_stmt_prepare(), INSERT failed");
    fprintf(stderr, "\n %s", mysql_stmt_error(stmt));
    exit(0);
}
memset(bind, 0, sizeof(bind));
bind[0].buffer_type= MYSQL_TYPE_STRING;
bind[0].length= &length;
bind[0].is_null= 0;

/* Bind the buffers */
if (mysql_stmt_bind_param(stmt, bind))
{
    fprintf(stderr, "\n param bind failed");
    fprintf(stderr, "\n %s", mysql_stmt_error(stmt));
    exit(0);
}

/* Supply data in chunks to server */
if (mysql_stmt_send_long_data(stmt,0,"MySQL",5))
{
    fprintf(stderr, "\n send_long_data failed");
    fprintf(stderr, "\n %s", mysql_stmt_error(stmt));
    exit(0);
}

/* Supply the next piece of data */
if (mysql_stmt_send_long_data(stmt,0,
    " - The most popular Open Source database",40))
{
    fprintf(stderr, "\n send_long_data failed");
    fprintf(stderr, "\n %s", mysql_stmt_error(stmt));
    exit(0);
}

/* Now, execute the query */
if (mysql_stmt_execute(stmt))
{
    fprintf(stderr, "\n mysql_stmt_execute failed");
    fprintf(stderr, "\n %s", mysql_stmt_error(stmt));
    exit(0);
}
```

### 20.9.7.26. `mysql_stmt_sqlstate()`

```
const char *mysql_stmt_sqlstate(MYSQL_STMT *stmt)
```

#### Description

For the statement specified by `stmt`, `mysql_stmt_sqlstate()` returns a null-terminated string containing the SQLSTATE error code for the most recently invoked prepared statement API function that can succeed or fail. The error code consists of five characters. "00000" means "no error." The values are specified by ANSI SQL and ODBC. For a list of possible values, see [Appendix B, Errors, Error Codes, and Common Problems](#).

Note that not all MySQL errors are yet mapped to SQLSTATE codes. The value "HY000" (general error) is used for unmapped errors.

**Return Values**

A null-terminated character string containing the SQLSTATE error code.

**20.9.7.27. `mysql_stmt_store_result()`**

```
int mysql_stmt_store_result(MYSQL_STMT *stmt)
```

**Description**

Result sets are produced by executing prepared statements for SQL statements such as `SELECT`, `SHOW`, `DESCRIBE`, and `EXPLAIN`. By default, result sets for successfully executed prepared statements are not buffered on the client and `mysql_stmt_fetch()` fetches them one at a time from the server. To cause the complete result set to be buffered on the client, call `mysql_stmt_store_result()` after binding data buffers with `mysql_stmt_bind_result()` and before calling `mysql_stmt_fetch()` to fetch rows. (For an example, see [Section 20.9.7.11](#), “`mysql_stmt_fetch()`”.)

`mysql_stmt_store_result()` is optional for result set processing, unless you will call `mysql_stmt_data_seek()`, `mysql_stmt_row_seek()`, or `mysql_stmt_row_tell()`. Those functions require a seekable result set.

It is unnecessary to call `mysql_stmt_store_result()` after executing an SQL statement that does not produce a result set, but if you do, it does not harm or cause any notable performance problem. You can detect whether the statement produced a result set by checking if `mysql_stmt_result_metadata()` returns `NULL`. For more information, refer to [Section 20.9.7.22](#), “`mysql_stmt_result_metadata()`”.

**Note**

MySQL doesn't by default calculate `MYSQL_FIELD->max_length` for all columns in `mysql_stmt_store_result()` because calculating this would slow down `mysql_stmt_store_result()` considerably and most applications doesn't need `max_length`. If you want `max_length` to be updated, you can call `mysql_stmt_attr_set(MYSQL_STMT, STMT_ATTR_UPDATE_MAX_LENGTH, &flag)` to enable this. See [Section 20.9.7.3](#), “`mysql_stmt_attr_set()`”.

**Return Values**

Zero if the results are buffered successfully. Nonzero if an error occurred.

**Errors**

- `CR_COMMANDS_OUT_OF_SYNC`  
Commands were executed in an improper order.
- `CR_OUT_OF_MEMORY`  
Out of memory.
- `CR_SERVER_GONE_ERROR`  
The MySQL server has gone away.
- `CR_SERVER_LOST`  
The connection to the server was lost during the query.
- `CR_UNKNOWN_ERROR`  
An unknown error occurred.

**20.9.8. C API Threaded Function Descriptions**

You need to use the following functions when you want to create a threaded client. See [Section 20.9.17](#), “[How to Make a Threaded Client](#)”.

**20.9.8.1. `my_init()`**

```
void my_init(void)
```

**Description**

`my_init()` initializes some global variables that MySQL needs. If you are using a thread-safe client library, it also calls `mysql_thread_init()` for this thread.

It is necessary for `my_init()` to be called early in the initialization phase of a program's use of the MySQL library. However, `my_init()` is automatically called by `mysql_init()`, `mysql_library_init()`, `mysql_server_init()`, and `mysql_connect()`. If you ensure that your program invokes one of those functions before any other MySQL calls, there is no need to invoke `my_init()` explicitly.

To access the prototype for `my_init()`, your program should include these header files:

```
#include <my_global.h>
#include <my_sys.h>
```

#### Return Values

None.

### 20.9.8.2. `mysql_thread_end()`

```
void mysql_thread_end(void)
```

#### Description

This function needs to be called before calling `pthread_exit()` to free memory allocated by `mysql_thread_init()`.

`mysql_thread_end()` is not invoked automatically by the client library. It must be called explicitly to avoid a memory leak.

#### Return Values

None.

### 20.9.8.3. `mysql_thread_init()`

```
my_bool mysql_thread_init(void)
```

#### Description

This function must be called early within each created thread to initialize thread-specific variables. However, you may not necessarily need to invoke it explicitly: `mysql_thread_init()` is automatically called by `my_init()`, which itself is automatically called by `mysql_init()`, `mysql_library_init()`, `mysql_server_init()`, and `mysql_connect()`. If you invoke any of those functions, `mysql_thread_init()` will be called for you.

#### Return Values

Zero if successful. Nonzero if an error occurred.

### 20.9.8.4. `mysql_thread_safe()`

```
unsigned int mysql_thread_safe(void)
```

#### Description

This function indicates whether the client library is compiled as thread-safe.

#### Return Values

1 if the client library is thread-safe, 0 otherwise.

## 20.9.9. C API Embedded Server Function Descriptions

MySQL applications can be written to use an embedded server. See [Section 20.8, “libmysqld, the Embedded MySQL Server Library”](#). To write such an application, you must link it against the `libmysqld` library by using the `-lmysqld` flag rather than linking it against the `libmysqlclient` client library by using the `-libmysqlclient` flag. However, the calls to initialize and finalize the library are the same whether you write a client application or one that uses the embedded server: Call `mysql_library_init()` to initialize the library and `mysql_library_end()` when you are done with it. See [Section 20.9.2, “C API Function Overview”](#).

`mysql_library_init()` and `mysql_library_end()` are available as of MySQL 5.0.3. For earlier versions of MySQL 5.0, call `mysql_server_init()` and `mysql_server_end()` instead, which are equivalent. `mysql_library_init()` and `mysql_library_end()` actually are `#define` symbols that make them equivalent to `mysql_server_init()` and

`mysql_server_end()`, but the names more clearly indicate that they should be called when beginning and ending use of a MySQL C API library no matter whether the application uses `libmysqlclient` or `libmysql`.

### 20.9.9.1. `mysql_server_init()`

```
int mysql_server_init(int argc, char **argv, char **groups)
```

#### Description

This function initializes the MySQL library, which must be done before you call any other MySQL function.

As of MySQL 5.0.3, `mysql_server_init()` is deprecated and you should call `mysql_library_init()` instead. See [Section 20.9.3.40](#), “`mysql_library_init()`”.

#### Return Values

Zero if successful. Nonzero if an error occurred.

### 20.9.9.2. `mysql_server_end()`

```
void mysql_server_end(void)
```

#### Description

This function finalizes the MySQL library. You should call it when you are done using the library.

As of MySQL 5.0.3, `mysql_server_end()` is deprecated and you should call `mysql_library_end()` instead. See [Section 20.9.3.39](#), “`mysql_library_end()`”.

#### Return Values

None.

## 20.9.10. Common Questions and Problems When Using the C API

### MySQL Enterprise

Subscribers to MySQL Enterprise will find articles about the C API in the MySQL Knowledge Base. Access to the Knowledge Base collection of articles is one of the advantages of subscribing to MySQL Enterprise. For more information, see <http://www.mysql.com/products/enterprise/advisors.html>.

### 20.9.10.1. Why `mysql_store_result()` Sometimes Returns `NULL` After `mysql_query()` Returns Success

It is possible for `mysql_store_result()` to return `NULL` following a successful call to `mysql_query()`. When this happens, it means one of the following conditions occurred:

- There was a `malloc()` failure (for example, if the result set was too large).
- The data couldn't be read (an error occurred on the connection).
- The query returned no data (for example, it was an `INSERT`, `UPDATE`, or `DELETE`).

You can always check whether the statement should have produced a non-empty result by calling `mysql_field_count()`. If `mysql_field_count()` returns zero, the result is empty and the last query was a statement that does not return values (for example, an `INSERT` or a `DELETE`). If `mysql_field_count()` returns a nonzero value, the statement should have produced a non-empty result. See the description of the `mysql_field_count()` function for an example.

You can test for an error by calling `mysql_error()` or `mysql_errno()`.

### 20.9.10.2. What Results You Can Get from a Query

In addition to the result set returned by a query, you can also get the following information:

- `mysql_affected_rows()` returns the number of rows affected by the last query when doing an `INSERT`, `UPDATE`, or `DELETE`.

For a fast re-create, use `TRUNCATE TABLE`.

- `mysql_num_rows()` returns the number of rows in a result set. With `mysql_store_result()`, `mysql_num_rows()` may be called as soon as `mysql_store_result()` returns. With `mysql_use_result()`, `mysql_num_rows()` may be called only after you have fetched all the rows with `mysql_fetch_row()`.
- `mysql_insert_id()` returns the ID generated by the last query that inserted a row into a table with an `AUTO_INCREMENT` index. See [Section 20.9.3.37](#), “`mysql_insert_id()`”.
- Some queries (`LOAD DATA INFILE ...`, `INSERT INTO ... SELECT ...`, `UPDATE`) return additional information. The result is returned by `mysql_info()`. See the description for `mysql_info()` for the format of the string that it returns. `mysql_info()` returns a `NULL` pointer if there is no additional information.

### 20.9.10.3. How to Get the Unique ID for the Last Inserted Row

If you insert a record into a table that contains an `AUTO_INCREMENT` column, you can obtain the value stored into that column by calling the `mysql_insert_id()` function.

You can check from your C applications whether a value was stored in an `AUTO_INCREMENT` column by executing the following code (which assumes that you've checked that the statement succeeded). It determines whether the query was an `INSERT` with an `AUTO_INCREMENT` index:

```
if ((result = mysql_store_result(&mysql)) == 0 &&
    mysql_field_count(&mysql) == 0 &&
    mysql_insert_id(&mysql) != 0)
{
    used_id = mysql_insert_id(&mysql);
}
```

When a new `AUTO_INCREMENT` value has been generated, you can also obtain it by executing a `SELECT LAST_INSERT_ID()` statement with `mysql_query()` and retrieving the value from the result set returned by the statement.

For `LAST_INSERT_ID()`, the most recently generated ID is maintained in the server on a per-connection basis. It is not changed by another client. It is not even changed if you update another `AUTO_INCREMENT` column with a non-magic value (that is, a value that is not `NULL` and not `0`). Using `LAST_INSERT_ID()` and `AUTO_INCREMENT` columns simultaneously from multiple clients is perfectly valid. Each client will receive the last inserted ID for the last statement *that* client executed.

If you want to use the ID that was generated for one table and insert it into a second table, you can use SQL statements like this:

```
INSERT INTO foo (auto,text)
VALUES(NULL,'text');          # generate ID by inserting NULL
INSERT INTO foo2 (id,text)
VALUES(LAST_INSERT_ID(),'text'); # use ID in second table
```

Note that `mysql_insert_id()` returns the value stored into an `AUTO_INCREMENT` column, whether that value is automatically generated by storing `NULL` or `0` or was specified as an explicit value. `LAST_INSERT_ID()` returns only automatically generated `AUTO_INCREMENT` values. If you store an explicit value other than `NULL` or `0`, it does not affect the value returned by `LAST_INSERT_ID()`.

For more information on obtaining the last ID in an `AUTO_INCREMENT` column:

- For information on `LAST_INSERT_ID()`, which can be used within an SQL statement, see [Section 11.10.3](#), “Information Functions”.
- For information on `mysql_insert_id()`, the function you use from within the C API, see [Section 20.9.3.37](#), “`mysql_insert_id()`”.
- For information on obtaining the auto-incremented value when using Connector/J see [Section 20.4.5](#), “Connector/J Notes and Tips”.
- For information on obtaining the auto-incremented value when using Connector/ODBC see [Section 20.1.7.1.1](#), “Obtaining Auto-Increment Values”.

### 20.9.10.4. Problems Linking with the C API

When linking with the C API, the following errors may occur on some systems:

```
gcc -g -o client test.o -L/usr/local/lib/mysql \
    -lmysqlclient -lsocket -lnsl
Undefined      first referenced
symbol         in file
```

```
floor      /usr/local/lib/mysql/libmysqlclient.a(password.o)
ld: fatal: Symbol referencing errors. No output written to client
```

If this happens on your system, you must include the math library by adding `-lm` to the end of the compile/link line.

## 20.9.11. Controlling Automatic Reconnection Behavior

The MySQL client library can perform an automatic reconnection to the server if it finds that the connection is down when you attempt to send a statement to the server to be executed. In this case, the library tries once to reconnect to the server and send the statement again.

If it is important for your application to know that the connection has been dropped (so that it can exit or take action to adjust for the loss of state information), be sure to disable auto-reconnect. This can be done explicitly by calling `mysql_options()` with the `MYSQL_OPT_RECONNECT` option:

```
my_bool reconnect = 0;
mysql_options(&mysql, MYSQL_OPT_RECONNECT, &reconnect);
```

In MySQL 5.0, auto-reconnect was enabled by default until MySQL 5.0.3, and disabled by default thereafter. The `MYSQL_OPT_RECONNECT` option is available as of MySQL 5.0.13.

If the connection has gone down, the `mysql_ping()` function performs a reconnect if auto-reconnect is enabled. If auto-reconnect is disabled, `mysql_ping()` returns an error instead.

Some client programs might provide the capability of controlling automatic reconnection. For example, `mysql` reconnects by default, but the `--skip-reconnect` option can be used to suppress this behavior.

If an automatic reconnection does occur (for example, as a result of calling `mysql_ping()`), there is no explicit indication of it. To check for reconnection, call `mysql_thread_id()` to get the original connection identifier before calling `mysql_ping()`, and then call `mysql_thread_id()` again to see whether the identifier has changed.

Automatic reconnection can be convenient because you need not implement your own reconnect code, but if a reconnection does occur, several aspects of the connection state are reset and your application will not know about it. The connection-related state is affected as follows:

- Any active transactions are rolled back and autocommit mode is reset.
- All table locks are released.
- All `TEMPORARY` tables are closed (and dropped).
- Session variables are reinitialized to the values of the corresponding variables. This also affects variables that are set implicitly by statements such as `SET NAMES`.
- User variable settings are lost.
- Prepared statements are released.
- `HANDLER` variables are closed.
- The value of `LAST_INSERT_ID()` is reset to 0.
- Locks acquired with `GET_LOCK()` are released.

If the connection drops, it is possible that the session associated with the connection on the server side will still be running if the server has not yet detected that the client is no longer connected. In this case, any locks held by the original connection still belong to that session, so you may want to kill it by calling `mysql_kill()`.

## 20.9.12. C API Support for Multiple Statement Execution

By default, `mysql_query()` and `mysql_real_query()` interpret their statement string argument as a single statement to be executed, and you process the result according to whether the statement produces a result set (a set of rows, as for `SELECT`) or an affected-rows count (as for `INSERT`, `UPDATE`, and so forth).

MySQL 5.0 also supports the execution of a string containing multiple statements separated by semicolon (“;”) characters. This capability is enabled by special options that are specified either when you connect to the server with `mysql_real_connect()` or after connecting by calling `mysql_set_server_option()`.

Executing a multiple-statement string can produce multiple result sets or row-count indicators. Processing these results involves a different approach than for the single-statement case: After handling the result from the first statement, it is necessary to check whether more results exist and process them in turn if so. To support multiple-result processing, the C API includes the `mysql_more_results()` and `mysql_next_result()` functions. These functions are used at the end of a loop that iterates as long as more results are available. *Failure to process the result this way may result in a dropped connection to the server.*

Multiple-result processing also is required if you execute `CALL` statements for stored procedures. Results from a stored procedure have these characteristics:

- Statements within the procedure may produce result sets (for example, if it executes `SELECT` statements). These result sets are returned in the order that they are produced as the procedure executes.

In general, the caller cannot know how many result sets a procedure will return. Procedure execution may depend on loops or conditional statements that cause the execution path to differ from one call to the next. Therefore, you must be prepared to retrieve multiple results.

- The final result from the procedure is a status result that includes no result set. The status indicates whether the procedure succeeded or an error occurred.

The multiple statement and result capabilities can be used only with `mysql_query()` or `mysql_real_query()`. They cannot be used with the prepared statement interface. Prepared statement handles are defined to work only with strings that contain a single statement. See [Section 20.9.4, “C API Prepared Statements”](#).

To enable multiple-statement execution and result processing, the following options may be used:

- The `mysql_real_connect()` function has a `flags` argument for which two option values are relevant:
  - `CLIENT_MULTI_RESULTS` enables the client program to process multiple results. This option *must* be enabled if you execute `CALL` statements for stored procedures that produce result sets. Otherwise, such procedures result in an error `Error 1312 (0A000): PROCEDURE proc_name can't return a result set in the given context`.
  - `CLIENT_MULTI_STATEMENTS` enables `mysql_query()` and `mysql_real_query()` to execute statement strings containing multiple statements separated by semicolons. This option also enables `CLIENT_MULTI_RESULTS` implicitly, so a `flags` argument of `CLIENT_MULTI_STATEMENTS` to `mysql_real_connect()` is equivalent to an argument of `CLIENT_MULTI_STATEMENTS | CLIENT_MULTI_RESULTS`. That is, `CLIENT_MULTI_STATEMENTS` is sufficient to enable multiple-statement execution and all multiple-result processing.
- After the connection to the server has been established, you can use the `mysql_set_server_option()` function to enable or disable multiple-statement execution by passing it an argument of `MYSQL_OPTION_MULTI_STATEMENTS_ON` or `MYSQL_OPTION_MULTI_STATEMENTS_OFF`. Enabling multiple-statement execution with this function also enables processing of “simple” results for a multiple-statement string where each statement produces a single result, but is *not* sufficient to allow processing of stored procedures that produce result sets.

The following procedure outlines a suggested strategy for handling multiple statements:

1. Pass `CLIENT_MULTI_STATEMENTS` to `mysql_real_connect()`, to fully enable multiple-statement execution and multiple-result processing.
2. After calling `mysql_query()` or `mysql_real_query()` and verifying that it succeeds, enter a loop within which you process statement results.
3. For each iteration of the loop, handle the current statement result, retrieving either a result set or an affected-rows count. If an error occurs, exit the loop.
4. At the end of the loop, call `mysql_next_result()` to check whether another result exists and initiate retrieval for it if so. If no more results are available, exit the loop.

One possible implementation of the preceding strategy is shown following. The final part of the loop can be reduced to a simple test of whether `mysql_next_result()` returns nonzero. The code as written distinguishes between no more results and an error, which allows a message to be printed for the latter occurrence.

```
/* connect to server with the CLIENT_MULTI_STATEMENTS option */
if (mysql_real_connect (mysql, host_name, user_name, password,
    db_name, port_num, socket_name, CLIENT_MULTI_STATEMENTS) == NULL)
{
    printf("mysql_real_connect() failed\n");
    mysql_close(mysql);
}
```

```

    exit(1);
}

/* execute multiple statements */
status = mysql_query(mysql,
    "DROP TABLE IF EXISTS test_table;\
    CREATE TABLE test_table(id INT);\
    INSERT INTO test_table VALUES(10);\
    UPDATE test_table SET id=20 WHERE id=10;\
    SELECT * FROM test_table;\
    DROP TABLE test_table");

if (status)
{
    printf("Could not execute statement(s)");
    mysql_close(mysql);
    exit(0);
}

/* process each statement result */
do {
    /* did current statement return data? */
    result = mysql_store_result(mysql);
    if (result)
    {
        /* yes; process rows and free the result set */
        process_result_set(mysql, result);
        mysql_free_result(result);
    }
    else /* no result set or error */
    {
        if (mysql_field_count(mysql) == 0)
        {
            printf("%lld rows affected\n",
                mysql_affected_rows(mysql));
        }
        else /* some error occurred */
        {
            printf("Could not retrieve result set\n");
            break;
        }
    }
}
/* more results? -1 = no, >0 = error, 0 = yes (keep looping) */
if ((status = mysql_next_result(mysql)) > 0)
    printf("Could not execute statement\n");
} while (status == 0);

mysql_close(mysql);

```

### 20.9.13. C API Prepared Statement Problems

Here follows a list of the currently known problems with prepared statements:

- `TIME`, `TIMESTAMP`, and `DATETIME` do not support parts of seconds (for example, from `DATE_FORMAT()`).
- When converting an integer to string, `ZEROFILL` is honored with prepared statements in some cases where the MySQL server doesn't print the leading zeros. (For example, with `MIN(number-with-zerofill)`).
- When converting a floating-point number to a string in the client, the rightmost digits of the converted value may differ slightly from those of the original value.
- *Prepared statements do not use the query cache, even in cases where a query does not contain any placeholders.* See [Section 7.5.5.1, “How the Query Cache Operates”](#).
- Prepared statements do not support multi-statements (that is, multiple statements within a single string separated by “;” characters).
- In MySQL 5.0, prepared `CALL` statements cannot invoke stored procedures that return result sets because prepared statements do not support multiple result sets. Nor can the calling application access a stored procedure's `OUT` or `INOUT` parameters when the procedure returns. These capabilities are supported beginning with MySQL 6.0.

### 20.9.14. C API Prepared Statement Handling of Date and Time Values

The binary (prepared statement) protocol allows you to send and receive date and time values (`DATE`, `TIME`, `DATETIME`, and `TIMESTAMP`), using the `MYSQL_TIME` structure. The members of this structure are described in [Section 20.9.5, “C API Prepared Statement Data types”](#).

To send temporal data values, create a prepared statement using `mysql_stmt_prepare()`. Then, before calling `mysql_stmt_execute()` to execute the statement, use the following procedure to set up each temporal parameter:

1. In the `MYSQL_BIND` structure associated with the data value, set the `buffer_type` member to the type that indicates what kind of temporal value you're sending. For `DATE`, `TIME`, `DATETIME`, or `TIMESTAMP` values, set `buffer_type` to `MYSQL_TYPE_DATE`, `MYSQL_TYPE_TIME`, `MYSQL_TYPE_DATETIME`, or `MYSQL_TYPE_TIMESTAMP`, respectively.
2. Set the `buffer` member of the `MYSQL_BIND` structure to the address of the `MYSQL_TIME` structure in which you pass the temporal value.
3. Fill in the members of the `MYSQL_TIME` structure that are appropriate for the type of temporal value to be passed.

Use `mysql_stmt_bind_param()` to bind the parameter data to the statement. Then you can call `mysql_stmt_execute()`.

To retrieve temporal values, the procedure is similar, except that you set the `buffer_type` member to the type of value you expect to receive, and the `buffer` member to the address of a `MYSQL_TIME` structure into which the returned value should be placed. Use `mysql_stmt_bind_result()` to bind the buffers to the statement after calling `mysql_stmt_execute()` and before fetching the results.

Here is a simple example that inserts `DATE`, `TIME`, and `TIMESTAMP` data. The `mysql` variable is assumed to be a valid connection handle.

```

MYSQL_TIME  ts;
MYSQL_BIND  bind[3];
MYSQL_STMT  *stmt;

strmov(query, "INSERT INTO test_table(date_field, time_field, \
              timestamp_field) VALUES(?,?,?);");

stmt = mysql_stmt_init(mysql);
if (!stmt)
{
    fprintf(stderr, " mysql_stmt_init(), out of memory\n");
    exit(0);
}
if (mysql_stmt_prepare(mysql, query, strlen(query)))
{
    fprintf(stderr, "\n mysql_stmt_prepare(), INSERT failed");
    fprintf(stderr, "\n %s", mysql_stmt_error(stmt));
    exit(0);
}

/* set up input buffers for all 3 parameters */
bind[0].buffer_type= MYSQL_TYPE_DATE;
bind[0].buffer= (char *)&ts;
bind[0].is_null= 0;
bind[0].length= 0;
...
bind[1]= bind[2]= bind[0];
...

mysql_stmt_bind_param(stmt, bind);

/* supply the data to be sent in the ts structure */
ts.year= 2002;
ts.month= 02;
ts.day= 03;

ts.hour= 10;
ts.minute= 45;
ts.second= 20;

mysql_stmt_execute(stmt);
..

```

## 20.9.15. C API Support for Prepared `CALL` Statements

In MySQL 5.0, prepared `CALL` statements can be used only for stored procedures that produce at most one result set. Nor can the calling application use placeholders for `OUT` or `INOUT` parameters.

MySQL 6.0 expands prepared `CALL` statement support for stored procedures that produce multiple result sets and to provide placeholder access to `OUT` and `INOUT` parameters.

## 20.9.16. Building Client Programs

If you compile MySQL clients that you've written yourself or that you obtain from a third-party, they must be linked using the `-lmysqlclient -lz` options in the link command. You may also need to specify a `-L` option to tell the linker where to find the library. For example, if the library is installed in `/usr/local/mysql/lib`, use `-L/usr/local/mysql/lib -lmysqlclient -lz` in the link command.

For clients that use MySQL header files, you may need to specify an `-I` option when you compile them (for example, `-I/usr/local/mysql/include`), so that the compiler can find the header files.

To make it simpler to compile MySQL programs on Unix, we have provided the `mysql_config` script for you. See [Section 4.7.2, “mysql\\_config — Get Compile Options for Compiling Clients”](#).

You can use it to compile a MySQL client as follows:

```
CFG=/usr/local/mysql/bin/mysql_config
sh -c "gcc -o progname ` $CFG --cflags ` progname.c ` $CFG --libs `"
```

The `sh -c` is needed to get the shell not to treat the output from `mysql_config` as one word.

#### MySQL Enterprise

Subscribers to MySQL Enterprise will find an example client program in the Knowledge Base article, [Sample C program using the embedded MySQL server library](#). Access to the MySQL Knowledge Base collection of articles is one of the advantages of subscribing to MySQL Enterprise. For more information, see <http://www.mysql.com/products/enterprise/advisors.html>.

## 20.9.17. How to Make a Threaded Client

The client library is almost thread-safe. The biggest problem is that the subroutines in `net.c` that read from sockets are not interrupt safe. This was done with the thought that you might want to have your own alarm that can break a long read to a server. If you install interrupt handlers for the `SIGPIPE` interrupt, the socket handling should be thread-safe.

To avoid aborting the program when a connection terminates, MySQL blocks `SIGPIPE` on the first call to `mysql_library_init()`, `mysql_init()`, or `mysql_connect()`. If you want to use your own `SIGPIPE` handler, you should first call `mysql_library_init()` and then install your handler.

Before MySQL 4.0, binary client libraries that we provided other than those for Windows were not normally compiled with the thread-safe option. Current binary distributions should have both a normal and a thread-safe client library.

To create a threaded client where you can interrupt the client from other threads and set timeouts when talking with the MySQL server, you should use the `net_serv.o` code that the server uses and the `-lmysys`, `-lmystrings`, and `-ldbbug` libraries.

If you don't need interrupts or timeouts, you can just compile a thread-safe client library (`mysqlclient_r`) and use it. In this case, you don't have to worry about the `net_serv.o` object file or the other MySQL libraries.

When using a threaded client and you want to use timeouts and interrupts, you can make great use of the routines in the `thr_alarm.c` file. If you are using routines from the `mysys` library, the only thing you must remember is to call `my_init()` first! See [Section 20.9.8, “C API Threaded Function Descriptions”](#).

In all cases, be sure to initialize the client library by calling `mysql_library_init()` before calling any other MySQL functions. When you are done with the library, call `mysql_library_end()`.

`mysql_real_connect()` is not thread-safe by default. The following notes describe how to compile a thread-safe client library and use it in a thread-safe manner. (The notes below for `mysql_real_connect()` also apply to the older `mysql_connect()` routine as well, although `mysql_connect()` is deprecated and should no longer be used.)

To make `mysql_real_connect()` thread-safe, you must configure your MySQL distribution with this command:

```
shell> ./configure --enable-thread-safe-client
```

Then recompile the distribution to create a thread-safe client library, `libmysqlclient_r`. (Assuming that your operating system has a thread-safe `gethostbyname_r()` function.) This library is thread-safe per connection. You can let two threads share the same connection with the following caveats:

- Two threads can't send a query to the MySQL server at the same time on the same connection. In particular, you have to ensure that between calls to `mysql_query()` and `mysql_store_result()`, no other thread is using the same connection.
- Many threads can access different result sets that are retrieved with `mysql_store_result()`.
- If you use `mysql_use_result()`, you must ensure that no other thread is using the same connection until the result set is closed. However, it really is best for threaded clients that share the same connection to use `mysql_store_result()`.
- If you want to use multiple threads on the same connection, you must have a mutex lock around your pair of `mysql_query()` and `mysql_store_result()` calls. Once `mysql_store_result()` is ready, the lock can be released and other threads may query the same connection.

- If you use POSIX threads, you can use `pthread_mutex_lock()` and `pthread_mutex_unlock()` to establish and release a mutex lock.

You need to know the following if a thread that is calling MySQL functions did not create the connection to the MySQL database:

When you call `mysql_init()`, MySQL creates a thread-specific variable for the thread that is used by the debug library (among other things). If you call a MySQL function before the thread has called `mysql_init()`, the thread does not have the necessary thread-specific variables in place and you are likely to end up with a core dump sooner or later. To get things to work smoothly you must do the following:

1. Call `mysql_library_init()` before any other MySQL functions. It is not thread-safe, so call it before threads are created, or protect the call with a mutex.
2. Arrange for `mysql_thread_init()` to be called early in the thread handler before calling any MySQL function. If you call `mysql_init()`, they will call `mysql_thread_init()` for you.
3. In the thread, call `mysql_thread_end()` before calling `pthread_exit()`. This frees the memory used by MySQL thread-specific variables.

The preceding notes regarding `mysql_init()` also apply to `mysql_connect()`, which calls `mysql_init()`.

If “undefined symbol” errors occur when linking your client with `libmysqlclient_r`, in most cases this is because you haven't included the thread libraries on the link/compile command.

## 20.10. MySQL PHP API

PHP is a server-side, HTML-embedded scripting language that may be used to create dynamic Web pages. It is available for most operating systems and Web servers, and can access most common databases, including MySQL. PHP may be run as a separate program or compiled as a module for use with the Apache Web server.

PHP actually provides two different MySQL API extensions:

- `mysql`: Available for PHP versions 4 and 5, this extension is intended for use with MySQL versions prior to MySQL 4.1. This extension does not support the improved authentication protocol used in MySQL 4.1, nor does it support prepared statements or multiple statements. If you wish to use this extension with MySQL 4.1, you will likely want to configure the MySQL server to use the `--old-passwords` option (see Section B.1.2.4, “Client does not support authentication protocol”). This extension is documented on the PHP Web site at <http://php.net/mysql>.
- Section 20.10.2, “MySQL Improved Extension (`mysqli`)” - Stands for “MySQL, Improved”; this extension is available only in PHP 5. It is intended for use with MySQL 4.1.1 and later. This extension fully supports the authentication protocol used in MySQL 5.0, as well as the Prepared Statements and Multiple Statements APIs. In addition, this extension provides an advanced, object-oriented programming interface. You can read the documentation for the `mysqli` extension at <http://php.net/mysql>. Helpful article can be found at <http://devzone.zend.com/node/view/id/686> and <http://devzone.zend.com/node/view/id/687>.

If you're experiencing problems with enabling both the `mysql` and the `mysqli` extension when building PHP on Linux yourself, see Section 20.10.6, “Enabling Both `mysql` and `mysqli` in PHP”.

The PHP distribution and documentation are available from the [PHP Web site](http://php.net).

### MySQL Enterprise

MySQL Enterprise subscribers will find more information about MySQL and PHP in the Knowledge Base articles found at [PHP](http://php.net). Access to the MySQL Knowledge Base collection of articles is one of the advantages of subscribing to MySQL Enterprise. For more information, see <http://www.mysql.com/products/enterprise/knowledgebase.html>.

*Portions of this section are Copyright (c) 1997-2008 the PHP Documentation Group* This material may be distributed only subject to the terms and conditions set forth in the Creative Commons Attribution 3.0 License or later. A copy of the Creative Commons Attribution 3.0 license is distributed with this manual. The latest version is presently available at <http://creativecommons.org/licenses/by/3.0/>. This material may be distributed only subject to the terms and conditions set forth in the Open Publication License, v1.0.8 or later (the latest version is presently available at <http://www.opencontent.org/openpub/>).

### 20.10.1. MySQL

Copyright 1997-2008 the PHP Documentation Group.

These functions allow you to access MySQL database servers. More information about MySQL can be found at <http://www.mysql.com/>.

Documentation for MySQL can be found at <http://dev.mysql.com/doc/>.

## 20.10.1.1. Installing/Configuring

Copyright 1997-2008 the PHP Documentation Group.

### 20.10.1.1.1. Requirements

Copyright 1997-2008 the PHP Documentation Group.

In order to have these functions available, you must compile PHP with MySQL support.

### 20.10.1.1.2. Installation

Copyright 1997-2008 the PHP Documentation Group.

For compiling, simply use the `--with-mysql[=DIR]` configuration option where the optional `[DIR]` points to the MySQL installation directory.

Although this MySQL extension is compatible with MySQL 4.1.0 and greater, it doesn't support the extra functionality that these versions provide. For that, use the [MySQLi](#) extension.

If you would like to install the `mysql` extension along with the `mysqli` extension you have to use the same client library to avoid any conflicts.

#### 20.10.1.1.2.1. Installation on Linux Systems

Copyright 1997-2008 the PHP Documentation Group.

##### 20.10.1.1.2.1.1. PHP 4

Copyright 1997-2008 the PHP Documentation Group.

The option `--with-mysql` is enabled by default. This default behavior may be disabled with the `--without-mysql` configure option. If MySQL is enabled without specifying the path to the MySQL install DIR, PHP will use the bundled MySQL client libraries.

Users who run other applications that use MySQL (for example, `auth-mysql`) should not use the bundled library, but rather specify the path to MySQL's install directory, like so: `--with-mysql=/path/to/mysql`. This will force PHP to use the client libraries installed by MySQL, thus avoiding any conflicts.

##### 20.10.1.1.2.1.2. PHP 5+

Copyright 1997-2008 the PHP Documentation Group.

MySQL is not enabled by default, nor is the MySQL library bundled with PHP. Read this [FAQ](#) for details on why. Use the `--with-mysql[=DIR]` configure option to include MySQL support. You can download *headers and libraries* from [MySQL](#).

#### 20.10.1.1.2.2. Installation on Windows Systems

Copyright 1997-2008 the PHP Documentation Group.

##### 20.10.1.1.2.2.1. PHP 4

Copyright 1997-2008 the PHP Documentation Group.

The PHP MySQL extension is compiled into PHP.

##### 20.10.1.1.2.2.2. PHP 5+

Copyright 1997-2008 the PHP Documentation Group.

MySQL is no longer enabled by default, so the `php_mysql.dll` DLL must be enabled inside of `php.ini`. Also, PHP needs access to the MySQL client library. A file named `libmysql.dll` is included in the Windows PHP distribution and in order for PHP to talk to MySQL this file needs to be available to the Windows systems `PATH`. See the FAQ titled "[How do I add my PHP directory to the PATH on Windows](#)" for information on how to do this. Although copying `libmysql.dll` to the Windows system directory also works (because the system directory is by default in the system's `PATH`), it's not recommended.

As with enabling any PHP extension (such as `php_mysql.dll`), the PHP directive `extension_dir` should be set to the directory where the PHP extensions are located. See also the [Manual Windows Installation Instructions](#). An example `extension_dir` value for PHP 5 is `c:\php\ext`

#### Note

If when starting the web server an error similar to the following occurs: "Unable to load dynamic library '.\php\_mysql.dll'", this is because `php_mysql.dll` and/or `libmysql.dll` cannot be found by the system.

### 20.10.1.1.2.3. MySQL Installation Notes

Copyright 1997-2008 the PHP Documentation Group.

#### Warning

Crashes and startup problems of PHP may be encountered when loading this extension in conjunction with the `recode` extension. See the [recode](#) extension for more information.

#### Note

If you need charsets other than *latin* (default), you have to install external (not bundled) `libmysql` with compiled charset support.

### 20.10.1.1.3. Runtime Configuration

Copyright 1997-2008 the PHP Documentation Group.

The behaviour of these functions is affected by settings in `php.ini`.

**Table 20.4. MySQL Configuration Options**

Name	Default	Changeable	Changelog
<code>mysql.allow_persistent</code>	"1"	PHP_INI_SYSTEM	
<code>mysql.max_persistent</code>	"-1"	PHP_INI_SYSTEM	
<code>mysql.max_links</code>	"-1"	PHP_INI_SYSTEM	
<code>mysql.trace_mode</code>	"0"	PHP_INI_ALL	Available since PHP 4.3.0.
<code>mysql.default_port</code>	NULL	PHP_INI_ALL	
<code>mysql.default_socket</code>	NULL	PHP_INI_ALL	Available since PHP 4.0.1.
<code>mysql.default_host</code>	NULL	PHP_INI_ALL	
<code>mysql.default_user</code>	NULL	PHP_INI_ALL	
<code>mysql.default_password</code>	NULL	PHP_INI_ALL	
<code>mysql.connect_timeout</code>	"60"	PHP_INI_ALL	PHP_INI_SYSTEM in PHP <= 4.3.2. Available since PHP 4.3.0.

For further details and definitions of the `PHP_INI_*` constants, see the [ini](#).

Here's a short explanation of the configuration directives.

<code>mysql.allow_persistent</code> boolean	Whether to allow <a href="#">persistent connections</a> to MySQL.
<code>mysql.max_persistent</code> integer	The maximum number of persistent MySQL connections per process.
<code>mysql.max_links</code> integer	The maximum number of MySQL connections per process, including persistent connections.
<code>mysql.trace_mode</code> boolean	Trace mode. When <code>mysql.trace_mode</code> is enabled, warnings for table/index scans, non free result sets, and SQL-Errors will be displayed. (Introduced in PHP 4.3.0)
<code>mysql.default_port</code> string	The default TCP port number to use when connecting to the database server if no other port is specified. If no default is specified, the port will be obtained from the <code>MYSQL_TCP_PORT</code> environment variable, the <code>mysql-tcp</code> entry in <code>/etc/services</code> or the compile-time

	<code>MYSQL_PORT</code> constant, in that order. Win32 will only use the <code>MYSQL_PORT</code> constant.
<code>mysql.default_socket</code> string	The default socket name to use when connecting to a local database server if no other socket name is specified.
<code>mysql.default_host</code> string	The default server host to use when connecting to the database server if no other host is specified. Doesn't apply in <a href="#">SQL safe mode</a> .
<code>mysql.default_user</code> string	The default user name to use when connecting to the database server if no other name is specified. Doesn't apply in <a href="#">SQL safe mode</a> .
<code>mysql.default_password</code> string	The default password to use when connecting to the database server if no other password is specified. Doesn't apply in <a href="#">SQL safe mode</a> .
<code>mysql.connect_timeout</code> integer	Connect timeout in seconds. On Linux this timeout is also used for waiting for the first answer from the server.

#### 20.10.1.1.4. Resource Types

Copyright 1997-2008 the PHP Documentation Group.

There are two resource types used in the MySQL module. The first one is the link identifier for a database connection, the second a resource which holds the result of a query.

#### 20.10.1.2. Predefined Constants

Copyright 1997-2008 the PHP Documentation Group.

The constants below are defined by this extension, and will only be available when the extension has either been compiled into PHP or dynamically loaded at runtime.

Since PHP 4.3.0 it is possible to specify additional client flags for the `mysql_connect` and `mysql_pconnect` functions. The following constants are defined:

**Table 20.5. MySQL client constants**

Constant	Description
<code>MYSQL_CLIENT_COMPRESS</code>	Use compression protocol
<code>MYSQL_CLIENT_IGNORE_SPACE</code>	Allow space after function names
<code>MYSQL_CLIENT_INTERACTIVE</code>	Allow interactive_timeout seconds (instead of wait_timeout) of inactivity before closing the connection.
<code>MYSQL_CLIENT_SSL</code>	Use SSL encryption. This flag is only available with version 4.x of the MySQL client library or newer. Version 3.23.x is bundled both with PHP 4 and Windows binaries of PHP 5.

The function `mysql_fetch_array` uses a constant for the different types of result arrays. The following constants are defined:

**Table 20.6. MySQL fetch constants**

Constant	Description
<code>MYSQL_ASSOC</code>	Columns are returned into the array having the fieldname as the array index.
<code>MYSQL_BOTH</code>	Columns are returned into the array having both a numerical index and the fieldname as the array index.
<code>MYSQL_NUM</code>	Columns are returned into the array having a numerical index to the fields. This index starts with 0, the first field in the result.

#### 20.10.1.3. Examples

Copyright 1997-2008 the PHP Documentation Group.

##### 20.10.1.3.1. Basic

This simple example shows how to connect, execute a query, print resulting rows and disconnect from a MySQL database.

### Example 20.13. MySQL extension overview example

Copyright 1997-2008 the PHP Documentation Group.

```
<?php
// Connecting, selecting database
$link = mysql_connect('mysql_host', 'mysql_user', 'mysql_password')
    or die('Could not connect: ' . mysql_error());
echo 'Connected successfully';
mysql_select_db('my_database') or die('Could not select database');

// Performing SQL query
$query = 'SELECT * FROM my_table';
$result = mysql_query($query) or die('Query failed: ' . mysql_error());

// Printing results in HTML
echo "<table>\n";
while ($line = mysql_fetch_array($result, MYSQL_ASSOC)) {
    echo "\t<tr>\n";
    foreach ($line as $col_value) {
        echo "\t\t<td>$col_value</td>\n";
    }
    echo "\t</tr>\n";
}
echo "</table>\n";

// Free resultset
mysql_free_result($result);

// Closing connection
mysql_close($link);
?>
```

## 20.10.1.4. MySQL Functions

Copyright 1997-2008 the PHP Documentation Group.

### Note

Most MySQL functions accept *link\_identifier* as the last optional parameter. If it is not provided, last opened connection is used. If it doesn't exist, connection is tried to establish with default parameters defined in `php.ini`. If it is not successful, functions return `FALSE`.

### 20.10.1.4.1. `mysql_affected_rows`

Copyright 1997-2008 the PHP Documentation Group.

- `mysql_affected_rows`

Get number of affected rows in previous MySQL operation

#### Description

```
int mysql_affected_rows(resource link_identifier);
```

Get the number of affected rows by the last INSERT, UPDATE, REPLACE or DELETE query associated with *link\_identifier*.

#### Parameters

*link\_identifier*

The MySQL connection. If the link identifier is not specified, the last link opened by `mysql_connect` is assumed. If no such link is found, it will try to create one as if `mysql_connect` was called with no arguments. If by chance no connection is found or established, an `E_WARNING` level error is generated.

#### Return Values

Returns the number of affected rows on success, and -1 if the last query failed.

If the last query was a DELETE query with no WHERE clause, all of the records will have been deleted from the table but this function will return zero with MySQL versions prior to 4.1.2.

When using UPDATE, MySQL will not update columns where the new value is the same as the old value. This creates the possibility that `mysql_affected_rows` may not actually equal the number of rows matched, only the number of rows that were literally affected by the query.

The REPLACE statement first deletes the record with the same primary key and then inserts the new record. This function returns the number of deleted records plus the number of inserted records.

### Examples

#### Example 20.14. `mysql_affected_rows` example

```
<?php
$link = mysql_connect('localhost', 'mysql_user', 'mysql_password');
if (!$link) {
    die('Could not connect: ' . mysql_error());
}
mysql_select_db('mydb');

/* this should return the correct numbers of deleted records */
mysql_query('DELETE FROM mytable WHERE id < 10');
printf("Records deleted: %d\n", mysql_affected_rows());

/* with a where clause that is never true, it should return 0 */
mysql_query('DELETE FROM mytable WHERE 0');
printf("Records deleted: %d\n", mysql_affected_rows());
?>
```

The above example will output something similar to:

```
Records deleted: 10
Records deleted: 0
```

#### Example 20.15. `mysql_affected_rows` example using transactions

```
<?php
$link = mysql_connect('localhost', 'mysql_user', 'mysql_password');
if (!$link) {
    die('Could not connect: ' . mysql_error());
}
mysql_select_db('mydb');

/* Update records */
mysql_query("UPDATE mytable SET used=1 WHERE id < 10");
printf ("Updated records: %d\n", mysql_affected_rows());
mysql_query("COMMIT");
?>
```

The above example will output something similar to:

```
Updated Records: 10
```

**Notes****Transactions**

If you are using transactions, you need to call `mysql_affected_rows` after your INSERT, UPDATE, or DELETE query, not after the COMMIT.

**SELECT Statements**

To retrieve the number of rows returned by a SELECT, it is possible to use `mysql_num_rows`.

**See Also**

`mysql_num_rows`  
`mysql_info`

**20.10.1.4.2. `mysql_change_user`**

Copyright 1997-2008 the PHP Documentation Group.

- `mysql_change_user`

Change logged in user of the active connection

**Description**

```
int mysql_change_user(string user,
                    string password,
                    string database,
                    resource link_identifier);
```

`mysql_change_user` changes the logged in user of the current active connection, or the connection given by the optional `link_identifier` parameter. If a database is specified, this will be the current database after the user has been changed. If the new user and password authorization fails, the current connected user stays active.

This function is deprecated and no longer exists in PHP.

**Parameters**

<code>user</code>	The new MySQL username.
<code>password</code>	The new MySQL password.
<code>database</code>	The MySQL database. If not specified, the current selected database is used.
<code>link_identifier</code>	The MySQL connection. If the link identifier is not specified, the last link opened by <code>mysql_connect</code> is assumed. If no such link is found, it will try to create one as if <code>mysql_connect</code> was called with no arguments. If by chance no connection is found or established, an <code>E_WARNING</code> level error is generated.

**Return Values**

Returns `TRUE` on success or `FALSE` on failure.

**ChangeLog**

Version	Description
3.0.14	This function was removed from PHP.

**Notes****Requirements**

This function requires MySQL 3.23.3 or higher.

#### See Also

[mysql\\_connect](#)  
[mysql\\_select\\_db](#)  
[mysql\\_query](#)

### 20.10.1.4.3. [mysql\\_client\\_encoding](#)

Copyright 1997-2008 the PHP Documentation Group.

- [mysql\\_client\\_encoding](#)

Returns the name of the character set

#### Description

```
string mysql_client_encoding(resource link_identifier);
```

Retrieves the `character_set` variable from MySQL.

#### Parameters

*link\_identifier* The MySQL connection. If the link identifier is not specified, the last link opened by [mysql\\_connect](#) is assumed. If no such link is found, it will try to create one as if [mysql\\_connect](#) was called with no arguments. If by chance no connection is found or established, an `E_WARNING` level error is generated.

#### Return Values

Returns the default character set name for the current connection.

#### Examples

#### Example 20.16. [mysql\\_client\\_encoding](#) example

```
<?php
$link      = mysql_connect('localhost', 'mysql_user', 'mysql_password');
$charset  = mysql_client_encoding($link);

echo "The current character set is: $charset\n";
?>
```

The above example will output something similar to:

```
The current character set is: latin1
```

#### See Also

[mysql\\_set\\_charset](#)  
[mysql\\_real\\_escape\\_string](#)

### 20.10.1.4.4. [mysql\\_close](#)

Copyright 1997-2008 the PHP Documentation Group.

- `mysql_close`

Close MySQL connection

### Description

```
bool mysql_close(resource link_identifier);
```

`mysql_close` closes the non-persistent connection to the MySQL server that's associated with the specified link identifier. If `link_identifier` isn't specified, the last opened link is used.

Using `mysql_close` isn't usually necessary, as non-persistent open links are automatically closed at the end of the script's execution. See also [freeing resources](#).

### Parameters

*link\_identifier*

The MySQL connection. If the link identifier is not specified, the last link opened by `mysql_connect` is assumed. If no such link is found, it will try to create one as if `mysql_connect` was called with no arguments. If by chance no connection is found or established, an `E_WARNING` level error is generated.

### Return Values

Returns `TRUE` on success or `FALSE` on failure.

### Examples

#### Example 20.17. `mysql_close` example

```
<?php
$link = mysql_connect('localhost', 'mysql_user', 'mysql_password');
if (!$link) {
    die('Could not connect: ' . mysql_error());
}
echo 'Connected successfully';
mysql_close($link);
?>
```

The above example will output:

```
Connected successfully
```

### Notes

#### Note

`mysql_close` will not close persistent links created by `mysql_pconnect`.

### See Also

`mysql_connect`  
`mysql_free_result`

#### 20.10.1.4.5. `mysql_connect`

Copyright 1997-2008 the PHP Documentation Group.

- `mysql_connect`

Open a connection to a MySQL Server

### Description

```
resource mysql_connect(string server,
                      string username,
                      string password,
                      bool new_link,
                      int client_flags);
```

Opens or reuses a connection to a MySQL server.

### Parameters

<code>server</code>	The MySQL server. It can also include a port number. e.g. "hostname:port" or a path to a local socket e.g. ":/path/to/socket" for the localhost.  If the PHP directive <code>mysql.default_host</code> is undefined (default), then the default value is 'localhost:3306'. In <a href="#">SQL safe mode</a> , this parameter is ignored and value 'localhost:3306' is always used.
<code>username</code>	The username. Default value is defined by <code>mysql.default_user</code> . In <a href="#">SQL safe mode</a> , this parameter is ignored and the name of the user that owns the server process is used.
<code>password</code>	The password. Default value is defined by <code>mysql.default_password</code> . In <a href="#">SQL safe mode</a> , this parameter is ignored and empty password is used.
<code>new_link</code>	If a second call is made to <code>mysql_connect</code> with the same arguments, no new link will be established, but instead, the link identifier of the already opened link will be returned. The <code>new_link</code> parameter modifies this behavior and makes <code>mysql_connect</code> always open a new link, even if <code>mysql_connect</code> was called before with the same parameters. In <a href="#">SQL safe mode</a> , this parameter is ignored.
<code>client_flags</code>	The <code>client_flags</code> parameter can be a combination of the following constants: 128 (enable <code>LOAD DATA LOCAL</code> handling), <code>MYSQL_CLIENT_SSL</code> , <code>MYSQL_CLIENT_COMPRESS</code> , <code>MYSQL_CLIENT_IGNORE_SPACE</code> or <code>MYSQL_CLIENT_INTERACTIVE</code> . Read the section about <a href="#">Table 20.5, "MySQL client constants"</a> for further information. In <a href="#">SQL safe mode</a> , this parameter is ignored.

### Return Values

Returns a MySQL link identifier on success, or `FALSE` on failure.

### ChangeLog

Version	Description
4.3.0	Added the <code>client_flags</code> parameter.
4.2.0	Added the <code>new_link</code> parameter.
3.0.10	Added support for ":/path/to/socket" with <code>server</code> .
3.0.0	Added support for ":port" with <code>server</code> .

### Examples

#### Example 20.18. `mysql_connect` example

```
<?php
$link = mysql_connect('localhost', 'mysql_user', 'mysql_password');
```

```

if (!$link) {
    die('Could not connect: ' . mysql_error());
}
echo 'Connected successfully';
mysql_close($link);
?>

```

### Example 20.19. `mysql_connect` example using `hostname:port` syntax

```

<?php
// we connect to example.com and port 3307
$link = mysql_connect('example.com:3307', 'mysql_user', 'mysql_password');
if (!$link) {
    die('Could not connect: ' . mysql_error());
}
echo 'Connected successfully';
mysql_close($link);

// we connect to localhost at port 3307
$link = mysql_connect('127.0.0.1:3307', 'mysql_user', 'mysql_password');
if (!$link) {
    die('Could not connect: ' . mysql_error());
}
echo 'Connected successfully';
mysql_close($link);
?>

```

### Example 20.20. `mysql_connect` example using `"/path/to/socket"` syntax

```

<?php
// we connect to localhost and socket e.g. /tmp/mysql.sock

//variant 1: omit localhost
$link = mysql_connect('/:tmp/mysql', 'mysql_user', 'mysql_password');
if (!$link) {
    die('Could not connect: ' . mysql_error());
}
echo 'Connected successfully';
mysql_close($link);

// variant 2: with localhost
$link = mysql_connect('localhost:/tmp/mysql.sock', 'mysql_user', 'mysql_password');
if (!$link) {
    die('Could not connect: ' . mysql_error());
}
echo 'Connected successfully';
mysql_close($link);
?>

```

## Notes

### Note

Whenever you specify "localhost" or "localhost:port" as server, the MySQL client library will override this and try to connect to a local socket (named pipe on Windows). If you want to use TCP/IP, use "127.0.0.1" instead of "localhost". If the MySQL client library tries to connect to the wrong local socket, you should set the correct path as [ini.mysql.default-host](#) in your PHP configuration and leave the server field blank.

### Note

The link to the server will be closed as soon as the execution of the script ends, unless it's closed earlier by explicitly calling `mysql_close`.

### Note

You can suppress the error message on failure by prepending a `@` to the function name.

**Note**

Error "Can't create TCP/IP socket (10106)" usually means that the `variables_order` configure directive doesn't contain character `E`. On Windows, if the environment is not copied the `SYSTEMROOT` environment variable won't be available and PHP will have problems loading Winsock.

**See Also**

`mysql_pconnect`  
`mysql_close`

**20.10.1.4.6. mysql\_create\_db**

Copyright 1997-2008 the PHP Documentation Group.

- `mysql_create_db`  
 Create a MySQL database

**Description**

```
bool mysql_create_db(string database_name,
                    resource link_identifier);
```

`mysql_create_db` attempts to create a new database on the server associated with the specified link identifier.

**Parameters**

<i>database_name</i>	The name of the database being created.
<i>link_identifier</i>	The MySQL connection. If the link identifier is not specified, the last link opened by <code>mysql_connect</code> is assumed. If no such link is found, it will try to create one as if <code>mysql_connect</code> was called with no arguments. If by chance no connection is found or established, an <code>E_WARNING</code> level error is generated.

**Return Values**

Returns `TRUE` on success or `FALSE` on failure.

**Examples****Example 20.21. mysql\_create\_db alternative example**

The function `mysql_create_db` is deprecated. It is preferable to use `mysql_query` to issue a sql `CREATE DATABASE` statement instead.

