If you are not currently running a web server on port 80 you may find it more convenient to use the well known port rather than 18080. Since port 80 is the default for a web server, you can then open the dashboard without specifying a port.

- Tomcat Shutdown port —the port used by the management scripts that is used to shut the Tomcat server down when you need to stop the Service Manager. The default value is 18005.
- Tomcat SSL Port — the standard port used to connect to the Service Manager when you want to use Secure Sockets Layer (SSL) encrypted communication. The default value is 18443.
- **Repository Configuration (MySQL Server)**
 - Repository Username — the user name created and used to store information within the MySQL server to hold the information used by the Service Manager. In normal use, you should not need to use or modify this information, but it may be required if you have a support issue. The default value is `service_manager`.
 - Repository User password — the password to be used for the Repository Username. This should be set to a secure password so that the repository data is secure.

The information that you configure during installation will always be recorded within the `configuration_report.txt` file within the installation directory for the Service Manager.

Caution

Because the information stored within the `configuration_report.txt` file is in plain text, the Repository user name and password information are also exposed within this file. Make sure that the installation directory and file are secure that they can only be accessed by those users who would need to use the information.

15.3.2.2. Service Manager Installation on Windows

On Windows the installation modes are `win32` and `unattended` only. `unattended` mode is especially useful if you are doing multiple installations. For more information on this topic see [Section 15.3.4, “Unattended Installation”](#).

Note

In order to install the Service Manager as a Windows service, you must do the installation as a privileged user.

On Windows Vista, if user account control is on, an operating system dialog box requests confirmation of the installation.

To install the Service Manager on Windows, find the executable file named `mysqlmonitor-version-windows-installer.exe` (where `version` represents the three-part version number).

1. Double click on the MySQL Monitor installer. You should be presented with the Language Selection prompt. Select the language to use for the installer and then click OK.

Figure 15.2. MySQL Enterprise Monitor: Installing Monitor on Windows: Language Selection

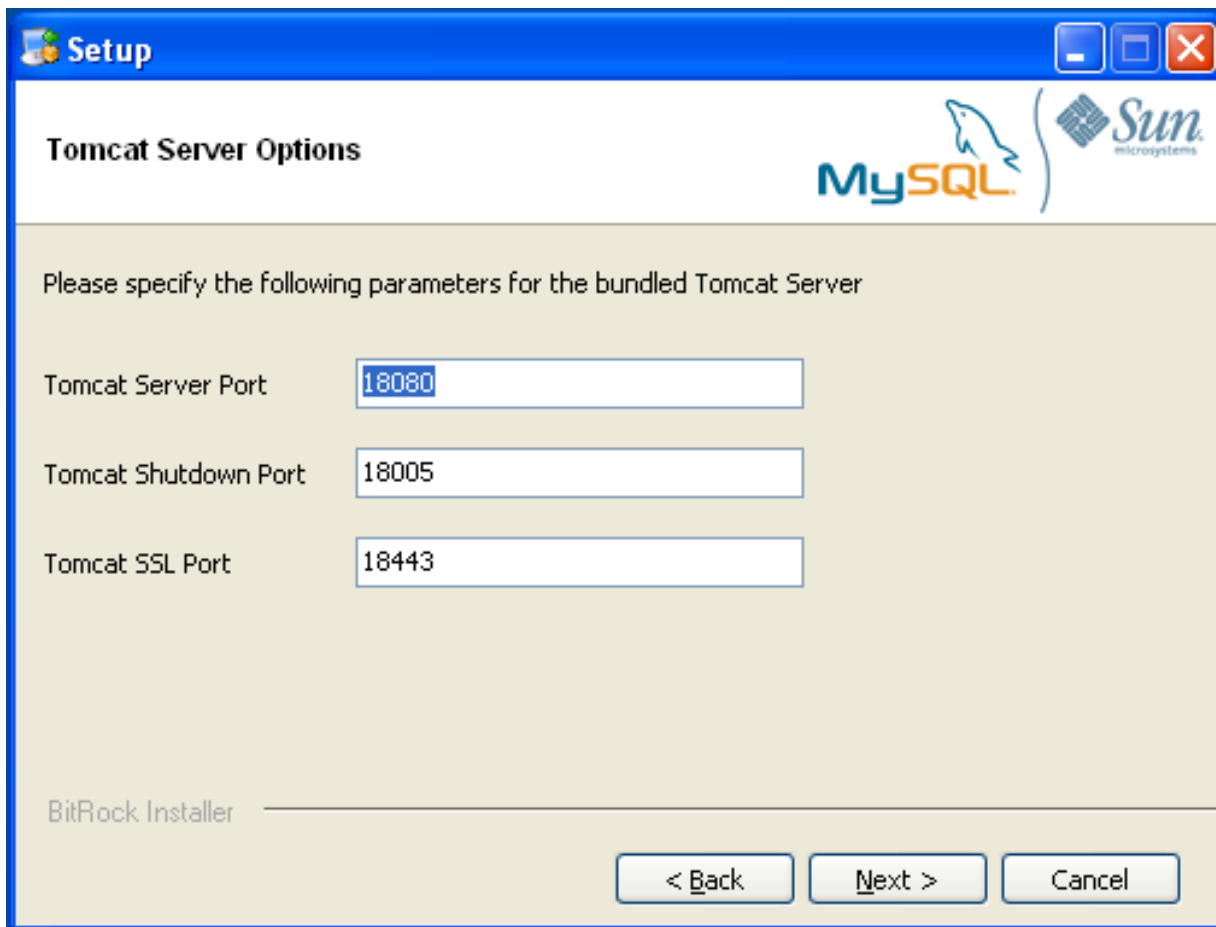

2. With the installation language selected, the remainder of the installation sets up the installation location and the main configuration parameters required by MySQL Enterprise Service Manager. Click NEXT to continue.
3. Select the installation directory where you want the MySQL Enterprise Service Manager components installed. By default on Windows the directory is `C:\Program Files\MySQL\Enterprise\Monitor`. You click the button next to the installation directory field to select a directory using the File chooser, or type the directory manually. Click NEXT to continue.

Figure 15.3. MySQL Enterprise Monitor: Installing Monitor on Windows: Installation Directory

4. Configure the options that set the network ports used by the Tomcat server. For more information, see [Section 15.3.2.1, “Service Manager Installation Common Parameters”](#). Click NEXT to continue.

Figure 15.4. MySQL Enterprise Monitor: Installing Monitor on Windows: Tomcat Server Options

5. Configure the repository settings, setting the user name, password and port used to communicate with the bundled MySQL server that will be used to store the information and statistics for your installation. For more information, see [Section 15.3.2.1, "Service Manager Installation Common Parameters"](#). Click NEXT to continue.

Note

If the Windows firewall is enabled you will be asked to unblock ports for Apache/Tomcat and the MySQL server.

Figure 15.5. MySQL Enterprise Monitor: Installing Monitor on Windows: Repository Configuration

6. You will be provided with information and a warning about the configuration options and how they are stored in the `configuration_report.txt` file, and its location. Take a note of the full path to this file in case you need to look up the information later. Click NEXT to continue.
7. You should now be prompted to start the installation process. Click NEXT to continue.
8. Once the installation has been completed, you will be provided with the information on how to uninstall MySQL Enterprise Service Manager. Click NEXT to continue.
9. To complete the installation and set up your MySQL Enterprise Service Manager, you will need to login to the Dashboard. You can do this automatically by checking the box on the final window before clicking FINISH. This checkbox is selected by default. If you do not want to run the Dashboard at this time, uncheck the box and click FINISH.

For instructions on starting the MySQL Enterprise Monitor services under Windows, see [Section 15.3.2.5, “Starting/Stopping the MySQL Enterprise Monitor Service on Windows”](#).

15.3.2.3. Service Manager Installation on Mac OS X

On Mac OS X there are three installation modes `osx`, `text`, and `unattended`. For more information on this topic see [Section 15.3.4, “Unattended Installation”](#). The `text` mode installation for Mac OS X is identical to `text` installation under Unix. For `text` mode installation instructions see [Section 15.3.2.4, “Service Manager Installation on Unix”](#).

Installing the MySQL Enterprise Service Manager on Mac OS X requires an existing installation of Java. The minimum required version is 1.5.0_7. If this version is not installed on your machine you can download it from Apple. This version of Java requires Mac OS X version 10.4.5 as a minimum, so you may need to upgrade your operating system in order to install it.

For reasons of backwards compatibility, Mac OS X is usually installed with multiple versions of Java. When installing in `osx` mode, version 1.5.0_7 must be the default version. Upon installation, Java 1.5.0_7 sets itself as the default so this is usually not a problem.

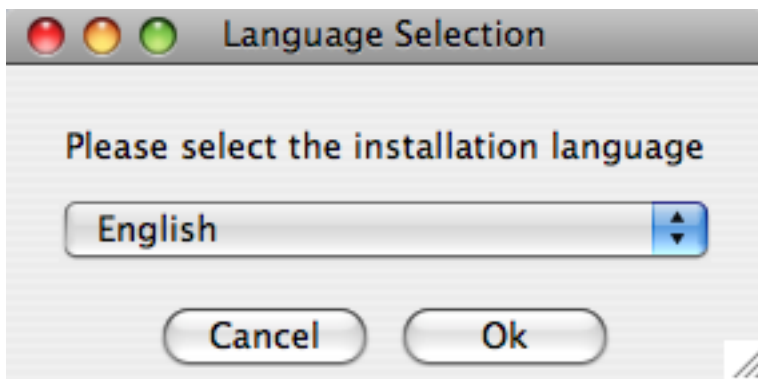

If you have changed the default you can reset it or you may install the MySQL Enterprise Service Manager in `text` mode, setting the environment variables to point to the correct version of Java. To install in `text` mode, find the `installbuilder` file in the

`Contents/MacOS` directory immediately below the `mysqlmonitor-version-osx-installer.app` directory. Installing the MySQL Enterprise Service Manager in `text` mode is identical to the procedure described in Section 15.3.2.4, “Service Manager Installation on Unix” with the minor differences noted above.

To install using the GUI (osx) installation, follow these instructions:

1. Double click on the MySQL Monitor installer. You should be presented with the Language Selection prompt. Select the language to use for the installer and then click OK.

Figure 15.6. MySQL Enterprise Monitor: Installing Monitor on OS X: Language Selection

2. If you have multiple Java installations on your machine, you will be asked to choose which Java to use with your MySQL Enterprise Service Manager installation. Choose the Java version you want to use (1.5.0 or later is required), and click OK.

Figure 15.7. MySQL Enterprise Monitor: Installing Monitor on OS X: Java Selection

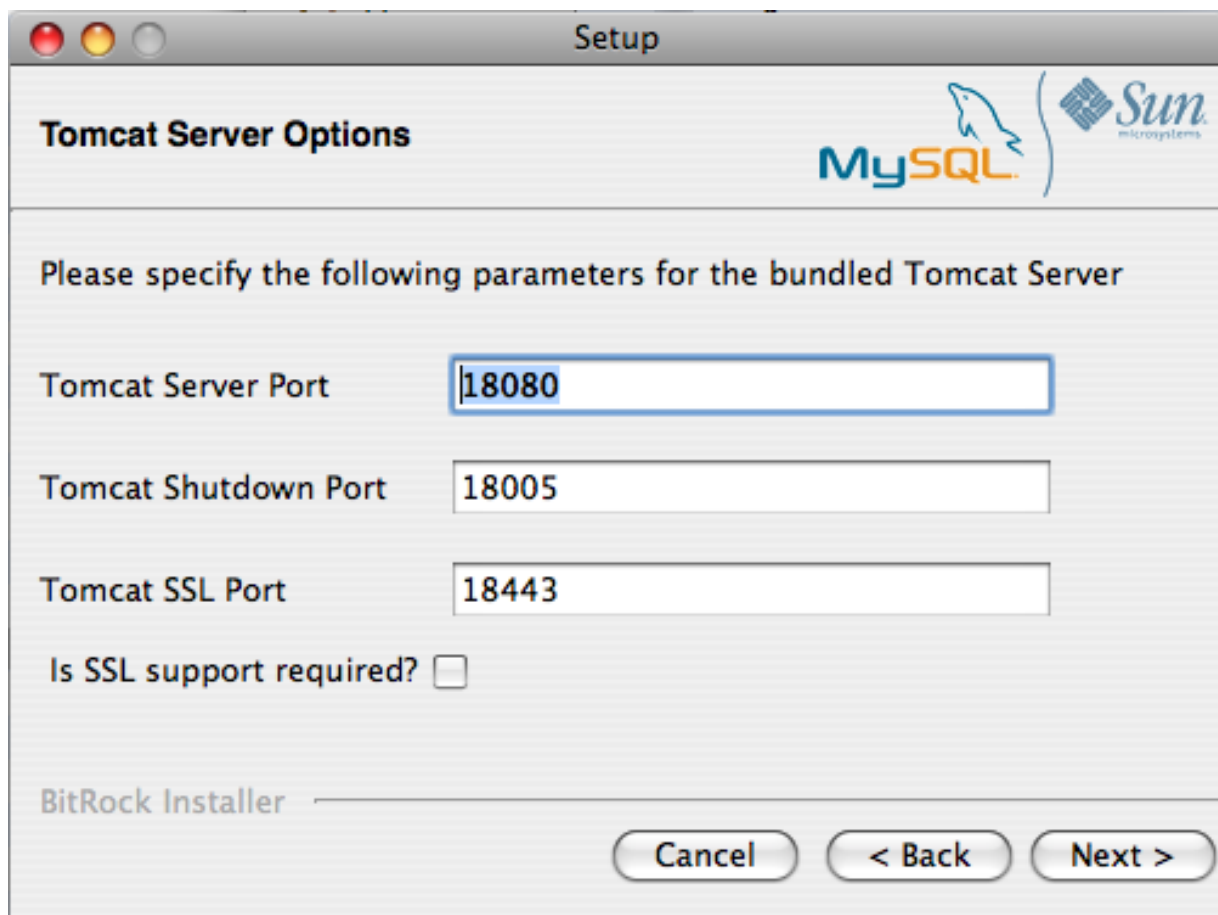

3. With the installation language and Java version selected, the remainder of the installation sets up the installation location and the main configuration parameters required by MySQL Enterprise Service Manager. Click NEXT to continue.
4. Select the installation directory where you want the MySQL Enterprise Service Manager components installed. By default on Mac OS X the directory is `/Applications/mysql/enterprise/monitor`. You click the button next to the installation directory field to select a directory using the File chooser, or type the directory manually. Click NEXT to continue.

Figure 15.8. MySQL Enterprise Monitor: Installing Monitor on OS X: Installation Directory

5. Configure the options that set the network ports used by the Tomcat server. For more information, see [Section 15.3.2.1, "Service Manager Installation Common Parameters"](#). Click NEXT to continue.

Figure 15.9. MySQL Enterprise Monitor: Installing Monitor on OS X: Tomcat Server Options

6. Configure the repository settings, setting the user name, password and port used to communicate with the bundled MySQL server that will be used to store the information and statistics for your installation. For more information, see [Section 15.3.2.1, "Service Manager Installation Common Parameters"](#). Click NEXT to continue.

Figure 15.10. MySQL Enterprise Monitor: Installing Monitor on OS X: Repository Configuration

7. You will be provided with information and a warning about the configuration options and how they are stored in the `configuration_report.txt` file, and its location. Take a note of the full path to this file in case you need to look up the information later. Click NEXT to continue.
8. You should now be prompted to start the installation process. Click NEXT to continue.
9. Once the installation has been completed, you will be provided with the information on how to uninstall MySQL Enterprise Service Manager. Click NEXT to continue.
10. To complete the installation and set up your MySQL Enterprise Service Manager, you will need to login to the Dashboard. You can do this automatically by checking the box on the final window before clicking FINISH. This checkbox is selected by default. If you do not want to run the Dashboard at this time, uncheck the box and click FINISH.

Your installation should now be complete. To continue with the configuration of MySQL Enterprise Service Manager, see [Section 15.3.2.7, “MySQL Enterprise Service Manager Configuration Settings and Advisor Installation”](#).

15.3.2.4. Service Manager Installation on Unix

To install the Service Manager find the file named `mysqlmonitor-version-installer.bin` (where *version* indicates the version number, the OS, and the architecture). Ensure that this file is executable by typing:

```
shell> chmod +x mysqlmonitor-version-installer.bin
```

To install to the default directory (`/opt/mysql/enterprise/monitor`) you need to be logged in as `root`. Installing as an unprivileged user installs to the `/home/user_name/mysql/enterprise/monitor/` directory.

What follows describes installation from the command line. You may install the Service Manager graphically by running the installer from within a windows manager. In both cases the steps are identical. You may also install the Service Manager in `unattended` mode. This is especially useful if you are doing multiple installations. For more information on this topic see [Section 15.3.4, “Unattended Installation”](#).

1. Begin installation by typing:

```
shell> ./mysqlmonitor-version-installer.bin
```

2. First choose the language for the installation:

```
Language Selection
Please select the installation language
[1] English
[2] Japanese
Please choose an option [1] :
```

3. Throughout the installation process you will be asked the configuration questions for different options. Default values are shown between square brackets; to use the default press **Enter**. Otherwise, enter the new value and press **Enter**:

First, select the directory where you want MySQL Enterprise Service Manager to be installed. The default is `/opt/mysql/enterprise/monitor/`. Make sure that the location you choose has enough space to hold the installation files and the database information that will be created when MySQL Enterprise Service Manager is running.

```
Please specify the directory where the MySQL Enterprise Service Manager
will be installed.
Installation directory [/opt/mysql/enterprise/monitor/]:
```

4. Now set the Tomcat Server options. For more details on these parameters, see [Section 15.3.2.1, “Service Manager Installation Common Parameters”](#).

```
-----
Tomcat Server Options
Please specify the following parameters for the bundled Tomcat Server
Tomcat Server Port [18080]:
Tomcat Shutdown Port [18005]:
Tomcat SSL Port [18443]:
```

You will also be asked if SSL support is required. SSL support allows your agents and monitor to communicate with each other using SSL. Using SSL means that the data exchanged by the agent and MySQL Enterprise Service Manager are secure and can be used to monitor servers securely, or to monitor agents over a public connection.

You can enable SSL by pressing **Y** when prompted during installation:

```
Is SSL support required?          [y/N]:
```

5. Set the repository (embedded MySQL server) configuration options. For more details on these parameters, see [Section 15.3.2.1, “Service Manager Installation Common Parameters”](#).

```
-----
Repository Configuration
Please specify the following parameters for the bundled MySQL server
Repository Username [service_manager]:
Password :
Re-enter :
Bundled MySQL Database Port [13306]:
```

6. Before the final installation process, you will be provided with the location of the file that contains a copy of all of the settings. Be sure to follow the instructions and store this report in a secure location. There is no password recovery feature.

```
-----
Configuration Report
Note:
The settings you specified will be saved here:
/opt/mysql/enterprise/monitor/configuration_report.txt
```

```
IMPORTANT: This configuration report includes passwords stored in plain text; it
is intended to help you install and configure your agents. We strongly advise
you to secure or delete this text file immediately after installation.
```

```
Press [Enter] to continue :
```

- You will now be asked to confirm the installation process.

```
Setup is now ready to begin installing MySQL Enterprise Monitor
on your computer.
```

```
Do you want to continue? [Y/n]: Y
```

```
Please wait while Setup installs MySQL Enterprise Monitor
on your computer.
```

The installation process may take a few minutes to complete. Upon completion you should see:

```
Completed installing files
```

```
Setup has completed installing MySQL Enterprise files on your computer
```

```
Uninstalling the MySQL Enterprise files can be done by invoking:
```

```
/opt/mysql/enterprise/monitor/uninstall
```

```
To complete the installation, launch the MySQL Enterprise Dashboard and complete
the initial setup and product activation information. Refer to the readme file
for additional information and a list of known issues.
```

```
Press [Enter] to continue :
```

- Finally, you will be given the opportunity to read a supplied [Readme](#) file that is supplied with the installation. The [Readme](#) contains important information about how to use and start your MySQL Enterprise Service Manager.

```
-----
Setup has finished installing MySQL Enterprise Monitor on your computer.
```

```
View Readme File [Y/n]: n
```

Once the [Readme](#) file has been displayed, or if you did not elect to read the file, the installation provides information about how to continue with your installation.

```
Info: To access the MySQL Enterprise Monitor please visit the
following page: http://localhost:18080/Auth.action
```

```
Press [Enter] to continue :
```

The Enterprise Dashboard will not start up automatically if you perform a [text](#) mode installation. For more information on starting and stopping MySQL Enterprise Service Manager, see [Section 15.3.2.6, “Starting/Stopping the MySQL Enterprise Monitor Service on Unix and Mac OS X”](#).

15.3.2.5. Starting/Stopping the MySQL Enterprise Monitor Service on Windows

You can choose to start up the MySQL Enterprise Service Manager on installation. The installed services are called:

- MySQL Enterprise Tomcat
- MySQL Enterprise MySQL

You can stop or start the services from the Microsoft Management Console Services window. Look for the [MySQL Enterprise Tomcat](#) and the [MySQL Enterprise MySQL](#) entries.

Note

On Windows Vista, starting these services requires administrative privileges — you must be logged in as an administrator. To start or stop a service right click it and choose the [RUN AS ADMINISTRATOR](#) menu option. The same restric-

tion applies to using the menu options discussed in the following and to starting the services from the command line. To open an administrator `cmd` window right click the `cmd` icon and choose the `RUN AS ADMINISTRATOR` menu option.

To start or stop a service, right click it and choose from the options in the pop-up menu.

There is also a menu entry for starting and stopping the services. Navigate to the `Program, MySQL, MySQL Enterprise Monitor, Services` entry to stop or start the services.

You can also stop or start a service from the command line. To start the Tomcat service type:

```
shell> sc start MySQLEnterpriseTomcat
```

or:

```
shell> net start MySQLEnterpriseTomcat
```

To stop this service type:

```
shell> sc stop MySQLEnterpriseTomcat
```

or:

```
shell> net stop MySQLEnterpriseTomcat
```

In similar fashion, you may stop or start the MySQL server from the command line. The service name is `MySQLEnterpriseMySQL`.

You may also start, stop, and restart a specific service or both services using the `mysqlmonitorctl.bat` file. To execute this file, go to the command line and navigate to the `C:\Program Files\MySQL\Enterprise\Monitor` directory. Typing `mysqlmonitorctl.bat help` produces the following output:

```
usage: mysqlmonitorctl.bat help
mysqlmonitorctl.bat (start|stop|restart|install|uninstall)
mysqlmonitorctl.bat (start|stop|restart) tomcat
mysqlmonitorctl.bat (start|stop|restart) mysql

help      - this screen
start     - start the service(s)
stop      - stop the service(s)
restart   - restart or start the service(s)
install   - install the service(s)
uninstall - uninstall the service(s)
```

To stop a specific service, pass the argument `tomcat` or `mysql` in addition to the status change argument. If you wish to change the status of both services, do not specify a service name. You may also uninstall the services using this batch file.

Configuration of the dashboard begins immediately after the Service Manager is installed. To continue a Windows installation skip the next section and go to [Section 15.3.2.7, "MySQL Enterprise Service Manager Configuration Settings and Advisor Installation"](#).

15.3.2.6. Starting/Stopping the MySQL Enterprise Monitor Service on Unix and Mac OS X

The services incorporated into the MySQL Enterprise Service Manager are:

- The MySQL Server
- The Apache/Tomcat Server

Should you need to stop, start, or restart the MySQL Enterprise Service Manager call the `mysqlmonitorctl.sh` file located in the `/opt/mysql/enterprise/monitor/` directory on Unix or the `/Applications/mysql/enterprise/monitor/` on Mac OS X. To see all the available options navigate to the appropriate directory and type:

```
shell> /opt/mysql/enterprise/monitor/mysqlmonitorctl.sh help
```

Executing this script produces the following output:

```
usage: ./mysqlmonitorctl.sh help
./mysqlmonitorctl.sh (start|stop|status|restart)
./mysqlmonitorctl.sh (start|stop|status|restart) mysql
./mysqlmonitorctl.sh (start|stop|status|restart) tomcat
```

```

help      - this screen
start     - start the service(s)
stop      - stop the service(s)
restart   - restart or start the service(s)
status    - report the status of the service

```

Using this script you can stop, start, or restart all the Service Manager components. To do this make a call to `mysqlmonitorctl.sh start` from your start-up script.

To start the service:

```

shell> ./mysqlmonitorctl.sh start
./mysqlmonitorctl.sh : mysql started
nohup: redirecting stderr to stdout
Starting mysqld daemon with databases from /opt/mysql/enterprise/monitor/mysql/data/
Using CATALINA_BASE:   /opt/mysql/enterprise/monitor/apache-tomcat
Using CATALINA_HOME:   /opt/mysql/enterprise/monitor/apache-tomcat
Using CATALINA_TMPDIR: /opt/mysql/enterprise/monitor/apache-tomcat/temp
Using JRE_HOME:        /opt/mysql/enterprise/monitor/java

```

If you try to start the service and it is already running, you will be warned that the services are already running:

```

shell> ./mysqlmonitorctl.sh start
./mysqlmonitorctl.sh : mysql (pid 18403) already running
./mysqlmonitorctl.sh : tomcat (pid 18480) already running

```

To stop the service:

```

shell> ./mysqlmonitorctl.sh stop
Using CATALINA_BASE:   /Applications/mysql/enterprise/monitor/apache-tomcat
Using CATALINA_HOME:   /Applications/mysql/enterprise/monitor/apache-tomcat
Using CATALINA_TMPDIR: /Applications/mysql/enterprise/monitor/apache-tomcat/temp
Using JRE_HOME:        /System/Library/Frameworks/JavaVM.framework/Versions/1.5.0/Home
Stopping tomcat service .. [ OK ]
STOPPING server from pid file /Applications/mysql/enterprise/monitor/mysql/data/mysqld.pid
090209 15:37:09 mysqld ended

```

The `restart` command is equivalent to executing a `stop` and then `start` operation.

This script can also be used to check the status of the Tomcat web server or the MySQL repository.

```

shell> ./mysqlmonitorctl.sh status
MySQL Network MySQL is running
MySQL Network Tomcat is running

```

Configuration of the dashboard begins immediately after the MySQL Enterprise Service Manager is installed.

15.3.2.7. MySQL Enterprise Service Manager Configuration Settings and Advisor Installation

The Enterprise Dashboard is the web-based interface to the Service Manager so the procedure for starting the dashboard is identical for all platforms. From the dashboard you can configure the settings necessary for receiving updates from MySQL Enterprise and for the initial installation of the Advisors.

If you installed the Service Manager using a graphical interface, you have the option of launching the dashboard on the final installation screen (as long as the LAUNCH MYSQL ENTERPRISE MONITOR NOW checkbox is checked).

Otherwise, you can view the dashboard by typing `http://localhost:18080/Auth.action` into the address bar of your web browser. If you are unsure of the host name and port to use, check the `configuration_report.txt` file.

Under Windows it is also possible to open the dashboard by choosing the `MySQL` menu item and finding the `MySQL Enterprise Monitor` entry. Under this entry choose `Start Service Manager`.

15.3.2.7.1. Initial Dashboard Log-in

If this is the first time that you have attempted to log in to the dashboard you should see a screen similar to the following:

Figure 15.11. MySQL Enterprise Monitor: Initial dashboard log-in

Welcome to the MySQL Enterprise Dashboard Setup.
Before proceeding, you must complete the form below.

Enterprise Credentials and Subscription Information

To enable this application, please provide a MySQL Enterprise Product Key or your MySQL Enterprise credentials
When you press "complete setup", your Enterprise credentials will be validated at enterprise.mysql.com. These credentials will that you may update your credentials or Product Key at any time on the Settings page.

Email Address (MySQL Enterprise Login)

Enterprise Password (MySQL Enterprise Password)

Confirm Password

- OR -

MySQL Enterprise Product Key

Advisor .jar File (recommended)

Create Administrator	Configure Agent Credentials
Username <input type="text" value="admin"/>	Username <input type="text" value="agent"/>
Password <input type="password"/>	Password <input type="password"/>
Confirm Password <input type="password"/>	Confirm Password <input type="password"/>

Use this screen to perform the following tasks:

- Install the Advisors
- Set up your MySQL Enterprise credentials
- Create a user name and password for the dashboard administrator
- Create a user name and password for the Monitor Agent

If you have been provided with a [MySQL Enterprise Product Key](#) and an Advisors file click the BROWSE button and locate these files. The advisor file bears the name, `AdvisorScript-version.jar` and the product key, `Subscription-level_date.xml`. If you do not allow Internet access from the dashboard you must install the advisors in this way. It is strongly recommended that you install the Advisors at this point, but you may do so later. For instructions on doing this see, [Section 15.3.2.7.3, "Installing Advisors After Initial Log-in"](#). If the product key that you provide is invalid a notification appears and you will be unable to import the advisors.

Note

If you are activating the MySQL Enterprise Monitor using a product key *do not* enter your MySQL credentials; entering both produces an error message.

If you have Internet access from the dashboard, activate MySQL Enterprise Monitor by supplying your MySQL Enterprise credentials. Enter your email address as the [MySQL Enterprise Login](#) and enter and confirm your MySQL Enterprise password. If you specify incorrect credentials, you receive the error message, “Unable to connect to verify credentials.”

In the **CREATE ADMINISTRATOR** section of this screen, enter credentials for the dashboard administrator. This creates the [root user](#) described in [Section 15.3.1.3, “Users Created on First Log-in”](#). Make note of the user name and password as these credentials are required for any future login.

In the **CONFIGURE AGENT CREDENTIALS** section of this screen enter the credentials for the agent. This is the [agent user](#) also described in [Section 15.3.1.3, “Users Created on First Log-in”](#). The agent needs to log in in order to report its findings. Make note of the agent's credentials; this information is required when installing the agent.

When all the settings have been specified, click the COMPLETE SETUP button. If you log in successfully you should see a message displaying the number of graphs and advisors that have been imported. This number varies depending upon your subscription level.

If importation of the advisor files fails, you will see the message:

```
Unable to import Advisor Jar. You may download the jar manually from the Enterprise Portal and import it from the 'Check For Updates' page.
```

In this case you may download the advisor file from the Enterprise website and install it as described in [Section 15.3.2.7.3, “Installing Advisors After Initial Log-in”](#).

15.3.2.7.2. Setting the Timezone and Locale

If this is the first time that you have launched the dashboard you are asked to set your time zone and locale. Choose the appropriate values from the drop-down list boxes. Setting the time zone ensures that you have an accurate time reference for any notifications from the MySQL Enterprise Advisors.

Warning

It is especially important that the time zone be set correctly as this may also affect the way the graphs display. For this reason, also ensure that the time reported by the operating system is correct. To change the time zone or locale see [Section 15.6.2, “User Preferences”](#).

The locale chosen determines the user's default language when logging in to the Dashboard. Note that this will override the default browser settings whenever this specific user logs in.

After specifying your time zone and locale, the dashboard opens on the [Monitor](#) page. For a detailed examination of the [Monitor](#) Screen see, [Section 15.5, “MySQL Enterprise Dashboard”](#).

15.3.2.7.3. Installing Advisors After Initial Log-in

The Advisors interpret the data sent by the Monitor Agents and display the results in the dashboard. A minimal set of Advisors are preinstalled with the Service Manager. To obtain the full set of Advisors and get the most value from the MySQL Enterprise Monitor, you must download Advisors from MySQL Enterprise.

If you did not install the Advisors when you first logged in to the MySQL Enterprise Dashboard, open the dashboard, find the [Advisors](#) tab, and choose the [Check for Updates](#) link. Doing this downloads the latest version of the Advisors from the MySQL Enterprise web site. In order to install the advisors in this fashion you must specify your MySQL Enterprise credentials. Find instructions for doing this in [Section 15.6.1, “Global Settings”](#).

If you do not allow Internet access from the dashboard, you must install the Advisors from a local file. To do this you need an advisor file bearing the name, [AdvisorScript-version.jar](#). If you don't already have this file, you can find it on the MySQL Enterprise downloads page. Download the Advisors file to a location that is accessible from the dashboard. Use the BROWSE button to find the Advisors file and then choose IMPORT to load the advisors.

15.3.2.7.4. Upgrading and Updating Advisors

The process for upgrading advisors is exactly the same as the initial installation. Advisors are updated by choosing the UPDATE button on the [Check for Updates](#) page. If you do not have Internet access from the dashboard you can import the Advisors from a local file as described in [Section 15.3.2.7.3, “Installing Advisors After Initial Log-in”](#).

Note

You may choose to upgrade your MySQL Enterprise Monitor subscription level at any time.

15.3.2.7.5. Outgoing Email Settings

Alert notification via email is a key component of the MySQL Enterprise Monitor Advisor solution. For this reason you may want to immediately configure an SMTP account for at least one recipient.

To do this choose the [Settings](#) tab and go to the [Global Settings](#) screen by clicking the appropriate link. Here you can configure the email settings. These settings apply to the currently logged-in user.

Find the [Outgoing Email Settings](#) on the left of this page.

Figure 15.12. MySQL Enterprise Monitor: Outgoing email settings

Outgoing Email Settings

Enable Email Notifications
From Address (ex. "MySQL Dashboard" <name@domain.com>)

SMTP Server

SMTP Server Login

Disable JavaMail TLS/SSL

Update Password On Save

SMTP Server Password **Confirm Password**

On Save, Send Test Email Message to (optional)

Ensure that the [Enable Email Notifications](#) checkbox is checked and enter information as appropriate.

The default value for the SMTP port is 25. If your mail server runs on a different port simply specify it, separating it from the server name using a colon. For example, if your mail server runs on port 587 enter `email.myserver.com:587` into the **SMTP SERVER** text box.

Note

An email server must be available for sending email alerts.

The SMTP client uses Transport Layer Security (TLS) if the SMTP server supports it.

If your SMTP server incorrectly indicates that it supports TLS, check the **DISABLE JAVAMAIL TLS/SSL** check box.

The email settings page is dealt with in more detail in [Section 15.6, "The Settings Page"](#).

15.3.3. Monitor Agent Installation

A MySQL Enterprise Monitor Agent monitors a MySQL server and sends data to the Advisors. These data are interpreted and displayed in the dashboard. The Monitor Agent is installed on all platforms using the steps described in the next section.

Warning

The MySQL Enterprise Service Manager version 2.0 or higher requires agents with a version number of 2.0 or higher.

15.3.3.1. Creating a MySQL User Account for the Monitor Agent

Before setting up an agent to monitor a MySQL server you need to ensure that there is a user account for the agent on that server.

The privileges required for this user account vary depending on the information you wish to gather using the MySQL Enterprise Monitor Agent. The following privileges allow the Monitor Agent to perform its assigned duties without limitation:

- **SHOW DATABASES:** Allows the MySQL Enterprise Monitor Agent to gather inventory about the monitored MySQL server.
- **REPLICATION CLIENT:** Allows the MySQL Enterprise Monitor Agent to gather Replication master/slave status data. This privilege is only needed if the MySQL Replication Advisor Rules are employed.
- **SELECT:** Allows the MySQL Enterprise Monitor Agent to collect statistics for table objects.
- **SUPER:** Allows the MySQL Enterprise Monitor Agent to execute `SHOW ENGINE INNODB STATUS` in order to collect data about InnoDB tables.
- **PROCESS:** When monitoring a MySQL server running MySQL 5.1.24 or above with InnoDB, the **PROCESS** privilege is required to execute `SHOW ENGINE INNODB STATUS`.
- **INSERT:** Required to create the UUID required by the agent.
- **CREATE:** Allows the MySQL Enterprise Monitor Agent to create tables. During discovery, the agent creates the table `inventory` within the `mysql` database that is used to the UUID for the server. Without this table, the agent cannot determine the UUID of the server and therefore use this when sending information to MySQL Enterprise Service Manager.

For example, the following **GRANT** statement will give the agent the required **SELECT**, **REPLICATION CLIENT**, **SHOW DATABASES** and **SUPER** rights:

```
GRANT SELECT, REPLICATION CLIENT, SHOW DATABASES, SUPER, PROCESS
ON *.*
TO 'mysqluser'@'localhost'
IDENTIFIED BY 'agent_password';
```

For security reasons, you may wish to limit the **CREATE** and **INSERT** privileges to the agent so that it can only create tables within the `mysql` database:

```
GRANT CREATE, INSERT
ON mysql.*
TO 'mysqluser'@'localhost'
IDENTIFIED BY 'agent_password';
```

To enable replication discovery to work, you should also grant the **SELECT** privilege on the `mysql.inventory` table for each user with replication privileges on the corresponding replication master. This is required to let the MySQL Enterprise Monitor Agent read the replication master UUID. For example:

```
GRANT SELECT
ON mysql.inventory
TO 'replicationuser'@'%'
IDENTIFIED BY 'replication_password';
```

If the agent is unable to access the information from the table then a warning containing this information will be written to the agent log.

Note

You may want to disable logging for the grant statement to prevent the grant information being replicated to the slaves. If this is the case, execute the statement `SET SQL_LOG_BIN=0` before you execute the above **GRANT** statement.

In a typical configuration, the agent runs on the same machine as the MySQL server it is monitoring so the host name will be `loc-`

alhost. However, this will change if the agent is running on a machine other than the one that hosts the monitored MySQL server. In this case, change *localhost* to the appropriate value. For more information about remote monitoring see [Section 15.3.3.6.4, “Configuring an Agent to Monitor a Remote MySQL Server”](#).

15.3.3.2. Installing the Agent on Microsoft Windows

To install the MySQL Enterprise Monitor Agent on Windows, double-click the `mysqlmonitoragent-version-windows-installer.exe` (where *version* indicates the three-part version number) installer.

Note

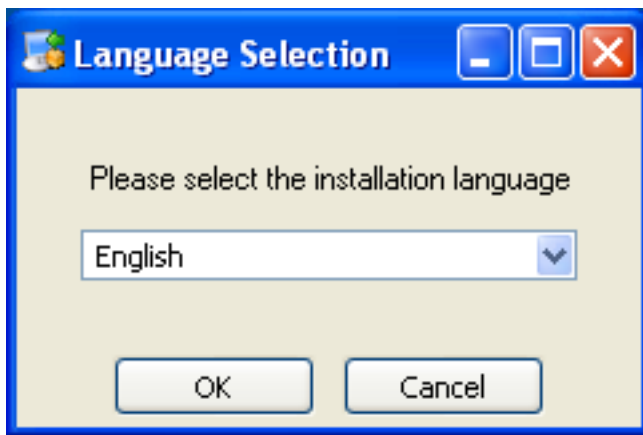

In order to install the agent as a Windows service, you must do the installation as a privileged user.

On Windows Vista, if user account control is on, an operating system dialog box requests confirmation of the installation.

You may also install the Monitor Agent in *unattended* mode. This is especially useful if you are doing multiple installations. For more information on this topic see, [Section 15.3.4, “Unattended Installation”](#).

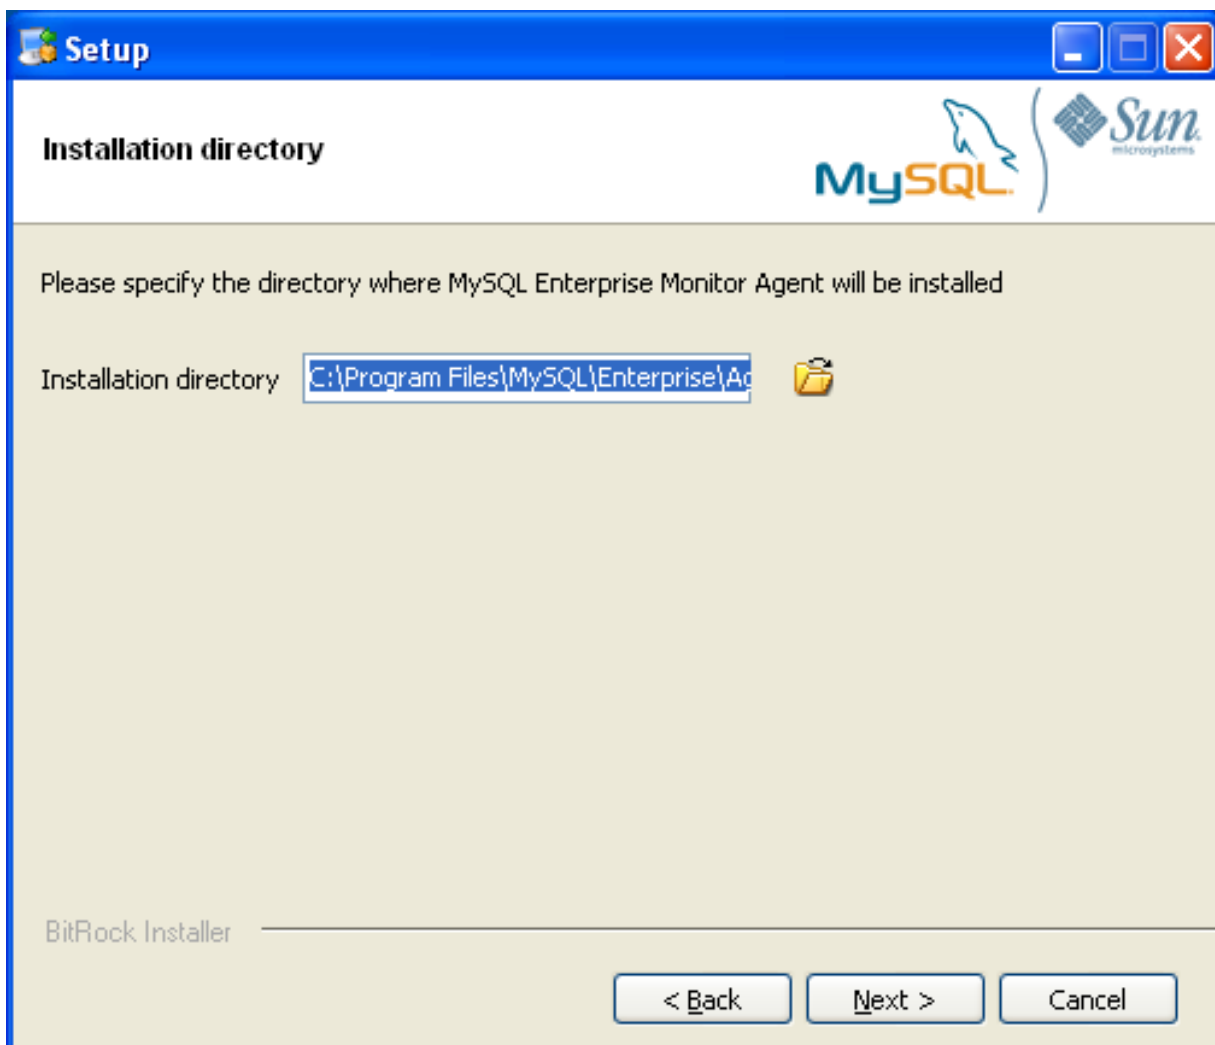

1. First, select the language for the MySQL Enterprise Monitor Agent installation. Click OK to continue installation.

Figure 15.13. MySQL Enterprise Monitor: Installing Agent on Windows: Language Selection

2. Click NEXT to start the installation process.
3. Select the installation directory. The default installation directory is `C:\Program Files\MySQL\Enterprise\Agent`. Select the installation directory, or type the new directory location. Click NEXT to continue the installation process.

Figure 15.14. MySQL Enterprise Monitor: Installing Agent on Windows: Installation Directory

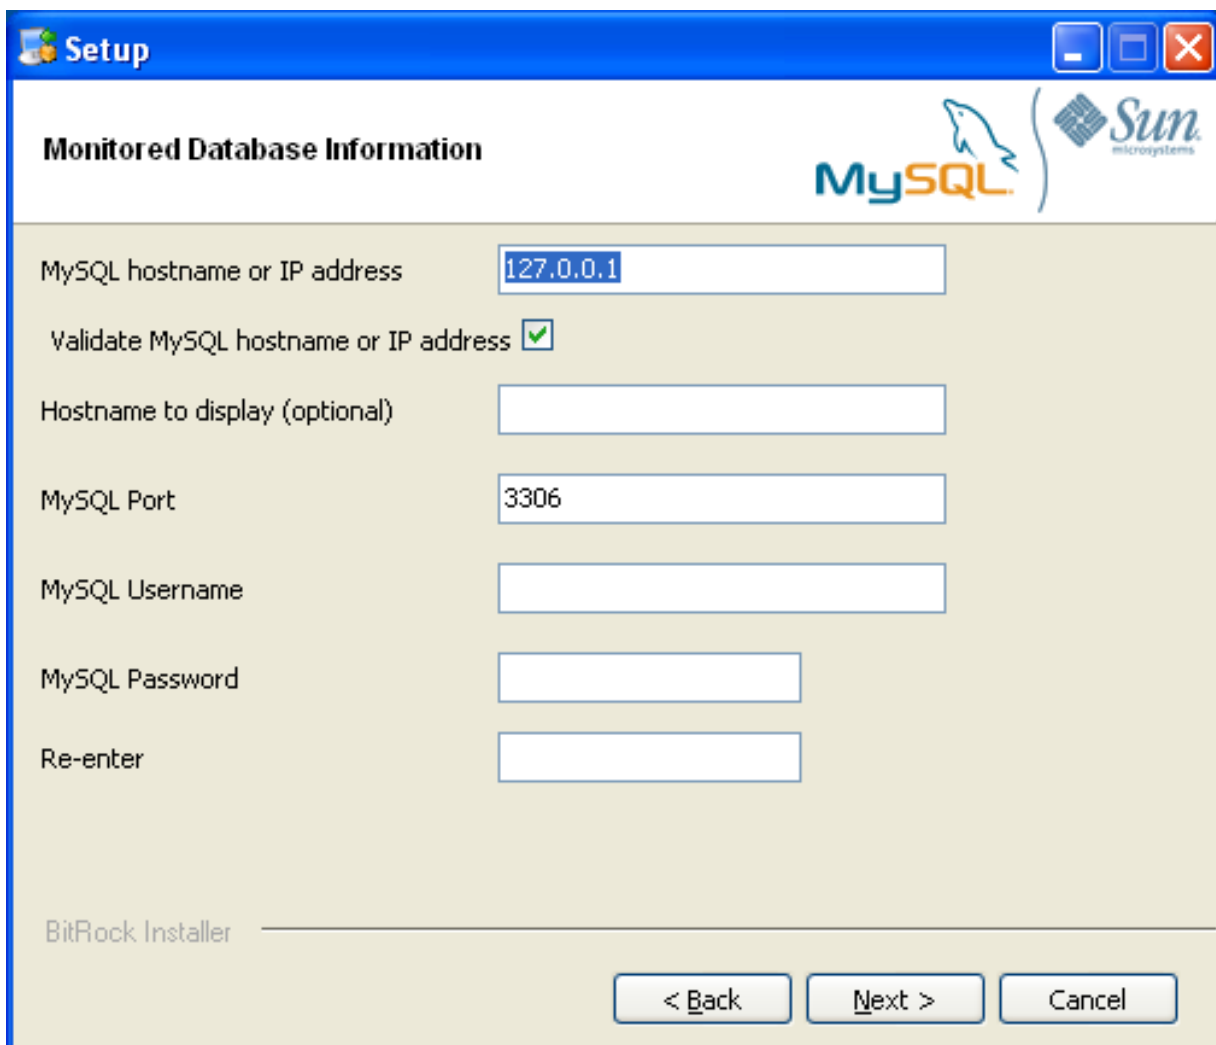

4. You need to specify the information about the MySQL server that you want to monitor. You must enter the IP address or host name of the host you want to monitor, and the port, user name and password that you will use to connect to the MySQL server. If you want to confirm that the MySQL server is currently reachable using the information, ensure that the **VALIDATE MYSQL HOST NAME OR IP ADDRESS** checkbox is selected.

Note

Currently, on Windows, the service agent only includes support for connecting to the server to be monitored via TCP/IP, so if the server has been started with `--skip-networking` it cannot be monitored.

If the MySQL server to be monitored has been started using the command option `--bind-address` then the server will only listen for connections on the IP address specified, that is, the IP address of the MySQL server. If the service agent has been started using TCP/IP networking and the default address of 127.0.0.1 it will not be able to connect to the server to be monitored. Also, if "localhost" is specified as the host name during agent configuration, a connection will not be established, as the server will be listening for connections on the address specified with the `--bind-address` option, not 127.0.0.1.

Figure 15.15. MySQL Enterprise Monitor: Installing Agent on Windows: Monitored Database Information

The screenshot shows a Windows-style window titled "Setup" with a blue header bar. The main content area is titled "Monitored Database Information" and features the MySQL and Sun Microsystems logos in the top right. The configuration fields are as follows:

MySQL hostname or IP address	<input type="text" value="127.0.0.1"/>
Validate MySQL hostname or IP address	<input checked="" type="checkbox"/>
Hostname to display (optional)	<input type="text"/>
MySQL Port	<input type="text" value="3306"/>
MySQL Username	<input type="text"/>
MySQL Password	<input type="password"/>
Re-enter	<input type="password"/>

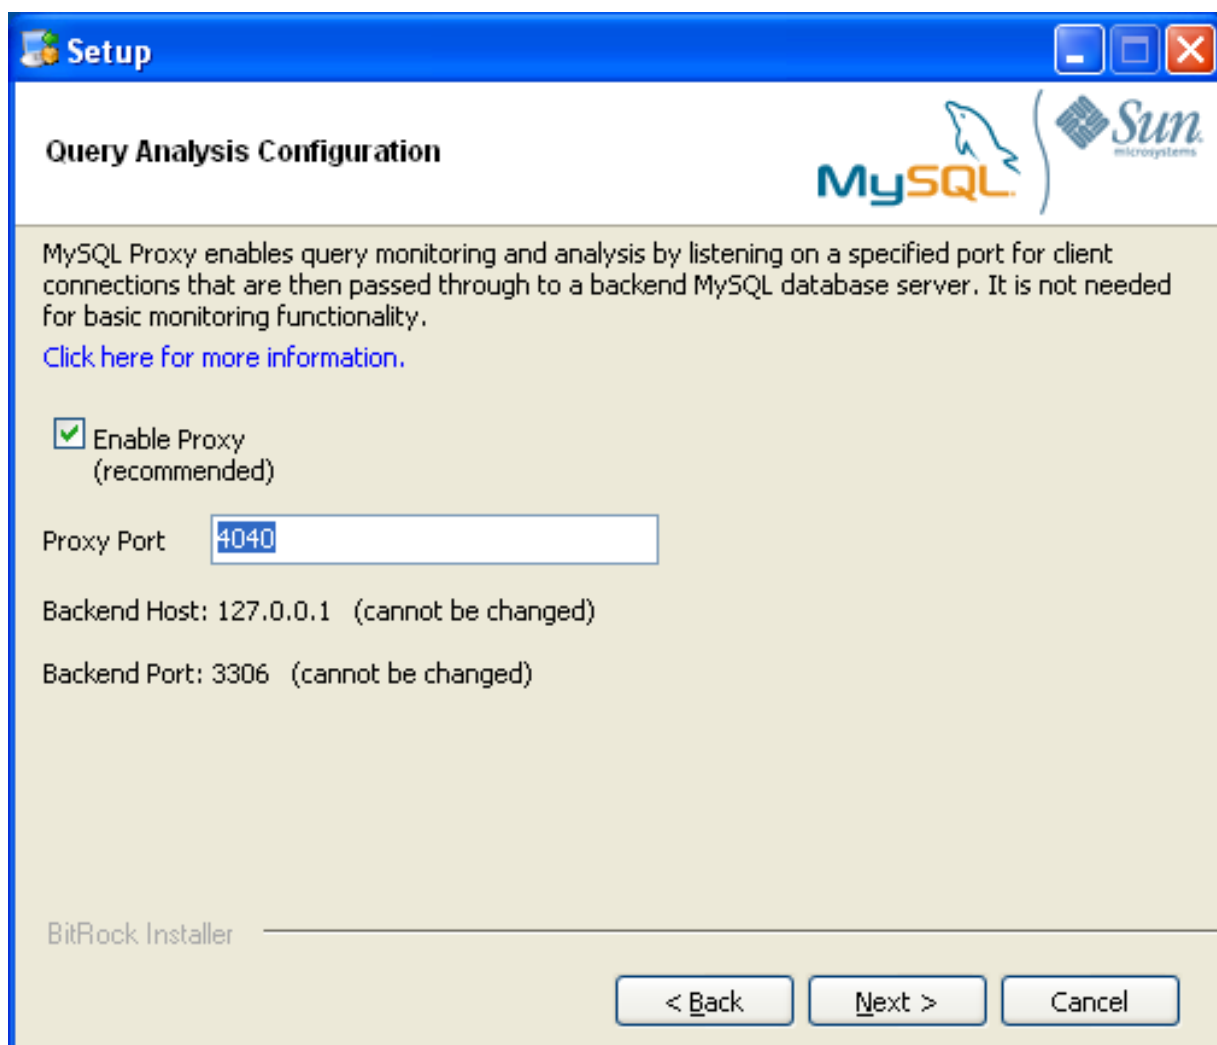

At the bottom left, it says "BitRock Installer". At the bottom right, there are three buttons: "< Back", "Next >", and "Cancel".

Click NEXT to continue the installation.

5. If you want to use Query Analyzer, then you need to enable the MySQL Enterprise Monitor Agent Proxy. The Proxy is enabled by default. If you disable the Proxy during installation, you will need to enable it later before you are able to use Query Analysis. For more information on Query Analyzer, see [Section 15.10, "The Query Analyzer Page"](#).

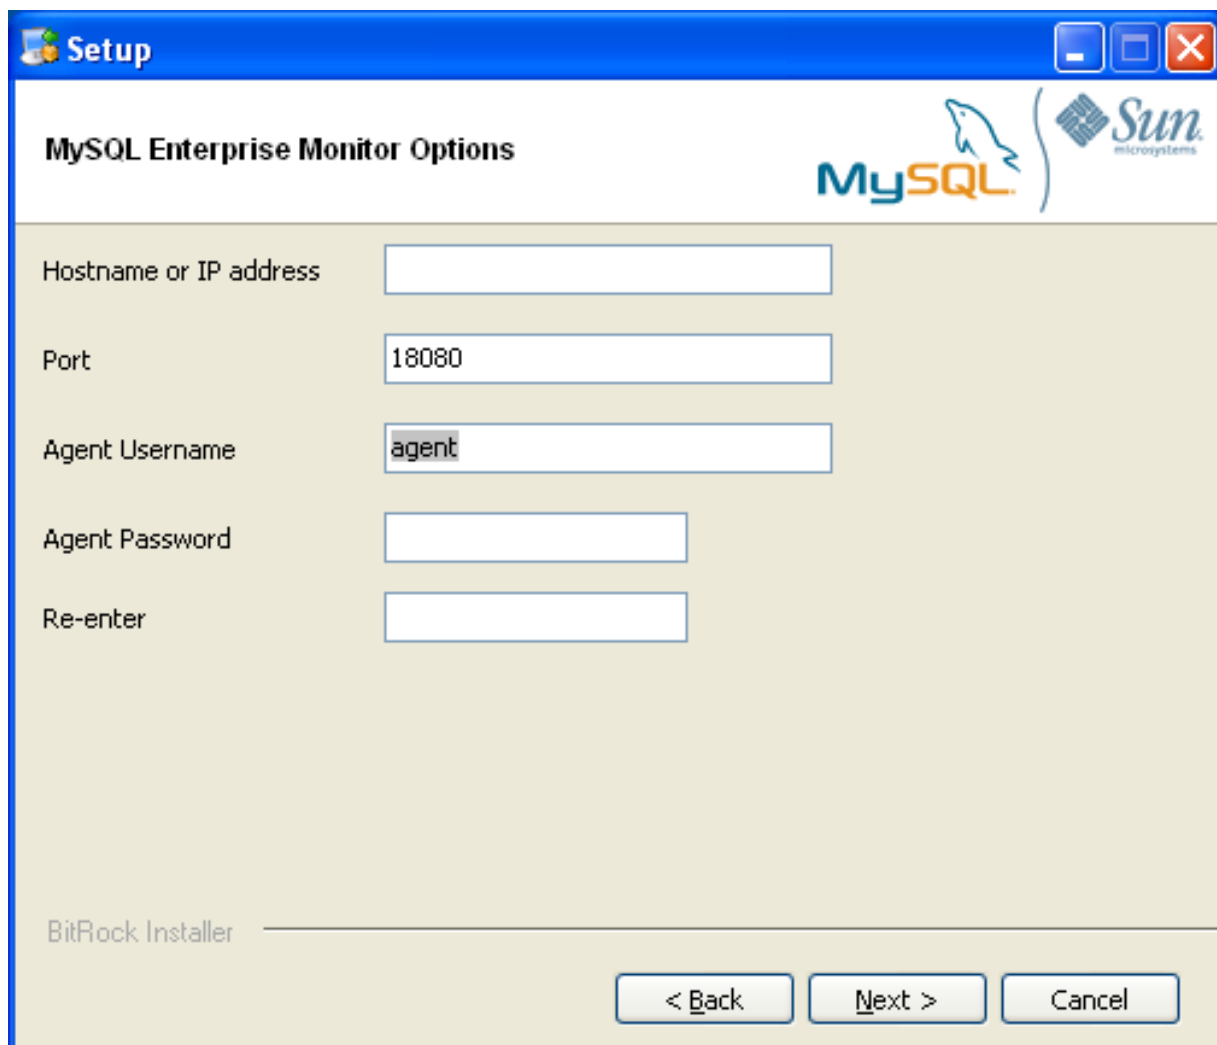

When Proxy is enabled, MySQL Enterprise Monitor Agent listens on a network port for client applications, and forwards the connections to the backend MySQL server. You can change the port number that MySQL Enterprise Monitor Agent listens for connections. The default port is 4040.

Figure 15.16. MySQL Enterprise Monitor: Installing Agent on Windows: Query Analyzer Configuration

- The MySQL Enterprise Service Manager that you want to use must be configured during installation. The host name, port and agent authentication information must be entered. If you have already installed MySQL Enterprise Service Manager then you can locate the information in the installation report file created during installation. Enter the required information and then click NEXT to continue.

Figure 15.17. MySQL Enterprise Monitor: Installing Agent on Windows: MySQL Enterprise Service Manager Options

7. You will be provided with a Configuration Report containing the information that you have entered during the installation. Check the information provided in the report. If you see a problem, use BACK to go back to the configuration screen and change the information. If the information is correct, click NEXT to continue.
8. You are given a final opportunity to change the installation parameters. Click NEXT to start the installation process.
9. Once the agent has been installed, you will get a confirmation message. Click NEXT to finalize the installation.
10. You can start the MySQL Enterprise Monitor Agent automatically now the installation has been completed. To allow the agent to be started, leave the checkbox selected. To start the agent separately, uncheck the checkbox. Click FINISH to exit the installation.

Once the Monitor Agent is installed, it needs to be started. For information on how to start and stop the Agent, see [Section 15.3.3.5.1, "Starting/Stopping the Agent on Windows"](#).

15.3.3.3. Installing the Agent on Mac OS X

To install the MySQL Enterprise Monitor Agent on Mac OS X, decompress the `mysqlmonitoragent-version-installer.app.zip` and then run the `mysqlenterpriseagent-version-installer` application.

1. First, select the language for the MySQL Enterprise Monitor Agent installation. Click OK to continue installation.

Figure 15.18. MySQL Enterprise Monitor: Installing Agent on Mac OS X: Language Selection

2. Click NEXT to start the installation process.
3. Select the installation directory. The default installation directory is `C:\Program Files\MySQL\Enterprise\Agent`. Select the installation directory, or type the new directory location.

You also need to select the method that the agent will use to communicate with the MySQL server. You can choose either to use a TCP/IP (network) connection, or a Socket (local) connection. Choose the connection method, and click NEXT.

Note

The service agent always associates “localhost” with the TCP/IP address 127.0.0.1, not the MySQL socket. This is in contrast to the MySQL Command Line Tool, which connects via the MySQL socket by default on Unix, if the host-name “localhost” is specified.

If the MySQL server you wish to monitor has been started with the `--skip-networking` command option then you will not be able to connect to it via TCP/IP, as the server will not listen for TCP/IP connections. In this case the service agent will need to be configured to use the MySQL socket. This can be done during installation by selecting “socket” rather than “TCP/IP” and then specifying the MySQL socket name. This can also be configured after installation by editing the `agent-instance.ini` configuration file, for further information on this refer to [Section 15.3.3.6.2, “MySQL Server \(agent-instance.ini\) Configuration”](#).

If the MySQL server to be monitored has been started using the command option `--bind-address` then the server will only listen for connections on the IP address specified, that is, the IP address of the MySQL server. If the service agent has been started using TCP/IP networking and the default address of 127.0.0.1 it will not be able to connect to the server to be monitored. Also, if “localhost” is specified as the host name during agent configuration, a connection will not be established, as the server will be listening for connections on the address specified with the `--bind-address` option, not 127.0.0.1.

Figure 15.19. MySQL Enterprise Monitor: Installing Agent on Mac OS X: Installation Directory

4. You need to specify the information about the MySQL server that you want to monitor. The configuration information you enter will depend on the connection method selected in the previous screen.
 - If you chose TCP/IP as the connection method, you must enter the IP address or host name of the host you want to monitor, and the port, user name and password that you will use to connect to the MySQL server. If you want to confirm that the MySQL server is currently reachable using the information, ensure that the **VALIDATE MYSQL HOST NAME OR IP ADDRESS** checkbox is selected.

Re-enter

BitRock Installer

Cancel < Back Next >

- If you chose Socket as the connection method, you must enter the full path name to the Unix socket created by your MySQL server, and the user name and password that will be used to authenticate with the server. Typical values include `/tmp/mysql.sock` and `/var/mysql/mysql.sock`.

Figure 15.21. MySQL Enterprise Monitor: Installing Agent on Mac OS X: Monitored Database Information

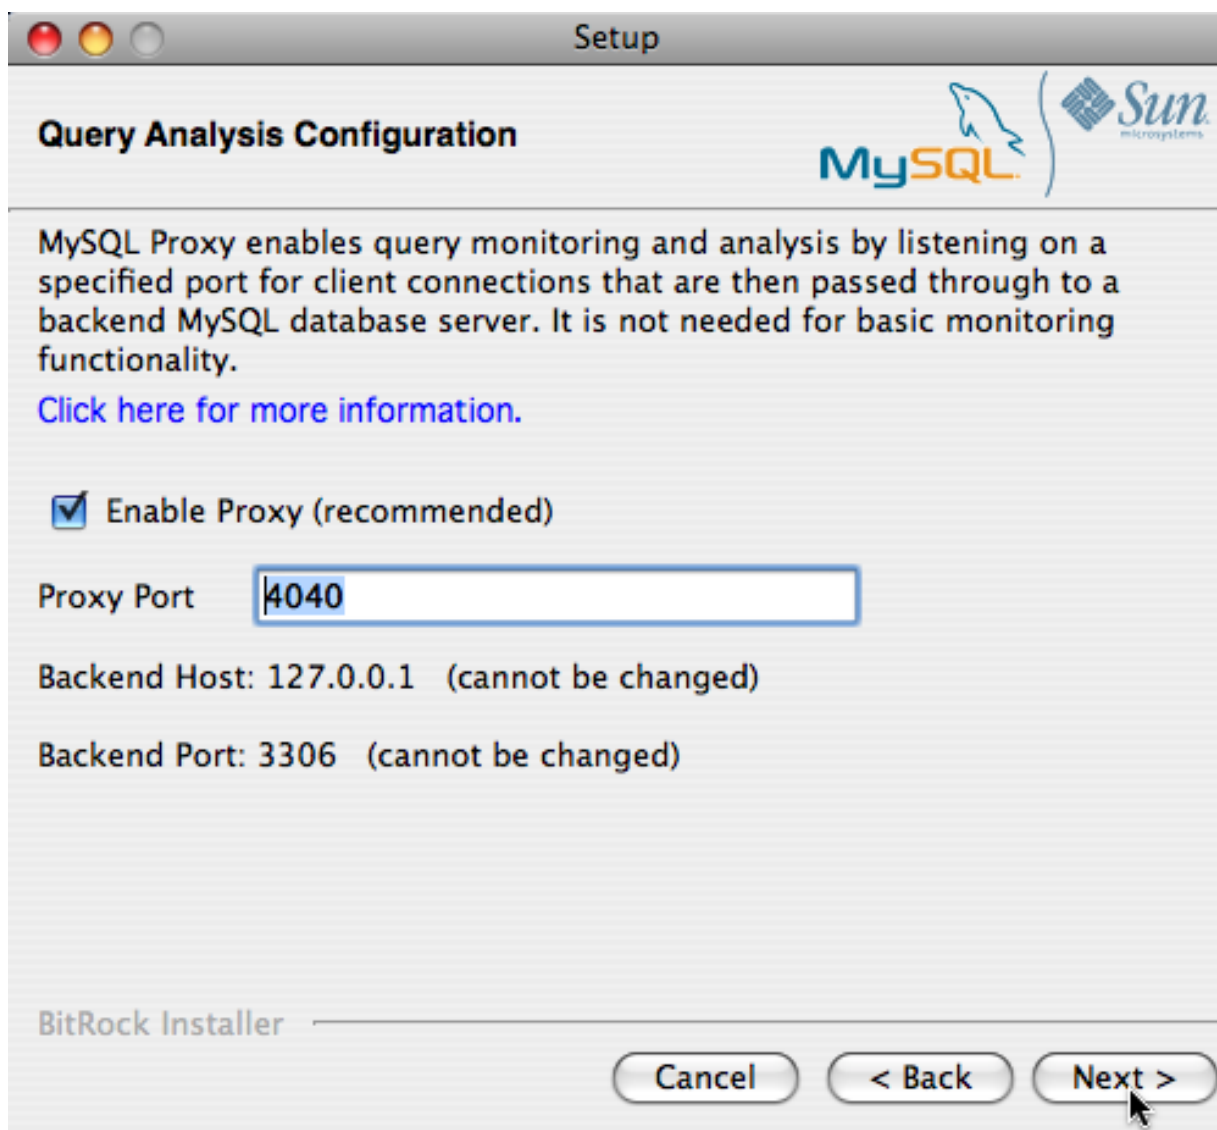

Click NEXT to continue the installation.

5. If you want to use Query Analyzer, then you need to enable the MySQL Enterprise Monitor Agent Proxy. The Proxy is enabled by default. If you disable the Proxy during installation, you will need to enable it later before you are able to use Query Analysis. For more information on Query Analyzer, see [Section 15.10, “The Query Analyzer Page”](#).

When Proxy is enabled, MySQL Enterprise Monitor Agent listens on a network port for client applications, and forwards the connections to the backend MySQL server. You can change the port number that MySQL Enterprise Monitor Agent listens for connections. The default port is 4040.

Figure 15.22. MySQL Enterprise Monitor: Installing Agent on Mac OS X: Query Analyzer Configuration

6. The MySQL Enterprise Service Manager that you want to use must be configured during installation. The host name, port and agent authentication information must be entered. If you have already installed MySQL Enterprise Service Manager then you can locate the information in the installation report file created during installation. Enter the required information and then click NEXT to continue.

Figure 15.23. MySQL Enterprise Monitor: Installing Agent on Mac OS X: MySQL Enterprise Service Manager Options

The screenshot shows a 'Setup' window for 'MySQL Enterprise Monitor Options'. The window has a title bar with three colored buttons (red, yellow, grey) and the text 'Setup'. Below the title bar, the text 'MySQL Enterprise Monitor Options' is displayed in bold. To the right of this text are the MySQL logo (a blue fish) and the Sun Microsystems logo (a blue sun). The main area of the window contains five input fields arranged vertically. The first field is labeled 'Hostname or IP address' and is empty. The second field is labeled 'Port' and contains the text '18080'. The third field is labeled 'Agent Username' and contains the text 'agent'. The fourth field is labeled 'Agent Password' and is empty. The fifth field is labeled 'Re-enter' and is empty. At the bottom of the window, there are three buttons: 'Cancel', '< Back', and 'Next >'. The text 'BitRock Installer' is visible in the bottom left corner of the window.

7. You will be provided with a Configuration Report containing the information that you have entered during the installation. Check the information provided in the report. If you see a problem, use BACK to go back to the configuration screen and change the information. If the information is correct, click NEXT to continue.
8. You are given a final opportunity to change the installation parameters. Click NEXT to start the installation process.
9. Once the agent has been installed, you will get a confirmation message. Click NEXT to finalize the installation.
10. You can start the MySQL Enterprise Monitor Agent automatically now the installation has been completed. To allow the agent to be started, leave the checkbox selected. To start the agent separately, uncheck the checkbox. Click FINISH to exit the installation.

Once the Monitor Agent is installed, it needs to be started. For information on how to start and stop the Agent, see [Section 15.3.3.5.2, "Starting/Stopping the Agent on Mac OS X"](#).

15.3.3.4. Installing the Monitor Agent on Unix

As a prerequisite for installing the MySQL Enterprise Monitor Agent on Linux systems you must have the Linux Standards Base (LSB) initialization functions installed.

To install the agent navigate to the directory that contains the file, `mysqlmonitoragent-version-installer.bin` (where *version* indicates the three-part version number, the OS, and the architecture). Ensure that this file is executable by typing:

```
shell> chmod +x mysqlmonitoragent-version-installer.bin
```

To install to the default directory (`/opt/mysql/enterprise/agent`) you need to be logged in as `root`. Installing as an unprivileged user installs to the `/home/user_name/mysql/enterprise/agent` directory.

Note

If you install the agent as an unprivileged user, it will not automatically start up on rebooting.

What follows describes installation from the command line. You may install the Monitor Agent graphically by running the installer from within a windows manager. In both cases the steps are identical. You may also install the Monitor Agent in `unattended` mode. This is especially useful if you are doing multiple installations. For more information on this topic see [Section 15.3.4, “Unattended Installation”](#).