```
<?php
$link = mysql_connect('localhost', 'mysql_user', 'mysql_password');
if (!$link) {
    die('Could not connect: ' . mysql_error());
}

$sql = 'CREATE DATABASE my_db';
if (mysql_query($sql, $link)) {
    echo "Database my_db created successfully\n";
} else {
    echo 'Error creating database: ' . mysql_error() . "\n";
}
?>
```

The above example will output something similar to:

```
Database my_db created successfully
```

## Notes

### Note

For backward compatibility, the following deprecated alias may be used: `mysql_createdb`

### Note

This function will not be available if the MySQL extension was built against a MySQL 4.x client library.

## See Also

[mysql\\_select\\_db](#)

### 20.10.1.4.7. `mysql_data_seek`

Copyright 1997-2008 the PHP Documentation Group.

- [mysql\\_data\\_seek](#)

Move internal result pointer

## Description

```
bool mysql_data_seek(resource result,
                    int row_number);
```

`mysql_data_seek` moves the internal row pointer of the MySQL result associated with the specified result identifier to point to the specified row number. The next call to a MySQL fetch function, such as `mysql_fetch_assoc`, would return that row.

`row_number` starts at 0. The `row_number` should be a value in the range from 0 to `mysql_num_rows` - 1. However if the result set is empty (`mysql_num_rows == 0`), a seek to 0 will fail with a **E\_WARNING** and `mysql_data_seek` will return `FALSE`.

## Parameters

`result` The result resource that is being evaluated. This result comes from a call to `mysql_query`.

`row_number` The desired row number of the new result pointer.

## Return Values

Returns `TRUE` on success or `FALSE` on failure.

## Examples

### Example 20.22. `mysql_data_seek` example

```
<?php
$link = mysql_connect('localhost', 'mysql_user', 'mysql_password');
if (!$link) {
    die('Could not connect: ' . mysql_error());
}
$db_selected = mysql_select_db('sample_db');
if (!$db_selected) {
    die('Could not select database: ' . mysql_error());
}
$query = 'SELECT last_name, first_name FROM friends';
```

```

$result = mysql_query($query);
if (!$result) {
    die('Query failed: ' . mysql_error());
}
/* fetch rows in reverse order */
for ($i = mysql_num_rows($result) - 1; $i >= 0; $i--) {
    if (!mysql_data_seek($result, $i)) {
        echo "Cannot seek to row $i: " . mysql_error() . "\n";
        continue;
    }

    if (!$row = mysql_fetch_assoc($result)) {
        continue;
    }

    echo $row['last_name'] . ' ' . $row['first_name'] . "<br />\n";
}
mysql_free_result($result);
?>

```

## Notes

### Note

The function `mysql_data_seek` can be used in conjunction only with `mysql_query`, not with `mysql_unbuffered_query`.

## See Also

### 20.10.1.4.8. `mysql_db_name`

Copyright 1997-2008 the PHP Documentation Group.

- `mysql_db_name`

Get result data

## Description

```

string mysql_db_name(resource result,
                    int row,
                    mixed field);

```

Retrieve the database name from a call to `mysql_list_dbs`.

## Parameters

<i>result</i>	The result pointer from a call to <code>mysql_list_dbs</code> .
<i>row</i>	The index into the result set.
<i>field</i>	The field name.

## Return Values

Returns the database name on success, and `FALSE` on failure. If `FALSE` is returned, use `mysql_error` to determine the nature of the error.

## Examples

**Example 20.23. `mysql_db_name` example**

```
<?php
error_reporting(E_ALL);

$link = mysql_connect('dbhost', 'username', 'password');
$db_list = mysql_list_dbs($link);

$i = 0;
$cnt = mysql_num_rows($db_list);
while ($i < $cnt) {
    echo mysql_db_name($db_list, $i) . "\n";
    $i++;
}
?>
```

**Notes****Note**

For backward compatibility, the following deprecated alias may be used: `mysql_dbname`

**See Also**

`mysql_list_dbs`  
`mysql_tablename`

**20.10.1.4.9. `mysql_db_query`**

Copyright 1997-2008 the PHP Documentation Group.

- `mysql_db_query`

Send a MySQL query

**Description**

```
resource mysql_db_query(string database,
                       string query,
                       resource link_identifier);
```

`mysql_db_query` selects a database, and executes a query on it.

**Parameters**

<code>database</code>	The name of the database that will be selected.
<code>query</code>	The MySQL query.
<code>link_identifier</code>	The MySQL connection. If the link identifier is not specified, the last link opened by <code>mysql_connect</code> is assumed. If no such link is found, it will try to create one as if <code>mysql_connect</code> was called with no arguments. If by chance no connection is found or established, an <code>E_WARNING</code> level error is generated.

**Return Values**

Returns a positive MySQL result resource to the query result, or `FALSE` on error. The function also returns `TRUE` / `FALSE` for `INSERT/UPDATE/DELETE` queries to indicate success/failure.

**ChangeLog**

Version	Description
5.3.0	This function now throws an E_DEPRECATED notice.
4.0.6	This function is deprecated, do not use this function. Use <a href="#">mysql_select_db</a> and <a href="#">mysql_query</a> instead.

## Examples

### Example 20.24. [mysql\\_db\\_query](#) alternative example

```
<?php
if (!$link = mysql_connect('mysql_host', 'mysql_user', 'mysql_password')) {
    echo 'Could not connect to mysql';
    exit;
}

if (!mysql_select_db('mysql_dbname', $link)) {
    echo 'Could not select database';
    exit;
}

$sql = 'SELECT foo FROM bar WHERE id = 42';
$result = mysql_query($sql, $link);

if (!$result) {
    echo "DB Error, could not query the database\n";
    echo 'MySQL Error: ' . mysql_error();
    exit;
}

while ($row = mysql_fetch_assoc($result)) {
    echo $row['foo'];
}

mysql_free_result($result);

?>
```

## Notes

### Note

Be aware that this function does *NOT* switch back to the database you were connected before. In other words, you can't use this function to *temporarily* run a sql query on another database, you would have to manually switch back. Users are strongly encouraged to use the [database.table](#) syntax in their sql queries or [mysql\\_select\\_db](#) instead of this function.

## See Also

### 20.10.1.4.10. [mysql\\_drop\\_db](#)

Copyright 1997-2008 the PHP Documentation Group.

- [mysql\\_drop\\_db](#)

Drop (delete) a MySQL database

## Description

```
bool mysql_drop_db(string database_name,
                  resource link_identifier);
```

[mysql\\_drop\\_db](#) attempts to drop (remove) an entire database from the server associated with the specified link identifier. This function is deprecated, it is preferable to use [mysql\\_query](#) to issue a sql `DROP DATABASE` statement instead.

## Parameters

<i>database_name</i>	The name of the database that will be deleted.
<i>link_identifier</i>	The MySQL connection. If the link identifier is not specified, the last link opened by <code>mysql_connect</code> is assumed. If no such link is found, it will try to create one as if <code>mysql_connect</code> was called with no arguments. If by chance no connection is found or established, an <code>E_WARNING</code> level error is generated.

## Return Values

Returns `TRUE` on success or `FALSE` on failure.

## Examples

### Example 20.25. `mysql_drop_db` alternative example

```
<?php
$link = mysql_connect('localhost', 'mysql_user', 'mysql_password');
if (!$link) {
    die('Could not connect: ' . mysql_error());
}

$sql = 'DROP DATABASE my_db';
if (mysql_query($sql, $link)) {
    echo "Database my_db was successfully dropped\n";
} else {
    echo 'Error dropping database: ' . mysql_error() . "\n";
}
?>
```

## Notes

### Warning

This function will not be available if the MySQL extension was built against a MySQL 4.x client library.

### Note

For backward compatibility, the following deprecated alias may be used: `mysql_dropdb`

## See Also

[mysql\\_query](#)

### 20.10.1.4.11. `mysql_errno`

Copyright 1997-2008 the PHP Documentation Group.

- [mysql\\_errno](#)

Returns the numerical value of the error message from previous MySQL operation

## Description

```
int mysql_errno(resource link_identifier);
```

Returns the error number from the last MySQL function.

Errors coming back from the MySQL database backend no longer issue warnings. Instead, use `mysql_errno` to retrieve the error code. Note that this function only returns the error code from the most recently executed MySQL function (not including `mysql_error` and `mysql_errno`), so if you want to use it, make sure you check the value before calling another MySQL func-

tion.

### Parameters

*link\_identifier*

The MySQL connection. If the link identifier is not specified, the last link opened by `mysql_connect` is assumed. If no such link is found, it will try to create one as if `mysql_connect` was called with no arguments. If by chance no connection is found or established, an `E_WARNING` level error is generated.

### Return Values

Returns the error number from the last MySQL function, or 0 (zero) if no error occurred.

### Examples

#### Example 20.26. `mysql_errno` example

```
<?php
$link = mysql_connect("localhost", "mysql_user", "mysql_password");
if (!mysql_select_db("nonexistentdb", $link)) {
    echo mysql_errno($link) . ": " . mysql_error($link). "\n";
}

mysql_select_db("kossu", $link);
if (!mysql_query("SELECT * FROM nonexistenttable", $link)) {
    echo mysql_errno($link) . ": " . mysql_error($link). "\n";
}
?>
```

The above example will output something similar to:

```
1049: Unknown database 'nonexistentdb'
1146: Table 'kossu.nonexistenttable' doesn't exist
```

### See Also

[mysql\\_error](#)  
[MySQL error codes](#)

#### 20.10.1.4.12. `mysql_error`

Copyright 1997-2008 the PHP Documentation Group.

- [mysql\\_error](#)

Returns the text of the error message from previous MySQL operation

### Description

```
string mysql_error(resource link_identifier);
```

Returns the error text from the last MySQL function. Errors coming back from the MySQL database backend no longer issue warnings. Instead, use `mysql_error` to retrieve the error text. Note that this function only returns the error text from the most recently executed MySQL function (not including `mysql_error` and `mysql_errno`), so if you want to use it, make sure you check the value before calling another MySQL function.

### Parameters

*link\_identifier*

The MySQL connection. If the link identifier is not specified, the last link opened by `mysql_connect` is assumed. If no such link is found, it will try to create one as if `mysql_connect` was called with no arguments. If by chance no connection is found or established, an `E_WARNING` level error is generated.

### Return Values

Returns the error text from the last MySQL function, or '' (empty string) if no error occurred.

### Examples

#### Example 20.27. `mysql_error` example

```
<?php
$link = mysql_connect("localhost", "mysql_user", "mysql_password");

mysql_select_db("nonexistentdb", $link);
echo mysql_errno($link) . ": " . mysql_error($link) . "\n";

mysql_select_db("kossu", $link);
mysql_query("SELECT * FROM nonexistenttable", $link);
echo mysql_errno($link) . ": " . mysql_error($link) . "\n";
?>
```

The above example will output something similar to:

```
1049: Unknown database 'nonexistentdb'
1146: Table 'kossu.nonexistenttable' doesn't exist
```

### See Also

#### 20.10.1.4.13. `mysql_escape_string`

Copyright 1997-2008 the PHP Documentation Group.

- [mysql\\_escape\\_string](#)

Escapes a string for use in a `mysql_query`

### Description

```
string mysql_escape_string(string unescaped_string);
```

This function will escape the *unescaped\_string*, so that it is safe to place it in a `mysql_query`. This function is deprecated.

This function is identical to `mysql_real_escape_string` except that `mysql_real_escape_string` takes a connection handler and escapes the string according to the current character set. `mysql_escape_string` does not take a connection argument and does not respect the current charset setting.

### Parameters

*unescaped\_string*

The string that is to be escaped.

**Return Values**

Returns the escaped string.

**ChangeLog**

Version	Description
5.3.0	This function now throws an E_DEPRECATED notice.
4.3.0	This function became deprecated, do not use this function. Instead, use <a href="#">mysql_real_escape_string</a> .

**Examples****Example 20.28. [mysql\\_escape\\_string](#) example**

```
<?php
$item = "Zak's Laptop";
$escaped_item = mysql_escape_string($item);
printf("Escaped string: %s\n", $escaped_item);
?>
```

The above example will output:

```
Escaped string: Zak\'s Laptop
```

**Notes****Note**

[mysql\\_escape\\_string](#) does not escape % and \_.

**See Also**

[mysql\\_real\\_escape\\_string](#)  
[addslashes](#)  
 The [magic\\_quotes\\_gpc](#) directive.

**20.10.1.4.14. [mysql\\_fetch\\_array](#)**

Copyright 1997-2008 the PHP Documentation Group.

- [mysql\\_fetch\\_array](#)

Fetch a result row as an associative array, a numeric array, or both

**Description**

```
array mysql_fetch_array(resource result,
                        int result_type);
```

Returns an array that corresponds to the fetched row and moves the internal data pointer ahead.

**Parameters**

<code>result</code>	The result resource that is being evaluated. This result comes from a call to <code>mysql_query</code> .
<code>result_type</code>	The type of array that is to be fetched. It's a constant and can take the following values: <code>MYSQL_ASSOC</code> , <code>MYSQL_NUM</code> , and the default value of <code>MYSQL_BOTH</code> .

### Return Values

Returns an array of strings that corresponds to the fetched row, or `FALSE` if there are no more rows. The type of returned array depends on how `result_type` is defined. By using `MYSQL_BOTH` (default), you'll get an array with both associative and number indices. Using `MYSQL_ASSOC`, you only get associative indices (as `mysql_fetch_assoc` works), using `MYSQL_NUM`, you only get number indices (as `mysql_fetch_row` works).

If two or more columns of the result have the same field names, the last column will take precedence. To access the other column(s) of the same name, you must use the numeric index of the column or make an alias for the column. For aliased columns, you cannot access the contents with the original column name.

### Examples

#### Example 20.29. Query with aliased duplicate field names

```
SELECT table1.field AS foo, table2.field AS bar FROM table1, table2
```

#### Example 20.30. `mysql_fetch_array` with `MYSQL_NUM`

```
<?php
mysql_connect("localhost", "mysql_user", "mysql_password") or
    die("Could not connect: " . mysql_error());
mysql_select_db("mydb");

$result = mysql_query("SELECT id, name FROM mytable");

while ($row = mysql_fetch_array($result, MYSQL_NUM)) {
    printf("ID: %s Name: %s", $row[0], $row[1]);
}

mysql_free_result($result);
?>
```

#### Example 20.31. `mysql_fetch_array` with `MYSQL_ASSOC`

```
<?php
mysql_connect("localhost", "mysql_user", "mysql_password") or
    die("Could not connect: " . mysql_error());
mysql_select_db("mydb");

$result = mysql_query("SELECT id, name FROM mytable");

while ($row = mysql_fetch_array($result, MYSQL_ASSOC)) {
    printf("ID: %s Name: %s", $row["id"], $row["name"]);
}

mysql_free_result($result);
?>
```

#### Example 20.32. `mysql_fetch_array` with `MYSQL_BOTH`

```

<?php
mysql_connect("localhost", "mysql_user", "mysql_password") or
    die("Could not connect: " . mysql_error());
mysql_select_db("mydb");

$result = mysql_query("SELECT id, name FROM mytable");

while ($row = mysql_fetch_array($result, MYSQL_BOTH)) {
    printf ("ID: %s Name: %s", $row[0], $row["name"]);
}

mysql_free_result($result);
?>

```

## Notes

### Performance

An important thing to note is that using `mysql_fetch_array` is *not significantly* slower than using `mysql_fetch_row`, while it provides a significant added value.

### Note

Field names returned by this function are *case-sensitive*.

### Note

This function sets NULL fields to the PHP `NULL` value.

## See Also

[mysql\\_fetch\\_row](#)  
[mysql\\_fetch\\_assoc](#)  
[mysql\\_data\\_seek](#)  
[mysql\\_query](#)

### 20.10.1.4.15. `mysql_fetch_assoc`

Copyright 1997-2008 the PHP Documentation Group.

- `mysql_fetch_assoc`

Fetch a result row as an associative array

## Description

```
array mysql_fetch_assoc(resource result);
```

Returns an associative array that corresponds to the fetched row and moves the internal data pointer ahead. `mysql_fetch_assoc` is equivalent to calling `mysql_fetch_array` with `MYSQL_ASSOC` for the optional second parameter. It only returns an associative array.

## Parameters

*result* The result resource that is being evaluated. This result comes from a call to `mysql_query`.

## Return Values

Returns an associative array of strings that corresponds to the fetched row, or `FALSE` if there are no more rows.

If two or more columns of the result have the same field names, the last column will take precedence. To access the other column(s) of the same name, you either need to access the result with numeric indices by using `mysql_fetch_row` or add alias names. See the example at the `mysql_fetch_array` description about aliases.

## Examples

**Example 20.33. An expanded `mysql_fetch_assoc` example**

```

<?php
$conn = mysql_connect("localhost", "mysql_user", "mysql_password");
if (!$conn) {
    echo "Unable to connect to DB: " . mysql_error();
    exit;
}
if (!mysql_select_db("mydbname")) {
    echo "Unable to select mydbname: " . mysql_error();
    exit;
}
$sql = "SELECT id as userid, fullname, userstatus
      FROM sometable
      WHERE userstatus = 1";
$result = mysql_query($sql);
if (!$result) {
    echo "Could not successfully run query ($sql) from DB: " . mysql_error();
    exit;
}
if (mysql_num_rows($result) == 0) {
    echo "No rows found, nothing to print so am exiting";
    exit;
}
// While a row of data exists, put that row in $row as an associative array
// Note: If you're expecting just one row, no need to use a loop
// Note: If you put extract($row); inside the following loop, you'll
//       then create $userid, $fullname, and $userstatus
while ($row = mysql_fetch_assoc($result)) {
    echo $row["userid"];
    echo $row["fullname"];
    echo $row["userstatus"];
}
mysql_free_result($result);
?>

```

**Notes****Performance**

An important thing to note is that using `mysql_fetch_assoc` is *not significantly* slower than using `mysql_fetch_row`, while it provides a significant added value.

**Note**

Field names returned by this function are *case-sensitive*.

**Note**

This function sets NULL fields to the PHP `NULL` value.

**See Also**

`mysql_fetch_array`  
`mysql_data_seek`  
`mysql_query`  
`mysql_error`

**20.10.1.4.16. `mysql_fetch_field`**

Copyright 1997-2008 the PHP Documentation Group.

- `mysql_fetch_field`

Get column information from a result and return as an object

### Description

```
object mysql_fetch_field(resource result,
                        int field_offset);
```

Returns an object containing field information. This function can be used to obtain information about fields in the provided query result.

### Parameters

<i>result</i>	The result resource that is being evaluated. This result comes from a call to <code>mysql_query</code> .
<i>field_offset</i>	The numerical field offset. If the field offset is not specified, the next field that was not yet retrieved by this function is retrieved. The <i>field_offset</i> starts at 0.

### Return Values

Returns an object containing field information. The properties of the object are:

- name - column name
- table - name of the table the column belongs to
- def - default value of the column
- max\_length - maximum length of the column
- not\_null - 1 if the column cannot be `NULL`
- primary\_key - 1 if the column is a primary key
- unique\_key - 1 if the column is a unique key
- multiple\_key - 1 if the column is a non-unique key
- numeric - 1 if the column is numeric
- blob - 1 if the column is a BLOB
- type - the type of the column
- unsigned - 1 if the column is unsigned
- zerofill - 1 if the column is zero-filled

### Examples

#### Example 20.34. `mysql_fetch_field` example

```
<?php
$conn = mysql_connect('localhost', 'mysql_user', 'mysql_password');
if (!$conn) {
    die('Could not connect: ' . mysql_error());
}
mysql_select_db('database');
$result = mysql_query('select * from table');
if (!$result) {
    die('Query failed: ' . mysql_error());
}
/* get column metadata */
$i = 0;
while ($i < mysql_num_fields($result)) {
    echo "Information for column $i:<br />\n";
```

```

    $meta = mysql_fetch_field($result, $i);
    if (!$meta) {
        echo "No information available<br />\n";
    }
    echo "<pre>
blob:          $meta->blob
max_length:   $meta->max_length
multiple_key: $meta->multiple_key
name:         $meta->name
not_null:     $meta->not_null
numeric:      $meta->numeric
primary_key:  $meta->primary_key
table:        $meta->table
type:         $meta->type
default:      $meta->def
unique_key:   $meta->unique_key
unsigned:     $meta->unsigned
zerofill:    $meta->zerofill
</pre>";
    $i++;
}
mysql_free_result($result);
?>

```

## Notes

### Note

Field names returned by this function are *case-sensitive*.

## See Also

[mysql\\_field\\_seek](#)

### 20.10.1.4.17. [mysql\\_fetch\\_lengths](#)

Copyright 1997-2008 the PHP Documentation Group.

- [mysql\\_fetch\\_lengths](#)

Get the length of each output in a result

## Description

```
array mysql_fetch_lengths(resource result);
```

Returns an array that corresponds to the lengths of each field in the last row fetched by MySQL.

[mysql\\_fetch\\_lengths](#) stores the lengths of each result column in the last row returned by [mysql\\_fetch\\_row](#), [mysql\\_fetch\\_assoc](#), [mysql\\_fetch\\_array](#), and [mysql\\_fetch\\_object](#) in an array, starting at offset 0.

## Parameters

*result* The result resource that is being evaluated. This result comes from a call to [mysql\\_query](#).

## Return Values

An array of lengths on success, or [FALSE](#) on failure.

## Examples

### Example 20.35. A [mysql\\_fetch\\_lengths](#) example

```

<?php
$result = mysql_query("SELECT id,email FROM people WHERE id = '42'");
if (!$result) {

```

```

    echo 'Could not run query: ' . mysql_error();
    exit;
}
$row    = mysql_fetch_assoc($result);
$lengths = mysql_fetch_lengths($result);

print_r($row);
print_r($lengths);
?>

```

The above example will output something similar to:

```

Array
(
    [id] => 42
    [email] => user@example.com
)
Array
(
    [0] => 2
    [1] => 16
)

```

### See Also

[mysql\\_field\\_len](#)  
[mysql\\_fetch\\_row](#)  
[strlen](#)

#### 20.10.1.4.18. [mysql\\_fetch\\_object](#)

Copyright 1997-2008 the PHP Documentation Group.

- [mysql\\_fetch\\_object](#)

Fetch a result row as an object

### Description

```

object mysql_fetch_object(resource result,
                        string class_name,
                        array params);

```

Returns an object with properties that correspond to the fetched row and moves the internal data pointer ahead.

### Parameters

<i>result</i>	The result resource that is being evaluated. This result comes from a call to <a href="#">mysql_query</a> .
<i>class_name</i>	The name of the class to instantiate, set the properties of and return. If not specified, a <a href="#">stdClass</a> object is returned.
<i>params</i>	An optional array of parameters to pass to the constructor for <i>class_name</i> objects.

### Return Values

Returns an object with string properties that correspond to the fetched row, or **FALSE** if there are no more rows.

[mysql\\_fetch\\_row](#) fetches one row of data from the result associated with the specified result identifier. The row is returned as an array. Each result column is stored in an array offset, starting at offset 0.

### ChangeLog

Version	Description
5.0.0	Added the ability to return as a different object.

## Examples

### Example 20.36. `mysql_fetch_object` example

```
<?php
mysql_connect("hostname", "user", "password");
mysql_select_db("mydb");
$result = mysql_query("select * from mytable");
while ($row = mysql_fetch_object($result)) {
    echo $row->user_id;
    echo $row->fullname;
}
mysql_free_result($result);
?>
```

### Example 20.37. `mysql_fetch_object` example

```
<?php
class foo {
    public $name;
}

mysql_connect("hostname", "user", "password");
mysql_select_db("mydb");

$result = mysql_query("select name from mytable limit 1");
$obj = mysql_fetch_object($result, 'foo');
var_dump($obj);
?>
```

## Notes

### Performance

Speed-wise, the function is identical to `mysql_fetch_array`, and almost as quick as `mysql_fetch_row` (the difference is insignificant).

### Note

`mysql_fetch_object` is similar to `mysql_fetch_array`, with one difference - an object is returned, instead of an array. Indirectly, that means that you can only access the data by the field names, and not by their offsets (numbers are illegal property names).

### Note

Field names returned by this function are *case-sensitive*.

### Note

This function sets NULL fields to the PHP `NULL` value.

#### 20.10.1.4.19. [mysql\\_fetch\\_row](#)

Copyright 1997-2008 the PHP Documentation Group.

- [mysql\\_fetch\\_row](#)

Get a result row as an enumerated array

##### Description

```
array mysql_fetch_row(resource result);
```

Returns a numerical array that corresponds to the fetched row and moves the internal data pointer ahead.

##### Parameters

*result* The result resource that is being evaluated. This result comes from a call to [mysql\\_query](#).

##### Return Values

Returns an numerical array of strings that corresponds to the fetched row, or `FALSE` if there are no more rows.

[mysql\\_fetch\\_row](#) fetches one row of data from the result associated with the specified result identifier. The row is returned as an array. Each result column is stored in an array offset, starting at offset 0.

##### Examples

#### Example 20.38. Fetching one row with [mysql\\_fetch\\_row](#)

```
<?php
$result = mysql_query("SELECT id,email FROM people WHERE id = '42'");
if (!$result) {
    echo 'Could not run query: ' . mysql_error();
    exit;
}
$row = mysql_fetch_row($result);

echo $row[0]; // 42
echo $row[1]; // the email value
?>
```

##### Notes

###### Note

This function sets NULL fields to the PHP `NULL` value.

##### See Also

[mysql\\_fetch\\_array](#)

[mysql\\_result](#)

#### 20.10.1.4.20. [mysql\\_field\\_flags](#)

Copyright 1997-2008 the PHP Documentation Group.

- `mysql_field_flags`

Get the flags associated with the specified field in a result

### Description

```
string mysql_field_flags(resource result,
                        int field_offset);
```

`mysql_field_flags` returns the field flags of the specified field. The flags are reported as a single word per flag separated by a single space, so that you can split the returned value using `explode`.

### Parameters

<code>result</code>	The result resource that is being evaluated. This result comes from a call to <code>mysql_query</code> .
<code>field_offset</code>	The numerical field offset. The <code>field_offset</code> starts at 0. If <code>field_offset</code> does not exist, an error of level <code>E_WARNING</code> is also issued.

### Return Values

Returns a string of flags associated with the result, or `FALSE` on failure.

The following flags are reported, if your version of MySQL is current enough to support them: `"not_null"`, `"primary_key"`, `"unique_key"`, `"multiple_key"`, `"blob"`, `"unsigned"`, `"zerofill"`, `"binary"`, `"enum"`, `"auto_increment"` and `"timestamp"`.

### Examples

#### Example 20.39. A `mysql_field_flags` example

```
<?php
$result = mysql_query("SELECT id,email FROM people WHERE id = '42'");
if (!$result) {
    echo 'Could not run query: ' . mysql_error();
    exit;
}
$flags = mysql_field_flags($result, 0);

echo $flags;
print_r(explode(' ', $flags));
?>
```

The above example will output something similar to:

```
not_null primary_key auto_increment
Array
(
    [0] => not_null
    [1] => primary_key
    [2] => auto_increment
)
```

### Notes

#### Note

For backward compatibility, the following deprecated alias may be used: `mysql_fieldflags`

`mysql_field_type`  
`mysql_field_len`

#### 20.10.1.4.21. `mysql_field_len`

Copyright 1997-2008 the PHP Documentation Group.

- `mysql_field_len`

Returns the length of the specified field

##### Description

```
int mysql_field_len(resource result,  
                    int field_offset);
```

`mysql_field_len` returns the length of the specified field.

##### Parameters

<code>result</code>	The result resource that is being evaluated. This result comes from a call to <code>mysql_query</code> .
<code>field_offset</code>	The numerical field offset. The <code>field_offset</code> starts at 0. If <code>field_offset</code> does not exist, an error of level <code>E_WARNING</code> is also issued.

##### Return Values

The length of the specified field index on success, or `FALSE` on failure.

##### Examples

#### Example 20.40. `mysql_field_len` example

```
<?php  
$result = mysql_query("SELECT id,email FROM people WHERE id = '42'");  
if (!$result) {  
    echo 'Could not run query: ' . mysql_error();  
    exit;  
}  
  
// Will get the length of the id field as specified in the database  
// schema.  
$length = mysql_field_len($result, 0);  
echo $length;  
?>
```

##### Notes

###### Note

For backward compatibility, the following deprecated alias may be used: `mysql_fieldlen`

##### See Also

`mysql_fetch_lengths`  
`strlen`

#### 20.10.1.4.22. `mysql_field_name`

Copyright 1997-2008 the PHP Documentation Group.

- `mysql_field_name`

Get the name of the specified field in a result

### Description

```
string mysql_field_name(resource result,
                       int field_offset);
```

`mysql_field_name` returns the name of the specified field index.

### Parameters

`result` The result resource that is being evaluated. This result comes from a call to `mysql_query`.

`field_offset` The numerical field offset. The `field_offset` starts at 0. If `field_offset` does not exist, an error of level `E_WARNING` is also issued.

### Return Values

The name of the specified field index on success, or `FALSE` on failure.

### Examples

#### Example 20.41. `mysql_field_name` example

```
<?php
/* The users table consists of three fields:
 * user_id
 * username
 * password.
 */
$link = @mysql_connect('localhost', 'mysql_user', 'mysql_password');
if (!$link) {
    die('Could not connect to MySQL server: ' . mysql_error());
}
$dbname = 'mydb';
$db_selected = mysql_select_db($dbname, $link);
if (!$db_selected) {
    die("Could not set $dbname: " . mysql_error());
}
$res = mysql_query('select * from users', $link);

echo mysql_field_name($res, 0) . "\n";
echo mysql_field_name($res, 2);
?>
```

The above example will output:

```
user_id
password
```

### Notes

#### Note

Field names returned by this function are *case-sensitive*.

#### Note

For backward compatibility, the following deprecated alias may be used: `mysql_fieldname`

**See Also**

[mysql\\_field\\_type](#)  
[mysql\\_field\\_len](#)

**20.10.1.4.23. mysql\_field\_seek**

Copyright 1997-2008 the PHP Documentation Group.

- [mysql\\_field\\_seek](#)

Set result pointer to a specified field offset

**Description**

```
bool mysql_field_seek(resource result,  
                    int field_offset);
```

Seeks to the specified field offset. If the next call to [mysql\\_fetch\\_field](#) doesn't include a field offset, the field offset specified in [mysql\\_field\\_seek](#) will be returned.

**Parameters**

<i>result</i>	The result resource that is being evaluated. This result comes from a call to <a href="#">mysql_query</a> .
<i>field_offset</i>	The numerical field offset. The <i>field_offset</i> starts at 0. If <i>field_offset</i> does not exist, an error of level <a href="#">E_WARNING</a> is also issued.

**Return Values**

Returns [TRUE](#) on success or [FALSE](#) on failure.

**See Also**

[mysql\\_fetch\\_field](#)

**20.10.1.4.24. mysql\_field\_table**

Copyright 1997-2008 the PHP Documentation Group.

- [mysql\\_field\\_table](#)

Get name of the table the specified field is in

**Description**

```
string mysql_field_table(resource result,  
                      int field_offset);
```

Returns the name of the table that the specified field is in.

**Parameters**

<i>result</i>	The result resource that is being evaluated. This result comes from a call to <a href="#">mysql_query</a> .
<i>field_offset</i>	The numerical field offset. The <i>field_offset</i> starts at 0. If <i>field_offset</i> does not exist, an error of level <a href="#">E_WARNING</a> is also issued.

**Return Values**

The name of the table on success.

## Examples

### Example 20.42. A `mysql_field_table` example

```
<?php
$query = "SELECT account.*, country.* FROM account, country WHERE country.name = 'Portugal' AND account.country_id = c";
// get the result from the DB
$result = mysql_query($query);
// Lists the table name and then the field name
for ($i = 0; $i < mysql_num_fields($result); ++$i) {
    $table = mysql_field_table($result, $i);
    $field = mysql_field_name($result, $i);
    echo "$table: $field\n";
}
?>
```

## Notes

### Note

For backward compatibility, the following deprecated alias may be used: `mysql_fieldtable`

## See Also

[mysql\\_list\\_tables](#)

### 20.10.1.4.25. `mysql_field_type`

Copyright 1997-2008 the PHP Documentation Group.

- [mysql\\_field\\_type](#)

Get the type of the specified field in a result

## Description

```
string mysql_field_type(resource result,
                        int field_offset);
```

`mysql_field_type` is similar to the `mysql_field_name` function. The arguments are identical, but the field type is returned instead.

## Parameters

*result* The result resource that is being evaluated. This result comes from a call to `mysql_query`.

*field\_offset* The numerical field offset. The *field\_offset* starts at 0. If *field\_offset* does not exist, an error of level `E_WARNING` is also issued.

## Return Values

The returned field type will be one of "int", "real", "string", "blob", and others as detailed in the [MySQL documentation](#).

## Examples

**Example 20.43. `mysql_field_type` example**

```
<?php
mysql_connect("localhost", "mysql_username", "mysql_password");
mysql_select_db("mysql");
$result = mysql_query("SELECT * FROM func");
$fields = mysql_num_fields($result);
$rows = mysql_num_rows($result);
$table = mysql_field_table($result, 0);
echo "Your '" . $table . "' table has " . $fields . " fields and " . $rows . " record(s)\n";
echo "The table has the following fields:\n";
for ($i=0; $i < $fields; $i++) {
    $type = mysql_field_type($result, $i);
    $name = mysql_field_name($result, $i);
    $len = mysql_field_len($result, $i);
    $flags = mysql_field_flags($result, $i);
    echo $type . " " . $name . " " . $len . " " . $flags . "\n";
}
mysql_free_result($result);
mysql_close();
?>
```

The above example will output something similar to:

```
Your 'func' table has 4 fields and 1 record(s)
The table has the following fields:
string name 64 not_null primary_key binary
int ret 1 not_null
string dl 128 not_null
string type 9 not_null enum
```

**Notes****Note**

For backward compatibility, the following deprecated alias may be used: `mysql_fieldtype`

**See Also**

`mysql_field_name`  
`mysql_field_len`

**20.10.1.4.26. `mysql_free_result`**

Copyright 1997-2008 the PHP Documentation Group.

- `mysql_free_result`

Free result memory

**Description**

```
bool mysql_free_result(resource result);
```

`mysql_free_result` will free all memory associated with the result identifier `result`.

`mysql_free_result` only needs to be called if you are concerned about how much memory is being used for queries that return large result sets. All associated result memory is automatically freed at the end of the script's execution.

**Parameters**

`result` The result resource that is being evaluated. This result comes from a call to `mysql_query`.

### Return Values

Returns `TRUE` on success or `FALSE` on failure.

If a non-resource is used for the `result`, an error of level `E_WARNING` will be emitted. It's worth noting that `mysql_query` only returns a resource for `SELECT`, `SHOW`, `EXPLAIN`, and `DESCRIBE` queries.

### Examples

#### Example 20.44. A `mysql_free_result` example

```
<?php
$result = mysql_query("SELECT id,email FROM people WHERE id = '42'");
if (!$result) {
    echo 'Could not run query: ' . mysql_error();
    exit;
}
/* Use the result, assuming we're done with it afterwards */
$row = mysql_fetch_assoc($result);

/* Now we free up the result and continue on with our script */
mysql_free_result($result);

echo $row['id'];
echo $row['email'];
?>
```

### Notes

#### Note

For backward compatibility, the following deprecated alias may be used: `mysql_freeresult`

### See Also

`mysql_query`  
`is_resource`

#### 20.10.1.4.27. `mysql_get_client_info`

Copyright 1997-2008 the PHP Documentation Group.

- `mysql_get_client_info`

Get MySQL client info

### Description

```
string mysql_get_client_info();
```

`mysql_get_client_info` returns a string that represents the client library version.

### Return Values

The MySQL client version.

### Examples

#### Example 20.45. `mysql_get_client_info` example

```
<?php
printf("MySQL client info: %s\n", mysql_get_client_info());
?>
```

The above example will output something similar to:

```
MySQL client info: 3.23.39
```

Copyright 1997-2008 the PHP Documentation Group.

- [mysql\\_get\\_host\\_info](#)

Get MySQL host info

### Description

```
string mysql_get_host_info(resource link_identifier);
```

Describes the type of connection in use for the connection, including the server host name.

### Parameters

*link\_identifier* The MySQL connection. If the link identifier is not specified, the last link opened by [mysql\\_connect](#) is assumed. If no such link is found, it will try to create one as if [mysql\\_connect](#) was called with no arguments. If by chance no connection is found or established, an [E\\_WARNING](#) level error is generated.

### Return Values

Returns a string describing the type of MySQL connection in use for the connection or [FALSE](#) on failure.

### Examples

#### Example 20.46. [mysql\\_get\\_host\\_info](#) example

```
<?php
$link = mysql_connect('localhost', 'mysql_user', 'mysql_password');
if (!$link) {
    die('Could not connect: ' . mysql_error());
}
printf("MySQL host info: %s\n", mysql_get_host_info());
?>
```

The above example will output something similar to:

```
MySQL host info: Localhost via UNIX socket
```

### See Also

```
mysql_get_client_info

```

#### 20.10.1.4.29. `mysql_get_proto_info`

Copyright 1997-2008 the PHP Documentation Group.

- `mysql_get_proto_info`

Get MySQL protocol info

### Description

```
int mysql_get_proto_info(resource link_identifier);
```

Retrieves the MySQL protocol.

### Parameters

*link\_identifier*

The MySQL connection. If the link identifier is not specified, the last link opened by `mysql_connect` is assumed. If no such link is found, it will try to create one as if `mysql_connect` was called with no arguments. If by chance no connection is found or established, an `E_WARNING` level error is generated.

### Return Values

Returns the MySQL protocol on success, or `FALSE` on failure.

### Examples

#### Example 20.47. `mysql_get_proto_info` example

```
<?php  
$link = mysql_connect('localhost', 'mysql_user', 'mysql_password');  
if (!$link) {  
    die('Could not connect: ' . mysql_error());  
}  
printf("MySQL protocol version: %s\n", mysql_get_proto_info());  
?>
```

The above example will output something similar to:

```
MySQL protocol version: 10
```

### See Also

- `mysql_get_server_info`

Get MySQL server info

#### Description

```
string mysql_get_server_info(resource link_identifier);
```

Retrieves the MySQL server version.

#### Parameters

*link\_identifier* The MySQL connection. If the link identifier is not specified, the last link opened by `mysql_connect` is assumed. If no such link is found, it will try to create one as if `mysql_connect` was called with no arguments. If by chance no connection is found or established, an `E_WARNING` level error is generated.

#### Return Values

Returns the MySQL server version on success, or `FALSE` on failure.

#### Examples

#### Example 20.48. `mysql_get_server_info` example

```
<?php
$link = mysql_connect('localhost', 'mysql_user', 'mysql_password');
if (!$link) {
    die('Could not connect: ' . mysql_error());
}
printf("MySQL server version: %s\n", mysql_get_server_info());
?>
```

The above example will output something similar to:

```
MySQL server version: 4.0.1-alpha
```

#### See Also

```
mysql_get_client_info
mysql_get_host_info
mysql_get_proto_info
phpversion
```

### 20.10.1.4.31. `mysql_info`

Copyright 1997-2008 the PHP Documentation Group.

- `mysql_info`

Get information about the most recent query

### Description

```
string mysql_info(resource link_identifier);
```

Returns detailed information about the last query.

### Parameters

*link\_identifier*

The MySQL connection. If the link identifier is not specified, the last link opened by `mysql_connect` is assumed. If no such link is found, it will try to create one as if `mysql_connect` was called with no arguments. If by chance no connection is found or established, an `E_WARNING` level error is generated.

### Return Values

Returns information about the statement on success, or `FALSE` on failure. See the example below for which statements provide information, and what the returned value may look like. Statements that are not listed will return `FALSE`.

### Examples

#### Example 20.49. Relevant MySQL Statements

Statements that return string values. The numbers are only for illustrating purpose; their values will correspond to the query.

```
INSERT INTO ... SELECT ...
String format: Records: 23 Duplicates: 0 Warnings: 0
INSERT INTO ... VALUES (...),(...),(...)...
String format: Records: 37 Duplicates: 0 Warnings: 0
LOAD DATA INFILE ...
String format: Records: 42 Deleted: 0 Skipped: 0 Warnings: 0
ALTER TABLE
String format: Records: 60 Duplicates: 0 Warnings: 0
UPDATE
String format: Rows matched: 65 Changed: 65 Warnings: 0
```

### Notes

#### Note

`mysql_info` returns a non-`FALSE` value for the `INSERT ... VALUES` statement only if multiple value lists are specified in the statement.

### See Also

`mysql_affected_rows`  
`mysql_insert_id`  
`mysql_stat`

#### 20.10.1.4.32. `mysql_insert_id`

Copyright 1997-2008 the PHP Documentation Group.

- `mysql_insert_id`

Get the ID generated from the previous INSERT operation

### Description

```
int mysql_insert_id(resource link_identifier);
```

Retrieves the ID generated for an AUTO\_INCREMENT column by the previous INSERT query.

#### Parameters

*link\_identifier* The MySQL connection. If the link identifier is not specified, the last link opened by `mysql_connect` is assumed. If no such link is found, it will try to create one as if `mysql_connect` was called with no arguments. If by chance no connection is found or established, an `E_WARNING` level error is generated.

#### Return Values

The ID generated for an AUTO\_INCREMENT column by the previous INSERT query on success, `0` if the previous query does not generate an AUTO\_INCREMENT value, or `FALSE` if no MySQL connection was established.

#### Examples

#### Example 20.50. `mysql_insert_id` example

```
<?php
$link = mysql_connect('localhost', 'mysql_user', 'mysql_password');
if (!$link) {
    die('Could not connect: ' . mysql_error());
}
mysql_select_db('mydb');

mysql_query("INSERT INTO mytable (product) values ('kossu')");
printf("Last inserted record has id %d\n", mysql_insert_id());
?>
```

#### Notes

##### Caution

`mysql_insert_id` converts the return type of the native MySQL C API function `mysql_insert_id()` to a type of `long` (named `int` in PHP). If your AUTO\_INCREMENT column has a column type of BIGINT, the value returned by `mysql_insert_id` will be incorrect. Instead, use the internal MySQL SQL function `LAST_INSERT_ID()` in an SQL query.

##### Note

Because `mysql_insert_id` acts on the last performed query, be sure to call `mysql_insert_id` immediately after the query that generates the value.

##### Note

The value of the MySQL SQL function `LAST_INSERT_ID()` always contains the most recently generated AUTO\_INCREMENT value, and is not reset between queries.

#### See Also

`mysql_query`  
`mysql_info`

#### 20.10.1.4.33. `mysql_list_dbs`

Copyright 1997-2008 the PHP Documentation Group.

- `mysql_list_dbs`

List databases available on a MySQL server

## Description

```
resource mysql_list_dbs(resource link_identifier);
```

Returns a result pointer containing the databases available from the current mysql daemon.

## Parameters

*link\_identifier* The MySQL connection. If the link identifier is not specified, the last link opened by `mysql_connect` is assumed. If no such link is found, it will try to create one as if `mysql_connect` was called with no arguments. If by chance no connection is found or established, an `E_WARNING` level error is generated.

## Return Values

Returns a result pointer resource on success, or `FALSE` on failure. Use the `mysql_tablename` function to traverse this result pointer, or any function for result tables, such as `mysql_fetch_array`.

## Examples

### Example 20.51. `mysql_list_dbs` example

```
<?php
$link = mysql_connect('localhost', 'mysql_user', 'mysql_password');
$db_list = mysql_list_dbs($link);

while ($row = mysql_fetch_object($db_list)) {
    echo $row->Database . "\n";
}
?>
```

The above example will output something similar to:

```
database1
database2
database3
```

## Notes

### Note

For backward compatibility, the following deprecated alias may be used: `mysql_listdbs`

## See Also

`mysql_db_name`  
`mysql_select_db`

### 20.10.1.4.34. `mysql_list_fields`

Copyright 1997-2008 the PHP Documentation Group.

- `mysql_list_fields`

List MySQL table fields

## Description

```
resource mysql_list_fields(string database_name,
                          string table_name,
                          resource link_identifier);
```

Retrieves information about the given table name.

This function is deprecated. It is preferable to use `mysql_query` to issue a `SQL SHOW COLUMNS FROM table [LIKE 'name']` statement instead.

### Parameters

<code>database_name</code>	The name of the database that's being queried.
<code>table_name</code>	The name of the table that's being queried.
<code>link_identifier</code>	The MySQL connection. If the link identifier is not specified, the last link opened by <code>mysql_connect</code> is assumed. If no such link is found, it will try to create one as if <code>mysql_connect</code> was called with no arguments. If by chance no connection is found or established, an <code>E_WARNING</code> level error is generated.

### Return Values

A result pointer resource on success, or `FALSE` on failure.

The returned result can be used with `mysql_field_flags`, `mysql_field_len`, `mysql_field_name` and `mysql_field_type`.

### Examples

#### Example 20.52. Alternate to deprecated `mysql_list_fields`

```
<?php
$result = mysql_query("SHOW COLUMNS FROM sometable");
if (!$result) {
    echo 'Could not run query: ' . mysql_error();
    exit;
}
if (mysql_num_rows($result) > 0) {
    while ($row = mysql_fetch_assoc($result)) {
        print_r($row);
    }
}
?>
```

The above example will output something similar to:

```
Array
(
    [Field] => id
    [Type] => int(7)
    [Null] =>
    [Key] => PRI
    [Default] =>
    [Extra] => auto_increment
)
Array
(
    [Field] => email
    [Type] => varchar(100)
    [Null] =>
    [Key] =>
    [Default] =>
    [Extra] =>
)
```

**Notes****Note**

For backward compatibility, the following deprecated alias may be used: `mysql_listfields`

**See Also**

`mysql_field_flags`  
`mysql_info`

**20.10.1.4.35. `mysql_list_processes`**

Copyright 1997-2008 the PHP Documentation Group.

- `mysql_list_processes`

List MySQL processes

**Description**

```
resource mysql_list_processes(resource link_identifier);
```

Retrieves the current MySQL server threads.

**Parameters**

*link\_identifier*

The MySQL connection. If the link identifier is not specified, the last link opened by `mysql_connect` is assumed. If no such link is found, it will try to create one as if `mysql_connect` was called with no arguments. If by chance no connection is found or established, an `E_WARNING` level error is generated.

**Return Values**

A result pointer resource on success, or `FALSE` on failure.

**Examples****Example 20.53. `mysql_list_processes` example**

```
<?php
$link = mysql_connect('localhost', 'mysql_user', 'mysql_password');

$result = mysql_list_processes($link);
while ($row = mysql_fetch_assoc($result)){
    printf("%s %s %s %s %s\n", $row["Id"], $row["Host"], $row["db"],
        $row["Command"], $row["Time"]);
}
mysql_free_result($result);
?>
```

The above example will output something similar to:

```
1 localhost test Processlist 0
4 localhost mysql sleep 5
```

**See Also**

```
mysql_thread_id
mysql_stat
```

### 20.10.1.4.36. `mysql_list_tables`

Copyright 1997-2008 the PHP Documentation Group.

- `mysql_list_tables`

List tables in a MySQL database

#### Description

```
resource mysql_list_tables(string database,
                          resource link_identifier);
```

Retrieves a list of table names from a MySQL database.

This function is deprecated. It is preferable to use `mysql_query` to issue a SQL `SHOW TABLES [FROM db_name] [LIKE 'pattern']` statement instead.

#### Parameters

<i>database</i>	The name of the database
<i>link_identifier</i>	The MySQL connection. If the link identifier is not specified, the last link opened by <code>mysql_connect</code> is assumed. If no such link is found, it will try to create one as if <code>mysql_connect</code> was called with no arguments. If by chance no connection is found or established, an <code>E_WARNING</code> level error is generated.

#### Return Values

A result pointer resource on success, or `FALSE` on failure.

Use the `mysql_tablename` function to traverse this result pointer, or any function for result tables, such as `mysql_fetch_array`.

#### ChangeLog

Version	Description
4.3.7	This function became deprecated.

#### Examples

##### Example 20.54. `mysql_list_tables` alternative example

```
<?php
$dbname = 'mysql_dbname';

if (!mysql_connect('mysql_host', 'mysql_user', 'mysql_password')) {
    echo 'Could not connect to mysql';
    exit;
}

$sql = "SHOW TABLES FROM $dbname";
$result = mysql_query($sql);

if (!$result) {
    echo "DB Error, could not list tables\n";
    echo 'MySQL Error: ' . mysql_error();
    exit;
}

while ($row = mysql_fetch_row($result)) {
    echo "Table: {$row[0]}\n";
}
```

```
}  
mysql_free_result($result);  
?>
```

## Notes

### Note

For backward compatibility, the following deprecated alias may be used: `mysql_listtables`

## See Also

`mysql_list_dbs`  
`mysql_tablename`

### 20.10.1.4.37. `mysql_num_fields`

Copyright 1997-2008 the PHP Documentation Group.

- `mysql_num_fields`

Get number of fields in result

## Description

```
int mysql_num_fields(resource result);
```

Retrieves the number of fields from a query.

## Parameters

`result` The result resource that is being evaluated. This result comes from a call to `mysql_query`.

## Return Values

Returns the number of fields in the result set resource on success, or `FALSE` on failure.

## Examples

### Example 20.55. A `mysql_num_fields` example

```
<?php  
$result = mysql_query("SELECT id,email FROM people WHERE id = '42'");  
if (!$result) {  
    echo 'Could not run query: ' . mysql_error();  
    exit;  
}  
  
/* returns 2 because id,email === two fields */  
echo mysql_num_fields($result);  
?>
```

## Notes

### Note

For backward compatibility, the following deprecated alias may be used: `mysql_numfields`

## See Also

### 20.10.1.4.38. [mysql\\_num\\_rows](#)

Copyright 1997-2008 the PHP Documentation Group.

- [mysql\\_num\\_rows](#)

Get number of rows in result

## Description

```
int mysql_num_rows(resource result);
```

Retrieves the number of rows from a result set. This command is only valid for statements like SELECT or SHOW that return an actual result set. To retrieve the number of rows affected by a INSERT, UPDATE, REPLACE or DELETE query, use [mysql\\_affected\\_rows](#).

## Parameters

*result* The result resource that is being evaluated. This result comes from a call to [mysql\\_query](#).

## Return Values

The number of rows in a result set on success, or [FALSE](#) on failure.

## Examples

### Example 20.56. [mysql\\_num\\_rows](#) example

```
<?php
$link = mysql_connect("localhost", "mysql_user", "mysql_password");
mysql_select_db("database", $link);

$result = mysql_query("SELECT * FROM table1", $link);
$num_rows = mysql_num_rows($result);

echo "$num_rows Rows\n";

?>
```

## Notes

### Note

If you use [mysql\\_unbuffered\\_query](#), [mysql\\_num\\_rows](#) will not return the correct value until all the rows in the result set have been retrieved.

### Note

For backward compatibility, the following deprecated alias may be used: [mysql\\_numrows](#)

## See Also

```
mysql_connect
mysql_data_seek
mysql_select_db
mysql_query
```

### 20.10.1.4.39. `mysql_pconnect`

Copyright 1997-2008 the PHP Documentation Group.

- `mysql_pconnect`

Open a persistent connection to a MySQL server

#### Description

```
resource mysql_pconnect(string server,
                        string username,
                        string password,
                        int client_flags);
```

Establishes a persistent connection to a MySQL server.

`mysql_pconnect` acts very much like `mysql_connect` with two major differences.

First, when connecting, the function would first try to find a (persistent) link that's already open with the same host, username and password. If one is found, an identifier for it will be returned instead of opening a new connection.

Second, the connection to the SQL server will not be closed when the execution of the script ends. Instead, the link will remain open for future use (`mysql_close` will not close links established by `mysql_pconnect`).

This type of link is therefore called 'persistent'.

#### Parameters

<code>server</code>	The MySQL server. It can also include a port number. e.g. "hostname:port" or a path to a local socket e.g. ":/path/to/socket" for the localhost.  If the PHP directive <code>mysql.default_host</code> is undefined (default), then the default value is 'localhost:3306'
<code>username</code>	The username. Default value is the name of the user that owns the server process.
<code>password</code>	The password. Default value is an empty password.
<code>client_flags</code>	The <code>client_flags</code> parameter can be a combination of the following constants: 128 (enable <code>LOAD DATA LOCAL</code> handling), <code>MYSQL_CLIENT_SSL</code> , <code>MYSQL_CLIENT_COMPRESS</code> , <code>MYSQL_CLIENT_IGNORE_SPACE</code> or <code>MYSQL_CLIENT_INTERACTIVE</code> .

#### Return Values

Returns a MySQL persistent link identifier on success, or `FALSE` on failure.

#### ChangeLog

Version	Description
4.3.0	Added the <code>client_flags</code> parameter.
3.0.10	Added support for ":/path/to/socket" with <code>server</code> .
3.0.0	Added support for ":port" with <code>server</code> .

#### Notes

##### ■ Note

Note, that these kind of links only work if you are using a module version of PHP. See the [Persistent Database Connections](#) section for more information.

### Warning

Using persistent connections can require a bit of tuning of your Apache and MySQL configurations to ensure that you do not exceed the number of connections allowed by MySQL.

### Note

You can suppress the error message on failure by prepending a `@` to the function name.

### See Also

[mysql\\_connect](#)  
[Persistent Database Connections](#)

## 20.10.1.4.40. `mysql_ping`

Copyright 1997-2008 the PHP Documentation Group.

- `mysql_ping`

Ping a server connection or reconnect if there is no connection

### Description

```
bool mysql_ping(resource link_identifier);
```

Checks whether or not the connection to the server is working. If it has gone down, an automatic reconnection is attempted. This function can be used by scripts that remain idle for a long while, to check whether or not the server has closed the connection and reconnect if necessary.

### Note

Since MySQL 5.0.13, automatic reconnection feature is disabled.

### Parameters

*link\_identifier* The MySQL connection. If the link identifier is not specified, the last link opened by `mysql_connect` is assumed. If no such link is found, it will try to create one as if `mysql_connect` was called with no arguments. If by chance no connection is found or established, an `E_WARNING` level error is generated.

### Return Values

Returns `TRUE` if the connection to the server MySQL server is working, otherwise `FALSE`.

### Examples

#### Example 20.57. A `mysql_ping` example

```
<?php
set_time_limit(0);

$conn = mysql_connect('localhost', 'mysqluser', 'mypass');
$db = mysql_select_db('mydb');

/* Assuming this query will take a long time */
$result = mysql_query($sql);
if (!$result) {
    echo 'Query #1 failed, exiting.';
    exit;
}

/* Make sure the connection is still alive, if not, try to reconnect */
```

```

if (!mysql_ping($conn)) {
    echo 'Lost connection, exiting after query #1';
    exit;
}
mysql_free_result($result);

/* So the connection is still alive, let's run another query */
$result2 = mysql_query($sql2);
?>

```

**See Also**

[mysql\\_thread\\_id](#)  
[mysql\\_list\\_processes](#)

**20.10.1.4.41. mysql\_query**

Copyright 1997-2008 the PHP Documentation Group.

- [mysql\\_query](#)

Send a MySQL query

**Description**

```

resource mysql_query(string query,
                    resource link_identifier);

```

[mysql\\_query](#) sends an unique query (multiple queries are not supported) to the currently active database on the server that's associated with the specified [link\\_identifier](#).

**Parameters**

<a href="#">query</a>	A SQL query  The query string should not end with a semicolon.
<a href="#">link_identifier</a>	The MySQL connection. If the link identifier is not specified, the last link opened by <a href="#">mysql_connect</a> is assumed. If no such link is found, it will try to create one as if <a href="#">mysql_connect</a> was called with no arguments. If by chance no connection is found or established, an <a href="#">E_WARNING</a> level error is generated.

**Return Values**

For SELECT, SHOW, DESCRIBE, EXPLAIN and other statements returning resultset, [mysql\\_query](#) returns a resource on success, or [FALSE](#) on error.

For other type of SQL statements, INSERT, UPDATE, DELETE, DROP, etc, [mysql\\_query](#) returns [TRUE](#) on success or [FALSE](#) on error.

The returned result resource should be passed to [mysql\\_fetch\\_array](#), and other functions for dealing with result tables, to access the returned data.

Use [mysql\\_num\\_rows](#) to find out how many rows were returned for a SELECT statement or [mysql\\_affected\\_rows](#) to find out how many rows were affected by a DELETE, INSERT, REPLACE, or UPDATE statement.

[mysql\\_query](#) will also fail and return [FALSE](#) if the user does not have permission to access the table(s) referenced by the query.

**Examples****Example 20.58. Invalid Query**

The following query is syntactically invalid, so `mysql_query` fails and returns `FALSE`.

```
<?php
$result = mysql_query('SELECT * WHERE 1=1');
if (!$result) {
    die('Invalid query: ' . mysql_error());
}
?>
```

### Example 20.59. Valid Query

The following query is valid, so `mysql_query` returns a resource.