Begin installation from the command line by typing:

```
shell> ./mysqlmonitoragent-version-installer.bin --mode text
```

The various options are shown in what follows. Default values are indicated by square brackets; to select them press ENTER. Otherwise enter a value of your choosing.

1. First, you must select the Language you want to use during the installation process:

```
Language Selection
Please select the installation language
[1] English
[2] Japanese
Please choose an option [1] :
```

2. Next, specify the directory where you want the agent installed:

```
-----
Welcome to the MySQL Enterprise Monitor Agent Setup Wizard.
-----
Please specify the directory where MySQL Enterprise Monitor Agent will be installed
Installation directory [/opt/mysql/enterprise/agent]:
```

3. Specify the MySQL server that you want to monitor. First, you must specify whether you want to use a TCP/IP or socket-based connection to communicate with the MySQL Server:

```
How will the agent connect to the database it is monitoring?

[1] TCP/IP
[2] Socket
Please choose an option [1] :
```

If you select TCP/IP, then you will be asked to enter the TCP/IP address and port number:

```
-----
Monitored Database Information
IMPORTANT: The agent user account specified below requires special MySQL privileges.
Visit the following URL for more information:
https://enterprise.mysql.com/docs/monitor/2.0/en/mem-install.html#mem-agent-rights
MySQL hostname or IP address [127.0.0.1]:

Validate MySQL hostname or IP address [Y/n]:

MySQL Port [3306]:
```

If you select Socket, then you will be asked to provide the path name to the MySQL socket. Typical values are `/tmp/mysql.sock`, `/var/lib/mysql.sock`, or `/var/run/mysql.sock`.

```
-----
Monitored Database Information
IMPORTANT: The agent user account specified below requires special MySQL privileges.
```

Visit the following URL for more information:
<https://enterprise.mysql.com/docs/monitor/2.0/en/mem-install.html#mem-agent-rights>
 MySQL Socket []:

Note

The service agent always associates “localhost” with the TCP/IP address 127.0.0.1, not the MySQL socket. This is in contrast to the MySQL Command Line Tool, which connects via the MySQL socket by default on Unix, if the host name “localhost” is specified.

If the MySQL server you wish to monitor has been started with the `--skip-networking` command option then you will not be able to connect to it via TCP/IP, as the server will not listen for TCP/IP connections. In this case the service agent will need to be configured to use the MySQL socket. This can be done during installation by selecting “socket” rather than “TCP/IP” and then specifying the MySQL socket name. This can also be configured after installation by editing the `agent-instance.ini` configuration file, for further information on this refer to [Section 15.3.3.6.2, “MySQL Server \(agent-instance.ini\) Configuration”](#).

If the MySQL server to be monitored has been started using the command option `--bind-address` then the server will only listen for connections on the IP address specified, that is, the IP address of the MySQL server. If the service agent has been started using TCP/IP networking and the default address of 127.0.0.1 it will not be able to connect to the server to be monitored. Also, if “localhost” is specified as the host name during agent configuration, a connection will not be established, as the server will be listening for connections on the address specified with the `--bind-address` option, not 127.0.0.1.

- Specify the user credentials for the MySQL server that you want to monitor:

```
MySQL Username []: service_agent
MySQL Password :
Re-enter :
```

- Select whether you want to enable Query Analyzer. If you disable the Query Analyzer during installation, you will need to manually edit the configuration file to re-enable the Query Analyzer functionality. If you enable Query Analysis (Proxy), you must specify the port on which the agent will listen for queries.

```
-----
Query Analyzer Configuration
MySQL Proxy enables query monitoring and analysis by listening on a specified port for client connections that are
Click here for more information.
[Y/n]:
Enable Proxy (recommended) [Y/n]:

Proxy Port [4040]:
Backend Host: 127.0.0.1 (cannot be changed)
Backend Port: 3306 (cannot be changed)
```

For more information on enabling Query Analyzer if you disabled it during installation, see [Section 15.10, “The Query Analyzer Page”](#).

- Enter the details of the MySQL Enterprise Service Manager that you want to use with this agent. The configuration information required is available within the installation report generated when you installed MySQL Enterprise Service Manager

```
-----
MySQL Enterprise Monitor Options

Hostname or IP address []: 192.168.0.197
Tomcat Server Port [18080]:
Tomcat SSL Port [18443]:
```

The agent and MySQL Enterprise Service Manager support using SSL for communication. If you want to enable SSL communication between the agent and the MySQL Enterprise Service Manager, you must reply **Y** to the following question.

```

Use SSL? [y/N]:
Agent Username [agent]:
Agent Password :
Re-enter :
-----

```

7. Before installation starts, you will be provided with a summary of the installation settings that you have specified:

```

Here are the settings you specified:
Installation directory: /opt/mysql/enterprise/agent
Monitored MySQL Database:
-----
Hostname or IP address: 127.0.0.1
Port: 3306
MySQL username: mysql_user
MySQL password: password
Query Analyzer Configuration
-----
Proxy Enabled: yes
Proxy Port: 4040
MySQL Enterprise Manager:
-----
Hostname or IP address: 192.168.0.197
Tomcat Server Port: 18080
Tomcat SSL Port: 18443
Use SSL: 0
Agent username: agent
Press [Enter] to continue :
-----
Setup is now ready to begin installing MySQL Enterprise Monitor Agent on your computer.
Do you want to continue? [Y/n]: y

```

8. The installer will copy the necessary files and create the configuration file required to run the agent:

```

-----
Please wait while Setup installs MySQL Enterprise Monitor Agent on your computer.

Installing
0% _____ 50% _____ 100%
#####
-----
Info to start MySQL Agent

The MySQL agent was successfully installed. To start the MySQL Agent please
invoke:
/opt/mysql/enterprise/agent/etc/init.d/mysql-monitor-agent start
Press [Enter] to continue :
-----
Setup has finished installing MySQL Enterprise Monitor Agent on your computer.

```

9. Finally, you can read the supplied [README](#) file when prompted. The file is provided within the [share/doc/README_en.txt](#) file within the agent installation directory if you would like to read this file separately.

For information on starting the agent, see [Section 15.3.3.5.3, “Starting/Stopping the Agent on Unix”](#).

15.3.3.5. Starting/Stopping the MySQL Enterprise Monitor Agent

The MySQL Enterprise Monitor Agent can be started and stopped at any time. When not running, information about the current status of your server will not be available, and MySQL Enterprise Service Manager will provide a warning if an agent and the MySQL server that it monitors is unavailable.

■ Warning

If you are using Query Analyzer, then turning off the agent will prevent your applications from communicating with the MySQL server. See [Section 15.10, “The Query Analyzer Page”](#).

15.3.3.5.1. Starting/Stopping the Agent on Windows

You have the option of starting the Monitor Agent from the final installation screen. Otherwise you can do this by going to the [Start Menu](#) and under [Programs](#) find [MySQL](#) and then the [MySQL Enterprise Monitor Agent](#) entry. Simply select the [Start MySQL Enterprise Monitor Agent](#) option.

Note

On Windows Vista, starting the agent requires administrative privileges — you must be logged in as an administrator. To start or stop the agent right click the menu item and choose the [RUN AS ADMINISTRATOR](#) menu option. The same restriction applies to starting the agent from the command line. To open an administrator [cmd](#) window right-click the [cmd](#) icon and choose the [RUN AS ADMINISTRATOR](#) menu option.

Warning

To report its findings, the agent needs to be able to connect to the dashboard through the port specified during installation. The default value for this port is [18080](#); ensure that this port is not blocked. If you need help troubleshooting the agent installation see, [Section 15.3.3.7, “Troubleshooting the Agent”](#).

Alternately, you can start the agent from the command line by entering:

```
shell> sc start MySQLEnterpriseMonitorAgent
```

or:

```
shell> net start MySQLEnterpriseMonitorAgent
```

You can also start the agent by issuing the command, [agentctl.bat start](#). Stop the agent by passing the argument, [stop](#). This batch file is found in the [Agent](#) directory.

For confirmation that the service is running you can open the Microsoft Management Console Services window. To do this go to the Control Panel, find [Administrative Tools](#) and click on the link to [Services](#). Locate the service named [MySQL Enterprise Monitor Agent](#) and look under the [STATUS](#) column.

You may also start the agent from this window rather than from the [Start](#) menu or the command line. Simply right click [MySQL Enterprise Monitor Agent](#) and choose [Start](#) from the pop-up menu. Starting the agent from this window opens an error dialog box if the agent cannot connect to the MySQL server it is monitoring. No error is displayed if the agent is unable to connect to the MySQL Enterprise Service Manager.

The pop-up menu for starting the agent also offers the option of stopping the agent. To stop the agent from the command line you only need type:

```
shell> sc stop MySQLEnterpriseMonitorAgent
```

or:

```
shell> net stop MySQLEnterpriseMonitorAgent
```

Note

[MySQLEnterpriseMonitorAgent](#) is the default name of the Monitor Agent service. If you have added an additional agent as described in [Section 15.3.3.6.2, “MySQL Server \(agent-instance.ini\) Configuration”](#), replace [MySQLEnterpriseMonitorAgent](#) with the appropriate agent name.

15.3.3.5.2. Starting/Stopping the Agent on Mac OS X

The script to start the agent on Mac OS X is located in the [/Applications/mysql/enterprise/agent/etc/init.d](#) directory. To start the agent navigate to this directory and at the command line type:

```
shell> ./mysql-monitor-agent start
```

To stop the agent, use the [stop](#) command:

```
shell> ./mysql-monitor-agent stop
```

If the agent cannot be stopped because the `pid` file that contains the agent's process ID cannot be found, you can use `kill` to send a `TERM` signal to the running process:

```
shell> kill -TERM PID
```

If you are running more than one agent on a specific machine, you must also specify the path to the `ini` file when you are stopping the agent. Executing `mysql-monitor-agent stop` without an `ini` file will only stop the agent associated with the default `ini` file.

For more information about creating additional agents see, [Section 15.3.3.6.2, “MySQL Server \(agent-instance.ini\) Configuration”](#).

To verify that the agent is running use the following command:

```
shell> ./mysql-monitor-agent status
```

The resulting message indicates whether the agent is running or not. If the agent is not running, use the following command to view the last ten entries in the agent log file:

```
shell> tail /Applications/mysql/enterprise/agent/log/mysql-monitor-agent.log
```

For further information on troubleshooting the agent see [Section 15.3.3.7, “Troubleshooting the Agent”](#).

Installation creates the directory `/Applications/mysql/enterprise/agent` with the settings stored in the `mysql-monitor-agent.ini` file located directly below this directory in the `etc` directory. The `log` directory is also located immediately below the `agent` directory.

To see all the command-line options available when running the service agent, navigate to the `/Applications/mysql/enterprise/agent/etc/init.d` directory and execute `mysql-monitor-agent help`. You should see the message:

```
Usage: ./mysql-monitor-agent {start|stop|restart|status} [ini-file-name]
```

The `ini-file-name` option only needs to be used if the `ini` file is not installed to the default location or you have changed the name of the `ini` file. You will need to use this option if you are installing more than one agent on the same machine. Pass the full path to the `ini` file. For example, after navigating to the `/Applications/mysql/enterprise/agent/etc/init.d` directory, issue the command:

```
shell> ./mysql-monitor-agent start /Applications/mysql/enterprise/agent/etc/new-mysql-monitor-agent.ini
```

If you installed the agent as `root`, on reboot the `mysql-monitor-agent` daemon will start up automatically. If you installed the agent as an unprivileged user, you must manually start the agent on reboot or write a script to perform this task. Likewise, if you have added an additional agent as described in [Section 15.3.3.6.2, “MySQL Server \(agent-instance.ini\) Configuration”](#), and you wish to start this agent on reboot, create a system initialization script appropriate to your operating system. To determine whether the agent is running or not navigate to the `init.d` directory and issue the command `./mysql-monitor-agent status`.

Warning

To report its findings, the agent needs to be able to connect to the dashboard through the port specified during installation. The default value for this port is `18080`; ensure that this port is not blocked. If you need help troubleshooting the agent installation see, [Section 15.3.3.7, “Troubleshooting the Agent”](#).

15.3.3.5.3. Starting/Stopping the Agent on Unix

When installation is finished, you can start the service agent from the command line by typing:

```
shell> /opt/mysql/enterprise/agent/etc/init.d/mysql-monitor-agent start
```

For a non-root installation the command would be:

```
shell> /home/<user name>/mysql/enterprise/agent/etc/init.d/mysql-monitor-agent start
```

To stop the agent, use the `stop` command:

```
shell> ./mysql-monitor-agent stop
```

If the agent cannot be stopped because the `pid` file that contains the agent's process ID cannot be found, you can use `kill` to send a `TERM` signal to the running process:

```
shell> kill -TERM PID
```

If you are running more than one agent on a specific machine, you must also specify the path to the `ini` file when you are stopping the agent. Executing `mysql-monitor-agent stop` without an `ini` file will only stop the agent associated with the default `ini` file. Likewise, when checking the status of an agent specify its `ini` file.

For more information about creating additional agents see, [Section 15.3.3.6.2, “MySQL Server \(agent-instance.ini\) Configuration”](#).

To verify that the agent is running use the following command:

```
shell> ./mysql-monitor-agent status
```

The resulting message indicates whether the agent is running or not. If the agent is not running, use the following command to view the last ten entries in the agent log file:

```
shell> tail /opt/mysql/enterprise/agent/log/mysql-monitor-agent.log
```

For further information on troubleshooting the agent see [Section 15.3.3.7, “Troubleshooting the Agent”](#).

Installation creates the directory `/opt/mysql/enterprise/agent` with the settings stored in the `mysql-monitor-agent.ini` file located directly below this directory in the `etc` directory. The `log` directory is also located immediately below the `agent` directory.

To see all the command-line options available when running the service agent, navigate to the `/opt/mysql/enterprise/agent/etc/init.d` directory and execute `mysql-monitor-agent help`. You should see the message:

```
Usage: ./mysql-monitor-agent {start|stop|restart|status} [ini-file-name]
```

The `ini-file-name` option only needs to be used if the `ini` file is not installed to the default location or you have changed the name of the `ini` file. You will need to use this option if you are installing more than one agent on the same machine. Pass the full path to the `ini` file. For example, after navigating to the `/opt/mysql/enterprise/agent/etc/init.d` directory, issue the command:

```
shell> ./mysql-monitor-agent start /opt/mysql/enterprise/agent/etc/new-mysql-monitor-agent.ini
```

If you installed the agent as `root`, on reboot the `mysql-monitor-agent` daemon will start up automatically. If you installed the agent as an unprivileged user, you must manually start the agent on reboot or write a script to perform this task. Likewise, if you have added an additional agent as described in [Section 15.3.3.6.2, “MySQL Server \(agent-instance.ini\) Configuration”](#), and you wish to start this agent on reboot, create a system initialization script appropriate to your operating system. To determine whether the agent is running or not navigate to the `init.d` directory and issue the command `./mysql-monitor-agent status`.

Warning

To report its findings, the agent needs to be able to connect to the dashboard through the port specified during installation. The default value for this port is `18080`; ensure that this port is not blocked. If you need help troubleshooting the agent installation see, [Section 15.3.3.7, “Troubleshooting the Agent”](#).

15.3.3.6. Advanced Agent Configuration

The MySQL Enterprise Monitor Agent is configured through files located within the `etc` directory within the directory where you installed the agent.

Configuration is stored in multiple files, according to a predetermined file and directory layout. The primary configuration file contains specific information about the agent and how the agent communicates with MySQL Enterprise Service Manager. The main configuration is located within the `mysql-monitor-agent.ini` file.

Additional configuration files contain information about the MySQL server that is being monitored. You can configure which directory is used for storing this information within the `mysql-monitor-agent.ini` file. The default location is the `etc/instances` directory within the MySQL Enterprise Monitor Agent directory.

The server you want to monitor should have a directory within the specified location, optionally using the name of the server you are monitoring, and within that directory, an `agent-instance.ini` file. This file contains the configuration information for

connecting to the MySQL server, including the host name, port, user credentials and display name.

You can see an example of the file layout of the `etc` directory:

```
./init.d
./init.d/mysql-monitor-agent
./instances
./instances/agent
./instances/agent/agent-instance.ini
./mysql-monitor-agent.ini
```

For more information on the configuration of the `mysql-monitor-agent.ini` file, see [Section 15.3.3.6.1, “MySQL Enterprise Monitor Agent \(`mysql-monitor-agent.ini`\) Configuration”](#). For details on the content of the individual MySQL instance configuration files, see [Section 15.3.3.6.2, “MySQL Server \(`agent-instance.ini`\) Configuration”](#).

15.3.3.6.1. MySQL Enterprise Monitor Agent (`mysql-monitor-agent.ini`) Configuration

The `mysql-monitor-agent.ini` files contains the base configuration information for the MySQL Enterprise Monitor Agent. The file sets the core information about the supported functionality for the entire agent.

You can see a sample of the configuration file below:

```
# WARNING - the UUID defined below must be unique for each agent.
#
# To use this .ini file as a template for configuring additional
# agents, do not simply copy and start a new agent without first
# modifying the UUID.
#
# Refer to the documentation for more detailed information and
# instructions.
#
# Version: 20080718_230416_r7011

[mysql-proxy]

plugins=proxy,agent
agent-mgmt-hostname = http://agent:password@monitor-server:18080/heartbeat
mysql-instance-dir= etc/instances
agent-item-files = share/mysql-proxy/items/quan.lua,share/mysql-proxy/items/items-mysql-monitor.xml
proxy-address=:4040
proxy-backend-addresses = 127.0.0.1:3306
proxy-lua-script = share/mysql-proxy/quan.lua

agent-uuid = 8770ead5-3632-4b29-a413-4a7c92437e26
log-file = mysql-monitor-agent.log
pid-file=/Applications/mysql/enterprise/agent/mysql-monitor-agent.pid
```

Note

Do not copy the agent configuration information from one machine to another without changing the `agent-uuid`. Each agent instance must have a unique agent id.

The main configuration information must be located within the `[mysql-proxy]` section of the configuration file. The main configurable parameters within this file are:

- `plugins` — configures the plugins to be used by the agent. When monitoring servers you must have the `agent` plugin configured. If you want to support Query Analyzer then you must also have the `proxy` module enabled. Plugins should be specified as a comma separated list of plugin names.

If you selected to support Query Analyzer during installation of the agent, the default value will be `proxy,agent`. If you disabled Query Analysis during installation, the default value will be `agent`.

- `log-level` — sets the logging level of the agent. The default level is `message`.

Valid values for `log-level` are as follows:

- `debug` — provides detailed information about what the agent is doing and the information being provided by the agent to the MySQL Enterprise Service Manager.
- `critical` — lists critical messages highlighting problems with the agent.
- `error` — lists error messages.
- `warning` — provides only warning messages generated by the agent.
- `message` — provides information about the agent and basic processing information.

- `info` — provides messages used for informational purposes.

Warning

Be careful when setting the `log-level` to `debug`. Doing this will rapidly increase the size of your `mysql-monitor-agent.log` file. To avoid disk space problems, put the log files on a different drive from your MySQL server and the MySQL Enterprise Dashboard.

It is strongly recommended that you use a `log-level` of `critical` or `error` in a production server. Use the higher-levels to provide more detailed information only for debugging problems with your agent.

Under Windows, if you restart the agent from the command line after setting the `log-level` to `debug`, extensive debug information is displayed to the console as well as to the log file.

- `agent-mgmt-hostname` — sets the URL to use when reporting information. This value will be automatically set to your MySQL Enterprise Service Manager during installation.
 - `mysqld-instance-dir` — sets the directory where the configuration files that specify the MySQL servers to be monitored can be located.
 - `agent-item-files` — sets the information that is provided up to the MySQL Enterprise Service Manager when the agent is reporting status information. You should leave this item with the default setting of the `share/mysql-proxy/items/quant.lua` (which provides Query Analyzer data) and `share/mysql-proxy/items/items-mysql-monitor.xml` (which provides the core agent monitoring data).
 - `proxy-address` — sets the address and/or port number for the proxy to listen to for connections. The setting is used when employing Query Analysis as the address/port that you must configure your application to use in place of your normal MySQL server. By default this item is set during installation. The default value is 4040. If you want to support a different local host name/IP address and port, specify the host name and the port number, separated by a colon.
 - `proxy-backend-addresses` — sets the host name and port number to be used when communicating the backend MySQL server when employing query analyzer. This is the MySQL server where packets from the client are sent when communicating with the proxy on the host name/port set by the `proxy-address`.
 - `proxy-lua-script` — sets the Lua script to be used by the proxy when forwarding queries. To use Query Analyzer, this parameter should be set to `share/mysql-proxy/quant.lua`. This is the default value.
 - `agent-uuid` — sets the UUID (Universally Unique ID) of the agent. This value should be unique for all agents communicating with the same server, as the UUID is used to uniquely ID the agent within MySQL Enterprise Service Manager
- If you are setting up multiple hosts and copying the configuration between hosts, make sure that the `agent-uuid` is unique. You can have the agent create a new UUID by leaving this configuration property blank.
- `log-file` — sets the location of the log file used to record information about the agent when it is running. If you do not specify a full path name, then the log file location is considered to be relative to the installation directory of the agent.
 - `pid-file` — sets the location of the file used to record the Process ID of the agent. This is used by the script that shuts down the agent to identify the process to be shutdown. The default value is the `mysql-monitor-agent.pid` file within the base installation directory as created by the agent installer.

A number of optional parameters are also configurable within the `mysql-monitor-agent.ini` file:

- `backlog-threshold` — determines the amount of time that the agent will collect information after detecting that the service manager is down. The default value for this option is 600 seconds. In cases where there is a short network outage no information will be lost. If the outage is longer than the value of `backlog-threshold` older data is dropped as the new data is acquired.

A setting of 600 seconds means that excessive memory usage is avoided should there be a long outage. In most circumstances, there is no need to change this option. To set `backlog-threshold` to a value other than the default, add a line with the information specifying the number of seconds.

Warning

Setting this option to a value higher than the default can exhaust memory.

15.3.3.6.2. MySQL Server (`agent-instance.ini`) Configuration

For the MySQL server that you want to monitor, you must create an `agent-instance.ini` within the directory specified by the `mysqld-instance-dir` configuration parameter within the main `mysql-monitor-agent.ini` file.

The `agent-instance.ini` file contains the host name and user credentials for connecting to the MySQL server that you want the agent to monitor. The format of the file is as follows:

```
# WARNING - the displayname defined below must be unique for each
# MySQL server being monitored.
#
# To use this .ini file as a template for configuring additional
# instances to monitor, do not simply copy and start a new agent
# without first modifying the displayname.
#
# Refer to the documentation for more detailed information and
# instructions.
#
# Version: 20080718_230416_r7011

[mysqld]
hostname = 127.0.0.1
port     = 3306
user     = root
password =
```

The individual configuration parameters can be defined as follows:

- `hostname` — the host name of the MySQL server that you want to monitor.
- `port` — the TCP/IP port of the MySQL server that you want to monitor.
- `user` — the user to use when connecting to the MySQL server that you want to monitor.
- `password` — the corresponding password to use when connecting to the MySQL server that you want to monitor.

It is also possible to configure the agent to use sockets. This can be done during installation by selecting “socket” rather than “TCP/IP” from the menu and then specifying the socket name. This can also be configured after installation by editing the `agent-instance.ini` configuration file, and adding the line:

```
socket = /full/path/to/mysql.sock
```

15.3.3.6.3. Monitoring Multiple MySQL Servers

You can monitor multiple MySQL servers (either on the same machine, or across different machines) using two different methods:

- By using a single agent instance to monitor multiple MySQL servers. You can use this method if you want to monitor multiple servers, but do not want or need to support Query Analysis on the additional servers.
- By using multiple copies of the MySQL Enterprise Monitor Agent to monitor each server individually. Using this method requires additional overhead to monitor each server, while also allowing you to supply Query Analysis data.

Using a Single Agent Instance

To use a single agent to monitor multiple instances, you can create additional directories and configuration files within the `instances` directory for the agent. For example, you can see the default structure of the agent configuration directory:

```
./init.d
./init.d/mysql-monitor-agent
./instances
./instances/agent
./instances/agent/agent-instance.ini
./mysql-monitor-agent.ini
```

Within the `instances` directory, you can add further directories, one for each monitored server. Each additional directory must have a suitable `agent-instance.ini` file containing the connection information for the new MySQL server instance. For example, the following structure demonstrates an agent monitoring four MySQL servers:

```
./init.d
./init.d/mysql-monitor-agent
./instances
./instances/agent
./instances/agent/agent-instance.ini
./instances/mysql2
./instances/mysql2/agent-instance.ini
./instances/mysql-rep
```

```
./instances/mysql-rep/agent-instance.ini
./instances/mysql-backup
./instances/mysql-backup/agent-instance.ini
./mysql-monitor-agent.ini
```

To add another MySQL monitored server, follow these steps:

1. Make sure that the MySQL instance that you want to monitor has a suitable user to use for connecting to the server. For more information, see [Section 15.3.3.1, “Creating a MySQL User Account for the Monitor Agent”](#).
2. Copy an existing configuration directory and configuration files to the new directory:

```
shell> cp -R etc/instances/agent etc/instances/mysql2
```

3. Edit the configuration file within the new directory, for example `mysql2/agent-instance.ini`, and set the `user`, `password` and either the `hostname` and `port`, or `socket` parameters.
4. Restart the agent:

```
shell> mysql-monitor-agent restart
```

Using Multiple Agent Instances

To use multiple agents to monitor multiple MySQL servers you need to create a new configuration structure for both the agent and the MySQL server instances you need to monitor, including the binaries and configuration files, and then update the configuration to set the corresponding parameters to monitor the new server. Using this method allows you to enable query analysis by redirecting requests to the target server using the built-in proxy service within the agent.

For example, the directory structure below shows the configuration directory for two agents monitoring a single MySQL server each:

```
./init.d
./init.d/mysql-monitor-agent
./instances
./instances/agent
./instances/agent/agent-instance.ini
./instances-second/agent
./instances-second/agent/agent-instance.ini
./mysql-monitor-agent.ini
./mysql-second-agent.ini
```

The `mysql-monitor-agent.ini` file contains the configuration for the first agent, with the MySQL servers monitored defined within the `instances` directory. The `mysql-second-agent.ini` file contains the configuration information for the second agent, with the MySQL servers monitor defined within the `instances-second` directory.

To set up multiple agents:

1. Make sure that the MySQL instance that you want to monitor has a suitable user to use for connecting to the server. For more information, see [Section 15.3.3.1, “Creating a MySQL User Account for the Monitor Agent”](#).
2. You need to generate a new UUID for the new agent:

```
shell> mysql-monitor-agent --agent-generate-uuid
ee9296d7-f7cd-4fee-8b26-ead884ebf398
2009-03-05 11:49:37: (critical) shutting down normally
```

Keep a record of the UUID to update the configuration file.

Note, the agent should not be running when the UUID is generated.

3. Copy the main agent configuration file, `mysql-monitor-agent.ini`:

```
shell> cp mysql-monitor-agent.ini mysql-second-agent.ini
```

4. Edit the new configuration file, changing the following settings:

- Change the `mysql-d-instance-dir` to the new directory that will contain the individual MySQL server configuration files.

- Change the `proxy-address` to a different value than the first agent configuration.
 - Change the `proxy-backend-addresses` to specify the IP address and MySQL port number for the MySQL server.
 - Change the `agent-uuid` to the new value obtained in an earlier step.
 - Change the `log-file` parameter to specify a different file to use when logging errors and problems. You cannot log to the same file from two different agents.
 - Change the `pid-file` parameter to specify the file that will be used to store the process ID of the agent.
5. Copy an existing configuration directory and configuration files to the new directory:

```
shell> cp -R etc/instances etc/instances-second
```

6. Edit the configuration file, `instances/second/agent/agent-instance.ini` within the new directory, and set the `user`, `password` and either the `hostname` and `port`, or `socket` parameters.
7. With multiple instances, you must start each agent individually, specifying the location of the main configuration file. For example, to start the original (default) service:

```
shell> mysql-monitor-agent start /opt/mysql/monitor/agent/etc/mysql-monitor-agent.ini
```

To start the second instance:

```
shell> mysql-monitor-agent start /opt/mysql/monitor/agent/etc/mysql-second-agent.ini
```

15.3.3.6.4. Configuring an Agent to Monitor a Remote MySQL Server

Typically, the agent runs on the same machine as the MySQL server it is monitoring. Fortunately, this is not a requirement. If you want to monitor a MySQL server running on an operating system for which there is no agent available, you can install the agent on a machine other than the one hosting the MySQL server.

The process for installing an agent to monitor a MySQL server on a remote machine is identical to the process described in [Section 15.3.3, “Monitor Agent Installation”](#). Follow the directions given there, being careful to specify the correct IP address or host name for the MySQL Enterprise Service Manager and likewise for the MySQL server — since the agent is not running on the same machine as the MySQL server, it cannot be the default, `localhost`.

Don't forget that the agent must be given rights to log in to the MySQL server from a host other than `localhost` and that the port used by the MySQL server, typically `3306` must be open for remote access. For more information about the database credentials required by agents see, [Section 15.3.3.1, “Creating a MySQL User Account for the Monitor Agent”](#).

The agent also needs to be able to log in to the MySQL Enterprise Service Manager, typically using port `18080`, so ensure that the appropriate port is open.

Note

Monitoring a MySQL server from a remote machine affects how information is displayed in the dashboard. The `OS` and `CPU` information applies to the machine on which the agent is running not the machine hosting the monitored server. For more information on this topic see [Section 15.5, “MySQL Enterprise Dashboard”](#).

If your subscription level entitles you to replication autodiscovery, do **not** use remote monitoring with replication slaves or masters. The agent must be installed on the same machine as the server you are monitoring in order for discovery to work properly. For more information, see [Section 15.11, “The Replication Page”](#).

15.3.3.6.5. Monitoring Outside the Firewall with an SSH Tunnel

If you run an SSH server on the machine that hosts the MySQL Enterprise Service Manager and an SSH client on the machine that hosts the agent, you can create an SSH tunnel so that the agent can bypass your firewall. First, you need to make an adjustment to the `hostname` value specified in the `[mysql-proxy]` section of the `.ini` file. (For more information about the contents and location of the `.ini` file see [Section 15.3.3.6.1, “MySQL Enterprise Monitor Agent \(`mysql-monitor-agent.ini`\) Configuration”](#).) Stop the agent and change the `hostname` value as shown in the following:

```
hostname = http://agent_name:password@localhost:18080/heartbeat
```

Replace the `agent_name` and `password` with suitable values. Likewise replace port `18080` if you are not running the dashboard on this port. Use `localhost` for the host name, since the agent is connecting through an SSH tunnel.

Next, execute the following command on the machine where the agent is running:

```
shell> ssh -L 18080:Dashboard_Host:18080 -l user_name -N Dashboard_Host
```

When prompted, enter the password for `user_name`.

If you are not running the MySQL Enterprise Service Manager on port 18080, substitute the appropriate port number. Likewise, replace `Dashboard_Host` with the correct value. `user_name` represents a valid operating system user on the machine that hosts the MySQL Enterprise Service Manager.

Be sure to restart the agent so that the new value for the `hostname` takes effect. For instructions on restarting the agent see:

- Under Windows see, [Section 15.3.3.5.1, “Starting/Stopping the Agent on Windows”](#).
- Under Unix see, [Section 15.3.3.5.3, “Starting/Stopping the Agent on Unix”](#).
- Under Mac OS X see, [Section 15.3.3.5.2, “Starting/Stopping the Agent on Mac OS X”](#).

15.3.3.6.6. Generating a new UUID

In Unix go to the command line and type:

```
shell> /opt/mysql/enterprise/agent/bin/mysql-monitor-agent --agent-generate-uuid
```

In Mac OS X go to the command line and type:

```
shell> /Applications/mysql/enterprise/agent/bin/mysql-monitor-agent --agent-generate-uuid
```

This should display a line similar to the following:

```
ee9296d7-f7cd-4fee-8b26-ead884ebf398
```

Paste this line into the `[mysql-proxy]` section of the `ini` file for the `agent-uuid` parameter.

Ensure that the newly created file `mysql-service-agent-3307.ini`, is in the `C:\Program Files\MySQL\Enterprise\Agent` directory.

Navigate to this directory and execute `mysql-service-agent -uf mysql-service-agent-3307.ini`. Doing this generates a new UUID and inserts it into the configuration file.

15.3.3.7. Troubleshooting the Agent

The first step in troubleshooting the agent is finding out whether it is running or not. To do this see:

- Windows – [Section 15.3.3.5.1, “Starting/Stopping the Agent on Windows”](#)
- Unix – [Section 15.3.3.5.3, “Starting/Stopping the Agent on Unix”](#)
- Mac OS X – [Section 15.3.3.5.2, “Starting/Stopping the Agent on Mac OS X”](#)

If incorrect credentials are specified for the agent login to the MySQL server that it is monitoring, then the agent will not run on start-up. Log in to the monitored MySQL server and check the agent's credentials. Compare the values of the `Host`, `User`, and `Password` fields in the `mysql.user` table with the values shown in the `[mysqld]` section of the `etc/instances/mysql/agent-instance.ini`. If incorrect credentials are specified in the `ini` file, simply correct them and restart the agent. Remember, changes to the `ini` file do not take effect until the agent is restarted.

The agent will not start up if incorrect credentials are specified for the service manager login. Using incorrect credentials for logging in to the service manager creates an entry in the agent log file. For the location of this log file see [Agent Log and PID Files](#).

If the agent starts up but no server appears in the dashboard, check the `hostname` specified in the `[mysql-proxy]` portion of the `mysql-monitor-agent.ini` file. Incorrect credentials, IP address, or port will all cause the MySQL server to fail to appear in the dashboard. Also, ensure that the port specified in this file is not blocked on the machine hosting the MySQL Enterprise Service Manager.

An easy way to confirm that the agent can log in to the service manager is to type `http://Dashboard_Host:18080/`

heartbeat into the address bar of your web browser, substituting the appropriate host name and port. When the HTTP authentication dialog box opens, enter the agent user name and password. If you log in successfully, you should see the following message:

```
<exceptions>
<error>E1031: Agent payload parameter NULL.</error>
</exceptions>
```

Note

Despite the fact that the preceding listing shows an error, you have logged in successfully. This error appears *because* you have logged in but with no “payload”.

If you can log in successfully in the way described above and the agent is running, then there are errors in the `mysql-monitor-agent.ini` file. Compare the host name, port, agent name, and password found in the `ini` file with the values you entered into the address bar of your web browser.

If HTTP authentication fails then you are using incorrect credentials for the agent. Attempting to log in to the service manager using incorrect credentials creates an entry in the agent log file. For the location of this log file see [Agent Log and PID Files](#).

If no HTTP authentication dialog box appears, and you are unable to connect at all, then you may have specified an incorrect host name or port. Confirm the values you entered against those described as the `Application hostname and port:` in the `configuration_report.txt` file. Failure to connect could also indicate that the port is blocked on the machine hosting the MySQL Enterprise Service Manager.

To check if a blocked port is the problem, temporarily bring down your firewall. If the agent is then able to connect, open up the port specified during installation and restart the agent. If necessary you can monitor outside the firewall using an SSH tunnel. For more information, see [Section 15.3.3.6.5, “Monitoring Outside the Firewall with an SSH Tunnel”](#).

You can also check the agent error log file to help determine any problems. An error such as the following might indicate a blocked port:

```
(critical) connection to merlin-server
'http://agent:test@172.11.1.1:18080/heartbeat' failed:
"connect() timed out!" error.
```

For the location of the agent error log file see, [Agent Log and PID Files](#).

Setting the `log-level` entry in your `ini` file is also a good debugging technique. For more information on this subject see, [Section 15.3.3.6.1, “MySQL Enterprise Monitor Agent \(mysql-monitor-agent.ini\) Configuration”](#).

Running the agent from the command line sometimes displays errors that fail to appear in the log file or on the screen when the agent is started from a menu option. To start the agent from the command line see the instructions given at the start of this section.

If you have more than one agent running on the same machine, the `UUID` must be unique and the `log-file` and `pid-file` values must be different. For more information, see [Section 15.3.3.6.2, “MySQL Server \(agent-instance.ini\) Configuration”](#).

If the agent is not running on the same machine that hosts the MySQL server it is monitoring, then you must ensure that the correct `host` is specified for the agent account. The correct port, typically 3306, must also be open for remote login. For more information about remote monitoring see, [Section 15.3.3.6.4, “Configuring an Agent to Monitor a Remote MySQL Server”](#).

15.3.4. Unattended Installation

It is possible to install the MySQL Enterprise Monitor without any direct user interaction. This is done by passing the command-line option `--mode unattended` to the installation file.

Using this mode and other command-line parameters means the user will not be prompted for input during installation. This is especially useful when doing multiple installations of the MySQL Enterprise Monitor.

However, rather than passing numerous parameters from the command line, it is usually more convenient to save your options in a text file and invoke the installer using the `optionfile` option. This is a more reusable and less error-prone solution.

Before attempting an unattended installation, it is recommended that you install the MySQL Enterprise Monitor interactively at least once. Failing this, as a minimum, read the regular installation instructions since some tasks still remain after an unattended installation; you must configure the MySQL Enterprise settings, import the advisors, and start up all the services/daemons.

15.3.4.1. Command-Line Options

To view the available options for the monitor installer or for the agent installer, at the command line type the executable file name along with the `help` option.

15.3.4.1.1. MySQL Enterprise Service Manager Options

The following listing shows the command line options for the MySQL Enterprise Service Manager.

```
--help                Display the list of valid options
--version             Display product information
--optionfile <optionfile> Installation option file
                    Default:
--mode <mode>        Installation mode
                    (Windows)Default: win32
                    (Unix)Default: gtk
                    (Mac OS X)Default: osx
                    (Windows)Allowed: win32 unattended
                    (Unix)Allowed: gtk text xwindow unattended
                    (Mac OS X)Allowed: osx text unattended
```

Note

The default modes are different for different operating systems. The values allowed also differ. There is no `text` installation mode under Windows.

```
--debugtrace <debugtrace> Debug filename
                    Default:
--installer-language <installer-language> Language selection
                    Default:
                    Allowed: en jp
--installdir <installdir> Installation directory
                    (Windows)Default:C:\Program »
                    Files\MySQL\Enterprise\Monitor
                    (Unix)Default:/opt/mysql/enterprise/monitor/
                    (Mac OS X)Default:/Applications/mysql/enterprise/monitor/
--tomcatport <tomcatport> Tomcat Server Port
                    Default: 18080
--tomcatshutdownport <tomcatshutdownport> Tomcat Shutdown Port
                    Default: 18005
--tomcatsslport <tomcatsslport> Tomcat SSL Port
                    Default: 18443
--usessl <usessl>    Should communication between the Dashboard »
                    and Service Manager be encrypted?
                    Default: 0
--adminuser <adminuser> Repository Username
                    Default: service_manager
--adminpassword <adminpassword> Password
                    Default:
```

Warning

The repository user name and password are stored in unencrypted form in the `config.properties` file. To locate this file on your operating system see [The config.properties File](#).

```
--dbport <dbport>    Bundled MySQL Database Port
                    Default: 13306
```

The monitor installation options are the same for all operating systems except as noted in the preceding listing.

15.3.4.1.2. MySQL Enterprise Monitor Agent Options

To view all the options available for an unattended *agent* installation, invoke the agent installer file passing in the `help` option. (Under Windows you must redirect the output to a file as shown in [Section 15.3.4.1, “Command-Line Options”](#)). You should see a listing similar to the following:

```
--help                Display the list of valid options
--version             Display product information
                    Default:
--optionfile <optionfile> Installation option file
                    Default:
--mode <mode>        Installation mode
```

```
(Windows)Default: win32
(Unix)Default: gtk
(Mac OS X)Default: osx
(Windows)Allowed: win32 unattended
(Unix)Allowed: gtk text xwindow unattended
(Mac OS X)Allowed: osx text unattended
```

Note

The default modes are different for different operating systems. The values allowed also differ. There is no `text` installation mode under Windows.

```
--debugtrace <debugtrace>      Debug filename
                                Default:
--installer-language <installer-language> Language selection
                                Default:
                                Allowed: en  jp
--installdir <installdir>       Installation directory
                                (Windows)Default: C:\Program Files\MySQL\Enterprise\Agent
                                (Unix)Default: /opt/mysql/enterprise/agent
                                (Mac OS X)Default: /Applications/mysql/enterprise/agent
--mysqlhost <mysqlhost>         MySQL hostname or IP address
                                Default: 127.0.0.1
--checkmysqlhost <checkmysqlhost> Validation of MySQL hostname or IP address
                                Default: yes
--mysqlport <mysqlport>         MySQL port on 127.0.0.1
                                Default: 3306
--mysqluser <mysqluser>         User name on 127.0.0.1:3306
                                Default:
--mysqlpassword <mysqlpassword> Password for mysqluser on 127.0.0.1:3306
                                Default:
--managerhost <managerhost>     Hostname or IP address
                                Default: 127.0.0.1
--tomcatport <tomcatport>       Port on 127.0.0.1
                                Default: 18080
--agentuser <agentuser>         Agent username on 127.0.0.1:18080
                                Default: agent
--agentpassword <agentpassword> Agent password for agent on 127.0.0.1:18080
                                Default:
--servername <servername>      Hostname to display
                                Default:
```

Again, the agent options are the same for all operating systems except as noted.

15.3.4.2. Unattended Windows Installation

For unattended installation on Windows, create an option file named `options.server.txt`. The following is an example of what the contents of an option file might be.

```
debugtrace=C:\Program Files\MySQL\Enterprise\install.debugtrace.log
mode=unattended
installdir=C:\Program Files\MySQL\Enterprise
tomcatport=8080
tomcatshutdownport=8005
tomcatsslport=8443
adminpassword=myadminpassword
dbport=3300
```

This file identifies a directory and file name for a log file, sets the `mode` to `unattended`, and uses the `installdir` option to specify an installation directory. The meaning of the other options is fairly self-evident.

Note

Set the `installdir` and `debugtrace` options to values appropriate to your locale and operating system.

The only options that must be specified in an option file when installing the MySQL Enterprise Service Manager are `mode` (if not specified at the command line), `installdir`, and `adminpassword`.

Check the options in your option file closely before installation; no warnings will be issued if there are errors.

Ensure that the monitor installer file and the options file are in the same directory and, if you saved the options file as `options.server.txt`, you can invoke an unattended installation from the command line by typing:

```
C:\mysqlmonitor-version-windows-installer.exe --optionfile options.server.txt
```

You can install the MySQL Enterprise Monitor Agent in exactly the same fashion. Create an agent option file and call the agent installer using the `optionfile` option.

As a minimum for the agent installation, you must specify the `mode` (if not specified at the command line), `mysqluser`, `installdir`, `mysqlpassword`, `installdir`, `managerhost`, and `agentpassword` options. Create a file containing these values and use it with the `optionfile` option for unattended agent installation.

If you wish, you can create one script that calls both the Service Manager and the Monitor Agent programs passing appropriate `optionfile` options.

15.3.4.3. Unattended Unix and Mac OS X Installation

For unattended installation on Unix, create an option file named `options.server.txt`. The following is an example of what the contents of an option file might be for installation on Unix.

```
debugtrace=/opt/mysql/enterprise/install.debugtrace.monitor.log
mode=unattended
installdir=/opt/mysql/enterprise/monitor
tomcatport=8080
tomcatshutdownport=8005
tomcatsslport=8443
adminpassword=myadminpassword
dbport=3300
```

This file identifies a directory and file name for a log file, sets the `mode` to `unattended`, and uses the `installdir` option to specify an installation directory. The meaning of the other options is fairly self-evident.

Note

Set the `installdir` and `debugtrace` options to values appropriate to your locale and operating system.

The only options that must be specified in an option file when installing the MySQL Enterprise Service Manager are `mode` (if not specified at the command line), `installdir`, and `adminpassword`.

Check the options in your option file closely before installation; no warnings will be issued if there are errors.

Ensure that the monitor installer file and the options file are in the same directory and, if you saved the options file as `options.server.txt`, you can invoke an unattended installation from the command line by typing:

```
shell> mysqlmonitor-version-installer.bin --optionfile options.server.txt
```

You can install the MySQL Enterprise Monitor Agent in exactly the same fashion. Create an agent option file and call the agent installer using the `optionfile` option.

As a minimum for the agent installation, you must specify the `mode` (if not specified at the command line), `mysqluser`, `installdir`, `mysqlpassword`, and `agentpassword` options. Create a file containing these values and use it with the `optionfile` option for unattended agent installation.

If you wish, you can create one script that calls both the Service Manager and the Monitor Agent programs passing appropriate `optionfile` options.

Note

The Service Manager does not automatically start up on rebooting. For more information, see [Bug#31676](#).

The procedure for unattended agent installation under Mac OS X is identical to the procedure under Unix.

15.3.4.4. Starting the Services

For instructions on starting the services needed by the MySQL Enterprise Service Manager see, [Section 15.3.2.5, “Starting/Stopping the MySQL Enterprise Monitor Service on Windows”](#) for Windows and, [Section 15.3.2.6, “Starting/Stopping the MySQL Enterprise Monitor Service on Unix and Mac OS X”](#) for Unix and Mac OS X.

For instructions on starting the MySQL Enterprise Monitor Agent see:

- Windows – [Section 15.3.3.5.1, “Starting/Stopping the Agent on Windows”](#)
- Unix – [Section 15.3.3.5.3, “Starting/Stopping the Agent on Unix”](#)
- Mac OS X – [Section 15.3.3.5.2, “Starting/Stopping the Agent on Mac OS X”](#)

If you wish, you can script the startup of these services.

15.3.5. Post-Installation Considerations

Depending upon how you plan to use the MySQL Enterprise Monitor, there are some tasks you may want to perform after installation. Find some suggestions in the following list:

- **Email settings** — Test email notification by deliberately triggering an alert.
- **Auto Startup** — On Unix systems, the MySQL Enterprise Service Manager does not automatically restart when the system is rebooted. You may wish to create a system initialization script appropriate to your operating system.
- **Log files** — Check the log files for any irregularities. For the locations of the various log files see [Files Associated with The MySQL Enterprise Monitor](#).
- **Agent Log file rotation** — Implement log file rotation for the service agent.
- **Back up the repository** — For a back-up strategy suitable to your circumstances, see the [MySQL reference manual documentation](#).
- **Configuration backup** — Back up the `mysql-monitor-agent.ini` file and the associated `instances` directory and contents.

For more information about the `mysql-monitor-agent.ini` file see [Section 15.3.3.6, “Advanced Agent Configuration”](#).

- **Configuration file** — Store the `configuration_report.txt` in a safe place. There is no mechanism for retrieving the password stored in this file.
- **Repository credentials** — The repository user name and password are stored in unencrypted form in the `config.properties` file. Take care to protect this file.
- **Disk management** — Remove installation files, and monitor the space used by the repository. Ensure that you have adequate disk space by regularly purging data. For more information, see [??? \[1290\]](#)
- **Firewall changes** — You may want to limit or expand access to the MySQL Enterprise Service Manager.
- **Open ports** — As with firewall changes, you may want to limit or expand access to the MySQL Enterprise Service Manager. The dashboard uses non-standard ports, none of which are usually open by default.
- **Server upgrades** — See [Section 15.3.6.3.1, “Upgrading the Monitored MySQL Server”](#) for instructions on upgrading a server.
- **Repository access** — You may want to add other users.

15.3.6. Upgrading, Re-Installing or Changing Your Installation

You can upgrade

- For instructions on upgrading your existing installation, see [Section 15.3.6.1, “Upgrading MySQL Enterprise Monitor”](#).
- For more information on re-installing an existing installation, see [Section 15.3.6.2, “Reinstalling MySQL Enterprise Monitor”](#).
- To change an existing installation, such as changing the monitored server, see [Section 15.3.6.3, “Changing Your MySQL Enterprise Monitor Installation”](#).

15.3.6.1. Upgrading MySQL Enterprise Monitor

From time to time there may be updates to the MySQL Enterprise Service Manager or the MySQL Enterprise Monitor Agent. This section describes how to perform an update for either of these components.

You cannot use the update installers to change to a different operating system or chip architecture. For example, you cannot update a 32-bit Linux installation to a 64-bit version using an update installer — in cases such as this you must do a fresh installation.

The name of the update file varies but it shows the target operating system and the version the update applies to. If a specific component is being updated it may also appear in the file name. For example, a file named `mysqlenterprise-2.0.0-windows-update-installer.exe` would indicate a Windows update to MySQL Enterprise Service Manager version 2.0.0.

You may install an update in the same way that you initially installed the service manager or the agent; in `win32` or `unattended` mode on Windows in `gtk`, `text`, `xwindow`, or `unattended` mode on Unix and in `osx`, `text`, or `unattended` mode on OS X.

Warning

Before updating the MySQL Enterprise Service Manager stop all agents that are reporting to that MySQL Enterprise Service Manager. If you are updating the MySQL Enterprise Monitor Agent you must also stop the MySQL Enterprise Service Manager. On a machine that runs more than one agent, the primary agent will restart when the update is complete. Any secondary agents must be restarted manually. To stop or start agents see:

- Windows – [Section 15.3.3.5.1, “Starting/Stopping the Agent on Windows”](#)
- Unix – [Section 15.3.3.5.3, “Starting/Stopping the Agent on Unix”](#)
- Mac OS X – [Section 15.3.3.5.2, “Starting/Stopping the Agent on Mac OS X”](#)

Important

The upgrade installer will overwrite `items-mysql-monitor.xml`. On Windows this file is found in the `C:\Program Files\MySQL\Enterprise\Agent\share\mysql-monitor-agent` directory and on Unix in the `/opt/mysql/enterprise/agent/share/mysql-monitor-agent` directory. You should back this file up if you have made any changes to it.

Warning

If you use the Upgrade installer to update MySQL Enterprise Service Manager and you have made any changes to the `my.cnf` within your MySQL Enterprise Service Manager installation, any changes will be lost. You should copy the existing `my.cnf` file before starting the upgrade installer.

Otherwise, updating is a fairly straightforward process. Run the installation file and choose the directory of your current installation and whether or not you wish to back up your current installation. The time required to complete the process varies depending upon the nature of the update.

If you chose to back up your current installation, a directory named `backup` will be created in the current installation directory. This directory will contain copies of the directory or directories that were replaced during the update. In cases where only specific files are replaced, the `backup` directory may contain only these files. If you are unhappy with the update simply overwrite the new files or directories with the originals found in the `backup` directory. Be sure to stop both the MySQL Enterprise Service Manager and MySQL Enterprise Monitor Agent before restoring the original files. You can delete or archive this directory when you are satisfied that the update was successful.

If you choose to back up your current installation, the installer checks that there is adequate disk space for your repository backup. If there is not enough space, you are given the option of choosing another location; you may also choose not to back up the repository.

To update your Advisors see, [Section 15.3.2.7.4, “Upgrading and Updating Advisors”](#).

15.3.6.1.1. Upgrading from MySQL Enterprise Monitor 1.3 to 2.0

To upgrade your existing installation from MySQL Enterprise Monitor 1.3 to MySQL Enterprise Monitor 2.0, you need to upgrade both your MySQL Enterprise Service Manager and your MySQL Enterprise Monitor Agent on each machine that you are monitoring.

To perform the update process you must use an `update` installer. This ensures that your current configuration information is migrated to the new version of MySQL Enterprise Service Manager.

Before you start the migration, shutdown your MySQL Enterprise Service Manager and MySQL Enterprise Monitor Agent on each monitored host. Then install the updated MySQL Enterprise Service Manager application to migrate the configuration and data of the main application and repository. Once the new MySQL Enterprise Service Manager is running, you can start to update and migrate each agent.

For more information on upgrading your MySQL Enterprise Service Manager, see [Section 15.3.6.1.1.1, “Upgrading to MySQL Enterprise Service Manager 2.0”](#). For more information on upgrading an MySQL Enterprise Monitor Agent, see [Section 15.3.6.1.1.2, “Upgrading to MySQL Enterprise Monitor Agent 2.0”](#).

15.3.6.1.1.1. Upgrading to MySQL Enterprise Service Manager 2.0

Upgrading MySQL Enterprise Service Manager requires you to use one of the *update* installers. The update installer performs a number of operations during installation:

- A new database, required to support 2.0 functionality, is created.
- Your core dashboard, user, and rule information is migrated from the old database to the new database.
- The core configuration parameters for the MySQL Enterprise Service Manager are migrated from MySQL Enterprise Monitor 1.3 are migrated to MySQL Enterprise Monitor 2.0.

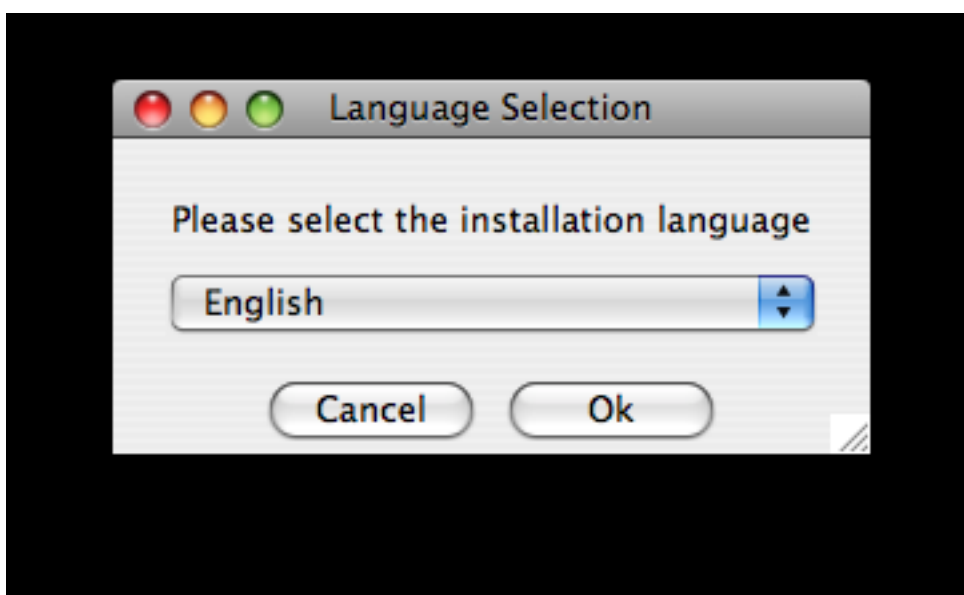

The installation of the new software using the update installer follows this basic sequence:

1. Request the installation language.
2. Confirm the location of the current MySQL Enterprise Service Manager installation.
3. Specify whether you want to keep a copy of the old server, application, and database files.
4. Configure the Tomcat server settings, including whether the new server should support SSL connections from agents.
5. If requested, the application and database information is backed up and upgraded, before the new application is installed.

The installation process is consistent for all platforms. A sample of the process for Max OS X has been provided below:

1. Double click on the update installer. The update installer will have `update` in the file name. For example, `mysqlmonitor-2.0.0.7101-osx-update-installer.app`.
2. Confirm the language you want to use when installing the software.

Figure 15.24. MySQL Enterprise Monitor: Server Update: Language Selection

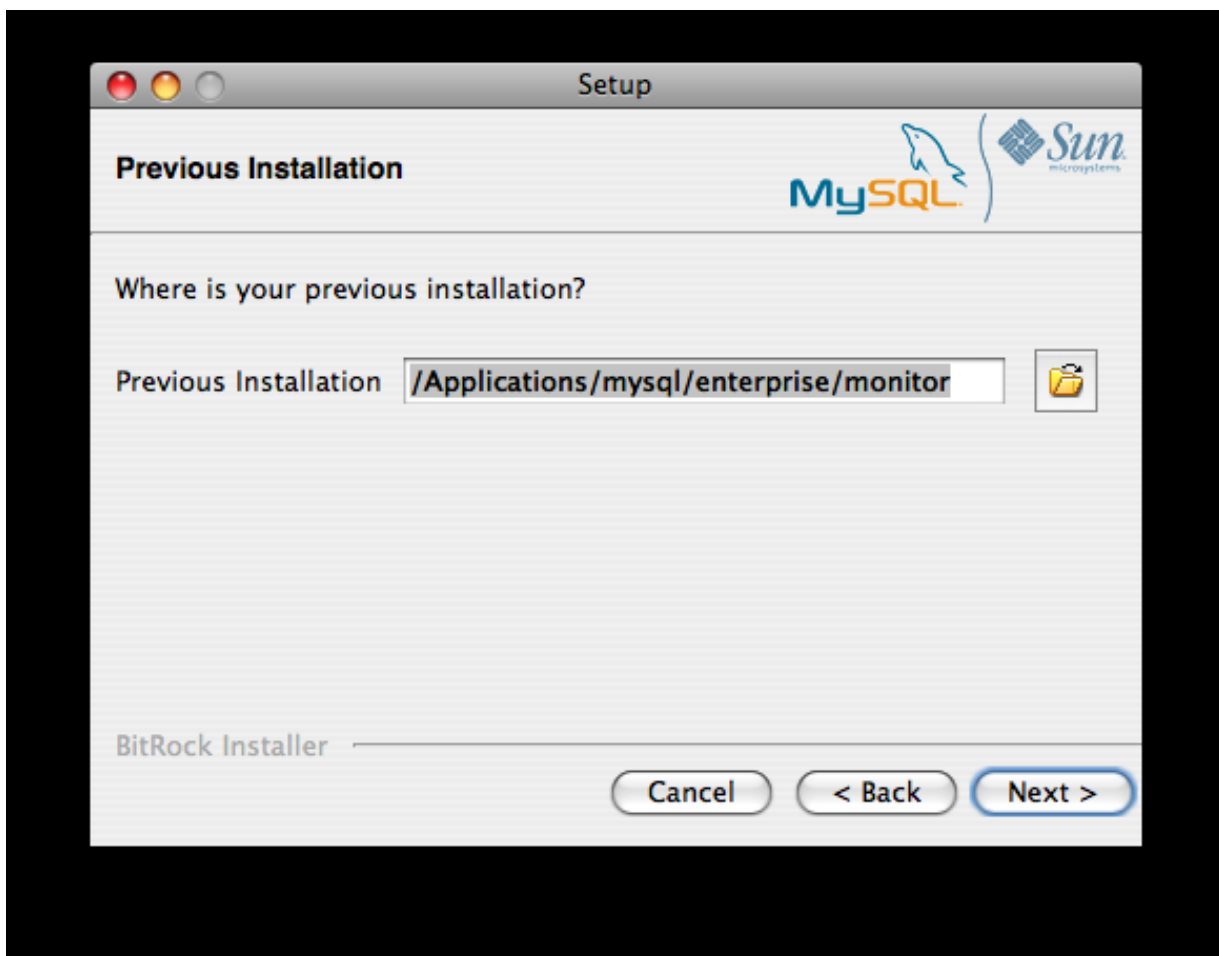

Click OK

3. You will be presented with an information screen showing the application you are installing. Click NEXT to continue.

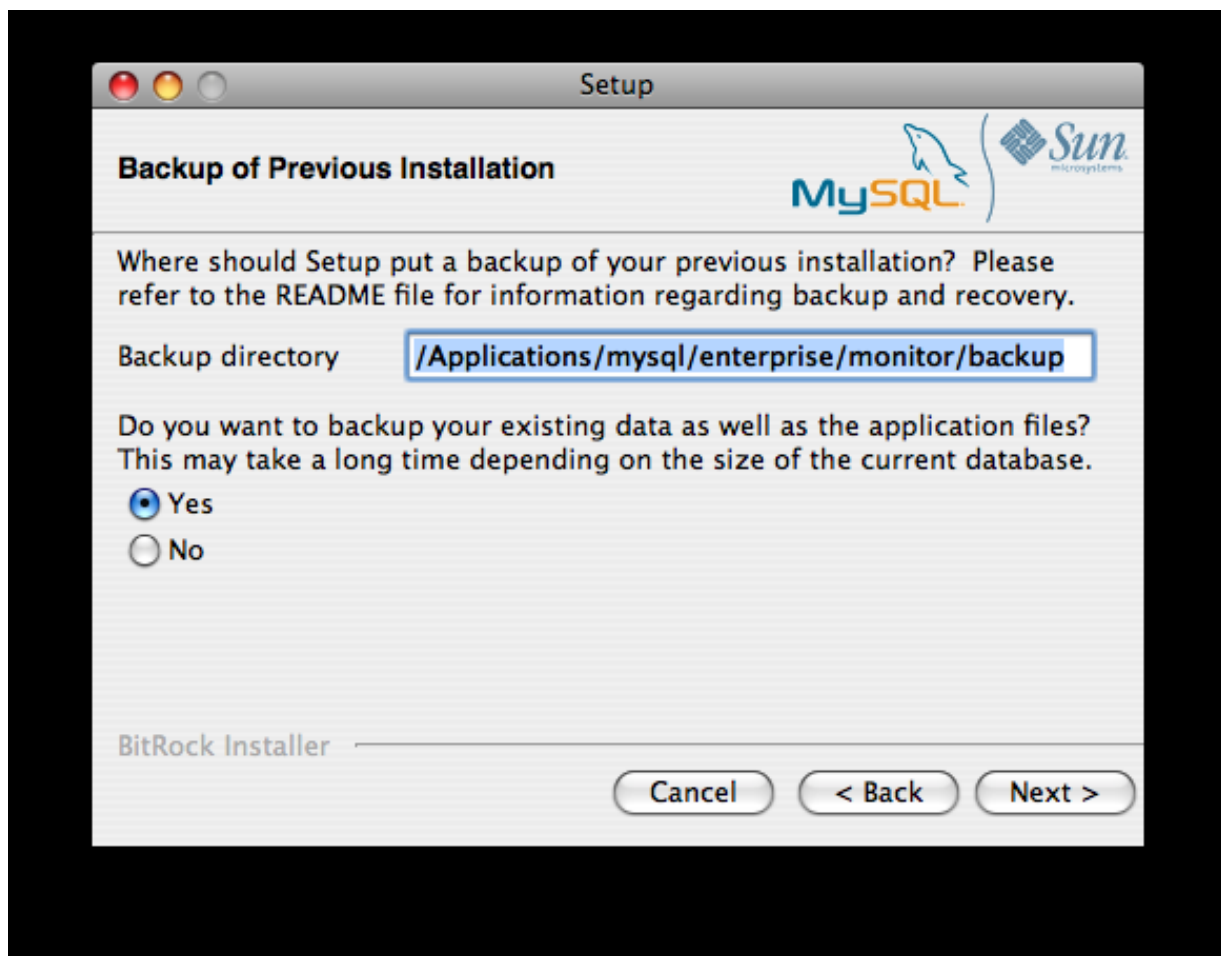

- Specify, or locate, the previous installation of MySQL Enterprise Service Manager. If you installed the server within the default location, the current version of the application should be located automatically.

Figure 15.25. MySQL Enterprise Monitor: Server Update: Previous Installation

- The installer can keep a backup copy of your existing application, including keeping a complete backup of the data stored within your MySQL Enterprise Monitor repository database.

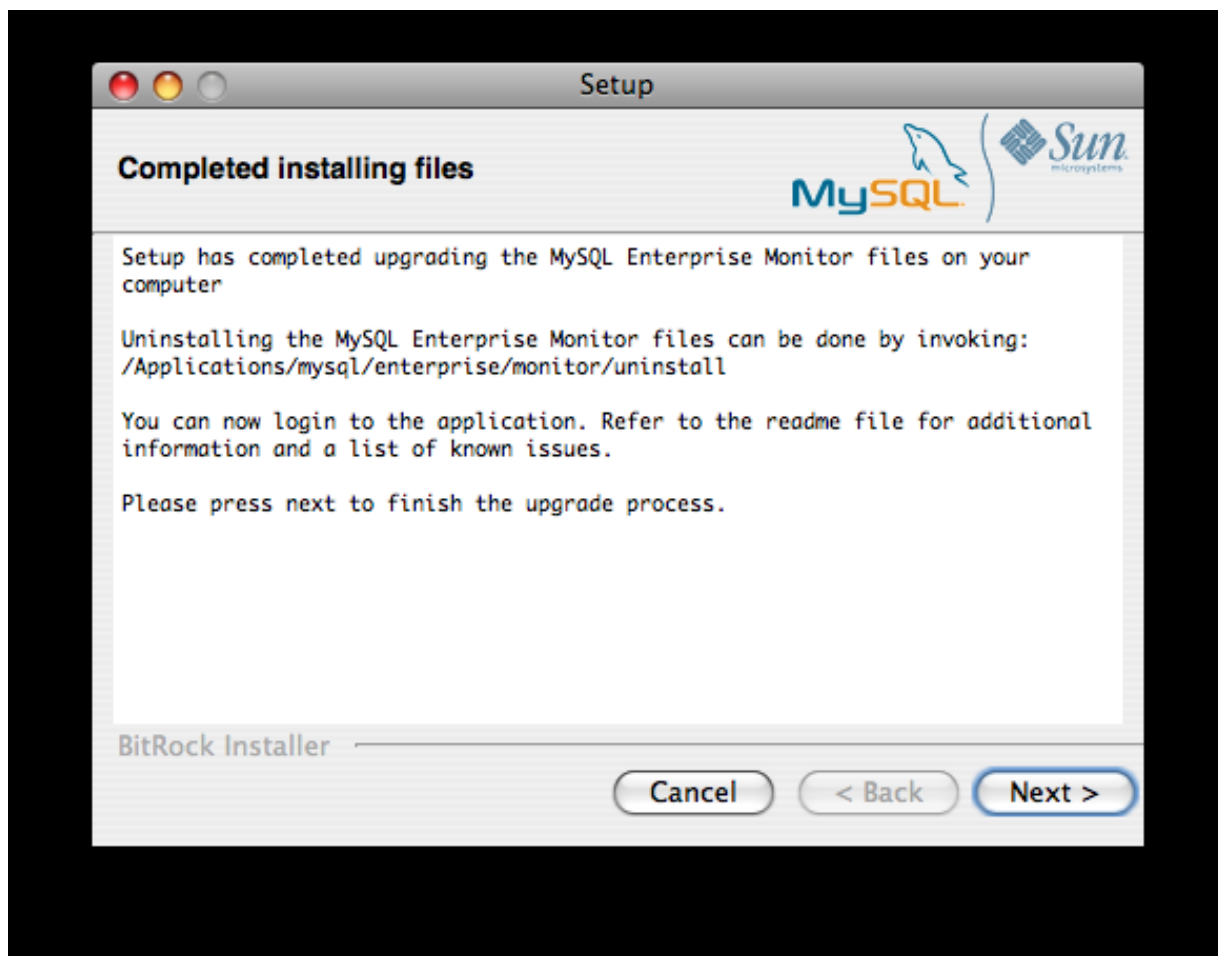

Figure 15.26. MySQL Enterprise Monitor: Server Update: Backup of Previous Installation

Specify the location of the backup (default is to use the `backup` directory within your installation directory). Note that backing up the database in addition to the main application will increase the installation time as the files have to be copied. The larger the size of your repository data, the longer the installation process will take.

6. Specify the Tomcat Server options. The Tomcat Server Port is the default port you will use to access the MySQL Enterprise Dashboard. If you want to support agents using SSL to communicate to MySQL Enterprise Service Manager, you must check the **IS SSL SUPPORT REQUIRED?**
7. Confirm that you want to continue the installation. Once installation has started, the backup of you existing application (and database) will start, although the process may take some time. Wait until the process completes.
8. Once the process has completed you will be provided with a notification of the installation process, including how to uninstall the application if you want to do so in the future. If any errors occurred, they will be reported here.

Figure 15.27. MySQL Enterprise Monitor: Server Update: Completed installing files

9. The installation has now completed. You can automatically start the MySQL Enterprise Service Manager and view the attached Readme file by ensuring the checkboxes on this page are selected.
10. You can now quit the installer.

Once the installation has completed, the first time you login to MySQL Enterprise Dashboard you will be asked to provide your login credentials, if they do not already exist in the server configuration, or to provide a copy of the Advisor jar suitable for your MySQL Enterprise Service Manager version.

Figure 15.28. MySQL Enterprise Monitor: Server Update: Final Setup

MySQL Enterprise Monitor has now been updated. You must update each of your agents to MySQL Enterprise Monitor Agent 2.0 to ensure that they are providing the correct information to MySQL Enterprise Service Manager

15.3.6.1.1.2. Upgrading to MySQL Enterprise Monitor Agent 2.0

To upgrade an agent you should use a [update](#) installer. This will migrate your configuration information, simplifying the upgrade process significantly.

Note

The agent log file, `mysql-service-agent.log`, if it exists, will be retained during the upgrade. A new log file, `mysql-monitor-agent.log` is used by MySQL Enterprise Monitor Agent 2.0.

The core sequence is the same on all platforms, the update process on Linux is shown below:

1. Start the update installer.

```
shell> ./mysqlmonitoragent-2.0.0.7101-linux-glibc2.3-x86-32bit-update-installer.bin
```

2. Set the language for the installation process.

```
Language Selection
Please select the installation language
[1] English
[2] Japanese
Please choose an option [1] :
```

3. Confirm or update the location of the installation directory of the previous version.

```
-----
Welcome to the setup wizard for the MySQL Enterprise Monitor Agent Update
-----
Please specify the directory that contains the previous installation of
the MySQL Enterprise Monitor Agent
Installation directory [/opt/mysql/enterprise/agent]:
```

- Specify whether you want to create a backup of the current application and configuration information, and if so, where the backup directory should be created.

```
-----
Current installation backup
Do you want to create a backup during the update process?
Backup the current installation [Y/n]: Y

Backup directory [/opt/mysql/enterprise/agent/patchbackup]:
```

- You will be asked whether you want to enable the Query Analyzer. The Query Analyzer enables you to monitor the execution statistics for individual queries executed through your MySQL servers. To enable, you must specify the proxy port, MySQL server and MySQL server port that you want to use. If you do not enable Query Analyzer now, you can enable it later. See [Section 15.10, “The Query Analyzer Page”](#).

```
-----
Query Analysis Configuration

MySQL Proxy enables query monitoring and analysis by listening on the port
specified below for client connections that are then passed through to a
backend MySQL database server. It is not needed for basic monitoring
functionality, but is required for query monitoring and analysis.

Visit the following URL for more information:
https://enterprise.mysql.com/docs/monitor/2.0/en/mem-query-analysis.html

Enable Proxy (recommended) [Y/n]:

Proxy Port [4040]:
Backend Host: 127.0.0.1 (cannot be changed)
Backend Port: 3306 (cannot be changed)
```

- You are now ready to complete the installation. Confirm that you want to continue.

```
-----
Setup is now ready to begin installing MySQL Enterprise Monitor Agent Update on your computer.
Do you want to continue? [Y/n]:

-----
Please wait while Setup installs MySQL Enterprise Monitor Agent Update on your computer.

Installing
0% _____ 50% _____ 100%
#####

-----
Setup has finished installing MySQL Enterprise Monitor Agent Update on your computer.
Restart MySQL Enterprise Monitor Agent now [Y/n]:
View Readme File [Y/n]: n
```

Before connecting your MySQL Enterprise Monitor Agent to your MySQL server you must update the grants for the MySQL Enterprise Monitor Agent. Connect to the MySQL server and run this statement to update the required grants:

```
GRANT CREATE, INSERT
ON mysql.*
TO 'mysqluser'@'localhost'
IDENTIFIED BY 'agent_password';
```

Replacing the `mysqluser` and `agent_password` parameters with the values used for connecting your agent to your MySQL server.

Once the update agent has communicated with the MySQL Enterprise Service Manager the core information about the agent and the MySQL server it is monitoring will be migrated to the new data format required by MySQL Enterprise Service Manager 2.0. To migrate the existing stored data, see [Section 15.4.2, “Migrating 1.3.x Historical Data to MySQL Enterprise Monitor 2.0”](#).

15.3.6.1.2. Unattended MySQL Enterprise Monitor Update

The options available when performing an unattended MySQL Enterprise Service Manager update are as follows:

```
--help                Display the list of valid options
--version             Display product information
--optionfile <optionfile>  Installation option file
                        Default:
--mode <mode>         Installation mode
                        (Windows)Default: win32
                        (Unix)Default: gtk
                        (Mac OS X)Default: osx
                        (Windows)Allowed: win32 unattended
                        (Unix)Allowed: gtk text xwindow unattended
                        (Mac OS X)Allowed: osx text unattended
--debugtrace <debugtrace>  Debug filename
                        Default:
--installer-language <installer-language>  Language selection
                        Default:
                        Allowed: en jp
--installdir <installdir>  Previous Installation
                        Default:
--createDataBackup <createDataBackup>
                        Default: 1
--backupDir <backupDir>   Backup directory
                        Default:
```

The options for an unattended update of the agent differ only in that the `createDataBackup` option is replaced by `createBackup`.

If you did not install the MySQL Enterprise Service Manager to the default directory the `installdir` option must be specified. `mode` must also be specified when performing an unattended update. Otherwise, performing an unattended update is identical to the process described in [Section 15.3.4, “Unattended Installation”](#).

15.3.6.2. Reinstalling MySQL Enterprise Monitor

In some cases you may want to reinstall MySQL Enterprise Monitor rather than updating your current installation. To reinstall rather than update MySQL Enterprise Monitor follow these steps:

1. Stop all the Monitor Agents
2. Run the `uninstall` programs for both the MySQL Enterprise Service Manager and the MySQL Enterprise Monitor Agent
3. Begin the new installation

To stop the Monitor Agents see:

- Windows – [Section 15.3.3.5.1, “Starting/Stopping the Agent on Windows”](#)
- Unix – [Section 15.3.3.5.3, “Starting/Stopping the Agent on Unix”](#)
- Mac OS X – [Section 15.3.3.5.2, “Starting/Stopping the Agent on Mac OS X”](#)

Instructions for removing the MySQL Enterprise Service Manager and the MySQL Enterprise Monitor Agent are given in [Section 15.3.7, “Uninstalling the MySQL Enterprise Monitor”](#).

15.3.6.3. Changing Your MySQL Enterprise Monitor Installation

This section describes the best practices to employ when changing your MySQL Enterprise Monitor installation.

15.3.6.3.1. Upgrading the Monitored MySQL Server

When upgrading a monitored MySQL server first stop the agent. To stop the agent see:

- Windows – [Section 15.3.3.5.1, “Starting/Stopping the Agent on Windows”](#)

- Unix – [Section 15.3.3.5.3, “Starting/Stopping the Agent on Unix”](#)
- Mac OS X – [Section 15.3.3.5.2, “Starting/Stopping the Agent on Mac OS X”](#)

Stop the MySQL server and perform the upgrade. For instructions on stopping and restarting the MySQL service under Windows see [Section 15.3.2.5, “Starting/Stopping the MySQL Enterprise Monitor Service on Windows”](#).

To stop and restart the MySQL daemon under Unix and Mac OS X, see, [Section 15.3.2.6, “Starting/Stopping the MySQL Enterprise Monitor Service on Unix and Mac OS X”](#).

Once the service/daemon is stopped you may upgrade your server. For instructions on upgrading your MySQL server see the reference manual pertaining to your server version. When the upgrade is complete restart the MySQL server.

Note

The agent's log file will show that the server was down.

15.3.6.3.2. Changing the Server That an Agent Monitors

You need not reinstall the MySQL Enterprise Monitor Agent in order to change the MySQL server that it monitors. It is possible to adapt an existing agent so that it monitors a different server.

To do this you must stop the service agent and then remove the server that it is monitoring. To stop the agent see:

- Windows – [Section 15.3.3.5.1, “Starting/Stopping the Agent on Windows”](#)
- Unix – [Section 15.3.3.5.3, “Starting/Stopping the Agent on Unix”](#)
- Mac OS X – [Section 15.3.3.5.2, “Starting/Stopping the Agent on Mac OS X”](#)

For instructions on removing a server see, [Section 15.6.3.3, “Removing a Server From the Dashboard”](#).

Once the agent is stopped and the server is removed from the Dashboard, changes may be made to the `mysql-monitor-agent.ini`, or the `agent-instance.ini` file within the agent `instances` directory. You can find the location of the directory by examining the content of the `mysql-monitor-agent.ini` and checking the value of the `mysqld-instance-dir` parameter.

If you want to make changes to the monitored MySQL server, edit the `agent-instance.ini` file. Change the `user`, `password`, `hostname`, and `port` values if required. For more information, see [Section 15.3.3.6.2, “MySQL Server \(agent-instance.ini\) Configuration”](#).

To change other settings, such as enabling proxy support (required for Query Analyzer), the management host, or the port number used by the agent, modify the `mysql-monitor-agent.ini` file. For more information, see [Section 15.3.3.6.1, “MySQL Enterprise Monitor Agent \(mysql-monitor-agent.ini\) Configuration”](#).

To restart the agent see:

- Windows – [Section 15.3.3.5.1, “Starting/Stopping the Agent on Windows”](#)
- Unix – [Section 15.3.3.5.3, “Starting/Stopping the Agent on Unix”](#)
- Mac OS X – [Section 15.3.3.5.2, “Starting/Stopping the Agent on Mac OS X”](#)

Note

If you are adapting an existing agent to monitor a remote server make sure that the agent has the credentials for remote access and that the port on the remote MySQL server instance is open. For more information, see [Section 15.3.3.6.4, “Configuring an Agent to Monitor a Remote MySQL Server”](#).

If you experience difficulties starting the agent, check [Section 15.3.3.7, “Troubleshooting the Agent”](#).

Log in to the Dashboard and you should find your new server in the `All Servers` group.

15.3.6.3.3. Temporarily Suspending the Agent

In some situations you may need to bring down a monitored server. When this is necessary, it is good practice to stop the agent first—doing so will avoid generating a “Server is unreachable” event.

For instance, suppose you need to stop the server in order to do a backup. The steps to follow are:

1. Stop the agent
2. Stop the service/daemon
3. Perform the backup
4. Restart the service/daemon
5. Restart the agent

To stop or start the agent see:

- Windows – see [Section 15.3.3.5.1, “Starting/Stopping the Agent on Windows”](#)
- Unix – see [Section 15.3.3.5.3, “Starting/Stopping the Agent on Unix”](#)
- Mac OS X – see [Section 15.3.3.5.2, “Starting/Stopping the Agent on Mac OS X”](#)

To stop the MySQL service/daemon see the MySQL reference manual for your server version. You can find the manual online at <http://dev.mysql.com/doc/refman>.

Follow these steps and there will be no “noise” associated with backing up your server. In contrast, if you leave the agent running while bringing down the server, you will generate a “Server is unreachable” event.

As an alternative to stopping the agent, you can change the logic associated with a rule. For instance, you could alter the threshold of the rule “Server is unreachable”:

```
%server.reachable% == THRESHOLD
```

to:

```
%server.reachable% == THRESHOLD && CURTIME() NOT BETWEEN '22:00:00' AND '23:00:00'
```

This would effectively blackout the rule between 10 and 11 pm, during which time you could perform a backup.

For more information about editing rules see [Section 15.7.3, “Editing Built-in Rules”](#). To blackout all events associated with a specific server or group of servers see [Section 15.7.6, “Advisor Blackout Periods”](#).

15.3.7. Uninstalling the MySQL Enterprise Monitor

Removal of the MySQL Enterprise Monitor requires removal of the MySQL Enterprise Service Manager and the MySQL Enterprise Monitor Agent Service. In some circumstances, when running multiple agents on one machine for instance, you may not want to remove the entire MySQL Enterprise Monitor Agent Service but only a single monitored server.

15.3.7.1. Removing the MySQL Enterprise Monitor: Windows

15.3.7.1.1. Removing the MySQL Enterprise Service Manager

Remove the MySQL Enterprise Service Manager by going to the [Control Panel](#) and choosing [Add or Remove Programs](#). Find the entry for [MySQL Enterprise Monitoring and Advisory Service](#) and remove it. During the uninstall process you will be given the option of saving existing data and log files. Choose this option if you plan to reinstall the MySQL Enterprise Monitor.

If you are not saving existing data, after MySQL Enterprise Service Manager has been removed you may delete the [C:\Program Files\MySQL\Enterprise\Monitor](#) directory.

Warning

If you chose not to remove existing data and log files when uninstalling MySQL Enterprise Service Manager do **not** remove the [C:\Program Files\MySQL\Enterprise\Monitor](#) directory. Doing so will delete these files.

If you added the Tomcat/Apache web server to the list of Windows firewall exceptions, remove this service by opening the [Windows Firewall](#) from the [Control Panel](#). Choose the [Exceptions](#) tab and delete the [Tomcat/Apache](#) entry.

15.3.7.1.1.1. Removing MySQL Enterprise Monitor Services Only

When the MySQL Enterprise Service Manager is installed, the Tomcat/Apache and MySQL server services are started. It is possible to remove these services without also removing your MySQL Enterprise Service Manager installation. (For more information about these services see, [Section 15.3.2.5, “Starting/Stopping the MySQL Enterprise Monitor Service on Windows”](#) or, [Section 15.3.2.6, “Starting/Stopping the MySQL Enterprise Monitor Service on Unix and Mac OS X”](#).)

Do this by finding the [MySQL Enterprise Monitor](#) menu option and choosing [Services](#) and then [Uninstall MySQL Enterprise Monitor Services](#). This will remove all the services associated with MySQL Enterprise Service Manager.

You can confirm that these services have been removed by checking services in the Microsoft Management Console Services window.

If you wish to reinstall these services you can do this by using the [Install MySQL Enterprise Monitor Services](#) menu option.

It is also possible to remove services using the `mysqlmonitorctl.bat` file found in the `C:\Program Files\MySQL\Enterprise\Monitor` directory. To see the available options, go to the command line and type: `mysqlnet-workctrl help`. This batch file is discussed in more detail in [Section 15.3.2.5, “Starting/Stopping the MySQL Enterprise Monitor Service on Windows”](#).

15.3.7.1.2. Removing the Monitor Agent

To remove the Monitor Agent itself, open the [Control Panel](#) and choose [Add or Remove Programs](#). Find the entry for [MySQL Enterprise Monitor Agent](#) and remove it. This will execute the uninstall program located in the `C:\Program Files\MySQL\MySQL\Enterprise\Agent` directory.

Warning

If you are running more than one agent on the same machine and wish to remove only one of the agents, do **not** remove the [MySQL Enterprise Monitor Agent](#) entry from the [Add or Remove Programs](#) menu. To remove a single agent see [Section 15.3.7.1.2.1, “Removing a Single Agent”](#).

After removing the Monitor Agent you may also need to remove the directories, `C:\Program Files\MySQL\Enterprise` and `C:\Program Files\MySQL\Enterprise\Agent`.

Removing the Monitor Agent in this fashion will remove the default service. However, if you are running additional Monitor Agents as described in [Section 15.3.3.6.2, “MySQL Server \(agent-instance.ini\) Configuration”](#), you will have to remove those agents manually. See the next section for instructions on doing this.

15.3.7.1.2.1. Removing a Single Agent

If you are running more than one agent on the same machine and wish to remove only one of the agents, do **not** remove the [MySQL Enterprise Monitor Agent](#) entry from the [Add or Remove Programs](#) menu. To remove a single agent and leave other agents intact follow these steps:

1. Stop the agent
2. Confirm the location of the log files
3. Remove the agent as a service
4. Remove/Archive the associated files

It is best to stop the agent before removing it; for instructions on stopping an agent see, [Section 15.3.3.5.1, “Starting/Stopping the Agent on Windows”](#).

You can confirm the location of the agent log files by checking the `ini` file. For more information on this topic see [Section 15.3.3.6.1, “MySQL Enterprise Monitor Agent \(mysql-monitor-agent.ini\) Configuration”](#).

Go to the command line and remove the MySQL Enterprise Monitor Agent as a Windows service by typing:

```
shell> sc delete AgentName
```

You can confirm that the agent has been removed by checking the Microsoft Management Console Services window. There should

no longer be an entry for the removed agent.

You should also remove or archive any log or configuration files associated with this agent. If you have installed any additional agents, remove them in the same fashion.

15.3.7.2. Removing the MySQL Enterprise Monitor: Unix and Mac OS X

15.3.7.2.1. Removing the MySQL Enterprise Service Manager

To remove the MySQL Enterprise Service Manager, find the `uninstall` file in the `/opt/mysql/enterprise/monitor` directory.

Execute this file by typing:

```
shell> ./uninstall
```

During the uninstall process you will be given the option of saving existing data and log files. Choose this option if you plan to re-install the MySQL Enterprise Monitor.

If you are not saving existing data, after uninstalling the MySQL Enterprise Service Manager you may remove the `/opt/mysql/enterprise/monitor` directory.

Warning

If you chose not to remove existing data and log files when uninstalling the MySQL Enterprise Monitor do **not** remove the `/opt/mysql/enterprise/monitor` directory; doing so will delete these files.

On Red Hat Enterprise Linux 4 and Fedora Core 4, the uninstall script may not stop the Tomcat server. Do this manually if necessary. To do this see, [Section 15.3.2.6, “Starting/Stopping the MySQL Enterprise Monitor Service on Unix and Mac OS X”](#).

There may be other Java processes running on your system. Be careful not to accidentally stop them.

15.3.7.2.2. Removing the Monitor Agent

Prior to removal of the Monitor Agent Service you should stop any agents. Do this by changing to the `init.d` directory and issuing the command, `./mysql-monitor-agent stop`.

You will find the `uninstall` file in the `/opt/mysql/enterprise/agent` directory under Unix and in the `/Applications/mysql/enterprise/agent` directory on Mac OS X. Execute this file by navigating to this directory and typing:

```
shell> ./uninstall
```

After uninstalling the Monitor Agent you may remove the `/opt/mysql/enterprise/agent` directory. Under Mac OS X this directory is called `/Applications/mysql/enterprise/agent`.

Removing the Monitor Agent in this fashion will remove the default service, and all the configuration files for different instances.

15.3.7.2.2.1. Removing a Single Agent

If you are running more than one agent on the same machine and wish to remove only one of the agents, do **not** run the uninstall program. To remove a single agent and leave other agents intact follow these steps:

1. Stop the agent
2. Confirm the location of the log files
3. Remove the agent as a service
4. Remove/Archive associated files

It is best to stop the agent before removing it; for instructions on stopping an agent see:

- Unix – [Section 15.3.3.5.3, “Starting/Stopping the Agent on Unix”](#)
- Mac OS X – [Section 15.3.3.5.2, “Starting/Stopping the Agent on Mac OS X”](#)

You can confirm the location of the agent log files by checking the `ini` file. For more information on this topic see [Section 15.3.3.6.1, “MySQL Enterprise Monitor Agent \(`mysql-monitor-agent.ini`\) Configuration”](#).

You may then remove the agent as a daemon by removing its entry in the `init.d` directory. You should also remove or archive any log or configuration files associated with this agent.

If you have installed any additional agents, remove them in the same fashion.

15.4. Deploying MySQL Enterprise Service Manager

Note

MySQL Enterprise subscription, MySQL Enterprise Monitor, MySQL Replication Monitor, and MySQL Query Analyzer are only available to commercial customers. To learn more, see: <http://www.mysql.com/products/enterprise/features.html>.

This chapter provides some notes and guidance on deploying MySQL Enterprise Service Manager, including hardware and server requirements for the MySQL Enterprise Service Manager, and how to backup the monitoring data.

15.4.1. Backing up MySQL Enterprise Service Manager

If you want to backup the data stored within your MySQL Enterprise Service Manager, you can use any of the typical backup solutions, such as `mysqldump`, to save your data. All you need to backup the information is host name, user name and password details that were set during the installation of the MySQL Enterprise Service Manager

You can locate this information by examining the contents of the `configuration_report.txt` file that was generated when MySQL Enterprise Service Manager was installed. A sample of the file is provided below:

```
MySQL Enterprise Monitor (Version 2.0.0.7088 : 20081031_152749_r7088)
Here are the settings you specified:
Application hostname and port: http://127.0.0.1:18080
Tomcat Ports: 18080 - 18443 (SSL)
MySQL Port : 13306
Repository Credentials (bundled MySQL):
-----
service_manager/Password
Use the following command to login to the MySQL Enterprise Monitor database:
mysql -uservice_manager -pPassword -P13306 -h127.0.0.1
```

The last line provides the information about how to connect to the server using the standard `mysql` command line client.

All the MySQL Enterprise Monitor repository information, including your configuration, rule and historical data is stored within the `mem` database.

To backup this information using `mysqldump` you might use the following command:

```
shell> mysqldump --single-transaction >
-uservice_manager -pPassword -P13306 -h127.0.0.1 mem >mem.dump
```

The above command would create a file, `mem.dump`, containing all of the MySQL Enterprise Monitor data.

To ensure consistency in a recovery situation, you may also want to backup the agent configuration and metadata stored on each monitored MySQL server. To do this:

- Backup the configuration files of each agent. You should keep a copy of the `etc` directory for each agent. This directory contains the main configuration file, `mysql-monitor-agent.ini`, and the configuration information for each server being monitored, which is stored within the `etc/instances` directory.
- On each server being monitored, retain a copy of the `mysql.inventory` table, which contains the unique ID of the MySQL server.

15.4.2. Migrating 1.3.x Historical Data to MySQL Enterprise Monitor 2.0

You can migrate the data generated during a MySQL Enterprise Monitor 1.3.x installation using the Data Migration functionality of the **SERVER CONFIGURATION** panel.

To use the data migration feature, you must have installed MySQL Enterprise Service Manager using an *update* installer. The update installer performs the initial migration of your configuration, rules, schedule, and events data. The historical data is not migrated until you explicitly request the migration of information within the **MANAGE SERVERS** section of the **SETTINGS** panel.

Data migration works on a single server, allowing you to select on which servers you want to migrate information. The migration is subject to the following:

- You must elect to migrate the data from each server individually.
- Migration takes approximately 5-6 hours, for each month, for each server. Therefore, if you have six months of data on 10 servers it could take between 300 and 360 hours (15 days) to migrate all of your historical data one server at a time.
- To limit the data migration, set the **DATA PURGE BEHAVIOR** within the **SETTINGS** page. Only data more recent than the specified purge period will be migrated. Data older than the purge period will be ignored.
- To prevent performance issues, migrate only one or a small number of servers concurrently.
- You can start and stop the migration of the data at any time. As a general guide, you should avoid stopping the data migration process and allow it to complete unless:
 - Run out of disk space.
 - MySQL Enterprise Service Manager becomes too slow and unresponsive.
 - Migration never completes.

With the last item, where the migration never completes, occasionally there are some aspects of the data that cannot be migrated successfully. This will prevent the migration process completing, but does not affect the conversion of any data that could be migrated.

Starting Historical Data Migration

To start data migration:

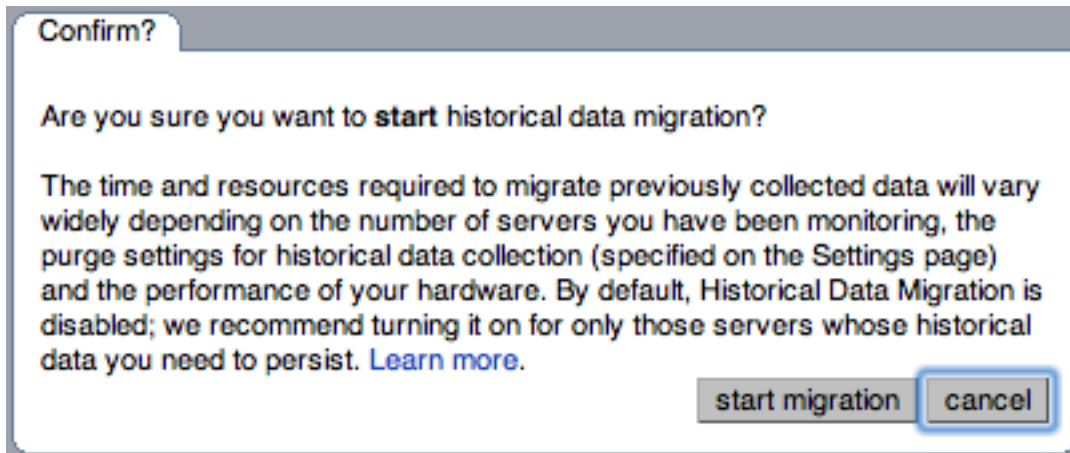

- Switch to the **MANAGE SERVERS** display of the **SETTINGS** panel within MySQL Enterprise Dashboard.
- Ensure that the data migration functionality has been enabled. The **START** and **STOP** buttons next to **HISTORICAL DATA MIGRATION** will be visible.

Figure 15.29. MySQL Enterprise Monitor: Historical Data Migration Availability

Server	Query Analyzer Enabled	Query Analyzer Examples	Query Analyzer Explains	MySQL	Up Since	Last MySQL	Agent	Last Agent	Migration Status
<input type="checkbox"/> All Servers (3)									
<input type="checkbox"/> bear:3306 (ungrouped)	On	Off	Off	5.0.60-log	Sep 13, 2008 6:37:12 PM	Nov 19, 2008 1:36:00 PM	2.0.0.7085	Nov 19, 2008 1:36:19 PM	N/A
<input type="checkbox"/> gentoo1.vmbear:3306 (ungrouped)	On	Off	Off	5.0.60-log	Nov 17, 2008 10:26:45 AM	Nov 19, 2008 2:12:00 PM	2.0.0.7101	Nov 19, 2008 1:36:19 PM	Not Migrated
<input type="checkbox"/> gentoo2.vmbear:6906 (ungrouped)	On	Off	Off	5.0.60-log	Stopped		2.0.0.7101	Nov 19, 2008 1:36:17 PM	Not Migrated

- Select the servers you want to migrate by using the checkbox next to each server name. You can select one or more servers to migrate. Servers that are suitable for migration will show their migration status within the **MIGRATION STATUS** column. If the server is not able to be migrated, **N/A** will be shown.
- Click **START** next to **HISTORICAL DATA MIGRATION**.
- You will be presented with a confirmation dialog box. To start the migration, click **START MIGRATION**. To cancel migration, click **CANCEL**.
- The servers that have been selected for migration will show **Queued for Migration** in the **MIGRATION STATUS** column.

Figure 15.30. MySQL Enterprise Monitor: Confirming Historical Data Migration

Monitoring Historical Data Migration

You can check the migration status of any individual server by examining the **MIGRATION STATUS** column for each server. You can see an example of the migration status below.

Figure 15.31. MySQL Enterprise Monitor: Historical Data Migration Progress

Manage Groups & Servers									
Server	Query Analyzer			MySQL	Up Since	Last MySQL	Agent	Last Agent	Migration Status
	Enabled	Examples	Explains						
<input type="checkbox"/> All Servers (3)									
<input type="checkbox"/> bear:3306 (ungrouped)	On	Off	Off	5.0.60-log	Sep 13, 2008 6:37:12 PM	Nov 19, 2008 1:51:00 PM	2.0.0.7085	Nov 19, 2008 1:51:55 PM	N/A
<input type="checkbox"/> gentoo1.vmbear:3306 (ungrouped)	On	Off	Off	5.0.60-log	Nov 17, 2008 10:26:45 AM	Nov 19, 2008 2:27:00 PM	2.0.0.7101	Nov 19, 2008 1:51:55 PM	Migrating : 41 variables (50%) Start: Nov 19, 2008 1:51:28 PM
<input type="checkbox"/> gentoo2.vmbear:3306 (ungrouped)	On	Off	Off	5.0.60-log	Stopped		2.0.0.7101	Nov 19, 2008 1:51:54 PM	Migrating : 8 variables (9%) Start: Nov 19, 2008 1:51:27 PM

Note that the migration status is shown according to the state of migration at the time the page was loaded. The actual migration continues in the background, and the current state may not match the state of the migration at the time it is viewed.

Servers showing **Done** in the **MIGRATION STATUS** column have already completed their migration.

You can check the overall migration status by examining the **UPGRADE STATUS** display.

Stopping Historical Data Migration

You can stop the migration process for any server that is still migrating data. The migration can be restarted at any time without causing any problems.

To stop the historical data migration:

1. Select the servers you want to stop migrating by using the checkbox next to each server name. You can select one or more servers to stop migrating.
2. Click **STOP** next to **HISTORICAL DATA MIGRATION**.

Confirmation that the migration has been stopped will be provided. If migration has already completed, you will be notified.

Removing Old Data

Once data migration has been completed for all the servers you want to migrate, you may want to delete or remove access to the old data within your MySQL Enterprise Monitor repository. Data for MySQL Enterprise Monitor 1.3 was stored in a database called **merlin** within the MySQL repository. Data for MySQL Enterprise Monitor 2.0 is stored within a database called **mem**.

To create a backup of the old information, use `mysqldump`:

```
shell> mysqldump -uservice_manager -pPassword -P13306 -h127.0.0.1 merlin >data-1.3.sql
```

The above will create a file, `data-1.3.sql` containing all of the MySQL Enterprise Monitor 1.3 information.

If you remove access to the old data, then the data migration options for old servers will be removed from the **MANAGE SERVERS** panel within MySQL Enterprise Service Manager. To remove access, you need to **REVOKE** access to the `merlin` database:

```
mysql& REVOKE ALL on merlin.* FROM 'service_manager';
```

Note that revoking access to the old data will not reclaim any of the disk space used by the old data.

To delete the data from the database and free up the space being used by the historical information, **DROP** the `merlin` database:

```
mysql& DROP DATABASE merlin;
```

Once all the data has been migrated you can hide the migration user interface by clicking on the **HIDE MIGRATION INTERFACE** button.

15.4.3. Regular MySQL Enterprise Monitor Maintenance

MySQL Enterprise Monitor is generally self managing and does not need excessive maintenance. You should, however, be aware of certain maintenance tasks that you can automate or will need to manually perform to keep your MySQL Enterprise Monitor running efficiently.

- Make sure you have set the purge interval for your data to an appropriate value according to duration and history of data that you want to keep. For more information, see [??? \[1290\]](#)
- Check, and delete, the contents of the temporary directory with your MySQL Enterprise Service Manager installation directory.

15.4.4. Choosing Suitable MySQL Enterprise Service Manager Hardware Configurations

Running MySQL Enterprise Service Manager places a reasonable load on your system, and this load increases linearly as you add more agents monitoring more servers. Ideally, you should use a dedicated machine for MySQL Enterprise Service Manager, rather than running it alongside other applications and services.

Minimum System Requirements

- 2 or more CPU cores
- 2 or more GB of RAM
- Disk I/O subsystem applicable for a write-intensive database

Recommended System Requirements (if monitoring 100 or more MySQL servers)

- 4 or more CPU cores
- 8 or more GB of RAM
- Disk I/O subsystem applicable for a write-intensive database (RAID10, RAID 0+1)

15.5. MySQL Enterprise Dashboard

Note

MySQL Enterprise subscription, MySQL Enterprise Monitor, MySQL Replication Monitor, and MySQL Query Analyzer are only available to commercial customers. To learn more, see: <http://www.mysql.com/products/enterprise/features.html>.

The purpose of the MySQL Enterprise Dashboard is to provide you with information about your MySQL servers. It provides a list of the latest MySQL Enterprise Advisor reports, server status information, MySQL Enterprise alerts, and updated views of monitored MySQL servers. The **Monitor** screen gives a quick overview of the status of your MySQL servers.

Open the Dashboard by typing the host name into the address bar of your web browser. If you are unsure of the host name check the [Application host name and port](#) in the [configuration_report.txt](#) file. The default value is `http://127.0.0.1:18080/Auth.action` but this login is only valid if you are logging in from the machine that hosts the dashboard. If you are logging in from a remote machine you will have to specify a value other than `127.0.0.1`. Likewise, choose a different port if you are not using the default. After logging in, select the [Monitor](#) tab.

The Monitoring page provides an instant health check for all of the MySQL servers across the enterprise.

From this page users can:

- View monitoring data and all critical MySQL Advisor Rule violations for all or selected servers.
- Close and annotate MySQL Advisor Rule violations.
- Quickly determine if there is a Monitor Agent that is not communicating with the Service Manager.
- Quickly determine if there is a server that is in trouble or completely down.
- View indicator value graphs for key MySQL and operating system (OS) level metrics. Graph presentation will default to a thumbnail view but will open into a larger image upon being clicked.

The monitored server or servers are displayed in a tab on the left known as the [Server Tree](#). You can navigate to a number pages that provide more detailed information. These pages include:

- [Monitor](#) — the overview page providing you with a quick summary of the servers, their status, events, availability and load. The remainder of this chapter details the contents of this page.
- [Advisors](#) — shows the various advisors configured in your installation and allows you to schedule their execution on different servers, apply and manage rules and manage the advisor installation itself. For more information, see [Section 15.7, “The Advisors Page”](#).
- [Events](#) — provides an interface into the event system that highlights specific issues and problems on your monitored servers. For more information on using Events, see [Section 15.8, “The Events Page”](#).
- [Query Analyzer](#) — interfaces to the query monitoring system that can be used to monitor and track the individual queries that are being executed on a system and help to highlight problem queries that may need optimization or that may be affecting server load. For more information, see [Section 15.10, “The Query Analyzer Page”](#).
- [Graphs](#) — enables you to view and configure a number of individual graphs covering a range of different statistics. For more details on how to view and use these graphs, see [Section 15.9, “The Graphs Page”](#).
- [Replication](#) — provides information on the status and structure of your servers that are using replication. This page is only available if you have a suitable subscription level. For more information, see [Section 15.11, “The Replication Page”](#).
- [Settings](#) — controls the settings for the server, including email configuration, passwords, and server and user management. For more information, see [Section 15.6, “The Settings Page”](#).

Graphs are shown in the center of the page beneath the tabs. If applicable, you'll also find a list of critical events.

On the right is the color-coded [Heat Chart](#), showing the advisors that are installed by default. The [Heat Chart](#) shows the most important advisors, allowing a quick overview of the state of your servers. You may open the [Heat Chart](#) in its own window by clicking the [Standalone Heat Chart](#) link. If applicable, you'll also find a list of critical events.

The [Show/Hide Legend](#) link toggles display of the key to the icons used in the [Heat Chart](#).

Note

Find colorblind-accessible icons in the [alternate](#) directory. On Linux this directory is immediately below the `/monitor/apache-tomcat/webapps/ROOT/web/resources/images/` directory. These images are stored in the same directory on Windows. To use them, backup the originals and then copy and paste the alternate set into the [images](#) directory.

If a specific server is selected in the [Server Tree](#) details about this server are shown beneath the legend in the [Meta Info](#) area. The information shown in this area is the host name, the MySQL version number, the number of scheduled rules, the operating system, and the CPU.

The [Meta Info](#) section also shows how long the agent has been running, when it last contacted the MySQL server it is monitor-

ing, and the last time the agent contacted the dashboard. Mouse over the date shown beside **UP SINCE** and a pop-up box displays the time that has elapsed since the server instance was last started. You can also mouse over the **LAST MYSQL CONTACT** and the **LAST AGENT CONTACT** dates.

Note

In the case of remote monitoring, the agent runs on a different machine than the MySQL server that it is monitoring. The [Hostname](#), [MySQL](#), and [Rules](#) information applies to the system being monitored. The [OS](#) and [CPU](#) information applies to the machine on which the agent is running. For more information about remote monitoring see, [Section 15.3.3.6.4, “Configuring an Agent to Monitor a Remote MySQL Server”](#).

The top of the screen shows the refresh cycle and [Help](#) and [Log Out](#) links. Click the [Help](#) link to open the documentation in a separate browser window. Choose [Log Out](#) if you wish to leave the Dashboard or to log in as a different user. Different refresh rates are available from the drop-down listbox.

In the footer are external links to MySQL Enterprise and information about the current user. Users can remain connected to the Dashboard and update their subscription, use the Enterprise Knowledge Base, and contact technical support. Your subscription information is also displayed here, showing the number of days remaining and the number of licenses. The number of licenses indicates to the number of machines that may be monitored; any number of MySQL servers may be running on a specific machine.

The footer also contains a link to the [Settings](#) page. If your subscription is current it reads **SUBSCRIPTION IS UP-TO-DATE. MORE INFO.....** For more information about the [Settings](#) page see [Section 15.6.7, “The Product Information Screen”](#).

15.5.1. The Server Tree

The tab on the left displays the Server tree. By default the first group of servers is selected. This selection determines the information shown on the [Monitor](#) page.

If a server group is selected, the information presented on the [Monitor](#) page is aggregate information for this group; if only one server is selected the information applies to that server only.

Change your server selection and the information shown in the graphs and in the [Heat Chart](#) changes.

Note

For more information about server groups see, [Section 15.6.3.2, “Grouping Servers”](#).

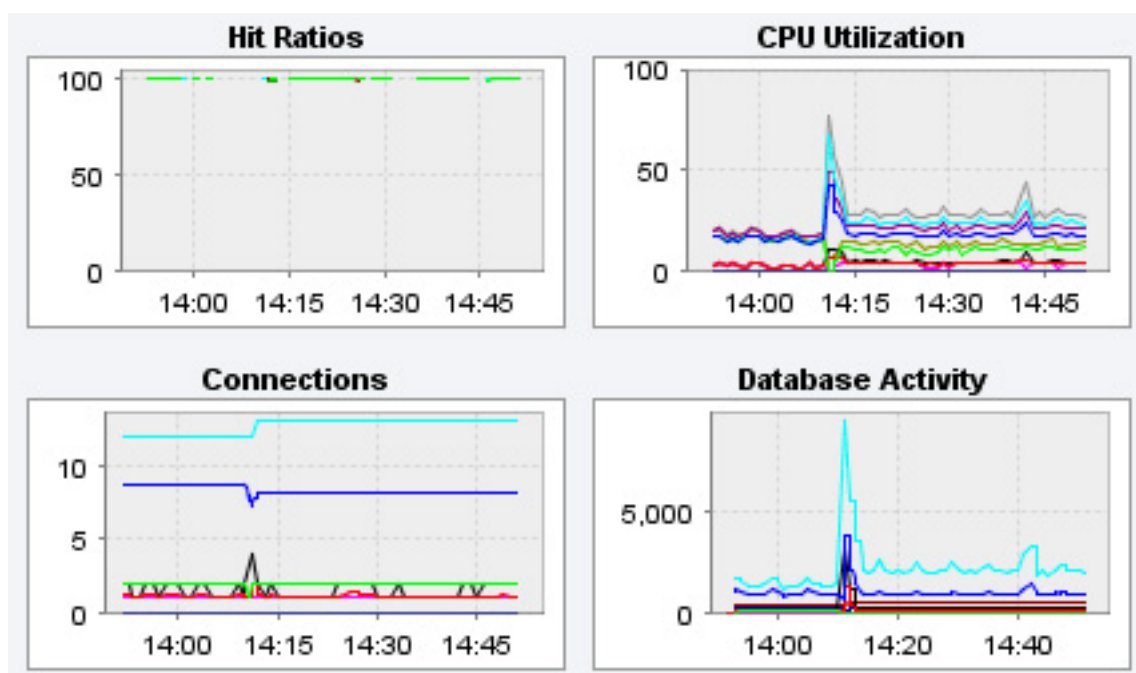

The individual server, or server group, selected in the Server Tree also determines what information appears when the [Advisors](#) tab or the [Events](#) tab is selected.

The Server Tree presents an easy way to navigate to different groups or to specific servers.

15.5.2. The Server Graphs and Critical Events

The center of the [Monitor](#) page gives a visual representation of the state of your servers.

Figure 15.32. MySQL Enterprise Dashboard: The Graphs screen

The graphs present information about the currently selected server or server group. The default graphs show the hit ratios, CPU utilization, connections, and database activity for a specific interval.

To set the interval click the [configure graphs](#) link immediately below the graphs. This opens a dialog box where you can choose the default interval for the x-axis of the graphs. Defining a shorter or longer interval gives you a shorter or longer term view of server activity. The thumbnail and full-size graph dimensions can also be adjusted from this dialog box. Save any changes that you have made and the values chosen will be the defaults whenever you log in.

You can also choose the default graphs shown on the [Monitor](#) page. To do this click the [edit favorites](#) link and choose the graphs you want from the drop-down list box. To choose contiguous graphs, hold down the **Shift** key and click on the desired graphs. For a non-contiguous selection, click the desired graphs while holding down the **Ctrl** key. The maximum number of graphs that can be displayed on the [Monitor](#) page is six. Save your changes and these will be the default graphs whenever you log in.

Color coding helps distinguish different aspects of each graph. With [Database Activity](#) for example, you can readily distinguish [SELECT](#) statements from database insertions.

Clicking a graph opens a detailed view with **GRAPH DISPLAY** and **CONFIGURE** tabs. Choose the [Configure](#) tab to temporarily change the way that a graph displays. Changes made from this tab only apply to the standalone graph while it is open. Persistent changes are made as described above.

Dismiss the enlarged graph by clicking the **HIDE** button.

[Critical](#) alerts appear on this page immediately below the graphs—quickly attracting your attention. For a description of all the different alarm levels see, [Section 15.5.3, “The Heat Chart”](#). This is the subject of discussion in [Section 15.8, “The Events Page”](#).

15.5.3. The Heat Chart

The [Heat Chart](#) is found on the right side of the [Monitor](#) page and shows the status of critical rules. Monitored servers are organized by groups. To view the status of a specific server, click the + button next to the appropriate server group.

Whenever a new agent contacts the Service Manager for the first time, all the rules in the Heat Chart Advisor are automatically activated. These Advisors monitor the status of the server and agent, critical operating system indicators, and important events related to your MySQL servers. An example follows.

Figure 15.33. MySQL Enterprise Dashboard: The Heat Chart

	Agent Status	Server Status	CPU Usage	IO Usage	RAM Usage	Lock Contention	My/SAM Usage	Query Cache	Temp Tables	Table Cache	Table to Disk	Critical Scans	Warnings	Info

To interpret the Heat Chart see the following legend.

Figure 15.34. MySQL Enterprise Dashboard: The Heat Chart legend

Server & Agent Status	Monitored Events
● up	○ ok
● down	● info
⊗ unknown	● warning
	● critical
	⊗ unknown

The status **unknown** will typically apply when an agent is down and can no longer report the status of the server that it is monitoring. The status **unknown** may also apply if the data collection that should be collected is not available on the server being monitored.

You may open the Heat Chart in its own browser window by clicking the [Standalone Heat Chart](#) link immediately below the [Heat Chart](#) on the left. If you like, the refresh rate can be set to a different rate than the setting on the [Monitor](#) page.

In addition to showing the most important advisors, the [Heat Chart](#) also has columns that display the number of critical, warning, and informational alarms. Clicking the hyperlink in any one of these columns takes you to the [Event](#) screen, which gives more detailed information. For more information about events see, [Section 15.8, “The Events Page”](#).

When the Dashboard is first installed no notification groups are associated with the Advisors shown in the Heat Chart. For more information on this topic see, [Section 15.3.2.7.3, “Installing Advisors After Initial Log-in”](#) and, [Section 15.6.5, “Manage Notification Groups”](#).

15.6. The Settings Page

Note

MySQL Enterprise subscription, MySQL Enterprise Monitor, MySQL Replication Monitor, and MySQL Query Analyzer are only available to commercial customers. To learn more, see: <http://www.mysql.com/products/enterprise/features.html>.

Upon initial installation you may have configured your MySQL Enterprise credentials and also outgoing email settings. This section explores the configuration settings in more detail, and also shows how to manage servers, users, notification groups, Simple Network Management Protocol (SNMP) traps, log files, and the product information screen.

Knowledge of server management is a prerequisite for properly configuring advisors — the subject of [Section 15.7, “The Advisors Page”](#).

To get to the [Settings](#) page open the Dashboard and choose the [Settings](#) tab.

15.6.1. Global Settings

The **GLOBAL SETTINGS** control the main configuration parameters for the entire MySQL Enterprise Monitor system, including your email notifications, data purge, and Enterprise website credentials.

Figure 15.35. MySQL Enterprise Dashboard: Settings

The screenshot shows the MySQL Enterprise Monitor interface with the following sections and settings:

- Outgoing Email Settings:**
 - Enable Email Notifications
 - From Address (ex. "MySQL Dashboard" <name@domain.com>): [text box]
 - SMTP Server: [text box]
 - SMTP Server Login: [text box]
 - Disable JavaMail TLS/SSL
 - Update Password On Save
 - SMTP Server Password: [text box] Confirm Password: [text box]
 - On Save, Send Test Email Message to (optional): [text box]
 - [save]
- Data Purge Behavior:**
 - Remove Historical Data Collection Older Than: never [dropdown]
 - Remove Service Manager Logs Older Than: never [dropdown]
 - Remove Query Analyzer Data Older Than: never [dropdown]
 - [save]
- Remote Server Inventory Schedule:**
 - Re-inventory Remote Servers Every: 12 hours [dropdown]
 - This will re-inventory all connected servers. The information collected may be used in custom data collection.
 - [save]
- MySQL Enterprise Credentials:**
 - These credentials are used to login to MySQL Enterprise at mysql.com to enable subscription updates.
 - Email Address (MySQL Enterprise Login): [text box]
 - Enterprise Password (MySQL Enterprise Password): [text box]
 - Confirm Password: [text box]
 - [save]
- MySQL Enterprise Product Key:**
 - In the event that this machine cannot connect to mysql.com to verify subscription information, you may manually import this information from a file provided by MySQL Enterprise. Subscription updates will require that you retrieve a new file from MySQL Enterprise.
 - MySQL Enterprise Product Key: Choose File [button] no file selected
 - [save]
- Server Locale:**
 - Locale: English (United States) [dropdown]
 - This locale overrides the operating system locale for use in notifications.
 - [save]

Footer: MySQL Enterprise © 2005-2008 MySQL AB, 2008 Sun Microsystems, Inc. All rights reserved. Enterprise Software | Update Service | Knowledge Base | Technical Support | About. Logged in as "admin" (Nov 19, 2008 3:38:40 PM). Monitoring 3 instances on 2 hosts (198 hosts remaining). Subscription is up-to-date. More info...

The **GLOBAL SETTINGS** page is divided into a number of different sections:

- **OUTGOING EMAIL SETTINGS**

Configures the settings for email notified by MySQL Enterprise Service Manager. You must configure the **FROM ADDRESS** **SMTP SERVER** settings. If your server requires authorization, complete the necessary server login details, and whether SSL is required.

You can test your configuration immediately by adding an email address to the **ON SAVE, SEND TEST EMAIL MESSAGE TO** box.

For more information about [Outgoing Email Settings](#) see, [Section 15.3.2.7.5, "Outgoing Email Settings"](#).

- **SNMP TRAPS**

The **SNMP Traps** section of the [Global Preferences](#) page allows you to enable Simple Network Management Protocol so that your Network Management System (NMS) can handle events created by the MySQL Enterprise Monitor. Configure this section to route alerts and notifications to standard SNMP-enabled nodes on your network.

In the **TARGET** text box enter the IP address or the host name of your NMS listener. The port number defaults to the well-known SNMP port, **162**. If you are not using this port, enter the port that your Network Management System is listening on.

Enter the appropriate community string in the **Community String** text box. The default value for this string is **public**.

To ensure that the target you have specified is valid, check the **On Save, Send Test Trap** check box. The remaining check boxes help you to configure how your NMS responds to MySQL Enterprise Monitor. Check the **UP/DOWN APPLICATION** check box to configure NMS for starting up or shutting down the MySQL Enterprise Monitor. For configuration of advisor events choose a level of severity and check the **ADVISOR EVENT WITH THE SEVERITY OF CRITICAL** check box. Finally,

choose the **APPLICATION ERROR** check box to configure NMS to support application error traps. Be sure to save your settings before exiting.

If you wish to enable SNMP traps globally, check the [Enable SNMP Notifications](#) checkbox. To enable SNMP traps only for specific rules run against specific servers or server groups leave this checkbox unchecked — enabling specific SNMP traps is done as rules are scheduled. For instructions on doing this see [Section 15.7.2, “Scheduling Rules”](#).

The Management Information Base (MIB) file associated with SNMP trapping is called `MONITOR.MIB`. For the location this file see [The Management Information Base \(MIB\) File](#).

- **SERVER LOCALE**

The [Server Locale](#) setting determines the language of notification for the following items:

- Email notifications
- SNMP traps
- The naming conventions for shared resources such as a replication group name prefix

The initial value in this drop down list box is the locale for the OS on which the Dashboard is running.

- **DATA PURGE BEHAVIOR**

The [Data Purge Behavior](#) section of the [Global Preferences](#) page lets you remove old log files and also old data from the repository. The default purge interval is `never`. If you wish to purge data, change this setting by choosing from the drop-down list. Choosing `52 weeks`, for example, will remove all data that is older than a year.

Warning

Purging data will permanently remove information from the repository. Since events are derived from data contained in the repository, they will be purged along with the data.

Ensure that there is adequate disk space for the repository. If you are monitoring numerous servers and running many rules the size of the repository can increase rapidly. Choose purge behavior accordingly.

The default value for purging, `never`, is the safest option. However, please choose a purge setting that makes sense for your environment.

Note

The purge process is started approximately once every minute. If you change the purge duration from a larger timespan to a smaller one, the data may start to be purged immediately.

You can configure the data purge behavior for a number of different systems individually:

- **Remove Historical Data Collection Older Than** configures the duration that the main data about your servers is retained. This includes all data collections, including CPU, memory and connections and activity statistics.
- **Remove Service Manager Logs Older Than** configures the duration that the main MySQL Enterprise Service Manager logs are retained.
- **Remove Query Analyzer Data Older Than** configures the duration that the query analyzer statistics and information about individual queries is retained.

Note

Purging can be carried out manually by enabling the `innodb_file_per_table` for the repository database and then using an `OPTIMIZE TABLE` operation to reclaim space from deleted rows in the table.

- **REMOTE SERVER INVENTORY SCHEDULE**

MySQL Enterprise Monitor keeps track of all the databases and tables in a server, as well as the amount of RAM, disk space, and other items. A re-inventory updates this information in case you've added or dropped databases and tables. Depending upon the configuration of your system, this operation can tax resources. If you are monitoring many remote servers this is an operation you may want to perform in off-peak hours only.

- **MYSQL ENTERPRISE CREDENTIALS**

You can specify the credentials for logging into the MySQL Enterprise Website. These should match the user name and password that you have registered with MySQL for your enterprise subscription.

Note

Only administrators can change the [MySQL Enterprise Credentials](#) section or enter a product key; for other users, this section does not show up in the interface. For more information about different users and their rights see [Section 15.6.4, “Managing Users”](#). Specifying incorrect credentials results in the error message, “Your credentials do not appear to be valid.”

- **MYSQL ENTERPRISE PRODUCT KEY**

You may update your [MySQL Enterprise Product Key](#). If you do not have access to the Internet from the Dashboard, this provides an alternate way to update or activate the MySQL Enterprise Monitor.

To enter your product key first download it from the MySQL Enterprise website. Copy the key to a location accessible from the Dashboard. Use the BROWSE button to locate the key and then press the SAVE button.

If you wish to switch from using your MySQL Enterprise credentials to using a product key to update MySQL Enterprise Monitor, you must first clear your credentials. Do this by removing the email address from the **MYSQL ENTERPRISE CREDENTIALS** section and then clicking the SAVE button. You may then enter and save your MySQL Enterprise product key.

Note

Only administrators can change the [MySQL Enterprise Credentials](#) section or enter a product key; for other users, this section does not show up in the interface. For more information about different users and their rights see [Section 15.6.4, “Managing Users”](#). Specifying incorrect credentials results in the error message, “Your credentials do not appear to be valid.”

15.6.2. User Preferences

On this page users can change their passwords, user names, and locale information.

Figure 15.36. MySQL Enterprise Dashboard: User Preferences

The screenshot shows the 'User Preferences' section of the MySQL Enterprise Monitor dashboard. At the top, there are navigation tabs: Monitor, Advisors, Events, Graphs, Query Analyzer, Replication, Settings, and What's New?. Below these are sub-tabs: Global Settings, User Preferences (selected), Manage Servers, Manage Users, Manage Notification Groups, Logs, and Product Information. The main content area is titled 'User Preferences' and contains the following fields:

- User Name:** A text input field containing 'admin'.
- Role:** A dropdown menu currently set to 'manager'.
- Password:** A text input field with the instruction '(Leave empty to keep password unchanged)'. It is currently empty.
- Confirm Password:** A text input field, currently empty.
- Timezone:** A dropdown menu set to '(GMT+00:00) Greenwich Mean Time - Europe/London'.
- Locale:** A dropdown menu set to 'English'.
- save:** A button at the bottom left of the form.

Change your password by entering a new value into the **PASSWORD** text box. To change your user name enter a new value into the **USERNAME** text box. Click the **SAVE USER PROPERTIES** button to commit this change.

You may also adjust your time zone and locale information from this page. The settings on this page apply only to the user who is currently logged in.

The MySQL Enterprise Service Manager determines the default value for the locale by looking at your browser settings. Changing this value, determines the language setting for any future logins to the Dashboard, overriding your browser settings.

Note

Be sure to set the correct time zone so that alerts are time stamped correctly.

This setting applies only to the specific user.

15.6.3. Manage Servers

To help with server management, the Service Manager supports the logical grouping of MySQL servers. This allows you to group servers in any fashion you choose. For example, you can manage servers according to purpose. You can group servers by whether the servers handle Internet or intranet data, by whether they power finance or HR applications, or, if you prefer, you may organize them by physical location rather than by functionality.

Figure 15.37. MySQL Enterprise Dashboard: Manage Servers

Server	Query Analyzer			MySQL	Up Since	Last MySQL	Agent	Last Agent	Migration Status
	Enabled	Examples	Explains						
<input type="checkbox"/> All Servers (3)									
<input type="checkbox"/> bear:3306 (ungrouped)	On	On	On	5.0.60-log	Sep 13, 2008 6:37:12 PM	Nov 19, 2008 4:07:00 PM	2.0.0.7085	Nov 19, 2008 4:07:13 PM	N/A
<input type="checkbox"/> gentoo1.vmbear:3306 (ungrouped)	On	Off	Off	5.0.60-log	Nov 17, 2008 10:26:45 AM	Nov 19, 2008 4:42:00 PM	2.0.0.7101	Nov 19, 2008 4:07:13 PM	Done
<input type="checkbox"/> gentoo2.vmbear:3306 (ungrouped)	On	Off	Off	5.0.60-log	Nov 17, 2008 9:04:53 AM	Nov 19, 2008 1:51:00 PM	2.0.0.7101	Nov 19, 2008 4:07:11 PM	Done

For a server to appear in the Dashboard there must be an agent monitoring it. If you wish to add a server to the Dashboard follow the procedure for installing an agent found at [Section 15.3.3, “Monitor Agent Installation”](#). Instructions for adding a remote server are found at [Section 15.3.3.6.4, “Configuring an Agent to Monitor a Remote MySQL Server”](#).

The **MANAGE SERVERS** panel also allows you control the Query Analyzer and Data Migration. For more information, see [Section 15.10.6, “Query Analyzer Settings”](#) and [Section 15.4.2, “Migrating 1.3.x Historical Data to MySQL Enterprise Monitor 2.0”](#).

Note

The **All Servers** group is built in and every monitored server is a member of this group.

15.6.3.1. Renaming a Server

You can rename an existing server without losing the current historical data or configuration information. Renaming the server also allows you to modify the name of the server to be more descriptive according to the server's role within your organization. For example, you may want to rename a server from the default host name to include the department and application for the MySQL server.

To rename a server, click the **RENAME** link next to the server. You will be prompted with information about the server, including the host name and registered IP addresses for the agent. Fill in the alternative name that you want to be displayed in the text box at the bottom of the window.

Figure 15.38. MySQL Enterprise Dashboard: Server Renaming

Rename Server

Rename Server "bear:3306".

host
bear.mcslp.pri
localhost

ip
192.168.0.2
127.0.0.1
192.168.92.1
172.16.217.1

port
3306

name

save cancel

15.6.3.2. Grouping Servers

All monitored servers are automatically included in the top level server grouping, [All Servers](#). Other server groupings are replication groups or user-defined groups.

You can create a user-defined group by clicking on the [Manage Servers](#) link. Add a group name and then click the CREATE GROUP button. The new group will be displayed immediately.

Replication groups are automatically discovered by MySQL Enterprise Monitor and in this respect differ from user-defined groups. For more information about replication groups see [Section 15.11, "The Replication Page"](#). However, like user-defined groups you can edit the name of a replication group and add other servers to it.

To add to a group, select the [add to group](#) link. Choose the server or servers you wish to add and then complete the operation by choosing the ADD TO GROUP button. You can add a server to a group even if the agent is down.

To remove a server from a group expand the server group tree and click the [remove from group](#) link. To delete a server altogether see [Section 15.6.3.3, "Removing a Server From the Dashboard"](#).

Note

Slaves removed from a replication group will be rediscovered and re-added to that group.

There are three ways to modify an existing group; by renaming it, adding to it, or removing it. Select the [rename](#) link to change the name of a group and [add to group](#) to add additional servers. Deleting a group simply requires clicking the [remove all from group](#) link. This removes the server group but has no effect on individual servers.

15.6.3.3. Removing a Server From the Dashboard

If you no longer wish to monitor a MySQL server you can remove it from the Dashboard. There is no provision for deleting an active server from the Dashboard—to remove a server you must make it inactive by stopping the agent.

For instructions on stopping an agent see:

- Windows – [Section 15.3.3.5.1, "Starting/Stopping the Agent on Windows"](#)
- Unix – [Section 15.3.3.5.3, "Starting/Stopping the Agent on Unix"](#)
- Mac OS X – [Section 15.3.3.5.2, "Starting/Stopping the Agent on Mac OS X"](#)

Once the agent is stopped you may delete the monitored server. Deleting a server simply means that it will no longer show up in the Dashboard.

Remove a server by choosing the [Settings](#) tab and then the [Manage Servers](#) link. Find the server you wish to remove and delete it by clicking the [delete](#) link. Deleting a server from the [All Servers](#) group or from any other group will remove it from the Dashboard entirely.

Note

A [delete](#) link will not appear beside an active server. You must stop the agent before this link will appear.

You may remove a server from any group at any time. Removing the last server from a group also removes that group.

15.6.4. Managing Users

The **MANAGE SERVERS** panel allows to create, delete and manage individual users that have access to MySQL Enterprise Service Manager

Figure 15.39. MySQL Enterprise Dashboard: Manage Users

To log in to the Dashboard a user account is required. There are three types of users with varying privileges; Administrators, Database Administrators, and Agents. The **Administrator** can create additional users and differs from a **DBA** in this respect. For this reason the **Manage Users** does not display if a **DBA** user logs in. Additionally, only administrators can change the MySQL Enterprise Credentials section or enter a product key on the [Global Settings](#) page. These sections do not appear when **DBA** users log in. For more information on this subject see [Section 15.6.1, "Global Settings"](#). The **Agent** account simply allows the MySQL Enterprise Monitor Agent to communicate with the Dashboard. There is no need for more than one agent account but defining an account for each server that is monitored can be an advantage since this minimizes exposure should any one agent be compromised. You cannot log in to the Dashboard using the agent's credentials.

When the Dashboard is first launched there are two default users, **Administrator** and **Agent**, both created during installation. Their default user names are respectively, **admin** and **agent**. The Administrator defined during installation as having the root role is unique; this user cannot be deleted.

If you are logged in as an **Administrator**, you can add a new user by choosing the **Manage Users** link from the [Settings](#) page. To create a user click the **CREATE USER** button, select a role for the user, and enter a user name and password.

When a new user first logs in, a dialog box opens requesting time zone and locale information. This information may be changed later from the [User Preferences](#) page. For more information, see [Section 15.6.2, "User Preferences"](#).

If you installed the Advisors through the Dashboard you should have already configured the settings for the root role user. (See [Section 15.6.1, "Global Settings"](#) and following for more information about this topic.)

Warning

To receive MySQL Enterprise and Advisor updates configure the MySQL Enterprise settings for at least one user. The MySQL Enterprise settings were set up on the first login to the Dashboard. For information on changing these settings see, [Section 15.6.1, "Global Settings"](#).

To edit an existing user's information, select the **Manage Users** link, then select the user you wish to edit. Make your desired changes in the fields provided and then save your changes.

To delete an existing user, merely select the [delete](#) link.

15.6.5. Manage Notification Groups

The **MANAGE NOTIFICATION GROUPS** panels allows you to create and manage the notification groups used when different notifications and warnings are distributed.

Figure 15.40. MySQL Enterprise Dashboard: Manage Notification Groups

Notification groups are collections of users who should be notified when advisor alerts occur. These users may have login credentials for the Dashboard but this is not a requirement.

You can create a group by clicking on the [create group](#) link. Specify a group name and add recipients. When adding a user an email address must be specified. If you are adding multiple users separate them with commas.

To modify an existing notification group, select the [edit](#) link next to the group name. Deleting a group simply requires clicking the [delete](#) link.

If a rule triggers an alarm, an email will be sent to the members of the notification group specified when the rule was scheduled. For more information about scheduling rules see [Section 15.7.2, “Scheduling Rules”](#).

Note

You should ensure that there is a mail server available for sending out alerts and that there is an account configured for receiving any alerts that are created.

15.6.6. Logs

Use the [Logs](#) link to inspect the various log files associated with the MySQL Enterprise Service Manager. The following image is an example of this screen.

Figure 15.41. MySQL Enterprise Dashboard: Logs

Log Name	Threshold	Last Modified	Entries	
All	N/A	Nov 19, 2008 4:07:37 PM	838	clear all logs
Advisors	Info	Nov 19, 2008 11:44:28 AM	338	clear log edit log level
Agent Monitoring	Info	N/A	0	clear log edit log level
Agent Tasks	Info	N/A	0	clear log edit log level
Data Collection	Info	N/A	0	clear log edit log level
Graphs	Info	Nov 19, 2008 11:44:12 AM	4	clear log edit log level
Groups	Info	N/A	0	clear log edit log level
Inventory	Info	Nov 19, 2008 11:44:24 AM	4	clear log edit log level
JDBC	Info	N/A	0	clear log edit log level
Misc	Info	Nov 19, 2008 11:44:29 AM	11	clear log edit log level
Migration	Info	Nov 19, 2008 1:52:09 PM	340	clear log edit log level
Notification	Info	N/A	0	clear log edit log level
Preferences	Info	N/A	0	clear log edit log level
Replication	Info	N/A	0	clear log edit log level
Security	Info	N/A	0	clear log edit log level
SQL	Info	N/A	0	clear log edit log level
Timing	Info	Nov 19, 2008 4:07:37 PM	140	clear log edit log level
Xwork	Warning	N/A	0	clear log edit log level
Apache	Warning	Nov 19, 2008 11:26:32 AM	1	clear log edit log level
Catalina	Warning	N/A	0	clear log edit log level
Hibernate	Warning	N/A	0	clear log edit log level
Freemarker	Warning	N/A	0	clear log edit log level
Spring	Warning	N/A	0	clear log edit log level
EH Cache	Warning	N/A	0	clear log edit log level

The various categories of logs are shown in alphabetical order. The most recent changes to each log are shown in the **LAST MODIFIED** column. The number of entries in any specific log is shown under the **ENTRIES** column.

To view detailed information click the [Log Name](#). This will open a separate browser window showing the date, time, alert type, and accompanying message.

On this screen you can filter log information in a couple of ways; by the message type and by time period .

To filter by message type select from the options in the **LEVEL** drop-down box. These are, in order of decreasing severity:

- All
- Error
- Warning

- Information
- Trace
- Debug

You can also adjust the number of items that appear on each page.

Press the [clear all logs](#) link to remove all log entries. To remove entries of a specific kind click the [clear logs](#) link associated with the specific log you would like to remove. A confirmation dialog box allows you to back out of this operation and avoid accidentally removing log information.

To clear log files of a specific age see the [Data Purge Behavior](#) section of the [Global Preferences](#) page. For more information on this topic see [??? \[1290\]](#).

Use the [edit log level](#) link to change the type of error logged. The value selected from the [Edit Log Level](#) dialog box determines what appears under the **THRESHOLD** column (second from the left in [??? \[1290\]](#)).

Selecting [Error](#) from the list box will create the least number of log entries and [Debug](#) the most. Choosing [None](#) turns off logging altogether.

It is also possible to download a compressed version of all the log files. For more information, see [Section 15.6.7, “The Product Information Screen”](#).

15.6.7. The Product Information Screen

Use the [Product Information](#) link to view detailed information about your subscription level and contract status.

The **CONTRACT STATUS** section displays the subscription level, expiration date, contract number, the number of servers supported, and your MySQL Enterprise user name. The **SUBSCRIPTION LEVEL** section gives more detailed information, including features and any restrictions that may apply. You may update your subscription at any time by clicking the **UPDATE** button.

Note

The **UPDATE** button was added in version 1.3 of the MySQL Enterprise Monitor. If your version of MySQL Enterprise Monitor does not have an **UPDATE** button, saving your credentials again will download a new key. See [Section 15.6.1, “Global Settings”](#) for instructions on doing this. If you do not have Internet access from the Dashboard, you can install a new key manually. This process is described in [Section 15.6.1, “Global Settings”](#).

This page also contains Enterprise Dashboard Server information; the version number, uptime, and other information related to the memory used by the Java Virtual Machine.

The [Enterprise Dashboard Server information](#) section also contains the hyperlink, [Download diagnostic report](#). Click this link to download a compressed version of the MySQL Enterprise Service Manager log files. All the log files found on the [Logs](#) page (for more information about logs see [Section 15.6.6, “Logs”](#)) are contained in this file. It also contains the Java properties file, the monitored MySQL servers property file, information about the status of the JDBC connection and Java threads, and the [subscription.xml](#) file. This report is especially useful for debugging the MySQL Enterprise Service Manager and the MySQL Enterprise Monitor Agent.

15.6.7.1. Subscription Warning

The [Subscriptions Warning](#) section on the product information page displays any warnings relative to your subscription. For example, if your subscription has expired you may receive a message such as the following:

```
Your Subscription Needs to be Updated
* Your Platinum subscription expired 3 days ago on Feb 14, 2008 11:59:59 PM.
If the subscription information on this page is not current, you can
update it by going to the Enterprise Monitor Global Settings page and
providing MySQL Enterprise credentials or by importing a new product
key that you downloaded from http://www.mysql.com/enterprise/download.php.
To update or renew your subscription, please contact your MySQL
Account Representative at sales@mysql.com or visit
http://www.mysql.com/about/contact/renew.html. After the update or
renewal is complete you can then follow the above instructions for
updating your subscription.
```

Follow these instructions to update your subscription. If you see this message and your subscription has already been updated, simply click the **UPDATE** button in the **CONTRACT STATUS** section of this page. This should update your subscription and remove the warning.

Note

After updating your subscription remember to also update your advisors. For instructions on doing this see [Section 15.7.1, “Installing and Updating Advisors”](#).

15.7. The Advisors Page

Note

MySQL Enterprise subscription, MySQL Enterprise Monitor, MySQL Replication Monitor, and MySQL Query Analyzer are only available to commercial customers. To learn more, see: <http://www.mysql.com/products/enterprise/features.html>.

MySQL Enterprise Advisors are a series of scripts that gather information from your MySQL servers via the Service Manager and the Service Agents, analyze that information based on custom rules developed by MySQL AB, and then offer alerts and advice when necessary. As new rules are introduced, the MySQL Enterprise Advisors can be updated through the MySQL Enterprise website.

The MySQL Enterprise Advisors fall into the following categories:

- Administration
 - Better manage databases
 - Suggest improvements for smoother operation
- Heat Chart
 - Drive the status indicators in the Heat Chart
 - Identify up/down status and performance issues
- Performance
 - Identify potential performance bottlenecks
 - Make suggestions for improved database speed
- Replication
 - Identify replication bottlenecks
 - Improve replication design
- Schema
 - Identify schema changes
 - Find security loopholes
- Security
 - Protect MySQL servers
 - Find security loopholes

An advisor category provides a set of rules designed to enforce MySQL best practices for that specific category. Rules can be targeted to run at the individual server or group level and, upon rule violation, provide alerts and expert advice on how to address and correct a problem before it becomes a costly outage.

Individual rules are defined in the `items-mysql-monitor.xml` file. On Windows this file is found in the `C:\Program Files\MySQL\Enterprise\Agent\share\mysql-monitor-agent` directory and on Unix in the `/opt/mysql/enterprise/agent/share/mysql-monitor-agent` directory. Find below the rule for discovering a root account with no password.

```
<ITEM>
<NAME>no_root_password</NAME>
<FIELD>no_password</FIELD>
<SCOPE>table</SCOPE>
<CODE>
<![CDATA[SELECT COUNT(*) AS no_password FROM mysql.user WHERE user='root' AND password='']]>
</CODE>
<NAMESPACE>mysql</NAMESPACE>
```

```
<RETURNS>INTEGER</RETURNS>
<SOURCE>table</SOURCE>
<INSTANCE>mysql.user</INSTANCE>
</ITEM>
```

Your MySQL Enterprise subscription level determines which rules are available to you. Subscription levels are cumulative, meaning that higher MySQL Enterprise levels have access to all the rules of the lower levels.

When the Dashboard is first installed, the only rules that are scheduled are those that belong to the [Heat Chart](#) group.

Go to the Advisors screen by logging in to the Dashboard and choosing the [Advisors](#) tab.

15.7.1. Installing and Updating Advisors

Instructions for installing Advisors are given in [Section 15.3.2.7.3, “Installing Advisors After Initial Log-in”](#), and following. Principally, you need to configure your MySQL Enterprise login or enter your product key before you can update your Advisors.

If your MySQL Enterprise login is configured, you can download the latest Advisors by navigating to the [Advisors](#) page and finding the [Check for Updates](#) link. You can periodically update advisors in this way.

Note

If you do not have Internet access and cannot use the online update option you can manually import advisors. This process is described in [Section 15.3.2.7.3, “Installing Advisors After Initial Log-in”](#).

15.7.2. Scheduling Rules

Once the MySQL Enterprise Advisors have been installed, you can configure which advisors you would like to run on a scheduled basis.

You can schedule rules by individual server or by group. This is done by first selecting the desired server or server group from the [Server](#) tree found on the left side of the screen. Next select the [Advisors](#) tab.

Opening the [Advisors](#) tab takes you to the [Current Schedule](#) page. If you have only just installed the MySQL Enterprise Monitor then you will only see the [Heat Chart](#) group of advisors. Clicking the + button will show all the rules in the Heat Chart group.

Clicking the + button beside any specific rule will show the servers that this rule is running on, its frequency, and its status. Initially, all the [Heat Chart](#) rules are enabled.

For a more complete description of a rule, click the rule's name. This opens a dialog box that gives detailed information about the rule.