```
<?php
// This could be supplied by a user, for example
$firstname = 'fred';
$lastname = 'fox';

// Formulate Query
// This is the best way to perform a SQL query
// For more examples, see mysql_real_escape_string()
$query = sprintf("SELECT firstname, lastname, address, age FROM friends WHERE firstname='%s' AND lastname='%s'",
    mysql_real_escape_string($firstname),
    mysql_real_escape_string($lastname));

// Perform Query
$result = mysql_query($query);

// Check result
// This shows the actual query sent to MySQL, and the error. Useful for debugging.
if (!$result) {
    $message = 'Invalid query: ' . mysql_error() . "\n";
    $message .= 'Whole query: ' . $query;
    die($message);
}

// Use result
// Attempting to print $result won't allow access to information in the resource
// One of the mysql result functions must be used
// See also mysql_result(), mysql_fetch_array(), mysql_fetch_row(), etc.
while ($row = mysql_fetch_assoc($result)) {
    echo $row['firstname'];
    echo $row['lastname'];
    echo $row['address'];
    echo $row['age'];
}

// Free the resources associated with the result set
// This is done automatically at the end of the script
mysql_free_result($result);
?>
```

### See Also

[mysql\\_fetch\\_assoc](#)  
[mysql\\_unbuffered\\_query](#)

#### 20.10.1.4.42. [mysql\\_real\\_escape\\_string](#)

Copyright 1997-2008 the PHP Documentation Group.

- [mysql\\_real\\_escape\\_string](#)

Escapes special characters in a string for use in a SQL statement

**Description**

```
string mysql_real_escape_string(string unescaped_string,
                               resource link_identifier);
```

Escapes special characters in the *unescaped\_string*, taking into account the current character set of the connection so that it is safe to place it in a *mysql\_query*. If binary data is to be inserted, this function must be used.

*mysql\_real\_escape\_string* calls MySQL's library function *mysql\_real\_escape\_string*, which prepends backslashes to the following characters: `\x00`, `\n`, `\r`, `\`, `'`, `"` and `\x1a`.

This function must always (with few exceptions) be used to make data safe before sending a query to MySQL.

**Parameters**

<i>unescaped_string</i>	The string that is to be escaped.
<i>link_identifier</i>	The MySQL connection. If the link identifier is not specified, the last link opened by <i>mysql_connect</i> is assumed. If no such link is found, it will try to create one as if <i>mysql_connect</i> was called with no arguments. If by chance no connection is found or established, an <code>E_WARNING</code> level error is generated.

**Return Values**

Returns the escaped string, or `FALSE` on error.

**Examples****Example 20.60. Simple *mysql\_real\_escape\_string* example**

```
<?php
// Connect
$link = mysql_connect('mysql_host', 'mysql_user', 'mysql_password')
      OR die(mysql_error());

// Query
$query = sprintf("SELECT * FROM users WHERE user='%s' AND password='%s'",
                mysql_real_escape_string($user),
                mysql_real_escape_string($password));
?>
```

**Example 20.61. An example SQL Injection Attack**

```
<?php
// Query database to check if there are any matching users
$query = "SELECT * FROM users WHERE user='{$_POST['username']}' AND password='{$_POST['password']}'";
mysql_query($query);

// We didn't check $_POST['password'], it could be anything the user wanted! For example:
$_POST['username'] = 'aidan';
$_POST['password'] = "' OR ''='";

// This means the query sent to MySQL would be:
echo $query;
?>
```

The query sent to MySQL:

```
SELECT * FROM users WHERE user='aidan' AND password='' OR ''=''
```

This would allow anyone to log in without a valid password.

### Example 20.62. A "Best Practice" query

Using `mysql_real_escape_string` around each variable prevents SQL Injection. This example demonstrates the "best practice" method for querying a database, independent of the [Magic Quotes](#) setting.

```
<?php
if (isset($_POST['product_name']) && isset($_POST['product_description']) && isset($_POST['user_id'])) {
    // Connect

    $link = mysql_connect('mysql_host', 'mysql_user', 'mysql_password');

    if(!is_resource($link)) {
        echo "Failed to connect to the server\n";
        // ... log the error properly
    } else {
        // Reverse magic_quotes_gpc/magic_quotes_sybase effects on those vars if ON.
        if(get_magic_quotes_gpc()) {
            $product_name      = stripslashes($_POST['product_name']);
            $product_description = stripslashes($_POST['product_description']);
        } else {
            $product_name      = $_POST['product_name'];
            $product_description = $_POST['product_description'];
        }

        // Make a safe query
        $query = sprintf("INSERT INTO products (`name`, `description`, `user_id`) VALUES ('%s', '%s', %d)",
            mysql_real_escape_string($product_name, $link),
            mysql_real_escape_string($product_description, $link),
            $_POST['user_id']);

        mysql_query($query, $link);

        if (mysql_affected_rows($link) > 0) {
            echo "Product inserted\n";
        }
    } else {
        echo "Fill the form properly\n";
    }
}
?>
```

The query will now execute correctly, and SQL Injection attacks will not work.

#### Notes

##### Note

A MySQL connection is required before using `mysql_real_escape_string` otherwise an error of level `E_WARNING` is generated, and `FALSE` is returned. If `link_identifier` isn't defined, the last MySQL connection is used.

##### Note

If `magic_quotes_gpc` is enabled, first apply `stripslashes` to the data. Using this function on data which has already been escaped will escape the data twice.

##### Note

If this function is not used to escape data, the query is vulnerable to [SQL Injection Attacks](#).

##### Note

`mysql_real_escape_string` does not escape `%` and `_`. These are wildcards in MySQL if combined with `LIKE`, `GRANT`, or `REVOKE`.

#### See Also

[mysql\\_client\\_encoding](#)

 The [magic\\_quotes\\_runtime](#) directive

#### 20.10.1.4.43. [mysql\\_result](#)

Copyright 1997-2008 the PHP Documentation Group.

- [mysql\\_result](#)

Get result data

##### Description

```
string mysql_result(resource result,
                   int row,
                   mixed field);
```

Retrieves the contents of one cell from a MySQL result set.

When working on large result sets, you should consider using one of the functions that fetch an entire row (specified below). As these functions return the contents of multiple cells in one function call, they're MUCH quicker than [mysql\\_result](#). Also, note that specifying a numeric offset for the field argument is much quicker than specifying a fieldname or `tablename.fieldname` argument.

##### Parameters

<i>result</i>	The result resource that is being evaluated. This result comes from a call to <a href="#">mysql_query</a> .
<i>row</i>	The row number from the result that's being retrieved. Row numbers start at 0.
<i>field</i>	The name or offset of the field being retrieved.  It can be the field's offset, the field's name, or the field's table dot field name ( <code>tablename.fieldname</code> ). If the column name has been aliased ('select foo as bar from...'), use the alias instead of the column name. If undefined, the first field is retrieved.

##### Return Values

The contents of one cell from a MySQL result set on success, or `FALSE` on failure.

##### Examples

#### Example 20.63. [mysql\\_result](#) example

```
<?php
$link = mysql_connect('localhost', 'mysql_user', 'mysql_password');
if (!$link) {
    die('Could not connect: ' . mysql_error());
}
$result = mysql_query('SELECT name FROM work.employee');
if (!$result) {
    die('Could not query:' . mysql_error());
}
echo mysql_result($result, 2); // outputs third employee's name

mysql_close($link);
?>
```

##### Notes

**Note**

Calls to `mysql_result` should not be mixed with calls to other functions that deal with the result set.

**See Also**

`mysql_fetch_row`  
`mysql_fetch_array`  
`mysql_fetch_assoc`  
`mysql_fetch_object`

**20.10.1.4.44. `mysql_select_db`**

Copyright 1997-2008 the PHP Documentation Group.

- `mysql_select_db`  
 Select a MySQL database

**Description**

```
bool mysql_select_db(string database_name,
                    resource link_identifier);
```

Sets the current active database on the server that's associated with the specified link identifier. Every subsequent call to `mysql_query` will be made on the active database.

**Parameters**

<i>database_name</i>	The name of the database that is to be selected.
<i>link_identifier</i>	The MySQL connection. If the link identifier is not specified, the last link opened by <code>mysql_connect</code> is assumed. If no such link is found, it will try to create one as if <code>mysql_connect</code> was called with no arguments. If by chance no connection is found or established, an <code>E_WARNING</code> level error is generated.

**Return Values**

Returns `TRUE` on success or `FALSE` on failure.

**Examples****Example 20.64. `mysql_select_db` example**

```
<?php
$link = mysql_connect('localhost', 'mysql_user', 'mysql_password');
if (!$link) {
    die('Not connected : ' . mysql_error());
}

// make foo the current db
$db_selected = mysql_select_db('foo', $link);
if (!$db_selected) {
    die ('Can\'t use foo : ' . mysql_error());
}
?>
```

**Notes****Note**

For backward compatibility, the following deprecated alias may be used: `mysql_selectdb`

#### See Also

`mysql_connect`  
`mysql_pconnect`  
`mysql_query`

#### 20.10.1.4.45. `mysql_set_charset`

Copyright 1997-2008 the PHP Documentation Group.

- `mysql_set_charset`

Sets the client character set

#### Description

```
bool mysql_set_charset(string charset,
                      resource link_identifier);
```

Sets the default character set for the current connection.

#### Parameters

*charset*

A valid character set name.

*link\_identifier*

The MySQL connection. If the link identifier is not specified, the last link opened by `mysql_connect` is assumed. If no such link is found, it will try to create one as if `mysql_connect` was called with no arguments. If by chance no connection is found or established, an `E_WARNING` level error is generated.

#### Return Values

Returns `TRUE` on success or `FALSE` on failure.

#### Notes

##### Note

This function requires MySQL 5.0.7 or later.

##### Note

This is the preferred way to change the charset. Using `mysql_query` to execute `SET NAMES ..` is not recommended.

#### See Also

`mysql_client_encoding`  
[List of character sets that MySQL supports](#)

#### 20.10.1.4.46. `mysql_stat`

Copyright 1997-2008 the PHP Documentation Group.

- `mysql_stat`

Get current system status

#### Description

```
string mysql_stat(resource link_identifier);
```

`mysql_stat` returns the current server status.

### Parameters

*link\_identifier* The MySQL connection. If the link identifier is not specified, the last link opened by `mysql_connect` is assumed. If no such link is found, it will try to create one as if `mysql_connect` was called with no arguments. If by chance no connection is found or established, an `E_WARNING` level error is generated.

### Return Values

Returns a string with the status for uptime, threads, queries, open tables, flush tables and queries per second. For a complete list of other status variables, you have to use the `SHOW STATUS` SQL command. If *link\_identifier* is invalid, `NULL` is returned.

### Examples

#### Example 20.65. `mysql_stat` example

```
<?php
$link = mysql_connect('localhost', 'mysql_user', 'mysql_password');
$status = explode(' ', mysql_stat($link));
print_r($status);
?>
```

The above example will output something similar to:

```
Array
(
    [0] => Uptime: 5380
    [1] => Threads: 2
    [2] => Questions: 1321299
    [3] => Slow queries: 0
    [4] => Opens: 26
    [5] => Flush tables: 1
    [6] => Open tables: 17
    [7] => Queries per second avg: 245.595
)
```

#### Example 20.66. Alternative `mysql_stat` example

```
<?php
$link = mysql_connect('localhost', 'mysql_user', 'mysql_password');
$result = mysql_query('SHOW VARIABLES', $link);
while ($row = mysql_fetch_assoc($result)) {
    echo $row['Variable_name'] . ' = ' . $row['Value'] . "\n";
}
?>
```

The above example will output something similar to:

```
back_log = 50
basedir = /usr/local/
bdb_cache_size = 8388600
bdb_log_buffer_size = 32768
bdb_home = /var/db/mysql/
bdb_max_lock = 10000
bdb_logdir =
bdb_shared_data = OFF
```

```
bdb_tmpdir = /var/tmp/  
...
```

### See Also

[mysql\\_list\\_processes](#)

#### 20.10.1.4.47. [mysql\\_tablename](#)

Copyright 1997-2008 the PHP Documentation Group.

- [mysql\\_tablename](#)

Get table name of field

### Description

```
string mysql_tablename(resource result,  
int i);
```

Retrieves the table name from a *result*.

This function deprecated. It is preferable to use [mysql\\_query](#) to issue a SQL `SHOW TABLES [FROM db_name] [LIKE 'pattern']` statement instead.

### Parameters

*result* A result pointer resource that's returned from [mysql\\_list\\_tables](#).  
*i* The integer index (row/table number)

### Return Values

The name of the table on success, or `FALSE` on failure.

Use the [mysql\\_tablename](#) function to traverse this result pointer, or any function for result tables, such as [mysql\\_fetch\\_array](#).

### Examples

#### Example 20.67. [mysql\\_tablename](#) example

```
<?php  
mysql_connect("localhost", "mysql_user", "mysql_password");  
$result = mysql_list_tables("mydb");  
$num_rows = mysql_num_rows($result);  
for ($i = 0; $i < $num_rows; $i++) {  
    echo "Table: ", mysql_tablename($result, $i), "\n";  
}  
  
mysql_free_result($result);  
?>
```

### Notes

#### ■ Note

The `mysql_num_rows` function may be used to determine the number of tables in the result pointer.

#### See Also

[mysql\\_list\\_tables](#)  
[mysql\\_field\\_table](#)  
[mysql\\_db\\_name](#)

### 20.10.1.4.48. `mysql_thread_id`

Copyright 1997-2008 the PHP Documentation Group.

- [mysql\\_thread\\_id](#)

Return the current thread ID

#### Description

```
int mysql_thread_id(resource link_identifier);
```

Retrieves the current thread ID. If the connection is lost, and a reconnect with `mysql_ping` is executed, the thread ID will change. This means only retrieve the thread ID when needed.

#### Parameters

*link\_identifier*                      The MySQL connection. If the link identifier is not specified, the last link opened by `mysql_connect` is assumed. If no such link is found, it will try to create one as if `mysql_connect` was called with no arguments. If by chance no connection is found or established, an `E_WARNING` level error is generated.

#### Return Values

The thread ID on success, or `FALSE` on failure.

#### Examples

#### Example 20.68. `mysql_thread_id` example

```
<?php
$link = mysql_connect('localhost', 'mysql_user', 'mysql_password');
$thread_id = mysql_thread_id($link);
if ($thread_id){
    printf("current thread id is %d\n", $thread_id);
}
?>
```

The above example will output something similar to:

```
current thread id is 73
```

#### See Also

[mysql\\_ping](#)  
[mysql\\_list\\_processes](#)

### 20.10.1.4.49. `mysql_unbuffered_query`

Copyright 1997-2008 the PHP Documentation Group.

- `mysql_unbuffered_query`

Send an SQL query to MySQL, without fetching and buffering the result rows

#### Description

```
resource mysql_unbuffered_query(string query,
                               resource link_identifier);
```

`mysql_unbuffered_query` sends a SQL query *query* to MySQL, without fetching and buffering the result rows automatically, as `mysql_query` does. On the one hand, this saves a considerable amount of memory with SQL queries that produce large result sets. On the other hand, you can start working on the result set immediately after the first row has been retrieved: you don't have to wait until the complete SQL query has been performed. When using multiple DB-connects, you have to specify the optional parameter *link\_identifier*.

#### Parameters

<i>query</i>	A SQL query
<i>link_identifier</i>	The MySQL connection. If the link identifier is not specified, the last link opened by <code>mysql_connect</code> is assumed. If no such link is found, it will try to create one as if <code>mysql_connect</code> was called with no arguments. If by chance no connection is found or established, an <code>E_WARNING</code> level error is generated.

#### Return Values

For SELECT, SHOW, DESCRIBE or EXPLAIN statements, `mysql_unbuffered_query` returns a resource on success, or `FALSE` on error.

For other type of SQL statements, UPDATE, DELETE, DROP, etc, `mysql_unbuffered_query` returns `TRUE` on success or `FALSE` on error.

#### Notes

##### Note

The benefits of `mysql_unbuffered_query` come at a cost: You cannot use `mysql_num_rows` and `mysql_data_seek` on a result set returned from `mysql_unbuffered_query`. You also have to fetch all result rows from an unbuffered SQL query, before you can send a new SQL query to MySQL.

#### See Also

`mysql_query`

## 20.10.2. MySQL Improved Extension (`Mysqli`)

Copyright 1997-2008 the PHP Documentation Group.

The `mysqli` extension allows you to access the functionality provided by MySQL 4.1 and above. More information about the MySQL Database server can be found at <http://www.mysql.com/>

An overview of software available for using MySQL from PHP can be found at [Section 20.10.2.2, "Overview"](#)

Documentation for MySQL can be found at <http://dev.mysql.com/doc/>.

Parts of this documentation included from MySQL manual with permissions of MySQL AB.

### 20.10.2.1. Examples

Copyright 1997-2008 the PHP Documentation Group.

All Examples in the MySQLI documentation use the world database from MySQL AB. The world database can be found at <http://dev.mysql.com/get/Downloads/Manual/world.sql.gz/from/pick>

## 20.10.2.2. Overview

Copyright 1997-2008 the PHP Documentation Group.

This section provides an introduction to the options available to you when developing a PHP application that needs to interact with a MySQL database.

*What is an API?*

An Application Programming Interface, or API, defines the classes, methods, functions and variables that your application will need to call in order to carry out its desired task. In the case of PHP applications that need to communicate with databases the necessary APIs are usually exposed via PHP extensions.

APIs can be procedural or object-oriented. With a procedural API you call functions to carry out tasks, with the object-oriented API you instantiate classes and then call methods on the resulting objects. Of the two the latter is usually the preferred interface, as it is more modern and leads to better organised code.

When writing PHP applications that need to connect to the MySQL server there are several API options available. This document discusses what is available and how to select the best solution for your application.

*What is a Connector?*

In the MySQL documentation, the term *connector* refers to a piece of software that allows your application to connect to the MySQL database server. MySQL provides connectors for a variety of languages, including PHP.

If your PHP application needs to communicate with a database server you will need to write PHP code to perform such activities as connecting to the database server, querying the database and other database-related functions. Software is required to provide the API that your PHP application will use, and also handle the communication between your application and the database server, possibly using other intermediate libraries where necessary. This software is known generically as a connector, as it allows your application to *connect* to a database server.

*What is a Driver?*

A driver is a piece of software designed to communicate with a specific type of database server. The driver may also call a library, such as the MySQL Client Library or the MySQL Native Driver. These libraries implement the low-level protocol used to communicate with the MySQL database server.

By way of an example, the [PHP Data Objects \(PDO\)](#) database abstraction layer may use one of several database-specific drivers. One of the drivers it has available is the PDO MySQL driver, which allows it to interface with the MySQL server.

Sometimes people use the terms connector and driver interchangeably, this can be confusing. In the MySQL-related documentation the term “driver” is reserved for software that provides the database-specific part of a connector package.

*What is an Extension?*

In the PHP documentation you will come across another term - *extension*. The PHP code consists of a core, with optional extensions to the core functionality. PHP's MySQL-related extensions, such as the `mysqli` extension, and the `mysql` extension, are implemented using the PHP extension framework.

An extension typically exposes an API to the PHP programmer, to allow its facilities to be used programmatically. However, some extensions which use the PHP extension framework do not expose an API to the PHP programmer.

The PDO MySQL driver extension, for example, does not expose an API to the PHP programmer, but provides an interface to the PDO layer above it.

The terms API and extension should not be taken to mean the same thing, as an extension may not necessarily expose an API to the programmer.

*What are the main PHP API offerings for using MySQL?*

There are three main API options when considering connecting to a MySQL database server:

- PHP's MySQL Extension
- PHP's `mysqli` Extension
- PHP Data Objects (PDO)

Each has its own advantages and disadvantages. The following discussion aims to give a brief introduction to the key aspects of each API.

#### *What is PHP's MySQL Extension?*

This is the original extension designed to allow you to develop PHP applications that interact with a MySQL database. The `mysql` extension provides a procedural interface and is intended for use only with MySQL versions older than 4.1.3. This extension can be used with versions of MySQL 4.1.3 or newer, but not all of the latest MySQL server features will be available.

#### **Note**

If you are using MySQL versions 4.1.3 or later it is *strongly* recommended that you use the `mysqli` extension instead.

The `mysql` extension source code is located in the PHP extension directory `ext/mysql`.

For further information on the `mysql` extension, see [Section 20.10.1, “MySQL”](#).

#### *What is PHP's mysqli Extension?*

The `mysqli` extension, or as it is sometimes known, the MySQL *improved* extension, was developed to take advantage of new features found in MySQL systems versions 4.1.3 and newer. The `mysqli` extension is included with PHP versions 5 and later.

The `mysqli` extension has a number of benefits, the key enhancements over the `mysql` extension being:

- Object-oriented interface
- Support for Prepared Statements
- Support for Multiple Statements
- Support for Transactions
- Enhanced debugging capabilities
- Embedded server support

#### **Note**

If you are using MySQL versions 4.1.3 or later it is *strongly* recommended that you use this extension.

As well as the object-oriented interface the extension also provides a procedural interface.

The `mysqli` extension is built using the PHP extension framework, its source code is located in the directory `ext/mysqli`.

For further information on the `mysqli` extension, see [Section 20.10.2, “MySQL Improved Extension \(Mysqli\)”](#).

#### *What is PDO?*

PHP Data Objects, or PDO, is a database abstraction layer specifically for PHP applications. PDO provides a consistent API for your PHP application regardless of the type of database server your application will connect to. In theory, if you are using the PDO API, you could switch the database server you used, from say Firebird to MySQL, and only need to make minor changes to your PHP code.

Other examples of database abstraction layers include JDBC for Java applications and DBI for Perl.

While PDO has its advantages, such as a clean, simple, portable API, its main disadvantage is that it doesn't allow you to use all of the advanced features that are available in the latest versions of MySQL server. For example, PDO does not allow you to use MySQL's support for Multiple Statements.

PDO is implemented using the PHP extension framework, its source code is located in the directory `ext/pdo`.

For further information on PDO, see the [Section 20.10.3, “MySQL Functions \(PDO\\_MYSQL\)”](#).

#### *What is the PDO MYSQL driver?*

The PDO MYSQL driver is not an API as such, at least from the PHP programmer's perspective. In fact the PDO MYSQL driver sits in the layer below PDO itself and provides MySQL-specific functionality. The programmer still calls the PDO API, but PDO uses the PDO MYSQL driver to carry out communication with the MySQL server.

The PDO MYSQL driver is one of several available PDO drivers. Other PDO drivers available include those for the Firebird and PostgreSQL database servers.

The PDO MYSQL driver is implemented using the PHP extension framework. Its source code is located in the directory `ext/pdo_mysql`. It does not expose an API to the PHP programmer.

For further information on the PDO MYSQL driver, see [Section 20.10.3, “MySQL Functions \(PDO\\_MYSQL\)”](#).

*What is PHP's MySQL Native Driver?*

In order to communicate with the MySQL database server the `mysql` extension, `mysqli` and the PDO MYSQL driver each use a low-level library that implements the required protocol. In the past, the only available library was the MySQL Client Library, otherwise known as `libmysql`.

However, the interface presented by `libmysql` was not optimized for communication with PHP applications, as `libmysql` was originally designed with C applications in mind. For this reason the MySQL Native Driver, `mysqlnd`, was developed as an alternative to `libmysql` for PHP applications.

The `mysql` extension, the `mysqli` extension and the PDO MySQL driver can each be individually configured to use either `libmysql` or `mysqlnd`. As `mysqlnd` is designed specifically to be utilised in the PHP system it has numerous memory and speed enhancements over `libmysql`. You are strongly encouraged to take advantage of these improvements.

### Note

The MySQL Native Driver can only be used with MySQL server versions 4.1.3 and later.

The MySQL Native Driver is implemented using the PHP extension framework. The source code is located in `ext/mysqlnd`. It does not expose an API to the PHP programmer.

### Comparison of Features

The following table compares the functionality of the three main methods of connecting to MySQL from PHP:

	PHP's <code>mysqli</code> Extension	PDO (Using PDO MySQL Driver and MySQL Native Driver)	PHP's MySQL Extension
PHP version introduced	5.0	5.0	Prior to 3.0
Included with PHP 5.x	yes	yes	Yes
Comes with PHP 6.0	Yes	Yes	Yes
MySQL development status	Active development	Active development as of PHP 5.3	Maintenance only
Recommended by MySQL for new projects	Yes - preferred option	Yes	No
API supports Charsets	Yes	Yes	No
API supports server-side Prepared Statements	Yes	Yes	No
API supports client-side Prepared Statements	No	Yes	No
API supports Stored Procedures	Yes	Yes	No
API supports Multiple Statements	Yes	Most	No
Supports all MySQL 4.1+ functionality	Yes	Most	No

## 20.10.2.3. Installing/Configuring

Copyright 1997-2008 the PHP Documentation Group.

### 20.10.2.3.1. Requirements

Copyright 1997-2008 the PHP Documentation Group.

In order to have these functions available, you must compile PHP with support for the `mysqli` extension.

**Note**

The `mysqli` extension is designed to work with the version 4.1.3 or above of MySQL. For previous versions, please see the [MySQL extension documentation](#).

**20.10.2.3.2. Installation**

Copyright 1997-2008 the PHP Documentation Group.

To install the `mysqli` extension for PHP, use the `--with-mysqli=mysql_config_path/mysql_config` configuration option where `mysql_config_path` represents the location of the `mysql_config` program that comes with MySQL versions greater than 4.1.

If you would like to install the `mysql` extension along with the `mysqli` extension you have to use the same client library to avoid any conflicts.

**20.10.2.3.2.1. Installation on Windows Systems**

Copyright 1997-2008 the PHP Documentation Group.

MySQLi is not enabled by default, so the `php_mysqli.dll` DLL must be enabled inside of `php.ini`. Also, PHP needs access to the MySQL client library. A file named `libmysql.dll` is included in the Windows PHP distribution and in order for PHP to talk to MySQL this file needs to be available to the Windows systems `PATH`. See the FAQ titled "[How do I add my PHP directory to the PATH on Windows](#)" for information on how to do this. Although copying `libmysql.dll` to the Windows system directory also works (because the system directory is by default in the system's `PATH`), it's not recommended.

As with enabling any PHP extension (such as `php_mysqli.dll`), the PHP directive `extension_dir` should be set to the directory where the PHP extensions are located. See also the [Manual Windows Installation Instructions](#). An example `extension_dir` value for PHP 5 is `c:\php\ext`

**Note**

If when starting the web server an error similar to the following occurs: "Unable to load dynamic library '`./php_mysqli.dll`'", this is because `php_mysqli.dll` and/or `libmysql.dll` cannot be found by the system.

**20.10.2.3.3. Runtime Configuration**

Copyright 1997-2008 the PHP Documentation Group.

The behaviour of these functions is affected by settings in `php.ini`.

**Table 20.7. MySQLi Configuration Options**

Name	Default	Changeable	Changelog
<code>mysqli.max_links</code>	"-1"	PHP_INI_SYSTEM	Available since PHP 5.0.0.
<code>mysqli.default_port</code>	"3306"	PHP_INI_ALL	Available since PHP 5.0.0.
<code>mysqli.default_socket</code>	NULL	PHP_INI_ALL	Available since PHP 5.0.0.
<code>mysqli.default_host</code>	NULL	PHP_INI_ALL	Available since PHP 5.0.0.
<code>mysqli.default_user</code>	NULL	PHP_INI_ALL	Available since PHP 5.0.0.
<code>mysqli.default_pw</code>	NULL	PHP_INI_ALL	Available since PHP 5.0.0.

For further details and definitions of the above `PHP_INI_*` constants, see the chapter on [configuration changes](#).

Here's a short explanation of the configuration directives.

<code>mysqli.max_links</code> integer	The maximum number of MySQL connections per process.
<code>mysqli.default_port</code> string	The default TCP port number to use when connecting to the database server if no other port is specified. If no default is specified, the port will be obtained from the <code>MYSQL_TCP_PORT</code> environment variable, the <code>mysql-tcp</code> entry in <code>/etc/services</code> or the compile-time <code>MYSQL_PORT</code> constant, in that order. Win32 will only use the <code>MYSQL_PORT</code> constant.

---

<code>mysqli.default_socket</code> string	The default socket name to use when connecting to a local database server if no other socket name is specified.
<code>mysqli.default_host</code> string	The default server host to use when connecting to the database server if no other host is specified. Doesn't apply in <a href="#">safe mode</a> .
<code>mysqli.default_user</code> string	The default user name to use when connecting to the database server if no other name is specified. Doesn't apply in <a href="#">safe mode</a> .
<code>mysqli.default_pw</code> string	The default password to use when connecting to the database server if no other password is specified. Doesn't apply in <a href="#">safe mode</a> .

#### 20.10.2.3.4. Resource Types

Copyright 1997-2008 the PHP Documentation Group.

This extension has no resource types defined.

#### 20.10.2.4. Predefined Constants

Copyright 1997-2008 the PHP Documentation Group.

<code>MYSQLI_READ_DEFAULT_GROUP</code>	Read options from the named group from <code>my.cnf</code> or the file specified with <code>MYSQLI_READ_DEFAULT_FILE</code>
<code>MYSQLI_READ_DEFAULT_FILE</code>	Read options from the named option file instead of from <code>my.cnf</code>
<code>MYSQLI_OPT_CONNECT_TIMEOUT</code>	Connect timeout in seconds
<code>MYSQLI_OPT_LOCAL_INFILE</code>	Enables command <code>LOAD LOCAL INFILE</code>
<code>MYSQLI_INIT_COMMAND</code>	Command to execute when connecting to MySQL server. Will automatically be re-executed when reconnecting.
<code>MYSQLI_CLIENT_SSL</code>	Use SSL (encrypted protocol). This option should not be set by application programs; it is set internally in the MySQL client library
<code>MYSQLI_CLIENT_COMPRESS</code>	Use compression protocol
<code>MYSQLI_CLIENT_INTERACTIVE</code>	Allow <code>interactive_timeout</code> seconds (instead of <code>wait_timeout</code> seconds) of inactivity before closing the connection. The client's session <code>wait_timeout</code> variable will be set to the value of the session <code>interactive_timeout</code> variable.
<code>MYSQLI_CLIENT_IGNORE_SPACE</code>	Allow spaces after function names. Makes all functions names reserved words.
<code>MYSQLI_CLIENT_NO_SCHEMA</code>	Don't allow the <code>db_name.tbl_name.col_name</code> syntax.
<code>MYSQLI_CLIENT_MULTI_QUERIES</code>	Allows multiple semicolon-delimited queries in a single <code>mysqli_query</code> call.
<code>MYSQLI_STORE_RESULT</code>	For using buffered resultsets
<code>MYSQLI_USE_RESULT</code>	For using unbuffered resultsets
<code>MYSQLI_ASSOC</code>	Columns are returned into the array having the fieldname as the array index.
<code>MYSQLI_NUM</code>	Columns are returned into the array having an enumerated index.
<code>MYSQLI_BOTH</code>	Columns are returned into the array having both a numerical index and the fieldname as the associative index.
<code>MYSQLI_NOT_NULL_FLAG</code>	Indicates that a field is defined as <code>NOT NULL</code>
<code>MYSQLI_PRI_KEY_FLAG</code>	Field is part of a primary index
<code>MYSQLI_UNIQUE_KEY_FLAG</code>	Field is part of a unique index.
<code>MYSQLI_MULTIPLE_KEY_FLAG</code>	Field is part of an index.
<code>MYSQLI_BLOB_FLAG</code>	Field is defined as <code>BLOB</code>

<code>MYSQLI_UNSIGNED_FLAG</code>	Field is defined as <code>UNSIGNED</code>
<code>MYSQLI_ZEROFILL_FLAG</code>	Field is defined as <code>ZEROFILL</code>
<code>MYSQLI_AUTO_INCREMENT_FLAG</code>	Field is defined as <code>AUTO_INCREMENT</code>
<code>MYSQLI_TIMESTAMP_FLAG</code>	Field is defined as <code>TIMESTAMP</code>
<code>MYSQLI_SET_FLAG</code>	Field is defined as <code>SET</code>
<code>MYSQLI_NUM_FLAG</code>	Field is defined as <code>NUMERIC</code>
<code>MYSQLI_PART_KEY_FLAG</code>	Field is part of an multi-index
<code>MYSQLI_GROUP_FLAG</code>	Field is part of <code>GROUP BY</code>
<code>MYSQLI_TYPE_DECIMAL</code>	Field is defined as <code>DECIMAL</code>
<code>MYSQLI_TYPE_NEWDECIMAL</code>	Precision math <code>DECIMAL</code> or <code>NUMERIC</code> field (MySQL 5.0.3 and up)
<code>MYSQLI_TYPE_BIT</code>	Field is defined as <code>BIT</code> (MySQL 5.0.3 and up)
<code>MYSQLI_TYPE_TINY</code>	Field is defined as <code>TINYINT</code>
<code>MYSQLI_TYPE_SHORT</code>	Field is defined as <code>SMALLINT</code>
<code>MYSQLI_TYPE_LONG</code>	Field is defined as <code>INT</code>
<code>MYSQLI_TYPE_FLOAT</code>	Field is defined as <code>FLOAT</code>
<code>MYSQLI_TYPE_DOUBLE</code>	Field is defined as <code>DOUBLE</code>
<code>MYSQLI_TYPE_NULL</code>	Field is defined as <code>DEFAULT NULL</code>
<code>MYSQLI_TYPE_TIMESTAMP</code>	Field is defined as <code>TIMESTAMP</code>
<code>MYSQLI_TYPE_LONGLONG</code>	Field is defined as <code>BIGINT</code>
<code>MYSQLI_TYPE_INT24</code>	Field is defined as <code>MEDIUMINT</code>
<code>MYSQLI_TYPE_DATE</code>	Field is defined as <code>DATE</code>
<code>MYSQLI_TYPE_TIME</code>	Field is defined as <code>TIME</code>
<code>MYSQLI_TYPE_DATETIME</code>	Field is defined as <code>DATETIME</code>
<code>MYSQLI_TYPE_YEAR</code>	Field is defined as <code>YEAR</code>
<code>MYSQLI_TYPE_NEWDATE</code>	Field is defined as <code>DATE</code>
<code>MYSQLI_TYPE_ENUM</code>	Field is defined as <code>ENUM</code>
<code>MYSQLI_TYPE_SET</code>	Field is defined as <code>SET</code>
<code>MYSQLI_TYPE_TINY_BLOB</code>	Field is defined as <code>TINYBLOB</code>
<code>MYSQLI_TYPE_MEDIUM_BLOB</code>	Field is defined as <code>MEDIUMBLOB</code>
<code>MYSQLI_TYPE_LONG_BLOB</code>	Field is defined as <code>LOB</code>
<code>MYSQLI_TYPE_BLOB</code>	Field is defined as <code>BLOB</code>
<code>MYSQLI_TYPE_VAR_STRING</code>	Field is defined as <code>VARCHAR</code>
<code>MYSQLI_TYPE_STRING</code>	Field is defined as <code>CHAR</code>
<code>MYSQLI_TYPE_GEOMETRY</code>	Field is defined as <code>GEOMETRY</code>
<code>MYSQLI_NEED_DATA</code>	More data available for bind variable
<code>MYSQLI_NO_DATA</code>	No more data available for bind variable

`MYSQLI_DATA_TRUNCATED` Data truncation occurred. Available since PHP 5.1.0 and MySQL 5.0.5.

`MYSQLI_ENUM_FLAG` Field is defined as `ENUM`. Available since PHP 5.3.0.

## 20.10.2.5. The MySQLi Extension Function Summary

Copyright 1997-2008 the PHP Documentation Group.

MySQLi Class			
OOP Interface	Procedural Interface	Alias (Do not use)	Description
<i>Properties</i>			
<code>\$mysqli-&gt;affected_rows</code>	<code>mysqli_affected_rows</code>	N/A	Gets the number of affected rows in a previous MySQL operation
<code>\$mysqli-&gt;connect_errno</code>	<code>mysqli_connect_errno</code>	N/A	Returns the error code from last connect call
<code>\$mysqli-&gt;connect_error</code>	<code>mysqli_connect_error</code>	N/A	Returns a string description of the last connect error
<code>\$mysqli-&gt;errno</code>	<code>mysqli_errno</code>	N/A	Returns the error code for the most recent function call
<code>\$mysqli-&gt;error</code>	<code>mysqli_error</code>	N/A	Returns a string description of the last error
<code>\$mysqli-&gt;field_count</code>	<code>mysqli_field_count</code>	N/A	Returns the number of columns for the most recent query
<code>\$mysqli-&gt;host_info</code>	<code>mysqli_get_host_info</code>	N/A	Returns a string representing the type of connection used
<code>\$mysqli-&gt;protocol_version</code>	<code>mysqli_get_proto_info</code>	N/A	Returns the version of the MySQL protocol used
<code>\$mysqli-&gt;server_info</code>	<code>mysqli_get_server_info</code>	N/A	Returns the version of the MySQL server
<code>\$mysqli-&gt;server_version</code>	<code>mysqli_get_server_version</code>	N/A	Returns the version of the MySQL server as an integer
<code>\$mysqli-&gt;info</code>	<code>mysqli_info</code>	N/A	Retrieves information about the most recently executed query
<code>\$mysqli-&gt;insert_id</code>	<code>mysqli_insert_id</code>	N/A	Returns the auto generated id used in the last query
<code>\$mysqli-&gt;sqlstate</code>	<code>mysqli_sqlstate</code>	N/A	Returns the SQLSTATE error from previous MySQL operation
<code>\$mysqli-&gt;warning_count</code>	<code>mysqli_warning_count</code>	N/A	Returns the number of warnings from the last query for the given link
<i>Methods</i>			
<code>mysqli-&gt;autocommit</code>	<code>mysqli_autocommit</code>	N/A	Turns on or off auto-committing database modifications
<code>mysqli-&gt;change_user</code>	<code>mysqli_change_user</code>	N/A	Changes the user of the specified database connection
<code>mysqli-&gt;character_set_name</code> , <code>mysqli-&gt;client_encoding</code>	<code>mysqli_character_set_name</code>	<code>mysqli_client_encoding</code>	Returns the default character set for the database connection
<code>mysqli-&gt;close</code>	<code>mysqli_close</code>	N/A	Closes a previously opened database connection
<code>mysqli-&gt;commit</code>	<code>mysqli_commit</code>	N/A	Commits the current transaction
<code>mysqli::__construct</code>	<code>mysqli_connect</code>	N/A	Open a new connection to the MySQL server [Note: static (i.e. class) method]
<code>mysqli-&gt;debug</code>	<code>mysqli_debug</code>	N/A	Performs debugging operations

MySQLi Class			
OOP Interface	Procedural Interface	Alias (Do not use)	Description
<code>mysqli-&gt;dump_debug_info</code>	<code>mysqli_dump_debug_info</code>	N/A	Dump debugging information into the log
<code>mysqli-&gt;get_charset</code>	<code>mysqli_get_charset</code>	N/A	Returns a character set object
<code>mysqli-&gt;get_client_info</code>	<code>mysqli_get_client_info</code>	N/A	Returns the MySQL client version as a string
<code>mysqli-&gt;get_client_version</code>	<code>mysqli_get_client_version</code>	N/A	Get MySQL client info
<code>\$mysqli-&gt;get_connection_stats()</code>	<code>mysqli_get_connection_stats()</code>	N/A	NOT DOCUMENTED [mysqli only]
<code>mysqli-&gt;get_server_info</code>	<code>mysqli_get_server_info</code>	N/A	NOT DOCUMENTED
<code>mysqli-&gt;get_warnings</code>	<code>mysqli_get_warnings</code>	N/A	NOT DOCUMENTED
<code>mysqli_init</code>	<code>mysqli_init</code>	N/A	Initializes MySQLi and returns a resource for use with <code>mysqli_real_connect</code> . [Not called on an object, as it returns a <code>\$mysqli</code> object.]
<code>mysqli-&gt;kill</code>	<code>mysqli_kill</code>	N/A	Asks the server to kill a MySQL thread
<code>mysqli-&gt;more_results</code>	<code>mysqli_more_results</code>	N/A	Check if there are any more query results from a multi query
<code>mysqli-&gt;multi_query</code>	<code>mysqli_multi_query</code>	N/A	Performs a query on the database
<code>mysqli-&gt;next_result</code>	<code>mysqli_next_result</code>	N/A	Prepare next result from multi_query
<code>mysqli-&gt;options</code>	<code>mysqli_options</code>	<code>mysqli_set_opt</code>	Set options
<code>mysqli-&gt;ping</code>	<code>mysqli_ping</code>	N/A	Pings a server connection, or tries to reconnect if the connection has gone down
<code>mysqli-&gt;prepare</code>	<code>mysqli_prepare</code>	N/A	Prepare a SQL statement for execution
<code>mysqli-&gt;query</code>	<code>mysqli_query</code>	N/A	Performs a query on the database
<code>mysqli-&gt;real_connect</code>	<code>mysqli_real_connect</code>	N/A	Opens a connection to a mysql server
<code>mysqli-&gt;real_escape_string</code> , <code>mysqli-&gt;escape_string</code>	<code>mysqli_real_escape_string</code>	<code>mysqli_escape_string</code>	Escapes special characters in a string for use in a SQL statement, taking into account the current charset of the connection
<code>mysqli-&gt;real_query</code>	<code>mysqli_real_query</code>	N/A	Execute an SQL query
<code>mysqli-&gt;rollback</code>	<code>mysqli_rollback</code>	N/A	Rolls back current transaction
<code>mysqli-&gt;select_db</code>	<code>mysqli_select_db</code>	N/A	Selects the default database for database queries
<code>mysqli-&gt;set_charset</code>	<code>mysqli_set_charset</code>	N/A	Sets the default client character set
<code>mysqli-&gt;set_local_infile_default</code>	<code>mysqli_set_local_infile_default</code>	N/A	Unsets user defined handler for load local infile command
<code>mysqli-&gt;set_local_infile_handler</code>	<code>mysqli_set_local_infile_handler</code>	N/A	Set callback function for LOAD DATA LOCAL INFILE command
<code>mysqli-&gt;ssl_set</code>	<code>mysqli_ssl_set</code>	N/A	Used for establishing secure connections using SSL

MySQLi Class			
OOP Interface	Procedural Interface	Alias (Do not use)	Description
<code>mysqli-&gt;stat</code>	<code>mysqli_stat</code>	N/A	Gets the current system status
<code>mysqli-&gt;stmt_init</code>	<code>mysqli_stmt_init</code>	N/A	Initializes a statement and returns an object for use with <code>mysqli_stmt_prepare</code>
<code>mysqli-&gt;store_result</code>	<code>mysqli_store_result</code>	N/A	Transfers a result set from the last query
<code>mysqli-&gt;thread_id</code>	<code>mysqli_thread_id</code>	N/A	Returns the thread ID for the current connection
<code>mysqli-&gt;thread_safe</code>	<code>mysqli_thread_safe</code>	N/A	Returns whether thread safety is given or not
<code>mysqli-&gt;use_result</code>	<code>mysqli_use_result</code>	N/A	Initiate a result set retrieval

MySQL_STMT			
OOP Interface	Procedural Interface	Alias (Do not use)	Description
<i>Properties</i>			
<code>\$mysqli_stmt-&gt;affected_rows</code>	<code>mysqli_stmt_affected_rows</code>	N/A	Returns the total number of rows changed, deleted, or inserted by the last executed statement
<code>\$mysqli_stmt-&gt;errno</code>	<code>mysqli_stmt_errno</code>	N/A	Returns the error code for the most recent statement call
<code>\$mysqli_stmt-&gt;error</code>	<code>mysqli_stmt_error</code>	N/A	Returns a string description for last statement error
<code>\$mysqli_stmt-&gt;field_count</code>	<code>mysqli_stmt_field_count</code>	N/A	Returns the number of field in the given statement - not documented
<code>\$mysqli_stmt-&gt;insert_id</code>	<code>mysqli_stmt_insert_id</code>	N/A	Get the ID generated from the previous INSERT operation
<code>\$mysqli_stmt-&gt;num_rows</code>	<code>mysqli_stmt_num_rows</code>	N/A	Return the number of rows in statements result set
<code>\$mysqli_stmt-&gt;param_count</code>	<code>mysqli_stmt_param_count</code>	<code>mysqli_param_count</code>	Returns the number of parameter for the given statement
<code>\$mysqli_stmt-&gt;sqlstate</code>	<code>mysqli_stmt_sqlstate</code>	N/A	Returns SQLSTATE error from previous statement operation
<i>Methods</i>			
<code>mysqli_stmt-&gt;attr_get</code>	<code>mysqli_stmt_attr_get</code>	N/A	NOT DOCUMENTED
<code>mysqli_stmt-&gt;attr_set</code>	<code>mysqli_stmt_attr_set</code>	N/A	NOT DOCUMENTED
<code>mysqli_stmt-&gt;bind_param</code>	<code>mysqli_stmt_bind_param</code>	<code>mysqli_bind_param</code>	Binds variables to a prepared statement as parameters
<code>mysqli_stmt-&gt;bind_result</code>	<code>mysqli_stmt_bind_result</code>	<code>mysqli_bind_result</code>	Binds variables to a prepared statement for result storage
<code>mysqli_stmt-&gt;close</code>	<code>mysqli_stmt_close</code>	N/A	Closes a prepared statement
<code>mysqli_stmt-&gt;data_seek</code>	<code>mysqli_stmt_data_seek</code>	N/A	Seeks to an arbitrary row in statement result set
<code>mysqli_stmt-&gt;execute</code>	<code>mysqli_stmt_execute</code>	<code>mysqli_execute</code>	Executes a prepared Query
<code>mysqli_stmt-&gt;fetch</code>	<code>mysqli_stmt_fetch</code>	<code>mysqli_fetch</code>	Fetch results from a prepared statement into the bound variables
<code>mysqli_stmt-&gt;free_result</code>	<code>mysqli_stmt_free_result</code>	N/A	Frees stored result memory for the given statement handle
<code>\$mysqli_stmt-&gt;get_result()</code>	<code>mysqli_stmt_get_result</code>	N/A	NOT DOCUMENTED [mysqlnd only]
<code>mysqli_stmt-&gt;get_warnings</code>	<code>mysqli_stmt_get_warnings</code>	N/A	NOT DOCUMENTED

<b>MySQL_STMT</b>			
<b>OOP Interface</b>	<b>Procedural Interface</b>	<b>Alias (Do not use)</b>	<b>Description</b>
<code>ings</code>	<code>ngs</code>		
<code>\$mysqli_stmt-&gt;more_results()</code>	<code>mysqli_stmt_more_results()</code>	N/A	NOT DOCUMENTED [mysqli only]
<code>\$mysqli_stmt-&gt;next_result()</code>	<code>mysqli_stmt_next_result()</code>	N/A	NOT DOCUMENTED [mysqli only]
<code>mysqli_stmt-&gt;num_rows</code>	<code>mysqli_stmt_num_rows</code>	N/A	NOT DOCUMENTED [see also num_rows property]
<code>mysqli_stmt-&gt;prepare</code>	<code>mysqli_stmt_prepare</code>	N/A	Prepare a SQL statement for execution
<code>mysqli_stmt-&gt;reset</code>	<code>mysqli_stmt_reset</code>	N/A	Resets a prepared statement
<code>mysqli_stmt-&gt;result_metadata</code>	<code>mysqli_stmt_result_metadata</code>	<code>mysqli_get_metadata</code>	Returns result set metadata from a prepared statement
<code>mysqli_stmt-&gt;send_long_data</code>	<code>mysqli_stmt_send_long_data</code>	<code>mysqli_send_long_data</code>	Send data in blocks
<code>mysqli_stmt-&gt;store_result</code>	<code>mysqli_stmt_store_result</code>	N/A	Transfers a result set from a prepared statement

<b>MySQLi_RESULT</b>			
<b>OOP Interface</b>	<b>Procedural Interface</b>	<b>Alias (Do not use)</b>	<b>Description</b>
<i>Properties</i>			
<code>\$mysqli_result-&gt;current_field</code>	<code>mysqli_field_tell</code>	N/A	Get current field offset of a result pointer
<code>\$mysqli_result-&gt;field_count</code>	<code>mysqli_num_fields</code>	N/A	Get the number of fields in a result
<code>\$mysqli_result-&gt;lengths</code>	<code>mysqli_fetch_lengths</code>	N/A	Returns the lengths of the columns of the current row in the result set
<code>\$mysqli_result-&gt;num_rows</code>	<code>mysqli_num_rows</code>	N/A	Gets the number of rows in a result
<i>Methods</i>			
<code>mysqli_result-&gt;data_seek</code>	<code>mysqli_data_seek</code>	N/A	Adjusts the result pointer to an arbitrary row in the result
<code>\$mysqli_result-&gt;fetch_all()</code>	<code>mysqli_fetch_all()</code>	N/A	NOT DOCUMENTED [mysqli only]
<code>mysqli_result-&gt;fetch_array</code>	<code>mysqli_fetch_array</code>	N/A	Fetch a result row as an associative, a numeric array, or both
<code>mysqli_result-&gt;fetch_assoc</code>	<code>mysqli_fetch_assoc</code>	N/A	Fetch a result row as an associative array
<code>mysqli_result-&gt;fetch_field_direct</code>	<code>mysqli_fetch_field_direct</code>	N/A	Fetch meta-data for a single field
<code>mysqli_result-&gt;fetch_field</code>	<code>mysqli_fetch_field</code>	N/A	Returns the next field in the result set
<code>mysqli_result-&gt;fetch_fields</code>	<code>mysqli_fetch_fields</code>	N/A	Returns an array of objects representing the fields in a result set
<code>mysqli_result-&gt;fetch_object</code>	<code>mysqli_fetch_object</code>	N/A	Returns the current row of a result set as an object
<code>mysqli_result-&gt;fetch_row</code>	<code>mysqli_fetch_row</code>	N/A	Get a result row as an enumerated array
<code>mysqli_result-&gt;field_seek</code>	<code>mysqli_field_seek</code>	N/A	Set result pointer to a specified field offset
<code>mysqli_result-&gt;free,</code> <code>mysqli_result-&gt;close,</code> <code>mysqli_result-&gt;free_result</code>	<code>mysqli_free_result</code>	N/A	Frees the memory associated with a result

MySQL_Driver			
OOP Interface	Procedural Interface	Alias (Do not use)	Description
<i>Properties</i>			
N/A			
<i>Methods</i>			
<code>mysqli_driver-&gt;embedded_server_end</code>	<code>mysqli_embedded_server_end</code>	N/A	NOT DOCUMENTED
<code>mysqli_driver-&gt;embedded_server_start</code>	<code>mysqli_embedded_server_start</code>	N/A	NOT DOCUMENTED

### Note

Alias functions are provided for backward compatibility purposes only. Do not use them in new projects.

## 20.10.2.6. The MySQLi class (**MySQLi**)

Copyright 1997-2008 the PHP Documentation Group.

Represents a connection between PHP and a MySQL database.