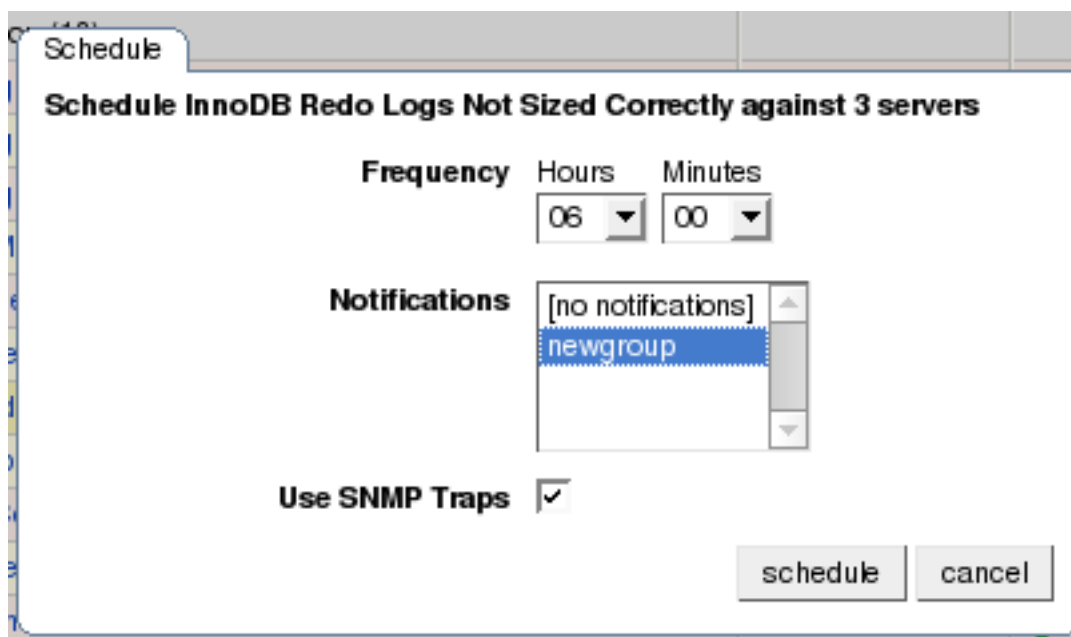

To view the advisors other than the Heat Chart group, select the [Add to Schedule](#) link. This will show all the advisors available for your subscription level.

Rules are grouped by functionality and displayed in alphabetic order. To expand a group click the + button to the left of the advisor name.

You may activate all the rules in a group by selecting the checkbox beside the group name. Once selected you may apply rules against a specific server or a group of servers. A message showing the group of servers or the specific server you have selected will display immediately below the SCHEDULE button. For example, if the [All Servers](#) group is selected in the server tree, then the message will read, “Schedule Advisors Against **All Servers**”.

To select a specific rule, expand the group tree by clicking the + button. Select the checkbox to the left of the rule you wish to schedule. Click SCHEDULE to display the following dialog box:

Figure 15.42. MySQL Enterprise Dashboard: Scheduling Dialog

The Schedule dialog box allows you to configure the following fields:

- **Frequency** – Dictates how often the rule will run. The default value for different rules varies but a rule can be set to run at any interval desired.

Warning

Setting the frequency of a rule involves tradeoffs. Rule evaluation consumes system resources — CPU, memory, and disk space. While the amount consumed is small, if you run all the rules against dozens of servers on a very frequent basis, you may put a significant load on the Service Manager. So select an appropriate frequency. For example, unless you are stopping and restarting your servers frequently, rules that check server configuration variables probably don't need to run very often.

Another consideration is that certain status variables increase monotonically until a server is restarted. Examples of these are `Key_reads`, `Qcache_hits`, `Questions`, `Table_locks_waited`, and similar variables. The value returned by `SHOW STATUS` for these variables is the value since the server was started (or since the last `FLUSH STATUS` command), which is not very useful for performance tuning, especially if the server has been running for an extended period of time. For performance tuning it is much better to know the change in state (i.e. delta) of these values over the last 10 minutes, 1 hour, or whatever time frame is appropriate for your application. The frequency at which you schedule a rule is the time frame used to calculate the delta values of these variables, and it is the delta that is used in expression evaluation, not the absolute value. Consequently, select a frequency that is appropriate for the metrics being used in the expression.

- **Notifications** – A listbox of users and/or notification groups who will be emailed when an advisor reaches an alert level. Single or multiple selections are allowed. For instructions on setting up notification groups see, [Section 15.6.5, “Manage Notification Groups”](#).

Set the frequency, identify whomever you wish to notify, and click SCHEDULE to schedule the advisor. Upon completion, you should see the message, [Successfully scheduled](#).

If you haven't set up global SNMP traps and would like your Network Management System (NMS) to handle events related to a specific rule then check the [Use SNMP Traps](#) checkbox. For more information about Simple Network Management Protocol (SNMP) see [Simple Network Management Protocol \(SNMP\) Traps](#).

Scheduling rules using the checkbox and the SCHEDULE button is an effective way to schedule multiple rules. To schedule a single rule you may also use the [schedule](#) link.

When scheduling more than one rule, you have the option of selecting a checkbox to use the default frequency of each rule or you may choose a frequency that will apply to all selected rules. When customizing the frequency, take care that you choose a value that is appropriate to all the rules selected.

Note

If the agent does not have the `SUPER` privilege and InnoDB-related rules are scheduled, a warning will appear in the `DataCollection` log. This also occurs if `mysqld` is started with the `skip-innodb` option. For more information about agent rights see Section 15.3.3.1, “Creating a MySQL User Account for the Monitor Agent”.

15.7.2.1. Heat Chart Notifications

It is particularly important that `Notifications` be set for the `Heat Chart` group of rules. This is easily done from the `Current Schedule` page by clicking the + button beside a rule and then clicking a server.

Doing this opens a window with three tabs—`Overview`, `Settings`, and `Advanced`.

The `Overview` tab shows which advisor group a rule belongs to, a description of its purpose, and a link to the history of this alert.

In the `Settings` tab you can adjust the frequency of this rule and also specify a notification group. To select more than one contiguous group press the `Shift` key and click the desired groups. (Some web browsers may require that you drag your selection.) Non-contiguous selections are made by holding down the `Control` key and clicking the desired groups.

If you haven't set up global SNMP traps and would like your Network Management System (NMS) to handle events related to a specific rule then check the `Use SNMP Traps` checkbox. For more information about Simple Network Management Protocol (SNMP) see ??? [1289].

The `Advanced` tab gives detailed information about how this rule is implemented.

15.7.3. Editing Built-in Rules

The frequency and thresholds defined for a rule are default recommendations. To edit these properties choose the `Create/Edit Rule` link.

The following image shows the screen used to edit rules:

Figure 15.43. MySQL Enterprise Dashboard: Editing Rules

Rule Name	Advisor	Version	
Temporary Tables To Disk Ratio Excessive - copy	Heat Chart	1.0	
Expression			
(%Uptime% > 10800) && (((%Created_tmp_disk_tables% / (%Created_tmp_tables%)) * 100) > THRESHOLD)			
Thresholds			
Critical Alert	<input type="text" value="90"/>		
Warning Alert	<input type="text" value="75"/>		
Info Alert	<input type="text" value="50"/>		
Variable Assignment			
Variable	Data Item	Instance	
%Uptime%	mysql:server:Uptime	local	delete
%Created_tmp_disk_table	mysql:server:Created_tmp_disk_tables	local	delete
%Created_tmp_tables%	mysql:server:Created_tmp_tables	local	delete
%tmp_table_size%	mysql:server:tmp_table_size	local	delete
%max_heap_table_size%	mysql:server:max_heap_table_size	local	delete
<input type="button" value="add row"/>			
Default Frequency			
Hours	Minutes		
<input type="text" value="00"/>	<input type="text" value="05"/>		

Beside the rule name is the [Advisor](#) drop-down list box, used for setting the advisor group. This list box shows existing groupings and any you may have added. The [Expression](#) text area shows the advisor rule, [Variable Assignment](#) the data item associated with variable(s) used in the rule and [Thresholds](#) determines when to trigger each alert type.

The three levels of [Thresholds](#) are [Info Alert](#), [Warning Alert](#), and [Critical Alert](#) indicating increasing levels of severity. Levels can be triggered by the expression result being equal to a certain value, greater than a certain value, or less than a certain value.

The data items that variables are associated with are operating system (OS) properties such as available RAM or MySQL characteristics such as the InnoDB buffer pool. To see all available data items drop down the [Data Item](#) list box. For a listing of these data items see [The Data Collection Items Used to Create Rules](#).

In [Figure 15.43, “MySQL Enterprise Dashboard: Editing Rules”](#) the drop-down [Data Item](#) list box within the [Variable Assignment](#) frame shows the various MySQL server status or operating system specific variables that may be used in expressions. The text boxes below [Thresholds](#) define the levels at which informational, warning, or critical alerts are issued.

To lower the threshold for an informational alert, simply increase the number given in the [Info Alert](#) text box.

When a data item can apply to multiple objects, you need to specify which instance to use for that item, hence the [Instance](#) text box. In almost all cases this should be set to `local`. The exceptions are as follows:

- For CPU-related items set **INSTANCE** to `cpu0`. Additional CPUs on a system are referred to as `cpu1`, `cpu2` and so on.
- There can be multiple disks mounted on a system. To refer to a specific drive set **INSTANCE** to the name of the mounted drive. On Windows this would be `C:`, `D:`, and so on. On Unix systems, use whatever is valid for the `df` command.
- For RAM-related items set **INSTANCE** to `mem`.

- Where there are table-specific variables, the database name and table name must be specified in the **INSTANCE** text box. This topic is discussed in detail in what follows.

Note

It is not possible to have a data item that is unrelated to an instance. This raises the error, `You must map "<variable>" to an instance`, and you will be unable to save the rule.

An agent can only collect data from one MySQL server, so the `instance` entry for a variable in a rule does not need to specify which MySQL server to use; no matter how many servers are being monitored there is always a one-to-one relationship between an agent and its monitored server.

However, on one server there may be multiple occurrences of a variable. For example, there are multiple possible occurrences of table-specific variables such as `Avg_row_length` because there can be multiple databases and tables defined in a MySQL server. In this case, the “instance” refers to the database and table that a data item should be associated with, specified in the form `tablename.tablename`. So, for example, if you want to reference the `Avg_row_length` of the `mysql` database `user` table in an expression, select the `mysql:tablestatus:Avg_row_length` from the **DATA ITEM** list box and specify `mysql.user` in the **INSTANCE** text box.

On the other hand, in the case of a global server variable, there is only one possible target. For example, there can only be one instance of `delay_key_write` because this variable is global and applies to the server as a whole. In this case specify `local` in the **INSTANCE** text box.

To save your changes click the **SAVE** button at the bottom of the page.

Note

You can change only the thresholds and the frequency of built-in rules. So that rules function properly when updated, other changes are prohibited.

Should you wish to make other changes to a built-in rule, copy it and modify it as desired.

You can edit a rule even if it is currently scheduled. Your changes will not be overwritten when new rules are imported using the [Check for Updates](#) link.

15.7.4. Creating Advisors and Rules

In addition to using and editing the advisors and rules provided by MySQL Enterprise, users can create their own advisors and rules to meet their own unique needs. To do this go to the [Advisors](#) page and choose the [Create/Edit Rule](#) link.

15.7.4.1. Creating Advisors

Similar existing rules are grouped together in advisor groups.

The built-in advisors are:

- Administration
- Heat Chart
- Performance
- Replication
- Schema
- Security

The ability to create your own advisor group allows you to create groupings suitable to your circumstances.

You can create your own grouping by simply clicking the **CREATE ADVISOR** button. Enter an appropriate name and click the **ADD** button. The newly created group will appear in the [Advisor](#) column.

The newly created advisor is added to the list box of advisors shown in [Figure 15.43, “MySQL Enterprise Dashboard: Editing Rules”](#). You can now use this category of advisors when you create a new rule.

15.7.4.2. Overview of Rule Creation

Rules are created using the same screen seen in [Figure 15.43, “MySQL Enterprise Dashboard: Editing Rules”](#). To begin creating a rule from scratch, click the **CREATE RULE** button. However, the simplest way to create a new rule is to copy an existing one. Unlike editing an existing rule, when you copy a rule, every element of that rule is editable.

You can change the rule name, the advisor group that a rule belongs to and you can set your own version number. In [Figure 15.43, “MySQL Enterprise Dashboard: Editing Rules”](#), you have already seen how the threshold and frequency of a rule may be altered.

Most importantly you can alter a rule's expression. Expressions are the core of a MySQL Enterprise Advisor and are used to define the scenario being monitored. An expression can be as simple as a single server parameter or can be quite complex, combining multiple parameters with various mathematical operations.

An expression has two main characteristics:

- An expression defines a situation where a best practice is not being followed
- The result of an expression must always be 1 or 0 (that is, true or false)

If an expression evaluates to true for a specific server, an alarm is raised, indicating that a best practice is not being followed. If an expression evaluates to false no alarm is raised because the best practice is indeed being followed.

For example, if having binary logging enabled is considered a best practice for a production server (which we believe it is), then this best practice is being violated if `log_bin` is `OFF`. Consequently, the expression for the “Binary Logging Not Enabled” rule is “`%log_bin% == OFF`”. If this evaluates to 1, an alarm is raised because the best practice is not being followed.

An expression is made up of one or more variables and zero or more mathematical operators. The MySQL Enterprise Monitor uses the MySQL database server's expression parser and evaluator. For a complete list of operators and functions see <http://dev.mysql.com/doc/refman/5.0/en/functions.html>. For a complete list of the built-in variables used when creating rules see <http://dev.mysql.com/doc/refman/5.0/en/mysqld-option-tables.html>.

Creating an expression is dependent on variables defined in the **VARIABLE ASSIGNMENT** frame. This frame links variables used in the expression field with data gathered from the target MySQL server instance—server status variables, operating system status information, and table information. Variable names are associated with elements in the **DATA ITEM** drop-down list. If you need to define more than one variable simply click the **ADD ROW** button. For a complete listing of the data collection items used in creating rules see [The Data Collection Items Used to Create Rules](#).

The remaining fields determine the information that displays in a notification email or the informational pop-up window associated with each advisor.

Note

When saving a new rule ensure that you do not duplicate the name of an existing rule.

15.7.4.3. Variables

When an expression is evaluated variables get replaced by values. For example, part of the expression for the “MyISAM Key Cache Has Sub-Optimal Hit Rate” rule calculates the hit rate as follows:

```
100 - ((%Key_reads% / %Key_read_requests%)*100)
```

If the current value of `%Key_reads%` is 4522 and the current value of `%Key_read_requests%` is 125989, the hit ratio assesses to 96.4%:

```
100 - ((4522 / 125989) * 100)
```

By convention, the Advisors supplied by MySQL use ‘%’ as the delimiter, for example, `%Key_reads%`. This makes variables more readily identifiable.

In addition to being used in an expression, variables may also be used in the **Description**, **Advice**, **Action**, and **Links** attributes of a rule. This allows you to report the current value of an expression.

For instance, you can add the message, “The current value of Key_reads is `%Key_reads%`.” to the **Advice** text box. When this is displayed on the screen, the value of `%Key_reads%` is substituted into the text. Supposing `%Key_reads%` has a value of 4522, the message becomes “The current value of Key_reads is 4522.”

15.7.4.4. Thresholds

Each expression has a threshold value that triggers an alert. The **THRESHOLD** keyword is used to associate that value with an alert level—either an **Info**, **Warning**, or **Critical** alert.

For example, the expression for the performance advisor, “Thread Cache Size May Not Be Optimal”, is:

```
100-((%Threads_created% / %Connections%) * 100) < THRESHOLD
```

The `THRESHOLD` is set at 95% for an Info level alert, 85% for a Warning alert, and 75% for a Critical alert; producing alerts of three different levels.

Expressions can be quite simple. The expression for “Binary Logging Not Enabled” (one of the Administration alerts) is:

```
%log_bin% == THRESHOLD
```

When the result is `OFF`, only one alert is triggered—a Warning level alert. In this situation you might think we could just use the expression `%log_bin% == "OFF"`. However, doing this would not test binary logging against a threshold so would not result in an alert.

When you create an expression, think carefully about the conditions under which it should be evaluated and the conditions under which it should not. For example, the expression for the “MyISAM Key Cache Has Sub-Optimal Hit Rate” rule is:

```
(%Uptime% > 10800) && (%Key_read_requests% > 10000) >
&& (100-((%Key_reads% / %Key_read_requests%) * 100) < THRESHOLD)
```

The essence of the rule is really: `(100-((%Key_reads% / %Key_read_requests%) * 100) < THRESHOLD)`. However, when a server is first starting up, it may take a while to reach a state that is representative of normal operations. For example, the key cache and the query cache may need some period of time before they have cached typical application data as opposed to start-up and initialization data. In this case, the first part of the expression, `(%Uptime% > 10800)`, holds off evaluating this expression until the system has been running for 10800 seconds (3 hours).

In addition, if some part of the system is not heavily used an alert may be triggered based on limited data. For example, if your application does not use the MyISAM storage engine, the “MyISAM Key Cache Has Sub-Optimal Hit Rate” rule may be triggered based on very limited use of other MyISAM tables such as the `mysql.user` table. For this reason, this advisor has a second part—`(%Key_read_requests% > 10000)`—meaning the rule won't be evaluated unless there is plenty of activity associated with the key cache.

In other circumstances, there may be periods of time during which you don't want a rule to be evaluated—a blackout period. For example, the expression for the “Slave Too Far Behind Master” rule is: `%Seconds_Behind_Master% > THRESHOLD`. However, suppose you run a backup process between 6 and 7 pm on a replication slave, and it's normal for that slave to get behind the master by an amount more than the `THRESHOLD` during that time. In that case you don't want to receive an alert because the rule violation is expected. You can achieve this by adding the following to the expression: `&& CURTIME() NOT BETWEEN '18:00:00' AND '19:00:00'` In essence, this means “don't trigger an alert between 18:00:00 and 19:00:00 (6 pm and 7 pm)”.

15.7.4.5. Using Strings

String values may appear in the `Expression` or the `Thresholds` text boxes. In both cases, they must be enclosed within quotation marks. For example, the expression for the “Slave I/O Thread Not Running” rule is:

```
(%Slave_running% == "ON") && (%Slave_IO_Running% != THRESHOLD)
```

In similar fashion the `Critical Alerts` threshold text box is set to a value of `"Yes"`.

When the expression is evaluated, either `"OFF"` or `"ON"` will be substituted for `%Slave_running%`, and `"Yes"` or `"No"` for `%Slave_IO_Running%`, depending on the state of your system. If the slave is running but the I/O thread is not, the expression then becomes:

```
("ON" == "ON") && ("No" != "Yes")
```

Without quotation marks this expression would not evaluate to `TRUE` as it should.

Note

So that it is interpreted properly, the `==` operator is converted to `=` before being passed to the MySQL expression parser.

15.7.4.6. Wiki Format

When editing or defining a rule, the text entered in the `Problem Description`, `Advice`, `Recommended Action`, and `Links and Further Reading` text boxes may be formatted in Wiki format. This allows you to format text and add hyperlinks when creating or editing your own rules.

Find a brief introduction to using Wiki formatting in the following table.

Table 15.1. MySQL Enterprise Monitor: Wiki formatting

Example	Description
<code>__bold__</code>	boldface text
<code>~~italic~~</code>	italicize text
<code>\\</code>	create a line break
<code>\\\</code>	create a double line break
<code>\\\\G</code>	create a backslash
<code>*item 1</code>	create a bulleted list item
<code>#item 1</code>	create a numbered list item
<code>\</code>	use the ‘\’ to escape special characters
<code>{moreInfo:name url}</code>	create a hyperlink

So the following Wiki text:

```
Replication is a __very nice feature__ of MySQL.  Replication can be very
useful for solving problems in the following areas:
* Data Distribution
* Load Balancing
* Backup and Recovery
You can check replication status and start a slave using the following
commands: SHOW SLAVE STATUS \G; \START SLAVE;
{moreInfo:MySQL Manual: Replication
FAQ|http://dev.mysql.com/doc/refman/5.0/en/replication-faq.html}
```

Would be translated into the following HTML markup:

```
Replication is a <b>very nice feature</b> of MySQL.  Replication can be very
useful for solving problems in the following areas:
<ul>
  <li>Data distribution</li>
  <li>Load Balancing</li>
  <li>Backup and recovery</li>
</ul>You can check replication status and start a slave with the following
commands: SHOW SLAVE STATUS \G;<br/>START SLAVE;
<a href=" ../mysql-monitor-2.0/http://dev.mysql.com/doc/refman/5.0/en/replication-faq.html"
target="_blank" >MySQL Manual: Replication FAQ</a>
```

To find out more about this format go to the wikipedia.org web site.

15.7.4.7. Creating a New Rule: An Example

This section documents the steps required to create a rule. Before attempting to create a rule, please review the preceding sections of this chapter.

This example creates a rule that checks the number of rows in a table. Having 50,000 rows in this table is deemed to warrant a critical alert. Lesser numbers are assigned to informational and warning level alerts.

Begin by navigating to the [Advisors](#) tab and clicking the [manage rules](#) link. Then choose the CREATE RULE button.

Create your custom rule by following these steps:

1. Using the [Rule Name](#) text box, give the rule an appropriate name. Something such as "Excessive number of records in *table_name* table", may be appropriate.
2. From the [Advisor](#) drop down list box choose an advisor group for your rule. The [Administration](#) group of rules might be suitable but if you wish, create your own group of advisors. For instructions on doing this see [Section 15.7.4.1, "Creating Advisors"](#).
3. Enter the following expression in the **EXPRESSION** text area: '%*table_name*_num_rows% > THRESHOLD'. Replace *table_name* with the name of the table you wish to monitor. Note that the variable %*table_name*_num_rows% has not yet been defined.
4. Set the Thresholds.

- a. Set the **Critical Alert** level to 50000.
 - b. Set the **Warning Alert** level to 10000.
 - c. Set the **Info Alert** level to 5000.
5. Define your variable in the **Variable Assignment** frame.
 - a. In the **Variable** text box enter `'%table_name_num_rows%`, the variable used in the **Expression** text box
 - b. In the **Data Item** drop down list box find and select the `mysql:table:numrows` entry. (For a description of all the data items available see [The Data Collection Items Used to Create Rules](#).)
 - c. In the **Instance** text box enter `database_name.table_name`.
 6. Add appropriate entries for the **Problem Description**, the **Advice**, and the **Links** text areas. If you wish, use Wiki markup for these text areas. See [Section 15.7.4.6, “Wiki Format”](#) for more information. Note that you can also reference the `'%table_name_num_rows%` variable in these text areas. For example, you can display the current number of rows with a message such as `'table_name currently has %table_name_num_rows% rows.'`
 7. Save the rule.

Once the rule is created it needs to be scheduled against the server that contains the database table you wish to monitor. For instructions on scheduling rules see [Section 15.7.2, “Scheduling Rules”](#).

15.7.4.8. Creating a Custom Data Collection Item

[Section 15.7.4.7, “Creating a New Rule: An Example”](#) shows how to create a custom rule and [The Data Collection Items Used to Create Rules](#) shows the data items that can be used in rule creation. However, in some circumstances you may want to create a rule that uses a custom data collection item.

This section describes how to create a custom data collection item. The steps are as follows:

1. Create an XML file to define how the data is collected.
2. Point the agent configuration file to this XML file.
3. Restart the agent.

15.7.4.8.1. Creating and Using a Custom Data Item XML File

As an example, this section shows how to create a data item for monitoring the amount of free InnoDB tablespace. The format and content of the XML file that defines the data to be collected is as follows:

```
<?xml version="1.0" encoding="utf-8"?>
<classes>
  <class>
    <classname>innodb_min_free</classname>
    <namespace>mysql</namespace>
    <query><![CDATA[SELECT MIN(substring_index(substring_index(table_comment, " ", 3), " ", -1)/1024/1024)
      as Free FROM INFORMATION_SCHEMA.TABLES WHERE engine = 'InnoDB']]></query>
  </class>
</classes>
```

Save this file as:

- Windows – `C:\Program Files\MySQL\Enterprise\Agent\share\mysql-proxy\items\innodb_min_free.xml`
- Unix – `/opt/mysql/enterprise/agent/share/mysql-proxy/items/innodb_min_free.xml`
- Mac OS X – `/Applications/mysql/enterprise/agent/share/mysql-proxy/items/innodb_min_free.xml`

After saving this file, you must point your `mysql-monitor-agent.ini` file to it. (For the location of this file on your operating system see [Section 15.3.3.6.1, “MySQL Enterprise Monitor Agent \(mysql-monitor-agent.ini\) Configuration”](#).) Find the `[mysql-proxy]` section and add the file name `innodb_min_free.xml` to the `item-files` parameter using a semi-colon as a separator. For example:

```
[mysql-proxy]
...
item-files = items-mysql-monitor.xml,innodb_min_free.xml
...
```

For this change to take effect you must restart the agent. To do this see:

- Windows – [Section 15.3.3.5.1, “Starting/Stopping the Agent on Windows”](#)
- Unix – [Section 15.3.3.5.3, “Starting/Stopping the Agent on Unix”](#)
- Mac OS X – [Section 15.3.3.5.2, “Starting/Stopping the Agent on Mac OS X”](#)

Once the agent has restarted, you will find the new data item in the [Data Item](#) drop down list box on the [Rule Definition](#) page. Its fully qualified name is `mysql:table:innodb_min_free`.

15.7.5. Disabling and Uncheduling Rules

In some circumstances you may no longer wish to apply a rule against a specific server or group of servers and in other circumstances you may want to suspend a rule for a short length of time. With this in mind, it is possible to disable or unschedule a rule.

To disable or unschedule an advisor choose the [Current Schedule](#) screen of the [Advisors](#) tab.

Rules may be disabled or unscheduled using the buttons on the upper or lower left of the screen. You may also change a rule by clicking the [enabled](#) or [unschedule](#) hyperlink to the right of a rule. The buttons are particularly useful when you are altering more than one rule.

To no longer run a rule against a specific server, expand the advisor group and the specific rule by clicking the + button. You may then click the UNSCHEDULE button. When the dialog window opens, choose the UNSCHEDULE button and that rule will no longer be applied. If you wish to back out of the operation choose CANCEL. If, at a later date, you wish to institute this rule again, you may do so from the [Add to Schedule](#) page.

If you want to suspend a rule temporarily, use the DISABLE button and follow the same process you would for uncheduling. Once a rule is disabled the link under the status column changes to red and reads [disabled](#). When a rule is disabled, data is no longer collected for that rule. A disabled rule is easily re-enabled by clicking the [disabled](#) link or by using the ENABLE button.

Multiple rules may be altered for one or more servers by selecting the appropriate checkbox and then clicking the UNSCHEDULE, ENABLE, or DISABLE button.

Note

Rules associated with the heat chart cannot be disabled or unscheduled as they are required by MySQL Enterprise Monitor.

15.7.6. Advisor Blackout Periods

Database servers require regular maintenance and during these periods you may wish to stop Monitor Agents from reporting their findings. During a blackout period rules are not evaluated and notifications are put on hold but Monitor Agents continue to collect data. In this respect blacked-out rules differ from disabled rules; data continues to be collected and stored in the repository.

Blackout periods are enabled by entering the following URL into the address bar of your browser, substituting the appropriate host name, port and server name:

```
http://localhost:18080/rest?command=blackout »
&server_name=SuSE:3306&blackout_state=true
```

If you are unsure of the host name and port to use, check the [configuration_report.txt](#) file. Be sure to specify the correct port for the Tomcat server. Specify the server you wish to blackout using the name that appears in the Server Tree, being sure to include a colon and port number as shown in the preceding example.

An HTTP authentication dialog box requesting your Dashboard user name and password will open. Specify the administrator's credentials. The default user name is `admin`; use the password you specified when you initially logged in to the Dashboard.

You can also blackout a server group by entering the following URL into the address bar of your browser, substituting the appropriate host name, and server group name:

```
http://localhost:18080/rest?command=blackout »
&group_name=Finance&blackout_state=true
```

When the HTTP authentication dialog box opens, enter the administrator's credentials.

You can confirm that a server is blacked out by looking at the server name in the Dashboard; the name of a blacked out server is greyed.

To reactivate the blacked-out server or server group, use the appropriate URL and query string, changing the `blackout_state=true` name/value pair to `blackout_state=false`. Again, this must be done by a user with administrative privileges.

Note

Restarting MySQL Enterprise Monitor will **not** reactivate a blacked out server.

15.7.6.1. Scripting Blackouts

Rather than opening your web browser and blacking out a server by typing entries into the address bar, you can write a script to achieve the same effect. This section documents a sample blackout script that can be run from the command line.

Create the following file and save it as `blackout.pl`.

```
#!/usr/bin/perl
use LWP 5.64;
# USAGE: blackout.pl servicemanager:18080 admin password servername:3306 true
# $ARGV[0] = management server hostname:port
# $ARGV[1] = management server username
# $ARGV[2] = management server password
# $ARGV[3] = mysqld managed instance server name and port
# $ARGV[4] = blackout state (true/false)
my $browser = LWP::UserAgent->new;
$browser->credentials(
    $ARGV[0],
    ' ',
    $ARGV[1],
    $ARGV[2]
);
my $url = URI->new('http://'.$ARGV[0].'/rest');
$url->query_form( # And here the form data pairs:
    'command' => 'blackout',
    'server_name' => $ARGV[3],
    'blackout_state' => $ARGV[4]
);
my $response = $browser->post( $url );
if (!$response->is_success) {
    die $response->status_line . "\n";
}
```

Note

Windows users can omit the shebang line.

On Unix systems use the `chmod +x blackout.pl` command to make the file executable.

At the command line enter `blackout.pl servicemanager:18080 admin password servername:3306 true`.

If you are unsure of the host name and port to use, check the `configuration_report.txt` file. Be sure to specify the correct port for the Tomcat server. Specify the server you wish to blackout using the name that appears in the Server Tree, being sure to include a colon and port number as shown in the preceding example. Make sure that the user you specify is a "manager". Specifying a user with "dba" rights only will not black out a server and no error will be displayed.

You can confirm that a server is blacked out by looking at the server name in the Dashboard; the name of a blacked out server is greyed. To end the blackout, run the same script, changing the final argument to `false`.

Note

Restarting MySQL Enterprise Monitor will **not** reactivate a blacked out server.

15.8. The Events Page

Note

MySQL Enterprise subscription, MySQL Enterprise Monitor, MySQL Replication Monitor, and MySQL Query Analyzer are only available to commercial customers. To learn more, see: <http://www.mysql.com/products/enterprise/features.html>.

Once an advisor has been scheduled, it will run at set intervals. If it finds nothing of interest no alerts or emails will be created.

When alerts are triggered, they appear on the [Events](#) screen. Alerts also appear on the [Monitor](#) screen in order of severity. The notification group or groups associated with a specific rule receive email notification when an alert is triggered. For more information about creating notification groups see [Section 15.6.5, “Manage Notification Groups”](#).

To view open events, click on the [Events](#) tab. The tree-view on the left determines which server or server group these events belong to. Open events are shown in tabular format.

Figure 15.44. MySQL Enterprise Dashboard: Events screen

Severity	From	To	Advisors	Rules
All			All Categories	All
Status	Limit			
All	20	filter	reset	

<input type="checkbox"/>	Severity	Server	Advisor	Rule	Time	Status	
<input type="checkbox"/>		susieQ:3306	Heat Chart	CPU I/O Usage Excessive	2/22/2007 12:51 PM	Open	close
<input type="checkbox"/>		susieQ:3306	Heat Chart	CPU Usage Excessive	2/22/2007 12:35 PM	Open	close
<input type="checkbox"/>		susieQ:3306	Heat Chart	RAM Usage Excessive	2/22/2007 11:35 AM	Open	close
<input type="checkbox"/>		susieQ:3306	Heat Chart	MySQL Agent Not Reachable	2/22/2007 7:01 AM	Open	close
<input type="checkbox"/>		susieQ:3306	Heat Chart	Table Scans Excessive	2/21/2007 8:24 PM	Open	close
<input type="checkbox"/>		susieQ:3306	Security	Users Can View All Databases On MySQL Server	2/21/2007 8:20 PM	Open	close
<input type="checkbox"/>		susieQ:3306	Security	Server Includes A Root User Account	2/21/2007 8:20 PM	Open	close
<input type="checkbox"/>		susieQ:3306	Security	Server Has Anonymous Accounts	2/21/2007 8:20 PM	Open	close

The event table has the following columns:

- **SEVERITY** – An icon indicating the severity of the alert
- **SERVER** – The name of the server the alert applies to
- **ADVISOR** – The category of the advisor
- **RULE** – A short description of the rule that has been violated
- **TIME** – The approximate time the event occurred
- **STATUS** – The status of the event
- **UNNAMED COLUMN** – Provides a link to the [Close](#) dialog box

By default, all events are shown but the list of events can be filtered using the form displayed above the event list. The options include filtering by:

- Severity
- Date
- Advisor group
- Specific rule
- Status

Choose the options you are interested in and click the **FILTER** button to refresh the display. You may limit the number of items that appear on a page by choosing a different value from the **LIMIT** drop down listbox.

The drop down list box showing severity has the options: [All](#), [Alerts](#), [Critical](#), [Warning](#), [Info](#), [Success](#), and [Unknown](#). Selecting the option [All](#) shows all alerts and also those rules that have run successfully. A successful rule is one that has not been violated and is indicated by a star icon. [Alerts](#) shows only those rules that have been violated.

Columns are sorted by clicking on the individual column headings. The alerts shown in [Figure 15.44, “MySQL Enterprise Dashboard: Events screen”](#), are sorted by decreasing severity. An octagonal red icon indicates a critical alert, a triangular yellow icon a

warning, and a conversation bubble an informational alert. A star beside an event indicates that the rule has run successfully and no alert created. A question mark icon indicates that the status of the rule is unknown.

The server shown in [Figure 15.44, “MySQL Enterprise Dashboard: Events screen”](#), is filtered for **All**. Typically, when filtering by severity you would choose **Alerts** and, if you see a **Critical**, **Warning**, or **Info** alert, use the **All** filter to see when the rule last ran successfully. This may assist in determining the cause of the alert.

Besides filtering for severity, you can also choose to filter for a specific time period using the **From** and **To** text boxes. You also have the choice of filtering by specific rules or categories of rules. The **Status** drop-down list box let's you choose **All**, **Open**, or **Closed** events. To avoid excessive scrolling, you can also limit the number of events that show on a specific page.

For more information about an alert, click on the rule name. A pop-up window will appear showing a description of the alert and the exact time of occurrence. This pop-up windows provides links to useful resources and advice for resolution. You can also view the exact expression that generated the event.

15.8.1. Closing an Event

After determining what action to take, events should be closed.

To resolve an individual alert click the **close** link in the **OPERATIONS/NOTES** column. Document the resolution using the **Notes** text area and choose the **CLOSE EVENT(S)** button.

To close a number of alerts simultaneously, select the checkbox beside the alerts you wish to close and then click the **CLOSE** button to the lower or upper left side of the screen.

Once an event has been closed it appears on the **Events** screen showing a **resolution notes** link. Click this link to review the notes. Events that have been closed are saved in the Repository. If you wish to view closed events filter the display by choosing **Closed** from the **STATUS** drop-down box.

15.9. The Graphs Page

Note

MySQL Enterprise subscription, MySQL Enterprise Monitor, MySQL Replication Monitor, and MySQL Query Analyzer are only available to commercial customers. To learn more, see: <http://www.mysql.com/products/enterprise/features.html>.

Navigate to the **Graphs** page by choosing the **GRAPHS** tab.

By default four graphs are displayed on the **Monitor** page. These graphs present information about the currently selected server or server group, showing the hit ratios, CPU utilization, connections, and database activity. Color coding helps distinguish different aspects of each graph.

From the **Monitor** page you can make permanent or temporary changes to the way a graph is displayed. For example, you can choose to display the last hour's activity or you can choose to view a specific period of time.

Persistent changes to the way the graphs display are only made from the **Monitor** page. You can set the size of the thumbnails and the full-sized graphs and you can also set their refresh interval. For more information, see [Section 15.5.2, “The Server Graphs and Critical Events”](#). As with the **Monitor** page, the data shown in the graphs is determined by the server or group of servers selected in the server tree.

The **Graphs** page shows all the available graphs and provides the capability of adjusting the scale of the graphs, allowing a more or less detailed view as the situation requires. To ensure that you have the latest versions of the various graphs click on the **CHECK FOR UPDATES** link on the top left of this page.

15.9.1. Displaying Graphs

The total number of graphs varies depending upon your subscription level. The four graphs that appear by default on the **Monitor** page are:

- Hit Ratios
- Database Activity
- Connections
- CPU Utilization

When the [Graphs](#) page is first opened, no graphs are visible. To view a graph click the + button on the left or, to view all graphs, use the EXPAND ALL button.

The larger size of graphs is the primary reason for viewing graphs on the [Graphs](#) page rather than on the [Monitor](#) page. Additionally, you can only show a maximum of six graphs on the [Monitor](#) page; the remaining graphs can only be viewed from the [Graphs](#) page.

15.9.2. Setting an Interval

Change the interval for a graph by choosing values from the **HOURS** and **MINUTES** drop-down list boxes. If necessary adjust the width and height of the graph and then click the UPDATE button. The changes to the time span apply to all the graphs on the [Graphs](#) page but have *no* effect on the graphs on the [Monitor](#) page.

To change the graphs both here and on the [Monitor](#) page use the [configure graphs](#) link on the top right. This opens a dialog box for setting the default interval for the x-axis. Save any changes that you have made and the values chosen will be the defaults whenever you log in. You can also change the defaults from the [Monitor](#) page as described in [Section 15.5.2, “The Server Graphs and Critical Events”](#); defaults for other users will be unchanged.

Use the RESET button to restore the default value for the interval. Doing this will also reset the default size of the graphs.

15.9.3. Setting a Time Span

Setting a graph to display a time span gives you a historical perspective on server activity. You may want to know what was happening at a specific point in time or you may wish to look at an extended period in order to determine patterns or trends. Changing the time span gives you the flexibility to do this.

In the **TIME DISPLAY** drop-down list box select the [From/To](#) option. Choosing this option updates the display to include **TO** and **FROM** text boxes.

Set the date you wish to start viewing from by manually entering the date in year, month, and day format (2007-03-14). However, it is much easier to click the calendar icon and choose a date from the drop-down calendar. Enter a terminating date in the same way. If you wish, you may also choose the specific time of day by selecting the hour and minute.

If necessary adjust the width and height of the graph and then click the UPDATE button. The changes to the time span apply to all the graphs on the [Graphs](#) page but have *no* effect on the graphs on the [Monitor](#) page. You cannot change the time span of the graphs that appear on the [Monitor](#) page. Changes apply only to the current user; defaults for other users will be unchanged.

Use the RESET button to cancel your changes.

15.10. The Query Analyzer Page

Note

MySQL Enterprise subscription, MySQL Enterprise Monitor, MySQL Replication Monitor, and MySQL Query Analyzer are only available to commercial customers. To learn more, see: <http://www.mysql.com/products/enterprise/features.html>.

Query Analyzer enables you to monitor the statements being executed on a monitored server and retrieve information about the query, number of executions and the execution times of each query. Queries are normalized, so that the unique data defined within each query has been removed. By removing the data specific elements of the queries, the generic queries can be counted and identified more easily.

Important

After this release is pronounced Generally Available, the MySQL Agent will be ready for use in your production systems; however, we strongly recommend reading these guidelines before using/deploying MySQL Query Analyzer.

MySQL Query Analyzer is designed to gather query performance information from a variety of sources. In this initial release, Query Analyzer uses a new agent plug-in to proxy your queries and collect performance data that is then transmitted to the Enterprise Monitor. This is a new role for the Agent: it is no longer just monitoring, it is now **optionally** between your MySQL client application and the mysql server.

Depending upon your system load, it is possible to overload the proxy or have the proxy/agent consume system resources needed by mysql itself. In particular, the memory needed by the MySQL Agent for basic monitoring is fairly small and consistent and depends on the number of rules you have enabled. However, when the Query Analyzer is enabled, the Agent can use significantly more memory to monitor and analyze whatever queries you direct through it. In this case, the amount of memory used depends on the number of unique normalized queries, example queries and example [EXPLAINs](#) being processed plus the network bandwidth required to send this query performance data to the

Service Manager. In general, the amount of memory used for the Query Analyzer is well-bounded, but under heavy load or, in some cases under older versions of linux, RAM usage by Query Analyzer may be too high for your environment and load.

Therefore we advise you to use this initial release of Query Analyzer extensively in development, test and stage environments under load for an extended period of time before considering usage in a production environment. For all deployments:

1. We recommend carefully monitoring the Agent's resource consumption using the new graph **MEMORY USAGE - AGENT** graphs available on the **GRAPH** tab. You can also add an SMTP or SNMP notification to the new Heat Chart rule **MYSQL AGENT MEMORY USAGE EXCESSIVE**.
2. If the amount of memory consumed is too high, consider sampling queries during non-peak hours or monitoring only a subset of queries on this system.

If you experience any problems with Query Analyzer, we're interested in working with you closely and quickly to resolve them. Please open a Support issue right away. We're already working hard on optimizing Agent/proxy RAM usage and are planning a series of rapid releases to quickly distribute these and other improvements to you.

Query Analyzer works by intercepting the SQL statements that your MySQL client application sends to the MySQL server. Instead of connecting direct to the MySQL Server, queries are routed through the MySQL Enterprise Monitor Agent, the agent/proxy forwards the queries on to the server and sends the replies back to the client application as normal. In addition to forwarding the queries, the agent/proxy will also normalize the queries and then supply the execution information about each query to the monitor. The forwarding functionality is provided by the same module that supports the MySQL Proxy application. For information on MySQL Proxy, see [Section 14.6, "MySQL Proxy"](#).

Important

The MySQL Proxy component, and Query Analyzer, require that clients connecting through MySQL Enterprise Monitor Agent are using MySQL 5.0 or later. Clients that use the library provided with MySQL 4.1 or earlier will not work with MySQL Enterprise Monitor Agent.

Once your MySQL client application has been configured to communicate via the MySQL Enterprise Monitor Agent, queries will be monitored and the simplified queries, without the query specific data, will be sent to the MySQL Enterprise Monitor Agent.

There are a number of different ways that you can enable Query Analysis. For more information on the different options, see [Section 15.10.1, "Enabling Query Analyzer"](#).

To analyse the queries captured by the agent/proxy, change to the [Query Analyzer](#) page. You can see an example of the table on that page in the figure below.

Figure 15.45. MySQL Enterprise Dashboard: Query Analyzer

Query	Database	Exec Count	Exec Time (hh:mm:ss.ms)			Rows			Bytes			First Seen
			Total	r Max	Avg	Total	Max	Avg	Total	Max	Avg

The main Query Analyzer table provides the summary information for all of the queries executed via the agent/proxy. The table will track all the queries submitted to the server via the agent/proxy. The table will show a maximum of 20 rows, and you can page through the list of queries by using the page numbers, or the **NEXT**, **PREVIOUS**, **FIRST**, and **LAST** buttons. To filter the list of queries that are displayed, or to change the number of queries, see [Section 15.10.3, “Filtering Query Analyzer Data”](#).

Each row within the table provides the statistical information for one normalized query statement. If you have configured multiple agent/proxies to accept and forward queries to different servers, then you can expand the server view. The summary information displayed is different depending on whether you have selected a server group or an individual server.

If you have selected a server group, then the information displayed is aggregated from across the entire group. The same query executed on multiple servers will show average, total and minimum/maximum information for that query across all the servers. If you select an individual server, then only queries executed on that server are included within the table.

For each row, the following columns are populated according to the selected filtering options. For example, if the filter have been configured to show queries within the last 30 minutes (**INTERVAL**), then only queries executed during that time will be displayed, and the corresponding statistics, such as execution times, rows returned and bytes returned will be according to that 30 minute timespan.

- **QUERY** — the normalized version of the query. Normalization removes the query-specific data so that different queries with different data parameters are identified as the same basic query.

The information is shown as one query per row. Each query row is expandable, and can be expanded to show the execution times for individual servers for that query.

- **DATABASE** — the name of the database used in the query. The column may be blank if the database name has not been explicitly stated within the query.
- **EXEC COUNT** — the number of times that the query has been executed.
- **EXEC TIME** — the execution time for all the matching queries. This is the time, for every invocation of the corresponding query, as calculated by comparing the time when the query was submitted and when the results were returned by the server. Times are expressed in HH:MM::SS.MS (hours, minutes, seconds, and milliseconds).

The **EXECUTION** column is further subdivided into the following columns:

- **COUNT** — the total number of executions.
- **TOTAL** — the cumulative execution time for all the executions of this query.
- **MAX** — the maximum execution time for an execution of this query.
- **AVG** — the average execution time for the execution of this query.

When looking at the information provided in this query, you should consider comparing the average and maximum execution times to see if there was a problem on a specific server or during a specific time period when the query took place, as this may indicate an issue that needs to be investigated. For more information, see [Section 15.10.4, “Using Query Analyzer Data”](#).

- **ROWS** — the rows returned by the query. The column is sub-divided into the following columns:
 - **TOTAL** — the sum total number of rows returned by all executions of the query.
 - **MAX** — the maximum number of rows returned by a single execution of the query.
 - **AVG** — the average number of rows returned by all executions of the query.
- **BYTES** — the number of bytes returned by each query. The column is sub-divided into the following columns:
 - **TOTAL** — the sum total bytes returned by all executions of the query.
 - **MAX** — the maximum number of bytes returned by a single execution of the query.
 - **AVG** — the average number of bytes returned by all executions of the query.
- **FIRST SEEN** — the first time the query was seen within the given filter conditions.

You can sort the list of queries by clicking on the column name. The direction of the sort (highest to lowest, or lowest to highest) is indicated by a triangle next to the currently selected column. The default is to sort the list of queries by the Total Execution time.

15.10.1. Enabling Query Analyzer

There are three different ways of enabling query analyzer:

- Change your MySQL client application to talk to the Proxy port you configured during installation. This requires changing your MySQL client application code, and may require that you stop and restart your MySQL client application, but does not require any changes to your MySQL server. For more information, see [Section 15.10.1.1, “Enabling Query Analyzer by Changing the MySQL Client Application”](#).
- Change your MySQL server to listen on a different port, and configure the Agent/proxy to listen on the original MySQL server port. This does not require any changes to your MySQL client application, but will require shutting down and restarting your MySQL server, which may affect your cache and performance. For more information, see [Section 15.10.1.2, “Enabling Query Analyzer by Changing MySQL Server”](#).
- Use IP tables to redirect the network packets to the agent/proxy.

Important

After this release is pronounced Generally Available, the MySQL Agent/proxy will be ready for use in your production systems; however, we strongly recommend reading these guidelines before using/deploying MySQL Query Analyzer.

MySQL Query Analyzer is designed to gather query performance information from a variety of sources. In this initial release, Query Analyzer uses a new agent plug-in to proxy your queries and collect performance data that is then transmitted to the Enterprise Monitor. This is a new role for the Agent: it is no longer just monitoring, it is now *optionally* between your MySQL client application and the mysql server.

Depending upon your system load, it is possible to overload the proxy or have the proxy/agent consume system resources needed by mysql itself. In particular, the memory needed by the MySQL Agent for basic monitoring is fairly small and consistent and depends on the number of rules you have enabled. However, when the Query Analyzer is enabled, the Agent can use significantly more memory to monitor and analyze whatever queries you direct through it. In this case, the amount of memory used depends on the number of unique normalized queries, example queries and example [EXPLAINs](#) being processed plus the network bandwidth required to send this query performance data to the Service Manager. In general, the amount of memory used for the Query Analyzer is well-bounded, but under heavy load or, in some cases under older versions of linux, RAM usage by Query Analyzer may be too high for your environment and load.

Therefore we advise you to use this initial release of Query Analyzer extensively in development, test and stage environments under load for an extended period of time before considering usage in a production environment. For all deployments:

1. We recommend carefully monitoring the Agent's resource consumption using the new graph **MEMORY USAGE - AGENT** graphs available on the **GRAPH** tab. You can also add an SMTP or SNMP notification to the new Heat Chart rule **MYSQL AGENT MEMORY USAGE EXCESSIVE**.
2. If the amount of memory consumed is too high, consider sampling queries during non-peak hours or monitoring only a subset of queries on this system.

If you experience any problems with Query Analyzer, we're interested in working with you closely and quickly to resolve them. Please open a Support issue right away. We're already working hard on optimizing Agent/proxy RAM usage and are planning a series of rapid releases to quickly distribute these and other improvements to you.

Note that you must have enabled Query Analyzer within the agent/proxy during installation. If you did not enable Query Analyzer during the installation of the agent/proxy, check the following elements within the main `mysql-monitor-agent.ini` configuration file:

- Add the `proxy` plugin to the `plugins` parameter:

```
plugins=proxy,agent
```

- Ensure that the `quan.lua` items file is enabled in the `agent-item-files` configuration property:

```
agent-item-files = share/mysql-proxy/items/quan.lua,share/mysql-proxy/items/items-mysql-monitor.xml
```

- Check and set the `proxy-address`, `proxy-backend-addresses`, and `proxy-lua-script` settings are configured:

```
proxy-address=:4040
proxy-backend-addresses = 127.0.0.1:3306
```

```
proxy-lua-script = share/mysql-proxy/luan.lua
```

For more information on these configuration options, see [Section 15.3.3.6.1, “MySQL Enterprise Monitor Agent \(mysql-monitor-agent.ini\) Configuration”](#).

Note

The Query Analyzer functionality may show as being enabled on a server, even though the modules within MySQL Enterprise Monitor Agent may not have been enabled.

You may also need to make some additional changes to the security configuration on your server to ensure that queries are correctly reported to MySQL Enterprise Service Manager:

- You must ensure that each user configured within your MySQL client application that connects through the agent/proxy and is required to report query analyzer information is allowed to connect to the server from the host on which the agent/proxy is running. When the user connects to the agent/proxy, and the agent/proxy connects to the server the host of the agent/proxy will be used as the identifying client host name during the connection.

To update your user credentials, you need to use the [GRANT](#) statement. For example:

```
mysql> GRANT SELECT,UPDATE,INSERT on database.* to 'user'@'localhost' IDENTIFIED BY 'password';
```

- The MySQL client application user must have [SELECT](#) privileges on the `mysql.inventory` table. This table contains the server UUID and is required to report the query analyzer data to the MySQL Enterprise Service Manager. To enable this, use the [GRANT](#) option:

```
mysql> GRANT SELECT on mysql.inventory to 'user'@'localhost' IDENTIFIED BY 'password';
```

15.10.1.1. Enabling Query Analyzer by Changing the MySQL Client Application

Generally, changing your MySQL client application is the easiest and recommended method. For example, given a typical structure like the one shown in the figure below, the client application would need to be modified so that it no longer communicated directly with the MySQL server, but to the agent/proxy.

Figure 15.46. MySQL Enterprise Dashboard: Standard agent/monitor topology

You can see an example of the structure when communicating via the agent/proxy below.

Figure 15.47. MySQL Enterprise Dashboard: Query Analyzer agent/monitor topology

To enable query analyzer within your MySQL client application:

1. Make sure that the MySQL Enterprise Service Manager and your MySQL Enterprise Monitor Agent are configured and running.
2. Confirm the configuration of your agent by examining the contents of the `etc/mysql-monitor-agent.ini` file within your installed Agent directory.

Queries will be sent to the host specified in the `proxy-backend-addresses` parameter, and the agent will listen for connections to be redirected to the server on the host name and port configured in the `proxy-address` parameter.

3. Now modify your MySQL client application to communicate with the address specified in the `proxy-address` parameter.

Alternatively, if you do not want to modify your application directly, you can use iptables or firewall rules to redirect queries from the original host/port combination to the agent's port.

Because connections to the MySQL server will be coming from the agent/proxy, not the original host, the user credentials used must be have a suitable `GRANT` statement for connections from `localhost`, or the host on which the agent/proxy is executing. The user name and password information will be passed on directly through the agent/proxy from the client to the server.

4. Confirm that your MySQL client application still operates normally. There should be no difference between communicating directly with the MySQL server and communicating via the agent/proxy.

Note

If you are using the `mysql` client to connect to the agent/proxy and your backend servers, make sure that you are communicating with the proxy over the right port. By default, if you specify `localhost` as the host name, then `mysql` will connect using the local Unix domain socket, rather than the TCP/IP socket.

You can enforce `mysql` to use the right port either by explicitly requesting the protocol type, or by using the IP address rather than `localhost`. For example, both of these command lines will start the client using the right protocol:

```
shell> mysql --port=4040 --protocol=tcp
shell> mysql --port=4040 --host=127.0.0.1
```

Note

It is recommended that you use one agent/proxy per MySQL server instance. The agent/proxy is not able to forward queries to multiple MySQL server backends.

15.10.1.2. Enabling Query Analyzer by Changing MySQL Server

When enabling Query Analyzer by changing the MySQL Server, you need to shutdown your server, edit the MySQL configuration file, and then restart MySQL. You will also need to change your Agent/proxy configuration so that the Agent/proxy is listening on the original MySQL TCP/IP port. To use this method:

1. Edit the `/etc/my.cnf` or other MySQL configuration file and change or add the `port` setting from it's current value (default 3306), to another value. For example:

```
port = 3307
```

2. Shutdown your MySQL Server.
3. Startup your MySQL Server and confirm that is running.
4. Edit your MySQL Enterprise Monitor Agent configuration so that the agent/proxy is listening for connections on the original MySQL port:

```
proxy-address=:3306  
proxy-backend-addresses = 127.0.0.1:3307
```

5. Stop and restart MySQL Enterprise Monitor Agent.

You should now be able to connect to your MySQL server through the MySQL Enterprise Monitor Agent by connecting on the original port:

```
shell> mysql --host=127.0.0.1
```

15.10.2. Getting Detailed Query Information

If you click on an individual query, a pop-up window will provide more detailed information about the individual query. You can see an example of this in the figure below. The available tabs within this window will depend on whether you have configured the more detailed query information. By default, you will always be provided the Summary Details page. If enabled, you may also view Example Details, which provide more detailed data about a specific query, including the data and parameters submitted. In addition, you may also enable Example Explain, which provides you with the ability to remotely execute an [EXPLAIN](#) statement with the specified query and view the resulting information.

- The **Canonical Query** tab:

Figure 15.48. MySQL Enterprise Dashboard: Canonical Query Tab for a Query

Canonical Query
Example Query
Explain Query
908 B
165 B
1

Overview of information collected and aggregated for queries of this form.

Alias
None specified.

Canonical Form
[truncated](#) | [full](#) | [formatted](#)

```
SELECT
  COUNT( message_id ) AS cnt,
  DATE_FORMAT(FROM_UNIXTIME(datetime), ?) AS
  fmtdate
, process_mode, process_type
FROM
  logs_amavis
WHERE
  datetime >= ? AND datetime <= ?
GROUP BY
  process_mode ASC, process_type ASC, fmtdate
ASC
```

Execution Time Statistics

Max Time	Min Time	Avg Time	Total Time	Standard Deviation
11.123	0.274	2.140	12.838	

Row Statistics

Max Rows	Min Rows	Avg Rows	Total Rows	Standard Deviation	Total Size	Max Size
408	37	129	776	82	24.21 KB	12.8 KB

Number of Executions
6

Time Span
From Oct 27, 2008 10:16:07 AM to Oct 27, 2008 10:46:07 AM.

[expand »](#)

In addition to the summary information given in the table, you will get detailed execution statistics, including the minimum time, maximum time, average time, total time and the standard deviation. The standard deviation will enable you to determine whether a particular invocation of a query is outside the normal distribution of times for the given query.

Row statistics provide more detailed contents on the maximum, minimum, average, total, and standard deviation for the number of rows returned by the query, and the total size and maximum size of the data returned. The time period for the total and average figures is shown under the Summary Time Span.

The detailed view for a query also provides three different views of the query. The [truncated](#) version is a shortened version of the query. The [full](#) version of the query is the entire query statement. Normalization removes the constants from the indi-

vidual queries so that queries following the same logical structure are identified as the same basic query.

To close the query detail window, click the HIDE button.

To simplify the identification of a given query, you can create a query alias. The alias will be used in place of the normalized query text within the Query Analyzer table. To create an alias for a query, click the CREATE ALIAS link against the query. The maximum length for a query alias is 255 characters.

- The **Example Query** tab:

Figure 15.49. MySQL Enterprise Dashboard: Example Query Tab for a Query

Canonical Query	Example Query	Explain Query	908 B	165 B	134.
<p>The query with the longest execution time during the Time Span (usually the slowest but not always).</p> <p>Sampled Query truncated full formatted</p> <hr/> <pre> SELECT COUNT(message_id) AS cnt, date_format(from_unixtime(datetime), "%Y-%m-%d") AS fmtdate , process_mode, process_type FROM logs_amavis WHERE datetime >= 1224498843 and datetime <= 1225080000 GROUP BY process_mode ASC, process_type ASC, fmtdate ASC </pre> <hr/> <p>Execution Time 11,122 ms</p> <p>Date Oct 27, 2008 10:35:01 AM</p> <p>User root</p> <p>Thread ID 298107</p> <p>From Host 192.168.0.2:22717</p> <p>To Host 127.0.0.1:3306</p> <p>Comments</p> <p style="text-align: right;"><input type="button" value="hide"/></p> <p style="text-align: right;">expand »</p>					

The Example Details tab provides detailed information about the most expensive query executed, as determined by the execution time.

In addition to the full query, with data, that was executed, the tab shows the execution time, data, user, thread ID, client host and execution host for the given query.

- The **Explain Query** tab:

Figure 15.50. MySQL Enterprise Dashboard: Explain Query Tab for a Query

id	select_type	table	type	possible_keys	key	key_len	ref	rows	extra
1	SIMPLE	logs_amavis	index	null	mdatatimepmt	47	null	276087	Using where; Using index; Using temporary; Using filesort

The Example Explain tab enables you to view the output from running the query with the `EXPLAIN` prefix. For more information, see [Section 12.3.2, “EXPLAIN Syntax”](#).

15.10.3. Filtering Query Analyzer Data

You can filter the queries shown within the Query Analyzer table by using the form at the top of the table. The different fields of the form are used to specify the parameters for the filter process. Once you have specified a filter, all the queries and related statistics shown within the Query Analyzer table are displayed in relation to the filter settings. For example, by default, the filter settings show the queries for the last 30 minutes. All the statistics shown are relative to the last 30 minutes, including average, maximum and execution counts.

The filter fields are:

- **SEARCH TYPE** and **QUERY SEARCH** support text searching of the normalized query. For the search type you can specify either a basic text match, or a regular expression match. In addition to the basic text match, you can also search for a query that does not contain a particular string. For regular expression searches, you can specify whether the regular expression should match, or not match (negative regexp) the queries. Regular expressions are parsed using the standard MySQL `REGEXP ()` function. For more information, see [Section 11.4.2, “Regular Expressions”](#).

Note

The search is performed against the canonical version of the query. You cannot search against specific text or values within the parameters of the query itself.

- **DATABASE** — limit the queries to those executed within a specific database. The database match is performed using the `LIKE` match from the MySQL database, hence you can use the `%` and `_` characters to multiple and single character matches. For more information, see [Section 3.3.4.7, “Pattern Matching”](#).
- The **TIME DISPLAY** menu selects whether the time selection for filtering should be based on the time **INTERVAL** (only queries recorded within the displayed time period are shown, using the **HOURS** and **MINUTES** popup), or whether the selection should be based on a time period (**FROM/TO**), where you can select the time range to be displayed.

Using the **INTERVAL** mode shows queries within the given time period from the point the graph was updated. For example, if you select 30 minutes, then the queries shown were captured within the last 30 minutes. If you updated the display at 14:00, then the queries displayed would have been captured between 13:30 and 14:00. Using interval mode limits the timespan for the filter selection to a maximum of 23 hours and 59 minutes.

Using the **FROM/TO** mode enables you to show queries between specific dates and times. Using this mode you can show only the queries received during a specific time span, and you can display the query history for a much longer time period, for as long as you have been recording query analysis information.

- The **VIEW** selection determines whether the information should be returned on a group basis, where an aggregate of the same query executed on all monitored servers is shown, or on a **SERVER** basis, where queries are summarized by individual server. If the latter option has been selected, the table includes an additional column showing the server.

- **QUERY TYPE** lets you select the type of query on which to filter queries. Selecting **ALL** will show all queries. Additional query types you can select include **SELECT**, **INSERT**, **UPDATE** and other main SQL query types.
- **LIMIT** specifies the number of queries to be displayed within each page.

When you have set your filter parameters, you can update the Query Analysis display by clicking the **FILTER** button. To reset the fields to the default settings click the **RESET** button.

15.10.4. Using Query Analyzer Data

The information provided by Query Analyzer can be complex to understand and resolve into simple targets and resolutions for your MySQL client application. The information can be used in different ways to find problems in your queries or your servers, or both. Provided below are some tips on how to get the best out of the Query Analysis interface, and how to identify different queries and problems based on the information shown by the Query Analyzer system.

First, consider the information provided by individual columns by your queries. In particular, the following columns can highlight specific problems with your queries or database server:

- **Execution Count** — High execution counts, especially for a query that you expect to be executed very rarely, may indicate that your MySQL client application is either running a simple query to frequently, or may be running a query multiple times that could otherwise be cached. You should pay particular attention to queries where the execution count increases significantly in a short period of time compared to the normal execution rate.

How to find: Use the sort feature to sort the queries by execution count.

- **New queries** — new queries appearing in the Query Analyzer tab, especially if they appear after other queries have been in the display for a number of hours or days may indicate a number of issues:
- **Execution times** — long execution times, and a long max execution time compared to the average execution time may indicate a problem with a specific query and specific parameters.

How to find: Use the sort feature to sort the queries by execution count.

You can also use the filtering and sort options to get specific information about potential problem queries.

15.10.5. Troubleshooting Query Analyzer

If you are having trouble with Query Analyzer, either because the information is not being shown or the full range of queries that you expect are not appearing in the Query Analyzer page then there are a number of systems you can check.

To confirm that your system is correctly configured for Query Analysis, check the following:

- Confirm that the agent is running by checking the Agent log and the status of the server within MySQL Enterprise Service Manager
- Check the configuration of the agent. You must confirm the following:
 - The **plugins** parameter within the main configuration file, `mysql-monitor-agent.ini`, must contain the **proxy** plugin:

```
plugins=proxy,agent
```

- The **agent-item-files** parameter within the main configuration file, `mysql-monitor-agent.ini`, must specify the `share/mysql-proxy/items/quan.lua` script:

```
agent-item-files = share/mysql-proxy/items/quan.lua, »
                 share/mysql-proxy/items/items-mysql-monitor.xml
```

- The proxy configuration parameters must point to the MySQL server where you want your queries to be sent. For example, if you are running your agent on the same host as your MySQL server then you might have the following lines in your `mysql-monitor-agent.ini` file:

```
proxy-address=:4040
proxy-backend-addresses = 127.0.0.1:3306
proxy-lua-script         = share/mysql-proxy/quan.lua
```

The above configuration can mean:

- The agent/proxy will listen on the current machine, using port 4040 (`proxy-address`).
- The agent/proxy will send all queries received on to the host 127.0.0.1 on port 3306 (the standard MySQL port), as per the `proxy-backend-addresses` parameter.

You can see a sample complete configuration file (`mysql-monitor-agent.ini`), using the 127.0.0.1 as the MySQL backend server, and reporting to a MySQL Enterprise Service Manager called `monitor`:

```
[mysql-proxy]
plugins=proxy,agent
agent-mgmt-hostname = http://agent:password@monitor:18080/heartbeat
mysqld-instance-dir= etc/instances
agent-item-files = share/mysql-proxy/items/quant.lua,share/mysql-proxy/items/items-mysql-monitor.xml
proxy-address=:4040
proxy-backend-addresses = 127.0.0.1:3306
proxy-lua-script      = share/mysql-proxy/quant.lua
agent-uuid = a3113263-4993-4890-8235-cadef9617c4b
log-file = mysql-monitor-agent.log
pid-file=/opt/mysql/enterprise/agent/mysql-monitor-agent.pid
```

- Confirm that you can connect through the agent proxy to your backend MySQL server. You can do this by checking with the MySQL client. You must specify the same options as you would if you were connecting to the original server, including specifying the same user and password information:

```
shell> mysql -h 127.0.0.1 --port 4040 --user=root -p
Enter password:
Welcome to the MySQL monitor.  Commands end with ; or \g.
Your MySQL connection id is 299239
Server version: 5.0.60-log Gentoo Linux mysql-5.0.60-r1
Type 'help;' or '\h' for help. Type '\c' to clear the buffer.
mysql>
```

- Check that your MySQL client application is configured to use the configured proxy port, instead of the real MySQL port when sending queries.
- Confirm that Query Analyzer enabled for your host. For more information, see [Section 15.10.6, “Query Analyzer Settings”](#).

15.10.6. Query Analyzer Settings

There are a number of settings related to the Query Analyzer data. You can configure the query analyzer operation by using the **CONFIGURE QUERY ANALYZER** link within the **QUERY ANALYZER** tab, or through the **CONFIGURE QUERY ANALYZER** button within the **MANAGE SERVERS** tab within the **SETTINGS** tab. Both methods provide you with the same dialog:

Figure 15.51. MySQL Enterprise Dashboard: Query Analyzer Configuration

Through either solution, the configuration options that you select are applied to the individual server or server group selected within the **SERVICES** navigation panel.

There are three configuration options available through either method:

- **ENABLE QUERY ANALYZER** configures whether query analyzer should be enabled for this server or server group. If selected, query analyzer will be enabled. To disable, select the checkbox.

If Query Analyzer has been enabled, then you can additionally configure the Example Query function by selecting the **ENABLE EXAMPLE QUERY** checkbox. Enabling this option provides an additional tab when you open the **CANONICAL QUERY** window when clicking on a query.

- **ENABLE EXAMPLE QUERY** allows the Query Analyzer to display more information about individual queries. When enabled, queries and their data items (rather than the canonical form shown by default) will be provided. Enabling this option may expose the full query statements and therefore may present a security issue.

With the **EXAMPLE QUERY** option enabled, an additional tab within the query summary details is made available. For more information, see [Section 15.10.2, "Getting Detailed Query Information"](#).

If you have enabled **EXAMPLE QUERY**, then you can additionally enable **EXAMPLE EXPLAIN**. To enable this tab, select the **ENABLE EXAMPLE EXPLAIN** checkbox.

- **ENABLE EXAMPLE EXPLAIN** provides another tab when viewing a query where you can view the output from **EXPLAIN** output from MySQL for the selected query. This will show the full query and how the query was executed within the servers.

Enabling this option may add additional overhead to the execution of your server, as the server will run an **EXPLAIN** statement each time it identifies a long running query. For more information, see [Section 15.12, "MySQL Enterprise Monitor Frequently Asked Questions"](#).

To enable or disable query analyzer for an individual server, go to the **SETTINGS** page and click on the **MANAGE SERVERS** link. To configure all the properties, click the **CONFIGURE QUERY ANALYZER** link next to server you want modify.

Alternatively, for each server, the **QUERY ANALYZER** column shows the current setting, On or Off, and whether the **EXAMPLE** and **EXPLAIN** functionality is enabled. To change any setting, click on the current status to toggle between the On/Off position.

To disable or enable Query Analyzer for the selected servers, use the **DISABLE QUERY ANALYZER** or [enable query analyzer](#) buttons within the **SETTINGS** page. You must have selected one or more servers from the list of available servers before selecting these buttons.

You can use the options that you have just selected as the default for all new servers that register with MySQL Enterprise Service

Manager by using select the **MAKE THIS THE DEFAULT FOR ALL NEW SERVERS** checkbox. By default, when a new server registers with MySQL Monitor, the server is automatically configured to supply Query Analysis data. This can have impact on the performance of your monitor and agent as it increases the amount of information supplied to the MySQL Monitor.

Configuration of Query Analyzer occurs through the **CONFIGURE DEFAULTS** button from within the **QUERY ANALYZER** page.

15.11. The Replication Page

Note

MySQL Enterprise subscription, MySQL Enterprise Monitor, MySQL Replication Monitor, and MySQL Query Analyzer are only available to commercial customers. To learn more, see: <http://www.mysql.com/products/enterprise/features.html>.

Navigate to the [Replication](#) page by choosing the **REPLICATION** tab. This page provides a quick summary view of the state of your replication servers or, if you wish, you can drill down and determine specifics about any master or slave.

Note

Servers, whether masters or slaves, must be monitored in order for them to appear on this page.

Note

There will be no [Replication](#) page if your subscription level does not support this feature.

The [Replication](#) page groups all master servers with their slaves. Masters and their slaves are autodiscovered and a grouping is created. This grouping shows up on the replication page and also in the [Heat Chart](#) on the [Monitor](#) page. Scans run on a five minute interval, so depending upon the order of discovery, it can take as long as 2 polling intervals to create a complete group.

Figure 15.52. MySQL Enterprise Dashboard: Replication groups

Servers	Type	Slave IO	Slave SQL	Time Behind	Binlog
Replication 1 (5)	TREE	Running	Stopped		
local-tree-master:10001	master				master-bin.000035
local-tree-master-slave:10002	master/slave	Running	Running	00:00:00	master-slave-bin.000035
local-tree-slave3:10008	slave	Running	Running	00:00:00	
local-tree-slave2:10007	slave	Running	Running	00:00:00	
local-tree-slave:10003	slave	Running	Stopped		
Replication 4 (4)	MIXED	Running	Running		
ring1:10004	master/slave	Running	Running	00:00:00	master-bin.000030
ring2:10005	master/slave	Running	Running	00:00:00	master-bin.000030
ring2-slave:10009	slave	Running	Running	00:00:00	
ring3:10006	master/slave	Running	Running	00:00:00	master-bin.000030

Discovery events are logged to the [Replication](#) log. To view this log navigate to the [Settings](#) page and choose the **LOGS** link. View all replication-related events by clicking the **REPLICATION** link. This log can be a useful tool should you need to debug the replication topology discovery process.

Warning

The agent must be installed on the same machine as the server you are monitoring in order for discovery to work properly. Do **not** use remote monitoring.