```

MySQLi {
    MySQLi

    Properties

    int affected_rows ;

    string connect_errno ;

    string connect_error ;

    int errno ;

    string error ;

    int field_count ;

    string host_info ;

    string protocol_version ;

    string server_info ;

    int server_version ;

    string info ;

    int insert_id ;

    string sqlstate ;

    int thread_id ;

    int warning_count ;

    Methods

    int mysqli_affected_rows(mysqli link);

    bool mysqli::autocommit(bool mode);

    bool mysqli::change_user(string user,

```

```
        string password,
        string database);

string mysqli::character_set_name();

bool mysqli::close();

bool mysqli::commit();

int mysqli_connect_errno();

string mysqli_connect_error();

mysqli mysqli_connect(string host,
                    string username,
                    string passwd,
                    string dbname,
                    int port,
                    string socket);

bool mysqli::debug(string message);

bool mysqli::dump_debug_info();

mysqli_result use_result();

int mysqli_warning_count(mysqli link);
}
```

#### 20.10.2.6.1. `mysqli->affected_rows`, `mysqli_affected_rows`

Copyright 1997-2008 the PHP Documentation Group.

- `mysqli->affected_rows`  
`mysqli_affected_rows`

Gets the number of affected rows in a previous MySQL operation

### Description

Object oriented style (property):

```
mysqli {
    int affected_rows ;
}
```

Procedural style:

```
int mysqli_affected_rows(mysqli link);
```

Returns the number of rows affected by the last [INSERT](#), [UPDATE](#), [REPLACE](#) or [DELETE](#) query.

For SELECT statements [mysqli\\_affected\\_rows](#) works like [mysqli\\_num\\_rows](#).

### Parameters

[link](#) Procedural style only: A link identifier returned by [mysqli\\_connect](#) or [mysqli\\_init](#)

### Return Values

An integer greater than zero indicates the number of rows affected or retrieved. Zero indicates that no records were updated for an UPDATE statement, no rows matched the [WHERE](#) clause in the query or that no query has yet been executed. -1 indicates that the query returned an error.

#### Note

If the number of affected rows is greater than maximal int value, the number of affected rows will be returned as a string.

### Examples

#### Example 20.69. Object oriented style

```
<?php
$mysqli = new mysqli("localhost", "my_user", "my_password", "world");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

/* Insert rows */
$mysqli->query("CREATE TABLE Language SELECT * from CountryLanguage");
printf("Affected rows (INSERT): %d\n", $mysqli->affected_rows);

$mysqli->query("ALTER TABLE Language ADD Status int default 0");

/* update rows */
$mysqli->query("UPDATE Language SET Status=1 WHERE Percentage > 50");
printf("Affected rows (UPDATE): %d\n", $mysqli->affected_rows);

/* delete rows */
$mysqli->query("DELETE FROM Language WHERE Percentage < 50");
printf("Affected rows (DELETE): %d\n", $mysqli->affected_rows);

/* select all rows */
$result = $mysqli->query("SELECT CountryCode FROM Language");
printf("Affected rows (SELECT): %d\n", $mysqli->affected_rows);

$result->close();

/* Delete table Language */
$mysqli->query("DROP TABLE Language");

/* close connection */
$mysqli->close();
?>
```

**Example 20.70. Procedural style**

```

<?php
$link = mysqli_connect("localhost", "my_user", "my_password", "world");

if (!$link) {
    printf("Can't connect to localhost. Error: %s\n", mysqli_connect_error());
    exit();
}

/* Insert rows */
mysqli_query($link, "CREATE TABLE Language SELECT * from CountryLanguage");
printf("Affected rows (INSERT): %d\n", mysqli_affected_rows($link));

mysqli_query($link, "ALTER TABLE Language ADD Status int default 0");

/* update rows */
mysqli_query($link, "UPDATE Language SET Status=1 WHERE Percentage > 50");
printf("Affected rows (UPDATE): %d\n", mysqli_affected_rows($link));

/* delete rows */
mysqli_query($link, "DELETE FROM Language WHERE Percentage < 50");
printf("Affected rows (DELETE): %d\n", mysqli_affected_rows($link));

/* select all rows */
$result = mysqli_query($link, "SELECT CountryCode FROM Language");
printf("Affected rows (SELECT): %d\n", mysqli_affected_rows($link));

mysqli_free_result($result);

/* Delete table Language */
mysqli_query($link, "DROP TABLE Language");

/* close connection */
mysqli_close($link);
?>

```

The above example will output:

```

Affected rows (INSERT): 984
Affected rows (UPDATE): 168
Affected rows (DELETE): 815
Affected rows (SELECT): 169

```

**See Also**

[mysqli\\_num\\_rows](#)  
[mysqli\\_info](#)

**20.10.2.6.2. `mysqli::autocommit`, `mysqli_autocommit`**

Copyright 1997-2008 the PHP Documentation Group.

- [mysqli::autocommit](#)  
[mysqli\\_autocommit](#)

Turns on or off auto-committing database modifications

**Description**

Object oriented style (method)

```
bool mysqli::autocommit(bool mode);
```

Procedural style:

```
bool mysqli_autocommit(mysqli link,
                       bool mode);
```

Turns on or off auto-commit mode on queries for the database connection.

To determine the current state of autocommit use the SQL command `SELECT @@autocommit`.

### Parameters

*link* Procedural style only: A link identifier returned by `mysqli_connect` or `mysqli_init`

*mode* Whether to turn on auto-commit or not.

### Return Values

Returns `TRUE` on success or `FALSE` on failure.

### Notes

#### Note

This function doesn't work with non transactional table types (like MyISAM or ISAM).

### Examples

#### Example 20.71. Object oriented style

```
<?php
$link = new mysqli("localhost", "my_user", "my_password", "world");

if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

/* turn autocommit on */
$link->autocommit(TRUE);

if ($result = $link->query("SELECT @@autocommit")) {
    $row = $result->fetch_row();
    printf("Autocommit is %s\n", $row[0]);
    $result->free();
}

/* close connection */
$link->close();
?>
```

#### Example 20.72. Procedural style

```
<?php
$link = mysqli_connect("localhost", "my_user", "my_password", "world");

if (!$link) {
    printf("Can't connect to localhost. Error: %s\n", mysqli_connect_error());
    exit();
}

/* turn autocommit on */
mysqli_autocommit($link, TRUE);

if ($result = mysqli_query($link, "SELECT @@autocommit")) {
    $row = mysqli_fetch_row($result);
    printf("Autocommit is %s\n", $row[0]);
    mysqli_free_result($result);
}

/* close connection */
mysqli_close($link);
?>
```

The above example will output:

```
Autocommit is 1
```

#### See Also

[mysqli\\_commit](#)  
[mysqli\\_rollback](#)

### 20.10.2.6.3. [mysqli::change\\_user](#), [mysqli\\_change\\_user](#)

Copyright 1997-2008 the PHP Documentation Group.

- [mysqli::change\\_user](#)  
[mysqli\\_change\\_user](#)  
Changes the user of the specified database connection

#### Description

Object oriented style (method):

```
bool mysqli::change_user(string user,  
                        string password,  
                        string database);
```

Procedural style:

```
bool mysqli_change_user(mysqli link,  
                        string user,  
                        string password,  
                        string database);
```

Changes the user of the specified database connection and sets the current database.

In order to successfully change users a valid *username* and *password* parameters must be provided and that user must have sufficient permissions to access the desired database. If for any reason authorization fails, the current user authentication will remain.

#### Parameters

<i>link</i>	Procedural style only: A link identifier returned by <a href="#">mysqli_connect</a> or <a href="#">mysqli_init</a>
<i>user</i>	The MySQL user name.
<i>password</i>	The MySQL password.
<i>database</i>	The database to change to.  If desired, the <code>NULL</code> value may be passed resulting in only changing the user and not selecting a database. To select a database in this case use the <a href="#">mysqli_select_db</a> function.

#### Return Values

Returns `TRUE` on success or `FALSE` on failure.

## Notes

**Note**

Using this command will always cause the current database connection to behave as if was a completely new database connection, regardless of if the operation was completed successfully. This reset includes performing a rollback on any active transactions, closing all temporary tables, and unlocking all locked tables.

## Examples

**Example 20.73. Object oriented style**

```
<?php
/* connect database test */
$mysqli = new mysqli("localhost", "my_user", "my_password", "test");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

/* Set Variable a */
$mysqli->query("SET @a:=1");

/* reset all and select a new database */
$mysqli->change_user("my_user", "my_password", "world");

if ($result = $mysqli->query("SELECT DATABASE()")) {
    $row = $result->fetch_row();
    printf("Default database: %s\n", $row[0]);
    $result->close();
}

if ($result = $mysqli->query("SELECT @a")) {
    $row = $result->fetch_row();
    if ($row[0] === NULL) {
        printf("Value of variable a is NULL\n");
    }
    $result->close();
}

/* close connection */
$mysqli->close();
?>
```

**Example 20.74. Procedural style**

```
<?php
/* connect database test */
$link = mysqli_connect("localhost", "my_user", "my_password", "test");

/* check connection */
if (!$link) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

/* Set Variable a */
mysqli_query($link, "SET @a:=1");

/* reset all and select a new database */
mysqli_change_user($link, "my_user", "my_password", "world");

if ($result = mysqli_query($link, "SELECT DATABASE()")) {
    $row = mysqli_fetch_row($result);
    printf("Default database: %s\n", $row[0]);
    mysqli_free_result($result);
}

if ($result = mysqli_query($link, "SELECT @a")) {
    $row = mysqli_fetch_row($result);
    if ($row[0] === NULL) {
        printf("Value of variable a is NULL\n");
    }
    mysqli_free_result($result);
}

/* close connection */
mysqli_close($link);
```

```
?>
```

The above example will output:

```
Default database: world
Value of variable a is NULL
```

#### 20.10.2.6.4. [mysqli::character\\_set\\_name](#), [mysqli\\_character\\_set\\_name](#)

Copyright 1997-2008 the PHP Documentation Group.

- [mysqli::character\\_set\\_name](#)  
[mysqli\\_character\\_set\\_name](#)

Returns the default character set for the database connection

### Description

Object oriented style (method):

```
string mysqli::character_set_name();
```

Procedural style:

```
string mysqli_character_set_name(mysqli link);
```

Returns the current character set for the database connection.

### Parameters

[link](#) Procedural style only: A link identifier returned by [mysqli\\_connect](#) or [mysqli\\_init](#)

### Return Values

The default character set for the current connection

### Examples

#### Example 20.75. Object oriented style

```
<?php
/* Open a connection */
$mysqli = new mysqli("localhost", "my_user", "my_password", "world");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

/* Print current character set */
$charset = $mysqli->character_set_name();
printf ("Current character set is %s\n", $charset);
```

```
$mysqli->close();
?>
```

### Example 20.76. Procedural style

```
<?php
/* Open a connection */
$link = mysqli_connect("localhost", "my_user", "my_password", "world");

/* check connection */
if (!$link) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

/* Print current character set */
$charset = mysqli_character_set_name($link);
printf("Current character set is %s\n", $charset);

/* close connection */
mysqli_close($link);
?>
```

The above example will output:

```
Current character set is latin1_swedish_ci
```

- [mysqli::close](#)  
[mysqli\\_close](#)

Closes a previously opened database connection

#### Description

Object oriented style (method):

```
bool mysqli::close();
```

Procedural style:

```
bool mysqli_close(mysqli link);
```

Closes a previously opened database connection.

#### Parameters

*link*

Procedural style only: A link identifier returned by [mysqli\\_connect](#) or [mysqli\\_init](#)

**Return Values**

Returns `TRUE` on success or `FALSE` on failure.

**See Also**

`mysqli_connect`  
`mysqli_init`  
`mysqli_real_connect`

**20.10.2.6.6. `mysqli::commit`, `mysqli_commit`**

Copyright 1997-2008 the PHP Documentation Group.

- `mysqli::commit`

`mysqli_commit`

Commits the current transaction

**Description**

Object oriented style (method)

```
bool mysqli::commit();
```

Procedural style:

```
bool mysqli_commit(mysqli link);
```

Commits the current transaction for the database connection.

**Parameters**

*link* Procedural style only: A link identifier returned by `mysqli_connect` or `mysqli_init`

**Return Values**

Returns `TRUE` on success or `FALSE` on failure.

**Examples****Example 20.77. Object oriented style**

```
<?php
$mysqli = new mysqli("localhost", "my_user", "my_password", "world");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

$mysqli->query("CREATE TABLE Language LIKE CountryLanguage Type=InnoDB");

/* set autocommit to off */
$mysqli->autocommit(FALSE);

/* Insert some values */
$mysqli->query("INSERT INTO Language VALUES ('DEU', 'Bavarian', 'F', 11.2)");
$mysqli->query("INSERT INTO Language VALUES ('DEU', 'Swabian', 'F', 9.4)");

/* commit transaction */
$mysqli->commit();

/* drop table */
$mysqli->query("DROP TABLE Language");
```

```
/* close connection */
mysqli->close();
?>
```

### Example 20.78. Procedural style

```
<?php
$link = mysqli_connect("localhost", "my_user", "my_password", "test");

/* check connection */
if (!$link) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

/* set autocommit to off */
mysqli_autocommit($link, FALSE);

mysqli_query($link, "CREATE TABLE Language LIKE CountryLanguage Type=InnoDB");

/* Insert some values */
mysqli_query($link, "INSERT INTO Language VALUES ('DEU', 'Bavarian', 'F', 11.2)");
mysqli_query($link, "INSERT INTO Language VALUES ('DEU', 'Swabian', 'F', 9.4)");

/* commit transaction */
mysqli_commit($link);

/* close connection */
mysqli_close($link);
?>
```

Copyright 1997-2008 the PHP Documentation Group.

- [mysqli->connect\\_errno](#)  
[mysqli\\_connect\\_errno](#)

Returns the error code from last connect call

#### Description

```
mysqli {
    string connect_errno ;
}
```

```
int mysqli_connect_errno();
```

Returns the last error code number from the last call to [mysqli\\_connect](#).

#### Note

Client error message numbers are listed in the MySQL [errmsg.h](#) header file, server error message numbers are listed in [mysqld\\_error.h](#). In the MySQL source distribution you can find a complete list of error messages and error numbers in the file [Docs/mysqld\\_error.txt](#).

#### Return Values

An error code value for the last call to [mysqli\\_connect](#), if it failed. zero means no error occurred.

## Examples

### Example 20.79. `mysqli_connect_errno` example

```
<?php
$link = @mysqli_connect("localhost", "nonexisting_user", "");
if (!$link) {
    printf("Can't connect to localhost. Errorcode: %d\n", mysqli_connect_errno());
}
?>
```

Copyright 1997-2008 the PHP Documentation Group.

- [mysqli->connect\\_error](#)  
[mysqli\\_connect\\_error](#)

Returns a string description of the last connect error

## Description

```
mysqli {
    string connect_error ;
}
```

```
string mysqli_connect_error();
```

Returns the last error message string from the last call to `mysqli_connect`.

## Return Values

A string that describes the error. An empty string if no error occurred.

## Examples

### Example 20.80. `mysqli_connect_error` example

```
<?php
$link = @mysqli_connect("localhost", "nonexisting_user", "");
if (!$link) {
    printf("Can't connect to localhost. Error: %s\n", mysqli_connect_error());
}
?>
```

**See Also**

`mysqli_error`  
`mysqli_sqlstate`

**20.10.2.6.9. `mysqli::__construct`, `mysqli_connect`**

Copyright 1997-2008 the PHP Documentation Group.

- `mysqli::__construct`  
`mysqli_connect`

Open a new connection to the MySQL server

**Description**

Object oriented style (constructor):

```
mysqli::__construct(string host,  
                    string username,  
                    string passwd,  
                    string dbname,  
                    int port,  
                    string socket);
```

Procedural style

```
mysqli mysqli_connect(string host,  
                      string username,  
                      string passwd,  
                      string dbname,  
                      int port,  
                      string socket);
```

Opens a connection to the MySQL Server running on.

**Parameters**

<i>host</i>	Can be either a host name or an IP address. Passing the <code>NULL</code> value or the string "localhost" to this parameter, the local host is assumed. When possible, pipes will be used instead of the TCP/IP protocol.
<i>username</i>	The MySQL user name.
<i>passwd</i>	If not provided or <code>NULL</code> , the MySQL server will attempt to authenticate the user against those user records which have no password only. This allows one username to be used with different permissions (depending on if a password as provided or not).
<i>dbname</i>	If provided will specify the default database to be used when performing queries.
<i>port</i>	Specifies the port number to attempt to connect to the MySQL server.
<i>socket</i>	Specifies the socket or named pipe that should be used.

**Note**

Specifying the `socket` parameter will not explicitly determine the type of connection to be used when connecting to the MySQL server. How the connection is made to the MySQL database is determined by the `host` parameter.

**Return Values**

Returns a object which represents the connection to a MySQL Server.

## Examples

### Example 20.81. Object oriented style

```
<?php
$mysqli = new mysqli("localhost", "my_user", "my_password", "world");

/* check connection */
if ($mysqli->connect_error) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

printf("Host information: %s\n", $mysqli->host_info);

/* close connection */
$mysqli->close();
?>
```

### Example 20.82. Procedural style

```
<?php
$link = mysqli_connect("localhost", "my_user", "my_password", "world");

/* check connection */
if (!$link) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

printf("Host information: %s\n", mysqli_get_host_info($link));

/* close connection */
mysqli_close($link);
?>
```

The above example will output:

```
Host information: Localhost via UNIX socket
```

## Notes

### Note

OO syntax only: If a connection fails an object is still returned. To check if the connection failed then use the [mysqli->connect\\_error](#) property like in the examples above.

### Note

Error "Can't create TCP/IP socket (10106)" usually means that the [variables\\_order](#) configure directive doesn't contain character **E**. On Windows, if the environment is not copied the [SYSTEMROOT](#) environment variable won't be available and PHP will have problems loading Winsock.

#### 20.10.2.6.10. [mysqli::debug](#), [mysqli\\_debug](#)

Copyright 1997-2008 the PHP Documentation Group.

- [mysqli::debug](#)  
[mysqli\\_debug](#)

Performs debugging operations

**Description**

Object oriented style (method):

```
bool mysqli::debug(string message);
```

Procedural style:

```
bool mysqli_debug(string message);
```

Performs debugging operations using the Fred Fish debugging library.

**Parameters**

*message* A string representing the debugging operation to perform

**Return Values**

Returns `TRUE` .

**Notes****Note**

To use the `mysqli_debug` function you must compile the MySQL client library to support debugging.

**Examples****Example 20.83. Generating a Trace File**

```
<?php
/* Create a trace file in '/tmp/client.trace' on the local (client) machine: */
mysqli_debug("d:t:0,/tmp/client.trace");
?>
```

**See Also**

`mysqli_dump_debug_info`  
`mysqli_report`

**20.10.2.6.11. `mysqli::dump_debug_info`, `mysqli_dump_debug_info`**

Copyright 1997-2008 the PHP Documentation Group.

- `mysqli::dump_debug_info`  
`mysqli_dump_debug_info`

Dump debugging information into the log

**Description**

Object oriented style (method):

```
bool mysqli::dump_debug_info();
```

Procedural style:

---

```
bool mysqli_dump_debug_info(mysqli link);
```

This function is designed to be executed by a user with the SUPER privilege and is used to dump debugging information into the log for the MySQL Server relating to the connection.

#### Parameters

*link* Procedural style only: A link identifier returned by `mysqli_connect` or `mysqli_init`

#### Return Values

Returns `TRUE` on success or `FALSE` on failure.

#### See Also

`mysqli_debug`

### 20.10.2.6.12. `mysqli->errno`, `mysqli_errno`

Copyright 1997-2008 the PHP Documentation Group.

- `mysqli->errno`

`mysqli_errno`

Returns the error code for the most recent function call

#### Description

Object oriented style (property):

```
mysqli {
    int errno ;
}
```

Procedural style:

```
int mysqli_errno(mysqli link);
```

Returns the last error code for the most recent MySQLi function call that can succeed or fail.

Client error message numbers are listed in the MySQL `errmsg.h` header file, server error message numbers are listed in `mysqld_error.h`. In the MySQL source distribution you can find a complete list of error messages and error numbers in the file `Docs/mysqld_error.txt`.

#### Parameters

*link* Procedural style only: A link identifier returned by `mysqli_connect` or `mysqli_init`

#### Return Values

An error code value for the last call, if it failed. zero means no error occurred.

#### Examples

##### Example 20.84. Object oriented style

```
<?php
$mysqli = new mysqli("localhost", "my_user", "my_password", "world");
```

```

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

if (!$mysqli->query("SET a=1")) {
    printf("Errorcode: %d\n", $mysqli->errno);
}

/* close connection */
$mysqli->close();
?>

```

### Example 20.85. Procedural style

```

<?php
$link = mysqli_connect("localhost", "my_user", "my_password", "world");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

if (!mysqli_query($link, "SET a=1")) {
    printf("Errorcode: %d\n", mysqli_errno($link));
}

/* close connection */
mysqli_close($link);
?>

```

The above example will output:

```
Errorcode: 1193
```

### See Also

#### 20.10.2.6.13. [mysqli->error](#), [mysqli\\_error](#)

Copyright 1997-2008 the PHP Documentation Group.

- [mysqli->error](#)  
[mysqli\\_error](#)

Returns a string description of the last error

### Description

Object oriented style (property):

```

mysqli {
    string error ;
}

```

Procedural style:

```
string mysqli_error(mysqli link);
```

Returns the last error message for the most recent MySQLi function call that can succeed or fail.

### Parameters

*link* Procedural style only: A link identifier returned by `mysqli_connect` or `mysqli_init`

### Return Values

A string that describes the error. An empty string if no error occurred.

### Examples

#### Example 20.86. Object oriented style

```
<?php
$mysqli = new mysqli("localhost", "my_user", "my_password", "world");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

if (!$mysqli->query("SET a=1")) {
    printf("Errormessage: %s\n", $mysqli->error);
}

/* close connection */
$mysqli->close();
?>
```

#### Example 20.87. Procedural style

```
<?php
$link = mysqli_connect("localhost", "my_user", "my_password", "world");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

if (!mysqli_query($link, "SET a=1")) {
    printf("Errormessage: %s\n", mysqli_error($link));
}

/* close connection */
mysqli_close($link);
?>
```

The above example will output:

```
Errormessage: Unknown system variable 'a'
```

#### 20.10.2.6.14. `mysqli->field_count`, `mysqli_field_count`

Copyright 1997-2008 the PHP Documentation Group.

- `mysqli->field_count`  
`mysqli_field_count`

Returns the number of columns for the most recent query

#### Description

Object oriented style (property):

```
mysqli_result {
    int field_count ;
}
```

Procedural style:

```
int mysqli_field_count(mysqli link);
```

Returns the number of columns for the most recent query on the connection represented by the *link* parameter. This function can be useful when using the `mysqli_store_result` function to determine if the query should have produced a non-empty result set or not without knowing the nature of the query.

#### Parameters

*link* Procedural style only: A link identifier returned by `mysqli_connect` or `mysqli_init`

#### Return Values

An integer representing the number of fields in a result set.

#### Examples

##### Example 20.88. Object oriented style

```
<?php
$mysqli = new mysqli("localhost", "my_user", "my_password", "test");

$mysqli->query( "DROP TABLE IF EXISTS friends");
$mysqli->query( "CREATE TABLE friends (id int, name varchar(20))");
$mysqli->query( "INSERT INTO friends VALUES (1,'Hartmut'), (2, 'Ulf')");

$mysqli->real_query("SELECT * FROM friends");

if ($mysqli->field_count) {
    /* this was a select/show or describe query */
    $result = $mysqli->store_result();

    /* process resultset */
    $row = $result->fetch_row();

    /* free resultset */
    $result->close();
}

/* close connection */
$mysqli->close();
?>
```

**Example 20.89. Procedural style**

```

<?php
$link = mysqli_connect("localhost", "my_user", "my_password", "test");

mysqli_query($link, "DROP TABLE IF EXISTS friends");
mysqli_query($link, "CREATE TABLE friends (id int, name varchar(20))");
mysqli_query($link, "INSERT INTO friends VALUES (1, 'Hartmut'), (2, 'Ulf')");
mysqli_real_query($link, "SELECT * FROM friends");

if (mysqli_field_count($link)) {
    /* this was a select/show or describe query */
    $result = mysqli_store_result($link);

    /* process resultset */
    $row = mysqli_fetch_row($result);

    /* free resultset */
    mysqli_free_result($result);
}

/* close connection */
mysqli_close($link);
?>

```

**20.10.2.6.15. `mysqli::get_charset`, `mysqli_get_charset`**

Copyright 1997-2008 the PHP Documentation Group.

- `mysqli::get_charset`  
`mysqli_get_charset`  
Returns a character set object

**Description**

```
object mysqli::get_charset();
```

```
object mysqli_get_charset(mysqli link);
```

Returns a character set object providing several properties of the current active character set.

**Parameters**

*link* Procedural style only: A link identifier returned by `mysqli_connect` or `mysqli_init`

**Return Values**

The function returns a character set object with the following properties:

<i>charset</i>	Character set name
<i>collation</i>	Collation name
<i>dir</i>	Directory the charset description was fetched from (?) or "" for builtin character sets
<i>min_length</i>	Minimum character length in bytes
<i>max_length</i>	Maximum character length in bytes

<code>number</code>	Internal character set number
<code>state</code>	Characer set status (?)

**Examples****Example 20.90. Object oriented style**

```
<?php
$db = mysqli_init();
$db->real_connect("localhost","root","","test");
var_dump($db->get_charset());
?>
```

**Example 20.91. Procedural style**

```
<?php
$db = mysqli_init();
mysqli_real_connect($db, "localhost", "root", "", "test");
var_dump($db->get_charset());
?>
```

The above example will output:

```
object(stdClass)#2 (7) {
  ["charset"]=>
  string(6) "latin1"
  ["collation"]=>
  string(17) "latin1_swedish_ci"
  ["dir"]=>
  string(0) ""
  ["min_length"]=>
  int(1)
  ["max_length"]=>
  int(1)
  ["number"]=>
  int(8)
  ["state"]=>
  int(801)
}
```

**See Also**

[mysqli\\_set\\_charset](#)

**20.10.2.6.16. [mysqli::get\\_client\\_info](#), [mysqli\\_get\\_client\\_info](#)**

Copyright 1997-2008 the PHP Documentation Group.

- [mysqli::get\\_client\\_info](#)  
[mysqli\\_get\\_client\\_info](#)

Returns the MySQL client version as a string

**Description**

```
string mysqli::get_client_info();
```

```
string mysqli_get_client_info();
```

The `mysqli_get_client_info` function is used to return a string representing the client version being used in the MySQLi extension.

#### Return Values

A string that represents the MySQL client library version

#### Examples

#### Example 20.92. `mysqli_get_client_info`

```
<?php
/* We don't need a connection to determine
   the version of mysql client library */
printf("Client library version: %s\n", mysqli_get_client_info());
?>
```

#### See Also

[mysqli\\_get\\_client\\_version](#)  
[mysqli\\_get\\_server\\_info](#)  
[mysqli\\_get\\_server\\_version](#)

#### 20.10.2.6.17. `mysqli::get_client_version`, `mysqli_get_client_version`

Copyright 1997-2008 the PHP Documentation Group.

- [mysqli::get\\_client\\_version](#)  
[mysqli\\_get\\_client\\_version](#)  
Get MySQL client info

#### Description

```
int mysqli::get_client_version();
```

```
int mysqli_get_client_version();
```

Returns client version number as an integer.

#### Return Values

A number that represents the MySQL client library version in format: `main_version*10000 + minor_version *100 + sub_version`. For example, 4.1.0 is returned as 40100.

This is useful to quickly determine the version of the client library to know if some capability exists.

#### Examples

#### Example 20.93. `mysqli_get_client_version`

```
<?php
/* We don't need a connection to determine
   the version of mysql client library */
```

```
printf("Client library version: %d\n", mysqli_get_client_version());
?>
```

## 20.10.2.6.18. `mysqli->host_info`, `mysqli_get_host_info`

Copyright 1997-2008 the PHP Documentation Group.

- `mysqli->host_info`  
`mysqli_get_host_info`

Returns a string representing the type of connection used

### Description

Object oriented style (property):

```
mysqli {
    string host_info ;
}
```

Procdural style:

```
string mysqli_get_host_info(mysqli link);
```

The `mysqli_get_host_info` function returns a string describing the connection represented by the `link` parameter is using (including the server host name).

### Parameters

`link` Procedural style only: A link identifier returned by `mysqli_connect` or `mysqli_init`

### Return Values

A character string representing the server hostname and the connection type.

### Examples

#### Example 20.94. Object oriented style

```
<?php
$mysqli = new mysqli("localhost", "my_user", "my_password", "world");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

/* print host information */
printf("Host info: %s\n", $mysqli->host_info);

/* close connection */
$mysqli->close();
?>
```

**Example 20.95. Procedural style**

```
<?php
$link = mysqli_connect("localhost", "my_user", "my_password", "world");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

/* print host information */
printf("Host info: %s\n", mysqli_get_host_info($link));

/* close connection */
mysqli_close($link);
?>
```

The above example will output:

```
Host info: Localhost via UNIX socket
```

**See Also**

[mysqli\\_get\\_proto\\_info](#)

**20.10.2.6.19. [mysqli->protocol\\_version](#), [mysqli\\_get\\_proto\\_info](#)**

Copyright 1997-2008 the PHP Documentation Group.

- [mysqli->protocol\\_version](#)

[mysqli\\_get\\_proto\\_info](#)

Returns the version of the MySQL protocol used

**Description**

Object oriented style (property):

```
mysqli {
    string protocol_version ;
}
```

Procedural style:

```
int mysqli_get_proto_info(mysqli link);
```

Returns an integer representing the MySQL protocol version used by the connection represented by the *link* parameter.

**Parameters**

*link* Procedural style only: A link identifier returned by [mysqli\\_connect](#) or [mysqli\\_init](#)

**Return Values**

Returns an integer representing the protocol version.

## Examples

### Example 20.96. Object oriented style

```
<?php
$mysqli = new mysqli("localhost", "my_user", "my_password");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

/* print protocol version */
printf("Protocol version: %d\n", $mysqli->protocol_version);

/* close connection */
$mysqli->close();
?>
```

### Example 20.97. Procedural style

```
<?php
$link = mysqli_connect("localhost", "my_user", "my_password");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

/* print protocol version */
printf("Protocol version: %d\n", mysqli_get_proto_info($link));

/* close connection */
mysqli_close($link);
?>
```

The above example will output:

```
Protocol version: 10
```

## See Also

### 20.10.2.6.20. [mysqli->server\\_info](#), [mysqli\\_get\\_server\\_info](#)

Copyright 1997-2008 the PHP Documentation Group.

- [mysqli->server\\_info](#)  
[mysqli\\_get\\_server\\_info](#)

Returns the version of the MySQL server

## Description

Object oriented style (property):

```
mysqli {
```

```
string server_info ;
}
```

Procedural style:

```
string mysqli_get_server_info(mysqli link);
```

Returns a string representing the version of the MySQL server that the MySQLi extension is connected to.

#### Parameters

*link* Procedural style only: A link identifier returned by `mysqli_connect` or `mysqli_init`

#### Return Values

A character string representing the server version.

#### Examples

##### Example 20.98. Object oriented style

```
<?php
$mysqli = new mysqli("localhost", "my_user", "my_password");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

/* print server version */
printf("Server version: %s\n", $mysqli->server_info);

/* close connection */
$mysqli->close();
?>
```

##### Example 20.99. Procedural style

```
<?php
$link = mysqli_connect("localhost", "my_user", "my_password");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

/* print server version */
printf("Server version: %s\n", mysqli_get_server_info($link));

/* close connection */
mysqli_close($link);
?>
```

The above example will output:

```
Server version: 4.1.2-alpha-debug
```

**See Also**

[mysqli\\_get\\_client\\_info](#)  
[mysqli\\_get\\_client\\_version](#)  
[mysqli\\_get\\_server\\_version](#)

**20.10.2.6.21. [mysqli->server\\_version](#), [mysqli\\_get\\_server\\_version](#)**

Copyright 1997-2008 the PHP Documentation Group.

- [mysqli->server\\_version](#)  
[mysqli\\_get\\_server\\_version](#)

Returns the version of the MySQL server as an integer

**Description**

Object oriented style (property):

```
mysqli {  
    int server_version ;  
}
```

Procedural style:

```
int mysqli_get_server_version(mysqli link);
```

The [mysqli\\_get\\_server\\_version](#) function returns the version of the server connected to (represented by the *link* parameter) as an integer.

**Parameters**

*link* Procedural style only: A link identifier returned by [mysqli\\_connect](#) or [mysqli\\_init](#)

**Return Values**

An integer representing the server version.

The form of this version number is `main_version * 10000 + minor_version * 100 + sub_version` (i.e. version 4.1.0 is 40100).

**Examples****Example 20.100. Object oriented style**

```
<?php  
$mysqli = new mysqli("localhost", "my_user", "my_password");  
  
/* check connection */  
if (mysqli_connect_errno()) {  
    printf("Connect failed: %s\n", mysqli_connect_error());  
    exit();  
}  
  
/* print server version */  
printf("Server version: %d\n", $mysqli->server_version);  
  
/* close connection */  
$mysqli->close();  
?>
```

**Example 20.101. Procedural style**

```

<?php
$link = mysqli_connect("localhost", "my_user", "my_password");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

/* print server version */
printf("Server version: %d\n", mysqli_get_server_version($link));

/* close connection */
mysqli_close($link);
?>

```

The above example will output:

```
Server version: 40102
```

**20.10.2.6.22. [mysqli::get\\_warnings](#), [mysqli\\_get\\_warnings](#)**

Copyright 1997-2008 the PHP Documentation Group.

- [mysqli::get\\_warnings](#)  
[mysqli\\_get\\_warnings](#)

**Description**

```
object mysqli::get_warnings();
```

```
object mysqli_get_warnings(mysqli link);
```

**Warning**

This function is currently not documented; only its argument list is available.

**20.10.2.6.23. [mysqli->info](#), [mysqli\\_info](#)**

Copyright 1997-2008 the PHP Documentation Group.

- [mysqli->info](#)  
[mysqli\\_info](#)

Retrieves information about the most recently executed query

**Description**

Object oriented style (property)

```
mysql {
    string info ;
}
```

Procedural style:

```
string mysql_info(mysql link);
```

The `mysql_info` function returns a string providing information about the last query executed. The nature of this string is provided below:

**Table 20.8. Possible `mysql_info` return values**

Query type	Example result string
INSERT INTO...SELECT...	Records: 100 Duplicates: 0 Warnings: 0
INSERT INTO...VALUES (...),(...),(...)	Records: 3 Duplicates: 0 Warnings: 0
LOAD DATA INFILE ...	Records: 1 Deleted: 0 Skipped: 0 Warnings: 0
ALTER TABLE ...	Records: 3 Duplicates: 0 Warnings: 0
UPDATE ...	Rows matched: 40 Changed: 40 Warnings: 0

### Note

Queries which do not fall into one of the above formats are not supported. In these situations, `mysql_info` will return an empty string.

### Parameters

`link` Procedural style only: A link identifier returned by `mysql_connect` or `mysql_init`

### Return Values

A character string representing additional information about the most recently executed query.

### Examples

#### Example 20.102. Object oriented style

```
<?php
$mysql = new mysqli("localhost", "my_user", "my_password", "world");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

$mysql->query("CREATE TEMPORARY TABLE t1 LIKE City");

/* INSERT INTO .. SELECT */
$mysql->query("INSERT INTO t1 SELECT * FROM City ORDER BY ID LIMIT 150");
printf("%s\n", $mysql->info);

/* close connection */
$mysql->close();
?>
```

#### Example 20.103. Procedural style

```
<?php
```

```

$link = mysqli_connect("localhost", "my_user", "my_password", "world");
/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}
mysqli_query($link, "CREATE TEMPORARY TABLE t1 LIKE City");
/* INSERT INTO .. SELECT */
mysqli_query($link, "INSERT INTO t1 SELECT * FROM City ORDER BY ID LIMIT 150");
printf("%s\n", mysqli_info($link));
/* close connection */
mysqli_close($link);
?>

```

The above example will output:

```
Records: 150 Duplicates: 0 Warnings: 0
```

#### 20.10.2.6.24. [mysqli::init](#), [mysqli\\_init](#)

Copyright 1997-2008 the PHP Documentation Group.

- [mysqli::init](#)

[mysqli\\_init](#)

Initializes MySQLi and returns a resource for use with [mysqli\\_real\\_connect\(\)](#)

### Description

Object oriented style (method):

```
mysqli_init();
```

Procedural style:

```
mysqli_init();
```

Allocates or initializes a MySQL object suitable for [mysqli\\_options](#) and [mysqli\\_real\\_connect](#).

#### Note

Any subsequent calls to any [mysqli](#) function (except [mysqli\\_options](#)) will fail until [mysqli\\_real\\_connect](#) was called.

### Return Values

Returns an object.

### See Also

[mysqli\\_options](#)

### 20.10.2.6.25. `mysqli->insert_id`, `mysqli_insert_id`

Copyright 1997-2008 the PHP Documentation Group.

- `mysqli->insert_id`  
`mysqli_insert_id`

Returns the auto generated id used in the last query

#### Description

Object oriented style (property):

```
mysqli {
    int insert_id ;
}
```

Procedural style:

```
int mysqli_insert_id(mysqli link);
```

The `mysqli_insert_id` function returns the ID generated by a query on a table with a column having the `AUTO_INCREMENT` attribute. If the last query wasn't an `INSERT` or `UPDATE` statement or if the modified table does not have a column with the `AUTO_INCREMENT` attribute, this function will return zero.

#### Note

Performing an `INSERT` or `UPDATE` statement using the `LAST_INSERT_ID()` function will also modify the value returned by the `mysqli_insert_id` function.

#### Parameters

*link* Procedural style only: A link identifier returned by `mysqli_connect` or `mysqli_init`

#### Return Values

The value of the `AUTO_INCREMENT` field that was updated by the previous query. Returns zero if there was no previous query on the connection or if the query did not update an `AUTO_INCREMENT` value.

#### Note

If the number is greater than maximal int value, `mysqli_insert_id` will return a string.

#### Examples

##### Example 20.104. Object oriented style

```
<?php
$mysqli = new mysqli("localhost", "my_user", "my_password", "world");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

$mysqli->query("CREATE TABLE myCity LIKE City");

$query = "INSERT INTO myCity VALUES (NULL, 'Stuttgart', 'DEU', 'Stuttgart', 617000)";
$mysqli->query($query);

printf ("New Record has id %d.\n", $mysqli->insert_id);

/* drop table */
```

```
$mysqli->query("DROP TABLE myCity");
/* close connection */
$mysqli->close();
?>
```

### Example 20.105. Procedural style

```
<?php
$link = mysqli_connect("localhost", "my_user", "my_password", "world");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

mysqli_query($link, "CREATE TABLE myCity LIKE City");

$query = "INSERT INTO myCity VALUES (NULL, 'Stuttgart', 'DEU', 'Stuttgart', 617000)";
mysqli_query($link, $query);

printf ("New Record has id %d.\n", mysqli_insert_id($link));

/* drop table */
mysqli_query($link, "DROP TABLE myCity");

/* close connection */
mysqli_close($link);
?>
```

The above example will output:

```
New Record has id 1.
```

#### 20.10.2.6.26. `mysqli::kill`, `mysqli_kill`

Copyright 1997-2008 the PHP Documentation Group.

- `mysqli::kill`  
`mysqli_kill`

Asks the server to kill a MySQL thread

#### Description

Object oriented style (method)

```
bool mysqli::kill(int processid);
```

Procedural style:

```
bool mysqli_kill(mysqli link,
                 int processid);
```

This function is used to ask the server to kill a MySQL thread specified by the `processid` parameter. This value must be retrieved by calling the `mysqli_thread_id` function.

To stop a running query you should use the SQL command `KILL QUERY processid`.

#### Parameters

[link](#)Procedural style only: A link identifier returned by `mysqli_connect` or `mysqli_init`**Return Values**Returns `TRUE` on success or `FALSE` on failure.**Examples****Example 20.106. Object oriented style**

```

<?php
$mysqli = new mysqli("localhost", "my_user", "my_password", "world");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

/* determine our thread id */
$thread_id = $mysqli->thread_id;

/* Kill connection */
$mysqli->kill($thread_id);

/* This should produce an error */
if (!$mysqli->query("CREATE TABLE myCity LIKE City")) {
    printf("Error: %s\n", $mysqli->error);
    exit;
}

/* close connection */
$mysqli->close();
?>

```

**Example 20.107. Procedural style**

```

<?php
$link = mysqli_connect("localhost", "my_user", "my_password", "world");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

/* determine our thread id */
$thread_id = mysqli_thread_id($link);

/* Kill connection */
mysqli_kill($link, $thread_id);

/* This should produce an error */
if (!mysqli_query($link, "CREATE TABLE myCity LIKE City")) {
    printf("Error: %s\n", mysqli_error($link));
    exit;
}

/* close connection */
mysqli_close($link);
?>

```

The above example will output:

```
Error: MySQL server has gone away
```

**See Also**

`mysqli_thread_id`

**20.10.2.6.27. `mysqli::more_results`, `mysqli_more_results`**

Copyright 1997-2008 the PHP Documentation Group.

- `mysqli::more_results`  
`mysqli_more_results`

Check if there are any more query results from a multi query

**Description**

```
bool mysqli::more_results();
```

```
bool mysqli_more_results(mysqli link);
```

Indicates if one or more result sets are available from a previous call to `mysqli_multi_query`.

**Parameters**

*link* Procedural style only: A link identifier returned by `mysqli_connect` or `mysqli_init`

**Return Values**

Returns `TRUE` on success or `FALSE` on failure.

**Examples**

See `mysqli_multi_query`.

**See Also**

`mysqli_multi_query`  
`mysqli_next_result`  
`mysqli_store_result`  
`mysqli_use_result`

**20.10.2.6.28. `mysqli::multi_query`, `mysqli_multi_query`**

Copyright 1997-2008 the PHP Documentation Group.

- `mysqli::multi_query`  
`mysqli_multi_query`

Performs a query on the database

**Description**

Object oriented style (method):

```
bool mysqli::multi_query(string query);
```

Procedural style:

```
bool mysqli_multi_query(mysqli link,  
                        string query);
```

Executes one or multiple queries which are concatenated by a semicolon.

To retrieve the resultset from the first query you can use `mysqli_use_result` or `mysqli_store_result`. All subsequent query results can be processed using `mysqli_more_results` and `mysqli_next_result`.

### Parameters

`link` Procedural style only: A link identifier returned by `mysqli_connect` or `mysqli_init`

`query` The query, as a string.

### Return Values

Returns `FALSE` if the first statement failed. To retrieve subsequent errors from other statements you have to call `mysqli_next_result` first.

### Examples

#### Example 20.108. Object oriented style

```
<?php
$mysqli = new mysqli("localhost", "my_user", "my_password", "world");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

$query = "SELECT CURRENT_USER()";
$query .= "SELECT Name FROM City ORDER BY ID LIMIT 20, 5";

/* execute multi query */
if ($mysqli->multi_query($query)) {
    do {
        /* store first result set */
        if ($result = $mysqli->store_result()) {
            while ($row = $result->fetch_row()) {
                printf("%s\n", $row[0]);
            }
            $result->free();
        }
        /* print divider */
        if ($mysqli->more_results()) {
            printf("-----\n");
        }
    } while ($mysqli->next_result());
}

/* close connection */
$mysqli->close();
?>
```

#### Example 20.109. Procedural style

```
<?php
$link = mysqli_connect("localhost", "my_user", "my_password", "world");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

$query = "SELECT CURRENT_USER()";
$query .= "SELECT Name FROM City ORDER BY ID LIMIT 20, 5";

/* execute multi query */
if (mysqli_multi_query($link, $query)) {
    do {
        /* store first result set */
        if ($result = mysqli_store_result($link)) {
            while ($row = mysqli_fetch_row($result)) {
                printf("%s\n", $row[0]);
            }
        }
    }
}
```

```

        mysqli_free_result($result);
    }
    /* print divider */
    if (mysqli_more_results($link)) {
        printf("-----\n");
    }
    } while (mysqli_next_result($link));
}

/* close connection */
mysqli_close($link);
?>

```

The above example will output something similar to:

```

my_user@localhost
-----
Amersfoort
Maastricht
Dordrecht
Leiden
Haarlemmermeer

```

## 20.10.2.6.29. [mysqli::next\\_result](#), [mysqli\\_next\\_result](#)

Copyright 1997-2008 the PHP Documentation Group.

- [mysqli::next\\_result](#)  
[mysqli\\_next\\_result](#)

Prepare next result from `multi_query`

### Description

```
bool mysqli::next_result();
```

```
bool mysqli_next_result(mysqli link);
```

Prepares next result set from a previous call to [mysqli\\_multi\\_query](#) which can be retrieved by [mysqli\\_store\\_result](#) or [mysqli\\_use\\_result](#).

### Parameters

*link* Procedural style only: A link identifier returned by [mysqli\\_connect](#) or [mysqli\\_init](#)

### Return Values

Returns `TRUE` on success or `FALSE` on failure.

### Examples

See [mysqli\\_multi\\_query](#).

**20.10.2.6.30. mysqli::options, mysqli\_options**

Copyright 1997-2008 the PHP Documentation Group.

- `mysqli::options`

```
mysqli_options
```

Set options

**Description**

Object oriented style (method)

```
bool mysqli::options(int option,
                    mixed value);
```

Procedural style:

```
bool mysqli_options(mysqli link,
                   int option,
                   mixed value);
```

Used to set extra connect options and affect behavior for a connection.

This function may be called multiple times to set several options.

`mysqli_options` should be called after `mysqli_init` and before `mysqli_real_connect`.

**Parameters**

*link* Procedural style only: A link identifier returned by `mysqli_connect` or `mysqli_init`

*option* The option that you want to set. It can be one of the following values:

**Table 20.9. Valid options**

Name	Description
<code>MYSQLI_OPT_CONNECT_TIMEOUT</code>	connection timeout in seconds
<code>MYSQLI_OPT_LOCAL_INFILE</code>	enable/disable use of <code>LOAD LOCAL INFILE</code>
<code>MYSQLI_INIT_COMMAND</code>	command to execute after when connecting to MySQL server
<code>MYSQLI_READ_DEFAULT_FILE</code>	Read options from named option file instead of <code>my.cnf</code>
<code>MYSQLI_READ_DEFAULT_GROUP</code>	Read options from the named group from <code>my.cnf</code> or the file specified with <code>MYSQLI_READ_DEFAULT_FILE</code> .

*value* The value for the option.

**Return Values**

Returns `TRUE` on success or `FALSE` on failure.

**Examples**

See `mysqli_real_connect`.

**See Also**

`mysqli_init`  
`mysqli_real_connect`

**20.10.2.6.31. `mysqli::ping`, `mysqli_ping`**

Copyright 1997-2008 the PHP Documentation Group.

- `mysqli::ping`  
`mysqli_ping`

Pings a server connection, or tries to reconnect if the connection has gone down

**Description**

Object oriented style (method):

```
bool mysqli::ping();
```

Procedural style:

```
bool mysqli_ping(mysqli link);
```

Checks whether the connection to the server is working. If it has gone down, and global option `mysqli.reconnect` is enabled an automatic reconnection is attempted.

This function can be used by clients that remain idle for a long while, to check whether the server has closed the connection and reconnect if necessary.

**Parameters**

*link* Procedural style only: A link identifier returned by `mysqli_connect` or `mysqli_init`

**Return Values**

Returns `TRUE` on success or `FALSE` on failure.

**Examples****Example 20.110. Object oriented style**

```
<?php
$mysqli = new mysqli("localhost", "my_user", "my_password", "world");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

/* check if server is alive */
if ($mysqli->ping()) {
    printf("Our connection is ok!\n");
} else {
    printf("Error: %s\n", $mysqli->error);
}

/* close connection */
$mysqli->close();
?>
```

**Example 20.111. Procedural style**

```

<?php
$link = mysqli_connect("localhost", "my_user", "my_password", "world");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

/* check if server is alive */
if (mysqli_ping($link)) {
    printf("Our connection is ok!\n");
} else {
    printf("Error: %s\n", mysqli_error($link));
}

/* close connection */
mysqli_close($link);
?>

```

The above example will output:

```
Our connection is ok!
```

### 20.10.2.6.32. `mysqli::prepare`, `mysqli_prepare`

Copyright 1997-2008 the PHP Documentation Group.

- `mysqli::prepare`

`mysqli_prepare`

Prepare a SQL statement for execution

#### Description

Object oriented style (method)

```
mysqli_stmt prepare(string query);
```

Procedure style:

```
mysqli_stmt mysqli_prepare(mysqli link,
                           string query);
```

Prepares the SQL query pointed to by the null-terminated string query, and returns a statement handle to be used for further operations on the statement. The query must consist of a single SQL statement.

The parameter markers must be bound to application variables using `mysqli_stmt_bind_param` and/or `mysqli_stmt_bind_result` before executing the statement or fetching rows.

#### Parameters

*link* Procedural style only: A link identifier returned by `mysqli_connect` or `mysqli_init`

*query* The query, as a string.

#### Note

You should not add a terminating semicolon or `\g` to the statement.

This parameter can include one or more parameter markers in the SQL statement by embedding question mark (?) characters at the appropriate positions.

**Note**

The markers are legal only in certain places in SQL statements. For example, they are allowed in the `VALUES ( )` list of an `INSERT` statement (to specify column values for a row), or in a comparison with a column in a `WHERE` clause to specify a comparison value.

However, they are not allowed for identifiers (such as table or column names), in the select list that names the columns to be returned by a `SELECT` statement, or to specify both operands of a binary operator such as the `=` equal sign. The latter restriction is necessary because it would be impossible to determine the parameter type. It's not allowed to compare marker with `NULL` by `? IS NULL` too. In general, parameters are legal only in Data Manipulation Language (DML) statements, and not in Data Definition Language (DDL) statements.

**Return Values**

`mysqli_prepare` returns a statement object or `FALSE` if an error occurred.

**Examples****Example 20.112. Object oriented style**

```
<?php
mysqli = new mysqli("localhost", "my_user", "my_password", "world");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

$city = "Amersfoort";

/* create a prepared statement */
if ($stmt = $mysqli->prepare("SELECT District FROM City WHERE Name=?")) {

    /* bind parameters for markers */
    $stmt->bind_param("s", $city);

    /* execute query */
    $stmt->execute();

    /* bind result variables */
    $stmt->bind_result($district);

    /* fetch value */
    $stmt->fetch();

    printf("%s is in district %s\n", $city, $district);

    /* close statement */
    $stmt->close();
}

/* close connection */
mysqli->close();
?>
```

**Example 20.113. Procedural style**

```
<?php
$link = mysqli_connect("localhost", "my_user", "my_password", "world");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

$city = "Amersfoort";

/* create a prepared statement */
if ($stmt = mysqli_prepare($link, "SELECT District FROM City WHERE Name=?")) {

    /* bind parameters for markers */
    mysqli_stmt_bind_param($stmt, "s", $city);

    /* execute query */
```

```

mysqli_stmt_execute($stmt);
/* bind result variables */
mysqli_stmt_bind_result($stmt, $district);

/* fetch value */
mysqli_stmt_fetch($stmt);

printf("%s is in district %s\n", $city, $district);

/* close statement */
mysqli_stmt_close($stmt);
}
/* close connection */
mysqli_close($link);
?>

```

The above example will output:

```
Amersfoort is in district Utrecht
```

### 20.10.2.6.33. `mysqli::query`, `mysqli_query`

Copyright 1997-2008 the PHP Documentation Group.

- `mysqli::query`
- `mysqli_query`

Performs a query on the database

#### Description

Object oriented style (method):

```
mixed mysqli::query(string query,
                    int resultmode);
```

Procedural style:

```
mixed mysqli_query(mysqli link,
                   string query,
                   int resultmode);
```

Performs a *query* against the database.

Functionally, using this function is identical to calling `mysqli_real_query` followed either by `mysqli_use_result` or `mysqli_store_result`.

#### Parameters

<code>link</code>	Procedural style only: A link identifier returned by <code>mysqli_connect</code> or <code>mysqli_init</code>
<code>query</code>	The query string.

*resultmode*

Either the constant `MYSQLI_USE_RESULT` or `MYSQLI_STORE_RESULT` depending on the desired behavior. By default, `MYSQLI_STORE_RESULT` is used.

If you use `MYSQLI_USE_RESULT` all subsequent calls will return error `Commands out of sync` unless you call `mysqli_free_result`

**Return Values**

Returns `TRUE` on success or `FALSE` on failure. For `SELECT`, `SHOW`, `DESCRIBE` or `EXPLAIN` `mysqli_query` will return a result object.

**Examples****Example 20.114. Object oriented style**

```
<?php
$mysqli = new mysqli("localhost", "my_user", "my_password", "world");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

/* Create table doesn't return a resultset */
if ($mysqli->query("CREATE TEMPORARY TABLE myCity LIKE City") === TRUE) {
    printf("Table myCity successfully created.\n");
}

/* Select queries return a resultset */
if ($result = $mysqli->query("SELECT Name FROM City LIMIT 10")) {
    printf("Select returned %d rows.\n", $result->num_rows);

    /* free result set */
    $result->close();
}

/* If we have to retrieve large amount of data we use MYSQLI_USE_RESULT */
if ($result = $mysqli->query("SELECT * FROM City", MYSQLI_USE_RESULT)) {

    /* Note, that we can't execute any functions which interact with the
    server until result set was closed. All calls will return an
    'out of sync' error */
    if (!$mysqli->query("SET @a:='this will not work'")) {
        printf("Error: %s\n", $mysqli->error);
    }
    $result->close();
}

$mysqli->close();
?>
```

**Example 20.115. Procedural style**

```
<?php
$link = mysqli_connect("localhost", "my_user", "my_password", "world");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

/* Create table doesn't return a resultset */
if (mysqli_query($link, "CREATE TEMPORARY TABLE myCity LIKE City") === TRUE) {
    printf("Table myCity successfully created.\n");
}

/* Select queries return a resultset */
if ($result = mysqli_query($link, "SELECT Name FROM City LIMIT 10")) {
    printf("Select returned %d rows.\n", mysqli_num_rows($result));

    /* free result set */
    mysqli_free_result($result);
}

/* If we have to retrieve large amount of data we use MYSQLI_USE_RESULT */
if ($result = mysqli_query($link, "SELECT * FROM City", MYSQLI_USE_RESULT)) {
```

```

/* Note, that we can't execute any functions which interact with the
server until result set was closed. All calls will return an
'out of sync' error */
if (!mysqli_query($link, "SET @a:='this will not work'")) {
    printf("Error: %s\n", mysqli_error($link));
}
mysqli_free_result($result);
}
mysqli_close($link);
?>

```

The above example will output:

```

Table myCity successfully created.
Select returned 10 rows.
Error: Commands out of sync; You can't run this command now

```

[mysqli\\_free\\_result](#)

#### 20.10.2.6.34. [mysqli::real\\_connect](#), [mysqli\\_real\\_connect](#)

Copyright 1997-2008 the PHP Documentation Group.

- [mysqli::real\\_connect](#)  
[mysqli\\_real\\_connect](#)

Opens a connection to a mysql server

### Description

Object oriented style (method)

```

bool mysqli::real_connect(string host,
                        string username,
                        string passwd,
                        string dbname,
                        int port,
                        string socket,
                        int flags);

```

Procedural style

```

bool mysqli_real_connect(mysqli link,
                        string host,
                        string username,
                        string passwd,
                        string dbname,
                        int port,
                        string socket,
                        int flags);

```

Establish a connection to a MySQL database engine.

This function differs from [mysqli\\_connect](#):

- [mysqli\\_real\\_connect](#) needs a valid object which has to be created by function [mysqli\\_init](#).
- With function [mysqli\\_options](#) you can set various options for connection.

- There is a *flags* parameter.

## Parameters

<i>link</i>	Procedural style only: A link identifier returned by <code>mysqli_connect</code> or <code>mysqli_init</code>
<i>host</i>	Can be either a host name or an IP address. Passing the <code>NULL</code> value or the string "localhost" to this parameter, the local host is assumed. When possible, pipes will be used instead of the TCP/IP protocol.
<i>username</i>	The MySQL user name.
<i>passwd</i>	If provided or <code>NULL</code> , the MySQL server will attempt to authenticate the user against those user records which have no password only. This allows one username to be used with different permissions (depending on if a password as provided or not).
<i>dbname</i>	If provided will specify the default database to be used when performing queries.
<i>port</i>	Specifies the port number to attempt to connect to the MySQL server.
<i>socket</i>	Specifies the socket or named pipe that should be used.

### Note

Specifying the *socket* parameter will not explicitly determine the type of connection to be used when connecting to the MySQL server. How the connection is made to the MySQL database is determined by the *host* parameter.

*flags* With the parameter *flags* you can set different connection options:

**Table 20.10. Supported flags**

Name	Description
<code>MYSQLI_CLIENT_COMPRESS</code>	Use compression protocol
<code>MYSQLI_CLIENT_FOUND_ROWS</code>	return number of matched rows, not the number of affected rows
<code>MYSQLI_CLIENT_IGNORE_SPACE</code>	Allow spaces after function names. Makes all function names reserved words.
<code>MYSQLI_CLIENT_INTERACTIVE</code>	Allow <code>interactive_timeout</code> seconds (instead of <code>wait_timeout</code> seconds) of inactivity before closing the connection
<code>MYSQLI_CLIENT_SSL</code>	Use SSL (encryption)

### Note

For security reasons the `MULTI_STATEMENT` flag is not supported in PHP. If you want to execute multiple queries use the `mysqli_multi_query` function.

## Return Values

Returns `TRUE` on success or `FALSE` on failure.

## Examples

### Example 20.116. Object oriented style

```
<?php
/* create a connection object which is not connected */
$mysqli = mysqli_init();

/* set connection options */
$mysqli->options(MYSQLI_INIT_COMMAND, "SET AUTOCOMMIT=0");
$mysqli->options(MYSQLI_OPT_CONNECT_TIMEOUT, 5);

/* connect to server */
```

```

$mysqli->real_connect('localhost', 'my_user', 'my_password', 'world');

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

printf ("Connection: %s\n.", $mysqli->host_info);

$mysqli->close();
?>

```

### Example 20.117. Procedural style

```

<?php

/* create a connection object which is not connected */
$link = mysqli_init();

/* set connection options */
mysqli_options($link, MYSQLI_INIT_COMMAND, "SET AUTOCOMMIT=0");
mysqli_options($link, MYSQLI_OPT_CONNECT_TIMEOUT, 5);

/* connect to server */
mysqli_real_connect($link, 'localhost', 'my_user', 'my_password', 'world');

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

printf ("Connection: %s\n.", mysqli_get_host_info($link));

mysqli_close($link);
?>

```

The above example will output:

```

Connection: Localhost via UNIX socket

```

#### 20.10.2.6.35. [mysqli::real\\_escape\\_string](#), [mysqli\\_real\\_escape\\_string](#)

Copyright 1997-2008 the PHP Documentation Group.

- [mysqli::real\\_escape\\_string](#)  
[mysqli\\_real\\_escape\\_string](#)

Escapes special characters in a string for use in a SQL statement, taking into account the current charset of the connection

#### Description

Object oriented style (both methods are equivalent):

```
string mysqli::escape_string(string escapestr);
```

```
string real_escape_string(string escapestr);
```

Procedural style:

```
string mysqli_real_escape_string(mysqli link,
                                string escapestr);
```

This function is used to create a legal SQL string that you can use in an SQL statement. The given string is encoded to an escaped SQL string, taking into account the current character set of the connection.

### Parameters

*link* Procedural style only: A link identifier returned by `mysqli_connect` or `mysqli_init`

*escapestr* The string to be escaped.

Characters encoded are NUL (ASCII 0), `\n`, `\r`, `\`, `'`, `"`, and Control-Z.

### Return Values

Returns an escaped string.

### Examples

#### Example 20.118. Object oriented style

```
<?php
$mysqli = new mysqli("localhost", "my_user", "my_password", "world");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

$mysqli->query("CREATE TEMPORARY TABLE myCity LIKE City");

$city = "'s Hertogenbosch";

/* this query will fail, cause we didn't escape $city */
if (!$mysqli->query("INSERT into myCity (Name) VALUES ('$city')")) {
    printf("Error: %s\n", $mysqli->sqlstate);
}

$city = $mysqli->real_escape_string($city);

/* this query with escaped $city will work */
if ($mysqli->query("INSERT into myCity (Name) VALUES ('$city')")) {
    printf("%d Row inserted.\n", $mysqli->affected_rows);
}

$mysqli->close();
?>
```

#### Example 20.119. Procedural style

```
<?php
$link = mysqli_connect("localhost", "my_user", "my_password", "world");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

mysqli_query($link, "CREATE TEMPORARY TABLE myCity LIKE City");

$city = "'s Hertogenbosch";
```

```

/* this query will fail, cause we didn't escape $city */
if (!mysqli_query($link, "INSERT into myCity (Name) VALUES ('$city')")) {
    printf("Error: %s\n", mysqli_sqlstate($link));
}

$city = mysqli_real_escape_string($link, $city);

/* this query with escaped $city will work */
if (mysqli_query($link, "INSERT into myCity (Name) VALUES ('$city')")) {
    printf("%d Row inserted.\n", mysqli_affected_rows($link));
}

mysqli_close($link);
?>

```

The above example will output:

```

Error: 42000
1 Row inserted.

```

## 20.10.2.6.36. [mysqli::real\\_query](#), [mysqli\\_real\\_query](#)

Copyright 1997-2008 the PHP Documentation Group.

- [mysqli::real\\_query](#)  
[mysqli\\_real\\_query](#)

Execute an SQL query

### Description

Object oriented style (method):

```
bool real_query(string query);
```

Procedural style

```
bool mysqli_real_query(mysqli link,
                      string query);
```

Executes a single query against the database whose result can then be retrieved or stored using the [mysqli\\_store\\_result](#) or [mysqli\\_use\\_result](#) functions.

In order to determine if a given query should return a result set or not, see [mysqli\\_field\\_count](#).

### Parameters

*link* Procedural style only: A link identifier returned by [mysqli\\_connect](#) or [mysqli\\_init](#)

*query* The query, as a string.

### Return Values

Returns [TRUE](#) on success or [FALSE](#) on failure.

### See Also

```
mysqli_query
mysqli_store_result
mysqli_use_result
```

### 20.10.2.6.37. `mysqli::rollback`, `mysqli_rollback`

Copyright 1997-2008 the PHP Documentation Group.

- `mysqli::rollback`  
`mysqli_rollback`  
Rolls back current transaction

#### Description

Object oriented style (method):

```
bool mysqli::rollback();
```

Procedural style:

```
bool mysqli_rollback(mysqli link);
```

Rollbacks the current transaction for the database.

#### Parameters

*link* Procedural style only: A link identifier returned by `mysqli_connect` or `mysqli_init`

#### Return Values

Returns `TRUE` on success or `FALSE` on failure.

#### Examples

##### Example 20.120. Object oriented style

```
<?php
$mysqli = new mysqli("localhost", "my_user", "my_password", "world");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

/* disable autocommit */
$mysqli->autocommit(FALSE);

$mysqli->query("CREATE TABLE myCity LIKE City");
$mysqli->query("ALTER TABLE myCity Type=InnoDB");
$mysqli->query("INSERT INTO myCity SELECT * FROM City LIMIT 50");

/* commit insert */
$mysqli->commit();

/* delete all rows */
$mysqli->query("DELETE FROM myCity");

if ($result = $mysqli->query("SELECT COUNT(*) FROM myCity")) {
    $row = $result->fetch_row();
    printf("%d rows in table myCity.\n", $row[0]);
    /* Free result */
    $result->close();
}

/* Rollback */
$mysqli->rollback();

if ($result = $mysqli->query("SELECT COUNT(*) FROM myCity")) {
    $row = $result->fetch_row();
```

```

    printf("%d rows in table myCity (after rollback).\n", $row[0]);
    /* Free result */
    $result->close();
}

/* Drop table myCity */
$mysqli->query("DROP TABLE myCity");

$mysqli->close();
?>

```

### Example 20.121. Procedural style

```

<?php
$link = mysqli_connect("localhost", "my_user", "my_password", "world");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

/* disable autocommit */
mysqli_autocommit($link, FALSE);

mysqli_query($link, "CREATE TABLE myCity LIKE City");
mysqli_query($link, "ALTER TABLE myCity Type=InnoDB");
mysqli_query($link, "INSERT INTO myCity SELECT * FROM City LIMIT 50");

/* commit insert */
mysqli_commit($link);

/* delete all rows */
mysqli_query($link, "DELETE FROM myCity");

if ($result = mysqli_query($link, "SELECT COUNT(*) FROM myCity")) {
    $row = mysqli_fetch_row($result);
    printf("%d rows in table myCity.\n", $row[0]);
    /* Free result */
    mysqli_free_result($result);
}

/* Rollback */
mysqli_rollback($link);

if ($result = mysqli_query($link, "SELECT COUNT(*) FROM myCity")) {
    $row = mysqli_fetch_row($result);
    printf("%d rows in table myCity (after rollback).\n", $row[0]);
    /* Free result */
    mysqli_free_result($result);
}

/* Drop table myCity */
mysqli_query($link, "DROP TABLE myCity");

mysqli_close($link);
?>

```

The above example will output:

```

0 rows in table myCity.
50 rows in table myCity (after rollback).

```

#### 20.10.2.6.38. `mysqli::select_db`, `mysqli_select_db`

Copyright 1997-2008 the PHP Documentation Group.

- `mysqli::select_db`  
`mysqli_select_db`

Selects the default database for database queries

## Description

Object oriented style (method):

```
bool mysqli::select_db(string dbname);
```

Procedural style:

```
bool mysqli_select_db(mysqli link,
                     string dbname);
```

Selects the default database to be used when performing queries against the database connection.

### Note

This function should only be used to change the default database for the connection. You can select the default database with 4th parameter in `mysqli_connect`.

## Parameters

- link* Procedural style only: A link identifier returned by `mysqli_connect` or `mysqli_init`
- dbname* The database name.

## Return Values

Returns `TRUE` on success or `FALSE` on failure.

## Examples

### Example 20.122. Object oriented style

```
<?php
$mysqli = new mysqli("localhost", "my_user", "my_password", "test");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

/* return name of current default database */
if ($result = $mysqli->query("SELECT DATABASE()")) {
    $row = $result->fetch_row();
    printf("Default database is %s.\n", $row[0]);
    $result->close();
}

/* change db to world db */
$mysqli->select_db("world");

/* return name of current default database */
if ($result = $mysqli->query("SELECT DATABASE()")) {
    $row = $result->fetch_row();
    printf("Default database is %s.\n", $row[0]);
    $result->close();
}

$mysqli->close();
?>
```

### Example 20.123. Procedural style

```

<?php
$link = mysqli_connect("localhost", "my_user", "my_password", "test");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

/* return name of current default database */
if ($result = mysqli_query($link, "SELECT DATABASE())) {
    $row = mysqli_fetch_row($result);
    printf("Default database is %s.\n", $row[0]);
    mysqli_free_result($result);
}

/* change db to world db */
mysqli_select_db($link, "world");

/* return name of current default database */
if ($result = mysqli_query($link, "SELECT DATABASE())) {
    $row = mysqli_fetch_row($result);
    printf("Default database is %s.\n", $row[0]);
    mysqli_free_result($result);
}

mysqli_close($link);
?>

```

The above example will output:

```

Default database is test.
Default database is world.

```

[mysqli\\_real\\_connect](#)

### 20.10.2.6.39. [mysqli::set\\_charset](#), [mysqli\\_set\\_charset](#)

Copyright 1997-2008 the PHP Documentation Group.

- [mysqli::set\\_charset](#)  
[mysqli\\_set\\_charset](#)

Sets the default client character set

#### Description

Object oriented style (method):

```
bool mysqli::set_charset(string charset);
```

Procedural style:

```
bool mysqli_set_charset(mysqli link,
                        string charset);
```

Sets the default character set to be used when sending data from and to the database server.

#### Parameters

*link*

Procedural style only: A link identifier returned by [mysqli\\_connect](#) or [mysqli\\_init](#)

*charset*

The charset to be set as default.

**Return Values**Returns **TRUE** on success or **FALSE** on failure.**Notes****Note**

To use this function on a Windows platform you need MySQL client library version 4.1.11 or above (for MySQL 5.0 you need 5.0.6 or above).

**Note**

This is the preferred way to change the charset. Using `mysqli::query` to execute `SET NAMES ..` is not recommended.

**Examples****Example 20.124. Object oriented style**

```
<?php
$mysqli = new mysqli("localhost", "my_user", "my_password", "test");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

/* change character set to utf8 */
if (!$mysqli->set_charset("utf8")) {
    printf("Error loading character set utf8: %s\n", $mysqli->error);
} else {
    printf("Current character set: %s\n", $mysqli->character_set_name());
}

$mysqli->close();
?>
```

**Example 20.125. Procedural style**

```
<?php
$link = mysqli_connect('localhost', 'my_user', 'my_password', 'test');

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

/* change character set to utf8 */
if (!mysqli_set_charset($link, "utf8")) {
    printf("Error loading character set utf8: %s\n", mysqli_error($link));
} else {
    printf("Current character set: %s\n", mysqli_character_set_name($link));
}

mysqli_close($link);
?>
```

The above example will output:

```
Current character set: utf8
```

- [mysqli::set\\_local\\_infile\\_handler](#)  
[mysqli\\_set\\_local\\_infile\\_handler](#)  
 Set callback function for `LOAD DATA LOCAL INFILE` command

**Description**

```
bool mysqli_set_local_infile_handler(mysqli link,  
                                     callback read_func);
```

Object oriented style (method)

```
mysqli {  
    bool set_local_infile_handler(mysqli link,  
                                 callback read_func);  
}
```

Set callback function for `LOAD DATA LOCAL INFILE` command

The callback task is to read input from the file specified in the `LOAD DATA LOCAL INFILE` and to reformat it into the format understood by `LOAD DATA INFILE`.

The returned data needs to match the format specified in the `LOAD DATA`

### Parameters

<code>link</code>	Procedural style only: A link identifier returned by <code>mysqli_connect</code> or <code>mysqli_init</code>
<code>read_func</code>	A callback function or object method taking the following parameters:
<code>stream</code>	A PHP stream associated with the SQL commands <code>INFILE</code>
<code>&amp;buffer</code>	A string buffer to store the rewritten input into
<code>buflen</code>	The maximum number of characters to be stored in the buffer
<code>&amp;errmsg</code>	If an error occurs you can store an error message in here

The callback function should return the number of characters stored in the `buffer` or a negative value if an error occurred.

### Return Values

Returns `TRUE` on success or `FALSE` on failure.

### Examples

#### Example 20.126. Object oriented style

```
<?php
$db = mysqli_init();
$db->real_connect("localhost","root","","test");

function callme($stream, &$buffer, $buflen, &$errmsg)
{
    $buffer = fgets($stream);

    echo $buffer;

    // convert to upper case and replace "," delimiter with [TAB]
    $buffer = strtoupper(str_replace(",","\\t", $buffer));

    return strlen($buffer);
}

echo "Input:\\n";

$db->set_local_infile_handler("callme");
$db->query("LOAD DATA LOCAL INFILE 'input.txt' INTO TABLE t1");
$db->set_local_infile_default();

$res = $db->query("SELECT * FROM t1");

echo "\\nResult:\\n";
while ($row = $res->fetch_assoc()) {
    echo join(", ", $row). "\\n";
}
?>
```

#### Example 20.127. Procedural style

```
<?php
$db = mysqli_init();
mysqli_real_connect($db, "localhost","root","","test");

function callme($stream, &$buffer, $buflen, &$errmsg)
{
```

```

$buffer = fgets($stream);

echo $buffer;

// convert to upper case and replace "," delimiter with [TAB]
$buffer = strtoupper(str_replace(",","\\t", $buffer));

return strlen($buffer);
}

echo "Input:\\n";

mysqli_set_local_infile_handler($db, "callme");
mysqli_query($db, "LOAD DATA LOCAL INFILE 'input.txt' INTO TABLE t1");
mysqli_set_local_infile_default($db);

$res = mysqli_query($db, "SELECT * FROM t1");

echo "\\nResult:\\n";
while ($row = mysqli_fetch_assoc($res)) {
    echo join(", ", $row). "\\n";
}
?>

```

The above example will output:

```

Input:
23,foo
42,bar

Output:
23,FOO
42,BAR

```

## 20.10.2.6.42. [mysqli->sqlstate](#), [mysqli\\_sqlstate](#)

Copyright 1997-2008 the PHP Documentation Group.

- [mysqli->sqlstate](#)
- [mysqli\\_sqlstate](#)

Returns the SQLSTATE error from previous MySQL operation

### Description

Object oriented style (property):

```

mysqli {
    string sqlstate ;
}

```

Procedural style:

```

string mysqli_sqlstate(mysqli link);

```

Returns a string containing the SQLSTATE error code for the last error. The error code consists of five characters. '00000' means no error. The values are specified by ANSI SQL and ODBC. For a list of possible values, see <http://dev.mysql.com/doc/mysql/en/error-handling.html>.

**Note**

Note that not all MySQL errors are yet mapped to SQLSTATE's. The value `HY000` (general error) is used for unmapped errors.

**Parameters**

*link*

Procedural style only: A link identifier returned by `mysqli_connect` or `mysqli_init`

**Return Values**

Returns a string containing the SQLSTATE error code for the last error. The error code consists of five characters. `'00000'` means no error.

**Examples****Example 20.128. Object oriented style**

```
<?php
$mysqli = new mysqli("localhost", "my_user", "my_password", "world");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

/* Table City already exists, so we should get an error */
if (!$mysqli->query("CREATE TABLE City (ID INT, Name VARCHAR(30))")) {
    printf("Error - SQLSTATE %s.\n", $mysqli->sqlstate);
}

$mysqli->close();
?>
```

**Example 20.129. Procedural style**

```
<?php
$link = mysqli_connect("localhost", "my_user", "my_password", "world");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

/* Table City already exists, so we should get an error */
if (!$mysqli_query($link, "CREATE TABLE City (ID INT, Name VARCHAR(30))")) {
    printf("Error - SQLSTATE %s.\n", mysqli_sqlstate($link));
}

mysqli_close($link);
?>
```

The above example will output:

```
Error - SQLSTATE 42S01.
```

**See Also**

`mysqli_error`

#### 20.10.2.6.43. `mysqli::ssl_set`, `mysqli_ssl_set`

Copyright 1997-2008 the PHP Documentation Group.

- `mysqli::ssl_set`  
`mysqli_ssl_set`

Used for establishing secure connections using SSL

##### Description

Object oriented style (method):

```
bool mysqli::ssl_set(string key,  
                    string cert,  
                    string ca,  
                    string capath,  
                    string cipher);
```

Procedural style:

```
bool mysqli_ssl_set(mysqli link,  
                    string key,  
                    string cert,  
                    string ca,  
                    string capath,  
                    string cipher);
```

Used for establishing secure connections using SSL. It must be called before `mysqli_real_connect`. This function does nothing unless OpenSSL support is enabled.

##### Parameters

<i>link</i>	Procedural style only: A link identifier returned by <code>mysqli_connect</code> or <code>mysqli_init</code>
<i>key</i>	The path name to the key file.
<i>cert</i>	The path name to the certificate file.
<i>ca</i>	The path name to the certificate authority file.
<i>capath</i>	The pathname to a directory that contains trusted SSL CA certificates in PEM format.
<i>cipher</i>	A list of allowable ciphers to use for SSL encryption.

Any unused SSL parameters may be given as `NULL`

##### Return Values

This function always returns `TRUE` value. If SSL setup is incorrect `mysqli_real_connect` will return an error when you attempt to connect.

##### See Also

`mysqli_options`  
`mysqli_real_connect`

#### 20.10.2.6.44. `mysqli::stat`, `mysqli_stat`

Copyright 1997-2008 the PHP Documentation Group.

- `mysqli::stat`

`mysqli_stat`

Gets the current system status

**Description**

Object oriented style (method):

```
string mysqli::stat();
```

Procedural style:

```
string mysqli_stat(mysqli link);
```

`mysqli_stat` returns a string containing information similar to that provided by the 'mysqladmin status' command. This includes uptime in seconds and the number of running threads, questions, reloads, and open tables.

**Parameters***link*

Procedural style only: A link identifier returned by `mysqli_connect` or `mysqli_init`

**Return Values**

A string describing the server status. `FALSE` if an error occurred.

**Examples****Example 20.130. Object oriented style**

```
<?php
$mysqli = new mysqli("localhost", "my_user", "my_password", "world");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

printf ("System status: %s\n", $mysqli->stat());

$mysqli->close();
?>
```

**Example 20.131. Procedural style**

```
<?php
$link = mysqli_connect("localhost", "my_user", "my_password", "world");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

printf("System status: %s\n", mysqli_stat($link));

mysqli_close($link);
?>
```

The above example will output:

```
System status: Uptime: 272  Threads: 1  Questions: 5340  Slow queries: 0
Opens: 13  Flush tables: 1  Open tables: 0  Queries per second avg: 19.632
Memory in use: 8496K  Max memory used: 8560K
```

Copyright 1997-2008 the PHP Documentation Group.

- [mysqli::stmt\\_init](#)

[mysqli\\_stmt\\_init](#)

Initializes a statement and returns an object for use with [mysqli\\_stmt\\_prepare](#)

### Description

Object oriented style (property):

```
mysqli {
    mysqli_stmt stmt_init();
}
```

Procedural style :

```
mysqli_stmt mysqli_stmt_init(mysqli link);
```

Allocates and initializes a statement object suitable for [mysqli\\_stmt\\_prepare](#).

### Note

Any subsequent calls to any [mysqli\\_stmt](#) function will fail until [mysqli\\_stmt\\_prepare](#) was called.

### Parameters

*link*

Procedural style only: A link identifier returned by [mysqli\\_connect](#) or [mysqli\\_init](#)

### Return Values

Returns an object.

### See Also

[mysqli\\_stmt\\_prepare](#)

#### 20.10.2.6.46. [mysqli::store\\_result](#), [mysqli\\_store\\_result](#)

Copyright 1997-2008 the PHP Documentation Group.

- [mysqli::store\\_result](#)

[mysqli\\_store\\_result](#)

Transfers a result set from the last query

**Description**

Object oriented style (method):

```
mysqli_result store_result();
```

Procedural style:

```
mysqli_result mysqli_store_result(mysqli link);
```

Transfers the result set from the last query on the database connection represented by the *link* parameter to be used with the `mysqli_data_seek` function.

**Parameters**

*link* Procedural style only: A link identifier returned by `mysqli_connect` or `mysqli_init`

**Return Values**

Returns a buffered result object or `FALSE` if an error occurred.

**Note**

`mysqli_store_result` returns `FALSE` in case the query didn't return a result set (if the query was, for example an INSERT statement). This function also returns `FALSE` if the reading of the result set failed. You can check if you have got an error by checking if `mysqli_error` doesn't return an empty string, if `mysqli_errno` returns a non zero value, or if `mysqli_field_count` returns a non zero value. Also possible reason for this function returning `FALSE` after successful call to `mysqli_query` can be too large result set (memory for it cannot be allocated). If `mysqli_field_count` returns a non-zero value, the statement should have produced a non-empty result set.

**Notes****Note**

Although it is always good practice to free the memory used by the result of a query using the `mysqli_free_result` function, when transferring large result sets using the `mysqli_store_result` this becomes particularly important.

**Examples**

See `mysqli_multi_query`.

**See Also**

`mysqli_real_query`  
`mysqli_use_result`

**20.10.2.6.47. `mysqli::thread_id`, `mysqli_thread_id`**

Copyright 1997-2008 the PHP Documentation Group.

- `mysqli::thread_id`  
`mysqli_thread_id`

Returns the thread ID for the current connection

**Description**

Object oriented style (property):

```
mysqli {
    int thread_id ;
}
```

Procedural style:

```
int mysqli_thread_id(mysqli link);
```

The `mysqli_thread_id` function returns the thread ID for the current connection which can then be killed using the `mysqli_kill` function. If the connection is lost and you reconnect with `mysqli_ping`, the thread ID will be other. Therefore you should get the thread ID only when you need it.

### Note

The thread ID is assigned on a connection-by-connection basis. Hence, if the connection is broken and then re-established a new thread ID will be assigned.

To kill a running query you can use the SQL command `KILL QUERY processid`.

### Parameters

*link* Procedural style only: A link identifier returned by `mysqli_connect` or `mysqli_init`

### Return Values

Returns the Thread ID for the current connection.

### Examples

#### Example 20.132. Object oriented style

```
<?php
$mysqli = new mysqli("localhost", "my_user", "my_password", "world");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

/* determine our thread id */
$thread_id = $mysqli->thread_id;

/* Kill connection */
$mysqli->kill($thread_id);

/* This should produce an error */
if (!$mysqli->query("CREATE TABLE myCity LIKE City")) {
    printf("Error: %s\n", $mysqli->error);
    exit;
}

/* close connection */
$mysqli->close();
?>
```

#### Example 20.133. Procedural style

```
<?php
$link = mysqli_connect("localhost", "my_user", "my_password", "world");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

/* determine our thread id */
$thread_id = mysqli_thread_id($link);

/* Kill connection */
mysqli_kill($link, $thread_id);

/* This should produce an error */
if (!mysqli_query($link, "CREATE TABLE myCity LIKE City")) {
    printf("Error: %s\n", mysqli_error($link));
}
```

```
    exit;
}
/* close connection */
mysqli_close($link);
?>
```

The above example will output:

```
Error: MySQL server has gone away
```

### See Also

[mysqli\\_kill](#)

#### 20.10.2.6.48. [mysqli::thread\\_safe](#), [mysqli\\_thread\\_safe](#)

Copyright 1997-2008 the PHP Documentation Group.

- [mysqli::thread\\_safe](#)  
[mysqli\\_thread\\_safe](#)

Returns whether thread safety is given or not

### Description

Procedural style:

```
bool mysqli_thread_safe();
```

Tells whether the client library is compiled as thread-safe.

### Return Values

`TRUE` if the client library is thread-safe, otherwise `FALSE` .

#### 20.10.2.6.49. [mysqli::use\\_result](#), [mysqli\\_use\\_result](#)

Copyright 1997-2008 the PHP Documentation Group.

- [mysqli::use\\_result](#)  
[mysqli\\_use\\_result](#)

Initiate a result set retrieval

### Description

Object oriented style (method):

```
mysqli_result use_result();
```

Procedural style:

```
mysqli_result mysqli_use_result(mysqli link);
```

Used to initiate the retrieval of a result set from the last query executed using the [mysqli\\_real\\_query](#) function on the database connection.

Either this or the `mysqli_store_result` function must be called before the results of a query can be retrieved, and one or the other must be called to prevent the next query on that database connection from failing.

### Note

The `mysqli_use_result` function does not transfer the entire result set from the database and hence cannot be used functions such as `mysqli_data_seek` to move to a particular row within the set. To use this functionality, the result set must be stored using `mysqli_store_result`. One should not use `mysqli_use_result` if a lot of processing on the client side is performed, since this will tie up the server and prevent other threads from updating any tables from which the data is being fetched.

### Return Values

Returns an unbuffered result object or `FALSE` if an error occurred.

### Examples

#### Example 20.134. Object oriented style

```
<?php
$mysqli = new mysqli("localhost", "my_user", "my_password", "world");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

$query = "SELECT CURRENT_USER()";
$query .= "SELECT Name FROM City ORDER BY ID LIMIT 20, 5";

/* execute multi query */
if ($mysqli->multi_query($query)) {
    do {
        /* store first result set */
        if ($result = $mysqli->use_result()) {
            while ($row = $result->fetch_row()) {
                printf("%s\n", $row[0]);
            }
            $result->close();
        }
        /* print divider */
        if ($mysqli->more_results()) {
            printf("-----\n");
        }
    } while ($mysqli->next_result());
}

/* close connection */
$mysqli->close();
?>
```

#### Example 20.135. Procedural style

```
<?php
$link = mysqli_connect("localhost", "my_user", "my_password", "world");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

$query = "SELECT CURRENT_USER()";
$query .= "SELECT Name FROM City ORDER BY ID LIMIT 20, 5";

/* execute multi query */
if (mysqli_multi_query($link, $query)) {
    do {
        /* store first result set */
        if ($result = mysqli_use_result($link)) {
            while ($row = mysqli_fetch_row($result)) {
                printf("%s\n", $row[0]);
            }
            mysqli_free_result($result);
        }
        /* print divider */
        if (mysqli_more_results($link)) {
            printf("-----\n");
        }
    }
}
```

```

    }
  } while (mysqli_next_result($link));
}

/* close connection */
mysqli_close($link);
?>

```

The above example will output:

```

my_user@localhost
-----
Amersfoort
Maastricht
Dordrecht
Leiden
Haarlemmermeer

```

#### 20.10.2.6.50. [mysqli::warning\\_count](#), [mysqli\\_warning\\_count](#)

Copyright 1997-2008 the PHP Documentation Group.

- [mysqli::warning\\_count](#)  
[mysqli\\_warning\\_count](#)

Returns the number of warnings from the last query for the given link

### Description

Object oriented style (property):

```

mysqli {
    int warning_count ;
}

```

Procedural style:

```

int mysqli_warning_count(mysqli link);

```

Returns the number of warnings from the last query in the connection.

#### Note

For retrieving warning messages you can use the SQL command `SHOW WARNINGS [limit row_count]`.

### Parameters

*link* Procedural style only: A link identifier returned by [mysqli\\_connect](#) or [mysqli\\_init](#)

### Return Values

Number of warnings or zero if there are no warnings.

## Examples

### Example 20.136. Object oriented style

```
<?php
$mysqli = new mysqli("localhost", "my_user", "my_password", "world");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

$mysqli->query("CREATE TABLE myCity LIKE City");

/* a remarkable city in Wales */
$query = "INSERT INTO myCity (CountryCode, Name) VALUES('GBR',
'Llanfairpwllgwyngyllgogerychwyrndrobwlllllantysiliogogoch)";

$mysqli->query($query);

if ($mysqli->warning_count) {
    if ($result = $mysqli->query("SHOW WARNINGS")) {
        $row = $result->fetch_row();
        printf("%s (%d): %s\n", $row[0], $row[1], $row[2]);
        $result->close();
    }
}

/* close connection */
$mysqli->close();
?>
```

### Example 20.137. Procedural style

```
<?php
$link = mysqli_connect("localhost", "my_user", "my_password", "world");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

mysqli_query($link, "CREATE TABLE myCity LIKE City");

/* a remarkable long city name in Wales */
$query = "INSERT INTO myCity (CountryCode, Name) VALUES('GBR',
'Llanfairpwllgwyngyllgogerychwyrndrobwlllllantysiliogogoch)";

mysqli_query($link, $query);

if (mysqli_warning_count($link)) {
    if ($result = mysqli_query($link, "SHOW WARNINGS")) {
        $row = mysqli_fetch_row($result);
        printf("%s (%d): %s\n", $row[0], $row[1], $row[2]);
        mysqli_free_result($result);
    }
}

/* close connection */
mysqli_close($link);
?>
```

The above example will output:

```
Warning (1264): Data truncated for column 'Name' at row 1
```

}

```

### 20.10.2.7.1. `mysqli_stmt->affected_rows`, `mysqli_stmt_affected_rows`

Copyright 1997-2008 the PHP Documentation Group.

- `mysqli_stmt->affected_rows`  
`mysqli_stmt_affected_rows`

Returns the total number of rows changed, deleted, or inserted by the last executed statement

#### Description

Object oriented style (property):

```

mysqli_stmt {
    int affected_rows ;
}

```

Procedural style :

```

int mysqli_stmt_affected_rows(mysqli_stmt stmt);

```

Returns the number of rows affected by `INSERT`, `UPDATE`, or `DELETE` query.

This function only works with queries which update a table. In order to get the number of rows from a `SELECT` query, use `mysqli_stmt_num_rows` instead.

#### Parameters

*stmt*

Procedural style only: A statement identifier returned by `mysqli_stmt_init`.

#### Return Values

An integer greater than zero indicates the number of rows affected or retrieved. Zero indicates that no records were updated for an `UPDATE/DELETE` statement, no rows matched the `WHERE` clause in the query or that no query has yet been executed. -1 indicates that the query has returned an error. `NULL` indicates an invalid argument was supplied to the function.

#### Note

If the number of affected rows is greater than maximal PHP int value, the number of affected rows will be returned as

■ a string value.

## Examples

### Example 20.138. Object oriented style

```
<?php
$mysqli = new mysqli("localhost", "my_user", "my_password", "world");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

/* create temp table */
$mysqli->query("CREATE TEMPORARY TABLE myCountry LIKE Country");

$query = "INSERT INTO myCountry SELECT * FROM Country WHERE Code LIKE ?";

/* prepare statement */
if ($stmt = $mysqli->prepare($query)) {

    /* Bind variable for placeholder */
    $code = 'A%';
    $stmt->bind_param("s", $code);

    /* execute statement */
    $stmt->execute();

    printf("rows inserted: %d\n", $stmt->affected_rows);

    /* close statement */
    $stmt->close();
}

/* close connection */
$mysqli->close();
?>
```

### Example 20.139. Procedural style

```
<?php
$link = mysqli_connect("localhost", "my_user", "my_password", "world");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

/* create temp table */
mysqli_query($link, "CREATE TEMPORARY TABLE myCountry LIKE Country");

$query = "INSERT INTO myCountry SELECT * FROM Country WHERE Code LIKE ?";

/* prepare statement */
if ($stmt = mysqli_prepare($link, $query)) {

    /* Bind variable for placeholder */
    $code = 'A%';
    mysqli_stmt_bind_param($stmt, "s", $code);

    /* execute statement */
    mysqli_stmt_execute($stmt);

    printf("rows inserted: %d\n", mysqli_stmt_affected_rows($stmt));

    /* close statement */
    mysqli_stmt_close($stmt);
}

/* close connection */
mysqli_close($link);
?>
```

The above example will output:

```
rows inserted: 17
```

**See Also**

```
mysqli_stmt_num_rows
mysqli_prepare
```

**20.10.2.7.2. `mysqli_stmt::attr_get`, `mysqli_stmt_attr_get`**

Copyright 1997-2008 the PHP Documentation Group.

- `mysqli_stmt::attr_get`  
`mysqli_stmt_attr_get`

Used to get the current value of a statement attribute

**Description**

Object oriented style (method):

```
int mysqli_stmt::attr_get(int attr);
```

Procedural style:

```
int mysqli_stmt_attr_get(mysqli_stmt stmt,
                        int attr);
```

Gets the current value of a statement attribute.

**Parameters**

<i>stmt</i>	Procedural style only: A statement identifier returned by <code>mysqli_stmt_init</code> .
<i>attr</i>	The attribute that you want to get.

**Return Values**

Returns `FALSE` if the attribute is not found, otherwise returns the value of the attribute.

**20.10.2.7.3. `mysqli_stmt::attr_set`, `mysqli_stmt_attr_set`**

Copyright 1997-2008 the PHP Documentation Group.

- `mysqli_stmt::attr_set`  
`mysqli_stmt_attr_set`

Used to modify the behavior of a prepared statement

**Description**

Object oriented style (method):

```
bool mysqli_stmt::attr_set(int attr,
                          int mode);
```

Procedural style:

```
bool mysqli_stmt_attr_set(mysqli_stmt stmt,
                          int attr,
                          int mode);
```

Used to modify the behavior of a prepared statement. This function may be called multiple times to set several attributes.

#### Parameters

*stmt* Procedural style only: A statement identifier returned by `mysqli_stmt_init`.

*attr* The attribute that you want to set. It can have one of the following values:

**Table 20.11. Attribute values**

Character	Description
MYSQLI_STMT_ATTR_UPDATE_MAX_LENGTH	If set to 1, causes <code>mysqli_stmt_store_result</code> to update the metadata <code>MYSQL_FIELD-&gt;max_length</code> value.
MYSQLI_STMT_ATTR_CURSOR_TYPE	Type of cursor to open for statement when <code>mysqli_stmt_execute</code> is invoked. <i>mode</i> can be <code>MYSQLI_CURSOR_TYPE_NO_CURSOR</code> (the default) or <code>MYSQLI_CURSOR_TYPE_READ_ONLY</code> .
MYSQLI_STMT_ATTR_PREFETCH_ROWS	Number of rows to fetch from server at a time when using a cursor. <i>mode</i> can be in the range from 1 to the maximum value of unsigned long. The default is 1.

If you use the `MYSQLI_STMT_ATTR_CURSOR_TYPE` option with `MYSQLI_CURSOR_TYPE_READ_ONLY`, a cursor is opened for the statement when you invoke `mysqli_stmt_execute`. If there is already an open cursor from a previous `mysqli_stmt_execute` call, it closes the cursor before opening a new one. `mysqli_stmt_reset` also closes any open cursor before preparing the statement for re-execution. `mysqli_stmt_free_result` closes any open cursor.

If you open a cursor for a prepared statement, `mysqli_stmt_store_result` is unnecessary.

*mode* The value to assign to the attribute.

#### 20.10.2.7.4. `mysqli_stmt::bind_param`, `mysqli_stmt_bind_param`

Copyright 1997-2008 the PHP Documentation Group.

- `mysqli_stmt::bind_param`

`mysqli_stmt_bind_param`

Binds variables to a prepared statement as parameters

#### Description

Object oriented style (method):

```
bool mysqli_stmt::bind_param(string types,
                             mixed var1,
                             mixed ...);
```

Procedural style:

```
bool mysqli_stmt_bind_param(mysqli_stmt stmt,
                             string types,
                             mixed var1,
                             mixed ...);
```

Bind variables for the parameter markers in the SQL statement that was passed to `mysqli_prepare`.

**Note**

If data size of a variable exceeds max. allowed packet size (`max_allowed_packet`), you have to specify `b` in `types` and use `mysqli_stmt_send_long_data` to send the data in packets.

**Parameters**

`stmt` Procedural style only: A statement identifier returned by `mysqli_stmt_init`.

`types` A string that contains one or more characters which specify the types for the corresponding bind variables:

**Table 20.12. Type specification chars**

Character	Description
i	corresponding variable has type integer
d	corresponding variable has type double
s	corresponding variable has type string
b	corresponding variable is a blob and will be sent in packets

`var1` The number of variables and length of string `types` must match the parameters in the statement.

**Return Values**

Returns `TRUE` on success or `FALSE` on failure.

**Examples****Example 20.140. Object oriented style**

```
<?php
$mysqli = new mysqli('localhost', 'my_user', 'my_password', 'world');

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

$stmt = $mysqli->prepare("INSERT INTO CountryLanguage VALUES (?, ?, ?, ?)");
$stmt->bind_param('sssd', $code, $language, $official, $percent);

$code = 'DEU';
$language = 'Bavarian';
$official = "F";
$percent = 11.2;

/* execute prepared statement */
$stmt->execute();

printf("%d Row inserted.\n", $stmt->affected_rows);

/* close statement and connection */
$stmt->close();

/* Clean up table CountryLanguage */
$mysqli->query("DELETE FROM CountryLanguage WHERE Language='Bavarian'");
printf("%d Row deleted.\n", $mysqli->affected_rows);

/* close connection */
$mysqli->close();
?>
```

**Example 20.141. Procedural style**

```

<?php
$link = mysqli_connect('localhost', 'my_user', 'my_password', 'world');

/* check connection */
if (!$link) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

$stmt = mysqli_prepare($link, "INSERT INTO CountryLanguage VALUES (?, ?, ?, ?)");
mysqli_stmt_bind_param($stmt, 'sssd', $code, $language, $official, $percent);

$code = 'DEU';
$language = 'Bavarian';
$official = "F";
$percent = 11.2;

/* execute prepared statement */
mysqli_stmt_execute($stmt);

printf("%d Row inserted.\n", mysqli_stmt_affected_rows($stmt));

/* close statement and connection */
mysqli_stmt_close($stmt);

/* Clean up table CountryLanguage */
mysqli_query($link, "DELETE FROM CountryLanguage WHERE Language='Bavarian'");
printf("%d Row deleted.\n", mysqli_affected_rows($link));

/* close connection */
mysqli_close($link);
?>

```

The above example will output:

```

1 Row inserted.
1 Row deleted.

```

[mysqli\\_stmt\\_error](#)

#### 20.10.2.7.5. [mysqli\\_stmt::bind\\_result](#), [mysqli\\_stmt\\_bind\\_result](#)

Copyright 1997-2008 the PHP Documentation Group.

- [mysqli\\_stmt::bind\\_result](#)

[mysqli\\_stmt\\_bind\\_result](#)

Binds variables to a prepared statement for result storage

### Description

Object oriented style (method):

```

bool mysqli_stmt::bind_result(mixed var1,
                             mixed ...);

```

Procedural style:

```

bool mysqli_stmt_bind_result(mysqli_stmt stmt,
                             mixed var1,
                             mixed ...);

```

Binds columns in the result set to variables.

When `mysqli_stmt_fetch` is called to fetch data, the MySQL client/server protocol places the data for the bound columns into the specified variables `var1, ....`

### Note

Note that all columns must be bound after `mysqli_stmt_execute` and prior to calling `mysqli_stmt_fetch`. Depending on column types bound variables can silently change to the corresponding PHP type.

A column can be bound or rebound at any time, even after a result set has been partially retrieved. The new binding takes effect the next time `mysqli_stmt_fetch` is called.

### Parameters

<code>stmt</code>	Procedural style only: A statement identifier returned by <code>mysqli_stmt_init</code> .
<code>var1</code>	The variable to be bound.

### Return Values

Returns `TRUE` on success or `FALSE` on failure.

### Examples

#### Example 20.142. Object oriented style

```
<?php
$mysqli = new mysqli("localhost", "my_user", "my_password", "world");

if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

/* prepare statement */
if ($stmt = $mysqli->prepare("SELECT Code, Name FROM Country ORDER BY Name LIMIT 5")) {
    $stmt->execute();

    /* bind variables to prepared statement */
    $stmt->bind_result($col1, $col2);

    /* fetch values */
    while ($stmt->fetch()) {
        printf("%s %s\n", $col1, $col2);
    }

    /* close statement */
    $stmt->close();
}
/* close connection */
$mysqli->close();

?>
```

#### Example 20.143. Procedural style

```
<?php
$link = mysqli_connect("localhost", "my_user", "my_password", "world");

/* check connection */
if (!$link) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

/* prepare statement */
if ($stmt = mysqli_prepare($link, "SELECT Code, Name FROM Country ORDER BY Name LIMIT 5")) {
    mysqli_stmt_execute($stmt);

    /* bind variables to prepared statement */
    mysqli_stmt_bind_result($stmt, $col1, $col2);
```

```

/* fetch values */
while (mysqli_stmt_fetch($stmt)) {
    printf("%s %s\n", $col1, $col2);
}

/* close statement */
mysqli_stmt_close($stmt);
}

/* close connection */
mysqli_close($link);
?>

```

The above example will output:

```

AFG Afghanistan
ALB Albania
DZA Algeria
ASM American Samoa
AND Andorra

```

#### 20.10.2.7.6. `mysqli_stmt::close`, `mysqli_stmt_close`

Copyright 1997-2008 the PHP Documentation Group.

- `mysqli_stmt::close`  
`mysqli_stmt_close`

Closes a prepared statement

### Description

Object oriented style (method):

```
bool mysqli_stmt::close();
```

Procedural style:

```
bool mysqli_stmt_close(mysqli_stmt stmt);
```

Closes a prepared statement. `mysqli_stmt_close` also deallocates the statement handle. If the current statement has pending or unread results, this function cancels them so that the next query can be executed.

### Parameters

*stmt*

Procedural style only: A statement identifier returned by `mysqli_stmt_init`.

### Return Values

Returns `TRUE` on success or `FALSE` on failure.

### See Also

`mysqli_prepare`

## 20.10.2.7.7. `mysqli_stmt::data_seek`, `mysqli_stmt_data_seek`

Copyright 1997-2008 the PHP Documentation Group.

- `mysqli_stmt::data_seek`  
`mysqli_stmt_data_seek`

Seeks to an arbitrary row in statement result set

### Description

Object oriented style (method):

```
void mysqli_stmt::data_seek(int offset);
```

Procedural style:

```
void mysqli_stmt_data_seek(mysqli_stmt stmt,
int offset);
```

Seeks to an arbitrary result pointer in the statement result set.

`mysqli_stmt_store_result` must be called prior to `mysqli_stmt_data_seek`.

### Parameters

<code>stmt</code>	Procedural style only: A statement identifier returned by <code>mysqli_stmt_init</code> .
<code>offset</code>	Must be between zero and the total number of rows minus one (0.. <code>mysqli_stmt_num_rows - 1</code> ).

### Return Values

No value is returned.

### Examples

#### Example 20.144. Object oriented style

```
<?php
/* Open a connection */
$mysqli = new mysqli("localhost", "my_user", "my_password", "world");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

$query = "SELECT Name, CountryCode FROM City ORDER BY Name";
if ($stmt = $mysqli->prepare($query)) {

    /* execute query */
    $stmt->execute();

    /* bind result variables */
    $stmt->bind_result($name, $code);

    /* store result */
    $stmt->store_result();

    /* seek to row no. 400 */
```

```

$stmt->data_seek(399);

/* fetch values */
$stmt->fetch();

printf ("City: %s Countrycode: %s\n", $name, $code);

/* close statement */
$stmt->close();
}

/* close connection */
mysqli->close();
?>

```

### Example 20.145. Procedural style

```

<?php
/* Open a connection */
$link = mysqli_connect("localhost", "my_user", "my_password", "world");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

$query = "SELECT Name, CountryCode FROM City ORDER BY Name";
if ($stmt = mysqli_prepare($link, $query)) {

    /* execute query */
    mysqli_stmt_execute($stmt);

    /* bind result variables */
    mysqli_stmt_bind_result($stmt, $name, $code);

    /* store result */
    mysqli_stmt_store_result($stmt);

    /* seek to row no. 400 */
    mysqli_stmt_data_seek($stmt, 399);

    /* fetch values */
    mysqli_stmt_fetch($stmt);

    printf ("City: %s Countrycode: %s\n", $name, $code);

    /* close statement */
    mysqli_stmt_close($stmt);
}

/* close connection */
mysqli_close($link);
?>

```

The above example will output:

```
City: Benin City Countrycode: NGA
```

#### See Also

[mysqli\\_prepare](#)

#### 20.10.2.7.8. [mysqli\\_stmt->errno](#), [mysqli\\_stmt\\_errno](#)

Copyright 1997-2008 the PHP Documentation Group.

- [mysqli\\_stmt->errno](#)

`mysqli_stmt_errno`

Returns the error code for the most recent statement call

**Description**

Object oriented style (property):

```
mysqli_stmt {
    int errno ;
}
```

Procedural style :

```
int mysqli_stmt_errno(mysqli_stmt stmt);
```

Returns the error code for the most recently invoked statement function that can succeed or fail.

Client error message numbers are listed in the MySQL [errmsg.h](#) header file, server error message numbers are listed in [mysqld\\_error.h](#). In the MySQL source distribution you can find a complete list of error messages and error numbers in the file [Docs/mysqld\\_error.txt](#).

**Parameters**

*stmt* Procedural style only: A statement identifier returned by [mysqli\\_stmt\\_init](#).

**Return Values**

An error code value. Zero means no error occurred.

**Examples****Example 20.146. Object oriented style**

```
<?php
/* Open a connection */
$mysqli = new mysqli("localhost", "my_user", "my_password", "world");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

$mysqli->query("CREATE TABLE myCountry LIKE Country");
$mysqli->query("INSERT INTO myCountry SELECT * FROM Country");

$query = "SELECT Name, Code FROM myCountry ORDER BY Name";
if ($stmt = $mysqli->prepare($query)) {

    /* drop table */
    $mysqli->query("DROP TABLE myCountry");

    /* execute query */
    $stmt->execute();

    printf("Error: %d.\n", $stmt->errno);

    /* close statement */
    $stmt->close();
}

/* close connection */
$mysqli->close();
?>
```

**Example 20.147. Procedural style**

```

<?php
/* Open a connection */
$link = mysqli_connect("localhost", "my_user", "my_password", "world");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

mysqli_query($link, "CREATE TABLE myCountry LIKE Country");
mysqli_query($link, "INSERT INTO myCountry SELECT * FROM Country");

$query = "SELECT Name, Code FROM myCountry ORDER BY Name";
if ($stmt = mysqli_prepare($link, $query)) {

    /* drop table */
    mysqli_query($link, "DROP TABLE myCountry");

    /* execute query */
    mysqli_stmt_execute($stmt);

    printf("Error: %d.\n", mysqli_stmt_errno($stmt));

    /* close statement */
    mysqli_stmt_close($stmt);
}

/* close connection */
mysqli_close($link);
?>

```

The above example will output:

```
Error: 1146.
```

**See Also**

[mysqli\\_stmt\\_error](#)  
[mysqli\\_stmt\\_sqlstate](#)

**20.10.2.7.9. [mysqli\\_stmt->error](#), [mysqli\\_stmt\\_error](#)**

Copyright 1997-2008 the PHP Documentation Group.

- [mysqli\\_stmt->error](#)  
[mysqli\\_stmt\\_error](#)

Returns a string description for last statement error

**Description**

Object oriented style (property):

```

mysqli_stmt {
    string error ;
}

```

Procedural style:

```
string mysqli_stmt_error(mysqli_stmt stmt);
```

Returns a containing the error message for the most recently invoked statement function that can succeed or fail.

### Parameters

*stmt* Procedural style only: A statement identifier returned by `mysqli_stmt_init`.

### Return Values

A string that describes the error. An empty string if no error occurred.

### Examples

#### Example 20.148. Object oriented style

```
<?php
/* Open a connection */
$mysqli = new mysqli("localhost", "my_user", "my_password", "world");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

$mysqli->query("CREATE TABLE myCountry LIKE Country");
$mysqli->query("INSERT INTO myCountry SELECT * FROM Country");

$query = "SELECT Name, Code FROM myCountry ORDER BY Name";
if ($stmt = $mysqli->prepare($query)) {

    /* drop table */
    $mysqli->query("DROP TABLE myCountry");

    /* execute query */
    $stmt->execute();

    printf("Error: %s.\n", $stmt->error);

    /* close statement */
    $stmt->close();
}

/* close connection */
$mysqli->close();
?>
```

#### Example 20.149. Procedural style

```
<?php
/* Open a connection */
$link = mysqli_connect("localhost", "my_user", "my_password", "world");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

mysqli_query($link, "CREATE TABLE myCountry LIKE Country");
mysqli_query($link, "INSERT INTO myCountry SELECT * FROM Country");

$query = "SELECT Name, Code FROM myCountry ORDER BY Name";
if ($stmt = mysqli_prepare($link, $query)) {

    /* drop table */
    mysqli_query($link, "DROP TABLE myCountry");

    /* execute query */
    mysqli_stmt_execute($stmt);

    printf("Error: %s.\n", mysqli_stmt_error($stmt));

    /* close statement */
    mysqli_stmt_close($stmt);
}
```

```
/* close connection */
mysqli_close($link);
?>
```

The above example will output:

```
Error: Table 'world.myCountry' doesn't exist.
```

### See Also

[mysqli\\_stmt\\_errno](#)

#### 20.10.2.7.10. [mysqli\\_stmt->execute](#), [mysqli\\_stmt\\_execute](#)

Copyright 1997-2008 the PHP Documentation Group.

- [mysqli\\_stmt->execute](#)  
[mysqli\\_stmt\\_execute](#)

Executes a prepared Query

### Description

Object oriented style (method):

```
bool mysqli_stmt::execute();
```

Procedural style:

```
bool mysqli_stmt_execute(mysqli_stmt stmt);
```

Executes a query that has been previously prepared using the [mysqli\\_prepare](#) function. When executed any parameter markers which exist will automatically be replaced with the appropriate data.

If the statement is [UPDATE](#), [DELETE](#), or [INSERT](#), the total number of affected rows can be determined by using the [mysqli\\_stmt\\_affected\\_rows](#) function. Likewise, if the query yields a result set the [mysqli\\_stmt\\_fetch](#) function is used.

### Note

When using [mysqli\\_stmt\\_execute](#), the [mysqli\\_stmt\\_fetch](#) function must be used to fetch the data prior to performing any additional queries.

### Parameters

*stmt* Procedural style only: A statement identifier returned by [mysqli\\_stmt\\_init](#).

### Return Values

Returns [TRUE](#) on success or [FALSE](#) on failure.

### Examples

#### Example 20.150. Object oriented style

```

<?php
$mysqli = new mysqli("localhost", "my_user", "my_password", "world");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

$mysqli->query("CREATE TABLE myCity LIKE City");

/* Prepare an insert statement */
$query = "INSERT INTO myCity (Name, CountryCode, District) VALUES (?, ?, ?)";
$stmt = $mysqli->prepare($query);

$stmt->bind_param("sss", $val1, $val2, $val3);

$val1 = 'Stuttgart';
$val2 = 'DEU';
$val3 = 'Baden-Wuerttemberg';

/* Execute the statement */
$stmt->execute();

$val1 = 'Bordeaux';
$val2 = 'FRA';
$val3 = 'Aquitaine';

/* Execute the statement */
$stmt->execute();

/* close statement */
$stmt->close();

/* retrieve all rows from myCity */
$query = "SELECT Name, CountryCode, District FROM myCity";
if ($result = $mysqli->query($query)) {
    while ($row = $result->fetch_row()) {
        printf("%s (%s,%s)\n", $row[0], $row[1], $row[2]);
    }
    /* free result set */
    $result->close();
}

/* remove table */
$mysqli->query("DROP TABLE myCity");

/* close connection */
$mysqli->close();
?>

```

### Example 20.151. Procedural style

```

<?php
$link = mysqli_connect("localhost", "my_user", "my_password", "world");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

mysqli_query($link, "CREATE TABLE myCity LIKE City");

/* Prepare an insert statement */
$query = "INSERT INTO myCity (Name, CountryCode, District) VALUES (?, ?, ?)";
$stmt = mysqli_prepare($link, $query);

mysqli_stmt_bind_param($stmt, "sss", $val1, $val2, $val3);

$val1 = 'Stuttgart';
$val2 = 'DEU';
$val3 = 'Baden-Wuerttemberg';

/* Execute the statement */
mysqli_stmt_execute($stmt);

$val1 = 'Bordeaux';
$val2 = 'FRA';
$val3 = 'Aquitaine';

/* Execute the statement */
mysqli_stmt_execute($stmt);

/* close statement */
mysqli_stmt_close($stmt);

```

```

/* retrieve all rows from myCity */
$query = "SELECT Name, CountryCode, District FROM myCity";
if ($result = mysqli_query($link, $query)) {
    while ($row = mysqli_fetch_row($result)) {
        printf("%s (%s,%s)\n", $row[0], $row[1], $row[2]);
    }
    /* free result set */
    mysqli_free_result($result);
}

/* remove table */
mysqli_query($link, "DROP TABLE myCity");

/* close connection */
mysqli_close($link);
?>

```

The above example will output:

```

Stuttgart (DEU,Baden-Wuerttemberg)
Bordeaux (FRA,Aquitaine)

```

#### 20.10.2.7.11. [mysqli\\_stmt::fetch](#), [mysqli\\_stmt\\_fetch](#)

Copyright 1997-2008 the PHP Documentation Group.

- [mysqli\\_stmt::fetch](#)  
[mysqli\\_stmt\\_fetch](#)

Fetch results from a prepared statement into the bound variables

### Description

Object oriented style (method):

```
bool mysqli_stmt::fetch();
```

Procedural style:

```
bool mysqli_stmt_fetch(mysqli_stmt stmt);
```

Fetch the result from a prepared statement into the variables bound by [mysqli\\_stmt\\_bind\\_result](#).

#### Note

Note that all columns must be bound by the application before calling [mysqli\\_stmt\\_fetch](#).

#### Note

Data are transferred unbuffered without calling [mysqli\\_stmt\\_store\\_result](#) which can decrease performance (but reduces memory cost).

### Parameters

*stmt*

Procedural style only: A statement identifier returned by [mysqli\\_stmt\\_init](#).

**Return Values****Table 20.13. Return Values**

Value	Description
TRUE	Success. Data has been fetched
FALSE	Error occurred
NULL	No more rows/data exists or data truncation occurred

**Examples****Example 20.152. Object oriented style**

```

<?php
$mysqli = new mysqli("localhost", "my_user", "my_password", "world");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

$query = "SELECT Name, CountryCode FROM City ORDER by ID DESC LIMIT 150,5";

if ($stmt = $mysqli->prepare($query)) {

    /* execute statement */
    $stmt->execute();

    /* bind result variables */
    $stmt->bind_result($name, $code);

    /* fetch values */
    while ($stmt->fetch()) {
        printf ("%s (%s)\n", $name, $code);
    }

    /* close statement */
    $stmt->close();
}

/* close connection */
$mysqli->close();
?>

```

**Example 20.153. Procedural style**

```

<?php
$link = mysqli_connect("localhost", "my_user", "my_password", "world");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

$query = "SELECT Name, CountryCode FROM City ORDER by ID DESC LIMIT 150,5";

if ($stmt = mysqli_prepare($link, $query)) {

    /* execute statement */
    mysqli_stmt_execute($stmt);

    /* bind result variables */
    mysqli_stmt_bind_result($stmt, $name, $code);

    /* fetch values */
    while (mysqli_stmt_fetch($stmt)) {
        printf ("%s (%s)\n", $name, $code);
    }

    /* close statement */
    mysqli_stmt_close($stmt);
}

/* close connection */
mysqli_close($link);

```

```
?>
```

The above example will output:

```
Rockford (USA)
Tallahassee (USA)
Salinas (USA)
Santa Clarita (USA)
Springfield (USA)
```

Copyright 1997-2008 the PHP Documentation Group.

- `stmt::free_result`  
`mysqli_stmt_free_result`

Frees stored result memory for the given statement handle

### Description

Object oriented style (method):

```
void mysqli_stmt::free_result();
```

Procedural style:

```
void mysqli_stmt_free_result(mysqli_stmt stmt);
```

Frees the result memory associated with the statement, which was allocated by `mysqli_stmt_store_result`.

#### Parameters

`stmt` Procedural style only: A statement identifier returned by `mysqli_stmt_init`.

#### Return Values

No value is returned.

#### See Also

`mysqli_stmt_store_result`

### 20.10.2.7.16. `mysqli_stmt::num_rows`, `mysqli_stmt_num_rows`

Copyright 1997-2008 the PHP Documentation Group.

- `mysqli_stmt::num_rows`

`mysqli_stmt_num_rows`

Return the number of rows in statements result set

## Description

Object oriented style (property):

```
mysqli_stmt {
    int num_rows ;
}
```

Procedural style :

```
int mysqli_stmt_num_rows(mysqli_stmt stmt);
```

Returns the number of rows in the result set. The use of `mysqli_stmt_num_rows` depends on whether or not you used `mysqli_stmt_store_result` to buffer the entire result set in the statement handle.

If you use `mysqli_stmt_store_result`, `mysqli_stmt_num_rows` may be called immediately.

## Parameters

*stmt* Procedural style only: A statement identifier returned by `mysqli_stmt_init`.

## Return Values

An integer representing the number of rows in result set.

## Examples

### Example 20.154. Object oriented style

```
<?php
/* Open a connection */
$mysqli = new mysqli("localhost", "my_user", "my_password", "world");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

$query = "SELECT Name, CountryCode FROM City ORDER BY Name LIMIT 20";
if ($stmt = $mysqli->prepare($query)) {

    /* execute query */
    $stmt->execute();

    /* store result */
    $stmt->store_result();

    printf("Number of rows: %d.\n", $stmt->num_rows);

    /* close statement */
    $stmt->close();
}

/* close connection */
$mysqli->close();
?>
```

### Example 20.155. Procedural style

```

<?php
/* Open a connection */
$link = mysqli_connect("localhost", "my_user", "my_password", "world");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

$query = "SELECT Name, CountryCode FROM City ORDER BY Name LIMIT 20";
if ($stmt = mysqli_prepare($link, $query)) {

    /* execute query */
    mysqli_stmt_execute($stmt);

    /* store result */
    mysqli_stmt_store_result($stmt);

    printf("Number of rows: %d.\n", mysqli_stmt_num_rows($stmt));

    /* close statement */
    mysqli_stmt_close($stmt);
}

/* close connection */
mysqli_close($link);
?>

```

The above example will output:

```
Number of rows: 20.
```

#### 20.10.2.7.17. [mysqli\\_stmt->param\\_count](#), [mysqli\\_stmt\\_param\\_count](#)

Copyright 1997-2008 the PHP Documentation Group.

- [mysqli\\_stmt->param\\_count](#)
- [mysqli\\_stmt\\_param\\_count](#)

Returns the number of parameter for the given statement

#### Description

Object oriented style (property):

```

mysqli_stmt {
    int param_count ;
}

```

Procedural style:

```
int mysqli_stmt_param_count(mysqli_stmt stmt);
```

Returns the number of parameter markers present in the prepared statement.

#### Parameters

*stmt*Procedural style only: A statement identifier returned by `mysqli_stmt_init`.**Return Values**

Returns an integer representing the number of parameters.

**Examples****Example 20.156. Object oriented style**

```

<?php
$mysqli = new mysqli("localhost", "my_user", "my_password", "world");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

if ($stmt = $mysqli->prepare("SELECT Name FROM Country WHERE Name=? OR Code=?")) {

    $marker = $stmt->param_count;
    printf("Statement has %d markers.\n", $marker);

    /* close statement */
    $stmt->close();
}

/* close connection */
$mysqli->close();
?>

```

**Example 20.157. Procedural style**

```

<?php
$link = mysqli_connect("localhost", "my_user", "my_password", "world");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

if ($stmt = mysqli_prepare($link, "SELECT Name FROM Country WHERE Name=? OR Code=?")) {

    $marker = mysqli_stmt_param_count($stmt);
    printf("Statement has %d markers.\n", $marker);

    /* close statement */
    mysqli_stmt_close($stmt);
}

/* close connection */
mysqli_close($link);
?>

```

The above example will output:

Statement has 2 markers.