Replication groups can be managed from the [Manage Servers](#) page in the same way as other groups. However, any slaves removed from a server group will automatically be restored to that group. It is also possible to add non-slaves to a replication group-

ing. For more information about server groupings see [Section 15.6.3.2, “Grouping Servers”](#).

15.11.1. Replication Page Details

Choose a value from the **REFRESH** drop-down list box to set the rate at which information is updated. This refresh rate applies only to the information presented on this page: It is independent of the rate set for the [Monitor](#) page.

The following columns describe replication servers and their slaves:

- Servers – Displays the group name and any master servers and slaves
- Type – Indicates the topology of a server group or in the case of individual servers, whether a server is a master, a master/slave, or a slave
- Slave IO – Reports the status of the slave IO thread
- Slave SQL – Reports the status of the slave SQL thread
- Seconds Behind – The number of seconds the slave is behind the master. This column is blank if a server is a master.
- Binlog – The binlog file name
- Binlog Pos – The current position in the binlog file
- Master Binlog – The master binlog file name
- Master Binlog Pos – The current position in the master binlog file
- Last Error – The most recent error
- Unlabeled Column – Use the **RENAME GROUP** link on the server group line to edit the server group name

Levels of indentation in the [Servers](#) column show the relationship between master servers and their slaves. Most column headings are active links that allow you to change the order of display by clicking on the header. Sorting works differently for different column groupings. Click the [Seconds Behind](#) header to order servers by the number of seconds they are behind their master. However, in all cases, the server topology is respected. For example, in a [TREE](#) topology, ordering occurs within branches only.

If the agent is down, servers show in bold red in the [Servers](#) column. The [Slave IO](#) and the [Slave SQL](#) columns display **stopped** in red text if these threads are not running. If an agent is down, italics is used to display the last know status of the IO or SQL threads.

Clicking on a master server opens a dialog box that displays information about the server. The information shown includes:

- The number of slave servers
- The binlog file name
- The binlog position
- Which databases are replicated and which not

The dialog box also includes a link that allows the user to hide or show the slave servers.

Clicking on a slave server opens a dialog window showing extensive information about the slave.

15.12. MySQL Enterprise Monitor Frequently Asked Questions

Note

MySQL Enterprise subscription, MySQL Enterprise Monitor, MySQL Replication Monitor, and MySQL Query Analyzer are only available to commercial customers. To learn more, see: <http://www.mysql.com/products/enterprise/features.html>.

Questions

- **15.12.1:** While monitoring my network traffic I have noticed that the agents communicate information at irregular intervals to the MySQL Enterprise Service Manager. I cannot see anything in my configuration that would explain this behaviour. What is going on?
- **15.12.2:** How frequently is the data purge process executed?
- **15.12.3:** Does Query Analyzer work with all versions of MySQL and the MySQL Client Libraries?
- **15.12.4:** My MySQL Enterprise Service Manager is behind a firewall but it cannot communicate with the MySQL Enterprise website to register and download my license key and advisor bundle. I normally use a proxy service to access external websites. How do I configure the proxy settings for MySQL Enterprise Dashboard?
- **15.12.5:** What is the relationship between the advisor JAR file and the key?
- **15.12.6:** I have set the graphs to update every 5 minutes, and the page refresh to occur every minute. The page is refreshing correctly, but the graphs do not seem to update.
- **15.12.7:** Can the Trial-level key work with the Gold-level advisors JAR file?
- **15.12.8:** During query analysis, I am unable to obtain an [EXAMPLE](#) or [EXPLAIN](#) information when examining the detail of the analyzed query within the **QUERY ANALYZER** panel.
- **15.12.9:** Does the Gold-level key support Silver-level advisors?
- **15.12.10:** I have enabled [EXPLAIN](#) queries for Query Analyzer, but no queries with the [EXPLAIN](#) data are showing up in the display.
- **15.12.11:** Can I run MySQL Enterprise Service Manager on machine with other applications running?
- **15.12.12:** Why do some rules appear to have a **SEVERITY** of **UNKNOWN**?
- **15.12.13:** How do I change the name of a server?
- **15.12.14:** I have started a Data Migration of my old data for a server to MySQL Enterprise Service Manager 2.0, but I have noticed that the performance of the monitor server has degraded significantly. Can I stop the migration?

Questions and Answers

15.12.1: While monitoring my network traffic I have noticed that the agents communicate information at irregular intervals to the MySQL Enterprise Service Manager. I cannot see anything in my configuration that would explain this behaviour. What is going on?

Each MySQL Enterprise Monitor Agent periodically sends information to the server about a range of different information, including the core rule and statistical data, Query Analyzer information and other data used to monitor the status of your MySQL server.

One element of this is called the MySQL Enterprise Monitor Agent Heartbeat, which is core information exchange that indicates that the monitored server is still up and running. The heartbeat information is vital because it tells the MySQL Enterprise Service Manager that the agent and server are still communicating. This information is sent regularly to the MySQL Enterprise Service Manager, but to prevent multiple agents from sending the information at the same time, and creating a large network load (or storm), the interval is randomized with each heartbeat. The randomization ensures that the information is still uploaded periodically, but without the potential to overload the network with this data.

15.12.2: How frequently is the data purge process executed?

A data purge process is started approximately once a minute. If you have changed the purge period then the data will start to be purged within the next minute.

15.12.3: Does Query Analyzer work with all versions of MySQL and the MySQL Client Libraries?

The MySQL Proxy component, and Query Analyzer, require that clients connecting through MySQL Enterprise Monitor Agent are using MySQL 5.0 or later. Clients that use the library provided with MySQL 4.1 or earlier will not work with MySQL Enterprise Monitor Agent.

15.12.4: My MySQL Enterprise Service Manager is behind a firewall but it cannot communicate with the MySQL Enterprise website to register and download my license key and advisor bundle. I normally use a proxy service to access external websites. How do I configure the proxy settings for MySQL Enterprise Dashboard?

To configure a proxy service, you need to edit the `apache-tomcat/conf/catalina.properties` file within the MySQL Enterprise Service Manager installation directory. To make the changes, the proxy configuration information to the end of the file by setting the `http.proxyHost` and `http.proxyPort` properties:

```
http.proxyHost=proxy.example.com
http.proxyPort=8080
```

You will need to restart the MySQL Enterprise Service Manager for the change to take effect:

```
shell> mysqlmonitorctl.sh restart
```

15.12.5: What is the relationship between the advisor JAR file and the key?

The JAR file contains graph and advisor definitions. The key file contains typical customer validation data such as contract information, number of servers covered, subscription level and dates.

15.12.6: I have set the graphs to update every 5 minutes, and the page refresh to occur every minute. The page is refreshing correctly, but the graphs do not seem to update.

The graph refresh and page refresh are two different parameters. The graphs will update according to their refresh period, regardless of the refresh period set for the main display page.

15.12.7: Can the Trial-level key work with the Gold-level advisors JAR file?

The Trial-level key can only be used with the Trial-level advisors JAR file.

15.12.8: During query analysis, I am unable to obtain an `EXAMPLE` or `EXPLAIN` information when examining the detail of the analyzed query within the QUERY ANALYZER panel.

You must explicitly enable the `EXAMPLE` and `EXPLAIN` query functionality. Make sure that you have enabled both panels. See [Section 15.10.6, “Query Analyzer Settings”](#).

15.12.9: Does the Gold-level key support Silver-level advisors?

The Gold-level advisor JAR file will contain Silver-level advisors plus Gold-level advisors. However, you cannot use the Gold-level key with the Silver-level advisors JAR file. The Gold-level key can only be used with the Gold-level advisors JAR file.

15.12.10: I have enabled `EXPLAIN` queries for Query Analyzer, but no queries with the `EXPLAIN` data are showing up in the display.

Query Analyzer only obtains `EXPLAIN` information when the MySQL Enterprise Monitor Agent identifies a long running query. If none of your queries exceed the defined threshold, then the `EXPLAIN` information is not obtain and provided to the Query Analyzer for display.

To change the query duration at which an `EXPLAIN` is triggered, you must edit the `share/mysql-proxy/quant.lua` file within the MySQL Enterprise Monitor Agent directory on each server. You need to change the value configured in the `auto_explain_min_exec_time_us`. The default is 500ms:

```
---
-- configuration
--
-- SET GLOBAL analyze_query.auto_filter = 0
if not proxy.global.config.quan then
  proxy.global.config.quan = {
    analyze_queries = true,    -- track all queries
    query_cutoff   = 160,    -- only show the first 160 chars of the query
    num_worst_queries = 5,
    auto_explain   = true,
    auto_explain_min_exec_time_us = 500 * 1000
  }
end
```

The value is expressed in microseconds, which is why the value must be multiplied by 1000. To reduce this value to 100ms you would modify the line:

```
auto_explain_min_exec_time_us = 100 * 1000
```

You do not need to restart MySQL Enterprise Monitor Agent for the changes to take effect.

15.12.11: Can I run MySQL Enterprise Service Manager on machine with other applications running?

You can, but ideally you should be running your MySQL Enterprise Service Manager on a dedicated machine, especially if you are monitoring a number of different agents. For more information, see [Section 15.4.4, “Choosing Suitable MySQL Enterprise Service Manager Hardware Configurations”](#).

15.12.12: Why do some rules appear to have a SEVERITY of UNKNOWN?

Due to timing issues, certain rules such as “32-Bit Binary Running on 64-Bit AMD Or Intel System” and “Key Buffer Size Greater Than 4 GB” do not evaluate correctly due to timing issues. This is a known issue and will be resolved in future versions of MySQL Enterprise Monitor.

15.12.13: How do I change the name of a server?

Go to the **MANAGE SERVERS** panel within **SETTINGS** and click **RENAME SERVER**.

15.12.14: I have started a Data Migration of my old data for a server to MySQL Enterprise Service Manager 2.0, but I have noticed that the performance of the monitor server has degraded significantly. Can I stop the migration?

You can stop the migration of your historical data at any time. Go to the **MANAGE SERVERS** display of the **SETTINGS** panel and click **STOP** next to each server that is being migrated. You can restart the migration at any point.

- [15.12.22](#): What is MySQL Consultative Support?

Questions and Answers

15.12.1: How should I decide between MySQL Enterprise Basic, Silver, Gold and Platinum?

MySQL Enterprise subscriptions are available in 4 tiers, providing you the flexibility of choosing the capabilities and SLA that best meet your requirements. [Learn More](#) If you have questions and what to discuss your specific requirements, please [Contact MySQL Sales](#)

15.12.2: What is MySQL Enterprise Server?

MySQL Enterprise Server software is the most reliable, secure and up-to-date version of MySQL for cost-effectively delivering E-commerce, Online Transaction Processing (OLTP), and multi-terabyte Data Warehousing applications. It is a fully integrated transaction-safe, ACID compliant database with full commit, rollback, crash recovery and row level locking capabilities. MySQL delivers the ease of use, scalability, and performance that has made it MySQL the world's most popular open source database. [Learn More](#)

15.12.3: How do I get a 30-day trial on MySQL Enterprise?

You can experience the MySQL Enterprise Monitor for 30 days by registering to receive an email with login instructions. [Learn More](#)

15.12.4: Does MySQL Enterprise include Maintenance, Updates, and Upgrades?

Yes. As long as you have a valid contract for MySQL Enterprise, you will receive all new MySQL Enterprise Server software releases including Software Maintenance, Updates, and Upgrades. The Software Update Service will automatically notify you of the new releases.

15.12.5: What is a Technical Account Manager?

MySQL Enterprise, at the Platinum tier, provides the option for a Technical Account Manager (TAM). The TAM is your advocate within MySQL, who proactively works to maximize your benefits from MySQL Support Services. [Learn More](#)

15.12.6: Are there any Webinars available?

Yes. MySQL provides regularly scheduled Live Webinars. [Learn More](#) MySQL also provides On-Demand Webinars to fit your schedule. These are recordings of previously held Live Webinars that you can replay at any time. [Learn More](#)

15.12.7: What is the pricing of MySQL Enterprise?

The pricing model for MySQL Enterprise is based on two key components: per server and per year. MySQL Enterprise does not have artificial restrictions based on CPUs, Memory, Machine Size, or Named Users. MySQL Enterprise is available in 4 tiers (Basic, Silver, Gold and Platinum). Choose the tier that best meets your requirements and budget. [Learn More](#)

15.12.8: Does MySQL Enterprise include Emergency Hot Fix Builds?

MySQL Enterprise, at the Gold and Platinum tiers, gives you the ability to request an Emergency Hot Fix Build to fix issues not already fixed in a MySQL Rapid Update or MySQL Quarterly Service Pack.

15.12.9: Are there any MySQL Enterprise White Papers available?

Yes. Detailed architecture, technology, and business white papers are available. [Learn More](#)

15.12.10: How do I buy MySQL Enterprise?

For pricing and to buy MySQL Enterprise, visit the [Online Shop](#) For volume discounts or for more information, please [Contact MySQL Sales](#)

15.12.11: What is MySQL Enterprise?

The MySQL Enterprise subscription is the most comprehensive offering of MySQL database software, services and production support to ensure your business achieves the highest levels of reliability, security and uptime.

MySQL Enterprise includes:

- MySQL Enterprise Server software, the most reliable, secure and up-to date version of the world's most popular open source database
- MySQL Enterprise Monitor that continuously monitors your database and proactively advises you on how to implement MySQL best practices

- MySQL 24x7 Production Support with fast response times to assist you in the development, deployment and management of MySQL applications

MySQL Enterprise is available in 4 tiers (Basic, Silver, Gold, Platinum). [Learn More](#)

15.12.12: Does MySQL provide IP (Intellectual Property) Indemnification?

MySQL Enterprise, at the Gold and Platinum tiers, has the option of IP Indemnification, for qualifying customers at no extra cost. This provides you with legal protection that you expect from enterprise software providers. [Learn More](#)

15.12.13: Can I buy MySQL Enterprise subscriptions for multiple years?

MySQL Enterprise subscriptions have duration of at least 1 year. Customers have the flexibility of choosing terms with multi-year durations. To purchase multi-year contracts, please [Contact MySQL Sales](#)

15.12.14: What is MySQL Enterprise Unlimited?

MySQL Enterprise Unlimited is a unique offering that allows you to deploy an unlimited number of MySQL Enterprise Servers for the price of a single CPU of Oracle Enterprise Edition. [Learn More](#)

15.12.15: What is MySQL Production Support?

Production Support consists of 4 components:

- Problem Resolution Support
- Consultative Support
- Knowledge Base
- Technical Account Manager (option)

MySQL Production Support gives you priority access with guaranteed response times to assist you with the development, deployment and management of your MySQL applications. [Learn More](#)

15.12.16: Can I buy MySQL Enterprise subscriptions for only some of my production MySQL database servers?

When you choose MySQL Enterprise subscriptions, they must cover all database servers that power that specific application. To negotiate volume discounts, please [Contact MySQL Sales](#)

15.12.17: Are there any Demo/Tutorials available for MySQL Enterprise?

Yes. Multiple self-running demos are available. [Learn More](#)

15.12.18: Does MySQL Enterprise include 24x7 Technical Support?

MySQL Enterprise, at the Gold and Platinum tiers, includes 24x7 phone and email access to the MySQL Support Team. [Learn More](#)

15.12.19: What if I plan to add more MySQL servers to my MySQL Enterprise subscription?

A great option is the MySQL Enterprise Unlimited offering that allows you cover an unlimited number of MySQL servers for a fixed, low price. [Learn More](#)

15.12.20: What is the list of Supported Platforms?

MySQL Enterprise provides broad coverage in its list of Supported Platforms. [Learn More](#)

15.12.21: Do all my MySQL Enterprise subscriptions need to be at the same tier?

MySQL Enterprise subscriptions must be at the same tier (Basic, Silver, Gold, Platinum) for all database servers that power that specific application.

15.12.22: What is MySQL Consultative Support?

MySQL Enterprise, at the Gold and Platinum tiers, includes Consultative Support. This is a proactive approach to support that is designed to help you avoid critical outages. MySQL Support Engineers advise you on how to properly design and tune your MySQL servers, schema, queries, and replication set-up to maximize performance and availability. Also, by taking the initiative to properly design and tune your MySQL database applications you can avoid having to purchase expensive hardware for your IT infrastructure. [Learn More](#)

MySQL Monitor

Questions

- [15.12.1](#): What is MySQL Enterprise Monitor?
- [15.12.2](#): What versions of MySQL are supported by the MySQL Enterprise Monitor?
- [15.12.3](#): What MySQL Enterprise subscription levels include the MySQL Enterprise Monitor?
- [15.12.4](#): What are the features and related benefits of the MySQL Enterprise Monitor?
- [15.12.5](#): What are the MySQL Enterprise Advisors and Advisor Rules?

- [15.12.7](#): What operating system platforms are supported by the MySQL Enterprise Monitor?
- [15.12.8](#): How do I get the MySQL Enterprise Monitor?
- [15.12.9](#): What makes MySQL Enterprise unique?
- [15.12.10](#): What are the long-term benefits of the MySQL Enterprise Monitor?
- [15.12.11](#): Which set of Enterprise Advisors, Advisor Rules and features are best for my use of MySQL?
- [15.12.12](#): How is the MySQL Enterprise Monitor installed and deployed?
- [15.12.13](#): What are the immediate benefits of implementing the MySQL Enterprise Monitor?
- [15.12.14](#): How are subscribers notified about the availability of new or updated MySQL Enterprise Monitor, MySQL Enterprise Advisors and Advisor Rules?
- [15.12.15](#): Which Advisors and features are included under different MySQL Enterprise subscription levels?

Questions and Answers

15.12.1: What is MySQL Enterprise Monitor?

Included as part of a MySQL Enterprise subscription, the MySQL Enterprise Monitor is a distributed, web-based application that helps customers reduce downtime, tighten security and increase throughput of their MySQL servers by telling them about problems in their database applications before they occur. It is downloadable from the Enterprise Customer web site and is deployed within the safety of the customer datacenter. [Learn More](#)

15.12.2: What versions of MySQL are supported by the MySQL Enterprise Monitor?

The MySQL Enterprise Monitor can be used to monitor MySQL versions 4.0 – 5.x.

15.12.3: What MySQL Enterprise subscription levels include the MySQL Enterprise Monitor?

The Enterprise Monitor is available under MySQL Enterprise subscription levels Silver, Gold and Platinum. [Learn More](#)

15.12.4: What are the features and related benefits of the MySQL Enterprise Monitor?

The MySQL Enterprise Monitor is like having a "Virtual DBA Assistant" at your side to recommend best practices to eliminate security vulnerabilities, improve replication, and optimize performance. For the complete features and benefits, visit the [MySQL Enterprise Monitor Features and Benefits page](#).

15.12.5: What are the MySQL Enterprise Advisors and Advisor Rules?

The MySQL Enterprise Advisors are a set of best practice guidelines for the optimal use of MySQL. Advisors are spread across database specific disciplines and are comprised of a set of MySQL Advisor Rules that proactively monitor all MySQL servers and report on database application problems before they occur. Each Advisor Rule provides a detailed overview of the problem it is designed to identify, advices on how to correct the problem, specifies commands to implement the recommended fix and links to additional resources for additional research into the issue at hand. [Learn More](#)

15.12.6: How is the Enterprise Monitor web application architected?

The Enterprise Monitor web application is comprised of 3 components:

- **Service Agent:** A lightweight C program that is installed on each of the monitored MySQL servers. Its purpose is to collect MySQL SQL and operating system metrics that allow the DBA to monitor the overall health, availability and performance of the MySQL server. The Service Agent is the only component within the application that touches or connects to the MySQL Server. It reports the data it collects via XML over HTTP to the centralized Service Manager.
- **Service Manager:** The main server of the application. The Service Manager manages and stores the data collections that come in from each service agent. It analyzes these collections using MySQL provided best practice Advisor rules to determine the health, security, availability and performance of each of the monitored MySQL Servers. The Service Manager also provides the content for the Enterprise Dashboard which serves as the client user interface for the distributed web application.
- **Repository:** A MySQL database that is used to stored data collections and application-level configuration data.

15.12.7: What operating system platforms are supported by the MySQL Enterprise Monitor?

The Enterprise Monitor Service Manager is fully supported on most current versions of Linux, Windows XP and Server Editions, Solaris and Mac OSX. The Service Agent supports any platform supported by the MySQL Enterprise server. For the complete list of MySQL Enterprise supported operating systems and CPUs, visit the [Supported Platforms page](#).

15.12.8: How do I get the MySQL Enterprise Monitor?

The MySQL Enterprise Monitor is available for download to MySQL Enterprise customers at the Silver, Gold and Platinum subscription levels.

- To experience the MySQL Enterprise Monitor for 30 days, visit the [Trial Subscription page](#)
- To buy MySQL Enterprise, visit the [Online Shop](#)

15.12.9: What makes MySQL Enterprise unique?

Of the products on the market that monitor MySQL, SQL code and OS specific metrics, the MySQL Enterprise Monitor is the only solution that is built and supported by the engineers at MySQL. Unlike other solutions that report on raw MySQL and OS level metrics, the MySQL Enterprise Monitor is designed to optimize the use of MySQL by proactively monitoring MySQL instances and providing notifications and “MySQL DBA expertise in a box” advice on corrective measures DBAs can take before problems occur.

15.12.10: What are the long-term benefits of the MySQL Enterprise Monitor?

Over time, the task of managing even medium-scale MySQL server farms becomes exponentially more complicated, especially as the load of users, connections, application queries, and objects on each MySQL server increases. The Enterprise Monitor continually monitors the dynamic security, performance, replication and schema relevant metrics of all MySQL servers, so as the number of MySQL continues to grow, DBAs are kept up to date on potential problems and proactive measures that can be implemented to ensure each server continues to operate at the highest levels of security, performance and reliability.

15.12.11: Which set of Enterprise Advisors, Advisor Rules and features are best for my use of MySQL?

The Enterprise Monitor Advisors and Advisor Rules are available at 3 MySQL Enterprise subscription tiers: Choose MySQL Enterprise Silver if you need:

- Assurance you are running the most current, bug-free version of MySQL across all of your servers.
- Recoverability of your MySQL servers.
- The highest level of security for your MySQL servers.
- Monitoring of maximum or disallowed MySQL connections.
- Optimized startup configuration settings.

Choose MySQL Enterprise Gold, when you need everything in Silver, PLUS:

- Easy collection and detection of problematic SQL code running on your production or development systems.
- Insight and corrective advice on MySQL replication status, sync, and performance related issues.
- Auto detection and documenting of your Replication topologies.

- Advanced monitoring of your Replication and Scale-out environment.

Choose MySQL Enterprise Platinum, when you need everything in Gold, PLUS:

- Identification and advice on unplanned database and object level schema changes (Create, Alter, and Drop) across your MySQL servers.
- Proactive monitoring and advice on tuning the performance of your MySQL servers.

15.12.12: How is the MySQL Enterprise Monitor installed and deployed?

The Enterprise Monitor is powered by a distributed web application that is installed and deployed within the confines of the corporate firewall.

15.12.13: What are the immediate benefits of implementing the MySQL Enterprise Monitor?

Often MySQL installations are implemented with default settings that may not be best suited for specific applications or usage patterns. The MySQL Advisors go to work immediately in these environments to identify potential problems and proactively notify and advise DBAs on key MySQL settings that can be tuned to improve availability, tighten security, and increase the throughput of their existing MySQL servers

15.12.14: How are subscribers notified about the availability of new or updated MySQL Enterprise Monitor, MySQL Enterprise Advisors and Advisor Rules?

Customers will receive notifications of new and updated MySQL Enterprise Monitor and Advisors as they become available via the MySQL Enterprise Software Update Service. Notifications will be generated and sent based on the customer profile and the MySQL Enterprise subscription level.

15.12.15: Which Advisors and features are included under different MySQL Enterprise subscription levels?

For the complete list of the MySQL Enterprise Advisors that are available under each MySQL Enterprise subscription level, visit the [Features page](#).

MySQL Query Analyzer

Questions

- [15.12.1](#): Can I leave the MySQL Query Analyzer enabled at all times?
- [15.12.2](#): What are the typical use cases of the MySQL Query Analyzer?
- [15.12.3](#): What is the MySQL Query Analyzer?
- [15.12.4](#): What are the main features and benefits of the MySQL Query Analyzer?
- [15.12.5](#): What makes the MySQL Query Analyzer unique?
- [15.12.6](#): How are subscribers notified about updates to the MySQL Query Analyzer application components?
- [15.12.7](#): How can I get the MySQL Query Analyzer?
- [15.12.8](#): How is the MySQL Query Analyzer installed and enabled?
- [15.12.9](#): What overhead can I expect when the MySQL Query Analyzer is installed and enabled?

Questions and Answers

15.12.1: Can I leave the MySQL Query Analyzer enabled at all times?

We have customers who have the Query Analyzer enabled and collecting queries on their development and QA servers so they can tune their code and monitor the fixes as part of the development process. For production systems, Query collection and analysis can easily be toggled on when a slowdown occurs. To avoid collection mode overhead many users are using simple scripts to enable the Query Analyzer to sample queries during non-peak hours, typically during 30 minute windows. They can then view the collected queries using the date/time or interval filter options.

15.12.2: What are the typical use cases of the MySQL Query Analyzer?

The typical use cases for developers, DBAs and system administrators are:

- Developers – Monitor and tune application queries during development before they are promoted to production.
- DBAs and System Administrators – Identify problem SQL code as it runs in production and advise development teams on how to tune. This use case benefits the most from regular sampling of queries as they are running, most often during non-peak hours.

15.12.3: What is the MySQL Query Analyzer?

The MySQL Query Analyzer allows DBAs, developers and system administrators to improve application performance by collecting, monitoring, and analyzing queries as they run on their MySQL servers. [Learn More](#)

15.12.4: What are the main features and benefits of the MySQL Query Analyzer?

For the complete features and benefits, visit the [MySQL Enterprise Monitor Features and Benefits page](#).

15.12.5: What makes the MySQL Query Analyzer unique?

Other products (free, open source and commercial) that provide MySQL query monitoring are dependent on the MySQL Slow Query Log being enabled and available for sampling. While this provides some time savings over the DBA collecting and parsing the Log, the Slow Query Log comes with overhead and does not capture sub millisecond executions. The log data also grows very large very quickly.

The MySQL Query Analyzer collects queries and execution statistics with no dependence on the SQL Query Log, it captures all SQL statements sent to the MySQL server and provides an aggregated view into the most expensive queries in number of executions and total execution time. It is also fully supported as part of the MySQL Enterprise subscription.

15.12.6: How are subscribers notified about updates to the MySQL Query Analyzer application components?

Customers will receive notifications of the MySQL Query Analyzer updates as they become available via the MySQL Enterprise Software Update and Alert Service. Notifications will be generated and sent based on the customer profile and the MySQL Enterprise subscription level.

15.12.7: How can I get the MySQL Query Analyzer?

The MySQL Query Analyzer is available for download to MySQL Enterprise customers at the Gold and Platinum subscription levels.

- To experience the MySQL Enterprise Monitor for 30 days, visit the [Trial Subscription page](#)
- To buy MySQL Enterprise, visit the [Online Shop](#)

15.12.8: How is the MySQL Query Analyzer installed and enabled?

The Query Analyzer feature is installed with the Service Agent. It is enabled during agent installation and can be toggled between collection and pass-thru modes from the Query Analysis page of the Enterprise Monitor.

15.12.9: What overhead can I expect when the MySQL Query Analyzer is installed and enabled?

The average overhead when in active collection mode is in the 15-20% range. In pass-thru mode the overhead is minimal, weighing in at 1-5% on most MySQL systems of average load.

Chapter 16. Replication

Replication enables data from one MySQL database server (called the master) to be replicated to one or more MySQL database servers (slaves). Replication is asynchronous - your replication slaves do not need to be connected permanently to receive updates from the master, which means that updates can occur over long-distance connections and even temporary solutions such as a dial-up service. Depending on the configuration, you can replicate all databases, selected databases, or even selected tables within a database.

The target uses for replication in MySQL include:

- Scale-out solutions - spreading the load among multiple slaves to improve performance. In this environment, all writes and updates must take place on the master server. Reads, however, may take place on one or more slaves. This model can improve the performance of writes (since the master is dedicated to updates), while dramatically increasing read speed across an increasing number of slaves.
- Data security - because data is replicated to the slave, and the slave can pause the replication process, it is possible to run backup services on the slave without corrupting the corresponding master data.
- Analytics - live data can be created on the master, while the analysis of the information can take place on the slave without affecting the performance of the master.
- Long-distance data distribution - if a branch office would like to work with a copy of your main data, you can use replication to create a local copy of the data for their use without requiring permanent access to the master.

Replication in MySQL features support for one-way, asynchronous replication, in which one server acts as the master, while one or more other servers act as slaves. This is in contrast to the *synchronous* replication which is a characteristic of MySQL Cluster (see [Chapter 17, MySQL Cluster NDB 6.X/7.X](#)).

There are a number of solutions available for setting up replication between two servers, but the best method to use depends on the presence of data and the engine types you are using. For more information on the available options, see [Section 16.1.1, “How to Set Up Replication”](#).

There are two core types of replication format, Statement Based Replication (SBR), which replicates entire SQL statements, and Row Based Replication (RBR), which replicates only the changed rows. You may also use a third variety, Mixed Based Replication (MBR), which is the default mode within MySQL 5.1.12 and later. For more information on the different replication formats, see [Section 16.1.2, “Replication Formats”](#).

Replication is controlled through a number of different options and variables. These control the core operation of the replication, timeouts and the databases and filters that can be applied on databases and tables. For more information on the available options, see [Section 16.1.3, “Replication and Binary Logging Options and Variables”](#).

You can use replication to solve a number of different problems, including problems with performance, supporting the backup of different databases and for use as part of a larger solution to alleviate system failures. For information on how to address these issues, see [Section 16.2, “Replication Solutions”](#).

For notes and tips on how different data types and statements are treated during replication, including details of replication features, version compatibility, upgrades, and problems and their resolution, including an FAQ, see [Section 16.3, “Replication Notes and Tips”](#).

Detailed information on the implementation of replication, how replication works, the process and contents of the binary log, background threads and the rules used to decide how statements are recorded and replication, see [Section 16.4, “Replication Implementation”](#).

MySQL Enterprise

The MySQL Enterprise Monitor provides numerous advisors that provide immediate feedback about replication-related problems. For more information, see <http://www.mysql.com/products/enterprise/advisors.html>.

16.1. Replication Configuration

Replication between servers in MySQL works through the use of the binary logging mechanism. The MySQL instance operating as the master (the source of the database changes) writes updates and changes as “events” to the binary log. The information in the binary log is stored in different logging formats according to the database changes being recorded. Slaves are configured to read the binary log from the master and to execute the events in the binary log on the slave’s local database.

The master is “dumb” in this scenario. Once binary logging has been enabled, all statements are recorded in the binary log. Each slave will receive a copy of the entire contents of the binary log. It is the responsibility of the slave to decide which statements in the binary log should be executed; you cannot configure the master to log only certain events. If you do not specify otherwise, all

events in the master binary log are executed on the slave. If required, you can configure the slave to process only events that apply to particular databases or tables.

Each slave keeps a record of the binary log file and position within the log file that it has read and processed from the master. This means that multiple slaves can be connected to the master and executing different parts of the same binary log. Because the slaves control this process, individual slaves can be connected and disconnected from the server without affecting the master's operation. Also, because each slave remembers the position within the binary log, it is possible for slaves to be disconnected, reconnect and then “catch up” by continuing from the recorded position.

Both the master and each slave must be configured with a unique ID (using the `server-id` option). In addition, the slave must be configured with information about the master host name, log file name and position within that file. These details can be controlled from within a MySQL session using the `CHANGE MASTER TO` statement. The details are stored within the `master.info` file.

In this section the setup and configuration required for a replication environment is described, including step-by-step instructions for creating a new replication environment. The major components of this section are:

- For a guide to setting up two or more servers for replication see [Section 16.1.1, “How to Set Up Replication”](#). This section deals with the setup of the systems and provides methods for copying data between the master and slaves.
- Events in the binary log are recorded using a number of formats. These are referred to as statement-based replication (SBR) or row-based replication (RBR). A third type, mixed-format replication (MIXED), uses SBR or RBR replication automatically to take advantage of the benefits of both SBR and RBR formats when appropriate. The different formats are discussed in [Section 16.1.2, “Replication Formats”](#).
- Detailed information on the different configuration options and variables that apply to replication is provided in [Section 16.1.3, “Replication and Binary Logging Options and Variables”](#).
- Once started, the replication process should require little administration or monitoring. However, for advice on common tasks that you may want to execute, see [Section 16.1.4, “Common Replication Administration Tasks”](#).

16.1.1. How to Set Up Replication

This section describes how to set up complete replication of a MySQL server. There are a number of different methods for setting up replication, and the exact method that you use will depend on how you are setting up replication, and whether you already have data within your master database.

There are some generic tasks which may be required for all replication setups:

- You may want to create a separate user that will be used by your slaves to authenticate with the master to read the binary log for replication. The step is optional. See [Section 16.1.1.1, “Creating a User for Replication”](#).
- You must configure the master to support the binary log and configure a unique ID. See [Section 16.1.1.2, “Setting the Replication Master Configuration”](#).
- You must configure a unique ID for each slave that you want to connect to the master. See [Section 16.1.1.3, “Setting the Replication Slave Configuration”](#).
- Before starting a data snapshot or the replication process, you should record the position of the binary log on the master. You will need this information when configuring the slave so that the slave knows where within the binary log to start executing events. See [Section 16.1.1.4, “Obtaining the Master Replication Information”](#).
- If you already have data on your master and you want to synchronize your slave with this base data, then you will need to create a data snapshot of your database. You can create a snapshot using `mysqldump` (see [Section 16.1.1.5, “Creating a Data Snapshot Using `mysqldump`”](#)) or by copying the data files directly (see [Section 16.1.1.6, “Creating a Data Snapshot Using Raw Data Files”](#)).
- You will need to configure the slave with the master settings, such as the host name, login credentials and binary log name and positions. See [Section 16.1.1.10, “Setting the Master Configuration on the Slave”](#).

Once you have configured the basic options, you will need to follow the instructions for your replication setup. A number of alternatives are provided:

- If you are establishing a new MySQL master and one or more slaves, then you need only set up the configuration, as you have no data to exchange. For guidance on setting up replication in this situation, see [Section 16.1.1.7, “Setting Up Replication with New Master and Slaves”](#).

- If you are already running a MySQL server, and therefore already have data that will need to be transferred to your slaves before replication starts, have not previously configured the binary log and are able to shut down your MySQL server for a short period during the process, see [Section 16.1.1.8, “Setting Up Replication with Existing Data”](#).
- If you are setting up additional slaves to an existing replication environment then you can set up the slaves without affecting the master. See [Section 16.1.1.9, “Introducing Additional Slaves to an Existing Replication Environment”](#).

If you want to administer a MySQL replication setup, we suggest that you read this entire chapter through and try all statements mentioned in [Section 12.6.1, “SQL Statements for Controlling Master Servers”](#), and [Section 12.6.2, “SQL Statements for Controlling Slave Servers”](#). You should also familiarize yourself with the replication startup options described in [Section 16.1.3, “Replication and Binary Logging Options and Variables”](#).

Note

Note that certain steps within the setup process require the `SUPER` privilege. If you do not have this privilege then enabling replication may not be possible.

16.1.1.1. Creating a User for Replication

Each slave must connect to the master using a standard MySQL user name and password, so there must be a user account on the master that the slave can use to connect. Any account can be used for this operation, providing it has been granted the `REPLICATION SLAVE` privilege.

You do not need to create a specific user for replication. However, you should be aware that the user name and password will be stored in plain text within the `master.info` file. Therefore, you may want to create a user that only has privileges for the replication process.

To create a user or grant an existing user the privileges required for replication, use the `GRANT` statement. If you create a user solely for the purposes of replication then that user needs only the `REPLICATION SLAVE` privilege. For example, to create a user, `repl`, that can connect for replication from any host within the `mydomain.com` domain, issue this statement on the master:

```
mysql> GRANT REPLICATION SLAVE ON *.*
-> TO 'repl'@'%mydomain.com' IDENTIFIED BY 'slavepass';
```

See [Section 12.5.1.3, “GRANT Syntax”](#), for more information on the `GRANT` statement.

You may wish to create a different user for each slave, or use the same user for each slave that needs to connect. As long as each user that you want to use for the replication process has the `REPLICATION SLAVE` privilege you can create as many users as you require.

16.1.1.2. Setting the Replication Master Configuration

For replication to work you *must* enable binary logging on the master. If binary logging is not enabled, replication will not be possible as it is the binary log that is used to exchange data between the master and slaves.

Each server within a replication group must be configured with a unique `server-id` value. The server ID is used to identify individual servers within the group, and must be positive integer between 1 and $(2^{32})-1$. How you organize and select the numbers is entirely up to you.

To configure the binary log and server ID options, you will need to shut down your MySQL server and edit the configuration of the `my.cnf` or `my.ini` file.

You will need to add the following options to the configuration file within the `[mysqld]` section. If these options already exist, but are commented out, uncomment the options and alter them according to your needs. For example, to enable binary logging, using a log file name prefix of `mysql-bin`, and setting a server ID of 1:

```
[mysqld]
log-bin=mysql-bin
server-id=1
```

Note

For the greatest possible durability and consistency in a replication setup using `InnoDB` with transactions, you should use `innodb_flush_log_at_trx_commit=1` and `sync_binlog=1` in the master `my.cnf` file.

Note

Ensure that the `skip-networking` option has not been enabled on your replication master. If networking has been disabled, then your slave will not be able to communicate with the master and replication will fail.

16.1.1.3. Setting the Replication Slave Configuration

The only option you must configure on the slave is to set the unique server ID. If this option is not already set, or the current value conflicts with the value that you have chosen for the master server, then you should shut down your slave server, and edit the configuration to specify the server ID. For example:

```
[mysqld]
server-id=2
```

If you are setting up multiple slaves, each one must have a unique `server-id` value that differs from that of the master and from each of the other slaves. Think of `server-id` values as something similar to IP addresses: These IDs uniquely identify each server instance in the community of replication partners.

If you do not specify a `server-id` value, it defaults to 0.

Note

If you omit `server-id` (or set it explicitly to 0), a master refuses connections from all slaves, and a slave refuses to connect to a master. Thus, omitting `server-id` is good only for backup with a binary log.

You do not have to enable binary logging on the slave for replication to be enabled. However, if you enable binary logging on the slave then you can use the binary log for data backups and crash recovery on the slave, and also use the slave as part of a more complex replication topology (for example, where the slave acts as a master to other slaves).

16.1.1.4. Obtaining the Master Replication Information

To configure replication on the slave you must determine the master's current point within the master binary log. You will need this information so that when the slave starts the replication process, it is able to start processing events from the binary log at the correct point.

If you have existing data on your master that you want to synchronize on your slaves before starting the replication process, then you must stop processing statements on the master, obtain the current position, and then dump the data, before allowing the master to continue executing statements. If you do not stop the execution of statements, the data dump and the master status information that you use will not match and you will end up with inconsistent or corrupted databases on the slaves.

To get the master status information, follow these steps:

1. Start the command-line client and flush all tables and block write statements by executing the `FLUSH TABLES WITH READ LOCK` statement:

```
mysql> FLUSH TABLES WITH READ LOCK;
```

For `InnoDB` tables, note that `FLUSH TABLES WITH READ LOCK` also blocks `COMMIT` operations.

Warning

Leave the client from which you issued the `FLUSH TABLES` statement running so that the read lock remains in effect. If you exit the client, the lock is released.

2. Use the `SHOW MASTER STATUS` statement to determine the current binary log file name and offset on the master:

```
mysql > SHOW MASTER STATUS;
+-----+-----+-----+-----+
| File           | Position | Binlog_Do_DB | Binlog_Ignore_DB |
+-----+-----+-----+-----+
| mysql-bin.003 | 73       | test         | manual,mysql      |
+-----+-----+-----+-----+
```

The `File` column shows the name of the log file and `Position` shows the offset within the file. In this example, the binary log file is `mysql-bin.003` and the offset is 73. Record these values. You need them later when you are setting up the slave. They represent the replication coordinates at which the slave should begin processing new updates from the master.

If the master has been running previously without binary logging enabled, the log name and position values displayed by `SHOW MASTER STATUS` or `mysqldump --master-data` will be empty. In that case, the values that you need to use later when specifying the slave's log file and position are the empty string (' ') and 4.

You now have the information you need to enable the slave to start reading from the binary log in the correct place to start replication.

If you have existing data that needs to be synchronized with the slave before you start replication, leave the client running so that the lock remains in place and then proceed to [Section 16.1.1.5, “Creating a Data Snapshot Using `mysqldump`”](#), or [Section 16.1.1.6, “Creating a Data Snapshot Using Raw Data Files”](#).

If you are setting up a brand new master and slave replication group, then you can exit the client and release the locks.

16.1.1.5. Creating a Data Snapshot Using `mysqldump`

One way to create a snapshot of the data in an existing master database is to use the `mysqldump` tool. Once the data dump has been completed, you then import this data into the slave before starting the replication process.

To obtain a snapshot of the data using `mysqldump`:

- If you haven't already locked the tables on the server to prevent statements that update data from executing:

Start the command-line client and flush all tables and block write statements by executing the `FLUSH TABLES WITH READ LOCK` statement:

```
mysql> FLUSH TABLES WITH READ LOCK;
```

Remember to use `SHOW MASTER STATUS` and record the binary log details for use when starting up the slave. The point in time of your snapshot and the binary log position must match. See [Section 16.1.1.4, “Obtaining the Master Replication Information”](#).

- In another session, use `mysqldump` to create a dump either of all the databases you want to replicate, or of selected individual databases. For example:

```
shell> mysqldump --all-databases --lock-all-tables >dbdump.db
```

- An alternative to using a bare dump, is to use the `--master-data` option, which automatically appends the `CHANGE MASTER TO` statement required on the slave to start the replication process.

```
shell> mysqldump --all-databases --master-data >dbdump.db
```

- In the client where you acquired the read lock, release the lock:

```
mysql> UNLOCK TABLES;
```

When choosing databases to include in the dump, remember that you will need to filter out databases on each slave that you do not want to include in the replication process.

You will need either to copy the dump file to the slave, or to use the file from the master when connecting remotely to the slave to import the data.

16.1.1.6. Creating a Data Snapshot Using Raw Data Files

If your database is particularly large, copying the raw data files may be more efficient than using `mysqldump` and importing the file on each slave.

However, using this method with tables in storage engines with complex caching or logging algorithms may not give you a perfect “in time” snapshot as cache information and logging updates may not have been applied, even if you have acquired a global read lock. How the storage engine responds to this depends on its crash recovery abilities.

In addition, this method does not work reliably if the master and slave have different values for `ft_stopword_file`, `ft_min_word_len`, or `ft_max_word_len` and you are copying tables having fulltext indexes.

If you are using `InnoDB` tables, you should use the `InnoDB Hot Backup` tool to obtain a consistent snapshot. This tool records the log name and offset corresponding to the snapshot to be later used on the slave. `Hot Backup` is a non-free (commercial) tool that is not included in the standard MySQL distribution. See the `InnoDB Hot Backup` home page at <http://www.innodb.com/hot-backup> for detailed information.

Otherwise, you can obtain a reliable binary snapshot of `InnoDB` tables only after shutting down the MySQL Server.

To create a raw data snapshot of `MyISAM` tables you can use standard copy tools such as `cp` or `copy`, a remote copy tool such as `scp` or `rsync`, an archiving tool such as `zip` or `tar`, or a file system snapshot tool such as `dump`, providing that your MySQL data files exist on a single file system. If you are replicating only certain databases then make sure you copy only those files that related to those tables. (For `InnoDB`, all tables in all databases are stored in a single file unless you have the `in-`

`nodb_file_per_table` option enabled.)

You may want to specifically exclude the following files from your archive:

- Files relating to the `mysql` database.
- The `master.info` file.
- The master's binary log files.
- Any relay log files.

To get the most consistent results with a raw data snapshot you should shut down the server during the process, as below:

1. Acquire a read lock and get the master's status. See [Section 16.1.1.4, “Obtaining the Master Replication Information”](#).
2. In a separate session, shut down the MySQL server:

```
shell> mysqladmin shutdown
```

3. Make a copy of the MySQL data files. Examples are shown below for common ways to do this - you need to choose only one of them:

```
shell> tar cf /tmp/db.tar ./data
shell> zip -r /tmp/db.zip ./data
shell> rsync --recursive ./data /tmp/dbdata
```

4. Start up the MySQL instance on the master.

If you are not using `InnoDB` tables, you can get a snapshot of the system from a master without shutting down the server as described in the following steps:

1. Acquire a read lock and get the master's status. See [Section 16.1.1.4, “Obtaining the Master Replication Information”](#).
2. Take a copy of the MySQL data files. Examples are shown below for common solutions - you need to choose only one of these solutions:

```
shell> tar cf /tmp/db.tar ./data
shell> zip -r /tmp/db.zip ./data
shell> rsync --recursive ./data /tmp/dbdata
```

3. In the client where you acquired the read lock, release the lock:

```
mysql> UNLOCK TABLES;
```

Once you have created the archive or copy of the database, you will need to copy the files to each slave before starting the slave replication process.

16.1.1.7. Setting Up Replication with New Master and Slaves

Setting up replication with a new master and slaves (that is, with no existing data) is the easiest and most straightforward method for setting up replication.

You can also use this method if you are setting up new servers but have an existing dump of the databases from a different server that you want to load into your replication configuration. By loading the data into a new master, the data will be automatically replicated to the slaves.

To set up replication between a new master and slave:

1. Configure the MySQL master with the necessary configuration properties. See [Section 16.1.1.2, “Setting the Replication Master Configuration”](#).
2. Start up the MySQL master.
3. Set up a user. See [Section 16.1.1.1, “Creating a User for Replication”](#).

4. Obtain the master status information. See [Section 16.1.1.4, “Obtaining the Master Replication Information”](#).
5. On the master, release the read lock:

```
mysql> UNLOCK TABLES;
```

6. On the slave, edit the MySQL configuration. See [Section 16.1.1.3, “Setting the Replication Slave Configuration”](#).
7. Start up the MySQL slave.
8. Execute the `CHANGE MASTER TO` statement to set the master replication server configuration.

Perform the slave setup steps on each slave.

Because there is no data to load or exchange on a new server configuration you do not need to copy or import any information.

If you are setting up a new replication environment using the data from a different existing database server, you will now need to run the dump file generated from that server on the new master. The database updates will automatically be propagated to the slaves:

```
shell> mysql -h master < fulldb.dump
```

16.1.1.8. Setting Up Replication with Existing Data

When setting up replication with existing data, you will need to decide how best to get the data from the master to the slave before starting the replication service.

The basic process for setting up replication with existing data is as follows:

1. If you have not already configured the `server-id` and binary logging, you will need to shut down your master to configure these options. See [Section 16.1.1.2, “Setting the Replication Master Configuration”](#).

If you have to shut down your master server, this is a good opportunity to take a snapshot of its databases. You should obtain the master status (see [Section 16.1.1.4, “Obtaining the Master Replication Information”](#)) before taking down the master, updating the configuration and taking a snapshot. For information on how to create a snapshot using raw data files, see [Section 16.1.1.6, “Creating a Data Snapshot Using Raw Data Files”](#).

2. If your server is already correctly configured, obtain the master status (see [Section 16.1.1.4, “Obtaining the Master Replication Information”](#)) and then use `mysqldump` to take a snapshot (see [Section 16.1.1.5, “Creating a Data Snapshot Using `mysqldump`”](#)) or take a raw snapshot of the live server using the guide in [Section 16.1.1.6, “Creating a Data Snapshot Using Raw Data Files”](#).
3. With the MySQL master running, create a user to be used by the slave when connecting to the master during replication. See [Section 16.1.1.1, “Creating a User for Replication”](#).
4. Update the configuration of the slave. See [Section 16.1.1.3, “Setting the Replication Slave Configuration”](#).
5. The next step depends on how you created the snapshot of data on the master.

If you used `mysqldump`:

- a. Start the slave, skipping replication by using the `--skip-slave` option.
- b. Import the dump file:

```
shell> mysql < fulldb.dump
```

If you created a snapshot using the raw data files:

- a. Extract the data files into your slave data directory. For example:

```
shell> tar xvf dbdump.tar
```

You may need to set permissions and ownership on the files to match the configuration of your slave.

- b. Start the slave, skipping replication by using the `--skip-slave` option.

- Configure the slave with the master status information. This will tell the slave the binary log file and position within the file where replication needs to start, and configure the login credentials and host name of the master. For more information on the statement required, see [Section 16.1.1.10, “Setting the Master Configuration on the Slave”](#).
- Start the slave threads:

```
mysql> START SLAVE;
```

After you have performed this procedure, the slave should connect to the master and catch up on any updates that have occurred since the snapshot was taken.

If you have forgotten to set the `server-id` option for the master, slaves cannot connect to it.

If you have forgotten to set the `server-id` option for the slave, you get the following error in the slave's error log:

```
Warning: You should set server-id to a non-0 value if master_host
is set; we will force server id to 2, but this MySQL server will
not act as a slave.
```

You also find error messages in the slave's error log if it is not able to replicate for any other reason.

Once a slave is replicating, you can find in its data directory one file named `master.info` and another named `relay-log.info`. The slave uses these two files to keep track of how much of the master's binary log it has processed. Do *not* remove or edit these files unless you know exactly what you are doing and fully understand the implications. Even in that case, it is preferred that you use the `CHANGE MASTER TO` statement to change replication parameters. The slave will use the values specified in the statement to update the status files automatically.

Note

The content of `master.info` overrides some of the server options specified on the command line or in `my.cnf`. See [Section 16.1.3, “Replication and Binary Logging Options and Variables”](#), for more details.

Once you have a snapshot of the master, you can use it to set up other slaves by following the slave portion of the procedure just described. You do not need to take another snapshot of the master; you can use the same one for each slave.

16.1.1.9. Introducing Additional Slaves to an Existing Replication Environment

If you want to add another slave to the existing replication configuration then you can do so without stopping the master. Instead, you duplicate the settings on the slaves by making a copy of one of the slaves.

To duplicate the slave:

- Shut down the existing slave:

```
shell> mysqladmin shutdown
```

- Copy the data directory from the existing slave to the new slave. You can do this by creating an archive using `tar` or `Win-Zip`, or by performing a direct copy using a tool such as `cp` or `rsync`. Ensure that you also copy the log files and relay log files.

Note

A common problem that is encountered when adding new replication slaves is that the new slave fails with a series of warning and error messages like these:

```
071118 16:44:10 [Warning] Neither --relay-log nor --relay-log-index were used; so
replication may break when this MySQL server acts as a slave and has his hostname
changed!! Please use '--relay-log=new_slave_hostname-relay-bin' to avoid this problem.
071118 16:44:10 [ERROR] FAILED TO OPEN THE RELAY LOG './OLD_SLAVE_HOSTNAME-RELAY-BIN.003525'
(RELAY_LOG_POS 22940879)
071118 16:44:10 [ERROR] COULD NOT FIND TARGET LOG DURING RELAY LOG INITIALIZATION
071118 16:44:10 [ERROR] FAILED TO INITIALIZE THE MASTER INFO STRUCTURE
```

This is due to the fact that, if the `--relay-log` option is not specified, the relay log files contain the host name as part of their file names. (This is also true of the relay log index file if the `--relay-log-index` option is not used. See [Section 16.1.3, “Replication and Binary Logging Options and Variables”](#), for more information about these options.)

To avoid this problem, use the same value for `--relay-log` on the new slave that was used on the existing slave. (If this option was not set explicitly on the existing slave, use `existing_slave_hostname-relay-bin`.) If

this is not feasible, then copy the existing slave's relay log index file to the new slave and set the `-relay-log-index` option on the new slave to match what was used on the existing slave. (If this option was not set explicitly on the existing slave, use `existing_slave_hostname-relay-bin.index`.) Alternatively — if you have already tried to start the new slave (after following the remaining steps in this section) and have encountered errors like those described previously — then perform the following steps:

- a. If you have not already done so, issue a `STOP SLAVE` on the new slave.
If you have already started the existing slave again, issue a `STOP SLAVE` on the existing slave as well.
 - b. Copy the contents of the existing slave's relay log index file into the new slave's relay log index file, making sure to overwrite any content already in the file.
 - c. Proceed with the remaining steps in this section.
3. Copy the `master.info` and `relay-log.info` files from the existing slave to the new slave. These files hold the current log positions.
 4. Start the existing slave.
 5. On the new slave, edit the configuration and give the new slave a new unique `server-id`.
 6. Start the new slave; the `master.info` file options will be used to start the replication process.

16.1.1.10. Setting the Master Configuration on the Slave

To set up the slave to communicate with the master for replication, you must tell the slave the necessary connection information. To do this, execute the following statement on the slave, replacing the option values with the actual values relevant to your system:

```
mysql> CHANGE MASTER TO
->     MASTER_HOST='master_host_name',
->     MASTER_USER='replication_user_name',
->     MASTER_PASSWORD='replication_password',
->     MASTER_LOG_FILE='recorded_log_file_name',
->     MASTER_LOG_POS=recorded_log_position;
```

Note

Replication cannot use Unix socket files. You must be able to connect to the master MySQL server using TCP/IP.

The following table shows the maximum allowable length for the string-valued options.

Option	Maximum Length
<code>MASTER_HOST</code>	60
<code>MASTER_USER</code>	16
<code>MASTER_PASSWORD</code>	32
<code>MASTER_LOG_FILE</code>	255

16.1.2. Replication Formats

Replication works because events written to the binary log are read from the master and then processed on the slave. The events are recorded within the binary log in different formats according to the type of event being recorded. The different replication formats used correspond to the binary logging format used when the events were recorded in the master's binary log. The correlation between binary logging formats and the terms used during replication are:

- Replication capabilities in MySQL originally were based on propagation of SQL statements from master to slave. This is called *statement-based replication* (often abbreviated as *SBR*), which corresponds to the standard statement-based binary logging format. In MySQL 5.1.4 and earlier, binary logging and replication used this format exclusively.
- Row-based binary logging logs changes in individual table rows. When used with MySQL replication, this is known as *row-based replication* (often abbreviated as *RBR*). In row-based replication, the master writes messages known as *events* to the binary log that indicate how individual table rows are changed.
- As of MySQL 5.1.8, the binary logging format can be changed in real time according to the event being logged using *mixed-format logging*.

When the mixed format is in effect, statement-based logging is used by default, but automatically switches to row-based logging in particular cases as described below. Replication using the mixed format is often referred to as *mixed-based replication* or *mixed-format replication*. For more information, see [Section 5.2.4.3, “Mixed Binary Logging Format”](#).

From MySQL 5.1.12 to MySQL 5.1.28 (inclusive), the mixed format is the default for MySQL replication. Beginning with MySQL 5.1.29, statement-based format is the default.

Note

MySQL Cluster. The default binary logging format in all MySQL Cluster NDB 6.1, 6.2, 6.3, and later 6.x releases is `ROW`. MySQL Cluster Replication always uses row-based replication, and the `NDBCLUSTER` storage engine is incompatible with statement-based replication. Using `NDBCLUSTER` sets row-based logging format automatically.

See [Section 17.9.2, “MySQL Cluster Replication — Assumptions and General Requirements”](#), for more information.

Starting with MySQL 5.1.20, when using `MIXED` format, the binary logging format is determined in part by the storage engine being used and the statement being executed. For more information on mixed-format logging and the rules governing the support of different logging formats, see [Section 5.2.4.3, “Mixed Binary Logging Format”](#).

The logging format in a running MySQL server is controlled by setting the `binlog_format` server system variable. This variable can be set with session or global scope. The rules governing when and how the new setting takes effect are the same as for other MySQL server system variables — setting the variable for the current session lasts only until the end of that session, and the change is not visible to other sessions; setting the variable globally requires a restart of the server in order to take effect. For more information, see [Section 12.5.4, “SET Syntax”](#).

You must have the `SUPER` privilege to set the binary logging format on the global level. Starting with MySQL 5.1.29, you must also have the `SUPER` privilege to set the binary logging format for the current session. ([Bug#39106](#))

The statement-based and row-based replication formats have different issues and limitations. For a comparison of their relative advantages and disadvantages, see [Section 16.1.2.1, “Comparison of Statement-Based and Row-Based Replication”](#).

With statement-based replication, you may encounter issues with replicating stored routines or triggers. You can avoid these issues by using row-based replication instead. For more information, see [Section 19.6, “Binary Logging of Stored Programs”](#).

If you build MySQL from source, row-based replication is available by default unless you invoke `configure` with the `--without-row-based-replication` option.

For MySQL 5.1.20 and later (and MySQL 5.0.46 for backward compatibility), the following session variables are written to the binary log and honored by the replication slave when parsing the binary log:

- `sql_mode`
- `foreign_key_checks`
- `unique_checks`
- `character_set_client`
- `collation_connection`
- `collation_database`
- `collation_server`
- `sql_auto_is_null`

Important

Even though session variables relating to character sets and collations are written to the binary log, replication between different character sets is not supported.

16.1.2.1. Comparison of Statement-Based and Row-Based Replication

Each binary logging format has advantages and disadvantages. For most users, the mixed replication format should provide the best combination of data integrity and performance. If, however, you want to take advantage of the features specific to the statement-based or row-based replication format when performing certain tasks, then you can use the information in this section, which provides a summary of their relative advantages and disadvantages, to determine which is best for your needs.

Advantages of statement-based replication:

- Proven technology that has existed in MySQL since 3.23.
- Less data written to log files. When updates or deletes affect many rows, this results in *much* less storage space required for log files. This also means that taking and restoring from backups can be accomplished more quickly.
- Log files contain all statements that made any changes, so they can be used to audit the database.
- Tables replicated using statement-based replication are not required to have explicit primary keys.

Disadvantages of statement-based replication:

- **Statements which are unsafe for SBR.** Not all statements which modify data (such as `INSERT DELETE`, `UPDATE`, and `REPLACE` statements) can be replicated using statement-based replication. Any non-deterministic behavior is difficult to replicate when using statement-based replication. Examples of such DML (Data Modification Language) statements include the following:
 - A statement that depends on a UDF or stored program that is non-deterministic, since the value returned by such a UDF or stored program or depends on factors other than the parameters supplied to it. (Row-based replication, however, simply replicates the value returned by the UDF or stored program, so its effect on table rows and data is the same on both the master and slave.) See [Section 16.3.1.7, “Replication of Invoked Features”](#), for more information.
 - `DELETE` and `UPDATE` statements that use a `LIMIT` clause without an `ORDER BY` are also non-deterministic. See [Section 16.3.1.11, “Replication and LIMIT”](#).
 - Statements using any of the following functions cannot be replicated properly using statement-based replication:
 - `LOAD_FILE()`
 - `UUID()`, `UUID_SHORT()`
 - `USER()`
 - `FOUND_ROWS()`
 - `SYSDATE()` (unless the server is started with the `--sysdate-is-now` option)

However, all other functions are replicated correctly using statement-based replication, including `RAND()`, `NOW()`, `LOAD DATA INFILE`, and so forth.

For more information, see [Section 16.3.1.10, “Replication and System Functions”](#).

When using statement-based replication, statements that cannot be replicated correctly using statement-based mode are logged with a warning like the one shown here:

```
090213 16:58:54 [Warning] Statement is not safe to log in statement format.
```

A similar warning is also issued to the client in such cases.

- `INSERT ... SELECT` requires a greater number of row-level locks than with row-based replication.
- `UPDATE` statements that require a table scan (because no index is used in the `WHERE` clause) must lock a greater number of rows than with row-based replication.
- For InnoDB: An `INSERT` statement that uses `AUTO_INCREMENT` blocks other non-conflicting `INSERT` statements.
- For complex statements, the statement must be evaluated and executed on the slave before the rows are updated or inserted. With row-based replication, the slave only has to run the statement to apply the differences, not the full statement.
- Stored functions execute with the same `NOW()` value as the calling statement. However, this is not true of stored procedures.
- Deterministic UDFs must be applied on the slaves.
- If there is an error in evaluation on the slave, particularly when executing complex statements, then using statement-based replication may slowly increase the margin of error across the affected rows over time. See [Section 16.3.1.20, “Slave Errors during Replication”](#).

- Tables must be (nearly) identical on master and slave. See [Section 16.3.1.4, “Replication with Differing Tables on Master and Slave”](#), for more information.

Advantages of row-based replication:

- All changes can be replicated. This is the safest form of replication.

For MySQL versions earlier than 5.1.14, DDL (Data Definition Language) statements such as `CREATE TABLE` are replicated using statement-based replication, while DML statements, as well as `GRANT` and `REVOKE` statements, are replicated using row-based-replication.

In MySQL 5.1.14 and later, the `mysql` database is not replicated. The `mysql` database is instead seen as a node-specific database. Row-based replication is not supported on tables in this database. Instead, statements that would normally update this information — such as `GRANT`, `REVOKE` and the manipulation of triggers, stored routines (including stored procedures), and views — are all replicated to slaves using statement-based replication.

For statements like `CREATE . . . SELECT`, a `CREATE` statement is generated from the table definition and replicated using the statement-based format, while the row insertions are replicated using the row-based format.

- The technology is the same as in most other database management systems; knowledge about other systems transfers to MySQL.
- Fewer locks are needed (and thus higher concurrency) on the master for the following types of statements:
 - `INSERT . . . SELECT`
 - `INSERT` statements with `AUTO_INCREMENT`
 - `UPDATE` or `DELETE` statements with `WHERE` clauses that don't use keys or don't change most of the examined rows.
- Fewer locks are required on the slave for any `INSERT`, `UPDATE`, or `DELETE` statement.

Disadvantages of row-based replication:

- RBR tends to generate more data that must be logged. This is because, when using row-based replication to replicate a DML statement (such as an `UPDATE` or `DELETE` statement), each changed row must be written to the binary log. (When using statement-based replication, only the statement is written to the binary log.) This means that, if the statement changes many rows, row-based replication may write significantly more data to the binary log; this is true even for statements that are rolled back. This also means that taking and restoring from backup can require more time. In addition, the binary log is locked for a longer time to write the data, which may cause concurrency problems.
- All tables replicated using row-based replication must have explicit primary keys.
- Deterministic UDFs that generate large `BLOB` values take longer to replicate with row-based replication than with statement-based replication. This is because, when using row-based replication, the `BLOB` column data is itself logged, rather than the statement generating the data.
- You cannot examine the logs to see what statements were executed, nor can you see on the slave what statements were received from the master and executed.

However, beginning with MySQL 5.1.29, you can see what data was changed using `mysqlbinlog` with the options `--base64-output=DECODE-ROWS` and `--verbose`.

- When performing a bulk operation that includes non-transactional storage engines, changes are applied as the statement executes. With row-based replication logging, this means that the binary log is written while the statement is running. On the master, this does not cause problems with concurrency, because tables are locked until the bulk operation terminates. On the slave server, however, tables are not locked while the slave applies changes, because the slave does not know that those changes are part of a bulk operation.

In such cases, if you retrieve data from a table on the master (for example, using `SELECT * FROM table_name`), the server waits for the bulk operation to complete before executing the `SELECT` statement, because the table is read-locked. On the slave, the server does not wait (because there is no lock). This means that, until the bulk operation on the slave has completed, you obtain different results for the same `SELECT` query on the master and on the slave.

This behavior is expected to change in a future MySQL release; however, until it changes, you may prefer to use statement-based replication when your application requires concurrent large bulk inserts and selects.

16.1.2.2. Usage of Row-based Logging and Row-Based Replication

Using row-based logging or replication, rather than statement-based logging or replication, can result in major changes in the replication environment and in the behavior of applications. This section describes a number of issues known to exist when using row-based logging or row-based replication, and discusses some best practices for taking advantage of row-based logging (RBL) and row-based replication (RBR).

For additional information, see [Section 16.1.2.1, “Comparison of Statement-Based and Row-Based Replication”](#), and [Section 16.1.2, “Replication Formats”](#).

- **RBR and primary keys.** Currently, row-based replication may fail if any table to be replicated does not have an explicit primary key. This is a known issue which we are working to fix in a future MySQL release.

Note

Beginning with MySQL 5.1.7, it is possible to replicate `NDBCLUSTER` tables without explicit primary keys. However, in the event that a MySQL Cluster data node fails, MySQL Cluster Replication can also fail for tables without explicit primary keys. For this reason, it is highly recommended that all `NDBCLUSTER` tables being replicated have explicit primary keys. For more information, see [Section 17.9.3, “Known Issues in MySQL Cluster Replication”](#).

- **RBL, RBR, and temporary tables.** As noted elsewhere in this chapter (see [Section 16.3.1.22, “Replication and Temporary Tables”](#)), temporary tables are not replicated when using the row-based format. However, you can use the mixed format; when mixed format is in effect, “safe” statements involving temporary tables are logged using the statement-based format. For more information, see [Section 16.1.2.1, “Comparison of Statement-Based and Row-Based Replication”](#).

Note

There is actually no need to replicate temporary tables when using RBR. In addition, since temporary tables can be read only from the thread which created them, there is seldom if ever any benefit obtained from replicating them, even when using statement-based mode.

- **RBL and the `BLACKHOLE` storage engine.** Prior to MySQL 5.1.29, `DELETE` and `UPDATE` statements did not work with RBL and `BLACKHOLE` tables. ([Bug#38360](#))
- **RBL and synchronization of non-transactional tables.** When using row-based replication of a `MyISAM` or other non-transactional table, changed rows are written to the transaction cache. Often, when many rows are affected, the set of changes are split into several events; when the statement commits, all of these events are written to the binary log. When executing on the slave, a table lock is taken on all tables involved, then the rows are applied in batch mode. (This may or may not be effective, depending on the engine used for the slave’s copy of the table).
- **Latency and binary log size.** Because RBL writes changes for each row to the binary log, the size of the binary log can grow quite rapidly. When used in a replication environment, this can significantly increase the time required for making the changes on the slave that match those on the master. You should be aware of the potential for this delay in your applications.
- **Reading the binary log.** With the `--base64-output=DECODE-ROWS` and `--verbose` options, `mysqlbinlog` is able to format the contents of the binary log in a manner that is easily human-readable, in case you want to read or recover from a replication or database failure using the contents of the binary log. For more information, see [Section 4.6.7.2, “mysqlbinlog Row Event Display”](#). Before MySQL 5.1.28, this was not possible ([Bug#31455](#)).
- **Binary log execution errors and `slave_exec_mode`.** If you use `slave_exec_mode=IDEMPOTENT`, a failure to apply changes from RBL because the original row cannot be found does not trigger an error, and does not cause replication to fail. This means that it is possible that updates are not applied on the slave, so that the master and slave are no longer synchronized. Latency issues and use of non-transactional tables when using `slave_exec_mode=IDEMPOTENT` and RBR can cause the master and slave to diverge even further. For more information about `slave_exec_mode`, see [Section 5.1.3, “Server System Variables”](#).

Note

`slave_exec_mode=IDEMPOTENT` is generally useful only for circular replication or multi-master replication with MySQL Cluster (see [Section 17.9, “MySQL Cluster Replication”](#)). For other scenarios, the default value (`slave_exec_mode=STRICT`) is normally sufficient.

- **Lack of binary log checksums.** No checksums are used for RBL. This means that network, disk, and other errors may not be identified when processing the binary log. To ensure that data is transmitted without network corruption, you may want to consider using SSL, which adds another layer of checksumming, for replication connections. See [Section 5.5.7, “Using SSL for Secure Connections”](#), for more information about setting up MySQL with SSL.
- **Filtering based on server ID not supported.** A common practice is to filter out changes on some slaves by using a `WHERE` clause that includes the relation `@server_id <> server-id` clause with `UPDATE` and `DELETE` statements, a simple ex-

ample of such a clause being `WHERE @server_id <> 1`. However, this does not work correctly with row-based logging. If you must use the `server_id` system variable for statement filtering, then you must also use `--binlog_format=STATEMENT`.

- **Database-level replication options.** The effects of the options `--replicate-do-db`, `--replicate-ignore-db`, and `--replicate-rewrite-db` differ considerably depending on whether row-based or statement-based logging is in use. Because of this, we recommend that you avoid the database-level options and use the table-level options such as `--replicate-do-table` and `--replicate-ignore-table` instead. For more information about these options and the impact that your choice of replication format has on how they operate, see [Section 16.1.3, “Replication and Binary Logging Options and Variables”](#).

16.1.3. Replication and Binary Logging Options and Variables

The next few sections contain information about `mysqld` options and server variables that are used in replication and for controlling the binary log. Options and variables for use on replication masters and replication slaves are covered separately, as are options and variables relating to binary logging. A set of quick-reference tables providing basic information about these options and variables is also included (in the next section following this one).

Of particular importance is the `--server-id` option.

Command Line Format	<code>--server-id=#</code>	
Config File Format	<code>server-id</code>	
Option Sets Variable	Yes, <code>server_id</code>	
Variable Name	<code>server_id</code>	
Variable Scope	Global	
Dynamic Variable	Yes	
Value Set	Type	<code>numeric</code>
	Default	<code>0</code>
	Range	<code>0-4294967295</code>

This option is common to both master and slave replication servers, and is used in replication to enable master and slave servers to identify themselves uniquely. For additional information, see [Section 16.1.3.2, “Replication Master Options and Variables”](#), and [Section 16.1.3.3, “Replication Slave Options and Variables”](#).

On the master and each slave, you *must* use the `--server-id` option to establish a unique replication ID in the range from 1 to $2^{32} - 1$; by “unique”, we mean that each ID must be different from every other ID in use by any other replication master or slave. Example: `server-id=3`.

If you omit `--server-id`, it assumes the default value 0, in which case a master refuses connections from all slaves, and a slave refuses to connect to a master. See [Section 16.1.1.3, “Setting the Replication Slave Configuration”](#), for more information.