**See Also**[mysqli\\_prepare](#)**20.10.2.7.18. [mysqli\\_stmt::prepare](#), [mysqli\\_stmt\\_prepare](#)**

Copyright 1997-2008 the PHP Documentation Group.

- `mysqli_stmt::prepare`  
`mysqli_stmt_prepare`

Prepare a SQL statement for execution

## Description

Object oriented style (method)

```
mixed mysqli_stmt::prepare(string query);
```

Procedure style:

```
bool mysqli_stmt_prepare(mysqli_stmt stmt,
                        string query);
```

Prepares the SQL query pointed to by the null-terminated string query.

The parameter markers must be bound to application variables using `mysqli_stmt_bind_param` and/or `mysqli_stmt_bind_result` before executing the statement or fetching rows.

## Parameters

<i>stmt</i>	Procedural style only: A statement identifier returned by <code>mysqli_stmt_init</code> .
<i>query</i>	The query, as a string. It must consist of a single SQL statement.  You can include one or more parameter markers in the SQL statement by embedding question mark (?) characters at the appropriate positions.

### Note

You should not add a terminating semicolon or `\g` to the statement.

### Note

The markers are legal only in certain places in SQL statements. For example, they are allowed in the VALUES() list of an INSERT statement (to specify column values for a row), or in a comparison with a column in a WHERE clause to specify a comparison value.

However, they are not allowed for identifiers (such as table or column names), in the select list that names the columns to be returned by a SELECT statement), or to specify both operands of a binary operator such as the = equal sign. The latter restriction is necessary because it would be impossible to determine the parameter type. In general, parameters are legal only in Data Manipulation Language (DML) statements, and not in Data Definition Language (DDL) statements.

## Return Values

Returns `TRUE` on success or `FALSE` on failure.

## Examples

### Example 20.158. Object oriented style

```
<?php
$stmt = new mysqli("localhost", "my_user", "my_password", "world");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

$stmt->prepare("SELECT * FROM city WHERE city = ?");
```

```

/* create a prepared statement */
$stmt = $mysqli->stmt_init();
if ($stmt->prepare("SELECT District FROM City WHERE Name=?")) {

    /* bind parameters for markers */
    $stmt->bind_param("s", $city);

    /* execute query */
    $stmt->execute();

    /* bind result variables */
    $stmt->bind_result($district);

    /* fetch value */
    $stmt->fetch();

    printf("%s is in district %s\n", $city, $district);

    /* close statement */
    $stmt->close();
}

/* close connection */
$mysqli->close();
?>

```

### Example 20.159. Procedural style

```

<?php
$link = mysqli_connect("localhost", "my_user", "my_password", "world");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

$city = "Amersfoort";

/* create a prepared statement */
$stmt = mysqli_stmt_init($link);
if (mysqli_stmt_prepare($stmt, 'SELECT District FROM City WHERE Name=?')) {

    /* bind parameters for markers */
    mysqli_stmt_bind_param($stmt, "s", $city);

    /* execute query */
    mysqli_stmt_execute($stmt);

    /* bind result variables */
    mysqli_stmt_bind_result($stmt, $district);

    /* fetch value */
    mysqli_stmt_fetch($stmt);

    printf("%s is in district %s\n", $city, $district);

    /* close statement */
    mysqli_stmt_close($stmt);
}

/* close connection */
mysqli_close($link);
?>

```

The above example will output:

```
Amersfoort is in district Utrecht
```

### See Also

[mysqli\\_stmt\\_init](#), [mysqli\\_stmt\\_execute](#), [mysqli\\_stmt\\_fetch](#), [mysqli\\_stmt\\_bind\\_param](#), [mysqli\\_stmt\\_bind\\_result](#) [mysqli\\_stmt\\_close](#).

### 20.10.2.7.19. `mysqli_stmt::reset`, `mysqli_stmt_reset`

Copyright 1997-2008 the PHP Documentation Group.

- `mysqli_stmt::reset`  
`mysqli_stmt_reset`  
Resets a prepared statement

#### Description

Object oriented style (method):

```
bool mysqli_stmt::reset();
```

Procedural style:

```
bool mysqli_stmt_reset(mysqli_stmt stmt);
```

Resets a prepared statement on client and server to state after prepare.

For now this is mainly used to reset data sent with `mysqli_stmt_send_long_data`.

To prepare a statement with another query use function `mysqli_stmt_prepare`.

#### Parameters

*stmt* Procedural style only: A statement identifier returned by `mysqli_stmt_init`.

#### Return Values

Returns `TRUE` on success or `FALSE` on failure.

#### See Also

`mysqli_prepare`

### 20.10.2.7.20. `mysqli_stmt::result_metadata`, `mysqli_stmt_result_metadata`

Copyright 1997-2008 the PHP Documentation Group.

- `mysqli_stmt::result_metadata`  
`mysqli_stmt_result_metadata`  
Returns result set metadata from a prepared statement

#### Description

Object oriented style (method):

```
mysqli_result mysqli_stmt::result_metadata();
```

Procedural style:

```
mysqli_result mysqli_stmt_result_metadata(mysqli_stmt stmt);
```

If a statement passed to `mysqli_prepare` is one that produces a result set, `mysqli_stmt_result_metadata` returns the result object that can be used to process the meta information such as total number of fields and individual field information.

#### ■ Note

This result set pointer can be passed as an argument to any of the field-based functions that process result set metadata, such as:

- `mysqli_num_fields`
- `mysqli_fetch_field`
- `mysqli_fetch_field_direct`
- `mysqli_fetch_fields`
- `mysqli_field_count`
- `mysqli_field_seek`
- `mysqli_field_tell`
- `mysqli_free_result`

The result set structure should be freed when you are done with it, which you can do by passing it to `mysqli_free_result`

### Note

The result set returned by `mysqli_stmt_result_metadata` contains only metadata. It does not contain any row results. The rows are obtained by using the statement handle with `mysqli_stmt_fetch`.

### Parameters

*stmt* Procedural style only: A statement identifier returned by `mysqli_stmt_init`.

### Return Values

Returns a result object or `FALSE` if an error occurred.

### Examples

#### Example 20.160. Object oriented style

```
<?php
mysqli = new mysqli("localhost", "my_user", "my_password", "test");

mysqli->query("DROP TABLE IF EXISTS friends");
mysqli->query("CREATE TABLE friends (id int, name varchar(20))");

mysqli->query("INSERT INTO friends VALUES (1,'Hartmut'), (2, 'Ulf')");

$stmt = mysqli->prepare("SELECT id,name FROM friends");
$stmt->execute();

/* get resultset for metadata */
$result = $stmt->result_metadata();

/* retrieve field information from metadata result set */
$field = $result->fetch_field();

printf("Fieldname: %s\n", $field->name);

/* close resultset */
$result->close();

/* close connection */
mysqli->close();
?>
```

#### Example 20.161. Procedural style

```

<?php
$link = mysqli_connect("localhost", "my_user", "my_password", "test");

mysqli_query($link, "DROP TABLE IF EXISTS friends");
mysqli_query($link, "CREATE TABLE friends (id int, name varchar(20))");

mysqli_query($link, "INSERT INTO friends VALUES (1, 'Hartmut'), (2, 'Ulf')");

$stmt = mysqli_prepare($link, "SELECT id, name FROM friends");
mysqli_stmt_execute($stmt);

/* get resultset for metadata */
$result = mysqli_stmt_result_metadata($stmt);

/* retrieve field information from metadata result set */
$field = mysqli_fetch_field($result);

printf("Fieldname: %s\n", $field->name);

/* close resultset */
mysqli_free_result($result);

/* close connection */
mysqli_close($link);
?>

```

**See Also**

[mysqli\\_prepare](#)  
[mysqli\\_free\\_result](#)

**20.10.2.7.21. [mysqli\\_stmt::send\\_long\\_data](#), [mysqli\\_stmt\\_send\\_long\\_data](#)**

Copyright 1997-2008 the PHP Documentation Group.

- [mysqli\\_stmt::send\\_long\\_data](#)  
[mysqli\\_stmt\\_send\\_long\\_data](#)

Send data in blocks

**Description**

Object oriented style (method)

```
bool mysqli_stmt::send_long_data(int param_nr,
                                string data);
```

Procedural style:

```
bool mysqli_stmt_send_long_data(mysqli_stmt stmt,
                                int param_nr,
                                string data);
```

Allows to send parameter data to the server in pieces (or chunks), e.g. if the size of a blob exceeds the size of [max\\_allowed\\_packet](#). This function can be called multiple times to send the parts of a character or binary data value for a column, which must be one of the TEXT or BLOB datatypes.

**Parameters**

<i>stmt</i>	Procedural style only: A statement identifier returned by <a href="#">mysqli_stmt_init</a> .
<i>param_nr</i>	Indicates which parameter to associate the data with. Parameters are numbered beginning with 0.
<i>data</i>	A string containing data to be sent.

**Return Values**

Returns `TRUE` on success or `FALSE` on failure.

### Examples

#### Example 20.162. Object oriented style

```
<?php
$stmt = $mysqli->prepare("INSERT INTO messages (message) VALUES (?");
>null = NULL;
$stmt->bind_param("b", $null);
$fp = fopen("messages.txt", "r");
while (!feof($fp)) {
    $stmt->send_long_data(0, fread($fp, 8192));
}
fclose($fp);
$stmt->execute();
?>
```

#### 20.10.2.7.22. `mysqli_stmt::sqlstate`, `mysqli_stmt_sqlstate`

Copyright 1997-2008 the PHP Documentation Group.

- `mysqli_stmt::sqlstate`  
`mysqli_stmt_sqlstate`

Returns SQLSTATE error from previous statement operation

### Description

Object oriented style (property):

```
mysqli_stmt {
    string sqlstate ;
}
```

Procedural style:

```
string mysqli_stmt_sqlstate(mysqli_stmt stmt);
```

Returns a string containing the SQLSTATE error code for the most recently invoked prepared statement function that can succeed or fail. The error code consists of five characters. '00000' means no error. The values are specified by ANSI SQL and ODBC. For a list of possible values, see <http://dev.mysql.com/doc/mysql/en/error-handling.html>.

### Parameters

*stmt*

Procedural style only: A statement identifier returned by `mysqli_stmt_init`.

### Return Values

Returns a string containing the SQLSTATE error code for the last error. The error code consists of five characters. '00000' means no error.

### Notes

#### ■ Note

Note that not all MySQL errors are yet mapped to SQLSTATE's. The value `HY000` (general error) is used for un-mapped errors.

## Examples

### Example 20.163. Object oriented style

```
<?php
/* Open a connection */
$mysqli = new mysqli("localhost", "my_user", "my_password", "world");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

$mysqli->query("CREATE TABLE myCountry LIKE Country");
$mysqli->query("INSERT INTO myCountry SELECT * FROM Country");

$query = "SELECT Name, Code FROM myCountry ORDER BY Name";
if ($stmt = $mysqli->prepare($query)) {

    /* drop table */
    $mysqli->query("DROP TABLE myCountry");

    /* execute query */
    $stmt->execute();

    printf("Error: %s.\n", $stmt->sqlstate);

    /* close statement */
    $stmt->close();
}

/* close connection */
$mysqli->close();
?>
```

### Example 20.164. Procedural style

```
<?php
/* Open a connection */
$link = mysqli_connect("localhost", "my_user", "my_password", "world");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

mysqli_query($link, "CREATE TABLE myCountry LIKE Country");
mysqli_query($link, "INSERT INTO myCountry SELECT * FROM Country");

$query = "SELECT Name, Code FROM myCountry ORDER BY Name";
if ($stmt = mysqli_prepare($link, $query)) {

    /* drop table */
    mysqli_query($link, "DROP TABLE myCountry");

    /* execute query */
    mysqli_stmt_execute($stmt);

    printf("Error: %s.\n", mysqli_stmt_sqlstate($stmt));

    /* close statement */
    mysqli_stmt_close($stmt);
}

/* close connection */
mysqli_close($link);
?>
```

The above example will output:

```
Error: 42S02.
```

### See Also

`mysqli_stmt_errno`  
`mysqli_stmt_error`

### 20.10.2.7.23. `mysqli_stmt::store_result`, `mysqli_stmt_store_result`

Copyright 1997-2008 the PHP Documentation Group.

- `mysqli_stmt::store_result`

`mysqli_stmt_store_result`

Transfers a result set from a prepared statement

### Description

Object oriented style (method):

```
bool mysqli_stmt::store_result();
```

Procedural style:

```
bool mysqli_stmt_store_result(mysqli_stmt $stmt);
```

You must call `mysqli_stmt_store_result` for every query that successfully produces a result set (`SELECT`, `SHOW`, `DESCRIBE`, `EXPLAIN`), and only if you want to buffer the complete result set by the client, so that the subsequent `mysqli_stmt_fetch` call returns buffered data.

### Note

It is unnecessary to call `mysqli_stmt_store_result` for other queries, but if you do, it will not harm or cause any notable performance in all cases. You can detect whether the query produced a result set by checking if `mysqli_stmt_result_metadata` returns `NULL`.

### Parameters

*stmt*

Procedural style only: A statement identifier returned by `mysqli_stmt_init`.

### Return Values

Returns `TRUE` on success or `FALSE` on failure.

### Examples

#### Example 20.165. Object oriented style

```
<?php
/* Open a connection */
$mysqli = new mysqli("localhost", "my_user", "my_password", "world");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

$query = "SELECT Name, CountryCode FROM City ORDER BY Name LIMIT 20";
if ($stmt = $mysqli->prepare($query)) {
```

```

/* execute query */
$stmt->execute();

/* store result */
$stmt->store_result();

printf("Number of rows: %d.\n", $stmt->num_rows);

/* free result */
$stmt->free_result();

/* close statement */
$stmt->close();
}

/* close connection */
mysqli->close();
?>

```

### Example 20.166. Procedural style

```

<?php
/* Open a connection */
$link = mysqli_connect("localhost", "my_user", "my_password", "world");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

$query = "SELECT Name, CountryCode FROM City ORDER BY Name LIMIT 20";
if ($stmt = mysqli_prepare($link, $query)) {

    /* execute query */
    mysqli_stmt_execute($stmt);

    /* store result */
    mysqli_stmt_store_result($stmt);

    printf("Number of rows: %d.\n", mysqli_stmt_num_rows($stmt));

    /* free result */
    mysqli_stmt_free_result($stmt);

    /* close statement */
    mysqli_stmt_close($stmt);
}

/* close connection */
mysqli_close($link);
?>

```

The above example will output:

```
Number of rows: 20.
```

Get current field offset of a result pointer

#### Description

Object oriented style (property):

```

mysqli_result {
    int current_field ;
}

```

}

Procedural style:

```
int mysqli_field_tell(mysqli_result result);
```

Returns the position of the field cursor used for the last `mysqli_fetch_field` call. This value can be used as an argument to `mysqli_field_seek`.

### Parameters

`result` Procedural style only: A result set identifier returned by `mysqli_query`, `mysqli_store_result` or `mysqli_use_result`.

### Return Values

Returns current offset of field cursor.

### Examples

#### Example 20.167. Object oriented style

```
<?php
$mysqli = new mysqli("localhost", "my_user", "my_password", "world");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

$query = "SELECT Name, SurfaceArea from Country ORDER BY Code LIMIT 5";
if ($result = $mysqli->query($query)) {

    /* Get field information for all columns */
    while ($finfo = $result->fetch_field()) {

        /* get fieldpointer offset */
        $currentfield = $result->current_field;

        printf("Column %d:\n", $currentfield);
        printf("Name:      %s\n", $finfo->name);
        printf("Table:     %s\n", $finfo->table);
        printf("max. Len:  %d\n", $finfo->max_length);
        printf("Flags:    %d\n", $finfo->flags);
        printf("Type:     %d\n\n", $finfo->type);
    }
    $result->close();
}

/* close connection */
$mysqli->close();
?>
```

#### Example 20.168. Procedural style

```
<?php
$link = mysqli_connect("localhost", "my_user", "my_password", "world");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

$query = "SELECT Name, SurfaceArea from Country ORDER BY Code LIMIT 5";
if ($result = mysqli_query($link, $query)) {

    /* Get field information for all fields */
    while ($finfo = mysqli_fetch_field($result)) {

        /* get fieldpointer offset */
```

```

    $currentfield = mysqli_field_tell($result);

    printf("Column %d:\n", $currentfield);
    printf("Name:      %s\n", $finfo->name);
    printf("Table:     %s\n", $finfo->table);
    printf("max. Len:  %d\n", $finfo->max_length);
    printf("Flags:    %d\n", $finfo->flags);
    printf("Type:     %d\n\n", $finfo->type);
}
mysqli_free_result($result);
}

/* close connection */
mysqli_close($link);
?>

```

The above example will output:

```

Column 1:
Name:      Name
Table:     Country
max. Len:  11
Flags:     1
Type:      254

Column 2:
Name:      SurfaceArea
Table:     Country
max. Len:  10
Flags:     32769
Type:      4

```

#### See Also

[mysqli\\_fetch\\_field](#)  
[mysqli\\_field\\_seek](#)

### 20.10.2.8.2. [mysqli\\_result::data\\_seek](#), [mysqli\\_data\\_seek](#)

Copyright 1997-2008 the PHP Documentation Group.

- [mysqli\\_result::data\\_seek](#)

[mysqli\\_data\\_seek](#)

Adjusts the result pointer to an arbitrary row in the result

#### Description

Object oriented style (method):

```
bool mysqli_result::data_seek(int offset);
```

Procedural style:

```
bool mysqli_data_seek(mysqli_result result,
                      int offset);
```

The [mysqli\\_data\\_seek](#) function seeks to an arbitrary result pointer specified by the *offset* in the result set.

#### Parameters

*result* Procedural style only: A result set identifier returned by [mysqli\\_query](#), [mysqli\\_store\\_result](#) or [mysqli\\_use\\_result](#).

*offset*

The field offset. Must be between zero and the total number of rows minus one (0..*mysqli\_num\_rows* - 1).

**Return Values**

Returns **TRUE** on success or **FALSE** on failure.

**Notes****Note**

This function can only be used with buffered results attained from the use of the *mysqli\_store\_result* or *mysqli\_query* functions.

**Examples****Example 20.169. Object oriented style**

```
<?php
/* Open a connection */
$mysqli = new mysqli("localhost", "my_user", "my_password", "world");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

$query = "SELECT Name, CountryCode FROM City ORDER BY Name";
if ($result = $mysqli->query($query)) {

    /* seek to row no. 400 */
    $result->data_seek(399);

    /* fetch row */
    $row = $result->fetch_row();

    printf("City: %s Countrycode: %s\n", $row[0], $row[1]);

    /* free result set*/
    $result->close();
}

/* close connection */
$mysqli->close();
?>
```

**Example 20.170. Procedural style**

```
<?php
/* Open a connection */
$link = mysqli_connect("localhost", "my_user", "my_password", "world");

/* check connection */
if (!$link) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

$query = "SELECT Name, CountryCode FROM City ORDER BY Name";
if ($result = mysqli_query($link, $query)) {

    /* seek to row no. 400 */
    mysqli_data_seek($result, 399);

    /* fetch row */
    $row = mysqli_fetch_row($result);

    printf("City: %s Countrycode: %s\n", $row[0], $row[1]);

    /* free result set*/
    mysqli_free_result($result);
}

/* close connection */
mysqli_close($link);
?>
```

The above example will output:

```
City: Benin City Countrycode: NGA
```

### 20.10.2.8.3. `mysqli_result::fetch_all`, `mysqli_fetch_all`

Copyright 1997-2008 the PHP Documentation Group.

- `mysqli_result::fetch_all`  
`mysqli_fetch_all`

Fetches all result rows as an associative array, a numeric array, or both

#### Description

Object oriented style (method):

```
mixed mysqli_result::fetch_all(int resulttype);
```

Procedural style:

```
mixed mysqli_fetch_all(mysqli_result result,  
int resulttype);
```

Available only with `mysqlnd`.

#### Parameters

*result*

Procedural style only: A result set identifier returned by `mysqli_query`, `mysqli_store_result` or `mysqli_use_result`.

*resulttype*

This optional parameter is a constant indicating what type of array should be produced from the current row data. The possible values for this parameter are the constants `MYSQLI_ASSOC`, `MYSQLI_NUM`, or `MYSQLI_BOTH`. Defaults to `MYSQLI_NUM`.

#### Return Values

Returns an array of associative or numeric arrays holding result rows.

#### See Also

```
mysqli_fetch_array  
mysqli_query
```

#### 20.10.2.8.4. `mysqli_result::fetch_array`, `mysqli_fetch_array`

Copyright 1997-2008 the PHP Documentation Group.

- `mysqli_result::fetch_array`

`mysqli_fetch_array`

Fetch a result row as an associative, a numeric array, or both

##### Description

Object oriented style (method):

```
mixed mysqli_result::fetch_array(int resulttype);
```

Procedural style:

```
mixed mysqli_fetch_array(mysqli_result result,
                        int resulttype);
```

Returns an array that corresponds to the fetched row or `NULL` if there are no more rows for the resultset represented by the `result` parameter.

`mysqli_fetch_array` is an extended version of the `mysqli_fetch_row` function. In addition to storing the data in the numeric indices of the result array, the `mysqli_fetch_array` function can also store the data in associative indices, using the field names of the result set as keys.

##### Note

Field names returned by this function are *case-sensitive*.

##### Note

This function sets `NULL` fields to the PHP `NULL` value.

If two or more columns of the result have the same field names, the last column will take precedence and overwrite the earlier data. In order to access multiple columns with the same name, the numerically indexed version of the row must be used.

##### Parameters

`result` Procedural style only: A result set identifier returned by `mysqli_query`, `mysqli_store_result` or `mysqli_use_result`.

`resulttype` This optional parameter is a constant indicating what type of array should be produced from the current row data. The possible values for this parameter are the constants `MYSQLI_ASSOC`, `MYSQLI_NUM`, or `MYSQLI_BOTH`. Defaults to `MYSQLI_BOTH`.

By using the `MYSQLI_ASSOC` constant this function will behave identically to the `mysqli_fetch_assoc`, while `MYSQLI_NUM` will behave identically to the `mysqli_fetch_row` function. The final option `MYSQLI_BOTH` will create a single array with the attributes of both.

##### Return Values

Returns an array of strings that corresponds to the fetched row or `NULL` if there are no more rows in resultset.

##### Examples

#### Example 20.171. Object oriented style

```
<?php
$db = new mysqli("localhost", "my_user", "my_password", "world");
/* check connection */
```

```

if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

$query = "SELECT Name, CountryCode FROM City ORDER by ID LIMIT 3";
$result = $mysqli->query($query);

/* numeric array */
$row = $result->fetch_array(MYSQLI_NUM);
printf ("%s (%s)\n", $row[0], $row[1]);

/* associative array */
$row = $result->fetch_array(MYSQLI_ASSOC);
printf ("%s (%s)\n", $row["Name"], $row["CountryCode"]);

/* associative and numeric array */
$row = $result->fetch_array(MYSQLI_BOTH);
printf ("%s (%s)\n", $row[0], $row["CountryCode"]);

/* free result set */
$result->close();

/* close connection */
$mysqli->close();
?>

```

### Example 20.172. Procedural style

```

<?php
$link = mysqli_connect("localhost", "my_user", "my_password", "world");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

$query = "SELECT Name, CountryCode FROM City ORDER by ID LIMIT 3";
$result = mysqli_query($link, $query);

/* numeric array */
$row = mysqli_fetch_array($result, MYSQLI_NUM);
printf ("%s (%s)\n", $row[0], $row[1]);

/* associative array */
$row = mysqli_fetch_array($result, MYSQLI_ASSOC);
printf ("%s (%s)\n", $row["Name"], $row["CountryCode"]);

/* associative and numeric array */
$row = mysqli_fetch_array($result, MYSQLI_BOTH);
printf ("%s (%s)\n", $row[0], $row["CountryCode"]);

/* free result set */
mysqli_free_result($result);

/* close connection */
mysqli_close($link);
?>

```

The above example will output:

```

Kabul (AFG)
Qandahar (AFG)
Herat (AFG)

```

`mysqli_data_seek`

### 20.10.2.8.5. `mysqli_result::fetch_assoc`, `mysqli_fetch_assoc`

Copyright 1997-2008 the PHP Documentation Group.

- `mysqli_result::fetch_assoc`  
`mysqli_fetch_assoc`  
Fetch a result row as an associative array

#### Description

Object oriented style (method):

```
array mysqli_result::fetch_assoc();
```

Procedural style:

```
array mysqli_fetch_assoc(mysqli_result result);
```

Returns an associative array that corresponds to the fetched row or `NULL` if there are no more rows.

#### Note

Field names returned by this function are *case-sensitive*.

#### Note

This function sets `NULL` fields to the PHP `NULL` value.

#### Parameters

*result* Procedural style only: A result set identifier returned by `mysqli_query`, `mysqli_store_result` or `mysqli_use_result`.

#### Return Values

Returns an associative array of strings representing the fetched row in the result set, where each key in the array represents the name of one of the result set's columns or `NULL` if there are no more rows in resultset.

If two or more columns of the result have the same field names, the last column will take precedence. To access the other column(s) of the same name, you either need to access the result with numeric indices by using `mysqli_fetch_row` or add alias names.

#### Examples

##### Example 20.173. Object oriented style

```
<?php
mysqli = new mysqli("localhost", "my_user", "my_password", "world");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

$query = "SELECT Name, CountryCode FROM City ORDER by ID DESC LIMIT 50,5";
if ($result = $mysqli->query($query)) {
    /* fetch associative array */
    while ($row = $result->fetch_assoc()) {
        printf ("%s (%s)\n", $row["Name"], $row["CountryCode"]);
    }

    /* free result set */
    $result->close();
}
```

```

}
/* close connection */
$mysqli->close();
?>

```

### Example 20.174. Procedural style

```

<?php
$link = mysqli_connect("localhost", "my_user", "my_password", "world");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

$query = "SELECT Name, CountryCode FROM City ORDER by ID DESC LIMIT 50,5";

if ($result = mysqli_query($link, $query)) {

    /* fetch associative array */
    while ($row = mysqli_fetch_assoc($result)) {
        printf ("%s (%s)\n", $row["Name"], $row["CountryCode"]);
    }

    /* free result set */
    mysqli_free_result($result);
}

/* close connection */
mysqli_close($link);
?>

```

The above example will output:

```

Pueblo (USA)
Arvada (USA)
Cape Coral (USA)
Green Bay (USA)
Santa Clara (USA)

```

#### 20.10.2.8.6. [mysqli\\_result::fetch\\_field\\_direct](#), [mysqli\\_fetch\\_field\\_direct](#)

Copyright 1997-2008 the PHP Documentation Group.

- [mysqli\\_result::fetch\\_field\\_direct](#)  
[mysqli\\_fetch\\_field\\_direct](#)

Fetch meta-data for a single field

#### Description

Object oriented style (method):

```
object mysqli_result::fetch_field_direct(int fieldnr);
```

Procedural style:

```
object mysqli_fetch_field_direct(mysqli_result result,
                                int fieldnr);
```

Returns an object which contains field definition informations from specified resultset.

#### Parameters

*result* Procedural style only: A result set identifier returned by `mysqli_query`, `mysqli_store_result` or `mysqli_use_result`.

*fieldnr* The field number. This value must be in the range from 0 to `number of fields - 1`.

#### Return Values

Returns an object which contains field definition information or `FALSE` if no field information for specified `fieldnr` is available.

**Table 20.14. Object attributes**

Attribute	Description
name	The name of the column
orgname	Original column name if an alias was specified
table	The name of the table this field belongs to (if not calculated)
orgtable	Original table name if an alias was specified
def	The default value for this field, represented as a string
max_length	The maximum width of the field for the result set.
length	The width of the field, as specified in the tabl definition.
charsetnr	The character set number for the field.
flags	An integer representing the bit-flags for the field.
type	The data type used for this field
decimals	The number of decimals used (for integer fields)

#### Examples

##### Example 20.175. Object oriented style

```
<?php
$mysqli = new mysqli("localhost", "my_user", "my_password", "world");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

$query = "SELECT Name, SurfaceArea from Country ORDER BY Name LIMIT 5";
if ($result = $mysqli->query($query)) {
    /* Get field information for column 'SurfaceArea' */
    $finfo = $result->fetch_field_direct(1);

    printf("Name:      %s\n", $finfo->name);
    printf("Table:     %s\n", $finfo->table);
    printf("max. Len:  %d\n", $finfo->max_length);
    printf("Flags:    %d\n", $finfo->flags);
    printf("Type:     %d\n", $finfo->type);

    $result->close();
}

/* close connection */
```

```
$mysqli->close();
?>
```

### Example 20.176. Procedural style

```
<?php
$link = mysqli_connect("localhost", "my_user", "my_password", "world");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

$query = "SELECT Name, SurfaceArea from Country ORDER BY Name LIMIT 5";

if ($result = mysqli_query($link, $query)) {

    /* Get field information for column 'SurfaceArea' */
    $finfo = mysqli_fetch_field_direct($result, 1);

    printf("Name:      %s\n", $finfo->name);
    printf("Table:     %s\n", $finfo->table);
    printf("max. Len:  %d\n", $finfo->max_length);
    printf("Flags:    %d\n", $finfo->flags);
    printf("Type:     %d\n", $finfo->type);

    mysqli_free_result($result);
}

/* close connection */
mysqli_close($link);
?>
```

The above example will output:

```
Name:      SurfaceArea
Table:     Country
max. Len:  10
Flags:    32769
Type:     4
```

[mysqli\\_fetch\\_field](#)

Returns the next field in the result set

### Description

Object oriented style (method):

```
object mysqli_result::fetch_field();
```

Procedural style:

```
object mysqli_fetch_field(mysqli_result result);
```

Returns the definition of one column of a result set as an object. Call this function repeatedly to retrieve information about all columns in the result set.

### Parameters

*result* Procedural style only: A result set identifier returned by `mysqli_query`, `mysqli_store_result` or `mysqli_use_result`.

### Return Values

Returns an object which contains field definition information or `FALSE` if no field information is available.

**Table 20.15. Object properties**

Property	Description
name	The name of the column
orgname	Original column name if an alias was specified
table	The name of the table this field belongs to (if not calculated)
orgtable	Original table name if an alias was specified
def	The default value for this field, represented as a string
max_length	The maximum width of the field for the result set.
length	The width of the field, as specified in the table definition.
charsetnr	The character set number for the field.
flags	An integer representing the bit-flags for the field.
type	The data type used for this field
decimals	The number of decimals used (for integer fields)

### Examples

#### Example 20.177. Object oriented style

```
<?php
$mysqli = new mysqli("localhost", "my_user", "my_password", "world");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

$query = "SELECT Name, SurfaceArea from Country ORDER BY Code LIMIT 5";
if ($result = $mysqli->query($query)) {
    /* Get field information for all columns */
    while ($finfo = $result->fetch_field()) {
        printf("Name:      %s\n", $finfo->name);
        printf("Table:     %s\n", $finfo->table);
        printf("max. Len:  %d\n", $finfo->max_length);
        printf("Flags:     %d\n", $finfo->flags);
        printf("Type:      %d\n\n", $finfo->type);
    }
    $result->close();
}

/* close connection */
$mysqli->close();
?>
```

**Example 20.178. Procedural style**

```

<?php
$link = mysqli_connect("localhost", "my_user", "my_password", "world");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

$query = "SELECT Name, SurfaceArea from Country ORDER BY Code LIMIT 5";
if ($result = mysqli_query($link, $query)) {

    /* Get field information for all fields */
    while ($finfo = mysqli_fetch_field($result)) {

        printf("Name:      %s\n", $finfo->name);
        printf("Table:     %s\n", $finfo->table);
        printf("max. Len:  %d\n", $finfo->max_length);
        printf("Flags:    %d\n", $finfo->flags);
        printf("Type:     %d\n", $finfo->type);
    }
    mysqli_free_result($result);
}

/* close connection */
mysqli_close($link);
?>

```

The above example will output:

```

Name:      Name
Table:     Country
max. Len:  11
Flags:     1
Type:      254

Name:      SurfaceArea
Table:     Country
max. Len:  10
Flags:     32769
Type:      4

```

[mysqli\\_fetch\\_fields](#)

Returns an array of objects representing the fields in a result set

**Description**

Object oriented style (method):

```
array mysqli_result::fetch_fields();
```

Procedural Style:

```
array mysqli_fetch_fields(mysqli_result result);
```

This function serves an identical purpose to the `mysqli_fetch_field` function with the single difference that, instead of returning one object at a time for each field, the columns are returned as an array of objects.

### Parameters

`result` Procedural style only: A result set identifier returned by `mysqli_query`, `mysqli_store_result` or `mysqli_use_result`.

### Return Values

Returns an array of objects which contains field definition information or `FALSE` if no field information is available.

**Table 20.16. Object properties**

Property	Description
name	The name of the column
orgname	Original column name if an alias was specified
table	The name of the table this field belongs to (if not calculated)
orgtable	Original table name if an alias was specified
def	The default value for this field, represented as a string
max_length	The maximum width of the field for the result set.
length	The width of the field, as specified in the table definition.
charsetnr	The character set number for the field.
flags	An integer representing the bit-flags for the field.
type	The data type used for this field
decimals	The number of decimals used (for integer fields)

### Examples

#### Example 20.179. Object oriented style

```
<?php
$mysqli = new mysqli("localhost", "my_user", "my_password", "world");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

$query = "SELECT Name, SurfaceArea from Country ORDER BY Code LIMIT 5";
if ($result = $mysqli->query($query)) {

    /* Get field information for all columns */
    $finfo = $result->fetch_fields();

    foreach ($finfo as $val) {
        printf("Name:    %s\n", $val->name);
        printf("Table:    %s\n", $val->table);
        printf("max. Len: %d\n", $val->max_length);
        printf("Flags:    %d\n", $val->flags);
        printf("Type:    %d\n\n", $val->type);
    }
    $result->close();
}

/* close connection */
$mysqli->close();
?>
```

**Example 20.180. Procedural style**

```

<?php
$link = mysqli_connect("localhost", "my_user", "my_password", "world");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

$query = "SELECT Name, SurfaceArea from Country ORDER BY Code LIMIT 5";
if ($result = mysqli_query($link, $query)) {

    /* Get field information for all columns */
    $finfo = mysqli_fetch_fields($result);

    foreach ($finfo as $val) {
        printf("Name:      %s\n", $val->name);
        printf("Table:     %s\n", $val->table);
        printf("max. Len:  %d\n", $val->max_length);
        printf("Flags:    %d\n", $val->flags);
        printf("Type:     %d\n", $val->type);
    }
    mysqli_free_result($result);
}

/* close connection */
mysqli_close($link);
?>

```

The above example will output:

```

Name:      Name
Table:     Country
max. Len:  11
Flags:     1
Type:      254

Name:      SurfaceArea
Table:     Country
max. Len:  10
Flags:     32769
Type:      4

```

[mysqli\\_fetch\\_object](#)

Returns the current row of a result set as an object

**Description**

Object oriented style (method):

```

object mysqli_result::fetch_object(string class_name,
                                   array params);

```

Procedural style:

```
object mysqli_fetch_object(mysqli_result result,
                          string class_name,
                          array params);
```

The `mysqli_fetch_object` will return the current row result set as an object where the attributes of the object represent the names of the fields found within the result set.

### Parameters

<code>result</code>	Procedural style only: A result set identifier returned by <code>mysqli_query</code> , <code>mysqli_store_result</code> or <code>mysqli_use_result</code> .
<code>class_name</code>	The name of the class to instantiate, set the properties of and return. If not specified, a <code>stdClass</code> object is returned.
<code>params</code>	An optional array of parameters to pass to the constructor for <code>class_name</code> objects.

### Return Values

Returns an object with string properties that corresponds to the fetched row or `NULL` if there are no more rows in resultset.

#### Note

Field names returned by this function are *case-sensitive*.

#### Note

This function sets NULL fields to the PHP `NULL` value.

### ChangeLog

Version	Description
5.0.0	Added the ability to return as a different object.

### Examples

#### Example 20.181. Object oriented style

```
<?php
$mysqli = new mysqli("localhost", "my_user", "my_password", "world");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

$query = "SELECT Name, CountryCode FROM City ORDER by ID DESC LIMIT 50,5";
if ($result = $mysqli->query($query)) {
    /* fetch object array */
    while ($obj = $result->fetch_object()) {
        printf ("%s (%s)\n", $obj->Name, $obj->CountryCode);
    }

    /* free result set */
    $result->close();
}

/* close connection */
$mysqli->close();
?>
```

**Example 20.182. Procedural style**

```

<?php
$link = mysqli_connect("localhost", "my_user", "my_password", "world");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

$query = "SELECT Name, CountryCode FROM City ORDER by ID DESC LIMIT 50,5";
if ($result = mysqli_query($link, $query)) {

    /* fetch associative array */
    while ($obj = mysqli_fetch_object($result)) {
        printf ("%s (%s)\n", $obj->Name, $obj->CountryCode);
    }

    /* free result set */
    mysqli_free_result($result);
}

/* close connection */
mysqli_close($link);
?>

```

The above example will output:

```

Pueblo (USA)
Arvada (USA)
Cape Coral (USA)
Green Bay (USA)
Santa Clara (USA)

```

[mysqli\\_fetch\\_row](#)

Get a result row as an enumerated array

**Description**

Object oriented style (method):

```
mixed mysqli_result::fetch_row();
```

Procedural style:

```
mixed mysqli_fetch_row(mysqli_result result);
```

Fetches one row of data from the result set and returns it as an enumerated array, where each column is stored in an array offset

starting from 0 (zero). Each subsequent call to this function will return the next row within the result set, or `NULL` if there are no more rows.

### Parameters

`result` Procedural style only: A result set identifier returned by `mysqli_query`, `mysqli_store_result` or `mysqli_use_result`.

### Return Values

`mysqli_fetch_row` returns an array of strings that corresponds to the fetched row or `NULL` if there are no more rows in result set.

### Note

This function sets `NULL` fields to the PHP `NULL` value.

### Examples

#### Example 20.183. Object oriented style

```
<?php
$mysqli = new mysqli("localhost", "my_user", "my_password", "world");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

$query = "SELECT Name, CountryCode FROM City ORDER by ID DESC LIMIT 50,5";
if ($result = $mysqli->query($query)) {
    /* fetch object array */
    while ($row = $result->fetch_row()) {
        printf ("%s (%s)\n", $row[0], $row[1]);
    }

    /* free result set */
    $result->close();
}

/* close connection */
$mysqli->close();
?>
```

#### Example 20.184. Procedural style

```
<?php
$link = mysqli_connect("localhost", "my_user", "my_password", "world");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

$query = "SELECT Name, CountryCode FROM City ORDER by ID DESC LIMIT 50,5";
if ($result = mysqli_query($link, $query)) {
    /* fetch associative array */
    while ($row = mysqli_fetch_row($result)) {
        printf ("%s (%s)\n", $row[0], $row[1]);
    }

    /* free result set */
    mysqli_free_result($result);
}

/* close connection */
mysqli_close($link);
?>
```

The above example will output:

```
Pueblo (USA)
Arvada (USA)
Cape Coral (USA)
Green Bay (USA)
Santa Clara (USA)
```

#### 20.10.2.8.11. `mysqli_result->field_count`, `mysqli_num_fields`

Copyright 1997-2008 the PHP Documentation Group.

- `mysqli_result->field_count`  
`mysqli_num_fields`

Get the number of fields in a result

### Description

Object oriented style (property):

```
mysqli_result {
    int field_count ;
}
```

Procedural style:

```
int mysqli_num_fields(mysqli_result result);
```

Returns the number of fields from specified result set.

### Parameters

*result* Procedural style only: A result set identifier returned by `mysqli_query`, `mysqli_store_result` or `mysqli_use_result`.

### Return Values

The number of fields from a result set.

### Examples

#### Example 20.185. Object oriented style

```
<?php
```

```

$mysqli = new mysqli("localhost", "my_user", "my_password", "world");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

if ($result = $mysqli->query("SELECT * FROM City ORDER BY ID LIMIT 1")) {

    /* determine number of fields in result set */
    $field_cnt = $result->field_count;

    printf("Result set has %d fields.\n", $field_cnt);

    /* close result set */
    $result->close();
}

/* close connection */
$mysqli->close();
?>

```

### Example 20.186. Procedural style

```

<?php
$link = mysqli_connect("localhost", "my_user", "my_password", "world");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

if ($result = mysqli_query($link, "SELECT * FROM City ORDER BY ID LIMIT 1")) {

    /* determine number of fields in result set */
    $field_cnt = mysqli_num_fields($result);

    printf("Result set has %d fields.\n", $field_cnt);

    /* close result set */
    mysqli_free_result($result);
}

/* close connection */
mysqli_close($link);
?>

```

The above example will output:

```
Result set has 5 fields.
```

### See Also

[mysqli\\_fetch\\_field](#)

#### 20.10.2.8.12. [mysqli\\_result::field\\_seek](#), [mysqli\\_field\\_seek](#)

Copyright 1997-2008 the PHP Documentation Group.

- [mysqli\\_result::field\\_seek](#)

[mysqli\\_field\\_seek](#)

Set result pointer to a specified field offset

## Description

Object oriented style (method):

```
bool mysqli_result::field_seek(int fieldnr);
```

Procedural style:

```
bool mysqli_field_seek(mysqli_result result,
                       int fieldnr);
```

Sets the field cursor to the given offset. The next call to `mysqli_fetch_field` will retrieve the field definition of the column associated with that offset.

### Note

To seek to the beginning of a row, pass an offset value of zero.

## Parameters

*result* Procedural style only: A result set identifier returned by `mysqli_query`, `mysqli_store_result` or `mysqli_use_result`.

*fieldnr* The field number. This value must be in the range from 0 to `number of fields - 1`.

## Return Values

Returns `TRUE` on success or `FALSE` on failure.

## Examples

### Example 20.187. Object oriented style

```
<?php
$link = new mysqli("localhost", "my_user", "my_password", "world");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

$query = "SELECT Name, SurfaceArea from Country ORDER BY Code LIMIT 5";
if ($result = $link->query($query)) {

    /* Get field information for 2nd column */
    $result->field_seek(1);
    $finfo = $result->fetch_field();

    printf("Name:      %s\n", $finfo->name);
    printf("Table:     %s\n", $finfo->table);
    printf("max. Len:  %d\n", $finfo->max_length);
    printf("Flags:      %d\n", $finfo->flags);
    printf("Type:       %d\n\n", $finfo->type);

    $result->close();
}

/* close connection */
$link->close();
?>
```

### Example 20.188. Procedural style

```
<?php
$link = mysqli_connect("localhost", "my_user", "my_password", "world");

/* check connection */
if (mysqli_connect_errno()) {
```

```

    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

$query = "SELECT Name, SurfaceArea from Country ORDER BY Code LIMIT 5";
if ($result = mysqli_query($link, $query)) {
    /* Get field information for 2nd column */
    mysqli_field_seek($result, 1);
    $finfo = mysqli_fetch_field($result);

    printf("Name:      %s\n", $finfo->name);
    printf("Table:     %s\n", $finfo->table);
    printf("max. Len: %d\n", $finfo->max_length);
    printf("Flags:    %d\n", $finfo->flags);
    printf("Type:     %d\n\n", $finfo->type);

    mysqli_free_result($result);
}

/* close connection */
mysqli_close($link);
?>

```

The above example will output:

```

Name:      SurfaceArea
Table:     Country
max. Len: 10
Flags:    32769
Type:     4

```

### 20.10.2.8.13. [mysqli\\_result::free](#), [mysqli\\_free\\_result](#)

Copyright 1997-2008 the PHP Documentation Group.

- [mysqli\\_result::free](#)  
[mysqli\\_free\\_result](#)

Frees the memory associated with a result

## Description

Object oriented style (all methods are equivalent):

```
void mysqli_result::free();
```

```
void mysqli_result::close();
```

```
void mysqli_result::free_result();
```

Procedural style:

```
void mysqli_free_result(mysqli_result result);
```

Frees the memory associated with the result.

## ■ Note

You should always free your result with `mysqli_free_result`, when your result object is not needed anymore.

**Parameters**

`result` Procedural style only: A result set identifier returned by `mysqli_query`, `mysqli_store_result` or `mysqli_use_result`.

**Return Values**

No value is returned.

**See Also**

`mysqli_query`  
`mysqli_stmt_store_result`  
`mysqli_store_result`  
`mysqli_use_result`

**20.10.2.8.14. `mysqli_result->lengths`, `mysqli_fetch_lengths`**

Copyright 1997-2008 the PHP Documentation Group.

- `mysqli_result->lengths`  
`mysqli_fetch_lengths`

Returns the lengths of the columns of the current row in the result set

**Description**

Object oriented style (property):

```
mysqli_result {  
    array lengths ;  
}
```

Procedural style:

```
array mysqli_fetch_lengths(mysqli_result result);
```

The `mysqli_fetch_lengths` function returns an array containing the lengths of every column of the current row within the result set.

**Parameters**

`result` Procedural style only: A result set identifier returned by `mysqli_query`, `mysqli_store_result` or `mysqli_use_result`.

**Return Values**

An array of integers representing the size of each column (not including any terminating null characters). `FALSE` if an error occurred.

`mysqli_fetch_lengths` is valid only for the current row of the result set. It returns `FALSE` if you call it before calling `mysqli_fetch_row/array/object` or after retrieving all rows in the result.

**Examples****Example 20.189. Object oriented style**

```

<?php
$mysqli = new mysqli("localhost", "my_user", "my_password", "world");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

$query = "SELECT * from Country ORDER BY Code LIMIT 1";
if ($result = $mysqli->query($query)) {
    $row = $result->fetch_row();

    /* display column lengths */
    foreach ($result->lengths as $i => $val) {
        printf("Field %2d has Length %2d\n", $i+1, $val);
    }
    $result->close();
}

/* close connection */
$mysqli->close();
?>

```

### Example 20.190. Procedural style

```

<?php
$link = mysqli_connect("localhost", "my_user", "my_password", "world");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

$query = "SELECT * from Country ORDER BY Code LIMIT 1";
if ($result = mysqli_query($link, $query)) {
    $row = mysqli_fetch_row($result);

    /* display column lengths */
    foreach (mysqli_fetch_lengths($result) as $i => $val) {
        printf("Field %2d has Length %2d\n", $i+1, $val);
    }
    mysqli_free_result($result);
}

/* close connection */
mysqli_close($link);
?>

```

The above example will output:

```

Field 1 has Length 3
Field 2 has Length 5
Field 3 has Length 13
Field 4 has Length 9
Field 5 has Length 6
Field 6 has Length 1
Field 7 has Length 6
Field 8 has Length 4
Field 9 has Length 6
Field 10 has Length 6
Field 11 has Length 5
Field 12 has Length 44
Field 13 has Length 7
Field 14 has Length 3
Field 15 has Length 2

```

#### 20.10.2.8.15. `mysqli_result->num_rows`, `mysqli_num_rows`

Copyright 1997-2008 the PHP Documentation Group.

- `mysqli_result->num_rows`  
`mysqli_num_rows`  
Gets the number of rows in a result

### Description

Object oriented style (property):

```
mysqli_result {
    int num_rows ;
}
```

Procedural style:

```
int mysqli_num_rows(mysqli_result result);
```

Returns the number of rows in the result set.

The use of `mysqli_num_rows` depends on whether you use buffered or unbuffered result sets. In case you use unbuffered result-sets `mysqli_num_rows` will not correct the correct number of rows until all the rows in the result have been retrieved.

### Parameters

*result* Procedural style only: A result set identifier returned by `mysqli_query`, `mysqli_store_result` or `mysqli_use_result`.

### Return Values

Returns number of rows in the result set.

#### Note

If the number of rows is greater than maximal int value, the number will be returned as a string.

### Examples

#### Example 20.191. Object oriented style

```
<?php
$mysqli = new mysqli("localhost", "my_user", "my_password", "world");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

if ($result = $mysqli->query("SELECT Code, Name FROM Country ORDER BY Name")) {

    /* determine number of rows result set */
    $row_cnt = $result->num_rows;

    printf("Result set has %d rows.\n", $row_cnt);

    /* close result set */
    $result->close();
}

/* close connection */
$mysqli->close();
?>
```

**Example 20.192. Procedural style**

```

<?php
$link = mysqli_connect("localhost", "my_user", "my_password", "world");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

if ($result = mysqli_query($link, "SELECT Code, Name FROM Country ORDER BY Name")) {

    /* determine number of rows result set */
    $row_cnt = mysqli_num_rows($result);

    printf("Result set has %d rows.\n", $row_cnt);

    /* close result set */
    mysqli_free_result($result);
}

/* close connection */
mysqli_close($link);
?>

```

The above example will output:

```
Result set has 239 rows.
```

`mysqli_execute` is deprecated and will be removed.

**See Also**

`mysqli_stmt_execute`

### 20.10.2.10.10. `mysqli_fetch`

Copyright 1997-2008 the PHP Documentation Group.

- `mysqli_fetch`

Alias for `mysqli_stmt_fetch`

#### Description

This function is an alias of `mysqli_stmt_fetch`.

#### Notes

##### Note

`mysqli_fetch` is deprecated and will be removed.

#### See Also

`mysqli_stmt_fetch`

### 20.10.2.10.11. `mysqli_get_metadata`

Copyright 1997-2008 the PHP Documentation Group.

- `mysqli_get_metadata`

Alias for `mysqli_stmt_result_metadata`

#### Description

This function is an alias of `mysqli_stmt_result_metadata`.

#### Notes

##### Note

`mysqli_get_metadata` is deprecated and will be removed.

#### See Also

`mysqli_stmt_result_metadata`

### 20.10.2.10.12. `mysqli_master_query`

Copyright 1997-2008 the PHP Documentation Group.

- `mysqli_master_query`

Enforce execution of a query on the master in a master/slave setup

#### Description

```
bool mysqli_master_query(mysqli link,  
                        string query);
```

##### Warning

This function is currently not documented; only its argument list is available.

##### Warning

This function has been *DEPRECATED* and *REMOVED* as of PHP 5.3.0.

### 20.10.2.10.13. `mysqli_param_count`

Copyright 1997-2008 the PHP Documentation Group.

- `mysqli_param_count`  
Alias for `mysqli_stmt_param_count`

#### Description

This function is an alias of `mysqli_stmt_param_count`.

#### Notes

##### Note

`mysqli_param_count` is deprecated and will be removed.

#### See Also

`mysqli_stmt_param_count`

### 20.10.2.10.14. `mysqli_report`

Copyright 1997-2008 the PHP Documentation Group.

- `mysqli_report`  
Enables or disables internal report functions

#### Description

```
bool mysqli_report(int flags);
```

`mysqli_report` is a powerful function to improve your queries and code during development and testing phase. Depending on the flags it reports errors from `mysqli` function calls or queries which don't use an index (or use a bad index).

#### Parameters

*flags*

**Table 20.17. Supported flags**

Name	Description
<code>MYSQLI_REPORT_OFF</code>	Turns reporting off
<code>MYSQLI_REPORT_ERROR</code>	Report errors from <code>mysqli</code> function calls
<code>MYSQLI_REPORT_STRICT</code>	Report warnings from <code>mysqli</code> function calls
<code>MYSQLI_REPORT_INDEX</code>	Report if no index or bad index was used in a query
<code>MYSQLI_REPORT_ALL</code>	Set all options (report all)

#### Return Values

Returns `TRUE` on success or `FALSE` on failure.

#### Examples

**Example 20.193. Object oriented style**

```

<?php
/* activate reporting */
mysqli_report(MYSQLI_REPORT_ALL);

$mysqli = new mysqli("localhost", "my_user", "my_password", "world");

/* check connection */
if (mysqli_connect_errno()) {
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

/* this query should report an error */
$result = $mysqli->query("SELECT Name FROM Nonexistingtable WHERE population > 50000");

/* this query should report a warning */
$result = $mysqli->query("SELECT Name FROM City WHERE population > 50000");
$result->close();

$mysqli->close();
?>

```

**See Also**

[mysqli\\_debug](#)  
[mysqli\\_dump\\_debug\\_info](#)

**20.10.2.10.15. [mysqli\\_rpl\\_parse\\_enabled](#)**

Copyright 1997-2008 the PHP Documentation Group.

- [mysqli\\_rpl\\_parse\\_enabled](#)

Check if RPL parse is enabled

**Description**

```
int mysqli_rpl_parse_enabled(mysqli link);
```

**Warning**

This function is currently not documented; only its argument list is available.

**Warning**

This function has been *DEPRECATED* and *REMOVED* as of PHP 5.3.0.

**20.10.2.10.16. [mysqli\\_rpl\\_probe](#)**

Copyright 1997-2008 the PHP Documentation Group.

- [mysqli\\_rpl\\_probe](#)

RPL probe

**Description**

```
bool mysqli_rpl_probe(mysqli link);
```

**Warning**

This function is currently not documented; only its argument list is available.

**Warning**

This function has been *DEPRECATED* and *REMOVED* as of PHP 5.3.0.

**20.10.2.10.17. `mysqli_rpl_query_type`, `mysqli->rpl_query_type`**

Copyright 1997-2008 the PHP Documentation Group.

- `mysqli_rpl_query_type`  
`mysqli->rpl_query_type`

Returns RPL query type

**Description**

Procedural style:

```
int mysqli_rpl_query_type(mysqli link,
                        string query);
```

Object oriented style (method)

```
mysqli {
    int rpl_query_type(string query);
}
```

Returns `MYSQLI_RPL_MASTER`, `MYSQLI_RPL_SLAVE` or `MYSQLI_RPL_ADMIN` depending on a query type. `INSERT`, `UPDATE` and similar are *master* queries, `SELECT` is *slave*, and `FLUSH`, `REPAIR` and similar are *admin*.

**Warning**

This function is currently not documented; only its argument list is available.

**Warning**

This function has been *DEPRECATED* and *REMOVED* as of PHP 5.3.0.

**20.10.2.10.18. `mysqli_send_long_data`**

Copyright 1997-2008 the PHP Documentation Group.

- `mysqli_send_long_data`  
Alias for `mysqli_stmt_send_long_data`

**Description**

This function is an alias of `mysqli_stmt_send_long_data`.

**Notes****Note**

`mysqli_send_long_data` is deprecated and will be removed.

**See Also**

`mysqli_stmt_send_long_data`

**20.10.2.10.19. `mysqli_send_query`, `mysqli->send_query`**

Copyright 1997-2008 the PHP Documentation Group.

- `mysqli_send_query`  
`mysqli->send_query`  
Send the query and return

### Description

Procedural style:

```
bool mysqli_send_query(mysqli link,  
                        string query);
```

Object oriented style (method)

```
mysqli {  
    bool send_query(string query);  
}
```

#### Warning

This function is currently not documented; only its argument list is available.

#### Warning

This function has been *DEPRECATED* and *REMOVED* as of PHP 5.3.0.

### 20.10.2.10.20. `mysqli_set_opt`

[Copyright 1997-2008 the PHP Documentation Group.](#)

- `mysqli_set_opt`  
Alias of `mysqli_options`

### Description

This function is an alias of `mysqli_options`.

### 20.10.2.10.21. `mysqli_slave_query`

[Copyright 1997-2008 the PHP Documentation Group.](#)

- `mysqli_slave_query`  
Force execution of a query on a slave in a master/slave setup

### Description

```
bool mysqli_slave_query(mysqli link,  
                        string query);
```

#### Warning

This function is currently not documented; only its argument list is available.

#### Warning

This function has been *DEPRECATED* and *REMOVED* as of PHP 5.3.0.

## 20.10.3. MySQL Functions (PDO\_MYSQL)

[Copyright 1997-2008 the PHP Documentation Group.](#)

PDO\_MYSQL is a driver that implements the [PHP Data Objects \(PDO\) interface](#) to enable access from PHP to MySQL 3.x, 4.x and 5.x databases.

PDO\_MYSQL will take advantage of native prepared statement support present in MySQL 4.1 and higher. If you're using an older version of the mysql client libraries, PDO will emulate them for you.

### Warning

Beware: Some MySQL table types (storage engines) do not support transactions. When writing transactional database code using a table type that does not support transactions, MySQL will pretend that a transaction was initiated successfully. In addition, any DDL queries issued will implicitly commit any pending transactions.

The constants below are defined by this driver, and will only be available when the extension has been either compiled into PHP or dynamically loaded at runtime. In addition, these driver-specific constants should only be used if you are using this driver. Using mysql-specific attributes with the postgres driver may result in unexpected behaviour. `PDO::getAttribute` may be used to obtain the `PDO_ATTR_DRIVER_NAME` attribute to check the driver, if your code can run against multiple drivers.

`PDO::MYSQL_ATTR_USE_BUFFERED_QUERY` (integer) If this attribute is set to `TRUE` on a `PDOStatement`, the MySQL driver will use the buffered versions of the MySQL API. If you're writing portable code, you should use `PDOStatement::fetchAll` instead.

### Example 20.194. Forcing queries to be buffered in mysql

```
<?php
if ($db->getAttribute(PDO::ATTR_DRIVER_NAME) == 'mysql') {
    $stmt = $db->prepare('select * from foo',
        array(PDO::MYSQL_ATTR_USE_BUFFERED_QUERY => true));
} else {
    die("my application only works with mysql; I should use \$stmt->fetchAll() instead");
}
?>
```

`PDO::MYSQL_ATTR_LOCAL_INFILE` (integer) Enable `LOAD LOCAL INFILE`.

`PDO::MYSQL_ATTR_INIT_COMMAND` (integer) Command to execute when connecting to the MySQL server. Will automatically be re-executed when reconnecting.

`PDO::MYSQL_ATTR_READ_DEFAULT_FILE` (integer) Read options from the named option file instead of from `my.cnf`.

`PDO::MYSQL_ATTR_READ_DEFAULT_GROUP` (integer) Read options from the named group from `my.cnf` or the file specified with `MYSQL_READ_DEFAULT_FILE`.

`PDO::MYSQL_ATTR_MAX_BUFFER_SIZE` (integer) Maximum buffer size. Defaults to 1 MiB.

`PDO::MYSQL_ATTR_DIRECT_QUERY` (integer) Perform direct queries, don't use prepared statements.

#### 20.10.3.1. PDO\_MYSQL DSN

Copyright 1997-2008 the PHP Documentation Group.

- `PDO_MYSQL DSN`

Connecting to MySQL databases

#### Description

The PDO\_MYSQL Data Source Name (DSN) is composed of the following elements:

DSN prefix                      The DSN prefix is `mysql:`.

`host`                              The hostname on which the database server resides.

<code>port</code>	The port number where the database server is listening.
<code>dbname</code>	The name of the database.
<code>unix_socket</code>	The MySQL Unix socket (shouldn't be used with <code>host</code> or <code>port</code> ).

### Examples

#### Example 20.195. PDO\_MYSQL DSN examples

The following example shows a PDO\_MYSQL DSN for connecting to MySQL databases:

```
mysql:host=localhost;dbname=testdb
```

More complete examples:

```
mysql:host=localhost;port=3307;dbname=testdb
mysql:unix_socket=/tmp/mysql.sock;dbname=testdb
```

## 20.10.4. Connector/PHP

The MySQL Connector/PHP is a version of the `mysql` and `mysqli` extensions for PHP optimized for the Windows operating system. Later versions of the main PHP `mysql/mysqli` drivers are compatible with Windows and a separate, Windows specific driver is no longer required.

For PHP for all platforms, including Windows, you should use the `mysql` or `mysqli` extensions shipped with the PHP sources. See [Section 20.10, “MySQL PHP API”](#).

## 20.10.5. Common Problems with MySQL and PHP

- **Error: Maximum Execution Time Exceeded:** This is a PHP limit; go into the `php.ini` file and set the maximum execution time up from 30 seconds to something higher, as needed. It is also not a bad idea to double the RAM allowed per script to 16MB instead of 8MB.
- **Fatal error: Call to unsupported or undefined function mysql\_connect() in ...:** This means that your PHP version isn't compiled with MySQL support. You can either compile a dynamic MySQL module and load it into PHP or recompile PHP with built-in MySQL support. This process is described in detail in the PHP manual.
- **Error: Undefined reference to 'uncompress':** This means that the client library is compiled with support for a compressed client/server protocol. The fix is to add `-lz` last when linking with `-lmysqlclient`.
- **Error: Client does not support authentication protocol:** This is most often encountered when trying to use the older `mysql` extension with MySQL 4.1.1 and later. Possible solutions are: downgrade to MySQL 4.0; switch to PHP 5 and the newer `mysqli` extension; or configure the MySQL server with `--old-passwords`. (See [Section B.1.2.4, “Client does not support authentication protocol”](#), for more information.)

Those with PHP4 legacy code can make use of a compatibility layer for the old and new MySQL libraries, such as this one: <http://www.coggeshall.org/oss/mysqli2i>.

## 20.10.6. Enabling Both `mysql` and `mysqli` in PHP

If you're experiencing problems with enabling both the `mysql` and the `mysqli` extension when building PHP on Linux yourself, you should try the following procedure.

1. Configure PHP like this:

```
./configure --with-mysqli=/usr/bin/mysql_config --with-mysql=/usr
```

2. Edit the `Makefile` and search for a line that starts with `EXTRA_LIBS`. It might look like this (all on one line):

```
EXTRA_LIBS = -lcrypt -lcrypt -lmysqlclient -lz -lresolv -lm -ldl -lnsl
-lxml2 -lz -lm -lxml2 -lz -lm -lmysqlclient -lz -lcrypt -lnsl -lm
-lxml2 -lz -lm -lcrypt -lxml2 -lz -lm -lcrypt
```

Remove all duplicates, so that the line looks like this (all on one line):

```
EXTRA_LIBS = -lcrypt -lcrypt -lmysqlclient -lz -lresolv -lm -ldl -lnsl
-lxml2
```

3. Build and install PHP:

```
make
make install
```

#### MySQL Enterprise

MySQL Enterprise subscribers will find more information about the `mysql` extension in the Knowledge Base articles found at [mysql](http://mysql.com). Access to the MySQL Knowledge Base collection of articles is one of the advantages of subscribing to MySQL Enterprise. For more information, see <http://www.mysql.com/products/enterprise/advisors.html>.

## 20.11. MySQL Perl API

The Perl `DBI` module provides a generic interface for database access. You can write a `DBI` script that works with many different database engines without change. To use `DBI`, you must install the `DBI` module, as well as a DataBase Driver (DBD) module for each type of server you want to access. For MySQL, this driver is the `DBD: :mysql` module.

Perl `DBI` is the recommended Perl interface. It replaces an older interface called `mysqlperl`, which should be considered obsolete.

Installation instructions for Perl `DBI` support are given in [Section 2.21, “Perl Installation Notes”](#).

`DBI` information is available at the command line, online, or in printed form:

- Once you have the `DBI` and `DBD: :mysql` modules installed, you can get information about them at the command line with the `perldoc` command:

```
shell> perldoc DBI
shell> perldoc DBI: :FAQ
shell> perldoc DBD: :mysql
```

You can also use `pod2man`, `pod2html`, and so forth to translate this information into other formats.

- For online information about Perl `DBI`, visit the `DBI` Web site, <http://dbi.perl.org/>. That site hosts a general `DBI` mailing list. Sun Microsystems, Inc. hosts a list specifically about `DBD: :mysql`; see [Section 1.5.1, “MySQL Mailing Lists”](#).
- For printed information, the official `DBI` book is *Programming the Perl DBI* (Alligator Descartes and Tim Bunce, O'Reilly & Associates, 2000). Information about the book is available at the `DBI` Web site, <http://dbi.perl.org/>.

For information that focuses specifically on using `DBI` with MySQL, see *MySQL and Perl for the Web* (Paul DuBois, New Riders, 2001). This book's Web site is <http://www.kitebird.com/mysql-perl/>.

## 20.12. MySQL C++ API

`MySQL++` is a MySQL API for C++. Warren Young has taken over this project. More information can be found at <http://tangentsoft.net/mysql++/doc>.

#### MySQL Enterprise

MySQL Enterprise subscribers will find more information about using C++ with the MySQL API in the MySQL Knowledge Base. articles found at `C++`. Access to the MySQL Knowledge Base collection of articles is one of the advantages of subscribing to MySQL Enterprise. For more information, see <http://www.mysql.com/products/enterprise/advisors.html>.

## 20.13. MySQL Python API

`MySQLdb` provides MySQL support for Python, compliant with the Python DB API version 2.0. It can be found at <http://sourceforge.net/projects/mysql-python/>.

**MySQL Enterprise**

MySQL Enterprise subscribers will find more information about using Python with the MySQL API in the MySQL Knowledge Base articles found at [Python](#). Access to the MySQL Knowledge Base collection of articles is one of the advantages of subscribing to MySQL Enterprise. For more information, see <http://www.mysql.com/products/enterprise/advisors.html>.

## 20.14. MySQL Ruby APIs

Two APIs available for Ruby programmers. The MySQL/Ruby API is based on the `libmysql` API library. The Ruby/MySQL API is written to use the native MySQL network protocol (a native driver).

For more information on Ruby, see [Ruby Programming Language](#).

For information on installing and using the MySQL/Ruby API, see [Section 20.14.1, “The MySQL/Ruby API”](#).

For information on installing and using the Ruby/MySQL API, see [Section 20.14.2, “The Ruby/MySQL API”](#).

### 20.14.1. The MySQL/Ruby API

The MySQL/Ruby module provides access to MySQL databases using Ruby through `libmysql`.

For information on installing the module, and the functions exposed, see [MySQL/Ruby](#).

### 20.14.2. The Ruby/MySQL API

The Ruby/MySQL module provides access to MySQL databases using Ruby through a native driver interface using the MySQL network protocol.

For information on installing the module, and the functions exposed, see [Ruby/MySQL](#).

## 20.15. MySQL Tcl API

`MySQLtcl` is a simple API for accessing a MySQL database server from the Tcl programming language. It can be found at <http://www.xdobry.de/mysqltcl/>.

## 20.16. MySQL Eiffel Wrapper

Eiffel MySQL is an interface to the MySQL database server using the Eiffel programming language, written by Michael Ravits. It can be found at <http://efsa.sourceforge.net/archive/ravits/mysql.htm>.

---

# Chapter 21. Extending MySQL

## 21.1. MySQL Internals

This chapter describes a lot of things that you need to know when working on the MySQL code. If you plan to contribute to MySQL development, want to have access to the bleeding-edge versions of the code, or just want to keep track of development, follow the instructions in [Section 2.16.3, “Installing from the Development Source Tree”](#). If you are interested in MySQL internals, you should also subscribe to our `internals` mailing list. This list has relatively low traffic. For details on how to subscribe, please see [Section 1.5.1, “MySQL Mailing Lists”](#). All developers at MySQL AB are on the `internals` list and we help other people who are working on the MySQL code. Feel free to use this list both to ask questions about the code and to send patches that you would like to contribute to the MySQL project!

### 21.1.1. MySQL Threads

The MySQL server creates the following threads:

- Connection manager threads handle client connection requests on the network interfaces that the server listens to. On all platforms, one manager thread handles TCP/IP connection requests. On Unix, this manager thread also handles Unix socket file connection requests. On Windows, a manager thread handles shared-memory connection requests, and another handles named-pipe connection requests. The server does not create threads to handle interfaces that it does not listen to. For example, a Windows server that does not have support for named-pipe connections enabled does not create a thread to handle them.
- Connection manager threads associate each client connection with a thread dedicated to it that handles authentication and request processing for that connection. Manager threads create a new thread when necessary but try to avoid doing so by consulting the thread cache first to see whether it contains a thread that can be used for the connection. When a connection ends, its thread is returned to the thread cache if the cache is not full.

For information about tuning the parameters that control thread resources, see [Section 7.5.7, “How MySQL Uses Threads for Client Connections”](#).

- On a master replication server, connections from slave servers are handled like client connections: There is one thread per connected slave.
- On a slave replication server, an I/O thread is started to connect to the master server and read updates from it. An SQL thread is started to apply updates read from the master. These two threads run independently and can be started and stopped independently.
- A signal thread handles all signals. This thread also normally handles alarms and calls `process_alarm()` to force timeouts on connections that have been idle too long.
- If `InnoDB` is used, there will be 4 additional threads by default. Those are file I/O threads, controlled by the `innodb_file_io_threads` parameter. See [Section 13.2.3, “InnoDB Startup Options and System Variables”](#).
- If `mysqld` is compiled with `-DUSE_ALARM_THREAD`, a dedicated thread that handles alarms is created. This is only used on some systems where there are problems with `sigwait()` or if you want to use the `thr_alarm()` code in your application without a dedicated signal handling thread.
- If the server is started with the `--flush_time=val` option, a dedicated thread is created to flush all tables every `val` seconds.
- Each table for which `INSERT DELAYED` statements are issued gets its own thread. See [Section 12.2.5.2, “INSERT DELAYED Syntax”](#).

`mysqladmin processlist` only shows the connection, `INSERT DELAYED`, and replication threads.

#### MySQL Enterprise

For expert advice on thread management subscribe to the MySQL Enterprise Monitor. For more information, see <http://www.mysql.com/products/enterprise/advisors.html>.

### 21.1.2. MySQL Test Suite

The test system that is included in Unix source and binary distributions makes it possible for users and developers to perform regression tests on the MySQL code. These tests can be run on Unix.

You can also write your own test cases. For information about the MySQL Test Framework, including system requirements, see the manual available at <http://dev.mysql.com/doc/>.

The current set of test cases doesn't test everything in MySQL, but it should catch most obvious bugs in the SQL processing code, operating system or library issues, and is quite thorough in testing replication. Our goal is to have the tests cover 100% of the code. We welcome contributions to our test suite. You may especially want to contribute tests that examine the functionality critical to your system because this ensures that all future MySQL releases work well with your applications.

The test system consists of a test language interpreter (`mysqltest`), a Perl script to run all tests (`mysql-test-run.pl`), the actual test cases written in a special test language, and their expected results. To run the test suite on your system after a build, type `make test` from the source root directory, or change location to the `mysql-test` directory and type `./mysql-test-run.pl`. If you have installed a binary distribution, change location to the `mysql-test` directory under the installation root directory (for example, `/usr/local/mysql/mysql-test`), and run `./mysql-test-run.pl`. All tests should succeed. If any do not, feel free to try to find out why and report the problem if it indicates a bug in MySQL. See [Section 1.6, “How to Report Bugs or Problems”](#).

If one test fails, you should run `mysql-test-run.pl` with the `--force` option to check whether any other tests fail.

If you have a copy of `mysqld` running on the machine where you want to run the test suite, you do not have to stop it, as long as it is not using ports `9306` or `9307`. If either of those ports is taken, you should set the `MTR_BUILD_THREAD` environment variable to an appropriate value, and the test suite will use a different set of ports for master, slave, NDB, and Instance Manager). For example:

```
shell> export MTR_BUILD_THREAD=31
shell> ./mysql-test-run.pl [options] [test_name]
```

In the `mysql-test` directory, you can run an individual test case with `./mysql-test-run.pl test_name`.

If you have a question about the test suite, or have a test case to contribute, send an email message to the MySQL [internals](#) mailing list. See [Section 1.5.1, “MySQL Mailing Lists”](#). This list does not accept attachments, so you should FTP all the relevant files to: <ftp://ftp.mysql.com/pub/mysql/upload/>

## 21.2. Adding New Functions to MySQL

There are three ways to add new functions to MySQL:

- You can add functions through the user-defined function (UDF) interface. User-defined functions are compiled as object files and then added to and removed from the server dynamically using the `CREATE FUNCTION` and `DROP FUNCTION` statements. See [Section 12.5.3.1, “CREATE FUNCTION Syntax”](#).
- You can add functions as native (built-in) MySQL functions. Native functions are compiled into the `mysqld` server and become available on a permanent basis.
- Another way to add functions is by creating stored functions. These are written using SQL statements rather than by compiling object code. The syntax for writing stored functions is not covered here. See [Section 18.2, “Using Stored Routines \(Procedures and Functions\)”](#).

Each method of creating compiled functions has advantages and disadvantages:

- If you write user-defined functions, you must install object files in addition to the server itself. If you compile your function into the server, you don't need to do that.
- Native functions require you to modify a source distribution. UDFs do not. You can add UDFs to a binary MySQL distribution. No access to MySQL source is necessary.
- If you upgrade your MySQL distribution, you can continue to use your previously installed UDFs, unless you upgrade to a newer version for which the UDF interface changes. For native functions, you must repeat your modifications each time you upgrade.

Whichever method you use to add new functions, they can be invoked in SQL statements just like native functions such as `ABS()` or `SOUNDEX()`.

See [Section 8.2.3, “Function Name Parsing and Resolution”](#), for the rules describing how the server interprets references to different kinds of functions.

The following sections describe features of the UDF interface, provide instructions for writing UDFs, discuss security precautions that MySQL takes to prevent UDF misuse, and describe how to add native MySQL functions.

For example source code that illustrates how to write UDFs, take a look at the `sql/udf_example.c` file that is provided in

MySQL source distributions.

## 21.2.1. Features of the User-Defined Function Interface

The MySQL interface for user-defined functions provides the following features and capabilities:

- Functions can return string, integer, or real values and can accept arguments of those same types.
- You can define simple functions that operate on a single row at a time, or aggregate functions that operate on groups of rows.
- Information is provided to functions that enables them to check the number, types, and names of the arguments passed to them.
- You can tell MySQL to coerce arguments to a given type before passing them to a function.
- You can indicate that a function returns `NULL` or that an error occurred.

## 21.2.2. Adding a New User-Defined Function

For the UDF mechanism to work, functions must be written in C or C++ (or another language that can use C calling conventions), and your operating system must support dynamic loading. The MySQL source distribution includes a file `sql/udf_example.c` that defines 5 new functions. Consult this file to see how UDF calling conventions work. UDF-related symbols and data structures are defined in the `include/mysql_com.h` header file. (You need not include this header file directly because it is included by `mysql.h`.)

A UDF contains code that becomes part of the running server, so when you write a UDF, you are bound by any and all constraints that otherwise apply to writing server code. For example, you may have problems if you attempt to use functions from the `libstdc++` library. Note that these constraints may change in future versions of the server, so it is possible that server upgrades will require revisions to UDFs that were originally written for older servers. For information about these constraints, see [Section 2.16.2, “Typical configure Options”](#), and [Section 2.16.4, “Dealing with Problems Compiling MySQL”](#).

To be able to use UDFs, you need to link `mysqld` dynamically. Don't configure MySQL using `-with-mysqld-ldflags=-all-static`. If you want to use a UDF that needs to access symbols from `mysqld` (for example, the `metaphone` function in `sql/udf_example.c` that uses `default_charset_info`), you must link the program with `-rdynamic` (see `man dlopen`). If you plan to use UDFs, the rule of thumb is to configure MySQL with `-with-mysqld-ldflags=-rdynamic` unless you have a very good reason not to.

For each function that you want to use in SQL statements, you should define corresponding C (or C++) functions. In the following discussion, the name “xxx” is used for an example function name. To distinguish between SQL and C/C++ usage, `XXX()` (uppercase) indicates an SQL function call, and `xxx()` (lowercase) indicates a C/C++ function call.

The C/C++ functions that you write to implement the interface for `XXX()` are:

- `xxx()` (required)

The main function. This is where the function result is computed. The correspondence between the SQL function data type and the return type of your C/C++ function is shown here.

SQL Type	C/C++ Type
<code>STRING</code>	<code>char *</code>
<code>INTEGER</code>	<code>long long</code>
<code>REAL</code>	<code>double</code>

It is also possible to declare a `DECIMAL` function, but currently the value is returned as a string, so you should write the UDF as though it were a `STRING` function. `ROW` functions are not implemented.

- `xxx_init()` (optional)

The initialization function for `xxx()`. It can be used for the following purposes:

- To check the number of arguments to `XXX()`.
- To check that the arguments are of a required type or, alternatively, to tell MySQL to coerce arguments to the types you want when the main function is called.
- To allocate any memory required by the main function.

- To specify the maximum length of the result.
- To specify (for `REAL` functions) the maximum number of decimal places in the result.
- To specify whether the result can be `NULL`.
- `xxx_deinit()` (optional)

The deinitialization function for `xxx()`. It should deallocate any memory allocated by the initialization function.

When an SQL statement invokes `xxx()`, MySQL calls the initialization function `xxx_init()` to let it perform any required setup, such as argument checking or memory allocation. If `xxx_init()` returns an error, MySQL aborts the SQL statement with an error message and does not call the main or deinitialization functions. Otherwise, MySQL calls the main function `xxx()` once for each row. After all rows have been processed, MySQL calls the deinitialization function `xxx_deinit()` so that it can perform any required cleanup.

For aggregate functions that work like `SUM()`, you must also provide the following functions:

- `xxx_clear()`  
Reset the current aggregate value but do not insert the argument as the initial aggregate value for a new group.
- `xxx_add()`  
Add the argument to the current aggregate value.

MySQL handles aggregate UDFs as follows:

1. Call `xxx_init()` to let the aggregate function allocate any memory it needs for storing results.
2. Sort the table according to the `GROUP BY` expression.
3. Call `xxx_clear()` for the first row in each new group.
4. Call `xxx_add()` for each row that belongs in the same group.
5. Call `xxx()` to get the result for the aggregate when the group changes or after the last row has been processed.
6. Repeat 3-5 until all rows has been processed
7. Call `xxx_deinit()` to let the UDF free any memory it has allocated.

All functions must be thread-safe. This includes not just the main function, but the initialization and deinitialization functions as well, and also the additional functions required by aggregate functions. A consequence of this requirement is that you are not allowed to allocate any global or static variables that change! If you need memory, you should allocate it in `xxx_init()` and free it in `xxx_deinit()`.

### 21.2.2.1. UDF Calling Sequences for Simple Functions

This section describes the different functions that you need to define when you create a simple UDF. [Section 21.2.2, “Adding a New User-Defined Function”](#), describes the order in which MySQL calls these functions.

The main `xxx()` function should be declared as shown in this section. Note that the return type and parameters differ, depending on whether you declare the SQL function `XXX()` to return `STRING`, `INTEGER`, or `REAL` in the `CREATE FUNCTION` statement:

For `STRING` functions:

```
char *xxx(UDF_INIT *initid, UDF_ARGS *args,
         char *result, unsigned long *length,
         char *is_null, char *error);
```

For `INTEGER` functions:

```
long long xxx(UDF_INIT *initid, UDF_ARGS *args,
             char *is_null, char *error);
```

For **REAL** functions:

```
double xxx(UDF_INIT *initid, UDF_ARGS *args,
           char *is_null, char *error);
```

**DECIMAL** functions return string values and should be declared the same way as **STRING** functions. **ROW** functions are not implemented.

The initialization and deinitialization functions are declared like this:

```
my_bool xxx_init(UDF_INIT *initid, UDF_ARGS *args, char *message);
void xxx_deinit(UDF_INIT *initid);
```

The `initid` parameter is passed to all three functions. It points to a **UDF\_INIT** structure that is used to communicate information between functions. The **UDF\_INIT** structure members follow. The initialization function should fill in any members that it wishes to change. (To use the default for a member, leave it unchanged.)

- `my_bool maybe_null`

`xxx_init()` should set `maybe_null` to 1 if `xxx()` can return **NULL**. The default value is 1 if any of the arguments are declared `maybe_null`.

- `unsigned int decimals`

The number of decimal digits to the right of the decimal point. The default value is the maximum number of decimal digits in the arguments passed to the main function. For example, if the function is passed `1.34`, `1.345`, and `1.3`, the default would be 3, because `1.345` has 3 decimal digits.

For arguments that have no fixed number of decimals, the `decimals` value is set to 31, which is 1 more than the maximum number of decimals allowed for the **DECIMAL**, **FLOAT**, and **DOUBLE** data types.

A `decimals` value of 31 is used for arguments in cases such as a **FLOAT** or **DOUBLE** column declared without an explicit number of decimals (for example, **FLOAT** rather than **FLOAT(10,3)**) and for floating-point constants such as `1345E-3`. It is also used for string and other non-number arguments that might be converted within the function to numeric form.

The value to which the `decimals` member is initialized is only a default. It can be changed within the function to reflect the actual calculation performed. The default is determined such that the largest number of decimals of the arguments is used. If the number of decimals is 31 for even one of the arguments, that is the value used for `decimals`.

- `unsigned int max_length`

The maximum length of the result. The default `max_length` value differs depending on the result type of the function. For string functions, the default is the length of the longest argument. For integer functions, the default is 21 digits. For real functions, the default is 13 plus the number of decimal digits indicated by `initid->decimals`. (For numeric functions, the length includes any sign or decimal point characters.)

If you want to return a blob value, you can set `max_length` to 65KB or 16MB. This memory is not allocated, but the value is used to decide which data type to use if there is a need to temporarily store the data.

- `char *ptr`

A pointer that the function can use for its own purposes. For example, functions can use `initid->ptr` to communicate allocated memory among themselves. `xxx_init()` should allocate the memory and assign it to this pointer:

```
initid->ptr = allocated_memory;
```

In `xxx()` and `xxx_deinit()`, refer to `initid->ptr` to use or deallocate the memory.

- `my_bool const_item`

`xxx_init()` should set `const_item` to 1 if `xxx()` always returns the same value and to 0 otherwise.

### 21.2.2.2. UDF Calling Sequences for Aggregate Functions

This section describes the different functions that you need to define when you create an aggregate UDF. [Section 21.2.2, “Adding a New User-Defined Function”](#), describes the order in which MySQL calls these functions.

- `xxx_reset()`

This function is called when MySQL finds the first row in a new group. It should reset any internal summary variables and then use the given `UDF_ARGS` argument as the first value in your internal summary value for the group. Declare `xxx_reset()` as follows:

```
void xxx_reset(UDF_INIT *initid, UDF_ARGS *args,
              char *is_null, char *error);
```

`xxx_reset()` is not needed or used in MySQL 5.0, in which the UDF interface uses `xxx_clear()` instead. However, you can define both `xxx_reset()` and `xxx_clear()` if you want to have your UDF work with older versions of the server. (If you do include both functions, the `xxx_reset()` function in many cases can be implemented internally by calling `xxx_clear()` to reset all variables, and then calling `xxx_add()` to add the `UDF_ARGS` argument as the first value in the group.)

- `xxx_clear()`

This function is called when MySQL needs to reset the summary results. It is called at the beginning for each new group but can also be called to reset the values for a query where there were no matching rows. Declare `xxx_clear()` as follows:

```
void xxx_clear(UDF_INIT *initid, char *is_null, char *error);
```

`is_null` is set to point to `CHAR(0)` before calling `xxx_clear()`.

If something went wrong, you can store a value in the variable to which the `error` argument points. `error` points to a single-byte variable, not to a string buffer.

`xxx_clear()` is required by MySQL 5.0.

- `xxx_add()`

This function is called for all rows that belong to the same group. You should use it to add the value in the `UDF_ARGS` argument to your internal summary variable.

```
void xxx_add(UDF_INIT *initid, UDF_ARGS *args,
            char *is_null, char *error);
```

The `xxx()` function for an aggregate UDF should be declared the same way as for a non-aggregate UDF. See [Section 21.2.2.1, “UDF Calling Sequences for Simple Functions”](#).

For an aggregate UDF, MySQL calls the `xxx()` function after all rows in the group have been processed. You should normally never access its `UDF_ARGS` argument here but instead return a value based on your internal summary variables.

Return value handling in `xxx()` should be done the same way as for a non-aggregate UDF. See [Section 21.2.2.4, “UDF Return Values and Error Handling”](#).

The `xxx_reset()` and `xxx_add()` functions handle their `UDF_ARGS` argument the same way as functions for non-aggregate UDFs. See [Section 21.2.2.3, “UDF Argument Processing”](#).

The pointer arguments to `is_null` and `error` are the same for all calls to `xxx_reset()`, `xxx_clear()`, `xxx_add()` and `xxx()`. You can use this to remember that you got an error or whether the `xxx()` function should return `NULL`. You should not store a string into `*error`! `error` points to a single-byte variable, not to a string buffer.

`*is_null` is reset for each group (before calling `xxx_clear()`). `*error` is never reset.

If `*is_null` or `*error` are set when `xxx()` returns, MySQL returns `NULL` as the result for the group function.

### 21.2.2.3. UDF Argument Processing

The `args` parameter points to a `UDF_ARGS` structure that has the members listed here:

- `unsigned int arg_count`

The number of arguments. Check this value in the initialization function if you require your function to be called with a particular number of arguments. For example:

```
if (args->arg_count != 2)
{
    strcpy(message, "XXX() requires two arguments");
```

```
return 1;
}
```

For other `UDF_ARGS` member values that are arrays, array references are zero-based. That is, refer to array members using index values from 0 to `args->arg_count - 1`.

- `enum Item_result *arg_type`

A pointer to an array containing the types for each argument. The possible type values are `STRING_RESULT`, `INT_RESULT`, `REAL_RESULT`, and `DECIMAL_RESULT`.

To make sure that arguments are of a given type and return an error if they are not, check the `arg_type` array in the initialization function. For example:

```
if (args->arg_type[0] != STRING_RESULT ||
    args->arg_type[1] != INT_RESULT)
{
    strcpy(message, "XXX() requires a string and an integer");
    return 1;
}
```

Arguments of type `DECIMAL_RESULT` are passed as strings, so you should handle them the same way as `STRING_RESULT` values.

As an alternative to requiring your function's arguments to be of particular types, you can use the initialization function to set the `arg_type` elements to the types you want. This causes MySQL to coerce arguments to those types for each call to `xxx()`. For example, to specify that the first two arguments should be coerced to string and integer, respectively, do this in `xxx_init()`:

```
args->arg_type[0] = STRING_RESULT;
args->arg_type[1] = INT_RESULT;
```

Exact-value decimal arguments such as `1.3` or `DECIMAL` column values are passed with a type of `DECIMAL_RESULT`. However, the values are passed as strings. If you want to receive a number, use the initialization function to specify that the argument should be coerced to a `REAL_RESULT` value:

```
args->arg_type[2] = REAL_RESULT;
```

### Note

Prior to MySQL 5.0.3, decimal arguments were passed as `REAL_RESULT` values. If you upgrade to a newer version and find that your UDF now receives string values, use the initialization function to coerce the arguments to numbers as just described.

- `char **args`

`args->args` communicates information to the initialization function about the general nature of the arguments passed to your function. For a constant argument `i`, `args->args[i]` points to the argument value. (See below for instructions on how to access the value properly.) For a non-constant argument, `args->args[i]` is 0. A constant argument is an expression that uses only constants, such as `3` or `4*7-2` or `SIN(3.14)`. A non-constant argument is an expression that refers to values that may change from row to row, such as column names or functions that are called with non-constant arguments.

For each invocation of the main function, `args->args` contains the actual arguments that are passed for the row currently being processed.

If argument `i` represents `NULL`, `args->args[i]` is a null pointer (0). If the argument is not `NULL`, functions can refer to it as follows:

- An argument of type `STRING_RESULT` is given as a string pointer plus a length, to allow handling of binary data or data of arbitrary length. The string contents are available as `args->args[i]` and the string length is `args->lengths[i]`. Do not assume that the string is null-terminated.
- For an argument of type `INT_RESULT`, you must cast `args->args[i]` to a `long long` value:

```
long long int_val;
int_val = *((long long*) args->args[i]);
```

- For an argument of type `REAL_RESULT`, you must cast `args->args[i]` to a `double` value:

```
double real_val;
```

```
real_val = *((double*) args->args[i]);
```

- For an argument of type `DECIMAL_RESULT`, the value is passed as a string and should be handled like a `STRING_RESULT` value.
- `ROW_RESULT` arguments are not implemented.
- `unsigned long *lengths`

For the initialization function, the `lengths` array indicates the maximum string length for each argument. You should not change these. For each invocation of the main function, `lengths` contains the actual lengths of any string arguments that are passed for the row currently being processed. For arguments of types `INT_RESULT` or `REAL_RESULT`, `lengths` still contains the maximum length of the argument (as for the initialization function).

- `char *maybe_null`

For the initialization function, the `maybe_null` array indicates for each argument whether the argument value might be null (0 if no, 1 if yes).

- `char **attributes`

`args->attributes` communicates information about the names of the UDF arguments. For argument `i`, the attribute name is available as a string in `args->attributes[i]` and the attribute length is `args->attribute_lengths[i]`. Do not assume that the string is null-terminated.

By default, the name of a UDF argument is the text of the expression used to specify the argument. For UDFs, an argument may also have an optional `[AS] alias_name` clause, in which case the argument name is `alias_name`. The `attributes` value for each argument thus depends on whether an alias was given.

Suppose that a UDF `my_udf()` is invoked as follows:

```
SELECT my_udf(expr1, expr2 AS alias1, expr3 alias2);
```

In this case, the `attributes` and `attribute_lengths` arrays will have these values:

```
args->attributes[0] = "expr1"
args->attribute_lengths[0] = 5

args->attributes[1] = "alias1"
args->attribute_lengths[1] = 6

args->attributes[2] = "alias2"
args->attribute_lengths[2] = 6
```

- `unsigned long *attribute_lengths`

The `attribute_lengths` array indicates the length of each argument name.

#### 21.2.2.4. UDF Return Values and Error Handling

The initialization function should return 0 if no error occurred and 1 otherwise. If an error occurs, `xxx_init()` should store a null-terminated error message in the `message` parameter. The message is returned to the client. The message buffer is `MYSQL_ERRMSG_SIZE` characters long, but you should try to keep the message to less than 80 characters so that it fits the width of a standard terminal screen.

The return value of the main function `xxx()` is the function value, for `long long` and `double` functions. A string function should return a pointer to the result and set `*length` to the length (in bytes) of the return value. For example:

```
memcpy(result, "result string", 13);
*length = 13;
```

MySQL passes a buffer to the `xxx()` function via the `result` parameter. This buffer is sufficiently long to hold 255 characters, which can be multi-byte characters. The `xxx()` function can store the result in this buffer if it fits, in which case the return value should be a pointer to the buffer. If the function stores the result in a different buffer, it should return a pointer to that buffer.

If your string function does not use the supplied buffer (for example, if it needs to return a string longer than 255 characters), you must allocate the space for your own buffer with `malloc()` in your `xxx_init()` function or your `xxx()` function and free it in your `xxx_deinit()` function. You can store the allocated memory in the `ptr` slot in the `UDF_INIT` structure for reuse by fu-

ture `xxx()` calls. See [Section 21.2.2.1, “UDF Calling Sequences for Simple Functions”](#).

To indicate a return value of `NULL` in the main function, set `*is_null` to 1:

```
*is_null = 1;
```

To indicate an error return in the main function, set `*error` to 1:

```
*error = 1;
```

If `xxx()` sets `*error` to 1 for any row, the function value is `NULL` for the current row and for any subsequent rows processed by the statement in which `XXX()` was invoked. (`xxx()` is not even called for subsequent rows.)

### 21.2.2.5. Compiling and Installing User-Defined Functions

Files implementing UDFs must be compiled and installed on the host where the server runs. This process is described below for the example UDF file `sql/udf_example.c` that is included in the MySQL source distribution.

The immediately following instructions are for Unix. Instructions for Windows are given later in this section.

The `udf_example.c` file contains the following functions:

- `metaphon()` returns a metaphon string of the string argument. This is something like a soundex string, but it is more tuned for English.
- `myfunc_double()` returns the sum of the ASCII values of the characters in its arguments, divided by the sum of the length of its arguments.
- `myfunc_int()` returns the sum of the length of its arguments.
- `sequence([const int])` returns a sequence starting from the given number or 1 if no number has been given.
- `lookup()` returns the IP number for a host name.
- `reverse_lookup()` returns the host name for an IP number. The function may be called either with a single string argument of the form `'xxx.xxx.xxx.xxx'` or with four numbers.

A dynamically loadable file should be compiled as a sharable object file, using a command something like this:

```
shell> gcc -shared -o udf_example.so udf_example.c
```

If you are using `gcc` with `configure` and `libtool` (which is how MySQL is configured), you should be able to create `udf_example.so` with a simpler command:

```
shell> make udf_example.la
```

After you compile a shared object containing UDFs, you must install it and tell MySQL about it. Compiling a shared object from `udf_example.c` using `gcc` directly produces a file named `udf_example.so`. Compiling the shared object using `make` produces a file named something like `udf_example.so.0.0.0` in the `.libs` directory (the exact name may vary from platform to platform). Copy the shared object to some directory such as `/usr/lib` that is searched by your system's dynamic (runtime) linker, or add the directory in which you placed the shared object to the linker configuration file (for example, `/etc/ld.so.conf`).

The dynamic linker name is system-specific (for example, `ld-elf.so.1` on FreeBSD, `ld.so` on Linux, or `dyld` on Mac OS X). Consult your system documentation for information about the linker name and how to configure it.

On many systems, you can also set the `LD_LIBRARY` or `LD_LIBRARY_PATH` environment variable to point at the directory where you have the files for your UDF. The `dlopen` manual page tells you which variable you should use on your system. You should set this in `mysql.server` or `mysqld_safe` startup scripts and restart `mysqld`.

On some systems, the `ldconfig` program that configures the dynamic linker does not recognize a shared object unless its name begins with `lib`. In this case you should rename a file such as `udf_example.so` to `libudf_example.so`.

On Windows, you can compile user-defined functions by using the following procedure:

1. You need to obtain the Bazaar source repository for MySQL 5.0. See [Section 2.16.3, “Installing from the Development Source Tree”](#).

2. You must obtain the CMake build utility from <http://www.cmake.org>. (Version 2.4.2 or later is required).
3. In the source repository, look in the `sql` directory. There are files named `udf_example.def` `udf_example.c` there. Copy both files from this directory to your working directory.
4. Create a CMake `makefile` (`CMakeLists.txt`) with these contents:

```
PROJECT(udf_example)

# Path for MySQL include directory
INCLUDE_DIRECTORIES("c:/mysql/include")

ADD_DEFINITIONS("-DHAVE_DLOPEN")
ADD_LIBRARY(udf_example MODULE udf_example.c udf_example.def)
TARGET_LINK_LIBRARIES(udf_example wsock32)
```

5. Create the VC project and solution files:

```
cmake -G "<Generator>"
```

Invoking `cmake --help` shows you a list of valid Generators.

6. Create `udf_example.dll`:

```
devenv udf_example.sln /build Release
```

After the shared object file has been installed, notify `mysqld` about the new functions with these statements:

```
mysql> CREATE FUNCTION metaphon RETURNS STRING SONAME 'udf_example.dll';
mysql> CREATE FUNCTION myfunc_double RETURNS REAL SONAME 'udf_example.dll';
mysql> CREATE FUNCTION myfunc_int RETURNS INTEGER SONAME 'udf_example.dll';
mysql> CREATE FUNCTION sequence RETURNS INTEGER SONAME 'udf_example.dll';
mysql> CREATE FUNCTION lookup RETURNS STRING SONAME 'udf_example.dll';
mysql> CREATE FUNCTION reverse_lookup
-> RETURNS STRING SONAME 'udf_example.dll';
mysql> CREATE AGGREGATE FUNCTION avgcost
-> RETURNS REAL SONAME 'udf_example.dll';
```

Functions can be deleted using `DROP FUNCTION`:

```
mysql> DROP FUNCTION metaphon;
mysql> DROP FUNCTION myfunc_double;
mysql> DROP FUNCTION myfunc_int;
mysql> DROP FUNCTION sequence;
mysql> DROP FUNCTION lookup;
mysql> DROP FUNCTION reverse_lookup;
mysql> DROP FUNCTION avgcost;
```

The `CREATE FUNCTION` and `DROP FUNCTION` statements update the `func` system table in the `mysql` database. The function's name, type and shared library name are saved in the table. You must have the `INSERT` and `DELETE` privileges for the `mysql` database to create and drop functions.

You should not use `CREATE FUNCTION` to add a function that has previously been created. If you need to reinstall a function, you should remove it with `DROP FUNCTION` and then reinstall it with `CREATE FUNCTION`. You would need to do this, for example, if you recompile a new version of your function, so that `mysqld` gets the new version. Otherwise, the server continues to use the old version.

An active function is one that has been loaded with `CREATE FUNCTION` and not removed with `DROP FUNCTION`. All active functions are reloaded each time the server starts, unless you start `mysqld` with the `--skip-grant-tables` option. In this case, UDF initialization is skipped and UDFs are unavailable.

If the new function will be referred to in statements that will be replicated to slave servers, you must ensure that every slave server also has the function available. Otherwise, replication will fail on the slaves when they attempt to invoke the function.

### 21.2.2.6. User-Defined Function Security Precautions

MySQL takes the following measures to prevent misuse of user-defined functions.

You must have the `INSERT` privilege to be able to use `CREATE FUNCTION` and the `DELETE` privilege to be able to use `DROP FUNCTION`. This is necessary because these statements add and delete rows from the `mysql.func` table.

UDFs should have at least one symbol defined in addition to the `xxx` symbol that corresponds to the main `xxx()` function. These auxiliary symbols correspond to the `xxx_init()`, `xxx_deinit()`, `xxx_reset()`, `xxx_clear()`, and `xxx_add()` func-

tions. As of MySQL 5.0.3, `mysqld` supports an `--allow-suspicious-udfs` option that controls whether UDFs that have only an `xxx` symbol can be loaded. By default, the option is off, to prevent attempts at loading functions from shared object files other than those containing legitimate UDFs. If you have older UDFs that contain only the `xxx` symbol and that cannot be recompiled to include an auxiliary symbol, it may be necessary to specify the `--allow-suspicious-udfs` option. Otherwise, you should avoid enabling this capability.

UDF object files cannot be placed in arbitrary directories. They must be located in some system directory that the dynamic linker is configured to search. To enforce this restriction and prevent attempts at specifying path names outside of directories searched by the dynamic linker, MySQL checks the shared object file name specified in `CREATE FUNCTION` statements for path name delimiter characters. As of MySQL 5.0.3, MySQL also checks for path name delimiters in file names stored in the `mysql.func` table when it loads functions. This prevents attempts at specifying illegitimate path names through direct manipulation of the `mysql.func` table. For information about UDFs and the runtime linker, see [Section 21.2.2.5, “Compiling and Installing User-Defined Functions”](#).

### 21.2.3. Adding a New Native Function

To add a new native MySQL function, use the procedure described here, which requires that you use a source distribution. You cannot add native functions to a binary distribution because it is necessary to modify MySQL source code and compile MySQL from the modified source. If you migrate to another version of MySQL (for example, when a new version is released), you must repeat the procedure with the new version.

If the new native function will be referred to in statements that will be replicated to slave servers, you must ensure that every slave server also has the function available. Otherwise, replication will fail on the slaves when they attempt to invoke the function.

To add a new native function, follow these steps to modify source files in the `sql` directory:

1. Add one line to `lex.h` that defines the function name in the `sql_functions[]` array.
2. If the function prototype is simple (just takes zero, one, two, or three arguments), add a line to the `sql_functions[]` array in `lex.h` that specifies `SYM(FUNC_ARGN)` as the second argument (where `N` is the number of arguments the function takes). Also, add a function in `item_create.cc` that creates a function object. Look at `"ABS"` and `create_funcs_abs()` for an example of this.

If the function prototype is not simple (for example, if it takes a variable number of arguments), you should make two changes to `sql_yacc.yy`. One is a line that indicates the preprocessor symbol that `yacc` should define; this should be added at the beginning of the file. The other is an “item” to be added to the `simple_expr` parsing rule that defines the function parameters. You will need an item for each syntax with which the function can be called. For an example that shows how this is done, check all occurrences of `ATAN` in `sql_yacc.yy`.

3. In `item_func.h`, declare a class inheriting from `Item_num_func` or `Item_str_func`, depending on whether your function returns a number or a string.
4. In `item_func.cc`, add one of the following declarations, depending on whether you are defining a numeric or string function:

```
double Item_func_newname::val()
longlong Item_func_newname::val_int()
String *Item_func_newname::Str(String *str)
```

If you inherit your object from any of the standard items (like `Item_num_func`), you probably only have to define one of these functions and let the parent object take care of the other functions. For example, the `Item_str_func` class defines a `val()` function that executes `atof()` on the value returned by `::str()`.

5. If the function is non-deterministic, include the following statement in the item constructor to indicate that function results should not be cached:

```
current_thd->lex->safe_to_cache_query=0;
```

A function is non-deterministic if, given fixed values for its arguments, it can return different results for different invocations.

6. You should probably also define the following object function:

```
void Item_func_newname::fix_length_and_dec()
```

This function should at least calculate `max_length` based on the given arguments. `max_length` is the maximum number of characters the function may return. This function should also set `maybe_null = 0` if the main function can't return a `NULL` value. The function can check whether any of the function arguments can return `NULL` by checking the arguments' `maybe_null` variable. Look at `Item_func_mod::fix_length_and_dec` for a typical example of how to do this.

All functions must be thread-safe. In other words, do not use any global or static variables in the functions without protecting them with mutexes.

If you want to return `NULL` from `::val()`, `::val_int()`, or `::str()`, you should set `null_value` to 1 and return 0.

For `::str()` object functions, there are additional considerations to be aware of:

- The `String *str` argument provides a string buffer that may be used to hold the result. (For more information about the `String` type, take a look at the `sql_string.h` file.)
- The `::str()` function should return the string that holds the result, or `(char*) 0` if the result is `NULL`.
- All current string functions try to avoid allocating any memory unless absolutely necessary!

## 21.3. Adding New Procedures to MySQL

In MySQL, you can define a procedure in C++ that can access and modify the data in a query before it is sent to the client. The modification can be done on a row-by-row or `GROUP BY` level.

We have created an example procedure to show you what can be done.

Additionally, we recommend that you take a look at `mylua`. With this you can use the LUA language to load a procedure at runtime into `mysqld`.

### 21.3.1. PROCEDURE ANALYSE

```
analyse([max_elements[,max_memory]])
```

This procedure is defined in the `sql/sql_analyse.cc` file. It examines the result from a query and returns an analysis of the results that suggests optimal data types for each column. To obtain this analysis, append `PROCEDURE ANALYSE` to the end of a `SELECT` statement:

```
SELECT ... FROM ... WHERE ... PROCEDURE ANALYSE([max_elements,[max_memory]])
```

For example:

```
SELECT col1, col2 FROM table1 PROCEDURE ANALYSE(10, 2000);
```

The results show some statistics for the values returned by the query, and propose an optimal data type for the columns. This can be helpful for checking your existing tables, or after importing new data. You may need to try different settings for the arguments so that `PROCEDURE ANALYSE()` does not suggest the `ENUM` data type when it is not appropriate.

The arguments are optional and are used as follows:

- `max_elements` (default 256) is the maximum number of distinct values that `analyse` notices per column. This is used by `analyse` to check whether the optimal data type should be of type `ENUM`; if there are more than `max_elements` distinct values, then `ENUM` is not a suggested type.
- `max_memory` (default 8192) is the maximum amount of memory that `analyse` should allocate per column while trying to find all distinct values.

### 21.3.2. Writing a Procedure

For the moment, the only documentation for this is the source.

You can find all information about procedures by examining the following files:

- `sql/sql_analyse.cc`
- `sql/procedure.h`
- `sql/procedure.cc`
- `sql/sql_select.cc`

## 21.4. Debugging and Porting MySQL

This appendix helps you port MySQL to other operating systems. Do check the list of currently supported operating systems first. See [Section 2.4.2, “Operating Systems Supported by MySQL Community Server”](#). If you have created a new port of MySQL, please let us know so that we can list it here and on our Web site (<http://www.mysql.com/>), recommending it to other users.

Note: If you create a new port of MySQL, you are free to copy and distribute it under the GPL license, but it does not make you a copyright holder of MySQL.

A working POSIX thread library is needed for the server. On Solaris 2.5 we use Sun PThreads (the native thread support in 2.4 and earlier versions is not good enough), on Linux we use LinuxThreads by Xavier Leroy, <[Xavier.Leroy@inria.fr](mailto:Xavier.Leroy@inria.fr)>.

The hard part of porting to a new Unix variant without good native thread support is probably to port MIT-pthreads. See [mit-pthreads/README](#) and Programming POSIX Threads (<http://www.humanfactor.com/pthreads/>).

Up to MySQL 4.0.2, the MySQL distribution included a patched version of Chris Provenzano's Pthreads from MIT (see the MIT Pthreads Web page at <http://www.mit.edu/afs/sipb/project/pthreads/> and a programming introduction at [http://www.mit.edu:8001/people/proven/IAP\\_2000/](http://www.mit.edu:8001/people/proven/IAP_2000/)). These can be used for some operating systems that do not have POSIX threads. See [Section 2.16.5, “MIT-pthreads Notes”](#).

It is also possible to use another user level thread package named FSU Pthreads (see <http://moss.csc.ncsu.edu/~mueller/pthreads/>). This implementation is being used for the SCO port.

See the `thr_lock.c` and `thr_alarm.c` programs in the `mysys` directory for some tests/examples of these problems.

Both the server and the client need a working C++ compiler. We use `gcc` on many platforms. Other compilers that are known to work are SPARCworks, Sun Forte, Irix `cc`, HP-UX `aCC`, IBM AIX `x1C_r`, Intel `ecc/icc` and Compaq `cxx`.

### Important

If you are trying to build MySQL 5.1 with `icc` on the IA64 platform, and need support for MySQL Cluster, you should first ensure that you are using `icc` version 9.1.043 or later. (For details, see [Bug#21875](#).)

To compile only the client use `./configure --without-server`.

There is currently no support for only compiling the server, nor is it likely to be added unless someone has a good reason for it.

If you want/need to change any `Makefile` or the configure script you also need GNU Automake and Autoconf. See [Section 2.16.3, “Installing from the Development Source Tree”](#).

All steps needed to remake everything from the most basic files.

```
/bin/rm */.deps/*.P
/bin/rm -f config.cache
aclocal
autoheader
aclocal
automake
autoconf
./configure --with-debug=full --prefix='your installation directory'

# The makefiles generated above need GNU make 3.75 or newer.
# (called gmake below)
gmake clean all install init-db
```

If you run into problems with a new port, you may have to do some debugging of MySQL! See [Section 21.4.1, “Debugging a MySQL Server”](#).

### Note

Before you start debugging `mysqld`, first get the test programs `mysys/thr_alarm` and `mysys/thr_lock` to work. This ensures that your thread installation has even a remote chance to work!

### 21.4.1. Debugging a MySQL Server

If you are using some functionality that is very new in MySQL, you can try to run `mysqld` with the `--skip-new` (which disables all new, potentially unsafe functionality) or with `--safe-mode` which disables a lot of optimization that may cause problems. See [Section B.1.4.2, “What to Do If MySQL Keeps Crashing”](#).

If `mysqld` doesn't want to start, you should verify that you don't have any `my.cnf` files that interfere with your setup! You can check your `my.cnf` arguments with `mysqld --print-defaults` and avoid using them by starting with `mysqld --no-defaults ...`

If `mysqld` starts to eat up CPU or memory or if it “hangs,” you can use `mysqladmin processlist status` to find out if someone is executing a query that takes a long time. It may be a good idea to run `mysqladmin -i10 processlist status` in some window if you are experiencing performance problems or problems when new clients can't connect.

The command `mysqladmin debug` dumps some information about locks in use, used memory and query usage to the MySQL log file. This may help solve some problems. This command also provides some useful information even if you haven't compiled MySQL for debugging!

If the problem is that some tables are getting slower and slower you should try to optimize the table with `OPTIMIZE TABLE` or `myisamchk`. See [Chapter 5, MySQL Server Administration](#). You should also check the slow queries with `EXPLAIN`.

You should also read the OS-specific section in this manual for problems that may be unique to your environment. See [Section 2.19, “Operating System-Specific Notes”](#).

### 21.4.1.1. Compiling MySQL for Debugging

If you have some very specific problem, you can always try to debug MySQL. To do this you must configure MySQL with the `--with-debug` or the `--with-debug=full` option. You can check whether MySQL was compiled with debugging by doing: `mysqld --help`. If the `--debug` flag is listed with the options then you have debugging enabled. `mysqladmin ver` also lists the `mysqld` version as `mysql ... --debug` in this case.

If you are using `gcc`, the recommended `configure` line is:

```
CC=gcc CFLAGS="-O2" CXX=gcc CXXFLAGS="-O2 -felide-constructors \
-fno-exceptions -fno-rtti" ./configure --prefix=/usr/local/mysql \
--with-debug --with-extra-charsets=complex
```

This avoids problems with the `libstdc++` library and with C++ exceptions (many compilers have problems with C++ exceptions in threaded code) and compile a MySQL version with support for all character sets.

If you suspect a memory overrun error, you can configure MySQL with `--with-debug=full`, which installs a memory allocation (`SAFEMALLOC`) checker. However, running with `SAFEMALLOC` is quite slow, so if you get performance problems you should start `mysqld` with the `--skip-safemalloc` option. This disables the memory overrun checks for each call to `malloc()` and `free()`.

If `mysqld` stops crashing when you compile it with `--with-debug`, you probably have found a compiler bug or a timing bug within MySQL. In this case, you can try to add `-g` to the `CFLAGS` and `CXXFLAGS` variables above and not use `--with-debug`. If `mysqld` dies, you can at least attach to it with `gdb` or use `gdb` on the core file to find out what happened.

When you configure MySQL for debugging you automatically enable a lot of extra safety check functions that monitor the health of `mysqld`. If they find something “unexpected,” an entry is written to `stderr`, which `mysqld_safe` directs to the error log! This also means that if you are having some unexpected problems with MySQL and are using a source distribution, the first thing you should do is to configure MySQL for debugging! (The second thing is to send mail to a MySQL mailing list and ask for help. See [Section 1.5.1, “MySQL Mailing Lists”](#). If you believe that you have found a bug, please use the instructions at [Section 1.6, “How to Report Bugs or Problems”](#)).

In the Windows MySQL distribution, `mysqld.exe` is by default compiled with support for trace files. See also [Section 21.4.1.2, “Creating Trace Files”](#).

### 21.4.1.2. Creating Trace Files

If the `mysqld` server doesn't start or if you can cause it to crash quickly, you can try to create a trace file to find the problem.

To do this, you must have a `mysqld` that has been compiled with debugging support. You can check this by executing `mysqld -V`. If the version number ends with `-debug`, it is compiled with support for trace files. (On Windows, the debugging server is named `mysqld-debug` rather than `mysqld` as of MySQL 4.1.)

Start the `mysqld` server with a trace log in `/tmp/mysqld.trace` on Unix or `C:\mysqld.trace` on Windows:

```
shell> mysqld --debug
```

On Windows, you should also use the `--standalone` flag to not start `mysqld` as a service. In a console window, use this command:

```
C:\> mysqld-debug --debug --standalone
```

After this, you can use the `mysql.exe` command-line tool in a second console window to reproduce the problem. You can stop the `mysqld` server with `mysqladmin shutdown`.

Note that the trace file become **very big**! If you want to generate a smaller trace file, you can use debugging options something like this:

```
mysqld --debug=d,info,error,query,general,where:0,/tmp/mysqld.trace
```

This only prints information with the most interesting tags to the trace file.

If you make a bug report about this, please only send the lines from the trace file to the appropriate mailing list where something seems to go wrong! If you can't locate the wrong place, you can ftp the trace file, together with a full bug report, to <ftp://ftp.mysql.com/pub/mysql/upload/> so that a MySQL developer can take a look at it.

The trace file is made with the **DEBUG** package by Fred Fish. See [Section 21.4.3, “The DEBUG Package”](#).

### 21.4.1.3. Using `pdb` to create a Windows crashdump

Starting with MySQL 5.0.24 the Program Database files (extension `pdb`) are included in the Noinstall distribution of MySQL. These files provide information for debugging your MySQL installation in the event of a problem.

The PDB file contains more detailed information about `mysqld` and other tools that enables more detailed trace and dump files to be created. You can use these with Dr Watson, `WinDbg` and Visual Studio to debug `mysqld`.

For more information on PDB files, see [Microsoft Knowledge Base Article 121366](#). For more information on the debugging options available, see [Debugging Tools for Windows](#).

Dr Watson is installed with all Windows distributions, but if you have installed Windows development tools, Dr Watson may have been replaced with `WinDbg`, the debugger included with Visual Studio, or the debugging tools provided with Borland or Delphi.

To generate a crash file using Dr Watson, follow these steps:

1. Start Dr Watson by running `drwtsn32.exe` interactively using the `-i` option:

```
C:\> drwtsn32 -i
```

2. Set the **LOG FILE PATH** to the directory where you want to store trace files.
3. Make sure **DUMP ALL THREAD CONTEXTS** and **APPEND TO EXISTING LOG FILE**.
4. Uncheck **DUMP SYMBOL TABLE**, **VISUAL NOTIFICATION**, **SOUND NOTIFICATION** and **CREATE CRASH DUMP FILE**.
5. Set the **NUMBER OF INSTRUCTIONS** to a suitable value to capture enough calls in the stacktrace. A value of at 25 should be enough.