16.1.3.1. Replication and Binary Logging Option and Variable Reference

The following tables list basic information about the MySQL command-line options and system variables applicable to replication and the binary log.

Table 16.1. `mysqld` Replication Option/Variable Summary

Name	Cmd-Line	Option file	System Var	Status Var	Var Scope	Dynamic
<code>abort-slave-event-count</code>	Yes	Yes				
<code>Com_change_master</code>				Yes	Both	No
<code>Com_show_master_status</code>				Yes	Both	No
<code>Com_show_new_master</code>				Yes	Both	No
<code>Com_show_slave_hosts</code>				Yes	Both	No
<code>Com_show_slave_status</code>				Yes	Both	No
<code>Com_slave_start</code>				Yes	Both	No
<code>Com_slave_stop</code>				Yes	Both	No
<code>disconnect-slave-event-count</code>	Yes	Yes				

Name	Cmd-Line	Option file	System Var	Status Var	Var Scope	Dynamic
have_row_based_replication			Yes		Global	No
init_slave	Yes	Yes	Yes		Global	Yes
log_slave_updates	Yes	Yes			Global	No
- Variable: log_slave_updates			Yes		Global	No
master_bind	Yes	Yes	Yes			No
master_connect_retry	Yes	Yes				
master_host	Yes	Yes				
master_info_file	Yes	Yes				
master_password	Yes	Yes				
master_port	Yes	Yes				
master_retry_count	Yes	Yes				
master_ssl	Yes	Yes				
master_ssl_ca	Yes	Yes				
master_ssl_capath	Yes	Yes				
master_ssl_cert	Yes	Yes				
master_ssl_cipher	Yes	Yes				
master_ssl_key	Yes	Yes				
master_user	Yes	Yes				
relay_log	Yes	Yes				
relay_log_index	Yes	Yes				
- Variable: relay_log_index						
relay_log_purge	Yes	Yes	Yes		Global	Yes
replicate_do_db	Yes	Yes				
replicate_do_table	Yes	Yes				
replicate_ignore_db	Yes	Yes				
replicate_ignore_table	Yes	Yes				
replicate_rewrite_db	Yes	Yes				
replicate_same_server_id	Yes	Yes				
replicate_wild_do_table	Yes	Yes				
replicate_wild_ignore_table	Yes	Yes				
report_host	Yes	Yes			Global	No
- Variable: report_host			Yes		Global	No
report_password	Yes	Yes			Global	No
- Variable: report_password			Yes		Global	No
report_port	Yes	Yes			Global	No
- Variable: report_port			Yes		Global	No
report_user	Yes	Yes			Global	No
- Variable: report_user			Yes		Global	No
rpl_recovery_rank			Yes		Global	Yes
Rpl_status				Yes	Global	No
show_slave_auth_info	Yes	Yes				
skip_slave_start	Yes	Yes				
slave_compressed_protocol	Yes	Yes	Yes		Global	Yes
slave_exec_mode			Yes		Global	Yes
Slave_heartbeat_period				Yes	Global	No
slave_load_tmpdir	Yes	Yes			Global	No
- Variable: slave_load_tmpdir			Yes		Global	No

Name	Cmd-Line	Option file	System Var	Status Var	Var Scope	Dynamic
slave-net-timeout	Yes	Yes			Global	Yes
- Variable: <code>slave_net_timeout</code>			Yes		Global	Yes
Slave_open_temp_tables				Yes	Global	No
Slave_received_heartbeats				Yes	Global	No
Slave_retried_transactions				Yes	Global	No
Slave_running				Yes	Global	No
slave-skip-errors	Yes	Yes			Global	No
- Variable: <code>slave_skip_errors</code>			Yes		Global	No
slave_transaction_retries	Yes	Yes	Yes		Global	Yes
sql_slave_skip_counter			Yes		Global	Yes

Section 16.1.3.2, “Replication Master Options and Variables”, provides more detailed information about options and variables relating to replication master servers. For more information about options and variables relating to replication slaves Section 16.1.3.3, “Replication Slave Options and Variables”.

Table 16.2. `mysqld` Binary Logging Option/Variable Summary

Name	Cmd-Line	Option file	System Var	Status Var	Var Scope	Dynamic
Binlog_cache_disk_use				Yes	Global	No
binlog_cache_size	Yes	Yes	Yes		Global	Yes
Binlog_cache_use				Yes	Global	No

Com_show_binlogs				Yes	Both	No
max_binlog_cache_size	Yes	Yes	Yes		Global	Yes
max-binlog-dump-events	Yes	Yes				
max_binlog_size	Yes	Yes	Yes		Global	Yes
sporadic-binlog-dump-fail	Yes	Yes				

Section 16.1.3.4, “Binary Log Options and Variables”, provides more detailed information about options and variables relating to binary logging. For additional general information about the binary log, see Section 5.2.4, “The Binary Log”.

For a table showing *all* command-line options, system and status variables used with `mysqld`, see Section 5.1.1, “Server Option and Variable Reference”.

16.1.3.2. Replication Master Options and Variables

This section describes the server options and system variables that you can use on replication master servers. You can specify the options either on the [command line](#) or in an [option file](#). You can specify system variable values using [SET](#).

On the master and each slave, you must use the `server-id` option to establish a unique replication ID. For each server, you should pick a unique positive integer in the range from 1 to $2^{32} - 1$, and each ID must be different from every other ID in use by any other replication master or slave. Example: `server-id=3`.

For options used on the master for controlling binary logging, see Section 16.1.3.4, “Binary Log Options and Variables”.

- `auto_increment_increment`

Command Line Format	
	<code>--auto_increment_increment[=#]</code>

Config File Format	<code>auto_increment_increment</code>	
Option Sets Variable	Yes, <code>auto_increment_increment</code>	
Variable Name	<code>auto_increment_increment</code>	
Variable Scope	Both	
Dynamic Variable	Yes	
Value Set	Type	numeric
	Default	1
	Range	1-65535

`auto_increment_increment` and `auto_increment_offset` are intended for use with master-to-master replication, and can be used to control the operation of `AUTO_INCREMENT` columns. Both variables have global and session values, and each can assume an integer value between 1 and 65,535 inclusive. Setting the value of either of these two variables to 0 causes its value to be set to 1 instead. Attempting to set the value of either of these two variables to an integer greater than 65,535 or less than 0 causes its value to be set to 65,535 instead. Attempting to set the value of `auto_increment_increment` or `auto_increment_offset` to a non-integer value gives rise to an error, and the actual value of the variable remains unchanged.

Note

`auto_increment_increment` is supported for use with NDB tables beginning with MySQL 5.1.20, MySQL Cluster NDB 6.2.5, and MySQL Cluster NDB 6.3.2. Previously, setting it when using MySQL Cluster tables or MySQL Cluster Replication produced unpredictable results.

These two variables affect `AUTO_INCREMENT` column behavior as follows:

- `auto_increment_increment` controls the interval between successive column values. For example:

```
mysql> SHOW VARIABLES LIKE 'auto_inc%';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| auto_increment_increment | 1 |
| auto_increment_offset | 1 |
+-----+-----+
2 rows in set (0.00 sec)

mysql> CREATE TABLE autoinc1
-> (col INT NOT NULL AUTO INCREMENT PRIMARY KEY);
Query OK, 0 rows affected (0.04 sec)

mysql> SET @@auto_increment_increment=10;
Query OK, 0 rows affected (0.00 sec)

mysql> SHOW VARIABLES LIKE 'auto_inc%';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| auto_increment_increment | 10 |
| auto_increment_offset | 1 |
+-----+-----+
2 rows in set (0.01 sec)

mysql> INSERT INTO autoinc1 VALUES (NULL), (NULL), (NULL), (NULL);
Query OK, 4 rows affected (0.00 sec)
Records: 4 Duplicates: 0 Warnings: 0

mysql> SELECT col FROM autoinc1;
+----+
| col |
+----+
| 1 |
| 11 |
| 21 |
| 31 |
+----+
4 rows in set (0.00 sec)
```

(Note how `SHOW VARIABLES` is used here to obtain the current values for these variables.)

- `auto_increment_offset` determines the starting point for the `AUTO_INCREMENT` column value. Consider the following, assuming that these statements are executed during the same session as the example given in the description for `auto_increment_increment`:

```
mysql> SET @@auto_increment_offset=5;
Query OK, 0 rows affected (0.00 sec)
```

```
mysql> SHOW VARIABLES LIKE 'auto_inc%';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| auto_increment_increment | 10 |
| auto_increment_offset | 5 |
+-----+-----+
2 rows in set (0.00 sec)

mysql> CREATE TABLE autoinc2
-> (col INT NOT NULL AUTO_INCREMENT PRIMARY KEY);
Query OK, 0 rows affected (0.06 sec)

mysql> INSERT INTO autoinc2 VALUES (NULL), (NULL), (NULL), (NULL);
Query OK, 4 rows affected (0.00 sec)
Records: 4 Duplicates: 0 Warnings: 0

mysql> SELECT col FROM autoinc2;
+-----+
| col |
+-----+
| 5 |
| 15 |
| 25 |
| 35 |
+-----+
4 rows in set (0.02 sec)
```

If the value of `auto_increment_offset` is greater than that of `auto_increment_increment`, the value of `auto_increment_offset` is ignored.

Should one or both of these variables be changed and then new rows inserted into a table containing an `AUTO_INCREMENT` column, the results may seem counterintuitive because the series of `AUTO_INCREMENT` values is calculated without regard to any values already present in the column, and the next value inserted is the least value in the series that is greater than the maximum existing value in the `AUTO_INCREMENT` column. In other words, the series is calculated like so:

$$\text{auto_increment_offset} + N \times \text{auto_increment_increment}$$

where N is a positive integer value in the series [1, 2, 3, ...]. For example:

```
mysql> SHOW VARIABLES LIKE 'auto_inc%';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| auto_increment_increment | 10 |
| auto_increment_offset | 5 |
+-----+-----+
2 rows in set (0.00 sec)

mysql> SELECT col FROM autoinc1;
+-----+
| col |
+-----+
| 1 |
| 11 |
| 21 |
| 31 |
+-----+
4 rows in set (0.00 sec)

mysql> INSERT INTO autoinc1 VALUES (NULL), (NULL), (NULL), (NULL);
Query OK, 4 rows affected (0.00 sec)
Records: 4 Duplicates: 0 Warnings: 0

mysql> SELECT col FROM autoinc1;
+-----+
| col |
+-----+
| 1 |
| 11 |
| 21 |
| 31 |
| 35 |
| 45 |
| 55 |
| 65 |
+-----+
8 rows in set (0.00 sec)
```

The values shown for `auto_increment_increment` and `auto_increment_offset` generate the series $5 + N \times 10$, that is, [5, 15, 25, 35, 45, ...]. The greatest value present in the `col` column prior to the `INSERT` is 31, and the next available value in the `AUTO_INCREMENT` series is 35, so the inserted values for `col` begin at that point and the results are as shown for the `SELECT` query.

It is not possible to confine the effects of these two variables to a single table, and thus they do not take the place of the se-

quences offered by some other database management systems; these variables control the behavior of all `AUTO_INCREMENT` columns in *all* tables on the MySQL server. If the global value of either variable is set, its effects persist until the global value is changed or overridden by setting the session value, or until `mysqld` is restarted. If the local value is set, the new value affects `AUTO_INCREMENT` columns for all tables into which new rows are inserted by the current user for the duration of the session, unless the values are changed during that session.

The default value of `auto_increment_increment` is 1. See [Section 16.3.1.1, “Replication and AUTO_INCREMENT”](#).

- `auto_increment_offset`

Command Line Format	<code>--auto_increment_offset[=#]</code>	
Config File Format	<code>auto_increment_offset</code>	
Option Sets Variable	Yes, <code>auto_increment_offset</code>	
Variable Name	<code>auto_increment_offset</code>	
Variable Scope	Both	
Dynamic Variable	Yes	
Value Set	Type	numeric
	Default	1
	Range	1-65535

This variable has a default value of 1. For particulars, see the description for `auto_increment_increment`.

Note

`auto_increment_offset` is supported for use with NDB tables beginning with MySQL 5.1.20, MySQL Cluster NDB 6.2.5, and MySQL Cluster NDB 6.3.2. Previously, setting it when using MySQL Cluster tables or MySQL Cluster Replication produced unpredictable results.

16.1.3.3. Replication Slave Options and Variables

This section describes the server options and system variables that you can use on slave replication servers. You can specify the options either on the [command line](#) or in an [option file](#). Many of the options can be reset while the server is running by using the `CHANGE MASTER TO` statement. You can specify system variable values using `SET`.

Server ID. On the master and each slave, you must use the `server-id` option to establish a unique replication ID. For each server, you should pick a unique positive integer in the range from 1 to $2^{32} - 1$, and each ID must be different from every other ID. Example: `server-id=3`.

Important

Certain options are handled in a special way in order to ensure that the active replication configuration is not inadvertently altered or affected:

- In MySQL 5.1.16 and earlier, these options are ignored if the `master.info` file exists (i.e. when the MySQL server has already previously been configured for replication). If the file exists and these options are present in the `my.cnf` or as options on the command line to `mysqld`, they are silently ignored and the information in `master.info` used instead.
- **Options deprecated.** *Beginning with MySQL 5.1.17, these options are deprecated. As of MySQL 6.0, they have been removed.* In MySQL 5.1.17 and later versions of MySQL 5.1, these options have no effect when `mysqld` is started and an appropriate warning is written to the error log. To set the replication parameters associated with these you must use the `CHANGE MASTER TO ...` statement (see [Section 12.6.2.1, “CHANGE MASTER TO Syntax”](#)).

The options affected are shown in this list:

- `--master-host`
- `--master-user`

- `--master-password`
- `--master-port`
- `--master-connect-retry`
- `--master-ssl`
- `--master-ssl-ca`
- `--master-ssl-capath`
- `--master-ssl-cert`
- `--master-ssl-cipher`
- `--master-ssl-key`

The `master.info` file format in MySQL 5.1 includes values corresponding to the SSL options. In addition, the file format includes as its first line the number of lines in the file. (See [Section 16.4.2, “Replication Relay and Status Files”](#).) If you upgrade an older server (before MySQL 4.1.1) to a newer version, the new server upgrades the `master.info` file to the new format automatically when it starts. However, if you downgrade a newer server to an older version, you should remove the first line manually before starting the older server for the first time.

If no `master.info` file exists when the slave server starts, it uses the values for those options that are specified in option files or on the command line. This occurs when you start the server as a replication slave for the very first time, or when you have run `RESET SLAVE` and then have shut down and restarted the slave.

If the `master.info` file exists when the slave server starts, the server uses its contents and ignores any options that correspond to the values listed in the file. Thus, if you start the slave server with different values of the startup options that correspond to values in the `master.info` file, the different values have no effect, because the server continues to use the `master.info` file. To use different values, you must either restart after removing the `master.info` file or (preferably) use the `CHANGE MASTER TO` statement to reset the values while the slave is running.

Suppose that you specify this option in your `my.cnf` file:

```
[mysqld]
master-host=some_host
```

The first time you start the server as a replication slave, it reads and uses that option from the `my.cnf` file. The server then records the value in the `master.info` file. The next time you start the server, it reads the master host value from the `master.info` file only and ignores the value in the option file. If you modify the `my.cnf` file to specify a different master host of `some_other_host`, the change still has no effect. You should use `CHANGE MASTER TO` instead.

This example shows a more extensive use of startup options to configure a pre-5.1.17 slave server:

```
[mysqld]
server-id=2
master-host=db-master.mycompany.com
master-port=3306
master-user=pertinax
master-password=freitag
master-connect-retry=60
report-host=db-slave.mycompany.com
```

Note

Because the server gives an existing `master.info` file precedence over the startup options just described, you might prefer not to use startup options for these values at all, and instead to specify them by using the `CHANGE MASTER TO` statement. Beginning with MySQL 5.1.17, you *must* use `CHANGE MASTER TO` to set the values corresponding to the deprecated options listed earlier in this section.

Startup options for replication slaves. The following list describes startup options for controlling replication slaves. Many of these options can be reset while the server is running by using the `CHANGE MASTER TO` statement. Others, such as the `-replicate-*` options, can be set only when the slave server starts. Replication-related system variables are discussed later in this section.

- `--log-slave-updates`

Normally, a slave does not log to its own binary log any updates that are received from a master server. This option tells the

slave to log the updates performed by its SQL thread to its own binary log. For this option to have any effect, the slave must also be started with the `--log-bin` option to enable binary logging. `--log-slave-updates` is used when you want to chain replication servers. For example, you might want to set up replication servers using this arrangement:

```
A -> B -> C
```

Here, **A** serves as the master for the slave **B**, and **B** serves as the master for the slave **C**. For this to work, **B** must be both a master *and* a slave. You must start both **A** and **B** with `--log-bin` to enable binary logging, and **B** with the `--log-slave-updates` option so that updates received from **A** are logged by **B** to its binary log.

When using MySQL Cluster Replication prior to MySQL Cluster NDB 6.2.16 and MySQL Cluster NDB 6.3.13, records for “empty” epochs — that is, epochs in which no changes to `NDBCLUSTER` data or tables took place — were inserted into the `ndb_apply_status` and `ndb_binlog_index` tables on the slave even when `--log-slave-updates` was disabled ([Bug#37472](#)). Beginning with MySQL Cluster NDB 6.3.21 and MySQL Cluster NDB 6.4.1, it is possible to re-enable the older behavior by using the `--ndb-log-empty-epochs` option.

- `--log-slow-slave-statements`

Version Introduced	5.1.21	
Command Line Format	<code>--log-slow-slave-statements</code>	
Config File Format	<code>log-slow-slave-statements</code>	
Value Set	Type	boolean
	Default	off

When the slow query log is enabled, this option enables logging for queries that have taken more than `long_query_time` seconds to execute on the slave.

This option was added in MySQL 5.1.21.

- `--log-warnings[=level]`

This option causes a server to print more messages to the error log about what it is doing. With respect to replication, the server generates warnings that it succeeded in reconnecting after a network/connection failure, and informs you as to how each slave thread started. This option is enabled by default; to disable it, use `--skip-log-warnings`. Aborted connections are not logged to the error log unless the value is greater than 1.

Note that the effects of this option are not limited to replication. It produces warnings across a spectrum of server activities.

- `--master-connect-retry=seconds`

The number of seconds that the slave thread sleeps before trying to reconnect to the master in case the master goes down or the connection is lost. The value in the `master.info` file takes precedence if it can be read. If not set, the default is 60. Connection retries are not invoked until the slave times out reading data from the master according to the value of `--slave-net-timeout`. The number of reconnection attempts is limited by the `--master-retry-count` option.

This option is deprecated as of MySQL 5.1.17, and removed as of MySQL 6.0.

- `--master-host=host_name`

The host name or IP number of the master replication server. The value in `master.info` takes precedence if it can be read. If no master host is specified, the slave thread does not start.

This option is deprecated as of MySQL 5.1.17, and removed as of MySQL 6.0.

- `--master-info-file=file_name`

The name to use for the file in which the slave records information about the master. The default name is `master.info` in the data directory.

- `--master-password=password`

The password of the account that the slave thread uses for authentication when it connects to the master. The value in the `master.info` file takes precedence if it can be read. If not set, an empty password is assumed.

This option is deprecated as of MySQL 5.1.17, and removed as of MySQL 6.0.

- `--master-port=port_number`

The TCP/IP port number that the master is listening on. The value in the `master.info` file takes precedence if it can be read. If not set, the compiled-in setting is assumed (normally 3306).

This option is deprecated as of MySQL 5.1.17, and removed as of MySQL 6.0.

- `--master-retry-count=count`

The number of times that the slave tries to connect to the master before giving up. Reconnects are attempted at intervals set by `--master-connect-retry` and reconnects are triggered when data reads by the slave time out according to the `--slave-net-timeout` option. The default value is 86400.

You can also set the retry count by using the `MASTER_CONNECT_RETRY` option for the `CHANGE MASTER TO` statement.

- `--master-ssl, --master-ssl-ca=file_name, --master-ssl-capath=directory_name, --master-ssl-cert=file_name, --master-ssl-cipher=cipher_list, --master-ssl-key=file_name`

These options are used for setting up a secure replication connection to the master server using SSL. Their meanings are the same as the corresponding `--ssl, --ssl-ca, --ssl-capath, --ssl-cert, --ssl-cipher, --ssl-key` options that are described in [Section 5.5.7.3, “SSL Command Options”](#). The values in the `master.info` file take precedence if they can be read.

These options are deprecated as of MySQL 5.1.17, and removed as of MySQL 6.0.

- `--master-user=user_name`

The user name of the account that the slave thread uses for authentication when it connects to the master. This account must have the `REPLICATION SLAVE` privilege. The value in the `master.info` file takes precedence if it can be read. If the master user name is not set, the name `test` is assumed.

This option is deprecated as of MySQL 5.1.17, and removed as of MySQL 6.0.

- `--max-relay-log-size=size`

The size at which the server rotates relay log files automatically. For more information, see [Section 16.4.2, “Replication Relay and Status Files”](#). The default size is 1GB.

- `--read-only`

Cause the slave to allow no updates except from slave threads or from users having the `SUPER` privilege. On a slave server, this can be useful to ensure that the slave accepts updates only from its master server and not from clients. This variable does not apply to `TEMPORARY` tables.

- `--relay-log=file_name`

The basename for the relay log. The default basename is `host_name-relay-bin`. The server creates relay log files in sequence by adding a numeric suffix to the basename.

Due to the manner in which MySQL parses server options, if you specify this option, you must supply a value; *the default base-name is used only if the option is not actually specified*. If you use the `--relay-log` option without specifying a value, unexpected behavior is likely to result; this behavior depends on the other options used, the order in which they are specified, and whether they are specified on the command line or in an option file. For more information about how MySQL handles server options, see [Section 4.2.3, “Specifying Program Options”](#).

If you specify this option, the value specified is also used as the basename for the relay log index file. You can override this behavior by specifying a different relay log index file basename using the `--relay-log-index` option.

You may find the `--relay-log` option useful in performing the following tasks:

- Creating relay logs whose names are independent of host names.
- If you need to put the relay logs in some area other than the data directory, because your relay logs tend to be very large and you do not want to decrease `max_relay_log_size`.
- To increase speed by using load-balancing between disks.
- `--relay-log-index=file_name`

The name to use for the relay log index file. The default name is `host_name-relay-bin.index` in the data directory, where `host_name` is the name of the slave server.

Due to the manner in which MySQL parses server options, if you specify this option, you must supply a value; *the default base-name is used only if the option is not actually specified*. If you use the `--relay-log-index` option without specifying a value, unexpected behavior is likely to result; this behavior depends on the other options used, the order in which they are specified, and whether they are specified on the command line or in an option file. For more information about how MySQL handles server options, see [Section 4.2.3, “Specifying Program Options”](#).

If you specify this option, the value specified is also used as the basename for the relay logs. You can override this behavior by specifying a different relay log file basename using the `--relay-log` option.

- `--relay-log-info-file=file_name`

The name to use for the file in which the slave records information about the relay logs. The default name is `relay-log.info` in the data directory.

- `--relay-log-purge={0|1}`

Disable or enable automatic purging of relay logs as soon as they are no longer needed. The default value is 1 (enabled). This is a global variable that can be changed dynamically with `SET GLOBAL relay_log_purge = N`.

- `--relay-log-space-limit=size`

This option places an upper limit on the total size in bytes of all relay logs on the slave. A value of 0 means “no limit.” This is useful for a slave server host that has limited disk space. When the limit is reached, the I/O thread stops reading binary log events from the master server until the SQL thread has caught up and deleted some unused relay logs. Note that this limit is not absolute: There are cases where the SQL thread needs more events before it can delete relay logs. In that case, the I/O thread exceeds the limit until it becomes possible for the SQL thread to delete some relay logs, because not doing so would cause a deadlock. You should not set `--relay-log-space-limit` to less than twice the value of `--max-relay-log-size` (or `--max-binlog-size` if `--max-relay-log-size` is 0). In that case, there is a chance that the I/O thread waits for free space because `--relay-log-space-limit` is exceeded, but the SQL thread has no relay log to purge and is unable to satisfy the I/O thread. This forces the I/O thread to ignore `--relay-log-space-limit` temporarily.

- `--replicate-do-db=db_name`

The effects of this option depend on whether statement-based or row-based replication is in use.

Statement-based replication. Tell the slave to restrict replication to statements where the default database (that is, the one selected by `USE`) is `db_name`. To specify more than one database, use this option multiple times, once for each database; however, doing so does *not* replicate cross-database statements such as `UPDATE some_db.some_table SET foo='bar'` while a different database (or no database) is selected.

Warning

To specify multiple databases you *must* use multiple instances of this option. Because database names can contain commas, if you supply a comma separated list then the list will be treated as the name of a single database.

An example of what does not work as you might expect when using statement-based replication: If the slave is started with `--replicate-do-db=sales` and you issue the following statements on the master, the `UPDATE` statement is *not* replicated:

```
USE prices;
UPDATE sales.january SET amount=amount+1000;
```

The main reason for this “check just the default database” behavior is that it is difficult from the statement alone to know whether it should be replicated (for example, if you are using multiple-table `DELETE` statements or multiple-table `UPDATE` statements that act across multiple databases). It is also faster to check only the default database rather than all databases if there is no need.

Row-based replication. Tells the slave to restrict replication to database `db_name`. Only tables belonging to `db_name` are changed; the current database has no effect on this. For example, suppose that the slave is started with `--replicate-do-db=sales` and row-based replication is in effect, and then the following statements are run on the master:

```
USE prices;
UPDATE sales.february SET amount=amount+100;
```

The `february` table in the `sales` database on the slave is changed in accordance with the `UPDATE` statement; this occurs whether or not the `USE` statement was issued. However, issuing the following statements on the master has no effect on the slave when using row-based replication and `--replicate-do-db=sales`:

```
USE prices;
UPDATE prices.march SET amount=amount-25;
```

Even if the statement `USE prices` were changed to `USE sales`, the `UPDATE` statement's effects would still not be replicated.

Another important difference in how `--replicate-do-db` is handled in statement-based replication as opposed to row-based replication occurs with regard to statements that refer to multiple databases. Suppose the slave is started with `--replicate-do-db=db1`, and the following statements are executed on the master:

```
USE db1;
UPDATE db1.table1 SET col1 = 10, db2.table2 SET col2 = 20;
```

If you are using statement-based replication, then both tables are updated on the slave. However, when using row-based replication, only `table1` is affected on the slave; since `table2` is in a different database, `table2` on the slave is not changed by the `UPDATE`. Now suppose that, instead of the `USE db1` statement, a `USE db4` statement had been used:

```
USE db4;
UPDATE db1.table1 SET col1 = 10, db2.table2 SET col2 = 20;
```

In this case, the `UPDATE` statement would have no effect on the slave when using statement-based replication. However, if you are using row-based replication, the `UPDATE` would change `table1` on the slave, but not `table2` — in other words, only tables in the database named by `--replicate-do-db` are changed, and the choice of current database has no effect on this behavior.

If you need cross-database updates to work, use `--replicate-wild-do-table=db_name.%` instead. See [Section 16.4.3, “How Servers Evaluate Replication Rules”](#).

Note

This option effects replication in the same manner that `--binlog-do-db` affects binary logging, and the affects of the replication format on how `--replicate-do-db` affects replication behavior are the same as those of the logging format on the behavior of `--binlog-do-db`.

- `--replicate-ignore-db=db_name`

As with `--replicate-do-db`, the effects of this option depend on whether statement-based or row-based replication is in use.

Statement-based replication. Tells the slave to not replicate any statement where the default database (that is, the one selected by `USE`) is `db_name`.

Row-based replication. Tells the slave not to update any tables in the database `db_name`. The current database has no effect.

When using statement-based replication, the following example does not work as you might expect. Suppose that the slave is started with `--replicate-ignore-db=sales` and you issue the following statements on the master:

```
USE prices;
UPDATE sales.january SET amount=amount+1000;
```

The `UPDATE` statement *is* replicated in such a case because `--replicate-ignore-db` applies only to the default database (determined by the `USE` statement). Because the `sales` database was specified explicitly in the statement, the statement has not been filtered. However, when using row-based replication, the `UPDATE` statement's effects are *not* propagated to the slave, and the slave's copy of the `sales.january` table is unchanged; in this instance, `--replicate-ignore-db=sales` causes *all* changes made to tables in the master's copy of the `sales` database to be ignored by the slave.

To specify more than one database to ignore, use this option multiple times, once for each database. Because database names can contain commas, if you supply a comma separated list then the list will be treated as the name of a single database.

You should not use this option if you are using cross-database updates and you do not want these updates to be replicated. See [Section 16.4.3, “How Servers Evaluate Replication Rules”](#).

If you need cross-database updates to work, use `--replicate-wild-ignore-table=db_name.%` instead. See [Section 16.4.3, “How Servers Evaluate Replication Rules”](#).

Note

This option effects replication in the same manner that `--binlog-ignore-db` affects binary logging, and the affects of the replication format on how `--replicate-ignore-db` affects replication behavior are the same as those of the logging format on the behavior of `--binlog-ignore-db`.

- `--replicate-do-table=db_name.tbl_name`

Tells the slave thread to restrict replication to the specified table. To specify more than one table, use this option multiple times, once for each table. This works for cross-database updates, in contrast to `--replicate-do-db`. See [Section 16.4.3, “How Servers Evaluate Replication Rules”](#).

- `--replicate-ignore-table=db_name.tbl_name`

Tells the slave thread to not replicate any statement that updates the specified table, even if any other tables might be updated by the same statement. To specify more than one table to ignore, use this option multiple times, once for each table. This works for cross-database updates, in contrast to `--replicate-ignore-db`. See [Section 16.4.3, “How Servers Evaluate Replication Rules”](#).

- `--replicate-rewrite-db=from_name->to_name`

Tells the slave to translate the default database (that is, the one selected by `USE`) to `to_name` if it was `from_name` on the master. Only statements involving tables are affected (not statements such as `CREATE DATABASE`, `DROP DATABASE`, and `ALTER DATABASE`), and only if `from_name` is the default database on the master. This does not work for cross-database updates. To specify multiple rewrites, use this option multiple times. The server uses the first one with a `from_name` value that matches. The database name translation is done *before* the `--replicate-*` rules are tested.

If you use this option on the command line and the “>” character is special to your command interpreter, quote the option value. For example:

```
shell> mysqld --replicate-rewrite-db="olddb->newdb"
```

- `--replicate-same-server-id`

To be used on slave servers. Usually you should use the default setting of 0, to prevent infinite loops caused by circular replication. If set to 1, the slave does not skip events having its own server ID. Normally, this is useful only in rare configurations. Cannot be set to 1 if `--log-slave-updates` is used. By default, the slave I/O thread does not write binary log events to the relay log if they have the slave’s server ID (this optimization helps save disk usage). If you want to use `--replicate-same-server-id`, be sure to start the slave with this option before you make the slave read its own events that you want the slave SQL thread to execute.

- `--replicate-wild-do-table=db_name.tbl_name`

Tells the slave thread to restrict replication to statements where any of the updated tables match the specified database and table name patterns. Patterns can contain the “%” and “_” wildcard characters, which have the same meaning as for the `LIKE` pattern-matching operator. To specify more than one table, use this option multiple times, once for each table. This works for cross-database updates. See [Section 16.4.3, “How Servers Evaluate Replication Rules”](#).

Example: `--replicate-wild-do-table=foo%.bar%` replicates only updates that use a table where the database name starts with `foo` and the table name starts with `bar`.

If the table name pattern is `%`, it matches any table name and the option also applies to database-level statements (`CREATE DATABASE`, `DROP DATABASE`, and `ALTER DATABASE`). For example, if you use `--replicate-wild-do-table=foo%.%`, database-level statements are replicated if the database name matches the pattern `foo%`.

To include literal wildcard characters in the database or table name patterns, escape them with a backslash. For example, to replicate all tables of a database that is named `my_own%db`, but not replicate tables from the `mylowAABCdb` database, you should escape the “_” and “%” characters like this: `--replicate-wild-do-table=my_own\%db`. If you’re using the option on the command line, you might need to double the backslashes or quote the option value, depending on your command interpreter. For example, with the `bash` shell, you would need to type `--replicate-wild-do-table=my_own\\%db`.

- `--replicate-wild-ignore-table=db_name.tbl_name`

Tells the slave thread not to replicate a statement where any table matches the given wildcard pattern. To specify more than one table to ignore, use this option multiple times, once for each table. This works for cross-database updates. See [Section 16.4.3, “How Servers Evaluate Replication Rules”](#).

Example: `--replicate-wild-ignore-table=foo%.bar%` does not replicate updates that use a table where the database name starts with `foo` and the table name starts with `bar`.

For information about how matching works, see the description of the `--replicate-wild-do-table` option. The rules for including literal wildcard characters in the option value are the same as for `--replicate-wild-ignore-table` as well.

- `--report-host=host_name`

The host name or IP number of the slave to be reported to the master during slave registration. This value appears in the output of `SHOW SLAVE HOSTS` on the master server. Leave the value unset if you do not want the slave to register itself with the master. Note that it is not sufficient for the master to simply read the IP number of the slave from the TCP/IP socket after the slave connects. Due to NAT and other routing issues, that IP may not be valid for connecting to the slave from the master or other hosts.

- `--report-password=password`

The account password of the slave to be reported to the master during slave registration. This value appears in the output of `SHOW SLAVE HOSTS` on the master server if the `--show-slave-auth-info` option is given.

- `--report-port=slave_port_num`

The TCP/IP port number for connecting to the slave, to be reported to the master during slave registration. Set this only if the slave is listening on a non-default port or if you have a special tunnel from the master or other clients to the slave. If you are not sure, do not use this option.

- `--report-user=user_name`

The account user name of the slave to be reported to the master during slave registration. This value appears in the output of `SHOW SLAVE HOSTS` on the master server if the `--show-slave-auth-info` option is given.

- `--show-slave-auth-info`

Display slave user names and passwords in the output of `SHOW SLAVE HOSTS` on the master server for slaves started with the `--report-user` and `--report-password` options.

- `--skip-slave-start`

Tells the slave server not to start the slave threads when the server starts. To start the threads later, use a `START SLAVE` statement.

- `--slave_compressed_protocol={0|1}`

If this option is set to 1, use compression for the slave/master protocol if both the slave and the master support it. The default is 0 (no compression).

- `--slave-load-tmpdir=file_name`

The name of the directory where the slave creates temporary files. This option is by default equal to the value of the `tmpdir` system variable. When the slave SQL thread replicates a `LOAD DATA INFILE` statement, it extracts the file to be loaded from the relay log into temporary files, and then loads these into the table. If the file loaded on the master is huge, the temporary files on the slave are huge, too. Therefore, it might be advisable to use this option to tell the slave to put temporary files in a directory located in some file system that has a lot of available space. In that case, the relay logs are huge as well, so you might also want to use the `--relay-log` option to place the relay logs in that file system.

The directory specified by this option should be located in a disk-based file system (not a memory-based file system) because the temporary files used to replicate `LOAD DATA INFILE` must survive machine restarts. The directory also should not be one that is cleared by the operating system during the system startup process.

- `--slave-net-timeout=seconds`

The number of seconds to wait for more data from the master before the slave considers the connection broken, aborts the read, and tries to reconnect. The first retry occurs immediately after the timeout. The interval between retries is controlled by the `MASTER_CONNECT_RETRY` option for the `CHANGE MASTER TO` statement or `--master-connect-retry` option, and the number of reconnection attempts is limited by the `--master-retry-count` option. The default is 3600 seconds (one hour).

- `--slave-skip-errors=[err_code1,err_code2,...|all]`

Normally, replication stops when an error occurs on the slave. This gives you the opportunity to resolve the inconsistency in the data manually. This option tells the slave SQL thread to continue replication when a statement returns any of the errors listed in the option value.

Do not use this option unless you fully understand why you are getting errors. If there are no bugs in your replication setup and client programs, and no bugs in MySQL itself, an error that stops replication should never occur. Indiscriminate use of this option results in slaves becoming hopelessly out of synchrony with the master, with you having no idea why this has occurred.

Note

Prior to MySQL 5.1.35, this option had no effect with row-based logging. (Bug#39393)

For error codes, you should use the numbers provided by the error message in your slave error log and in the output of `SHOW SLAVE STATUS`. Appendix B, *Errors, Error Codes, and Common Problems*, lists server error codes.

You can also (but should not) use the very non-recommended value of `all` to cause the slave to ignore all error messages and keeps going regardless of what happens. Needless to say, if you use `all`, there are no guarantees regarding the integrity of your

data. Please do not complain (or file bug reports) in this case if the slave's data is not anywhere close to what it is on the master. *You have been warned.*

Examples:

```
--slave-skip-errors=1062,1053
--slave-skip-errors=all
```

- `sql_slave_skip_counter`

Variable Name	<code>sql_slave_skip_counter</code>	
Variable Scope	Global	
Dynamic Variable	Yes	
Value Set	Type	numeric

The number of events from the master that a slave server should skip.

Important

If skipping the number of events specified by setting this variable would cause the slave to begin in the middle of an event group, the slave continues to skip until it finds the beginning of the next event group and begins from that point. See [Section 12.6.2.6, “SET GLOBAL SQL_SLAVE_SKIP_COUNTER Syntax”](#), for more information.

- `--abort-slave-event-count`

Command Line Format	<code>--abort-slave-event-count=#</code>	
Config File Format	<code>abort-slave-event-count</code>	
Value Set	Type	numeric
	Default	0
	Min Value	0

When this option is set to some positive integer *value* other than 0 (the default) it affects replication behavior as follows: After the slave SQL thread has started, *value* log events are allowed to be executed; after that, the slave SQL thread does not receive any more events, just as if the network connection from the master were cut. The slave thread continues to run, and the output from `SHOW SLAVE STATUS` displays `Yes` in both the `Slave_IO_Running` and the `Slave_SQL_Running` columns, but no further events are read from the relay log.

This option is used internally by the MySQL test suite for replication testing and debugging. It is not intended for use in a production setting.

- `--disconnect-slave-event-count`

Command Line Format	<code>--disconnect-slave-event-count=#</code>	
Config File Format	<code>disconnect-slave-event-count</code>	
Value Set	Type	numeric
	Default	0

This option is used internally by the MySQL test suite for replication testing and debugging.

System variables used on replication slaves. The following system variables are used for controlling replication slave servers. Those that can be set are specified using `SET`. Server options used with replication slaves are listed earlier in this section.

- `init_slave`

Command Line Format	<code>--init-slave=name</code>
Config File Format	<code>init_slave</code>
Option Sets Variable	Yes, <code>init_slave</code>

Variable Name	<code>init_slave</code>	
Variable Scope	Global	
Dynamic Variable	Yes	
Value Set	Type	<code>string</code>

This variable is similar to `init_connect`, but is a string to be executed by a slave server each time the SQL thread starts. The format of the string is the same as for the `init_connect` variable.

Note

The SQL thread sends an acknowledgement to the client before `init_slave` is executed. Therefore, it is not guaranteed that `init_slave` has been executed when `START SLAVE` returns. See [Section 12.6.2.7, “START SLAVE Syntax”](#), for more information.

- `rpl_recovery_rank`
This variable is unused.
- `slave_compressed_protocol`

Command Line Format	<code>--slave_compressed_protocol</code>	
Config File Format	<code>slave_compressed_protocol</code>	
Option Sets Variable	Yes, <code>slave_compressed_protocol</code>	
Variable Name	<code>slave_compressed_protocol</code>	
Variable Scope	Global	
Dynamic Variable	Yes	
Value Set	Type	<code>boolean</code>
	Default	<code>FALSE</code>

Whether to use compression of the slave/master protocol if both the slave and the master support it.

- `slave_exec_mode`

Version Introduced	5.1.24	
Variable Name	<code>slave_exec_mode</code>	
Variable Scope	Global	
Dynamic Variable	Yes	
Value Set	Type	<code>enumeration</code>
	Default	<code>STRICT</code>
	Valid Values	<code>IDEMPOTENT, STRICT</code>

Controls whether `IDEMPOTENT` or `STRICT` mode is used in replication conflict resolution and error checking. `IDEMPOTENT` mode causes suppression of duplicate-key and no-key-found errors. Beginning with MySQL 5.1.23-ndb-6.2.14 and MySQL 5.1.24, this mode should be employed in multi-master replication, circular replication, and some other special replication scenarios. `STRICT` mode is the default, and is suitable for most other cases.

- `slave_load_tmpdir`

Command Line Format	<code>--slave-load-tmpdir=name</code>	
Config File Format	<code>slave-load-tmpdir</code>	
Option Sets Variable	Yes, <code>slave_load_tmpdir</code>	
Variable Name	<code>slave_load_tmpdir</code>	
Variable Scope	Global	
Dynamic Variable	No	

Value Set	Type	filename
	Default	/tmp

The name of the directory where the slave creates temporary files for replicating `LOAD DATA INFILE` statements.

- `slave_net_timeout`

Command Line Format	<code>--slave-net-timeout=#</code>	
Config File Format	<code>slave-net-timeout</code>	
Option Sets Variable	Yes, <code>slave_net_timeout</code>	
Variable Name	<code>slave_net_timeout</code>	
Variable Scope	Global	
Dynamic Variable	Yes	
Value Set	Type	numeric
	Default	3600
	Min Value	1

The number of seconds to wait for more data from a master/slave connection before aborting the read. This timeout applies only to TCP/IP connections, not to connections made via Unix socket files, named pipes, or shared memory.

- `slave_skip_errors`

Command Line Format	<code>--slave-skip-errors=name</code>	
Config File Format	<code>slave-skip-errors</code>	
Option Sets Variable	Yes, <code>slave_skip_errors</code>	
Variable Name	<code>slave_skip_errors</code>	
Variable Scope	Global	
Dynamic Variable	No	

Normally, replication stops when an error occurs on the slave. This gives you the opportunity to resolve the inconsistency in the data manually. This variable tells the slave SQL thread to continue replication when a statement returns any of the errors listed in the variable value.

- `sql_slave_skip_counter`

Variable Name	<code>sql_slave_skip_counter</code>	
Variable Scope	Global	
Dynamic Variable	Yes	
Value Set	Type	numeric

The number of events from the master that a slave server should skip.

Important

If skipping the number of events specified by setting this variable would cause the slave to begin in the middle of an event group, the slave continues to skip until it finds the beginning of the next event group and begins from that point. See [Section 12.6.2.6, “SET GLOBAL SQL_SLAVE_SKIP_COUNTER Syntax”](#), for more information.

- `slave_transaction_retries`

Command Line Format	<code>--slave_transaction_retries=#</code>	
Config File Format	<code>slave_transaction_retries</code>	
Option Sets Variable	Yes, <code>slave_transaction_retries</code>	
Variable Name	<code>slave_transaction_retries</code>	

Variable Scope	Global	
Dynamic Variable	Yes	
Value Set	Platform Bit Size	32
	Type	numeric
	Default	10
	Range	0-4294967295
Value Set	Platform Bit Size	64
	Type	numeric
	Default	10
	Range	0-18446744073709547520

If a replication slave SQL thread fails to execute a transaction because of an `InnoDB` deadlock or because the transaction's execution time exceeded `InnoDB`'s `innodb_lock_wait_timeout` or `NDBCLUSTER`'s `TransactionDeadlockDetectionTimeout` or `TransactionInactiveTimeout`, it automatically retries `slave_transaction_retries` times before stopping with an error. The default value is 10.

16.1.3.4. Binary Log Options and Variables

You can use the `mysqld` options and system variables that are described in this section to affect the operation of the binary log as well as to control which statements are written to the binary log. For additional information about the binary log, see [Section 5.2.4, “The Binary Log”](#). For additional information about using MySQL server options and system variables, see [Section 5.1.2, “Server Command Options”](#), and [Section 5.1.3, “Server System Variables”](#).

Startup options used with binary logging. The following list describes startup options for enabling and configuring the binary log. Many of these options can be reset while the server is running by using the `CHANGE MASTER TO` statement. Others, can be set only when the slave server starts. System variables used with binary logging are discussed later in this section.

- `--binlog-row-event-max-size=N`

Version Introduced	5.1.5	
Command Line Format	<code>--binlog-row-event-max-size=#</code>	
Config File Format	<code>binlog-row-event-max-size</code>	
Value Set	Platform Bit Size	32
	Type	numeric
	Default	1024
	Range	256-4294967295
Value Set	Platform Bit Size	64
	Type	numeric
	Default	1024
	Range	256-18446744073709547520

Specify the maximum size of a row-based binary log event, in bytes. Rows are grouped into events smaller than this size if possible. The value should be a multiple of 256. The default is 1024. See [Section 16.1.2, “Replication Formats”](#). This option was added in MySQL 5.1.5.

- `--log-bin[=base_name]`

Command Line Format	<code>--log-bin</code>
Config File Format	<code>log-bin</code>
Variable Name	<code>log_bin</code>
Variable Scope	Global
Dynamic Variable	No

Value Set	Type	filename
	Default	OFF

Enable binary logging. The server logs all statements that change data to the binary log, which is used for backup and replication. See [Section 5.2.4, “The Binary Log”](#).

The option value, if given, is the basename for the log sequence. The server creates binary log files in sequence by adding a numeric suffix to the basename. It is recommended that you specify a basename (see [Section B.1.8.2, “Additional Known Issues”](#), for the reason). Otherwise, MySQL uses `host_name-bin` as the basename.

- `--log-bin-index[=file_name]`

Command Line Format	<code>--log-bin-index=name</code>	
Config File Format	<code>log-bin-index</code>	
Value Set	Type	filename
	Default	OFF

The index file for binary log file names. See [Section 5.2.4, “The Binary Log”](#). If you omit the file name, and if you didn't specify one with `--log-bin`, MySQL uses `host_name-bin.index` as the file name.

- **Statement selection options.** The options in the following list affect which statements are written to the binary log, and thus sent by a replication master server to its slaves.
 - `--binlog-do-db=db_name`

This option affects binary logging in the same manner that `--replicate-do-db` affects replication.

The effects of this option depend on whether the statement-based or row-based logging format is in use, in the same way that the effects of `--replicate-do-db` depend on whether statement-based or row-based replication is in use.

Statement-based logging. Only those statements where the default database (that is, the one selected by `USE`) is `db_name` are written to the binary log. To specify more than one database, use this option multiple times, once for each database; however, doing so does *not* cause cross-database statements such as `UPDATE some_db.some_table SET foo='bar'` to be logged while a different database (or no database) is selected.

Warning

To specify multiple databases you *must* use multiple instances of this option. Because database names can contain commas, if you supply a comma separated list then the list will be treated as the name of a single database.

An example of what does not work as you might expect when using statement-based logging: If the server is started with `--binlog-do-db=sales` and you issue the following statements, the `UPDATE` statement is *not* logged:

```
USE prices;
UPDATE sales.january SET amount=amount+1000;
```

The main reason for this “just check the default database” behavior is that it is difficult from the statement alone to know whether it should be replicated (for example, if you are using multiple-table `DELETE` statements or multiple-table `UPDATE` statements that act across multiple databases). It is also faster to check only the default database rather than all databases if there is no need.

Row-based logging. Logging is restricted to database `db_name`. Only changes to tables belonging to `db_name` are logged; the current database has no effect on this. For example, suppose that the server is started with `--replicate-do-db=sales` and row-based logging is in effect, and then the following statements are executed:

```
USE prices;
UPDATE sales.february SET amount=amount+100;
```

The `february` table in the `sales` database is changed in accordance with the `UPDATE` statement; this occurs whether or not the `USE` statement was issued. However, the following statements are not logged when using the row-based logging format and `--binlog-do-db=sales`:

```
USE prices;
UPDATE prices.march SET amount=amount-25;
```

Even if the statement `USE prices` were changed to `USE sales`, the `UPDATE` statement's effects would still not be written to the binary log.

Another important difference in how `--binlog-do-db` is handled when using the statement-based logging format as opposed to the row-based format occurs with regard to statements that refer to multiple databases. Suppose the server is started with `--binlog-do-db=db1`, and the following statements are executed:

```
USE db1;
UPDATE db1.table1 SET col1 = 10, db2.table2 SET col2 = 20;
```

If you are using statement-based logging, then the updates to both tables are written to the binary log. However, when using the row-based format, only the changes to `table1` logged; since `table2` is in a different database, it is not changed by the `UPDATE`. Now suppose that, instead of the `USE db1` statement, a `USE db4` statement had been used:

```
USE db4;
UPDATE db1.table1 SET col1 = 10, db2.table2 SET col2 = 20;
```

In this case, the `UPDATE` statement would not be written to the binary log when using statement-based logging. However, if using row-based logging, the `UPDATE` would change `table1`, but not `table2` — in other words, only tables in the database named by `--binlog-do-db` are changed, and the choice of current database has no effect on this behavior.

- `--binlog-ignore-db=db_name`

This option affects binary logging in the same manner that `--replicate-ignore-db` affects replication.

The effects of this option depend on whether the statement-based or row-based logging format is in use, in the same way that the effects of `--replicate-ignore-db` depend on whether statement-based or row-based replication is in use.

Statement-based logging. Tells the server to not log any statement where the default database (that is, the one selected by `USE`) is `db_name`.

Row-based format. Tells the server not to log updates to any tables in the database `db_name`. The current database has no effect.

When using statement-based logging, the following example does not work as you might expect. Suppose that the server is started with `--binlog-ignore-db=sales` and you issue the following statements:

```
USE prices;
UPDATE sales.january SET amount=amount+1000;
```

The `UPDATE` statement *is* logged in such a case because `--binlog-ignore-db` applies only to the default database (determined by the `USE` statement). Because the `sales` database was specified explicitly in the statement, the statement has not been filtered. However, when using row-based logging, the `UPDATE` statement's effects are *not* written to the binary log, which means that no changes to the `sales.january` table are logged; in this instance, `--binlog-ignore-db=sales` causes *all* changes made to tables in the master's copy of the `sales` database to be ignored for purposes of binary logging.

To specify more than one database to ignore, use this option multiple times, once for each database. Because database names can contain commas, if you supply a comma separated list then the list will be treated as the name of a single database.

You should not use this option if you are using cross-database updates and you do not want these updates to be logged.

Additional server options that can be used to control logging also affect the binary log. For more information about these, see [Section 5.1.2, “Server Command Options”](#). For more information about how the options in the previous list are applied, see [Section 5.2.4, “The Binary Log”](#).

There are also options for slave servers that control which statements received from the master should be executed or ignored. For details, see [Section 16.1.3.3, “Replication Slave Options and Variables”](#).

- `--log-bin-trust-function-creators[={0|1}]`

Command Line Format	<code>--log-bin-trust-function-creators</code>	
Config File Format	<code>log-bin-trust-function-creators</code>	
Option Sets Variable	Yes, <code>log_bin_trust_function_creators</code>	
Variable Name	<code>log_bin_trust_function_creators</code>	
Variable Scope	Global	
Dynamic Variable	Yes	
Value Set	Type	<code>boolean</code>
	Default	<code>FALSE</code>

With no argument or an argument of 1, this option sets the `log_bin_trust_function_creators` system variable to 1. With an argument of 0, this option sets the system variable to 0. `log_bin_trust_function_creators` affects how MySQL enforces restrictions on stored function and trigger creation. See [Section 19.6, “Binary Logging of Stored Programs”](#).

Note

Previously, this option was known as `--log-bin-trust-routine-creators`, which is now deprecated.

Testing and debugging options. The following binary log options are used in replication testing and debugging. They are not intended for use in normal operations.

- `--max-binlog-dump-events`

Command Line Format	<code>--max-binlog-dump-events=#</code>	
Config File Format	<code>max-binlog-dump-events</code>	
Value Set	Type	numeric
	Default	0

This option is used internally by the MySQL test suite for replication testing and debugging.

- `--sporadic-binlog-dump-fail`

Command Line Format	<code>--sporadic-binlog-dump-fail</code>	
Config File Format	<code>sporadic-binlog-dump-fail</code>	
Value Set	Type	boolean
	Default	FALSE

This option is used internally by the MySQL test suite for replication testing and debugging.

System variables used with the binary log. The following system variables are used for controlling replication slave servers. Those that can be set are specified using `SET`. Server options used with replication slaves are listed earlier in this section.

- `binlog_cache_size`

Command Line Format	<code>--binlog_cache_size=#</code>	
Config File Format	<code>binlog_cache_size</code>	
Option Sets Variable	Yes, <code>binlog_cache_size</code>	
Variable Name	<code>binlog_cache_size</code>	
Variable Scope	Global	
Dynamic Variable	Yes	
Value Set	Platform Bit Size	32
	Type	numeric
	Default	32768
	Range	4096-4294967295
Value Set	Platform Bit Size	64
	Type	numeric
	Default	32768
	Range	4096-18446744073709547520

The size of the cache to hold the SQL statements for the binary log during a transaction. A binary log cache is allocated for each client if the server supports any transactional storage engines and if the server has the binary log enabled (`--log-bin`

option). If you often use large, multiple-statement transactions, you can increase this cache size to get more performance. The `Binlog_cache_use` and `Binlog_cache_disk_use` status variables can be useful for tuning the size of this variable. See Section 5.2.4, “The Binary Log”.

MySQL Enterprise

For recommendations on the optimum setting for `binlog_cache_size` subscribe to the MySQL Enterprise Monitor. For more information, see <http://www.mysql.com/products/enterprise/advisors.html>.

- `binlog_format`

Version Introduced	5.1.5	
Command Line Format	<code>--binlog-format</code>	
Config File Format	<code>binlog-format</code>	
Option Sets Variable	Yes, <code>binlog_format</code>	
Variable Name	<code>binlog_format</code>	
Variable Scope	Both	
Dynamic Variable	Yes	
Value Set (>= 5.1.5, <= 5.1.7)	Type	enumeration
	Default	STATEMENT
	Valid Values	ROW, STATEMENT
Value Set (>= 5.1.8, <= 5.1.11)	Type	enumeration
	Default	STATEMENT
	Valid Values	ROW, STATEMENT, MIXED
Value Set (>= 5.1.12, <= 5.1.28)	Type	enumeration
	Default	MIXED
	Valid Values	ROW, STATEMENT, MIXED
Value Set (>= 5.1.29)	Type	enumeration
	Default	STATEMENT
	Valid Values	ROW, STATEMENT, MIXED

This variable sets the binary logging format, and can be any one of `STATEMENT`, `ROW`, or `MIXED`. `binlog_format` is set by the `--binlog-format` option at startup, or by the `binlog_format` variable at runtime.

You must have the `SUPER` privilege to set this variable, which (unlike with most system variables) is true as of MySQL 5.1.29 even for the session value. See Section 16.1.2, “Replication Formats”.

The startup variable was added in MySQL 5.1.5, and the runtime variable in MySQL 5.1.8. `MIXED` was added in MySQL 5.1.8.

The rules governing when changing this variable takes effect and how long the effect lasts are the same as for other MySQL server system variables. See Section 12.5.4, “SET Syntax”, for more information.

`STATEMENT` was used by default prior to MySQL 5.1.12; in MySQL 5.1.12, the default was changed to `MIXED`. In MySQL 5.1.29, the default was changed back to `STATEMENT`.

When `MIXED` is specified, statement-based replication is used, except for cases where only row-based replication is guaranteed to lead to proper results. For example, this happens when statements contain user-defined functions (UDF) or the `UUID()` function. An exception to this rule is that `MIXED` always uses statement-based replication for stored functions and triggers.

As with other global variables, to set `binlog_format` globally, you must have the `SUPER` privilege. Starting with MySQL 5.1.29, you must also have the `SUPER` privilege to set `binlog_format` on the session level. (Bug#39106)

There are exceptions when you cannot switch the replication format at runtime:

- From within a stored function or a trigger.
- If the `NDBCLUSTER` storage engine is enabled.
- If the session is currently in row-based replication mode and has open temporary tables.

Trying to switch the format in those cases results in an error.

Before MySQL 5.1.8, switching to row-based replication format would implicitly set `--log-bin-trust-function-creators=1` and `--innodb_locks_unsafe_for_binlog`. MySQL 5.1.8 and later no longer implicitly set these options when row-based replication is used.

The binlog format affects the behavior of the following server options:

- `--replicate-do-db`
- `--replicate-ignore-db`
- `--binlog-do-db`
- `--binlog-ignore-db`

These effects are discussed in detail in the descriptions of the individual options.

- `max_binlog_cache_size`

Command Line Format	<code>--max_binlog_cache_size=#</code>	
Config File Format	<code>max_binlog_cache_size</code>	
Option Sets Variable	Yes, <code>max_binlog_cache_size</code>	
Variable Name	<code>max_binlog_cache_size</code>	
Variable Scope	Global	
Dynamic Variable	Yes	
Value Set	Platform Bit Size	32
	Type	numeric
	Default	4294967295
	Range	4096-4294967295
Value Set	Platform Bit Size	64
	Type	numeric
	Default	18446744073709547520
	Range	4096-18446744073709547520

If a multiple-statement transaction requires more than this many bytes of memory, the server generates a `MULTI-STATEMENT TRANSACTION REQUIRED MORE THAN 'MAX_BINLOG_CACHE_SIZE' BYTES OF STORAGE` error. The minimum value is 4096; the maximum and default values are 4GB on 32-bit platforms and 16 PB (petabytes) on 64-bit platforms.

- `max_binlog_size`

Command Line Format	<code>--max_binlog_size=#</code>	
Config File Format	<code>max_binlog_size</code>	
Option Sets Variable	Yes, <code>max_binlog_size</code>	
Variable Name	<code>max_binlog_size</code>	
Variable Scope	Global	
Dynamic Variable	Yes	
Value Set	Type	numeric
	Default	1073741824
	Min Value	4096

If a write to the binary log causes the current log file size to exceed the value of this variable, the server rotates the binary logs (closes the current file and opens the next one). You cannot set this variable to more than 1GB or to less than 4096 bytes. The default value is 1GB.

A transaction is written in one chunk to the binary log, so it is never split between several binary logs. Therefore, if you have big transactions, you might see binary logs larger than `max_binlog_size`.

If `max_relay_log_size` is 0, the value of `max_binlog_size` applies to relay logs as well.

- `sync_binlog`

Command Line Format	<code>--sync-binlog=#</code>	
Config File Format	<code>sync-binlog</code>	
Option Sets Variable	Yes, <code>sync_binlog</code>	
Variable Name	<code>sync_binlog</code>	
Variable Scope	Global	
Dynamic Variable	Yes	
Value Set	Platform Bit Size	32
	Type	numeric
	Default	0
	Range	0-4294967295
Value Set	Platform Bit Size	64
	Type	numeric
	Default	0
	Range	0-18446744073709547520

If the value of this variable is greater than 0, the MySQL server synchronizes its binary log to disk (using `fdatasync()`) after every `sync_binlog` writes to the binary log. There is one write to the binary log per statement if autocommit is enabled, and one write per transaction otherwise. The default value of `sync_binlog` is 0, which does no synchronizing to disk — in this case, the server relies on the operating system to flush the binary log's contents from time to time as for any other file. A value of 1 is the safest choice, because in the event of a crash you lose at most one statement or transaction from the binary log. However, it is also the slowest choice (unless the disk has a battery-backed cache, which makes synchronization very fast).

16.1.4. Common Replication Administration Tasks

Once replication has been started it should execute without requiring much regular administration. Depending on your replication environment, you will want to check the replication status of each slave either periodically, daily, or even more frequently.

MySQL Enterprise

For regular reports regarding the status of your slaves, subscribe to the MySQL Enterprise Monitor. For more information, see <http://www.mysql.com/products/enterprise/advisors.html>.

16.1.4.1. Checking Replication Status

The most common task when managing a replication process is to ensure that replication is taking place and that there have been no errors between the slave and the master.

The primary statement for this is `SHOW SLAVE STATUS` which you must execute on each slave:

```
mysql> SHOW SLAVE STATUS\G
***** 1. row *****
      Slave_IO_State: Waiting for master to send event
        Master_Host: master1
        Master_User: root
        Master_Port: 3306
        Connect_Retry: 60
        Master_Log_File: mysql-bin.000004
        Read_Master_Log_Pos: 931
        Relay_Log_File: slave1-relay-bin.000056
        Relay_Log_Pos: 950
        Relay_Master_Log_File: mysql-bin.000004
        Slave_IO_Running: Yes
        Slave_SQL_Running: Yes
        Replicate_Do_DB:
        Replicate_Ignore_DB:
        Replicate_Do_Table:
        Replicate_Ignore_Table:
        Replicate_Wild_Do_Table:
        Replicate_Wild_Ignore_Table:
          Last_Errno: 0
          Last_Error:
        Skip_Counter: 0
        Exec_Master_Log_Pos: 931
```

```

Relay_Log_Space: 1365
Until_Condition: None
Until_Log_File:
Until_Log_Pos: 0
Master_SSL_Allowed: No
Master_SSL_CA_File:
Master_SSL_CA_Path:
Master_SSL_Cert:
Master_SSL_Cipher:
Master_SSL_Key:
Seconds_Behind_Master: 0
1 row in set (0.01 sec)

```

The key fields from the status report to examine are:

- `Slave_IO_State` — indicates the current status of the slave. See [Section 7.5.6.5, “Replication Slave I/O Thread States”](#), and [Section 7.5.6.6, “Replication Slave SQL Thread States”](#), for more information.
- `Slave_IO_Running` — shows whether the IO thread for the reading the master's binary log is running.
- `Slave_SQL_Running` — shows whether the SQL thread for the executing events in the relay log is running.
- `Last_Error` — shows the last error registered when processing the relay log. Ideally this should be blank, indicating no errors.
- `Seconds_Behind_Master` — shows the number of seconds that the slave SQL thread is behind processing the master binary log. A high number (or an increasing one) can indicate that the slave is unable to cope with the large number of statements from the master.

A value of 0 for `Seconds_Behind_Master` can usually be interpreted as meaning that the slave has caught up with the master, but there are some cases where this is not strictly true. For example, this can occur if the network connection between master and slave is broken but the slave I/O thread has not yet noticed this — that is, `slave_net_timeout` has not yet elapsed.

It is also possible that transient values for `Seconds_Behind_Master` may not reflect the situation accurately. When the slave SQL thread has caught up on I/O, `Seconds_Behind_Master` displays 0; but when the slave I/O thread is still queuing up a new event, `Seconds_Behind_Master` may show a large value until the SQL thread finishes executing the new event. This is especially likely when the events have old timestamps; in such cases, if you execute `SHOW SLAVE STATUS` several times in a relatively short period, you may see this value change back and forth repeatedly between 0 and a relatively large value.

On the master, you can check the status of slaves by examining the list of running processes. Slaves execute the `Binlog Dump` command:

```

mysql> SHOW PROCESSLIST \G;
***** 4. row *****
  Id: 10
  User: root
  Host: slave1:58371
  db: NULL
  Command: Binlog Dump
  Time: 777
  State: Has sent all binlog to slave; waiting for binlog to be updated
  Info: NULL

```

Because it is the slave that drives the core of the replication process, very little information is available in this report.

If you have used the `--report-host` option, then the `SHOW SLAVE HOSTS` statement will show basic information about connected slaves:

```

mysql> SHOW SLAVE HOSTS;
+-----+-----+-----+-----+-----+
| Server_id | Host | Port | Rpl_recovery_rank | Master_id |
+-----+-----+-----+-----+-----+
| 10 | slave1 | 3306 | 0 | 1 |
+-----+-----+-----+-----+-----+
1 row in set (0.00 sec)

```

The output includes the ID of the slave server, the value of the `--report-host` option, the connecting port, master ID and the priority of the slave for receiving binary log updates.

16.1.4.2. Pausing Replication on the Slave

You can stop and start the replication of statements on the slave using the `STOP SLAVE` and `START SLAVE` statements.

To stop execution of the binary log from the master, use `STOP SLAVE`:

```
mysql> STOP SLAVE;
```

When execution is stopped, the slave does not read the binary log from the master (the `IO_THREAD`) and stops processing events from the relay log that have not yet been executed (the `SQL_THREAD`). You can pause either the IO or SQL threads individually by specifying the thread type. For example:

```
mysql> STOP SLAVE IO_THREAD;
```

Stopping the SQL thread can be useful if you want to perform a backup or other task on a slave that only processes events from the master. The IO thread will continue to be read from the master, but not executed, which will make it easier for the slave to catch up when you start slave operations again.

Stopping the IO thread will allow the statements in the relay log to be executed up until the point where the relay log has ceased to receive new events. Using this option can be useful when you want to pause execution to allow the slave to catch up with events from the master, when you want to perform administration on the slave but also ensure you have the latest updates to a specific point. This method can also be used to pause execution on the slave while you conduct administration on the master while ensuring that there is not a massive backlog of events to be executed when replication is started again.

To start execution again, use the `START SLAVE` statement:

```
mysql> START SLAVE;
```

If necessary, you can start either the `IO_THREAD` or `SQL_THREAD` threads individually.

16.2. Replication Solutions

Replication can be used in many different environments for a range of purposes. In this section you will find general notes and advice on using replication for specific solution types.

For information on using replication in a backup environment, including notes on the setup, backup procedure, and files to back up, see [Section 16.2.1, “Using Replication for Backups”](#).

For advice and tips on using different storage engines on the master and slaves, see [Section 16.2.2, “Using Replication with Different Master and Slave Storage Engines”](#).

Using replication as a scale-out solution requires some changes in the logic and operation of applications that use the solution. See [Section 16.2.3, “Using Replication for Scale-Out”](#).

For performance or data distribution reasons you may want to replicate different databases to different replication slaves. See [Section 16.2.4, “Replicating Different Databases to Different Slaves”](#).

As the number of replication slaves increases, the load on the master can increase (because of the need to replicate the binary log to each slave) and lead to a reduction in performance of the master. For tips on improving your replication performance, including using a single secondary server as a replication master, see [Section 16.2.5, “Improving Replication Performance”](#).

For guidance on switching masters, or converting slaves into masters as part of an emergency failover solution, see [Section 16.2.6, “Switching Masters During Failover”](#).

To secure your replication communication you can encrypt the communication channel by using SSL to exchange data. Step-by-step instructions can be found in [Section 16.2.7, “Setting Up Replication Using SSL”](#).

16.2.1. Using Replication for Backups

You can use replication as a backup solution by replicating data from the master to a slave, and then backing up the data slave. Because the slave can be paused and shut down without affecting the running operation of the master you can produce an effective snapshot of 'live' data that would otherwise require a shutdown of the master database.

How you back up the database will depend on the size of the database and whether you are backing up only the data, or the data and the replication slave state so that you can rebuild the slave in the event of failure. There are therefore two choices:

If you are using replication as a solution to enable you to back up the data on the master, and the size of your database is not too large, then the `mysqldump` tool may be suitable. See [Section 16.2.1.1, “Backing Up a Slave Using `mysqldump`”](#).

For larger databases, where `mysqldump` would be impractical or inefficient, you can back up the raw data files instead. Using the raw data files option also means that you can back up the binary and relay logs that will enable you to recreate the slave in the event of a slave failure. For more information, see [Section 16.2.1.2, “Backing Up Raw Data from a Slave”](#).

Another backup strategy, which can be used for either master or slave servers, is to put the server in a read-only state. The backup is performed against the read-only server, which then is changed back to its usual read/write operational status. See [Section 16.2.1.3, “Backing Up a Master or Slave by Making It Read Only”](#).

16.2.1.1. Backing Up a Slave Using `mysqldump`

Using `mysqldump` to create a copy of the database enables you to capture all of the data in the database in a format that allows the information to be imported into another instance of MySQL. Because the format of the information is SQL statements the file can easily be distributed and applied to running servers in the event that you need access to the data in an emergency. However, if the size of your data set is very large then `mysqldump` may be impractical.

When using `mysqldump` you should stop the slave before starting the dump process to ensure that the dump contains a consistent set of data:

1. Stop the slave from processing requests. You can either stop the slave completely using `mysqladmin`:

```
shell> mysqladmin stop-slave
```

Alternatively, you can stop processing the relay log files by stopping the replication SQL thread. Using this method will allow the binary log data to be transferred. Within busy replication environments this may speed up the catch-up process when you start the slave processing again:

```
shell> mysql -e 'STOP SLAVE SQL_THREAD;'
```

2. Run `mysqldump` to dump your databases. You may either select databases to be dumped, or dump all databases. For more information, see [Section 4.5.4, “mysqldump — A Database Backup Program”](#). For example, to dump all databases:

```
shell> mysqldump --all-databases >fulldb.dump
```

3. Once the dump has completed, start slave operations again:

```
shell> mysqladmin start-slave
```

In the preceding example you may want to add login credentials (user name, password) to the commands, and bundle the process up into a script that you can run automatically each day.

If you use this approach, make sure you monitor the slave replication process to ensure that the time taken to run the backup in this way is not affecting the slave's ability to keep up with events from the master. See [Section 16.1.4.1, “Checking Replication Status”](#). If the slave is unable to keep up you may want to add another server and distribute the backup process. For an example of how to configure this scenario, see [Section 16.2.4, “Replicating Different Databases to Different Slaves”](#).

16.2.1.2. Backing Up Raw Data from a Slave

To guarantee the integrity of the files that are copied, backing up the raw data files on your MySQL replication slave should take place while your slave server is shut down. If the MySQL server is still running then background tasks, particularly with storage engines with background processes such as InnoDB, may still be updating the database files. With InnoDB, these problems should be resolved during crash recovery, but since the slave server can be shut down during the backup process without affecting the execution of the master it makes sense to take advantage of this facility.