Note that the file generated can be very large.

### 21.4.1.4. Debugging `mysqld` under `gdb`

On most systems you can also start `mysqld` from `gdb` to get more information if `mysqld` crashes.

With some older `gdb` versions on Linux you must use `run --one-thread` if you want to be able to debug `mysqld` threads. In this case, you can only have one thread active at a time. We recommend you to upgrade to `gdb` 5.1 ASAP as thread debugging works much better with this version!

NPTL threads (the new thread library on Linux) may cause problems while running `mysqld` under `gdb`. Some symptoms are:

- `mysqld` hangs during startup (before it writes `ready for connections`).
- `mysqld` crashes during a `pthread_mutex_lock()` or `pthread_mutex_unlock()` call.

In this case, you should set the following environment variable in the shell before starting `gdb`:

```
LD_ASSUME_KERNEL=2.4.1
export LD_ASSUME_KERNEL
```

When running `mysqld` under `gdb`, you should disable the stack trace with `--skip-stack-trace` to be able to catch segfaults within `gdb`.

In MySQL 4.0.14 and above you should use the `--gdb` option to `mysqld`. This installs an interrupt handler for `SIGINT` (needed to stop `mysqld` with `^C` to set breakpoints) and disable stack tracing and core file handling.

It is very hard to debug MySQL under `gdb` if you do a lot of new connections the whole time as `gdb` doesn't free the memory for old threads. You can avoid this problem by starting `mysqld` with `thread_cache_size` set to a value equal to `max_connections + 1`. In most cases just using `--thread_cache_size=5` helps a lot!

If you want to get a core dump on Linux if `mysqld` dies with a `SIGSEGV` signal, you can start `mysqld` with the `--core-file` option. This core file can be used to make a backtrace that may help you find out why `mysqld` died:

```
shell> gdb mysqld core
gdb> backtrace full
gdb> quit
```

See [Section B.1.4.2, "What to Do If MySQL Keeps Crashing"](#).

If you are using `gdb` 4.17.x or above on Linux, you should install a `.gdb` file, with the following information, in your current directory:

```
set print sevenbit off
handle SIGUSR1 nostop noprint
handle SIGUSR2 nostop noprint
handle SIGWAITING nostop noprint
handle SIGLWP nostop noprint
handle SIGPIPE nostop
handle SIGALRM nostop
handle SIGHUP nostop
handle SIGTERM nostop noprint
```

If you have problems debugging threads with `gdb`, you should download `gdb` 5.x and try this instead. The new `gdb` version has very improved thread handling!

Here is an example how to debug `mysqld`:

```
shell> gdb /usr/local/libexec/mysqld
gdb> run
...
backtrace full # Do this when mysqld crashes
```

Include the above output in a bug report, which you can file using the instructions in [Section 1.6, "How to Report Bugs or Problems"](#).

If `mysqld` hangs you can try to use some system tools like `strace` or `/usr/proc/bin/pstack` to examine where `mysqld` has hung.

```
strace /tmp/log libexec/mysqld
```

If you are using the Perl `DBI` interface, you can turn on debugging information by using the `trace` method or by setting the `DBI_TRACE` environment variable.

### 21.4.1.5. Using a Stack Trace

On some operating systems, the error log contains a stack trace if `mysqld` dies unexpectedly. You can use this to find out where (and maybe why) `mysqld` died. See [Section 5.2.1, "The Error Log"](#). To get a stack trace, you must not compile `mysqld` with the `-fomit-frame-pointer` option to `gcc`. See [Section 21.4.1.1, "Compiling MySQL for Debugging"](#).

A stack trace in the error log looks something like this:

```
mysqld got signal 11;
Attempting backtrace. You can use the following information
to find out where mysqld died. If you see no messages after
this, something went terribly wrong...

stack range sanity check, ok, backtrace follows
0x40077552
0x81281a0
0x8128f47
0x8127be0
0x8127995
0x8104947
0x80ff28f
0x810131b
0x80ee4bc
0x80c3c91
0x80c6b43
0x80c1fd9
0x80c1686
```

You can use the `resolve_stack_dump` utility to determine where `mysqld` died by using the following procedure:

1. Copy the preceding numbers to a file, for example `mysqld.stack`:

```
0x9da402
0x6648e9
0x7f1a5af000f0
0x7f1a5a10f0f2
0x7412cb
0x688354
0x688494
0x67a170
0x67f0ad
0x67fd8f8
0x6811b6
0x66e05e
```

2. Make a symbol file for the `mysqld` server:

```
shell> nm -n libexec/mysqld > /tmp/mysqld.sym
```

If `mysqld` is not linked statically, use the following command instead:

```
shell> nm -D -n libexec/mysqld > /tmp/mysqld.sym
```

If you want to decode C++ symbols, use the `--demangle`, if available, to `nm`. If your version of `nm` does not have this option, you will need to use the `c++filt` command after the stack dump has been produced to demangle the C++ names.

3. Execute the following command:

```
shell> resolve_stack_dump -s /tmp/mysqld.sym -n mysqld.stack
```

If you were not able to include demangled C++ names in your symbol file, process the `resolve_stack_dump` output using `c++filt`:

```
shell> resolve_stack_dump -s /tmp/mysqld.sym -n mysqld.stack | c++filt
```

This prints out where `mysqld` died. If that does not help you find out why `mysqld` died, you should create a bug report and include the output from the preceding command with the bug report.

However, in most cases it does not help us to have just a stack trace to find the reason for the problem. To be able to locate the bug or provide a workaround, in most cases we need to know the statement that killed `mysqld` and preferably a test case so that we can repeat the problem! See [Section 1.6, “How to Report Bugs or Problems”](#).

### 21.4.1.6. Using Server Logs to Find Causes of Errors in `mysqld`

Note that before starting `mysqld` with the general query log enabled, you should check all your tables with `myisamchk`. See [Chapter 5, \*MySQL Server Administration\*](#).

If `mysqld` dies or hangs, you should start `mysqld` with the general query log enabled. See [Section 5.2.2, “The General Query Log”](#). When `mysqld` dies again, you can examine the end of the log file for the query that killed `mysqld`.

If you use the default general query log file, the log is stored in the database directory as `host_name.log`. In most cases it is the last query in the log file that killed `mysqld`, but if possible you should verify this by restarting `mysqld` and executing the found query from the `mysql` command-line tools. If this works, you should also test all complicated queries that didn't complete.

You can also try the command `EXPLAIN` on all `SELECT` statements that takes a long time to ensure that `mysqld` is using indexes properly. See [Section 12.3.2, “EXPLAIN Syntax”](#).

You can find the queries that take a long time to execute by starting `mysqld` with the slow query log enabled. See [Section 5.2.4, “The Slow Query Log”](#).

If you find the text `mysqld restarted` in the error log file (normally named `hostname.err`) you probably have found a query that causes `mysqld` to fail. If this happens, you should check all your tables with `myisamchk` (see [Chapter 5, \*MySQL Server Administration\*](#)), and test the queries in the MySQL log files to see whether one fails. If you find such a query, try first upgrading to the newest MySQL version. If this doesn't help and you can't find anything in the `mysql` mail archive, you should report the bug to a MySQL mailing list. The mailing lists are described at <http://lists.mysql.com/>, which also has links to online list archives.

If you have started `mysqld` with `--myisam-recover`, MySQL automatically checks and tries to repair `MyISAM` tables if they are marked as 'not closed properly' or 'crashed'. If this happens, MySQL writes an entry in the `hostname.err` file 'Warning:

`Checking table ...'` which is followed by `Warning: Repairing table` if the table needs to be repaired. If you get a lot of these errors, without `mysqld` having died unexpectedly just before, then something is wrong and needs to be investigated further. See [Section 5.1.2, “Server Command Options”](#).

It is not a good sign if `mysqld` did die unexpectedly, but in this case, you should not investigate the `Checking table...` messages, but instead try to find out why `mysqld` died.

### 21.4.1.7. Making a Test Case If You Experience Table Corruption

If you get corrupted tables or if `mysqld` always fails after some update commands, you can test whether this bug is reproducible by doing the following:

- Take down the MySQL daemon (with `mysqladmin shutdown`).
- Make a backup of the tables (to guard against the very unlikely case that the repair does something bad).
- Check all tables with `myisamchk -s database/*.MYI`. Repair any wrong tables with `myisamchk -r database/table.MYI`.
- Make a second backup of the tables.
- Remove (or move away) any old log files from the MySQL data directory if you need more space.
- Start `mysqld` with the binary log enabled. If you want to find a query that crashes `mysqld`, you should start the server with both the general query log enabled as well. See [Section 5.2.2, “The General Query Log”](#), and [Section 5.2.3, “The Binary Log”](#).
- When you have gotten a crashed table, stop the `mysqld server`.
- Restore the backup.
- Restart the `mysqld` server **without** the binary log enabled.
- Re-execute the commands with `mysqlbinlog binary-log-file | mysql`. The binary log is saved in the MySQL database directory with the name `hostname-bin.NNNNNN`.
- If the tables are corrupted again or you can get `mysqld` to die with the above command, you have found reproducible bug that should be easy to fix! FTP the tables and the binary log to <ftp://ftp.mysql.com/pub/mysql/upload/> and report it in our bugs database using the instructions given in [Section 1.6, “How to Report Bugs or Problems”](#). (Please note that the `/pub/mysql/upload/` FTP directory is not listable, so you'll not see what you've uploaded in your FTP client.) If you are a support customer, you can use the MySQL Customer Support Center <https://support.mysql.com/> to alert the MySQL team about the problem and have it fixed as soon as possible.

You can also use the script `mysql_find_rows` to just execute some of the update statements if you want to narrow down the problem.

The preceding discussion applies only to RHEL4. The patch is unnecessary for RHEL5.

## 21.4.2. Debugging a MySQL Client

To be able to debug a MySQL client with the integrated debug package, you should configure MySQL with `--with-debug` or `--with-debug=full`. See [Section 2.16.2, “Typical configure Options”](#).

Before running a client, you should set the `MYSQL_DEBUG` environment variable:

```
shell> MYSQL_DEBUG=d:t:O,/tmp/client.trace
shell> export MYSQL_DEBUG
```

This causes clients to generate a trace file in `/tmp/client.trace`.

If you have problems with your own client code, you should attempt to connect to the server and run your query using a client that is known to work. Do this by running `mysql` in debugging mode (assuming that you have compiled MySQL with debugging on):

```
shell> mysql --debug=d:t:O,/tmp/client.trace
```

This provides useful information in case you mail a bug report. See [Section 1.6, “How to Report Bugs or Problems”](#).

If your client crashes at some 'legal' looking code, you should check that your `mysql.h` include file matches your MySQL library file. A very common mistake is to use an old `mysql.h` file from an old MySQL installation with new MySQL library.

## 21.4.3. The DBUG Package

The MySQL server and most MySQL clients are compiled with the DBUG package originally created by Fred Fish. When you have configured MySQL for debugging, this package makes it possible to get a trace file of what the program is debugging. See [Section 21.4.1.2, “Creating Trace Files”](#).

This section summarizes the argument values that you can specify in debug options on the command line for MySQL programs that have been built with debugging support. For more information about programming with the DBUG package, see the DBUG manual in the `debug` directory of MySQL source distributions. It is best to use a recent distribution to get the most updated DBUG manual.

You use the debug package by invoking a program with the `--debug="..."` or the `-#...` option.

Most MySQL programs have a default debug string that is used if you don't specify an option to `--debug`. The default trace file is usually `/tmp/program_name.trace` on Unix and `\program_name.trace` on Windows.

The debug control string is a sequence of colon-separated fields as follows:

```
<field_1>:<field_2>:...:<field_N>
```

Each field consists of a mandatory flag character followed by an optional “,” and comma-separated list of modifiers:

```
flag[,modifier,modifier,...,modifier]
```

The following table shows the currently recognized flag characters.

Flag	Description
<code>d</code>	Enable output from <code>DEBUG_&lt;N&gt;</code> macros for the current state. May be followed by a list of keywords which selects output only for the DBUG macros with that keyword. An empty list of keywords implies output for all macros.
<code>D</code>	Delay after each debugger output line. The argument is the number of tenths of seconds to delay, subject to machine capabilities. For example, <code>-#D, 20</code> specifies a delay of two seconds.
<code>f</code>	Limit debugging, tracing, and profiling to the list of named functions. Note that a null list disables all functions. The appropriate <code>d</code> or <code>t</code> flags must still be given; this flag only limits their actions if they are enabled.
<code>F</code>	Identify the source file name for each line of debug or trace output.
<code>i</code>	Identify the process with the PID or thread ID for each line of debug or trace output.
<code>g</code>	Enable profiling. Create a file called <code>debugmon.out</code> containing information that can be used to profile the program. May be followed by a list of keywords that select profiling only for the functions in that list. A null list implies that all functions are considered.
<code>L</code>	Identify the source file line number for each line of debug or trace output.
<code>n</code>	Print the current function nesting depth for each line of debug or trace output.
<code>N</code>	Number each line of debug output.
<code>o</code>	Redirect the debugger output stream to the specified file. The default output is <code>stderr</code> .
<code>O</code>	Like <code>o</code> , but the file is really flushed between each write. When needed, the file is closed and reopened between each write.
<code>p</code>	Limit debugger actions to specified processes. A process must be identified with the <code>DEBUG_PROCESS</code> macro and match one in the list for debugger actions to occur.
<code>P</code>	Print the current process name for each line of debug or trace output.
<code>r</code>	When pushing a new state, do not inherit the previous state's function nesting level. Useful when the output is to start at the left margin.
<code>S</code>	Do function <code>_sanity(_file_, _line_)</code> at each debugged function until <code>_sanity()</code> returns something that differs from 0. (Mostly used with <code>safemalloc</code> to find memory leaks)
<code>t</code>	Enable function call/exit trace lines. May be followed by a list (containing only one modifier) giving a numeric maximum trace level, beyond which no output occurs for either debugging or tracing macros. The default is a compile time option.

Some examples of debug control strings that might appear on a shell command line (the `-#` is typically used to introduce a control string to an application program) are:

```
-#d:t
-#d:f,main,subr1:F:L:t,20
-#d,input,output,files:n
-#d:t:i:0,\\mysql.trace
```

In MySQL, common tags to print (with the `d` option) are `enter`, `exit`, `error`, `warning`, `info`, and `loop`.

## 21.4.4. Comments about RTS Threads

I have tried to use the RTS thread packages with MySQL but stumbled on the following problems:

They use old versions of many POSIX calls and it is very tedious to make wrappers for all functions. I am inclined to think that it would be easier to change the thread libraries to the newest POSIX specification.

Some wrappers are currently written. See [mysys/my\\_pthread.c](#) for more info.

At least the following should be changed:

`pthread_get_specific` should use one argument. `sigwait` should take two arguments. A lot of functions (at least `pthread_cond_wait`, `pthread_cond_timedwait()`) should return the error code on error. Now they return -1 and set `errno`.

Another problem is that user-level threads use the `ALRM` signal and this aborts a lot of functions (`read`, `write`, `open`...). MySQL should do a retry on interrupt on all of these but it is not that easy to verify it.

The biggest unsolved problem is the following:

To get thread-level alarms I changed `mysys/thr_alarm.c` to wait between alarms with `pthread_cond_timedwait()`, but this aborts with error `EINTR`. I tried to debug the thread library as to why this happens, but couldn't find any easy solution.

If someone wants to try MySQL with RTS threads I suggest the following:

- Change functions MySQL uses from the thread library to POSIX. This shouldn't take that long.
- Compile all libraries with the `-DHAVE_rts_threads`.
- Compile `thr_alarm`.
- If there are some small differences in the implementation, they may be fixed by changing `my_pthread.h` and `my_pthread.c`.
- Run `thr_alarm`. If it runs without any “warning,” “error,” or aborted messages, you are on the right track. Here is a successful run on Solaris:

```

Main thread: 1
Thread 0 (5) started
Thread: 5 Waiting
process_alarm
Thread 1 (6) started
Thread: 6 Waiting
process_alarm
process_alarm
thread_alarm
Thread: 6 Slept for 1 (1) sec
Thread: 6 Waiting
process_alarm
process_alarm
thread_alarm
Thread: 6 Slept for 2 (2) sec
Thread: 6 Simulation of no alarm needed
Thread: 6 Slept for 0 (3) sec
Thread: 6 Waiting
process_alarm
process_alarm
thread_alarm
Thread: 6 Slept for 4 (4) sec
Thread: 6 Waiting
process_alarm
thread_alarm
Thread: 5 Slept for 10 (10) sec
Thread: 5 Waiting
process_alarm
process_alarm
thread_alarm
Thread: 6 Slept for 5 (5) sec
Thread: 6 Waiting
process_alarm
process_alarm
...
thread_alarm
Thread: 5 Slept for 0 (1) sec
end
    
```

## 21.4.5. Differences Between Thread Packages

MySQL is very dependent on the thread package used. So when choosing a good platform for MySQL, the thread package is very important.

There are at least three types of thread packages:

- User threads in a single process. Thread switching is managed with alarms and the threads library manages all non-thread-safe functions with locks. Read, write and select operations are usually managed with a thread-specific select that switches to another thread if the running threads have to wait for data. If the user thread packages are integrated in the standard libs (FreeBSD and BSDI threads) the thread package requires less overhead than thread packages that have to map all unsafe calls (MIT-pthreads, FSU Pthreads and RTS threads). In some environments (for example, SCO), all system calls are thread-safe so the mapping can be done very easily (FSU Pthreads on SCO). Downside: All mapped calls take a little time and it is quite tricky to be able to handle all situations. There are usually also some system calls that are not handled by the thread package (like MIT-pthreads and sockets). Thread scheduling isn't always optimal.
- User threads in separate processes. Thread switching is done by the kernel and all data are shared between threads. The thread package manages the standard thread calls to allow sharing data between threads. LinuxThreads is using this method. Downside: Lots of processes. Thread creating is slow. If one thread dies the rest are usually left hanging and you must kill them all before restarting. Thread switching is somewhat expensive.
- Kernel threads. Thread switching is handled by the thread library or the kernel and is very fast. Everything is done in one process, but on some systems, `ps` may show the different threads. If one thread aborts, the whole process aborts. Most system calls are thread-safe and should require very little overhead. Solaris, HP-UX, AIX and OSF/1 have kernel threads.

In some systems kernel threads are managed by integrating user level threads in the system libraries. In such cases, the thread switching can only be done by the thread library and the kernel isn't really "thread aware."

---

# Appendix A. MySQL 5.0 Frequently Asked Questions

## A.1. MySQL 5.0 FAQ — General

### Questions

- [22.1.1](#): Which version of MySQL is production-ready (GA)?
- [22.1.2](#): Can MySQL 5.0 do subqueries?
- [22.1.3](#): Can MySQL 5.0 perform multiple-table inserts, updates, and deletes?
- [22.1.4](#): Does MySQL 5.0 have a Query Cache? Does it work on Server, Instance or Database?
- [22.1.5](#): Does MySQL 5.0 have Sequences?
- [22.1.6](#): Does MySQL 5.0 have a `NOW( )` function with fractions of seconds?
- [22.1.7](#): Does MySQL 5.0 work with multi-core processors?
- [22.1.8](#): Is there a hot backup tool for MyISAM like InnoDB Hot Backup?
- [22.1.9](#): Have there been there any improvements in error reporting when foreign keys fail? Does MySQL now report which column and reference failed?
- [22.1.10](#): Can MySQL 5.0 perform ACID transactions?

### Questions and Answers

#### 22.1.1: Which version of MySQL is production-ready (GA)?

Currently, both MySQL 5.0 and MySQL 5.1 are supported for production use.

MySQL 5.0 achieved General Availability (GA) status with MySQL 5.0.15, which was released for production use on 19 October 2005.

MySQL 5.1 achieved General Availability (GA) status with MySQL 5.1.30, which was released for production use on 14 November 2008.

Development work on MySQL 5.4 has started; currently, MySQL 5.4 is in beta status.

Development work on MySQL 6.0 has started; currently, MySQL 6.0 is in alpha status.

#### 22.1.2: Can MySQL 5.0 do subqueries?

Yes. See [Section 12.2.9](#), “Subquery Syntax”.

#### 22.1.3: Can MySQL 5.0 perform multiple-table inserts, updates, and deletes?

Yes. For the syntax required to perform multiple-table updates, see [Section 12.2.11](#), “UPDATE Syntax”; for that required to perform multiple-table deletes, see [Section 12.2.2](#), “DELETE Syntax”.

A multiple-table insert can be accomplished using a trigger whose `FOR EACH ROW` clause contains multiple `INSERT` statements within a `BEGIN . . . END` block. See [Section 18.3](#), “Using Triggers”.

#### 22.1.4: Does MySQL 5.0 have a Query Cache? Does it work on Server, Instance or Database?

Yes. The query cache operates on the server level, caching complete result sets matched with the original query string. If an exactly identical query is made (which often happens, particularly in web applications), no parsing or execution is necessary; the result is sent directly from the cache. Various tuning options are available. See [Section 7.5.5](#), “The MySQL Query Cache”.

#### 22.1.5: Does MySQL 5.0 have Sequences?

No. However, MySQL has an `AUTO_INCREMENT` system, which in MySQL 5.0 can also handle inserts in a multi-master replication setup. With the `auto_increment_increment` and `auto_increment_offset` system variables, you can set each server to generate auto-increment values that don't conflict with other servers. The `auto_increment_increment` value should be greater than the number of servers, and each server should have a unique offset.

**22.1.6: Does MySQL 5.0 have a `NOW()` function with fractions of seconds?**

No. This is on the MySQL roadmap as a “rolling feature”. This means that it is not a flagship feature, but will be implemented, development time permitting. Specific customer demand may change this scheduling.

However, MySQL does parse time strings with a fractional component. See [Section 10.3.2, “The `TIME` Type”](#).

**22.1.7: Does MySQL 5.0 work with multi-core processors?**

Yes. MySQL is fully multi-threaded, and will make use of multiple CPUs, provided that the operating system supports them.

**22.1.8: Is there a hot backup tool for MyISAM like InnoDB Hot Backup?**

This is currently under development for a future MySQL release.

**22.1.9: Have there been any improvements in error reporting when foreign keys fail? Does MySQL now report which column and reference failed?**

The foreign key support in [InnoDB](#) has seen improvements in each major version of MySQL. Foreign key support generic to all storage engines is scheduled for MySQL 6.x; this should resolve any inadequacies in the current storage engine specific implementation.

**22.1.10: Can MySQL 5.0 perform ACID transactions?**

Yes. All current MySQL versions support transactions. The [InnoDB](#) storage engine offers full ACID transactions with row-level locking, multi-versioning, non-locking repeatable reads, and all four SQL standard isolation levels.

The [NDB](#) storage engine supports the [READ COMMITTED](#) transaction isolation level only.

## A.2. MySQL 5.0 FAQ — Storage Engines

### Questions

- [22.2.1](#): Where can I obtain complete documentation for MySQL storage engines?
- [22.2.2](#): Are there any new storage engines in MySQL 5.0?
- [22.2.3](#): Have any storage engines been removed in MySQL 5.0?
- [22.2.4](#): What are the unique benefits of the [ARCHIVE](#) storage engine?
- [22.2.5](#): Do the new features in MySQL 5.0 apply to all storage engines?

### Questions and Answers

**22.2.1: Where can I obtain complete documentation for MySQL storage engines?**

See [Chapter 13, \*Storage Engines\*](#). That chapter contains information about all MySQL storage engines except for the [NDB](#) storage engine used for MySQL Cluster; [NDB](#) is covered in [Chapter 17, \*MySQL Cluster\*](#).

**22.2.2: Are there any new storage engines in MySQL 5.0?**

Yes. The [FEDERATED](#) storage engine, new in MySQL 5.0, allows the server to access tables on other (remote) servers. See [Section 13.7, “The `FEDERATED` Storage Engine”](#).

**22.2.3: Have any storage engines been removed in MySQL 5.0?**

Yes. MySQL 5.0 no longer supports the [ISAM](#) storage engine. If you have any existing [ISAM](#) tables from previous versions of MySQL, you should convert these to [MyISAM](#) before upgrading to MySQL 5.0.

**22.2.4: What are the unique benefits of the [ARCHIVE](#) storage engine?**

The [ARCHIVE](#) storage engine is ideally suited for storing large amounts of data without indexes; it has a very small footprint, and performs selects using table scans. See [Section 13.8, “The `ARCHIVE` Storage Engine”](#), for details.

**22.2.5: Do the new features in MySQL 5.0 apply to all storage engines?**

The general new features such as views, stored procedures, triggers, [INFORMATION\\_SCHEMA](#), precision math ([DECIMAL](#) column type), and the [BIT](#) column type, apply to all storage engines. There are also additions and changes for specific storage engines.

## A.3. MySQL 5.0 FAQ — Server SQL Mode

### Questions

- [22.3.1](#): What are server SQL modes?
- [22.3.2](#): How many server SQL modes are there?
- [22.3.3](#): How do you determine the server SQL mode?
- [22.3.4](#): Is the mode dependent on the database or connection?
- [22.3.5](#): Can the rules for strict mode be extended?
- [22.3.6](#): Does strict mode impact performance?
- [22.3.7](#): What is the default server SQL mode when My SQL 5.0 is installed?

### Questions and Answers

#### 22.3.1: What are server SQL modes?

Server SQL modes define what SQL syntax MySQL should support and what kind of data validation checks it should perform. This makes it easier to use MySQL in different environments and to use MySQL together with other database servers. The MySQL Server apply these modes individually to different clients. For more information, see [Section 5.1.7, “Server SQL Modes”](#).

#### 22.3.2: How many server SQL modes are there?

Each mode can be independently switched on and off. See [Section 5.1.7, “Server SQL Modes”](#), for a complete list of available modes.

#### 22.3.3: How do you determine the server SQL mode?

You can set the default SQL mode (for `mysqld` startup) with the `--sql-mode` option. Using the statement `SET [GLOBAL|SESSION] sql_mode='modes'`, you can change the settings from within a connection, either locally to the connection, or to take effect globally. You can retrieve the current mode by issuing a `SELECT @@sql_mode` statement.

#### 22.3.4: Is the mode dependent on the database or connection?

A mode is not linked to a particular database. Modes can be set locally to the session (connection), or globally for the server. you can change these settings using `SET [GLOBAL|SESSION] sql_mode='modes'`.

#### 22.3.5: Can the rules for strict mode be extended?

When we refer to *strict mode*, we mean a mode where at least one of the modes `TRADITIONAL`, `STRICT_TRANS_TABLES`, or `STRICT_ALL_TABLES` is enabled. Options can be combined, so you can add additional restrictions to a mode. See [Section 5.1.7, “Server SQL Modes”](#), for more information.

#### 22.3.6: Does strict mode impact performance?

The intensive validation of input data that some settings requires more time than if the validation is not done. While the performance impact is not that great, if you do not require such validation (perhaps your application already handles all of this), then MySQL gives you the option of leaving strict mode disabled. However — if you do require it — strict mode can provide such validation.

#### 22.3.7: What is the default server SQL mode when My SQL 5.0 is installed?

By default, no special modes are enabled. See [Section 5.1.7, “Server SQL Modes”](#), for information about all available modes and MySQL's default behavior.

## A.4. MySQL 5.0 FAQ — Stored Procedures and Functions

### Questions

- [22.4.1](#): Does MySQL 5.0 support stored procedures and functions?
- [22.4.2](#): Where can I find documentation for MySQL stored procedures and stored functions?

- [22.4.3](#): Is there a discussion forum for MySQL stored procedures?
- [22.4.4](#): Where can I find the ANSI SQL 2003 specification for stored procedures?
- [22.4.5](#): How do you manage stored routines?
- [22.4.6](#): Is there a way to view all stored procedures and stored functions in a given database?
- [22.4.7](#): Where are stored procedures stored?
- [22.4.8](#): Is it possible to group stored procedures or stored functions into packages?
- [22.4.9](#): Can a stored procedure call another stored procedure?
- [22.4.10](#): Can a stored procedure call a trigger?
- [22.4.11](#): Can a stored procedure access tables?
- [22.4.12](#): Do stored procedures have a statement for raising application errors?
- [22.4.13](#): Do stored procedures provide exception handling?
- [22.4.14](#): Can MySQL 5.0 stored routines return result sets?
- [22.4.15](#): Is `WITH RECOMPILE` supported for stored procedures?
- [22.4.16](#): Is there a MySQL equivalent to using `mod_plsql` as a gateway on Apache to talk directly to a stored procedure in the database?
- [22.4.17](#): Can I pass an array as input to a stored procedure?
- [22.4.18](#): Can I pass a cursor as an `IN` parameter to a stored procedure?
- [22.4.19](#): Can I return a cursor as an `OUT` parameter from a stored procedure?
- [22.4.20](#): Can I print out a variable's value within a stored routine for debugging purposes?
- [22.4.21](#): Can I commit or roll back transactions inside a stored procedure?
- [22.4.22](#): Do MySQL 5.0 stored procedures and functions work with replication?
- [22.4.23](#): Are stored procedures and functions created on a master server replicated to a slave?
- [22.4.24](#): How are actions that take place inside stored procedures and functions replicated?
- [22.4.25](#): Are there special security requirements for using stored procedures and functions together with replication?
- [22.4.26](#): What limitations exist for replicating stored procedure and function actions?
- [22.4.27](#): Do the preceding limitations affect MySQL's ability to do point-in-time recovery?
- [22.4.28](#): What is being done to correct the aforementioned limitations?

## Questions and Answers

### **22.4.1: Does MySQL 5.0 support stored procedures and functions?**

Yes. MySQL 5.0 supports two types of stored routines — stored procedures and stored functions.

### **22.4.2: Where can I find documentation for MySQL stored procedures and stored functions?**

See [Section 18.2, “Using Stored Routines \(Procedures and Functions\)”](#).

### **22.4.3: Is there a discussion forum for MySQL stored procedures?**

Yes. See <http://forums.mysql.com/list.php?98>.

### **22.4.4: Where can I find the ANSI SQL 2003 specification for stored procedures?**

Unfortunately, the official specifications are not freely available (ANSI makes them available for purchase). However, there are books — such as *SQL-99 Complete, Really* by Peter Gulutzan and Trudy Pelzer — which give a comprehensive overview of the

standard, including coverage of stored procedures.

#### 22.4.5: How do you manage stored routines?

It is always good practice to use a clear naming scheme for your stored routines. You can manage stored procedures with `CREATE [FUNCTION|PROCEDURE]`, `ALTER [FUNCTION|PROCEDURE]`, `DROP [FUNCTION|PROCEDURE]`, and `SHOW CREATE [FUNCTION|PROCEDURE]`. You can obtain information about existing stored procedures using the `ROUTINES` table in the `INFORMATION_SCHEMA` database (see [Section 19.14](#), “[The INFORMATION\\_SCHEMA ROUTINES Table](#)”).

#### 22.4.6: Is there a way to view all stored procedures and stored functions in a given database?

Yes. For a database named `dbname`, use this query on the `INFORMATION_SCHEMA.ROUTINES` table:

```
SELECT ROUTINE_TYPE, ROUTINE_NAME
FROM INFORMATION_SCHEMA.ROUTINES
WHERE ROUTINE_SCHEMA='dbname' ;
```

For more information, see [Section 19.14](#), “[The INFORMATION\\_SCHEMA ROUTINES Table](#)”.

The body of a stored routine can be viewed using `SHOW CREATE FUNCTION` (for a stored function) or `SHOW CREATE PROCEDURE` (for a stored procedure). See [Section 12.5.5.8](#), “[SHOW CREATE PROCEDURE Syntax](#)”, for more information.

#### 22.4.7: Where are stored procedures stored?

In the `proc` table of the `mysql` system database. However, you should not access the tables in the system database directly. Instead, use `SHOW CREATE FUNCTION` to obtain information about stored functions, and `SHOW CREATE PROCEDURE` to obtain information about stored procedures. See [Section 12.5.5.8](#), “[SHOW CREATE PROCEDURE Syntax](#)”, for more information about these statements.

You can also query the `ROUTINES` table in the `INFORMATION_SCHEMA` database — see [Section 19.14](#), “[The INFORMATION\\_SCHEMA ROUTINES Table](#)”, for information about this table.

#### 22.4.8: Is it possible to group stored procedures or stored functions into packages?

No. This is not supported in MySQL 5.0.

#### 22.4.9: Can a stored procedure call another stored procedure?

Yes.

#### 22.4.10: Can a stored procedure call a trigger?

A stored procedure can execute an SQL statement, such as an `UPDATE`, that causes a trigger to activate.

#### 22.4.11: Can a stored procedure access tables?

Yes. A stored procedure can access one or more tables as required.

#### 22.4.12: Do stored procedures have a statement for raising application errors?

Not in MySQL 5.0. The SQL standard `SIGNAL` and `RESIGNAL` statements are implemented in MySQL 6.0.

#### 22.4.13: Do stored procedures provide exception handling?

MySQL implements `HANDLER` definitions according to the SQL standard. See [Section 12.8.4.2](#), “[DECLARE for Handlers](#)”, for details.

#### 22.4.14: Can MySQL 5.0 stored routines return result sets?

*Stored procedures* can, but stored functions cannot. If you perform an ordinary `SELECT` inside a stored procedure, the result set is returned directly to the client. You need to use the MySQL 4.1 (or above) client-server protocol for this to work. This means that — for instance — in PHP, you need to use the `mysql_i` extension rather than the old `mysql` extension.

#### 22.4.15: Is `WITH RECOMPILE` supported for stored procedures?

Not in MySQL 5.0.

#### 22.4.16: Is there a MySQL equivalent to using `mod_plsql` as a gateway on Apache to talk directly to a stored procedure in the database?

There is no equivalent in MySQL 5.0.

#### 22.4.17: Can I pass an array as input to a stored procedure?

Not in MySQL 5.0.

**22.4.18: Can I pass a cursor as an `IN` parameter to a stored procedure?**

In MySQL 5.0, cursors are available inside stored procedures only.

**22.4.19: Can I return a cursor as an `OUT` parameter from a stored procedure?**

In MySQL 5.0, cursors are available inside stored procedures only. However, if you do not open a cursor on a `SELECT`, the result will be sent directly to the client. You can also `SELECT INTO` variables. See [Section 12.2.8, “SELECT Syntax”](#).

**22.4.20: Can I print out a variable's value within a stored routine for debugging purposes?**

Yes, you can do this in a *stored procedure*, but not in a stored function. If you perform an ordinary `SELECT` inside a stored procedure, the result set is returned directly to the client. You will need to use the MySQL 4.1 (or above) client-server protocol for this to work. This means that — for instance — in PHP, you need to use the `mysqli` extension rather than the old `mysql` extension.

**22.4.21: Can I commit or roll back transactions inside a stored procedure?**

Yes. However, you cannot perform transactional operations within a stored function.

**22.4.22: Do MySQL 5.0 stored procedures and functions work with replication?**

Yes, standard actions carried out in stored procedures and functions are replicated from a master MySQL server to a slave server. There are a few limitations that are described in detail in [Section 18.5, “Binary Logging of Stored Programs”](#).

**22.4.23: Are stored procedures and functions created on a master server replicated to a slave?**

Yes, creation of stored procedures and functions carried out through normal DDL statements on a master server are replicated to a slave, so the objects will exist on both servers. `ALTER` and `DROP` statements for stored procedures and functions are also replicated.

**22.4.24: How are actions that take place inside stored procedures and functions replicated?**

MySQL records each DML event that occurs in a stored procedure and replicates those individual actions to a slave server. The actual calls made to execute stored procedures are not replicated.

Stored functions that change data are logged as function invocations, not as the DML events that occur inside each function.

**22.4.25: Are there special security requirements for using stored procedures and functions together with replication?**

Yes. Because a slave server has authority to execute any statement read from a master's binary log, special security constraints exist for using stored functions with replication. If replication or binary logging in general (for the purpose of point-in-time recovery) is active, then MySQL DBAs have two security options open to them:

1. Any user wishing to create stored functions must be granted the `SUPER` privilege.
2. Alternatively, a DBA can set the `log_bin_trust_function_creators` system variable to 1, which enables anyone with the standard `CREATE ROUTINE` privilege to create stored functions.

**22.4.26: What limitations exist for replicating stored procedure and function actions?**

Non-deterministic (random) or time-based actions embedded in stored procedures may not replicate properly. By their very nature, randomly produced results are not predictable and cannot be exactly reproduced, and therefore, random actions replicated to a slave will not mirror those performed on a master. Note that declaring stored functions to be `DETERMINISTIC` or setting the `log_bin_trust_function_creators` system variable to 0 will not allow random-valued operations to be invoked.

In addition, time-based actions cannot be reproduced on a slave because the timing of such actions in a stored procedure is not reproducible through the binary log used for replication. It records only DML events and does not factor in timing constraints.

Finally, non-transactional tables for which errors occur during large DML actions (such as bulk inserts) may experience replication issues in that a master may be partially updated from DML activity, but no updates are done to the slave because of the errors that occurred. A workaround is for a function's DML actions to be carried out with the `IGNORE` keyword so that updates on the master that cause errors are ignored and updates that do not cause errors are replicated to the slave.

**22.4.27: Do the preceding limitations affect MySQL's ability to do point-in-time recovery?**

The same limitations that affect replication do affect point-in-time recovery.

**22.4.28: What is being done to correct the aforementioned limitations?**

MySQL 5.1 implements *row-based replication*, which resolves the limitations mentioned earlier.

We do not plan to backport row-based replication to MySQL 5.0. For additional information, see [Replication Formats](#), in the *MySQL 5.1 Manual*.

## A.5. MySQL 5.0 FAQ — Triggers

### Questions

- [22.5.1](#): Where can I find the documentation for MySQL 5.0 triggers?
- [22.5.2](#): Is there a discussion forum for MySQL Triggers?
- [22.5.3](#): Does MySQL 5.0 have statement-level or row-level triggers?
- [22.5.4](#): Are there any default triggers?
- [22.5.5](#): How are triggers managed in MySQL?
- [22.5.6](#): Is there a way to view all triggers in a given database?
- [22.5.7](#): Where are triggers stored?
- [22.5.8](#): Can a trigger call a stored procedure?
- [22.5.9](#): Can triggers access tables?
- [22.5.10](#): Can triggers call an external application through a UDF?
- [22.5.11](#): Is it possible for a trigger to update tables on a remote server?
- [22.5.12](#): Do triggers work with replication?
- [22.5.13](#): How are actions carried out through triggers on a master replicated to a slave?

### Questions and Answers

#### **22.5.1: Where can I find the documentation for MySQL 5.0 triggers?**

See [Section 18.3, “Using Triggers”](#).

#### **22.5.2: Is there a discussion forum for MySQL Triggers?**

Yes. It is available at <http://forums.mysql.com/list.php?99>.

#### **22.5.3: Does MySQL 5.0 have statement-level or row-level triggers?**

In MySQL 5.0, all triggers are `FOR EACH ROW` — that is, the trigger is activated for each row that is inserted, updated, or deleted. MySQL 5.0 does not support triggers using `FOR EACH STATEMENT`.

#### **22.5.4: Are there any default triggers?**

Not explicitly. MySQL does have specific special behavior for some `TIMESTAMP` columns, as well as for columns which are defined using `AUTO_INCREMENT`.

#### **22.5.5: How are triggers managed in MySQL?**

In MySQL 5.0, triggers can be created using the `CREATE TRIGGER` statement, and dropped using `DROP TRIGGER`. See [Section 12.1.11, “CREATE TRIGGER Syntax”](#), and [Section 12.1.18, “DROP TRIGGER Syntax”](#), for more about these statements.

Information about triggers can be obtained by querying the `INFORMATION_SCHEMA.TRIGGERS` table. See [Section 19.16, “The INFORMATION\\_SCHEMA TRIGGERS Table”](#).

#### **22.5.6: Is there a way to view all triggers in a given database?**

Yes. You can obtain a listing of all triggers defined on database `dbname` using a query on the `INFORMATION_SCHEMA.TRIGGERS` table such as the one shown here:

```
SELECT TRIGGER_NAME, EVENT_MANIPULATION, EVENT_OBJECT_TABLE, ACTION_STATEMENT
FROM INFORMATION_SCHEMA.TRIGGERS
```

```
WHERE TRIGGER_SCHEMA='dbname' ;
```

For more information about this table, see [Section 19.16](#), “The `INFORMATION_SCHEMA TRIGGERS` Table”.

You can also use the `SHOW TRIGGERS` statement, which is specific to MySQL. See [Section 12.5.5.35](#), “`SHOW TRIGGERS Syntax`”.

#### 22.5.7: Where are triggers stored?

Triggers for a table are currently stored in `.TRG` files, with one such file one per table.

#### 22.5.8: Can a trigger call a stored procedure?

Yes.

#### 22.5.9: Can triggers access tables?

A trigger can access both old and new data in its own table. A trigger can also affect other tables, but it is not permitted to modify a table that is already being used (for reading or writing) by the statement that invoked the function or trigger. (Before MySQL 5.0.10, a trigger cannot modify other tables.)

#### 22.5.10: Can triggers call an external application through a UDF?

Yes. For example, a trigger could invoke the `sys_exec()` UDF available at MySQL Forge here: <http://forge.mysql.com/projects/project.php?id=211>

#### 22.5.11: Is it possible for a trigger to update tables on a remote server?

Yes. A table on a remote server could be updated using the `FEDERATED` storage engine. (See [Section 13.7](#), “The `FEDERATED Storage Engine`”).

#### 22.5.12: Do triggers work with replication?

Triggers and replication in MySQL 5.0 work in the same way as in most other database systems: Actions carried out through triggers on a master are not replicated to a slave server. Instead, triggers that exist on tables that reside on a MySQL master server need to be created on the corresponding tables on any MySQL slave servers so that the triggers activate on the slaves as well as the master.

For more information, see [Section 16.3.1.24](#), “Replication and Triggers”.

#### 22.5.13: How are actions carried out through triggers on a master replicated to a slave?

First, the triggers that exist on a master must be re-created on the slave server. Once this is done, the replication flow works as any other standard DML statement that participates in replication. For example, consider a table `EMP` that has an `AFTER` insert trigger, which exists on a master MySQL server. The same `EMP` table and `AFTER` insert trigger exist on the slave server as well. The replication flow would be:

1. An `INSERT` statement is made to `EMP`.
2. The `AFTER` trigger on `EMP` activates.
3. The `INSERT` statement is written to the binary log.
4. The replication slave picks up the `INSERT` statement to `EMP` and executes it.
5. The `AFTER` trigger on `EMP` that exists on the slave activates.

For more information, see [Section 16.3.1.24](#), “Replication and Triggers”.

## A.6. MySQL 5.0 FAQ — Views

### Questions

- [22.6.1](#): Where can I find documentation covering MySQL Views?
- [22.6.2](#): Is there a discussion forum for MySQL Views?
- [22.6.3](#): What happens to a view if an underlying table is dropped or renamed?

- [22.6.4](#): Does MySQL 5.0 have table snapshots?
- [22.6.5](#): Does MySQL 5.0 have materialized views?
- [22.6.6](#): Can you insert into views that are based on joins?

### Questions and Answers

#### **22.6.1: Where can I find documentation covering MySQL Views?**

See [Section 18.4](#), “Using Views”.

#### **22.6.2: Is there a discussion forum for MySQL Views?**

Yes. See <http://forums.mysql.com/list.php?100>

#### **22.6.3: What happens to a view if an underlying table is dropped or renamed?**

After a view has been created, it is possible to drop or alter a table or view to which the definition refers. To check a view definition for problems of this kind, use the `CHECK TABLE` statement. (See [Section 12.5.2.3](#), “`CHECK TABLE` Syntax”.)

#### **22.6.4: Does MySQL 5.0 have table snapshots?**

No.

#### **22.6.5: Does MySQL 5.0 have materialized views?**

No.

#### **22.6.6: Can you insert into views that are based on joins?**

It is possible, provided that your `INSERT` statement has a column list that makes it clear there is only one table involved.

You *cannot* insert into multiple tables with a single insert on a view.

## A.7. MySQL 5.0 FAQ — **INFORMATION\_SCHEMA**

### Questions

- [22.7.1](#): Where can I find documentation for the MySQL `INFORMATION_SCHEMA` database?
- [22.7.2](#): Is there a discussion forum for `INFORMATION_SCHEMA`?
- [22.7.3](#): Where can I find the ANSI SQL 2003 specification for `INFORMATION_SCHEMA`?
- [22.7.4](#): What is the difference between the Oracle Data Dictionary and MySQL's `INFORMATION_SCHEMA`?
- [22.7.5](#): Can I add to or otherwise modify the tables found in the `INFORMATION_SCHEMA` database?

### Questions and Answers

#### **22.7.1: Where can I find documentation for the MySQL `INFORMATION_SCHEMA` database?**

See [Chapter 19](#), *INFORMATION\_SCHEMA Tables*

#### **22.7.2: Is there a discussion forum for `INFORMATION_SCHEMA`?**

See <http://forums.mysql.com/list.php?101>.

#### **22.7.3: Where can I find the ANSI SQL 2003 specification for `INFORMATION_SCHEMA`?**

Unfortunately, the official specifications are not freely available. (ANSI makes them available for purchase.) However, there are books available — such as *SQL-99 Complete, Really* by Peter Gultzan and Trudy Pelzer — which give a comprehensive overview of the standard, including `INFORMATION_SCHEMA`.

#### **22.7.4: What is the difference between the Oracle Data Dictionary and MySQL's `INFORMATION_SCHEMA`?**

Both Oracle and MySQL provide metadata in tables. However, Oracle and MySQL use different table names and column names.

MySQL's implementation is more similar to those found in DB2 and SQL Server, which also support `INFORMATION_SCHEMA` as defined in the SQL standard.

#### 22.7.5: Can I add to or otherwise modify the tables found in the `INFORMATION_SCHEMA` database?

No. Since applications may rely on a certain standard structure, this should not be modified. For this reason, *we cannot support bugs or other issues which result from modifying `INFORMATION_SCHEMA` tables or data.*

## A.8. MySQL 5.0 FAQ — Migration

### Questions

- [22.8.1](#): Where can I find information on how to migrate from MySQL 4.1 to MySQL 5.0?
- [22.8.2](#): How has storage engine (table type) support changed in MySQL 5.0 from previous versions?

### Questions and Answers

#### 22.8.1: Where can I find information on how to migrate from MySQL 4.1 to MySQL 5.0?

For detailed upgrade information, see [Section 2.18.1, “Upgrading MySQL”](#). We recommend that you do not skip a major version when upgrading, but rather complete the process in steps, upgrading from one major version to the next in each step. This may seem more complicated, but it will you save time and trouble — if you encounter problems during the upgrade, their origin will be easier to identify, either by you or — if you have a MySQL Enterprise subscription — by MySQL support.

#### 22.8.2: How has storage engine (table type) support changed in MySQL 5.0 from previous versions?

Storage engine support has changed as follows:

- Support for `ISAM` tables was removed in MySQL 5.0 and you should now use the `MyISAM` storage engine in place of `ISAM`. To convert a table `tblname` from `ISAM` to `MyISAM`, simply issue a statement such as this one:

```
ALTER TABLE tblname ENGINE=MYISAM;
```

- Internal `RAID` for `MyISAM` tables was also removed in MySQL 5.0. This was formerly used to allow large tables in file systems that did not support file sizes greater than 2GB. All modern file systems allow for larger tables; in addition, there are now other solutions such as `MERGE` tables and views.
- The `VARCHAR` column type now retains trailing spaces in all storage engines.
- `MEMORY` tables (formerly known as `HEAP` tables) can also contain `VARCHAR` columns.

## A.9. MySQL 5.0 FAQ — Security

### Questions

- [22.9.1](#): Where can I find documentation that addresses security issues for MySQL?
- [22.9.2](#): Does MySQL 5.0 have native support for SSL?
- [22.9.3](#): Is SSL support be built into MySQL binaries, or must I recompile the binary myself to enable it?
- [22.9.4](#): Does MySQL 5.0 have built-in authentication against LDAP directories?
- [22.9.5](#): Does MySQL 5.0 include support for Roles Based Access Control (RBAC)?

### Questions and Answers

#### 22.9.1: Where can I find documentation that addresses security issues for MySQL?

The best place to start is [Section 5.3, “General Security Issues”](#).

Other portions of the MySQL Documentation which you may find useful with regard to specific security concerns include the following:

- [Section 5.3.1](#), “General Security Guidelines”.
- [Section 5.3.2](#), “Making MySQL Secure Against Attackers”.
- [Section B.1.4.1](#), “How to Reset the Root Password”.
- [Section 5.3.5](#), “How to Run MySQL as a Normal User”.
- [Section 21.2.2.6](#), “User-Defined Function Security Precautions”.
- [Section 5.3.3](#), “Security-Related `mysqld` Options”.
- [Section 5.3.4](#), “Security Issues with `LOAD DATA LOCAL`”.
- [Section 2.17](#), “Post-Installation Setup and Testing”.
- [Section 2.19.1.11](#), “SELinux Notes”.
- [Section 5.5.7.1](#), “Basic SSL Concepts”.

**MySQL Enterprise**

The MySQL Enterprise Monitor enforces best practices for maximizing the security of your servers. For more information, see <http://www.mysql.com/products/enterprise/advisors.html>.

**22.9.2: Does MySQL 5.0 have native support for SSL?**

Most 5.0 binaries have support for SSL connections between the client and server. We can't currently build with the new YaSSL library everywhere, as it is still quite new and does not compile on all platforms yet. See [Section 5.5.7](#), “Using SSL for Secure Connections”.

You can also tunnel a connection via SSH, if (for instance) if the client application doesn't support SSL connections. For an example, see [Section 5.5.8](#), “Connecting to MySQL Remotely from Windows with SSH”.

**22.9.3: Is SSL support be built into MySQL binaries, or must I recompile the binary myself to enable it?**

Most 5.0 binaries have SSL enabled for client-server connections that are secured, authenticated, or both. However, the YaSSL library currently does not compile on all platforms. See [Section 5.5.7](#), “Using SSL for Secure Connections”, for a complete listing of supported and unsupported platforms.

**22.9.4: Does MySQL 5.0 have built-in authentication against LDAP directories?**

No. Support for external authentication methods is on the MySQL roadmap as a “rolling feature”, which means that we plan to implement it in the future, but we have not yet determined when this will be done.

**22.9.5: Does MySQL 5.0 include support for Roles Based Access Control (RBAC)?**

No. Support for roles is on the MySQL roadmap as a “rolling feature”, which means that we plan to implement it in the future, but we have not yet determined when this will be done.

## A.10. MySQL 5.0 FAQ — MySQL Cluster

In the following section, we answer questions that are frequently asked about MySQL Cluster and the `NDBCLUSTER` storage engine.

**Questions**

- [22.10.1](#): Which versions of the MySQL software support Cluster? Do I have to compile from source?
- [22.10.2](#): What does “NDB” mean?
- [22.10.3](#): What is the difference between using MySQL Cluster vs using MySQL replication?
- [22.10.4](#): Do I need to do any special networking to run MySQL Cluster? How do computers in a cluster communicate?
- [22.10.5](#): How many computers do I need to run a MySQL Cluster, and why?
- [22.10.6](#): What do the different computers do in a MySQL Cluster?
- [22.10.7](#): When I run the `SHOW` command in the MySQL Cluster management client, I see a line of output that looks like this:

```
id=2 @10.100.10.32 (Version: 5.1.34-ndb-6.3.26, Nodegroup: 0, Master)
```

What is a “master node”, and what does it do? How do I configure a node so that it is the master?

- [22.10.8](#): With which operating systems can I use Cluster?
- [22.10.9](#): What are the hardware requirements for running MySQL Cluster?
- [22.10.10](#): How much RAM do I need to use MySQL Cluster? Is it possible to use disk memory at all?
- [22.10.11](#): What file systems can I use with MySQL Cluster? What about network file systems or network shares?
- [22.10.12](#): Can I run MySQL Cluster nodes inside virtual machines (such as those created by VMWare, Parallels, or Xen)?
- [22.10.13](#): I am trying to populate a MySQL Cluster database. The loading process terminates prematurely and I get an error message like this one: `ERROR 1114: THE TABLE 'MY_CLUSTER_TABLE' IS FULL` Why is this happening?
- [22.10.14](#): MySQL Cluster uses TCP/IP. Does this mean that I can run it over the Internet, with one or more nodes in remote locations?
- [22.10.15](#): Do I have to learn a new programming or query language to use MySQL Cluster?
- [22.10.16](#): How do I find out what an error or warning message means when using MySQL Cluster?
- [22.10.17](#): Is MySQL Cluster transaction-safe? What isolation levels are supported?
- [22.10.18](#): What storage engines are supported by MySQL Cluster?
- [22.10.19](#): In the event of a catastrophic failure — say, for instance, the whole city loses power *and* my UPS fails — would I lose all my data?
- [22.10.20](#): Is it possible to use `FULLTEXT` indexes with MySQL Cluster?
- [22.10.21](#): Can I run multiple nodes on a single computer?
- [22.10.22](#): Can I add data nodes to a MySQL Cluster without restarting it?
- [22.10.23](#): Are there any limitations that I should be aware of when using MySQL Cluster?
- [22.10.24](#): How do I import an existing MySQL database into a MySQL Cluster?
- [22.10.25](#): How do cluster nodes communicate with one another?
- [22.10.26](#): What is an *arbiter*?
- [22.10.27](#): What data types are supported by MySQL Cluster?
- [22.10.28](#): How do I start and stop MySQL Cluster?
- [22.10.29](#): What happens to MySQL Cluster data when the cluster is shut down?
- [22.10.30](#): Is it a good idea to have more than one management node for a MySQL Cluster?
- [22.10.31](#): Can I mix different kinds of hardware and operating systems in one MySQL Cluster?
- [22.10.32](#): Can I run two data nodes on a single host? Two SQL nodes?
- [22.10.33](#): Can I use host names with MySQL Cluster?
- [22.10.34](#): How do I handle MySQL users in a MySQL Cluster having multiple MySQL servers?
- [22.10.35](#): How do I continue to send queries in the event that one of the SQL nodes fails?

## Questions and Answers

### 22.10.1: Which versions of the MySQL software support Cluster? Do I have to compile from source?

MySQL Cluster is supported in all server binaries in the 5.0 release series for operating systems on which MySQL Cluster is available. See [Section 4.3.1, “mysqld — The MySQL Server”](#). You can determine whether your server has NDB support using either of the statements `SHOW VARIABLES LIKE 'have_>%'` or `SHOW ENGINES`.

Linux users should note that **NDB** is *not* included in the standard MySQL server RPMs. Beginning with MySQL 5.0.4, there are separate RPM packages for the **NDB** storage engine and accompanying management and other tools; see the [NDB RPM Downloads](#) section of the MySQL 5.0 Downloads page for these. (Prior to 5.0.4, you had to use the `-max` binaries supplied as `.tar.gz` archives. This is still possible, but is not required, so you can use your Linux distribution's RPM manager if you prefer.)

You can also obtain **NDB** support by compiling MySQL from source, but it is not necessary to do so simply to use MySQL Cluster. To download the latest binary, RPM, or source distribution in the MySQL 5.0 series, visit <http://dev.mysql.com/downloads/mysql/5.0.html>.

However, you should use MySQL NDB Cluster NDB 6.2 or 6.3 for new deployments, and if you are already using MySQL 5.0 with clustering support, to upgrade to one of these MySQL Cluster NDB 6.x release series. For an overview of improvements made in MySQL Cluster NDB 6.2 and 6.3, see [Features Added in MySQL Cluster NDB 6.2](#), and [Features Added in MySQL Cluster NDB 6.3](#).

MySQL Cluster NDB 7.0 is the next MySQL Cluster release series following MySQL Cluster NDB 6.3; currently, it is in Beta development phase, available as source code only. For information about MySQL Cluster NDB 7.0, see [Features Added in MySQL Cluster NDB 7.0](#).

#### 22.10.2: What does “NDB” mean?

This stands for “Network Database”. **NDB** (also known as **NDBCLUSTER**) is the storage engine that enables clustering in MySQL.