To shut down the server and back up the files:

1. Shut down the slave MySQL server:

```
shell> mysqladmin shutdown
```

2. Copy the data files. You can use any suitable copying or archive utility, including `cp`, `tar` or `WinZip`:

```
shell> tar cf /tmp/dbbackup.tar ./data
```

3. Start up the `mysqld` process again:

```
shell> mysqld_safe &
```

Under Windows:

```
C:\> "C:\Program Files\MySQL\MySQL Server 5.1\bin\mysqld"
```

Normally you should back up the entire data folder for the slave MySQL server. If you want to be able to restore the data and operate as a slave (for example, in the event of failure of the slave), then when you back up the slave's data, you should back up the slave status files, `master.info` and `relay-log.info`, along with the relay log files. These files are needed to resume replication after you restore the slave's data.

If you lose the relay logs but still have the `relay-log.info` file, you can check it to determine how far the SQL thread has executed in the master binary logs. Then you can use `CHANGE MASTER TO` with the `MASTER_LOG_FILE` and `MASTER_LOG_POS` options to tell the slave to re-read the binary logs from that point. Of course, this requires that the binary logs still exist on the master server.

If your slave is subject to replicating `LOAD DATA INFILE` statements, you should also back up any `SQL_LOAD-*` files that exist in the directory that the slave uses for this purpose. The slave needs these files to resume replication of any interrupted `LOAD DATA INFILE` operations. The directory location is specified using the `--slave-load-tmpdir` option. If this option is not specified, the directory location is the value of the `tmpdir` system variable.

16.2.1.3. Backing Up a Master or Slave by Making It Read Only

It is possible to back up either master or slave servers in a replication setup by acquiring a global read lock and manipulating the `read_only` system variable to change the read-only state of the server to be backed up:

1. Make the server read-only, so that it processes only retrievals and blocks updates
2. Perform the backup
3. Change the server back to its normal read/write state

The following instructions describe how to do this for a master server and for a slave server.

These instructions require MySQL 5.1.15 or higher. For earlier versions, setting `read_only` did not block while table locks or outstanding transactions were pending, so that some data changes could still occur during the backup.

Note

The instructions in this section place the server to be backed up in a state that is safe for backup methods that get the data from the server, such as `mysqldump` (see [Section 4.5.4, “mysqldump — A Database Backup Program”](#)). You should not attempt to use these instructions to make a binary backup by copying files directly because the server may still have modified data cached in memory and not flushed to disk.

For both scenarios discussed here, suppose that you have the following replication setup:

- A master server M1
- A slave server S1 that has M1 as its master
- A client C1 connected to M1
- A client C2 connected to S1

Scenario 1: Backup with a Read-Only Master

Put the master M1 in a read-only state by executing these statements on it:

```
FLUSH TABLES WITH READ LOCK;
SET GLOBAL read_only = ON;
```

While M1 is in a read-only state, the following properties are true:

- Requests for updates sent by C1 to M1 will fail because the server is in read-only mode
- Requests for retrievals sent by C1 to M1 will succeed
- Making a backup on M1 is safe

- Making a backup on S1 is not safe: this server is still running, and might be processing the binary log or update requests coming from client C2 (S1 might not be in a read-only state)

While M1 is read only, perform the backup. For example, you can use `mysqldump`.

After the backup on M1 has been done, restore M1 to its normal operational state by executing these statements:

```
SET GLOBAL read_only = OFF;  
UNLOCK TABLES;
```

Although performing the backup on M1 is safe (as far as the backup is concerned), it is not optimal because clients of M1 are blocked from executing updates.

This strategy also applies to backing up a single server in a non-replication setting.

Scenario 2: Backup with a Read-Only Slave

Put the slave S1 in a read-only state by executing these statements on it:

```
FLUSH TABLES WITH READ LOCK;  
SET GLOBAL read_only = ON;
```

While S1 is in a read-only state, the following properties are true:

- The master M1 will continue to operate
- Making a backup on the master is not safe
- The slave S1 is stopped
- Making a backup on the slave S1 is safe

These properties provide the basis for a popular backup scenario: Having one slave busy performing a backup for a while is not a problem because it does not affect the entire network, and the system is still running during the backup. (For example, clients can still perform updates on the master server.)

While S1 is read only, perform the backup.

After the backup on S1 has been done, restore S1 to its normal operational state by executing these statements:

```
SET GLOBAL read_only = OFF;  
UNLOCK TABLES;
```

After the slave is restored to normal operation, it again synchronizes to the master by catching up with any outstanding updates in the binary log from the master.

In either scenario, the statements to acquire the global read lock and manipulate the `read_only` variable are performed on the server to be backed up and do not propagate to any slaves of that server.

16.2.2. Using Replication with Different Master and Slave Storage Engines

The replication process does not care if the source table on the master and the replicated table on the slave use different engine types. In fact, the system variables `storage_engine` and `table_type` are not replicated.

This provides a number of advantages in the replication process in that you can take advantage of different engine types for different replication scenarios. For example, in a typical scaleout scenario (see [Section 16.2.3, “Using Replication for Scale-Out”](#)), you want to use `InnoDB` tables on the master to take advantage of the transactional functionality, but use `MyISAM` on the slaves where transaction support is not required because the data is only read. When using replication in a data logging environment you may want to use the `Archive` storage engine on the slave.

Setting up different engines on the master and slave depends on how you set up the initial replication process:

- If you used `mysqldump` to create the database snapshot on your master then you could edit the dump text to change the engine type used on each table.

Another alternative for `mysqldump` is to disable engine types that you do not want to use on the slave before using the dump

to build the data on the slave. For example, you can add the `--skip-innodb` option on your slave to disable the `InnoDB` engine. If a specific engine does not exist, MySQL will use the default engine type, usually `MyISAM`. If you want to disable further engines in this way, you may want to consider building a special binary to be used on the slave that only supports the engines you want.

- If you are using raw data files for the population of the slave, you will be unable to change the initial table format. Instead, use `ALTER TABLE` to change the table types after the slave has been started.
- For new master/slave replication setups where there are currently no tables on the master, avoid specifying the engine type when creating new tables.

If you are already running a replication solution and want to convert your existing tables to another engine type, follow these steps:

1. Stop the slave from running replication updates:

```
mysql> STOP SLAVE;
```

This will enable you to change engine types without interruptions.

2. Execute an `ALTER TABLE ... Engine='enginetype'` for each table where you want to change the engine type.
3. Start the slave replication process again:

```
mysql> START SLAVE;
```

Although the `storage_engine` and `table_type` variables are not replicated, be aware that `CREATE TABLE` and `ALTER TABLE` statements that include the engine specification will be correctly replicated to the slave. For example, if you have a CSV table and you execute:

```
mysql> ALTER TABLE csvtable Engine='MyISAM';
```

The above statement will be replicated to the slave and the engine type on the slave will be converted to `MyISAM`, even if you have previously changed the table type on the slave to an engine other than CSV. If you want to retain engine differences on the master and slave, you should be careful to use the `storage_engine` variable on the master when creating a new table. For example, instead of:

```
mysql> CREATE TABLE tablea (columna int) Engine=MyISAM;
```

Use this format:

```
mysql> SET storage_engine=MyISAM;
mysql> CREATE TABLE tablea (columna int);
```

When replicated, the `storage_engine` variable will be ignored, and the `CREATE TABLE` statement will be executed with the slave's default engine type.

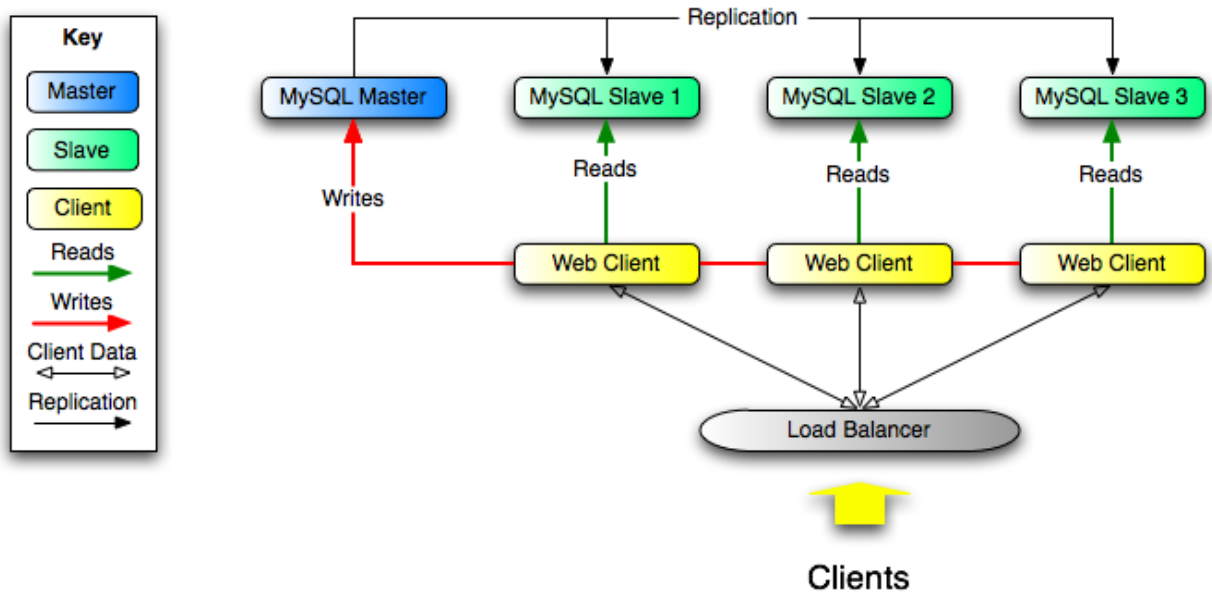

16.2.3. Using Replication for Scale-Out

You can use replication as a scale-out solution, i.e. where you want to split up the load of database queries across multiple database servers, within some reasonable limitations.

Because replication works from the distribution of one master to one or more slaves, using replication for scaleout works best in an environment where you have a high number of reads and low number of writes/updates. Most websites fit into this category, where users are browsing the website, reading articles, posts, or viewing products. Updates only occur during session management, or when making a purchase or adding a comment/message to a forum.

Replication in this situation enables you to distribute the reads over the replication slaves, while still allowing your web servers to communicate with the replication master when a write is required. You can see a sample replication layout for this scenario in [Figure 16.1, "Using replication to improve the performance during scaleout"](#).

Figure 16.1. Using replication to improve the performance during scaleout

If the part of your code that is responsible for database access has been properly abstracted/modularized, converting it to run with a replicated setup should be very smooth and easy. Change the implementation of your database access to send all writes to the master, and to send reads to either the master or a slave. If your code does not have this level of abstraction, setting up a replicated system gives you the opportunity and motivation to clean it up. Start by creating a wrapper library or module that implements the following functions:

- `safe_writer_connect()`
- `safe_reader_connect()`
- `safe_reader_statement()`
- `safe_writer_statement()`

`safe_` in each function name means that the function takes care of handling all error conditions. You can use different names for the functions. The important thing is to have a unified interface for connecting for reads, connecting for writes, doing a read, and doing a write.

Then convert your client code to use the wrapper library. This may be a painful and scary process at first, but it pays off in the long run. All applications that use the approach just described are able to take advantage of a master/slave configuration, even one involving multiple slaves. The code is much easier to maintain, and adding troubleshooting options is trivial. You need modify only one or two functions; for example, to log how long each statement took, or which statement among those issued gave you an error.

If you have written a lot of code, you may want to automate the conversion task by using the `replace` utility that comes with standard MySQL distributions, or write your own conversion script. Ideally, your code uses consistent programming style conventions. If not, then you are probably better off rewriting it anyway, or at least going through and manually regularizing it to use a consistent style.

16.2.4. Replicating Different Databases to Different Slaves

There may be situations where you have a single master and want to replicate different databases to different slaves. For example, you may want to distribute different sales data to different departments to help spread the load during data analysis. A sample of this layout is shown in [Figure 16.2, “Using replication to replicate databases to separate replication slaves”](#).

Figure 16.2. Using replication to replicate databases to separate replication slaves

You can achieve this separation by configuring the master and slaves as normal, and then limiting the binary log statements that each slave processes by using the `--replicate-wild-do-table` configuration option on each slave.

Important

You should *not* use `--replicate-do-db` for this purpose when using statement-based replication, since statement-based replication causes this option's affects to vary according to the database that is currently selected. This applies to mixed-format replication as well, since this allows some updates to be replicated using the statement-based format.

However, it should be to use `--replicate-do-db` for this purpose if you are using row-based replication only, since in this case the currently-selected database has no effect on the option's operation.

For example, to support the separation as shown in [Figure 16.2, “Using replication to replicate databases to separate replication slaves”](#), you should configure each replication slave as follows, before executing `START SLAVE`:

- Replication slave 1 should use `--replicate-wild-do-table=databaseA.%`.
- Replication slave 2 should use `--replicate-wild-do-table=databaseB.%`.
- Replication slave 3 should use `--replicate-wild-do-table=databaseC.%`.

If you have data that needs to be synchronized to the slaves before replication starts, you have a number of choices:

- Synchronize all the data to each slave, and delete the databases, tables, or both that you do not want to keep.
- Use `mysqldump` to create a separate dump file for each database and load the appropriate dump file on each slave.
- Use a raw data file dump and include only the specific files and databases that you need for each slave.

Note

This does not work with InnoDB databases unless you use `innodb_file_per_table`.

Each slave in this configuration receives the entire binary log from the master, but executes only those events from the binary log that apply to the databases and tables included by the `--replicate-wild-do-table` option in effect on that slave.

16.2.5. Improving Replication Performance

As the number of slaves connecting to a master increases, the load, although minimal, also increases, as each slave uses up a client connection to the master. Also, as each slave must receive a full copy of the master binary log, the network load on the master may also increase and start to create a bottleneck.

If you are using a large number of slaves connected to one master, and that master is also busy processing requests (for example, as part of a scaleout solution), then you may want to improve the performance of the replication process.

One way to improve the performance of the replication process is to create a deeper replication structure that enables the master to

replicate to only one slave, and for the remaining slaves to connect to this primary slave for their individual replication requirements. A sample of this structure is shown in [Figure 16.3, “Using an additional replication host to improve performance”](#).

Figure 16.3. Using an additional replication host to improve performance

For this to work, you must configure the MySQL instances as follows:

- Master 1 is the primary master where all changes and updates are written to the database. Binary logging should be enabled on this machine.
- Master 2 is the slave to the Master 1 that provides the replication functionality to the remainder of the slaves in the replication structure. Master 2 is the only machine allowed to connect to Master 1. Master 2 also has binary logging enabled, and the `--log-slave-updates` option so that replication instructions from Master 1 are also written to Master 2's binary log so that they can then be replicated to the true slaves.
- Slave 1, Slave 2, and Slave 3 act as slaves to Master 2, and replicate the information from Master 2, which is really the data logged on Master 1.

The above solution reduces the client load and the network interface load on the primary master, which should improve the overall performance of the primary master when used as a direct database solution.

If your slaves are having trouble keeping up with the replication process on the master then there are a number of options available:

- If possible, you should put the relay logs and the data files on different physical drives. To do this, use the `--relay-log` option to specify the location of the relay log.
- If the slaves are significantly slower than the master, then you may want to divide up the responsibility for replicating different databases to different slaves. See [Section 16.2.4, “Replicating Different Databases to Different Slaves”](#).
- If your master makes use of transactions and you are not concerned about transaction support on your slaves, then use `MyISAM` or another non-transactional engine. See [Section 16.2.2, “Using Replication with Different Master and Slave Storage Engines”](#).
- If your slaves are not acting as masters, and you have a potential solution in place to ensure that you can bring up a master in the event of failure, then you can switch off `--log-slave-updates`. This prevents 'dumb' slaves from also logging events they have executed into their own binary log.

16.2.6. Switching Masters During Failover

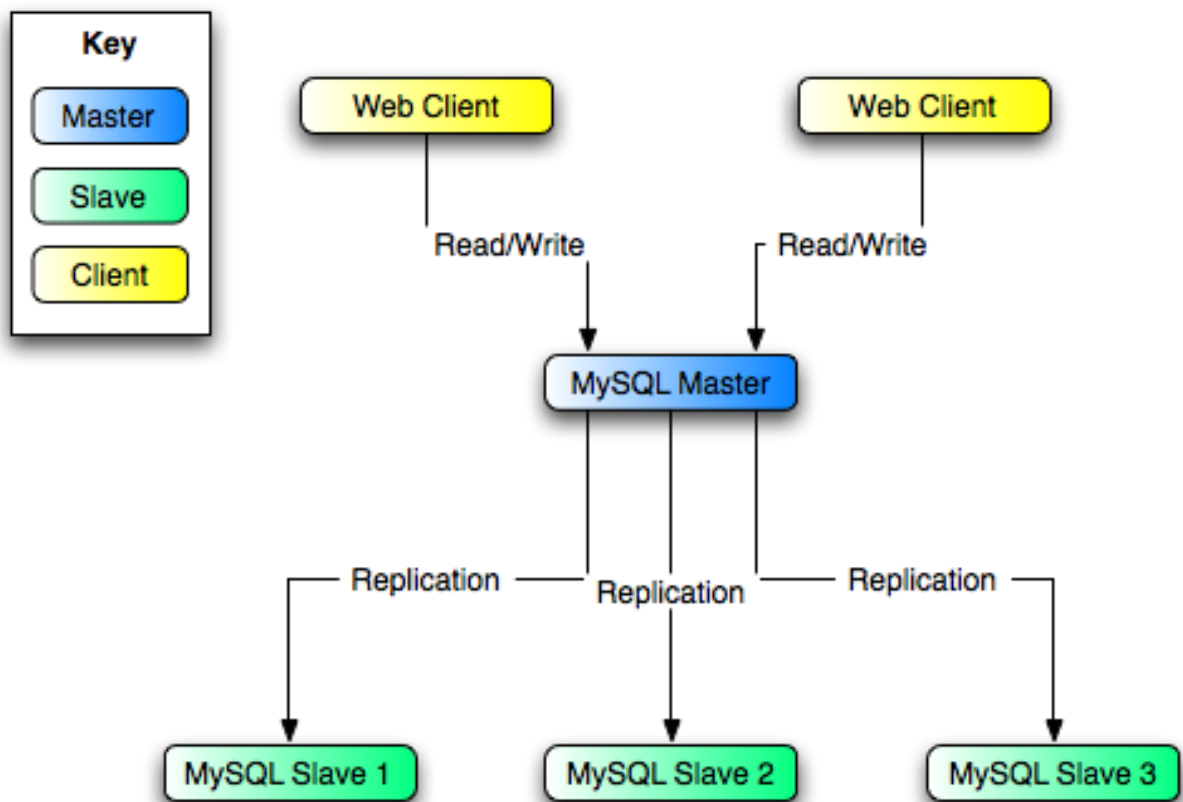

There is currently no official solution for providing failover between master and slaves in the event of a failure. With the currently available features, you would have to set up a master and a slave (or several slaves), and to write a script that monitors the master to check whether it is up. Then instruct your applications and the slaves to change master in case of failure.

Remember that you can tell a slave to change its master at any time, using the `CHANGE MASTER TO` statement. The slave will not check whether the databases on the master are compatible with the slave, it will just start executing events from the specified log and position on the new master. In a failover situation all the servers in the group are probably executing the same events from the same binary log, so changing the source of the events should not affect the database structure or integrity providing you are careful.

Run your slaves with the `--log-bin` option and without `--log-slave-updates`. In this way, the slave is ready to become a

master as soon as you issue `STOP SLAVE; RESET MASTER`, and `CHANGE MASTER TO` statement on the other slaves. For example, assume that you have the structure shown in Figure 16.4, “Redundancy using replication, initial structure”.

Figure 16.4. Redundancy using replication, initial structure

In this diagram, the `MySQL Master` holds the master database, the `MySQL Slave` computers are replication slaves, and the `Web Client` machines are issuing database reads and writes. Web clients that issue only reads (and would normally be connected to the slaves) are not shown, as they do not need to switch to a new server in the event of failure. For a more detailed example of a read/write scaleout replication structure, see Section 16.2.3, “Using Replication for Scale-Out”.

Each `MySQL Slave` (`Slave 1`, `Slave 2`, and `Slave 3`) are slaves running with `--log-bin` and without `--log-slave-updates`. Because updates received by a slave from the master are not logged in the binary log unless `--log-slave-updates` is specified, the binary log on each slave is empty initially. If for some reason `MySQL Master` becomes unavailable, you can pick one of the slaves to become the new master. For example, if you pick `Slave 1`, all `Web Clients` should be redirected to `Slave 1`, which will log updates to its binary log. `Slave 2` and `Slave 3` should then replicate from `Slave 1`.

The reason for running the slave without `--log-slave-updates` is to prevent slaves from receiving updates twice in case you cause one of the slaves to become the new master. Suppose that `Slave 1` has `--log-slave-updates` enabled. Then it will write updates that it receives from `Master` to its own binary log. When `Slave 2` changes from `Master` to `Slave 1` as its master, it may receive updates from `Slave 1` that it has already received from `Master`.

Make sure that all slaves have processed any statements in their relay log. On each slave, issue `STOP SLAVE IO_THREAD`, then check the output of `SHOW PROCESSLIST` until you see `Has read all relay log`. When this is true for all slaves, they can be reconfigured to the new setup. On the slave `Slave 1` being promoted to become the master, issue `STOP SLAVE` and `RESET MASTER`.

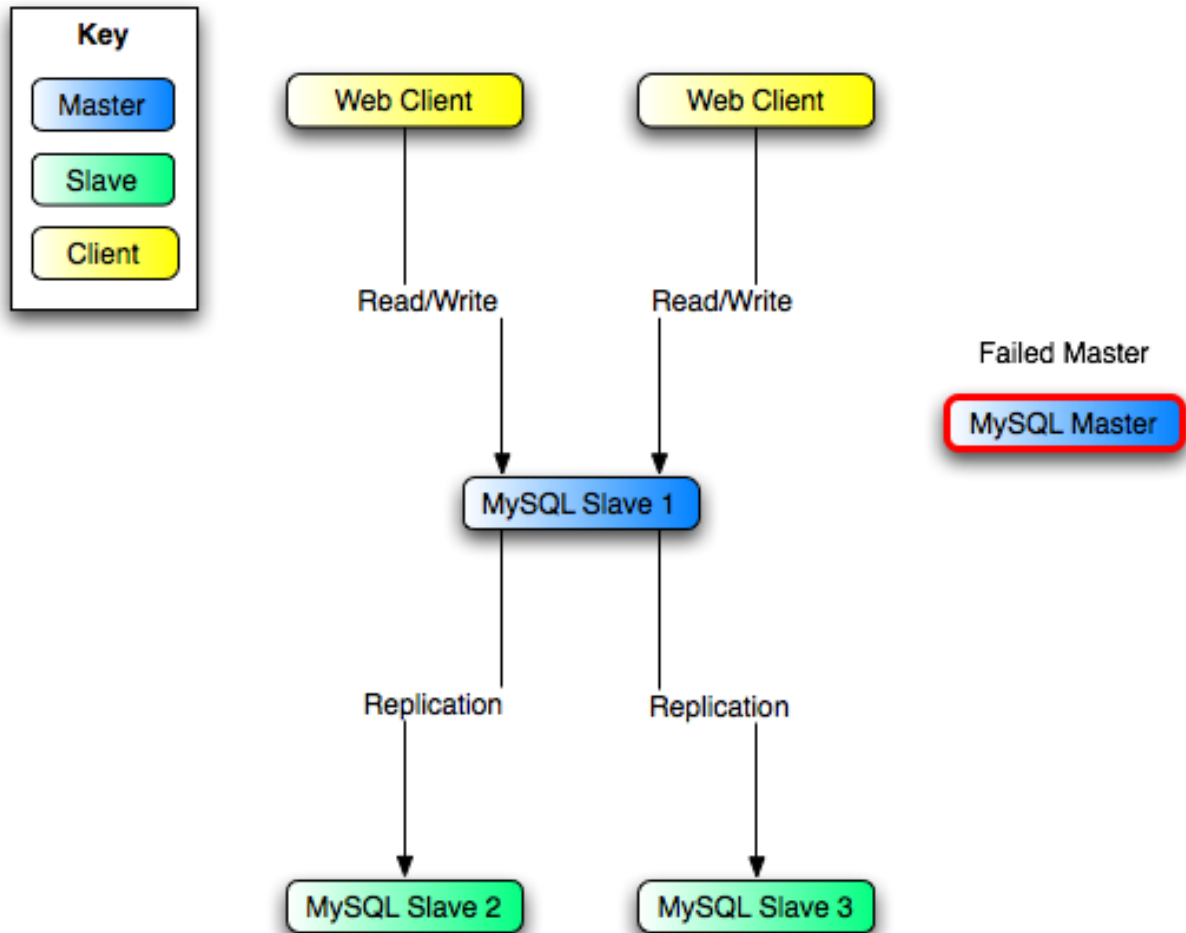

On the other slaves `Slave 2` and `Slave 3`, use `STOP SLAVE` and `CHANGE MASTER TO MASTER_HOST='Slave1'` (where `'Slave1'` represents the real host name of `Slave 1`). To use `CHANGE MASTER TO`, add all information about how to connect to `Slave 1` from `Slave 2` or `Slave 3` (`user`, `password`, `port`). In `CHANGE MASTER TO`, there is no need to specify the name of `Slave 1`'s binary log or binary log position to read from: We know it is the first binary log and position 4, which are the defaults for `CHANGE MASTER TO`. Finally, use `START SLAVE` on `Slave 2` and `Slave 3`.

Once the new replication is in place, you will then need to instruct each `Web Client` to direct their statements to `Slave 1`.

From that point on, all updates statements sent by `Web Client` to `Slave 1` are written to the binary log of `Slave 1`, which then contains every update statement sent to `Slave 1` since `Master` died.

The resulting server structure is shown in Figure 16.5, “Redundancy using replication, after master failure”.

Figure 16.5. Redundancy using replication, after master failure

When `Master` is up again, you must issue on it the same `CHANGE MASTER TO` as that issued on `Slave 2` and `Slave 3`, so that `Master` becomes a slave of `S1` and picks up each `Web Client` writes that it missed while it was down.

To make `Master` a master again (because it is the most powerful machine, for example), use the preceding procedure as if `Slave 1` was unavailable and `Master` was to be the new master. During this procedure, do not forget to run `RESET MASTER` on `Master` before making `Slave 1`, `Slave 2`, and `Slave 3` slaves of `Master`. Otherwise, they may pick up old `Web Client` writes from before the point at which `Master` became unavailable.

Note that there is no synchronization between the different slaves to a master. Some slaves might be ahead of others. This means that the concept outlined in the previous example might not work. In practice, however, the relay logs of different slaves will most likely not be far behind the master, so it would work, anyway (but there is no guarantee).

A good way to keep your applications informed as to the location of the master is by having a dynamic DNS entry for the master. With `bind` you can use `nsupdate` to dynamically update your DNS.

16.2.7. Setting Up Replication Using SSL

Setting up replication using an SSL connection is similar to setting up a server and client using SSL. You will need to obtain (or create) a suitable security certificate that you can use on the master, and a similar certificate (from the same certificate authority) on each slave.

To use SSL for encrypting the transfer of the binary log required during replication you must first set up the master to support SSL

network connections. If the master does not support SSL connections (because it has not been compiled or configured for SSL), then replication through an SSL connection will not be possible.

For more information on setting up a server and client for SSL connectivity, see [Section 5.5.7.2, “Using SSL Connections”](#).

To enable SSL on the master you will need to create or obtain suitable certificates and then add the following configuration options to the master's configuration within the `mysqld` section:

```
ssl-ca=cacert.pem
ssl-cert=server-cert.pem
ssl-key=server-key.pem
```

Note

You should use full path to specify the location of your certificate files.

The options are as follows:

- `ssl-ca` identifies the Certificate Authority (CA) certificate.
- `ssl-cert` identifies the server public key. This can be sent to the client and authenticated against the CA certificate that it has.
- `ssl-key` identifies the server private key.

On the slave, you have two options available for setting the SSL information. You can either add the slaves certificates to the `client` section of the slave configuration file, or you can explicitly specify the SSL information using the `CHANGE MASTER TO` statement.

Using the former option, add the following lines to the `client` section of the slave configuration file:

```
[client]
ssl-ca=cacert.pem
ssl-cert=server-cert.pem
ssl-key=server-key.pem
```

Restart the slave server, using the `--skip-slave` to prevent the slave from connecting to the master. Use `CHANGE MASTER TO` to specify the master configuration, using the `master_ssl` option to enable SSL connectivity:

```
mysql> CHANGE MASTER TO \
  MASTER_HOST='master_hostname', \
  MASTER_USER='replicate', \
  MASTER_PASSWORD='password', \
  MASTER_SSL=1;
```

To specify the SSL certificate options during the `CHANGE MASTER TO` command, append the SSL options:

```
CHANGE MASTER TO \
  MASTER_HOST='master_hostname', \
  MASTER_USER='replicate', \
  MASTER_PASSWORD='password', \
  MASTER_SSL=1, \
  MASTER_SSL_CA = 'ca_file_name', \
  MASTER_SSL_CAPATH = 'ca_directory_name', \
  MASTER_SSL_CERT = 'cert_file_name', \
  MASTER_SSL_KEY = 'key_file_name';
```

Once the master information has been updated, start the slave replication process:

```
mysql> START SLAVE;
```

You can use the `SHOW SLAVE STATUS` to confirm that SSL connection has been completed.

For more information on the `CHANGE MASTER TO` syntax, see [Section 12.6.2.1, “CHANGE MASTER TO Syntax”](#).

If you want to enforce SSL connections to be used during replication, then create a user with the `REPLICATION SLAVE` privilege and use the `REQUIRE SSL` option for that user. For example:

```
mysql> GRANT REPLICATION SLAVE ON *.*
-> TO 'repl'@'%'.mydomain.com IDENTIFIED BY 'slavepass' REQUIRE SSL;
```

16.3. Replication Notes and Tips

16.3.1. Replication Features and Issues

The following sections provide information about what is supported and what is not in MySQL replication, and about specific issues and situations that may occur when replicating certain statements.

Statement-based replication depends on compatibility at the SQL level between the master and slave. In others, successful SBR requires that any SQL features used be supported by both the master and the slave servers. For example, if you use a feature on the master server that is available only in MySQL 5.1 (or later), you cannot replicate to a slave that uses MySQL 5.0 (or earlier).

Such incompatibilities also can occur within a release series when using pre-production releases of MySQL. For example, the `SLEEP()` function is available beginning with MySQL 5.0.12. If you use this function on the master, you cannot replicate to a slave that uses MySQL 5.0.11 or earlier.

For this reason, we recommend that you use Generally Available (GA) releases of MySQL for statement-based replication in a production setting, since we do not introduce new SQL statements or change their behavior within a given release series once that series reaches GA release status.

If you are planning to use statement-based replication between MySQL 5.1 and a previous MySQL release series, it is also a good idea to consult the edition of the *MySQL Reference Manual* corresponding to the earlier release series for information regarding the replication characteristics of that series.

With MySQL's classic statement-based replication, there may be issues with replicating stored routines or triggers. You can avoid these issues by using MySQL's row-based replication instead. For a detailed list of issues, see [Section 19.6, “Binary Logging of Stored Programs”](#). For more information about row-based replication and row-based logging, see [Section 16.1.2, “Replication Formats”](#), and [Section 5.2.4.1, “Binary Logging Formats”](#).

For additional information specific to replication and InnoDB, see [Section 13.6.4.5, “InnoDB and MySQL Replication”](#). For information relating to replication with MySQL Cluster, see [Section 17.9, “MySQL Cluster Replication”](#).

16.3.1.1. Replication and `AUTO_INCREMENT`

Statement-based replication of `AUTO_INCREMENT`, `LAST_INSERT_ID()`, and `TIMESTAMP` values is done correctly, subject to the following exceptions:

- A stored procedure that uses `LAST_INSERT_ID()` does not replicate properly using statement-based binary logging. This limitation is lifted in MySQL 5.1.12.
- Prior to MySQL 5.1.12, when a stored routine or trigger caused an `INSERT` into an `AUTO_INCREMENT` column, the generated `AUTO_INCREMENT` value was not written into the binary log, so a different value could in some cases be inserted on the slave.
- An insert into an `AUTO_INCREMENT` column caused by a stored routine or trigger running on a master that uses MySQL 5.0.60 or earlier does not replicate correctly to a slave running MySQL 5.1.12 through 5.1.23 (inclusive). ([Bug#33029](#))
- Table-level `AUTO_INCREMENT` option values were not replicated correctly prior to MySQL 5.1.31. ([Bug#41986](#))
- Adding an `AUTO_INCREMENT` column to a table with `ALTER TABLE` might not produce the same ordering of the rows on the slave and the master. This occurs because the order in which the rows are numbered depends on the specific storage engine used for the table and the order in which the rows were inserted. If it is important to have the same order on the master and slave, the rows must be ordered before assigning an `AUTO_INCREMENT` number. Assuming that you want to add an `AUTO_INCREMENT` column to the table `t1`, the following statements produce a new table `t2` identical to `t1` but with an `AUTO_INCREMENT` column:

```
CREATE TABLE t2 LIKE t1;
ALTER TABLE t2 ADD id INT AUTO_INCREMENT PRIMARY KEY;
INSERT INTO t2 SELECT * FROM t1 ORDER BY col1, col2;
```

This assumes that the table `t1` has columns `col1` and `col2`.

Important

To guarantee the same ordering on both master and slave, *all* columns of `t1` must be referenced in the `ORDER BY` clause.

The instructions just given are subject to the limitations of `CREATE TABLE ... LIKE`: Foreign key definitions are ignored, as are the `DATA DIRECTORY` and `INDEX DIRECTORY` table options. If a table definition includes any of those characteristics, create `t2` using a `CREATE TABLE` statement that is identical to the one used to create `t1`, but with the addition of the `AUTO_INCREMENT` column.

Regardless of the method used to create and populate the copy having the `AUTO_INCREMENT` column, the final step is to drop the original table and then rename the copy:

```
DROP t1;
ALTER TABLE t2 RENAME t1;
```

See also [Section B.1.7.1, “Problems with ALTER TABLE”](#).

16.3.1.2. Replication and Character Sets

The following applies to replication between MySQL servers that use different character sets:

1. If the master uses MySQL 4.1, you must *always* use the same *global* character set and collation on the master and the slave, regardless of the MySQL version running on the slave. (These are controlled by the `--character-set-server` and `--collation-server` options.) Otherwise, you may get duplicate-key errors on the slave, because a key that is unique in the master character set might not be unique in the slave character set. Note that this is not a cause for concern when master and slave are both MySQL 5.0 or later.
2. If the master is older than MySQL 4.1.3, the character set of any client should never be made different from its global value because this character set change is not known to the slave. In other words, clients should not use `SET NAMES`, `SET CHARACTER SET`, and so forth. If both the master and the slave are 4.1.3 or newer, clients can freely set session values for character set variables because these settings are written to the binary log and so are known to the slave. That is, clients can use `SET NAMES` or `SET CHARACTER SET` or can set variables such as `collation_client` or `collation_server`. However, clients are prevented from changing the *global* value of these variables; as stated previously, the master and slave must always have identical global character set values. This is true whether you are using statement-based or row-based replication.
3. If you have databases on the master with character sets that differ from the global `character_set_server` value, you should design your `CREATE TABLE` statements so that tables in those databases do not implicitly rely on the database default character set. A good workaround is to state the character set and collation explicitly in `CREATE TABLE` statements.

16.3.1.3. Replication of CREATE TABLE ... SELECT Statements

This section discusses the rules that are applied when a `CREATE TABLE ... SELECT` statement is replicated.

Note

`CREATE TABLE ... SELECT` always performs an implicit commit ([Section 12.4.3, “Statements That Cause an Implicit Commit”](#)).

Statement succeeds. If the `CREATE TABLE ... SELECT` statement succeeds on the master, then it is replicated as follows:

- **STATEMENT or MIXED format.** The `CREATE TABLE ... SELECT` statement is itself replicated.
- **ROW format.** The statement is replicated as a `CREATE TABLE` statement followed by a series of `binwrite` events (that is, binary inserts).

Statement fails. The failure of a `CREATE TABLE ... SELECT` is handled according to the following criteria:

- **No IF NOT EXISTS option.** If the `CREATE TABLE ... SELECT` does not contain an `IF NOT EXISTS` option, then the statement has no effect. However, the implicit commit caused by the statement is logged. This is true regardless of the replication format, storage engine used, and the reason for which the statement failed.
- **Statement uses IF NOT EXISTS.** If the `CREATE TABLE ... SELECT` statement includes the `IF NOT EXISTS` option and fails, the failure is handled according to the replication format. If the row-based format is in use, the action taken depends additionally on whether or not the table to be created uses a transactional or non-transactional storage engine, and on the reason for the failure:
 - **STATEMENT or MIXED format.** When using statement-based or mixed-format replication, the `CREATE TABLE IF NOT EXISTS ... SELECT` is logged with an error.
 - **ROW format.** When row-based replication is used, failure of a `CREATE TABLE ... SELECT` that includes `IF NOT EXISTS` is handled differently depending on the reason for the failure, as shown in the following diagram:

Transactional Table?	Reason for Failure		
	CREATE Succeeded; SELECT or Inserts Failed	CREATE Failed (Table Already Exists)	CREATE Failed (Other Reason)
YES	<ol style="list-style-type: none"> 1. Table is dropped 2. Implicit commit is logged 	<ol style="list-style-type: none"> 1. CREATE TABLE statement is not logged 2. Applied rows are logged 3. Implicit commit is logged 	Only implicit commit is logged
NO	<ol style="list-style-type: none"> 1. CREATE TABLE statement is logged 2. Applied rows are logged 3. Implicit commit is logged 		

16.3.1.4. Replication with Differing Tables on Master and Slave

Starting with MySQL 5.1.21, source and target tables for replication do not have to be identical. A table on the master can have more or fewer columns than the slave's copy of the table. In addition — subject to certain conditions — corresponding table columns on the master and the slave can use different data types.

In all cases where the source and target tables do not have identical definitions, the following must be true in order for replication to work:

- You must be using row-based replication. (Using `MIXED` for the binary logging format does not work.)
- The database and table names must be the same on both the master and the slave.

Additional conditions are discussed (and examples provided) in the following two sections.

16.3.1.4.1. Replication with More Columns on Master or Slave

Starting with MySQL 5.1.21, you can replicate a table from the master to the slave such that the master's copy of the table and the slave's copy of the table do not have the same number of columns, subject to the following conditions:

- Each “extra” column in the version of the table having more columns must have a default value.

Note

A column's default value is determined by a number of factors, including its type, whether it is defined with a `DEFAULT` option, whether it is declared as `NULL`, and the server SQL mode in effect at the time of its creation; see [Section 10.1.4, “Data Type Default Values”](#), for more information.

- Matching columns must be defined in the same order on both the master and the slave.
- Any additional columns must be defined following the matching columns.

In addition, when the slave's copy of the table has more columns than the master's copy, then each matching column must use the same data type.

Examples. The following examples illustrate some valid and invalid table definitions:

- **More columns on the master.** The following table definitions are valid:

```
master> CREATE TABLE t1 (c1 INT, c2 INT, c3 INT);
slave> CREATE TABLE t1 (c1 INT, c2 INT);
```

The following table definitions would raise Error 1532 (`ER_BINLOG_ROW_RBR_TO_SBR`) because the definitions of the columns common to both versions of the table are in a different order on the slave than they are on the master:

```
master> CREATE TABLE t1 (c1 INT, c2 INT, c3 INT);
slave> CREATE TABLE t1 (c2 INT, c1 INT);
```

The following table definitions would also raise Error 1532, because the definition of the extra column on the master appears before the definitions of the columns common to both versions of the table:

```
master> CREATE TABLE t1 (c3 INT, c1 INT, c2 INT);
slave> CREATE TABLE t1 (c1 INT, c2 INT);
```

- **More columns on the slave.** The following definitions replicate correctly:

```
master> CREATE TABLE t1 (c1 INT, c2 INT);
slave> CREATE TABLE t1 (c1 INT, c2 INT, c3 INT);
```

The following definitions raise Error 1532 because the columns common to both versions of the table are not defined in the same order on both the master and the slave:

```
master> CREATE TABLE t1 (c1 INT, c2 INT);
slave> CREATE TABLE t1 (c2 INT, c1 INT, c3 INT);
```

The following table definitions also raise Error 1532 because the definition for the extra column in the slave's version of the table appears before the definitions for the columns which are common to both versions of the table:

```
master> CREATE TABLE t1 (c1 INT, c2 INT);
slave> CREATE TABLE t1 (c3 INT, c1 INT, c2 INT);
```

The following table definitions fail, because the slave's version of the table has additional columns compared to the master's version, and the two versions of the table define column `c2` as a different data type.

```
master> CREATE TABLE t1 (c1 INT, c2 BIGINT);
slave> CREATE TABLE t1 (c1 INT, c2 INT, c3 INT);
```

16.3.1.4.2. Replication of Columns Having Different Data Types

Corresponding columns on the master's and the slave's copies of the same table ideally should have the same data type. However, beginning with MySQL 5.1.21, this is not always strictly enforced, as long as certain conditions are met. These conditions are listed here:

- The slave's copy of the table cannot contain more columns than the master's copy.
- For columns holding numeric data types, the sizes may differ, as long as the size of the slave's version of the column is equal or greater to the size of the master's version of the column. This is sometimes referred to as *attribute promotion*, because the data type of the master's version of the column is promoted to a type that is the same size or larger on the slave.

Data type conversions currently supported by attribute promotion are shown in the following table, in which *X* and *N* both represent positive integers.

Original Data Type	Promoted Data Type(s)
CHAR(<i>X</i>)	CHAR(<i>X+N</i>)
VARCHAR(<i>X</i>)	VARCHAR(<i>X+N</i>)
CHAR(<i>X</i>)	VARCHAR(<i>X+N</i>)
BINARY(<i>X</i>)	BINARY(<i>X+N</i>)
VARBINARY(<i>X</i>)	VARBINARY(<i>X+N</i>)
BINARY(<i>X</i>)	VARBINARY(<i>X+N</i>)
BIT(<i>X</i>)	BIT(<i>X+N</i>)
TINYINT	SMALLINT, MEDIUMINT, INT, or BIGINT
SMALLINT	MEDIUMINT, INT, or BIGINT
MEDIUMINT	INT or BIGINT
INT	BIGINT

Unsigned integer columns can be promoted to larger unsigned types; for example, a column declared as `TINYINT UNSIGNED` can be restored to a column declared as `SMALLINT UNSIGNED`, `MEDIUMINT UNSIGNED`, `INT UNSIGNED`, or `BIGINT UNSIGNED`. You cannot promote a signed column to an unsigned type, or an unsigned column to a signed type.

For columns holding numeric data types the sizes may differ, as long as the size of the slave's version of the column is equal or greater to the size of the master's version of the column. For example, the following table definitions are allowed:

```
master> CREATE TABLE t1 (c1 TINYINT, c2 INT);
slave> CREATE TABLE t1 (c1 INT, c2 INT);
```

The slave's versions of both columns `c1` and `c2` are the same size as or larger than the master's versions of these columns. However, the following definitions would fail:

```
master> CREATE TABLE t1 (c1 INT, c2 FLOAT(8,3));
slave> CREATE TABLE t1 (c1 INT, c2 FLOAT(7,3));
```

In this case, Error 1532 would be raised because the master's copy of column `c2` is larger than its counterpart on the slave — that is, the master's copy of `c2` on the master can hold more digits than the slave's copy of the column.

- There is no conversion between integer (`TINYINT`, `SMALLINT`, `MEDIUMINT`, and so on) and non-integer (`FLOAT`, `DOUBLE`, `DECIMAL`, and so on) numeric data types, and so the following definitions would fail with Error 1532:

```
master> CREATE TABLE t1 (c1 INT, c2 FLOAT(8,3));
slave> CREATE TABLE t1 (c1 INT, c2 BIGINT);
```

A column using a non-integer numeric data type must always have the same definition on both the master and the slave.

- For columns storing `CHAR` and `BINARY` data, the size of the slave's copy of the column must be equal to or greater than the size of the master's copy. For example, the following table definitions would replicate successfully:

```
master> CREATE TABLE t1 (c1 INT, c2 CHAR(30));
slave> CREATE TABLE t1 (c1 INT, c2 CHAR(50));
```

If the size of the master's version of the column is greater than that of the slave's version of the column, replication fails with Error 1532.

- The replication process can convert freely between `BINARY`, `VARBINARY`, `CHAR` and `VARCHAR` columns, as long as the slave's version of the column is the same size as or larger than the master's version. For example, the following table definitions can be used successfully:

```
master> CREATE TABLE t1 (c1 INT, c2 VARBINARY(30));
slave> CREATE TABLE t1 (c1 INT, c2 CHAR(30));
```

Note

Since replication is currently not supported between different character sets, it is sufficient when comparing sizes of columns containing character data to count the number of characters rather than the number of bytes.

- Attribute promotion can be used with both statement-based and row-based replication, and is not dependent on the storage engine used by either the master or the slave.

16.3.1.5. Replication and `DIRECTORY` Table Options

If a `DATA DIRECTORY` or `INDEX DIRECTORY` table option is used in a `CREATE TABLE` statement on the master server, the table option is also used on the slave. This can cause problems if no corresponding directory exists in the slave host file system or if it exists but is not accessible to the slave server. This can be overridden by using the `NO_DIR_IN_CREATE` server SQL mode on the slave, which causes the slave to ignore the `DATA DIRECTORY` and `INDEX DIRECTORY` table options when replicating `CREATE TABLE` statements. The result is that `MyISAM` data and index files are created in the table's database directory.

For more information, see [Section 5.1.7, “Server SQL Modes”](#).

16.3.1.6. Replication of `DROP ... IF EXISTS` Statements

The statements `DROP DATABASE IF EXISTS`, `DROP TABLE IF EXISTS`, and `DROP VIEW IF EXISTS` are always replicated, even if the database, table, or view to be dropped does not exist on the master. This is to ensure that the object to be dropped no longer exists on either the master or the slave, once the slave has caught up with the master.

Beginning with MySQL 5.1.33, the statements `DROP PROCEDURE IF EXISTS` and `DROP FUNCTION IF EXISTS` are also replicated, even if the procedure or function to be dropped does not exist on the master. ([Bug#13684](#))

16.3.1.7. Replication of Invoked Features

Replication of invoked features such as scheduled events, user-defined functions (UDFs), stored routines (including both stored procedures and stored functions), and triggers was re-implemented in MySQL 5.1.18 to provide the following characteristics:

- The effects of the feature are always replicated.
- The following statements are replicated using statement-based replication:
 - `CREATE EVENT`
 - `ALTER EVENT`
 - `DROP EVENT`
 - `CREATE PROCEDURE`
 - `DROP PROCEDURE`
 - `CREATE FUNCTION`
 - `DROP FUNCTION`
 - `CREATE TRIGGER`
 - `DROP TRIGGER`

However, the *effects* of features created, modified, or dropped using these statements are replicated using row-based replication.

Note

Attempting to replicate invoked features using statement-based replication produces the warning `STATEMENT MAY NOT BE SAFE TO LOG IN STATEMENT FORMAT`. (Prior to MySQL 5.1.36, this was `STATEMENT IS NOT SAFE TO LOG IN STATEMENT FORMAT` — see [Bug#42415](#).) For example, trying to replicate a UDF with statement-based replication generates this warning because it currently cannot be determined by the MySQL server whether the UDF is deterministic. If you are absolutely certain that the invoked feature's effects are deterministic, you can safely disregard such warnings.

In a future MySQL release, we may implement ways for users to indicate that such features are deterministic, so that they can be recognized by the server as “safe” for statement-based replication. ([Bug#34597](#))

- In the case of `CREATE EVENT` and `ALTER EVENT`:
 - The status of the event is set to `SLAVESIDE_DISABLED` on the slave regardless of the state specified (this does not apply to `DROP EVENT`).
 - The master on which the event was created is identified on the slave by its server ID. The `ORIGINATOR` column in `INFORMATION_SCHEMA.EVENTS` and the `originator` column in `mysql.event` were added to these tables in MySQL 5.1.18 to store this information. (See [Section 20.20](#), “The `INFORMATION_SCHEMA.EVENTS` Table”, and [Section 12.5.5.19](#), “`SHOW EVENTS` Syntax”.)
- The feature implementation resides on the slave in a renewable state so that if the master fails, the slave can be used as the master without loss of event processing.

To determine whether there are any scheduled events on a MySQL server that were created on a different server (that was acting as a replication master), use `SHOW EVENTS`, like this:

```
SHOW EVENTS
WHERE STATUS = 'SLAVESIDE_DISABLED';
```

Alternatively, you might wish to query the `INFORMATION_SCHEMA.EVENTS` table as shown here:

```
SELECT EVENT_SCHEMA, EVENT_NAME, ORIGINATOR
FROM INFORMATION_SCHEMA.EVENTS
WHERE STATUS = 'SLAVESIDE_DISABLED';
```

When promoting a replication slave having such events to a replication master, use the following query to enable the events:

```
UPDATE mysql.event
SET STATUS = 'ENABLED'
WHERE STATUS = 'SLAVESIDE_DISABLED';
```

If more than one master was involved in creating events on this slave, and you wish to enable events that were created only on a given master having the server ID `master_id`, use the following query instead:

```
UPDATE mysql.event
SET STATUS = 'ENABLED'
WHERE ORIGINATOR = master_id
```

```
AND STATUS = 'SLAVESIDE_DISABLED';
```

Important

Before executing either of the previous two `UPDATE` statements, you should disable the Event Scheduler on the slave (using `SET GLOBAL EVENT_SCHEDULER = OFF;`), run the `UPDATE`, restart the server, then re-enable the Event Scheduler afterwards (using `SET GLOBAL EVENT_SCHEDULER = ON;`).

If you later demote the new master back to being a replication slave, you must disable manually all events enabled by the `UPDATE` statement. You can do this by storing in a separate table the event names from the `SELECT` statement shown previously, or using an `UPDATE` statement to rename the events with a common prefix to identify them, as shown in this example:

```
UPDATE mysql.event
SET name = CONCAT('replicated_', name)
WHERE status = 'SLAVESIDE_DISABLED';
```

When demoting this server back to being a replication slave, you can then rename and disable the events like this:

```
UPDATE mysql.event
SET name = REPLACE(name, 'replicated_', ''),
status = 'SLAVESIDE_DISABLED'
WHERE INSTR(name, 'replicated_') = 1;
```

16.3.1.8. Replication with Floating-Point Values

With statement-based replication, values are converted from decimal to binary. Because conversions between decimal and binary representations of them may be approximate, comparisons involving floating-point values are inexact. This is true for operations that use floating-point values explicitly, or that use values that are converted to floating-point implicitly. Comparisons of floating-point values might yield different results on master and slave servers due to differences in computer architecture, the compiler used to build MySQL, and so forth. See [Section 11.2.2, “Type Conversion in Expression Evaluation”](#), and [Section B.1.5.8, “Problems with Floating-Point Comparisons”](#).

16.3.1.9. Replication and `FLUSH`

Some forms of the `FLUSH` statement are not logged because they could cause problems if replicated to a slave: `FLUSH LOGS`, `FLUSH MASTER`, `FLUSH SLAVE`, and `FLUSH TABLES WITH READ LOCK`. For a syntax example, see [Section 12.5.6.3, “FLUSH Syntax”](#). The `FLUSH TABLES`, `ANALYZE TABLE`, `OPTIMIZE TABLE`, and `REPAIR TABLE` statements are written to the binary log and thus replicated to slaves. This is not normally a problem because these statements do not modify table data.

However, this behavior can cause difficulties under certain circumstances. If you replicate the privilege tables in the `mysql` database and update those tables directly without using `GRANT`, you must issue a `FLUSH PRIVILEGES` on the slaves to put the new privileges into effect. In addition, if you use `FLUSH TABLES` when renaming a `MyISAM` table that is part of a `MERGE` table, you must issue `FLUSH TABLES` manually on the slaves. These statements are written to the binary log unless you specify `NO_WRITE_TO_BINLOG` or its alias `LOCAL`.

16.3.1.10. Replication and System Functions

Certain functions do not replicate well under some conditions:

- The `USER()`, `CURRENT_USER()`, `UUID()`, `VERSION()`, and `LOAD_FILE()` functions are replicated without change and thus do not work reliably on the slave unless row-based replication is enabled. This is also true for `CURRENT_USER`. (See [Section 16.1.2, “Replication Formats”](#).)

For early implementations of mixed-format logging, stored functions, triggers, and views that use these functions in their body do not replicate reliably in mixed-format logging mode because the logging did not switch from statement-based to row-based format. For example, `INSERT INTO t SELECT FROM v`, where `v` is a view that selects `UUID()` could cause problems. This limitation is lifted in MySQL 5.1.12.

Beginning with MySQL 5.1.23, `USER()`, `CURRENT_USER()`, and `CURRENT_USER` are automatically replicated using row-based replication when using `MIXED` mode, and generate a warning in `STATEMENT` mode. ([Bug#28086](#))

- For `NOW()`, the binary log includes the timestamp and replicates correctly.

Unlike `NOW()`, the `SYSDATE()` function is not replication-safe because it is not affected by `SET TIMESTAMP` statements in the binary log and is non-deterministic if statement-based logging is used. This is not a problem if row-based logging is used. Another option is to start the server with the `--sysdate-is-now` option to cause `SYSDATE()` to be an alias for `NOW()`.

- *The following restriction applies to statement-based replication only, not to row-based replication.* The `GET_LOCK()`, `RELEASE_LOCK()`, `IS_FREE_LOCK()`, and `IS_USED_LOCK()` functions that handle user-level locks are replicated without

the slave knowing the concurrency context on master. Therefore, these functions should not be used to insert into a master's table because the content on the slave would differ. (For example, do not issue a statement such as `INSERT INTO mytable VALUES (GET_LOCK(...))`.)

As a workaround for the preceding limitations when statement-based replication is in effect, you can use the strategy of saving the problematic function result in a user variable and referring to the variable in a later statement. For example, the following single-row `INSERT` is problematic due to the reference to the `UUID()` function:

```
INSERT INTO t VALUES(UUID());
```

To work around the problem, do this instead:

```
SET @my_uuid = UUID();
INSERT INTO t VALUES(@my_uuid);
```

That sequence of statements replicates because the value of `@my_uuid` is stored in the binary log as a user-variable event prior to the `INSERT` statement and is available for use in the `INSERT`.

The same idea applies to multiple-row inserts, but is more cumbersome to use. For a two-row insert, you can do this:

```
SET @my_uuid1 = UUID(); @my_uuid2 = UUID();
INSERT INTO t VALUES(@my_uuid1),(@my_uuid2);
```

However, if the number of rows is large or unknown, the workaround is difficult or impracticable. For example, you cannot convert the following statement to one in which a given individual user variable is associated with each row:

```
INSERT INTO t2 SELECT UUID(), * FROM t1;
```

Within a stored function, `RAND()` replicates correctly as long as it is invoked only once during the execution of the function. (You can consider the function execution timestamp and random number seed as implicit inputs that are identical on the master and slave.)

The `FOUND_ROWS()` and `ROW_COUNT()` functions are not replicated reliably using statement-based replication. A workaround is to store the result of the function call in a user variable, and then use that in the `INSERT` statement. For example, if you wish to store the result in a table named `mytable`, you might normally do so like this:

```
SELECT SQL_CALC_FOUND_ROWS FROM mytable LIMIT 1;
INSERT INTO mytable VALUES( FOUND_ROWS() );
```

However, if you are replicating `mytable`, then you should use `SELECT INTO`, and then store the variable in the table, like this:

```
SELECT SQL_CALC_FOUND_ROWS INTO @found_rows FROM mytable LIMIT 1;
INSERT INTO mytable VALUES(@found_rows);
```

In this way, the user variable is replicated as part of the context, and applied on the slave correctly.

Beginning with MySQL 5.1.23, these functions are automatically replicated using row-based replication when using `MIXED` mode, and generate a warning in `STATEMENT` mode. ([Bug#12092](#), [Bug#30244](#))

16.3.1.11. Replication and `LIMIT`

Statement-based replication of `LIMIT` clauses in `DELETE`, `UPDATE`, and `INSERT ... SELECT` statements is unsafe since the order of the rows affected is not defined. (Such statements can be replicated correctly when using `STATEMENT` mode only if they also contain an `ORDER BY` clause.) Beginning with MySQL 5.1.24, when such a statement is encountered:

- When using `STATEMENT` mode, a warning that the statement is not safe for statement-based replication is now issued. Currently, when using `STATEMENT` mode, warnings are issued for DML statements containing `LIMIT` even when they also have an `ORDER BY` clause (and so are made deterministic). This is a known issue which we are working to resolve in a future MySQL release. ([Bug#42851](#))
- When using `MIXED` mode, the statement is now automatically replicated using row-based mode.

16.3.1.12. Replication and `LOAD DATA`

The `LOAD DATA` statement is not replicated correctly to a slave running MySQL 5.1 or later from a master running MySQL 4.0 or earlier.

When using statement-based replication, the `LOAD DATA INFILE` statement's `CONCURRENT` option is not replicated; that is, `LOAD DATA CONCURRENT INFILE` is replicated as `LOAD DATA INFILE`, and `LOAD DATA CONCURRENT LOCAL INFILE` is replicated as `LOAD DATA LOCAL INFILE`. The `CONCURRENT` option *is* replicated when using row-based replication. (Bug#34628)

16.3.1.13. Replication and the Slow Query Log

Replication slaves do not write replicated queries to the slow query log, even if the same queries were written to the slow query log on the master.

This is a known issue which we intend to fix in a future version of MySQL. (Bug#23300)

16.3.1.14. Replication During a Master Crash

A crash on the master side can result in the master's binary log having a final position less than the most recent position read by the slave, due to the master's binary log file not being flushed. This can cause the slave not to be able to replicate when the master comes back up. Setting `sync_binlog=1` in the master `my.cnf` file helps to minimize this problem because it causes the master to flush its binary log more frequently.

16.3.1.15. Replication During a Master Shutdown

It is safe to shut down a master server and restart it later. When a slave loses its connection to the master, the slave tries to reconnect immediately and retries periodically if that fails. The default is to retry every 60 seconds. This may be changed with the `CHANGE MASTER TO` statement or `--master-connect-retry` option. A slave also is able to deal with network connectivity outages. However, the slave notices the network outage only after receiving no data from the master for `slave_net_timeout` seconds. If your outages are short, you may want to decrease `slave_net_timeout`. See Section 5.1.3, “Server System Variables”.

16.3.1.16. Replication with MEMORY Tables

When a server shuts down and restarts, its `MEMORY` tables become empty. The master replicates this effect to slaves as follows: The first time that the master uses each `MEMORY` table after startup, it logs an event that notifies the slaves that the table needs to be emptied by writing a `DELETE` statement for that table to the binary log. See Section 13.9, “The MEMORY (HEAP) Storage Engine”, for more information about `MEMORY` tables.

16.3.1.17. Replication of the System `mysql` Database

MySQL 5.1.14 and later. Data modification statements made to tables in the `mysql` database are replicated according to the value of `binlog_format`; if this value is `MIXED`, then these statements are replicated using the row-based format. However, statements that would normally update this information indirectly — such as `GRANT`, `REVOKE`, and statements manipulating triggers, stored routines, and views — are replicated to slaves using statement-based replication.

MySQL 5.1.13 and earlier. User privileges are replicated only if the `mysql` database is replicated. That is, the `GRANT`, `REVOKE`, `SET PASSWORD`, `CREATE USER`, and `DROP USER` statements take effect on the slave only if the replication setup includes the `mysql` database.

16.3.1.18. Replication and the Query Optimizer

It is possible for the data on the master and slave to become different if a statement is designed in such a way that the data modification is non-deterministic; that is, left up to the query optimizer. (This is in general not a good practice, even outside of replication.) Examples of non-deterministic statements include `DELETE` or `UPDATE` statements that use `LIMIT` with no `ORDER BY` clause; see Section 16.3.1.11, “Replication and `LIMIT`”, for a detailed discussion of these.

16.3.1.19. Replication and Reserved Words

You can encounter problems when you are attempting to replicate from an older master to a newer slave and you make use of identifiers on the master that are reserved words in the newer MySQL version running on the slave. An example of this is using a table column named `current_user` on a 4.0 master that is replicating to a 4.1 or higher slave, because `CURRENT_USER` is a reserved word beginning in MySQL 4.1. Replication can fail in such cases with Error 1064 `YOU HAVE AN ERROR IN YOUR SQL SYNTAX . . .`, even if a database or table named using the reserved word or a table having a column named using the reserved word is excluded from replication. This is due to the fact that each SQL statement must be parsed by the slave prior to execution, so that the slave knows which database object or objects would be effected by the statement; only after the statement is parsed can the slave apply any filtering rules defined by `--replicate-do-db`, `--replicate-do-table`, `--replicate-ignore-db`, and `--replicate-ignore-table`.

To work around the problem of database, table, or column names on the master which would be regarded as reserved words by the slave, do one of the following:

- Use one or more `ALTER TABLE` statements on the master to change the names of any database objects where these names would be considered reserved words on the slave, and change any SQL statements that use the old names to use the new names instead.
- In any SQL statements using these database object names, set the names off using backtick characters (```).

For listings of reserved words by MySQL version, see [Reserved Words](#), in the *MySQL Server Version Reference*.

16.3.1.20. Slave Errors during Replication

If a statement on a slave produces an error, the slave SQL thread terminates, and the slave writes a message to its error log. You should then connect to the slave manually and determine the cause of the problem. (`SHOW SLAVE STATUS` is useful for this.) Then fix the problem (for example, you might need to create a non-existent table) and run `START SLAVE`.

16.3.1.21. Replication during a Slave Shutdown

Shutting down the slave (cleanly) is also safe because it keeps track of where it left off. Unclean shutdowns might produce problems, especially if the disk cache was not flushed to disk before the system went down. Your system fault tolerance is greatly increased if you have a good uninterruptible power supply. Unclean shutdowns of the master may cause inconsistencies between the content of tables and the binary log in master.

16.3.1.22. Replication and Temporary Tables

This item does not apply when row-based replication is in use because in that case temporary tables are not replicated (see [Section 16.1.2, “Replication Formats”](#)).

Safe shutdown of slaves when using temporary tables. Temporary tables are replicated except in the case where you shut down the slave server (not just the slave threads) and you have replicated temporary tables that are used in updates that have not yet been executed on the slave. If you shut down the slave server, the temporary tables needed by those updates are no longer available when the slave is restarted. To avoid this problem, do not shut down the slave while it has temporary tables open. Instead, use the following procedure:

1. Issue a `STOP SLAVE SQL_THREAD` statement.
2. Use `SHOW STATUS` to check the value of the `Slave_open_temp_tables` variable.
3. If the value is 0, issue a `mysqladmin shutdown` command to stop the slave.
4. If the value is not 0, restart the slave SQL thread with `START SLAVE SQL_THREAD`.
5. Repeat the procedure later until the `Slave_open_temp_tables` variable is 0 and you can stop the slave.

Temporary tables and replication options. By default, all temporary tables are replicated; this happens whether or not there are any matching `--replicate-do-db`, `--replicate-do-table`, or `--replicate-wild-do-table` options in effect. However, the `--replicate-ignore-table` and `--replicate-wild-ignore-table` options are honored for temporary tables.

A recommended practice when using statement-based or mixed-format replication is to designate a prefix for exclusive use in naming temporary tables that you do not want replicated, then employ a matching `--replicate-wild-ignore-table` option. For example, you might give all such tables names beginning with `norep_` (such as `norep_tablea`, `norep_tableb`, and so on), then use `--replicate-wild-ignore-table=norep_` to prevent the replication of these tables.

16.3.1.23. Replication Retries and Timeouts

The global system variable `slave_transaction_retries` affects replication as follows: If the replication slave SQL thread fails to execute a transaction because of an InnoDB deadlock or because it exceeded the InnoDB `innodb_lock_wait_timeout` value, or the NDBCLUSTER `TransactionDeadlockDetectionTimeout` or `TransactionInactiveTimeout` value, the transaction is automatically retried `slave_transaction_retries` times before stopping with an error. The default value is 10. The total retry count can be seen in the output of `SHOW STATUS`; see [Section 5.1.6, “Server Status Variables”](#).

16.3.1.24. Replication and Time Zones

If the master uses MySQL 4.1, the same system time zone should be set for both master and slave. Otherwise some statements will not be replicated properly, such as statements that use the `NOW()` or `FROM_UNIXTIME()` functions. You can set the time zone in which MySQL server runs by using the `--timezone=timezone_name` option of the `mysqld_safe` script or by setting the `TZ` environment variable. Both master and slave should also have the same default connection time zone setting; that is, the –

`-default-time-zone` parameter should have the same value for both master and slave. Note that this is not necessary when the master is MySQL 5.0 or later.

`CONVERT_TZ(..., ..., @@session.time_zone)` is properly replicated only if both master and slave are running MySQL 5.0.4 or newer.

16.3.1.25. Replication and Transactions

It is possible to replicate transactional tables on the master using non-transactional tables on the slave. For example, you can replicate an `InnoDB` master table as a `MyISAM` slave table. However, if you do this, there are problems if the slave is stopped in the middle of a `BEGIN/COMMIT` block because the slave restarts at the beginning of the `BEGIN` block.

Mixing transactional and non-transactional statements within the same transaction. The semantics of mixing non-transactional and transactional tables in a transaction in the first statement of a transaction changed in MySQL 5.1.31. Previously, if the first statement in a transaction contained non-transactional changes, the statement was written directly to the binary log, in an attempt to mimic the non-transactional behavior of the statement. Beginning with MySQL 5.1.31, any statement appearing after a `BEGIN` is always considered part of the transaction and cached. This means that non-transactional changes do not propagate to the slave until the transaction is committed and thus written to the binary log. In addition (also beginning with MySQL 5.1.31), if `AUTOMCOMMIT` is set to 0, any statement appearing immediately following a `COMMIT` is handled in the same way.

Previously, a statement was considered non-transactional if it changed a non-transactional table. This behavior had the following subtle but non-trivial consequences:

- A statement containing only non-transactional changes was written immediately to the binary log (sometime referred to as “write-ahead”).
- A statement containing only transactional changes was always cached while waiting for the transaction to be committed.
- A statement containing a mix of transactional and non-transactional changes (that is, a statement updating both transactional and non-transactional tables) could lead to mismatched tables on the master and the slave.

In situations where transactions mix updates to transactional and non-transactional tables, the order of statements in the binary log is correct, and all needed statements are written to the binary log even in case of a `ROLLBACK`. However, when a second connection updates the non-transactional table before the first connection's transaction is complete, statements can be logged out of order, because the second connection's update is written immediately after it is performed, regardless of the state of the transaction being performed by the first connection.

Due to the non-transactional nature of `MyISAM` tables, it is possible to have a statement that only partially updates a table and returns an error code. This can happen, for example, on a multiple-row insert that has one row violating a key constraint, or if a long update statement is killed after updating some of the rows. If that happens on the master, the slave thread exits and waits for the database administrator to decide what to do about it unless the error code is legitimate and execution of the statement results in the same error code on the slave. If this error code validation behavior is not desirable, some or all errors can be masked out (ignored) with the `--slave-skip-errors` option.

Caution

You should avoid transactions that update both transactional and non-transactional tables in a replication environment.

When the storage engine type of the slave is non-transactional, transactions on the master that mix updates of transactional and non-transactional tables should be avoided because they can cause inconsistency of the data between the master's transactional table and the slave's non-transactional table. That is, such transactions can lead to master storage engine-specific behavior with the possible effect of replication going out of synchrony. MySQL does not issue a warning about this currently, so extra care should be taken when replicating transactional tables from the master to non-transactional ones on the slaves.

16.3.1.26. Replication and Triggers

Triggers are not executed on the slave under row-based replication. However, they are executed on the slave under statement-based replication. Instead, when using row-based replication, the changes caused by executing the trigger on the master are applied on the slave.

This behavior is by design. The reason for this is that, if both the master and the slave applied the changes from the master and, in addition, the trigger causing these changes were applied on the slave, the changes would in effect be applied twice on the slave, leading to different data on the master and the slave.

If you wish for triggers to execute on both the master and the slave — perhaps because you have different triggers on the master and slave — then you must use statement-based replication. However, it is not necessary to use statement-based replication exclusively if you want to enable slave-side triggers; it is sufficient in such cases to switch to statement-based replication only for those statements where you want this effect, and to use row-based replication the rest of the time.

Before MySQL 5.1.31, a trigger that was defined on a transactional table but that updated a non-transactional tables could cause updates on the transactional table to be replicated before they were actually committed on the master, and not be rolled back correctly on the slave if they were rolled back on the master. (Bug#40116) See also [Section 16.3.1.25, “Replication and Transactions”](#).

16.3.1.27. Replication and TRUNCATE

`TRUNCATE` is normally regarded as a DML statement, and so would be expected to be logged and replicated using row-based format when the binary logging mode is `ROW` or `MIXED`. However this caused issues when logging or replicating, in `STATEMENT` or `MIXED` mode, tables that used transactional storage engines such as `InnoDB` when the transaction isolation level was `READ COMMITTED` or `READ UNCOMMITTED`, which precludes statement-based logging.

Beginning with MySQL 5.1.32, `TRUNCATE` is treated for purposes of logging and replication as DDL rather than DML so that it can be logged and replicated as a statement. However, the effects of the statement as applicable to `InnoDB` and other transactional tables on replication slaves still follow the rules described in [Section 12.2.10, “TRUNCATE Syntax”](#) governing such tables. (Bug#36763)

16.3.1.28. Replication and Variables

The `foreign_key_checks`, `unique_checks`, and `sql_auto_is_null` variables are all replicated.

`sql_mode` is also replicated except for the `NO_DIR_IN_CREATE` mode. However, when `mysqlbinlog` parses a `SET @@sql_mode = value` statement, the full `value`, including `NO_DIR_IN_CREATE`, is passed to the receiving server.

The `storage_engine` system variable is not replicated, which is a good thing for replication between different storage engines.

Session variables are not replicated properly when used in statements that update tables. For example, `SET MAX_JOIN_SIZE=1000` followed by `INSERT INTO mytable VALUES(@@MAX_JOIN_SIZE)` will not insert the same data on the master and the slave. This does not apply to the common sequence of `SET TIME_ZONE=...` followed by `INSERT INTO mytable VALUES(CONVERT_TZ(..., ..., @@time_zone))`.

Replication of session variables is not a problem when row-based replication is being used. See [Section 16.1.2, “Replication Formats”](#).

16.3.1.29. Replication and Views

Views are always replicated to slaves. Views are filtered by their own name, not by the tables they refer to. This means that a view can be replicated to the slave even if the view contains a table that would normally be filtered out by `replication-ignore-table` rules. Care should therefore be taken to ensure that views do not replicate table data that would normally be filtered for security reasons.

16.3.2. Replication Compatibility Between MySQL Versions

MySQL supports replication from one major version to the next higher major version. For example, you can replicate from a master running MySQL 4.1 to a slave running MySQL 5.0, from a master running MySQL 5.0 to a slave running MySQL 5.1, and so on.

In some cases, it is also possible to replicate between a master and a slave that is more than one major version newer than the master. However, there are known issues with trying to replicate from a master running MySQL 4.1 or earlier to a slave running MySQL 5.1 or later. To work around such problems, you can insert a MySQL server running an intermediate version between the two; for example, rather than replicating directly from a MySQL 4.1 master to a MySQL 5.1 slave, it is possible to replicate from a MySQL 4.1 server to a MySQL 5.0 server, and then from the MySQL 5.0 server to a MySQL 5.1 server.

Important

We strongly recommend using the most recent release available within a given MySQL major version because replication (and other) capabilities are continually being improved. We also recommend upgrading masters and slaves that use alpha or beta releases of a major version of MySQL to GA (production) releases when these become available for that major version.

Replication from newer masters to older slaves may be possible, but is generally not supported. This is due to a number of factors:

- **Binary log format changes.** The binary log format can change between major releases. While we attempt to maintain backward compatibility, this is not always possible. For example, the binary log format implemented in MySQL 5.0 changed considerably from that used in previous versions, especially with regard to handling of character sets, `LOAD DATA INFILE`, and time zones. This means that replication from a MySQL 5.0 (or later) master to a MySQL 4.1 (or earlier) slave is generally not supported.

This also has significant implications for upgrading replication servers; see [Section 16.3.3, “Upgrading a Replication Setup”](#),

for more information.

- **Use of row-based replication.** You cannot replicate using row-based replication from a MySQL 5.1.5 or later master to a slave running an earlier version of MySQL, since MySQL versions prior to 5.1.5 do not support RBR.

For more information about row-based replication, see [Section 16.1.2, “Replication Formats”](#).

- **SQL incompatibilities.** You cannot replicate from a newer master to an older slave using statement-based replication if the statements to be replicated use SQL features available on the master but not on the slave.

However, if both the master and the slave support row-based replication, and there are no data definition statements to be replicated that depend on SQL features found on the master but not on the slave, then you can use row-based replication to replicate the effects of data modification statements even if the DDL run on the master is not supported on the slave.

For more information on potential replication issues, see [Section 16.3.1, “Replication Features and Issues”](#).

16.3.3. Upgrading a Replication Setup

When you upgrade servers that participate in a replication setup, the procedure for upgrading depends on the current server versions and the version to which you are upgrading.

This section applies to upgrading replication from older versions of MySQL to MySQL 5.1. A 4.0 server should be 4.0.3 or newer.

When you upgrade a master to 5.1 from an earlier MySQL release series, you should first ensure that all the slaves of this master are using the same 5.1.x release. If this is not the case, you should first upgrade the slaves. To upgrade each slave, shut it down, upgrade it to the appropriate 5.1.x version, restart it, and restart replication. The 5.1 slave is able to read the old relay logs written prior to the upgrade and to execute the statements they contain. Relay logs created by the slave after the upgrade are in 5.1 format.

After the slaves have been upgraded, shut down the master, upgrade it to the same 5.1.x release as the slaves, and restart it. The 5.1 master is able to read the old binary logs written prior to the upgrade and to send them to the 5.1 slaves. The slaves recognize the old format and handle it properly. Binary logs created by the master following the upgrade are in 5.1 format. These too are recognized by the 5.1 slaves.

In other words, there are no measures to take when upgrading to MySQL 5.1, except that the slaves must be MySQL 5.1 before you can upgrade the master to 5.1. Note that downgrading from 5.1 to older versions does not work so simply: You must ensure that any 5.1 binary logs or relay logs have been fully processed, so that you can remove them before proceeding with the downgrade.

Downgrading a replication setup to a previous version cannot be done once you have switched from statement-based to row-based replication, and after the first row-based statement has been written to the binlog. See [Section 16.1.2, “Replication Formats”](#).

16.3.4. Replication FAQ

Questions

- [16.3.4.1](#): Does the slave need to be connected to the master all the time?
- [16.3.4.2](#): Do I have to enable networking on my master to enable replication?

Questions and Answers

16.3.4.1: Does the slave need to be connected to the master all the time?

No, it does not. The slave can go down or stay disconnected for hours or even days, and then reconnect and catch up on updates. For example, you can set up a master/slave relationship over a dial-up link where the link is up only sporadically and for short periods of time. The implication of this is that, at any given time, the slave is not guaranteed to be in sync with the master unless you take some special measures.

To ensure that this is the case, you must not remove binary logs from the master, where the information has not been replicated to the slaves. Asynchronous replication can only work if the slave is able to read the binary log from the last point in the binary logs where it had read the replication statements.

16.3.4.2: Do I have to enable networking on my master to enable replication?

Networking must be enabled on the master. If networking is not enabled, then the slave is unable to connect to the master and transfer the binary log. Check that the `skip-networking` option has not been enabled in your configuration file.

16.3.4.3: How do I know how late a slave is compared to the master? In other words, how do I know the date of the last statement replicated by the slave?

You can read the `Seconds_Behind_Master` column in `SHOW SLAVE STATUS`. See [Section 16.4.1, “Replication Implementation Details”](#).

When the slave SQL thread executes an event read from the master, it modifies its own time to the event timestamp. (This is why `TIMESTAMP` is well replicated.) In the `Time` column in the output of `SHOW PROCESSLIST`, the number of seconds displayed for the slave SQL thread is the number of seconds between the timestamp of the last replicated event and the real time of the slave machine. You can use this to determine the date of the last replicated event. Note that if your slave has been disconnected from the master for one hour, and then reconnects, you may immediately see `Time` values like 3600 for the slave SQL thread in `SHOW PROCESSLIST`. This is because the slave is executing statements that are one hour old.

16.3.4.4: How do I force the master to block updates until the slave catches up?

Use the following procedure:

1. On the master, execute these statements:

```
mysql> FLUSH TABLES WITH READ LOCK;
mysql> SHOW MASTER STATUS;
```

Record the replication coordinates (the log file name and offset) from the output of the `SHOW` statement.

2. On the slave, issue the following statement, where the arguments to the `MASTER_POS_WAIT()` function are the replication coordinate values obtained in the previous step:

```
mysql> SELECT MASTER_POS_WAIT('log_name', log_offset);
```

The `SELECT` statement blocks until the slave reaches the specified log file and offset. At that point, the slave is in synchrony with the master and the statement returns.

3. On the master, issue the following statement to allow the master to begin processing updates again:

```
mysql> UNLOCK TABLES;
```

16.3.4.5: What issues should I be aware of when setting up two-way replication?

MySQL replication currently does not support any locking protocol between master and slave to guarantee the atomicity of a distributed (cross-server) update. In other words, it is possible for client A to make an update to co-master 1, and in the meantime, before it propagates to co-master 2, client B could make an update to co-master 2 that makes the update of client A work differently than it did on co-master 1. Thus, when the update of client A makes it to co-master 2, it produces tables that are different from what you have on co-master 1, even after all the updates from co-master 2 have also propagated. This means that you should not chain

two servers together in a two-way replication relationship unless you are sure that your updates can safely happen in any order, or unless you take care of mis-ordered updates somehow in the client code.

You should also realize that two-way replication actually does not improve performance very much (if at all) as far as updates are concerned. Each server must do the same number of updates, just as you would have a single server do. The only difference is that there is a little less lock contention, because the updates originating on another server are serialized in one slave thread. Even this benefit might be offset by network delays.

16.3.4.6: How can I use replication to improve performance of my system?

You should set up one server as the master and direct all writes to it. Then configure as many slaves as you have the budget and rackspace for, and distribute the reads among the master and the slaves. You can also start the slaves with the `--skip-innodb`, `--low-priority-updates`, and `--delay-key-write=ALL` options to get speed improvements on the slave end. In this case, the slave uses non-transactional `MyISAM` tables instead of `InnoDB` tables to get more speed by eliminating transactional overhead.

16.3.4.7: What should I do to prepare client code in my own applications to use performance-enhancing replication?

See the guide to using replication as a scale-out solution, [Section 16.2.3, “Using Replication for Scale-Out”](#).

16.3.4.8: When and how much can MySQL replication improve the performance of my system?

MySQL replication is most beneficial for a system that processes frequent reads and infrequent writes. In theory, by using a single-master/multiple-slave setup, you can scale the system by adding more slaves until you either run out of network bandwidth, or your update load grows to the point that the master cannot handle it.

To determine how many slaves you can use before the added benefits begin to level out, and how much you can improve performance of your site, you need to know your query patterns, and to determine empirically by benchmarking the relationship between the throughput for reads (reads per second, or `reads`) and for writes (`writes`) on a typical master and a typical slave. The example here shows a rather simplified calculation of what you can get with replication for a hypothetical system.

Let's say that system load consists of 10% writes and 90% reads, and we have determined by benchmarking that `reads` is $1200 - 2 \times \text{writes}$. In other words, the system can do 1,200 reads per second with no writes, the average write is twice as slow as the average read, and the relationship is linear. Let us suppose that the master and each slave have the same capacity, and that we have one master and N slaves. Then we have for each server (master or slave):

$$\text{reads} = 1200 - 2 \times \text{writes}$$

$$\text{reads} = 9 \times \text{writes} / (N + 1) \text{ (reads are split, but writes go to all servers)}$$

$$9 \times \text{writes} / (N + 1) + 2 \times \text{writes} = 1200$$

$$\text{writes} = 1200 / (2 + 9/(N+1))$$

The last equation indicates the maximum number of writes for N slaves, given a maximum possible read rate of 1,200 per minute and a ratio of nine reads per write.

This analysis yields the following conclusions:

- If $N = 0$ (which means we have no replication), our system can handle about $1200/11 = 109$ writes per second.
- If $N = 1$, we get up to 184 writes per second.
- If $N = 8$, we get up to 400 writes per second.
- If $N = 17$, we get up to 480 writes per second.
- Eventually, as N approaches infinity (and our budget negative infinity), we can get very close to 600 writes per second, increasing system throughput about 5.5 times. However, with only eight servers, we increase it nearly four times.

Note that these computations assume infinite network bandwidth and neglect several other factors that could be significant on your system. In many cases, you may not be able to perform a computation similar to the one just shown that accurately predicts what will happen on your system if you add N replication slaves. However, answering the following questions should help you decide whether and by how much replication will improve the performance of your system:

- What is the read/write ratio on your system?
- How much more write load can one server handle if you reduce the reads?

- For how many slaves do you have bandwidth available on your network?

16.3.4.9: How can I use replication to provide redundancy or high availability?

How you implement redundancy is entirely dependent on your application and circumstances. High-availability solutions (with automatic failover) require active monitoring and either custom scripts or third party tools to provide the failover support from the original MySQL server to the slave.

To handle the process manually, you should be able to switch from a failed master to a pre-configured slave by altering your application to talk to the new server or by adjusting the DNS for the MySQL server from the failed server to the new server.

For more information and some example solutions, see [Section 16.2.6, “Switching Masters During Failover”](#).

16.3.4.10: How do I tell whether a master server is using statement-based or row-based binary logging format?

Check the value of the `binlog_format` system variable:

```
mysql> SHOW VARIABLES LIKE 'binlog_format';
```

The value shown is one of `STATEMENT`, `ROW`, or `MIXED`. When `MIXED` mode is in use, row-based replication is preferred but replication switches automatically to statement-based format under certain conditions; see [Section 5.2.4.3, “Mixed Binary Logging Format”](#), for information about when this may occur.

16.3.4.11: How do I tell a slave to use row-based replication?

Slaves automatically know which format to use.

16.3.4.12: How do I prevent `GRANT` and `REVOKE` statements from replicating to slave machines?

Start the server with the `--replicate-wild-ignore-table=mysql.%` option.

16.3.4.13: Does replication work on mixed operating systems (for example, the master runs on Linux while slaves run on Mac OS X and Windows)?

Yes.

16.3.4.14: Does replication work on mixed hardware architectures (for example, the master runs on a 64-bit machine while slaves run on 32-bit machines)?

Yes.

16.3.5. Troubleshooting Replication

If you have followed the instructions, and your replication setup is not working, the first thing to do is *check the error log for messages*. Many users have lost time by not doing this soon enough after encountering problems.

If you cannot tell from the error log what the problem was, try the following techniques:

- Verify that the master has binary logging enabled by issuing a `SHOW MASTER STATUS` statement. If logging is enabled, `Position` is nonzero. If binary logging is not enabled, verify that you are running the master with the `--log-bin` and `--server-id` options.
- Verify that the slave is running. Use `SHOW SLAVE STATUS` to check whether the `Slave_IO_Running` and `Slave_SQL_Running` values are both `Yes`. If not, verify the options that were used when starting the slave server. For example, `--skip-slave-start` prevents the slave threads from starting until you issue a `START SLAVE` statement.
- If the slave is running, check whether it established a connection to the master. Use `SHOW PROCESSLIST`, find the I/O and SQL threads and check their `State` column to see what they display. See [Section 16.4.1, “Replication Implementation Details”](#). If the I/O thread state says `Connecting to master`, check the following:
 - Verify the privileges for the user being used for replication on the master.
 - Check that the host name of the master is correct and that you are using the correct port to connect to the master. The port used for replication is the same as used for client network communication (the default is `3306`). For the host name, ensure that the name resolves to the correct IP address.
 - Check that networking on the master has not been disabled. Look for the `skip-networking` option in the configuration file. It should either be commented out or deleted entirely.

- If the master has a firewall or IP filtering configuration, ensure that the network port being used for MySQL is not being filtered.
- Check that you can reach the master by using `ping` or `traceroute/tracert` to reach the host.
- If the slave was running previously but has stopped, the reason usually is that some statement that succeeded on the master failed on the slave. This should never happen if you have taken a proper snapshot of the master, and never modified the data on the slave outside of the slave thread. If the slave stops unexpectedly, it is a bug or you have encountered one of the known replication limitations described in [Section 16.3.1, “Replication Features and Issues”](#). If it is a bug, see [Section 16.3.6, “How to Report Replication Bugs or Problems”](#), for instructions on how to report it.
- If a statement that succeeded on the master refuses to run on the slave, try the following procedure if it is not feasible to do a full database resynchronization by deleting the slave's databases and copying a new snapshot from the master:
 1. Determine whether the affected table on the slave is different from the master table. Try to understand how this happened. Then make the slave's table identical to the master's and run `START SLAVE`.
 2. If the preceding step does not work or does not apply, try to understand whether it would be safe to make the update manually (if needed) and then ignore the next statement from the master.
 3. If you decide that you can skip the next statement from the master, issue the following statements:

```
mysql> SET GLOBAL SQL_SLAVE_SKIP_COUNTER = N;
mysql> START SLAVE;
```

The value of *N* should be 1 if the next statement from the master does not use `AUTO_INCREMENT` or `LAST_INSERT_ID()`. Otherwise, the value should be 2. The reason for using a value of 2 for statements that use `AUTO_INCREMENT` or `LAST_INSERT_ID()` is that they take two events in the binary log of the master.

See also [Section 12.6.2.6, “SET GLOBAL SQL_SLAVE_SKIP_COUNTER Syntax”](#).

4. If you are sure that the slave started out perfectly synchronized with the master, and that no one has updated the tables involved outside of the slave thread, then presumably the discrepancy is the result of a bug. If you are running the most recent version of MySQL, please report the problem. If you are running an older version, try upgrading to the latest production release to determine whether the problem persists.

16.3.6. How to Report Replication Bugs or Problems

When you have determined that there is no user error involved, and replication still either does not work at all or is unstable, it is time to send us a bug report. We need to obtain as much information as possible from you to be able to track down the bug. Please spend some time and effort in preparing a good bug report.

If you have a repeatable test case that demonstrates the bug, please enter it into our bugs database using the instructions given in [Section 1.6, “How to Report Bugs or Problems”](#). If you have a “phantom” problem (one that you cannot duplicate at will), use the following procedure:

1. Verify that no user error is involved. For example, if you update the slave outside of the slave thread, the data goes out of synchrony, and you can have unique key violations on updates. In this case, the slave thread stops and waits for you to clean up the tables manually to bring them into synchrony. *This is not a replication problem. It is a problem of outside interference causing replication to fail.*
2. Run the slave with the `--log-slave-updates` and `--log-bin` options. These options cause the slave to log the updates that it receives from the master into its own binary logs.
3. Save all evidence before resetting the replication state. If we have no information or only sketchy information, it becomes difficult or impossible for us to track down the problem. The evidence you should collect is:
 - All binary logs from the master
 - All binary logs from the slave
 - The output of `SHOW MASTER STATUS` from the master at the time you discovered the problem
 - The output of `SHOW SLAVE STATUS` from the slave at the time you discovered the problem
 - Error logs from the master and the slave

- Use `mysqlbinlog` to examine the binary logs. The following should be helpful to find the problem statement. `log_pos` and `log_file` are the `Master_Log_File` and `Read_Master_Log_Pos` values from `SHOW SLAVE STATUS`.

```
shell> mysqlbinlog --start-position=log_pos log_file | head
```

After you have collected the evidence for the problem, try to isolate it as a separate test case first. Then enter the problem with as much information as possible into our bugs database using the instructions at [Section 1.6, “How to Report Bugs or Problems”](#).

16.4. Replication Implementation

The basic mechanics of replication is based on the master server keeping track of all changes to your databases (updates, deletes, and so on) in its binary logs. The binary log serves as a written record of each to the database from the moment the database was started. The binary log contains records of all the statements which edit or modify either the database structure or the data that the structure contains. Typically `SELECT` statements are not recorded, as they do not modify the database data or structure.

Each slave that connects to the master receives a copy of the binary log, and executes the events within the binary log. This has the effect of repeating the original statements and changes just as they were made on the master. Tables are created or their structure modified, and data is inserted, deleted and updated according to the statements that were originally executed on the master.

Because each slave is independent, the replaying of the statements in the masters binary log can occur on each slave that is connected to the master. In addition, because each slave only receives a copy of the binary log by requesting it from the master (it pulls the data from the master, rather than the master pushing the data to the slave), the slave is able to read and update the copy of the database at its own pace and rate and can start and stop the replication process at will without affecting the master or the slaves ability to update to the latest database status.

For more information on the specifics of the replication implementation, see [Section 16.4.1, “Replication Implementation Details”](#).

Slaves and masters report their status in respect of the replication process regularly so that you can monitor the situation. For information on slave states, see [Section 7.5.6.5, “Replication Slave I/O Thread States”](#), and [Section 7.5.6.6, “Replication Slave SQL Thread States”](#). For master states, see [Section 7.5.6.4, “Replication Master Thread States”](#).

The master binary log is written to a local relay log on the slave before it is processed. The slave also records information about the current position with the master's binary log and the local relayed log. See [Section 16.4.2, “Replication Relay and Status Files”](#).

Databases and tables are updated on the slave according to a set of rules that are applied according to the various configuration options and variables that control statement evaluation. For details on how these rules are applied, see [Section 16.4.3, “How Servers Evaluate Replication Rules”](#).

16.4.1. Replication Implementation Details

MySQL replication capabilities are implemented using three threads (one on the master server and two on the slave):

- Slave I/O thread.** When a `START SLAVE` statement is issued on a slave server, the slave creates an *I/O thread*, which connects to the master and asks it to send the updates recorded in its binary logs.

The slave I/O thread reads the updates that the master's `Binlog Dump` thread sends (see next item) and copies them to local files — known as *relay logs* - in the slave's data directory.

The state of this thread is shown as `Slave_IO_running` in the output of `SHOW SLAVE STATUS` or as `Slave_running` in the output of `SHOW STATUS`.

- Binlog dump thread.** The master creates a thread to send the binary log contents to the slave. This thread can be identified in the output of `SHOW PROCESSLIST` on the master as the `Binlog Dump` thread.

The binlog dump thread acquires a lock on the master's binary log for reading each event that is to be sent to the slave. As soon as the event has been read, the lock is released, even before the event is sent to the slave.

- Slave SQL thread.** The slave creates this thread to read the relay logs that were written by the slave I/O thread. The *slave SQL thread* is also used to execute the updates contained in the relay logs.

MySQL Enterprise

For constant monitoring of the status of slaves subscribe to the MySQL Enterprise Monitor. For more information, see <http://www.mysql.com/products/enterprise/advisors.html>.

In the preceding description, there are three threads per master/slave connection. A master that has multiple slaves creates one binlog dump thread for each currently-connected slave, and each slave has its own I/O and SQL threads.

The slave uses two threads so that reading updates from the master and executing them can be separated into two independent tasks. Thus, the task of reading statements is not slowed down if statement execution is slow. For example, if the slave server has not been running for a while, its I/O thread can quickly fetch all the binary log contents from the master when the slave starts, even if the SQL thread lags far behind. If the slave stops before the SQL thread has executed all the fetched statements, the I/O thread has at least fetched everything so that a safe copy of the statements is stored locally in the slave's relay logs, ready for execution the next time that the slave starts. This enables the master server to purge its binary logs sooner because it no longer needs to wait for the slave to fetch their contents.

The `SHOW PROCESSLIST` statement provides information that tells you what is happening on the master and on the slave regarding replication. See [Section 7.5.6, “Examining Thread Information”](#), for descriptions of all replicated-related states.

The following example illustrates how the three threads show up in the output from `SHOW PROCESSLIST`.

On the master server, the output from `SHOW PROCESSLIST` looks like this:

```
mysql> SHOW PROCESSLIST\G
***** 1. row *****
  Id: 2
  User: root
  Host: localhost:32931
  db: NULL
Command: Binlog Dump
  Time: 94
  State: Has sent all binlog to slave; waiting for binlog to
        be updated
  Info: NULL
```

Here, thread 2 is a `Binlog Dump` replication thread for a connected slave. The `State` information indicates that all outstanding updates have been sent to the slave and that the master is waiting for more updates to occur. If you see no `Binlog Dump` threads on a master server, this means that replication is not running — that is, that no slaves are currently connected.

On the slave server, the output from `SHOW PROCESSLIST` looks like this:

```
mysql> SHOW PROCESSLIST\G
***** 1. row *****
  Id: 10
  User: system user
  Host:
  db: NULL
Command: Connect
  Time: 11
  State: Waiting for master to send event
  Info: NULL
***** 2. row *****
  Id: 11
  User: system user
  Host:
  db: NULL
Command: Connect
  Time: 11
  State: Has read all relay log; waiting for the slave I/O
        thread to update it
  Info: NULL
```

This information indicates that thread 10 is the I/O thread that is communicating with the master server, and thread 11 is the SQL thread that is processing the updates stored in the relay logs. At the time that the `SHOW PROCESSLIST` was run, both threads were idle, waiting for further updates.

The value in the `Time` column can show how late the slave is compared to the master. See [Section 16.3.4, “Replication FAQ”](#). The amount of time that the slave lags behind the master that is required before the master determines that the slave is no longer connected — as with any other client connection — is dependent on the values of `net_write_timeout` and `net_retry_count`; for more information about these, see [Section 5.1.3, “Server System Variables”](#).

16.4.2. Replication Relay and Status Files

During replication the MySQL server creates a number of files that are used to hold the relayed binary log from the master, and record information about the current status and location within the relayed log. There are three file types used in the process:

- The *relay log* consists of the events read from the binary log of the master. Events in this binary log are executed on the slave as part of the replication thread.
- The *master.info* file contains the status and current configuration information for the slave's connectivity to the master. The file holds information on the master host name, login credentials, and the current position within the master's binary log.
- The *relay-log.info* file holds the status information about the execution point within the slave's relay log files.

The relationship between the three files and the replication process is as follows. The `master.info` file retains the point within the master binary log that has been read from the master. These read events are written to the relay log. The `relay-log.info` file records the position within the relay log of the statements that have been executed.

16.4.2.1. The Slave Relay Log

By default, relay log file names have the form `host_name-relay-bin.nnnnnn`, where `host_name` is the name of the slave server host and `nnnnnn` is a sequence number. Successive relay log files are created using successive sequence numbers, beginning with 000001. The slave uses an index file to track the relay log files currently in use. The default relay log index file name is `host_name-relay-bin.index`. By default, the slave server creates relay log files in its data directory.

The default file names for relay logs and relay log index files can be overridden with, respectively, the `--relay-log` and `--relay-log-index` server options (see Section 16.1.3, “Replication and Binary Logging Options and Variables”). For this reason, changing a replication slave's host name can cause replication to fail with the errors `FAILED TO OPEN THE RELAY LOG` and `COULD NOT FIND TARGET LOG DURING RELAY LOG INITIALIZATION`. This is a known issue which we intend to fix in a future MySQL release (see Bug#2122). If you anticipate that a slave's host name may change in the future (for example, if networking is set up on the slave such that its host name can be modified via DHCP), then you can use these options to prevent this problem from occurring. However, if you encounter this issue, one way to work around it is to stop the slave server, prepend the contents of the old relay log index file to the new one, then restart the slave. On a Unix system, this can be done as shown here, where `new_host_name` is the new host name and `old_host_name` is the old one:

```
shell> cat new_host_name-relay-bin.index >> old_host_name-relay-bin.index
shell> mv old_host_name-relay-bin.index new_host_name-relay-bin.index
```

Relay logs have the same format as binary logs and can be read using `mysqlbinlog`. The SQL thread automatically deletes each relay log file as soon as it has executed all events in the file and no longer needs it. There is no explicit mechanism for deleting relay logs because the SQL thread takes care of doing so. However, `FLUSH LOGS` rotates relay logs, which influences when the SQL thread deletes them.

A slave server creates a new relay log file under the following conditions:

- Each time the I/O thread starts.
- When the logs are flushed; for example, with `FLUSH LOGS` or `mysqladmin flush-logs`.
- When the size of the current relay log file becomes too large. The meaning of “too large” is determined as follows:
 - If the value of `max_relay_log_size` is greater than 0, that is the maximum relay log file size.
 - If the value of `max_relay_log_size` is 0, `max_binlog_size` determines the maximum relay log file size.

16.4.2.2. The Slave Status Files

A slave replication server creates two small files in the data directory. These *status files* are named `master.info` and `relay-log.info` by default. Their names can be changed by using the `--master-info-file` and `--relay-log-info-file` options. See Section 16.1.3, “Replication and Binary Logging Options and Variables”.

The two status files contain information like that shown in the output of the `SHOW SLAVE STATUS` statement, which is discussed in Section 12.6.2, “SQL Statements for Controlling Slave Servers”. Because the status files are stored on disk, they survive a slave server's shutdown. The next time the slave starts up, it reads the two files to determine how far it has proceeded in reading binary logs from the master and in processing its own relay logs.

The I/O thread updates the `master.info` file. The following table shows the correspondence between the lines in the file and the columns displayed by `SHOW SLAVE STATUS`.

Line	Status Column	Description
1		Number of lines in the file
2	<code>Master_Log_File</code>	The name of the master binary log currently being read from the master.
3	<code>Read_Master_Log_Pos</code>	The current position within the master binary log that have been read from the master.
4	<code>Master_Host</code>	The host name of the master.
5	<code>Master_User</code>	The user name used to connect to the master.
6	Password (not shown by <code>SHOW SLAVE</code>)	The password used to connect to the master.

	STATUS)	
7	Master_Port	The network port used to connect to the master.
8	Connect_Retry	The period (in seconds) that the slave will wait before trying to reconnect to the master.
9	Master_SSL_Allowed	Indicates whether the server supports SSL connections.
10	Master_SSL_CA_File	The file used for the Certificate Authority (CA) certificate.
11	Master_SSL_CA_Path	The path to the Certificate Authority (CA) certificates.
12	Master_SSL_Cert	The name of the SSL certificate file.
13	Master_SSL_Cipher	The name of the cipher in use for the SSL connection.
14	Master_SSL_Key	The name of the SSL key file.
15	Master_SSL_Verify_Server_Cert	Whether to verify the server certificate.

Master_SSL_Verify_Server_Cert is present in `master.info` as of MySQL 5.1.18. It is used as described for the `--ssl-verify-server-cert` option in [Section 5.5.7.3, “SSL Command Options”](#).

The SQL thread updates the `relay-log.info` file. The following table shows the correspondence between the lines in the file and the columns displayed by `SHOW SLAVE STATUS`.

Line	Status Column	Description
1	Relay_Log_File	The name of the current relay log file.
2	Relay_Log_Pos	The current position within the relay log file. Events up to this position have been executed on the slave database.
3	Relay_Master_Log_File	The name of the master binary log file from which the events in the relay log file were read.
4	Exec_Master_Log_Pos	The equivalent position within the master's binary log file of events that have already been executed.

The contents of the `relay-log.info` file and the states shown by the `SHOW SLAVE STATES` command may not match if the `relay-log.info` file has not been flushed to disk. Ideally, you should only view `relay-log.info` on a slave that is offline (i.e. `mysqld` is not running). For a running system, `SHOW SLAVE STATUS` should be used.

16.4.3. How Servers Evaluate Replication Rules

If a master server does not write a statement to its binary log, the statement is not replicated. If the server does log the statement, the statement is sent to all slaves and each slave determines whether to execute it or ignore it.

On the master you can control which databases write events to the binary log using the `--binlog-do-db` and `--binlog-ignore-db` options to control binary logging. For a description of the rules that servers use in evaluating these options, see [Section 5.2.4, “The Binary Log”](#). You should not use these options to control the databases and tables that are replicated, instead, use filtering on the slave to control the events that are executed on the slave.

On the slave side, decisions about whether to execute or ignore statements received from the master are made according to the `--replicate-*` options that the slave was started with. (See [Section 16.1.3, “Replication and Binary Logging Options and Variables”](#).) The slave evaluates these options using the following procedure, which first checks the database-level options and then the table-level options.

In the simplest case, when there are no `--replicate-*` options, the procedure yields the result that the slave executes all statements that it receives from the master. Otherwise, the result depends on the particular options given. In general, to make it easier to determine what effect an option set will have, it is recommended that you avoid mixing “do” and “ignore” options, or wildcard and non-wildcard options.

Stage 1. Check the database options.

At this stage, the slave checks whether there are any `--replicate-do-db` or `--replicate-ignore-db` options that specify database-specific conditions:

- *No*: Permit the statement and proceed to the table-checking stage.
- *Yes*: Test the options using the same rules as for the `--binlog-do-db` and `--binlog-ignore-db` options to determine whether to permit or ignore the statement. What is the result of the test?

- *Permit*: Do not execute the statement immediately. Defer the decision and proceed to the table-checking stage.
- *Ignore*: Ignore the statement and exit.

This stage can permit a statement for further option-checking, or cause it to be ignored. However, statements that are permitted at this stage are not actually executed yet. Instead, they pass to the following stage that checks the table options.

Stage 2. Check the table options.

First, as a preliminary condition, the slave checks whether statement-based replication is enabled. If so and the statement occurs within a stored function, execute the statement and exit. (If row-based replication is enabled, the slave does not know whether a statement occurred within a stored function on the master, so this condition does not apply.)

Next, the slave checks for table options and evaluates them. If the server reaches this point, it executes all statements if there are no table options. If there are “do” table options, the statement must match one of them if it is to be executed; otherwise, it is ignored. If there are any “ignore” options, all statements are executed except those that match any “ignore” option. The following steps describe how this evaluation occurs in more detail.

1. Are there any `--replicate-*-table` options?

- *No*: There are no table restrictions, so all statements match. Execute the statement and exit.
- *Yes*: There are table restrictions. Evaluate the tables to be updated against them. There might be multiple tables to update, so loop through the following steps for each table looking for a matching option. In this case, the behavior depends on whether statement-based replication or row-based replication is enabled:
 - *Statement-based replication*: Proceed to the next step and begin evaluating the table options in the order shown (first the non-wild options, and then the wild options). Only tables that are to be updated are compared to the options. For example, if the statement is `INSERT INTO sales SELECT * FROM prices`, only `sales` is compared to the options). If several tables are to be updated (multiple-table statement), the first table that matches “do” or “ignore” wins. That is, the server checks the first table against the options. If no decision could be made, it checks the second table against the options, and so on.
 - *Row-based replication*: All table row changes are filtered individually. For multiple-table updates, each table is filtered separately according to the options. Some updates may be executed and some not, depending on the options and the changes to be made. Row-based replication correctly handles cases that would not replicate correctly with statement-based replication, as in this example which assumes that tables in the `foo` database should be replicated:

```
mysql> USE bar;
mysql> INSERT INTO foo.sometable VALUES (1);
```

2. Are there any `--replicate-do-table` options?

- *No*: Proceed to the next step.
- *Yes*: Does the table match any of them?
 - *No*: Proceed to the next step.
 - *Yes*: Execute the statement and exit.

3. Are there any `--replicate-ignore-table` options?

- *No*: Proceed to the next step.
- *Yes*: Does the table match any of them?
 - *No*: Proceed to the next step.
 - *Yes*: Ignore the statement and exit.

4. Are there any `--replicate-wild-do-table` options?

- *No*: Proceed to the next step.
- *Yes*: Does the table match any of them?
 - *No*: Proceed to the next step.

- *Yes*: Execute the statement and exit.
5. Are there any `--replicate-wild-ignore-table` options?
- *No*: Proceed to the next step.
 - *Yes*: Does the table match any of them?
 - *No*: Proceed to the next step.
 - *Yes*: Ignore the statement and exit.
6. No `--replicate-*-table` option was matched. Is there another table to test against these options?
- *No*: We have now tested all tables to be updated and could not match any option. Are there `--replicate-do-table` or `--replicate-wild-do-table` options?
 - *No*: There were no “do” table options, so no explicit “do” match is required. Execute the statement and exit.
 - *Yes*: There were “do” table options, so the statement is executed only with an explicit match to one of them. Ignore the statement and exit.
 - *Yes*: Loop.

Examples:

- No `--replicate-*` options at all
The slave executes all statements that it receives from the master.
- `--replicate-*-db` options, but no table options
The slave permits or ignores statements using the database options. Then it executes all statements permitted by those options because there are no table restrictions.
- `--replicate-*-table` options, but no database options
All statements are permitted at the database-checking stage because there are no database conditions. The slave executes or ignores statements based on the table options.
- A mix of database and table options
The slave permits or ignores statements using the database options. Then it evaluates all statements permitted by those options according to the table options. In some cases, this process can yield what might seem a counterintuitive result. Consider the following set of options:

```
[mysqld]
replicate-do-db      = db1
replicate-do-table  = db2.mytbl2
```

Suppose that `db1` is the default database and the slave receives this statement:

```
INSERT INTO mytbl1 VALUES(1,2,3);
```

The database is `db1`, which matches the `--replicate-do-db` option at the database-checking stage. The algorithm then proceeds to the table-checking stage. If there were no table options, the statement would be executed. However, because the options include a “do” table option, the statement must match if it is to be executed. The statement does not match, so it is ignored. (The same would happen for any table in `db1`.)

Chapter 17. MySQL Cluster NDB 6.X/7.X

This chapter contains information about *MySQL Cluster*, which is a high-availability, high-redundancy version of MySQL adapted for the distributed computing environment. Current releases of MySQL Cluster use versions 6 and 7 of the `NDBCLUSTER` storage engine (also known as `NDB`) to enable running several computers with MySQL servers and other software in a cluster.

Beginning with MySQL 5.1.24, support for the `NDBCLUSTER` storage engine was removed from the standard MySQL server binaries built by MySQL. Instead, users of MySQL Cluster binaries built by MySQL should upgrade to the most recent binary release of MySQL Cluster NDB 6.2 or MySQL Cluster 6.3 for supported platforms — these include RPMs that should work with most Linux distributions. MySQL Cluster users who build from source should be aware that, also beginning with MySQL 5.1.24, `NDB-CLUSTER` sources in the standard MySQL 5.1 tree are no longer maintained; these users should use the sources provided for MySQL Cluster NDB 6.2 or later. (Locations where the sources can be obtained are listed later in this section.)

Note

MySQL Cluster NDB 6.1, 6.2, and 6.3 were formerly known as “MySQL Cluster Carrier Grade Edition”. Beginning with MySQL Cluster NDB 6.2.15 and MySQL Cluster NDB 6.3.14, this term is no longer applied to the MySQL Cluster software — which is now known simply as “MySQL Cluster” — but rather to a commercial licensing and support package. You can learn more about available options for commercial licensing of MySQL Cluster from [MySQL Cluster Features](#), on the MySQL web site.

This chapter contains information about MySQL Cluster in MySQL 5.1 mainline releases through MySQL 5.1.23, MySQL Cluster NDB 6.2 releases through 5.1.34-ndb-6.2.18, MySQL Cluster NDB 6.3 releases through 5.1.34-ndb-6.3.26, and MySQL Cluster NDB 7.0 releases through 5.1.34-ndb-7.0.7. Currently, the MySQL Cluster NDB 6.2, MySQL Cluster NDB 6.3, and MySQL Cluster NDB 7.0 (formerly known as “MySQL Cluster NDB 6.4”) release series are Generally Available (GA).

This chapter also contains historical information about MySQL Cluster NDB 6.1, although this release series is no longer in active development, and should not be used in new deployments. Users of MySQL Cluster NDB 6.1 should upgrade to a later MySQL Cluster NDB 6.x or 7.x release series as soon as possible.

Platforms supported. MySQL Cluster is currently available and supported on a number of platforms, including Linux, Solaris, Mac OS X, HP-UX, and other Unix-style operating systems on a variety of hardware. Beginning with MySQL Cluster NDB 7.0, MySQL Cluster is also available (on an experimental basis) on Microsoft Windows platforms. For exact levels of support available for on specific combinations of operating system versions, operating system distributions, and hardware platforms, please refer to the [Cluster Supported Platforms list](#), maintained by the MySQL Support Team on the MySQL web site.

We are continuing to work to make MySQL Cluster available on all operating systems supported by MySQL and will update the information provided here as this work continues.

Availability. MySQL Cluster NDB 6.2, MySQL Cluster NDB 6.3, and MySQL Cluster NDB 7.0 binary and source packages are available for supported platforms from <http://dev.mysql.com/downloads/cluster>.

Note

Binary releases and RPMs were not available for MySQL Cluster NDB 6.2 prior to MySQL Cluster NDB 6.2.15.

MySQL Cluster release numbers. Starting with MySQL Cluster NDB 6.1 and 6.2, MySQL Cluster follows a somewhat different release pattern from the mainline MySQL 5.1 Cluster series of releases. In this Manual and other MySQL documentation, we identify these and later MySQL Cluster releases employing a version number that begins with “NDB”. This version number is that of the `NDBCLUSTER` storage engine used, and not of the MySQL server version on which the MySQL Cluster release is based.

Version strings used in MySQL Cluster NDB 6.x and 7.x software. The version string displayed by MySQL Cluster NDB 6.x and 7.x software uses this format:

```
mysql-mysql_server_version-ndb-ndbcluster_engine_version
```

`mysql_server_version` represents the version of the MySQL Server on which the MySQL Cluster release is based. For all MySQL Cluster NDB 6.x and 7.x releases, this is “5.1”. `ndbcluster_engine_version` is the version of the `NDBCLUSTER` storage engine used by this release of the MySQL Cluster software. You can see this format used in the `mysql` client, as shown here:

```
shell> mysql
Welcome to the MySQL monitor.  Commands end with ; or \g.
Your MySQL connection id is 2
Server version: 5.1.34-ndb-7.0.7 Source distribution

Type 'help;' or '\h' for help. Type '\c' to clear the buffer.

mysql> SELECT VERSION()\G
***** 1. row *****
VERSION(): 5.1.34-ndb-7.0.7
1 row in set (0.00 sec)
```

This version string is also displayed in the output of the `SHOW` command in the `ndb_mgm` client:

```
ndb_mgm> SHOW
Connected to Management Server at: localhost:1186
Cluster Configuration
-----
[ndbd(NDB)] 2 node(s)
id=1 @10.0.10.6 (5.1.34-ndb-7.0.7, Nodegroup: 0, Master)
id=2 @10.0.10.8 (5.1.34-ndb-7.0.7, Nodegroup: 0)

[ndb_mgmd(MGM)] 1 node(s)
id=3 @10.0.10.2 (5.1.34-ndb-7.0.7)

[mysqld(API)] 2 node(s)
id=4 @10.0.10.10 (5.1.34-ndb-7.0.7)
id=5 (not connected, accepting connect from any host)
```

The version string identifies the mainline MySQL version from which the MySQL Cluster release was branched and the version of the `NDBCLUSTER` storage engine used. For example, the full version string for MySQL Cluster NDB 6.2.15 (the first MySQL Cluster NDB 6.2 binary release) was `mysql-5.1.24-ndb-6.2.15`. From this we can determine the following:

- Since the portion of the version string preceding “-ndb-” is the base MySQL Server version, this means that MySQL Cluster NDB 6.2.15 derives from the MySQL 5.1.24, and contains all feature enhancements and bugfixes from MySQL 5.1 up to and including MySQL 5.1.24.
- Since the portion of the version string following “-ndb-” represents the version number of the `NDB` (or `NDBCLUSTER`) storage engine, MySQL Cluster NDB 6.2.15 uses version 6.2.15 of the `NDBCLUSTER` storage engine.

MySQL Cluster development source trees. MySQL Cluster development trees can also be accessed via <https://code.launchpad.net/~mysql/>:

- [MySQL Cluster NDB 6.1](#) (*OBSOLETE — no longer maintained*)
- [MySQL Cluster NDB 6.2](#) (*CURRENT*)
- [MySQL Cluster NDB 6.3](#) (*CURRENT*)
- [MySQL Cluster NDB 7.0](#) (*CURRENT*)

The MySQL Cluster development sources maintained at <https://code.launchpad.net/~mysql/> are licensed under the GPL. For information about obtaining MySQL sources using Bazaar and building them yourself, see [Section 2.10.3, “Installing from the Development Source Tree”](#).

Currently, MySQL Cluster NDB 6.2, MySQL Cluster NDB 6.3, and MySQL Cluster NDB 7.0 releases are all Generally Available (GA). MySQL Cluster NDB 6.1 is no longer in active development. For an overview of major features added in MySQL Cluster NDB 6.x and 7.x, see [Section 17.13, “MySQL Cluster Development Roadmap”](#).

This chapter represents a work in progress, and its contents are subject to revision as MySQL Cluster continues to evolve. Additional information regarding MySQL Cluster can be found on the MySQL AB Web site at <http://www.mysql.com/products/cluster/>.

Additional resources. More information may be found in the following places:

- Answers to some commonly asked questions about Cluster may be found in the [Section A.10, “MySQL 5.1 FAQ — MySQL Cluster”](#).
- The MySQL Cluster mailing list: <http://lists.mysql.com/cluster>.
- The MySQL Cluster Forum: <http://forums.mysql.com/list.php?25>.
- Many MySQL Cluster users and some of the MySQL Cluster developers blog about their experiences with Cluster, and make feeds of these available through [PlanetMySQL](#).
- If you are new to MySQL Cluster, you may find our Developer Zone article [How to set up a MySQL Cluster for two servers](#) to be helpful.

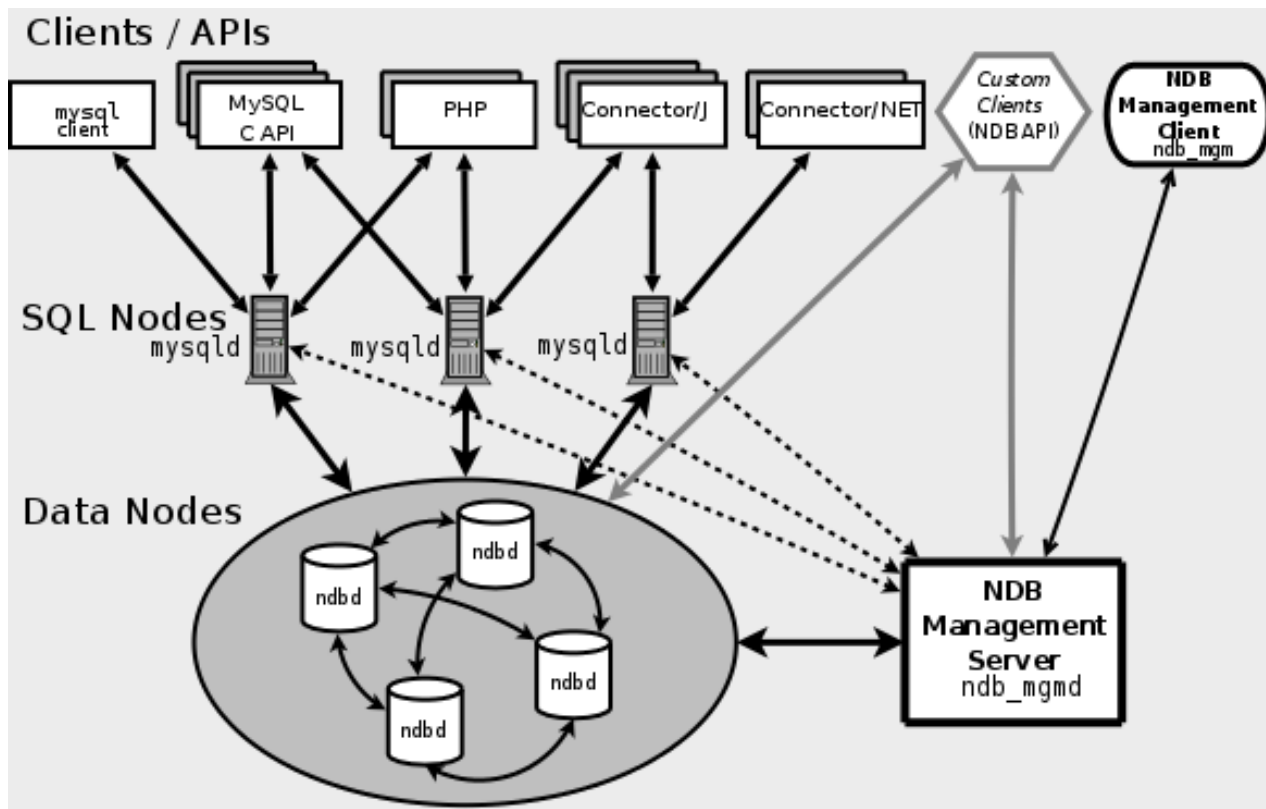

17.1. MySQL Cluster Overview

MySQL Cluster is a technology that enables clustering of in-memory databases in a shared-nothing system. The shared-nothing architecture allows the system to work with very inexpensive hardware, and with a minimum of specific requirements for hardware or software.

MySQL Cluster is designed not to have any single point of failure. For this reason, each component is expected to have its own memory and disk, and the use of shared storage mechanisms such as network shares, network file systems, and SANs is not recommended or supported.

MySQL Cluster integrates the standard MySQL server with an in-memory clustered storage engine called **NDB**. In our documentation, the term **NDB** refers to the part of the setup that is specific to the storage engine, whereas “MySQL Cluster” refers to the combination of MySQL and the **NDB** storage engine.

A MySQL Cluster consists of a set of computers, each running one or more processes which may include a MySQL server, a data node, a management server, and (possibly) specialized data access programs. The relationship of these components in a cluster is shown here:

All these programs work together to form a MySQL Cluster. When data is stored in the **NDBCLUSTER** storage engine, the tables are stored in the data nodes. Such tables are directly accessible from all other MySQL servers in the cluster. Thus, in a payroll application storing data in a cluster, if one application updates the salary of an employee, all other MySQL servers that query this data can see this change immediately.

The data stored in the data nodes for MySQL Cluster can be mirrored; the cluster can handle failures of individual data nodes with no other impact than that a small number of transactions are aborted due to losing the transaction state. Because transactional applications are expected to handle transaction failure, this should not be a source of problems.

17.1.1. MySQL Cluster Core Concepts

NDBCLUSTER (also known as **NDB**) is an in-memory storage engine offering high-availability and data-persistence features.

The **NDBCLUSTER** storage engine can be configured with a range of failover and load-balancing options, but it is easiest to start with the storage engine at the cluster level. MySQL Cluster's **NDB** storage engine contains a complete set of data, dependent only on other data within the cluster itself.

The “Cluster” portion of MySQL Cluster is configured independently of the MySQL servers. In a MySQL Cluster, each part of the cluster is considered to be a *node*.

Note

In many contexts, the term “node” is used to indicate a computer, but when discussing MySQL Cluster it means a *process*. It is possible to run multiple nodes on a single computer; for a computer on which one or more cluster nodes are being run we use the term *cluster host*.

There are three types of cluster nodes, and in a minimal MySQL Cluster configuration, there will be at least three nodes, one of each of these types:

- *Management node* (MGM node): The role of this type of node is to manage the other nodes within the MySQL Cluster, performing such functions as providing configuration data, starting and stopping nodes, running backup, and so forth. Because this node type manages the configuration of the other nodes, a node of this type should be started first, before any other node. An MGM node is started with the command `ndb_mgmd`.
- *Data node*: This type of node stores cluster data. There are as many data nodes as there are replicas, times the number of fragments. For example, with two replicas, each having two fragments, you need four data nodes. One replica is sufficient for data storage, but provides no redundancy; therefore, it is recommended to have 2 (or more) replicas to provide redundancy, and thus high availability. A data node is started with the command `ndbd`.
- *SQL node*: This is a node that accesses the cluster data. In the case of MySQL Cluster, an SQL node is a traditional MySQL server that uses the `NDBCLUSTER` storage engine. An SQL node is a `mysqld` process started with the `--ndbcluster` and `--ndb-connectstring` options, which are explained elsewhere in this chapter, possibly with additional MySQL server options as well.

An SQL node is actually just a specialized type of *API node*, which designates any application which accesses Cluster data. Another example of an API node is the `ndb_restore` utility that is used to restore a cluster backup. It is possible to write such applications using the NDB API. For basic information about the NDB API, see [Getting Started with the NDB API](#).

Important

It is not realistic to expect to employ a three-node setup in a production environment. Such a configuration provides no redundancy; in order to benefit from MySQL Cluster's high-availability features, you must use multiple data and SQL nodes. The use of multiple management nodes is also highly recommended.

For a brief introduction to the relationships between nodes, node groups, replicas, and partitions in MySQL Cluster, see [Section 17.1.2, “MySQL Cluster Nodes, Node Groups, Replicas, and Partitions”](#).

Configuration of a cluster involves configuring each individual node in the cluster and setting up individual communication links between nodes. MySQL Cluster is currently designed with the intention that data nodes are homogeneous in terms of processor power, memory space, and bandwidth. In addition, to provide a single point of configuration, all configuration data for the cluster as a whole is located in one configuration file.

The management server (MGM node) manages the cluster configuration file and the cluster log. Each node in the cluster retrieves the configuration data from the management server, and so requires a way to determine where the management server resides. When interesting events occur in the data nodes, the nodes transfer information about these events to the management server, which then writes the information to the cluster log.

In addition, there can be any number of cluster client processes or applications. These are of two types:

- **Standard MySQL clients.** MySQL Cluster can be used with existing MySQL applications written in PHP, Perl, C, C++, Java, Python, Ruby, and so on. Such client applications send SQL statements to and receive responses from MySQL servers acting as MySQL Cluster SQL nodes in much the same way that they interact with standalone MySQL servers. However, MySQL clients using a MySQL Cluster as a data source can be modified to take advantage of the ability to connect with multiple MySQL servers to achieve load balancing and failover. For example, Java clients using Connector/J 5.0.6 and later can use `jdbc:mysql:loadbalance://` URLs (improved in Connector/J 5.1.7) to achieve load balancing transparently.
- **Management clients.** These clients connect to the management server and provide commands for starting and stopping nodes gracefully, starting and stopping message tracing (debug versions only), showing node versions and status, starting and stopping backups, and so on. Such clients — such as the `ndb_mgm` management client supplied with MySQL Cluster — are written using the MGM API, a C-language API that communicates directly with one or more MySQL Cluster management servers. For more information, see [The MGM API](#).

17.1.2. MySQL Cluster Nodes, Node Groups, Replicas, and Partitions

This section discusses the manner in which MySQL Cluster divides and duplicates data for storage.

Central to an understanding of this topic are the following concepts, listed here with brief definitions:

- **(Data) Node.** An `ndbd` process, which stores a *replica* —that is, a copy of the *partition* (see below) assigned to the node group of which the node is a member.

Each data node should be located on a separate computer. While it is also possible to host multiple `ndbd` processes on a single computer, such a configuration is not supported.

It is common for the terms “node” and “data node” to be used interchangeably when referring to an `ndbd` process; where mentioned, management (MGM) nodes (`ndb_mgmd` processes) and SQL nodes (`mysqld` processes) are specified as such in this discussion.

- **Node Group.** A node group consists of one or more nodes, and stores partitions, or sets of *replicas* (see next item).

The number of node groups in a MySQL Cluster is not directly configurable; it is function of the number of data nodes and of the number of replicas (`NumberOfReplicas` configuration parameter), as shown here:

```
[number_of_node_groups] = number_of_data_nodes / NumberOfReplicas
```

Thus, a MySQL Cluster with 4 data nodes has 4 node groups if `NumberOfReplicas` is set to 1 in the `config.ini` file, 2 node groups if `NumberOfReplicas` is set to 2, and 1 node group if `NumberOfReplicas` is set to 4. Replicas are discussed later in this section; for more information about `NumberOfReplicas`, see [Section 17.3.4.6, “Defining MySQL Cluster Data Nodes”](#).

Note

All node groups in a MySQL Cluster must have the same number of data nodes.

Prior to MySQL Cluster NDB 7.0, it was not possible to add new data nodes to a MySQL Cluster without shutting down the cluster completely and reloading all of its data. In MySQL Cluster NDB 7.0 (beginning with MySQL Cluster version NDB 6.4.0), you can add new node groups (and thus new data nodes) to a running MySQL Cluster — see [Section 17.7.8, “Adding MySQL Cluster Data Nodes Online”](#), for information about how this can be done.

- **Partition.** This is a portion of the data stored by the cluster. There are as many cluster partitions as nodes participating in the cluster. Each node is responsible for keeping at least one copy of any partitions assigned to it (that is, at least one replica) available to the cluster.

A replica belongs entirely to a single node; a node can (and usually does) store several replicas.

MySQL Cluster normally partitions `NDBCLUSTER` tables automatically. However, in MySQL 5.1 and MySQL Cluster NDB 6.x, it is possible to employ user-defined partitioning with `NDBCLUSTER` tables. This is subject to the following limitations:

1. Only `KEY` and `LINEAR KEY` partitioning schemes can be used with `NDBCLUSTER` tables.
2. The maximum number of partitions that may be defined explicitly for any `NDBCLUSTER` table is 8 per node group. (The number of node groups in a MySQL Cluster is determined as discussed previously in this section.)

For more information relating to MySQL Cluster and user-defined partitioning, see [Section 17.12, “Known Limitations of MySQL Cluster”](#), and [Section 18.5.2, “Partitioning Limitations Relating to Storage Engines”](#).

- **Replica.** This is a copy of a cluster partition. Each node in a node group stores a replica. Also sometimes known as a *partition replica*. The number of replicas is equal to the number of nodes per node group.

The following diagram illustrates a MySQL Cluster with four data nodes, arranged in two node groups of two nodes each; nodes 1 and 2 belong to node group 0, and nodes 3 and 4 belong to node group 1. Note that only data (`ndbd`) nodes are shown here; although a working cluster requires an `ndb_mgmd` process for cluster management and at least one SQL node to access the data stored by the cluster, these have been omitted in the figure for clarity.

The data stored by the cluster is divided into four partitions, numbered 0, 1, 2, and 3. Each partition is stored — in multiple copies — on the same node group. Partitions are stored on alternate node groups:

- Partition 0 is stored on node group 0; a *primary replica* (primary copy) is stored on node 1, and a *backup replica* (backup copy of the partition) is stored on node 2.
- Partition 1 is stored on the other node group (node group 1); this partition's primary replica is on node 3, and its backup replica is on node 4.
- Partition 2 is stored on node group 0. However, the placing of its two replicas is reversed from that of Partition 0; for Partition 2, the primary replica is stored on node 2, and the backup on node 1.
- Partition 3 is stored on node group 1, and the placement of its two replicas are reversed from those of partition 1. That is, its primary replica is located on node 4, with the backup on node 3.

What this means regarding the continued operation of a MySQL Cluster is this: so long as each node group participating in the cluster has at least one node operating, the cluster has a complete copy of all data and remains viable. This is illustrated in the next diagram.

In this example, where the cluster consists of two node groups of two nodes each, any combination of at least one node in node group 0 and at least one node in node group 1 is sufficient to keep the cluster “alive” (indicated by arrows in the diagram). However, if *both* nodes from *either* node group fail, the remaining two nodes are not sufficient (shown by the arrows marked out with an X); in either case, the cluster has lost an entire partition and so can no longer provide access to a complete set of all cluster data.

17.2. MySQL Cluster Multi-Computer How-To

This section is a “How-To” that describes the basics for how to plan, install, configure, and run a MySQL Cluster. Whereas the examples in [Section 17.3, “MySQL Cluster Configuration”](#) provide more in-depth information on a variety of clustering options and configuration, the result of following the guidelines and procedures outlined here should be a usable MySQL Cluster which meets the *minimum* requirements for availability and safeguarding of data.

This section covers hardware and software requirements; networking issues; installation of MySQL Cluster; configuration issues; starting, stopping, and restarting the cluster; loading of a sample database; and performing queries.

Basic assumptions. This *How-To* makes the following assumptions:

1. The cluster is to be set up with four nodes, each on a separate host, and each with a fixed network address on a typical Ethernet network as shown here:

Node	IP Address
Management (MGMD) node	192.168.0.10
MySQL server (SQL) node	192.168.0.20
Data (NDBD) node "A"	192.168.0.30
Data (NDBD) node "B"	192.168.0.40

This may be made clearer in the following diagram:

In the interest of simplicity (and reliability), this *How-To* uses only numeric IP addresses. However, if DNS resolution is available on your network, it is possible to use host names in lieu of IP addresses in configuring Cluster. Alternatively, you can use the `/etc/hosts` file or your operating system's equivalent for providing a means to do host lookup if such is available.

Note

A common problem when trying to use host names for Cluster nodes arises because of the way in which some operating systems (including some Linux distributions) set up the system's own host name in the `/etc/hosts` during installation. Consider two machines with the host names `ndb1` and `ndb2`, both in the `cluster` network domain. Red Hat Linux (including some derivatives such as CentOS and Fedora) places the following entries in these machines' `/etc/hosts` files:

```
# ndb1 /etc/hosts:
127.0.0.1 ndb1.cluster ndb1 localhost.localdomain localhost
```

```
# ndb2 /etc/hosts:
127.0.0.1 ndb2.cluster ndb2 localhost.localdomain localhost
```

SUSE Linux (including OpenSUSE) places these entries in the machines' `/etc/hosts` files:

```
# ndb1 /etc/hosts:
127.0.0.1 localhost
127.0.0.2 ndb1.cluster ndb1
```

```
# ndb2 /etc/hosts:
127.0.0.1 localhost
127.0.0.2 ndb2.cluster ndb2
```

In both instances, `ndb1` routes `ndb1.cluster` to a loopback IP address, but gets a public IP address from DNS for `ndb2.cluster`, while `ndb2` routes `ndb2.cluster` to a loopback address and obtains a public address for `ndb1.cluster`. The result is that each data node connects to the management server, but cannot tell when any other data nodes have connected, and so the data nodes appear to hang while starting.

You should also be aware that you cannot mix `localhost` and other host names or IP addresses in `config.ini`. For these reasons, the solution in such cases (other than to use IP addresses for *all* `config.ini` `HostName` entries) is to remove the fully qualified host names from `/etc/hosts` and use these in `config.ini` for all cluster hosts.

2. Each host in our scenario is an Intel-based desktop PC running a common, generic Linux distribution installed to disk in a standard configuration, and running no unnecessary services. The core OS with standard TCP/IP networking capabilities should be sufficient. Also for the sake of simplicity, we also assume that the file systems on all hosts are set up identically. In the event that they are not, you will need to adapt these instructions accordingly.
3. Standard 100 Mbps or 1 gigabit Ethernet cards are installed on each machine, along with the proper drivers for the cards, and that all four hosts are connected via a standard-issue Ethernet networking appliance such as a switch. (All machines should use network cards with the same throughput. That is, all four machines in the cluster should have 100 Mbps cards *or* all four machines should have 1 Gbps cards.) MySQL Cluster will work in a 100 Mbps network; however, gigabit Ethernet will provide better performance.

Note that MySQL Cluster is *not* intended for use in a network for which throughput is less than 100 Mbps. For this reason (among others), attempting to run a MySQL Cluster over a public network such as the Internet is not likely to be successful, and is not recommended.

4. For our sample data, we will use the `world` database which is available for download from the MySQL AB Web site. As this database takes up a relatively small amount of space, we assume that each machine has 256MB RAM, which should be sufficient for running the operating system, host NDB process, and (for the data nodes) for storing the database.

Although we refer to a Linux operating system in this How-To, the instructions and procedures that we provide here should be easily adaptable to other supported operating systems. We also assume that you already know how to perform a minimal installation and configuration of the operating system with networking capability, or that you are able to obtain assistance in this elsewhere if needed.

We discuss MySQL Cluster hardware, software, and networking requirements in somewhat greater detail in the next section. (See [Section 17.2.1, “MySQL Cluster Hardware, Software, and Networking Requirements”](#).)

17.2.1. MySQL Cluster Hardware, Software, and Networking Requirements

One of the strengths of MySQL Cluster is that it can be run on commodity hardware and has no unusual requirements in this regard, other than for large amounts of RAM, due to the fact that all live data storage is done in memory. (It is possible to reduce this requirement using Disk Data tables — see [Section 17.10, “MySQL Cluster Disk Data Tables”](#), for more information about these.) Naturally, multiple and faster CPUs can enhance performance. Memory requirements for other Cluster processes are relatively small.

The software requirements for Cluster are also modest. Host operating systems do not require any unusual modules, services, applications, or configuration to support MySQL Cluster. For supported operating systems, a standard installation should be sufficient. The MySQL software requirements are simple: all that is needed is a production release of MySQL 5.1.34-ndb-6.2.18 or 5.1.34-ndb-6.3.26 to have Cluster support. It is not necessary to compile MySQL yourself merely to be able to use Cluster. In this *How-To*, we assume that you are using the server binary appropriate to your platform, available via the MySQL Cluster software downloads page at <http://dev.mysql.com/downloads/cluster>.

For communication between nodes, Cluster supports TCP/IP networking in any standard topology, and the minimum expected for each host is a standard 100 Mbps Ethernet card, plus a switch, hub, or router to provide network connectivity for the cluster as a whole. We strongly recommend that a MySQL Cluster be run on its own subnet which is not shared with non-Cluster machines for the following reasons:

- **Security.** Communications between Cluster nodes are not encrypted or shielded in any way. The only means of protecting transmissions within a MySQL Cluster is to run your Cluster on a protected network. If you intend to use MySQL Cluster for Web applications, the cluster should definitely reside behind your firewall and not in your network's De-Militarized Zone (DMZ) or elsewhere.

See [Section 17.8.1, “MySQL Cluster Security and Networking Issues”](#), for more information.

- **Efficiency.** Setting up a MySQL Cluster on a private or protected network allows the cluster to make exclusive use of bandwidth between cluster hosts. Using a separate switch for your MySQL Cluster not only helps protect against unauthorized access to Cluster data, it also ensures that Cluster nodes are shielded from interference caused by transmissions between other computers on the network. For enhanced reliability, you can use dual switches and dual cards to remove the network as a single point of failure; many device drivers support failover for such communication links.

It is also possible to use the high-speed Scalable Coherent Interface (SCI) with MySQL Cluster, but this is not a requirement. See [Section 17.11, “Using High-Speed Interconnects with MySQL Cluster”](#), for more about this protocol and its use with MySQL

Cluster.

17.2.2. MySQL Cluster Multi-Computer Installation

Each MySQL Cluster host computer running an SQL node must have installed on it a MySQL binary. For management nodes and data nodes, it is not necessary to install the MySQL server binary, but management nodes require the management server daemon (`ndb_mgmd`) and data nodes require the data node daemon (`ndbd`). It is also a good idea to install the management client (`ndb_mgm`) on the management server host. This section covers the steps necessary to install the correct binaries for each type of Cluster node.

MySQL AB provides precompiled binaries that support Cluster. However, we also include information relating to installing a MySQL Cluster after building MySQL from source. For setting up a cluster using MySQL's binaries, the first step in the installation process for each cluster host is to download the latest MySQL Cluster NDB 6.2 or MySQL Cluster NDB 6.3 binary archive (`mysql-cluster-gpl-6.2.18-linux-i686-glibc23.tar.gz` or `mysql-cluster-gpl-6.3.26-linux-i686-glibc23.tar.gz`, respectively) from the [MySQL Cluster downloads area](#). We assume that you have placed this file in each machine's `/var/tmp` directory. (If you do require a custom binary, see [Section 2.10.3](#), “Installing from the Development Source Tree”.)

Note

When compiling MySQL Cluster NDB 7.0 from source, no special options are required for building multi-threaded data node binaries. On Unix platforms, configuring the build with any of the options `--plugins=max`, `--plugins=max-no-innodb`, or `--with-ndbcluster` causes `ndbmttd` to be built automatically; `make install` places the `ndbmttd` binary in the `libexec` directory along with `mysqld`, `ndbd`, and `ndb_mgm`. Similarly, on Windows, using `WITH_NDBCLUSTER_STORAGE_ENGINE` with `configure.js` causes `ndbmttd.exe` to be built automatically, and to be found in the `bin` directory of the archive created by `make_win_bin_dist`.

RPMs are also available for both 32-bit and 64-bit Linux platforms. For a MySQL Cluster, three RPMs are required:

- The **Server** RPM (for example, `MySQL-Cluster-gpl-server-6.2.18-0.sles10.i586.rpm` or `MySQL-Cluster-gpl-server-6.3.26-0.sles10.i586.rpm`), which supplies the core files needed to run a MySQL Server with `NDBCLUSTER` storage engine support (that is, as a MySQL Cluster SQL node).

If you do not have your own client application capable of administering a MySQL server, you should also obtain and install the **Client** RPM (for example, `MySQL-Cluster-gpl-client-6.2.18-0.sles10.i586.rpm` or `MySQL-Cluster-gpl-client-6.3.26-0.sles10.i586.rpm`).

- The **Cluster storage engine** RPM (for example, `MySQL-Cluster-gpl-storage-6.2.18-0.sles10.i586.rpm` or `MySQL-Cluster-gpl-storage-6.3.26-0.sles10.i586.rpm`), which supplies the MySQL Cluster data node binary (`ndbd`).
- The **Cluster storage engine management RPM** (for example, `MySQL-Cluster-gpl-management-6.2.18-0.sles10.i586.rpm` or `MySQL-Cluster-gpl-management-6.3.26-0.sles10.i586.rpm`), which provides the MySQL Cluster management server binary (`ndb_mgmd`).

In addition, you should also obtain the **NDB Cluster - Storage engine basic tools** RPM (for example, `MySQL-Cluster-gpl-tools-6.2.18-0.sles10.i586.rpm` or `MySQL-Cluster-gpl-tools-6.3.26-0.sles10.i586.rpm`), which supplies several useful applications for working with a MySQL Cluster. The most important of these is the MySQL Cluster management client (`ndb_mgm`). The **NDB Cluster - Storage engine extra tools** RPM (for example, `MySQL-Cluster-gpl-extra-6.2.18-0.sles10.i586.rpm` or `MySQL-Cluster-gpl-extra-6.3.26-0.sles10.i586.rpm`) contains some additional testing and monitoring programs, but is not required to install a MySQL Cluster. (For more information about these additional programs, see [Section 17.6](#), “MySQL Cluster Programs”.)

The MySQL Cluster version number in the RPM file names (shown here as `6.2.18` or `6.3.26`) can vary according to the version which you are actually using. *It is very important that all of the Cluster RPMs to be installed have the same version number.* The `glibc` version number (if present), and architecture designation (shown here as `i586`) should be appropriate to the machine on which the RPM is to be installed.

See [Section 2.4](#), “Installing MySQL from RPM Packages on Linux”, for general information about installing MySQL using RPMs supplied by MySQL AB.

After installing from RPM, you still need to configure the cluster as discussed in [Section 17.2.3](#), “MySQL Cluster Multi-Computer Configuration”.

Note

After completing the installation, do not yet start any of the binaries. We show you how to do so following the config-

uration of all nodes.

Data and SQL Node Installation — .tar.gz Binary. On each of the machines designated to host data or SQL nodes, perform the following steps as the system `root` user:

1. Check your `/etc/passwd` and `/etc/group` files (or use whatever tools are provided by your operating system for managing users and groups) to see whether there is already a `mysql` group and `mysql` user on the system. Some OS distributions create these as part of the operating system installation process. If they are not already present, create a new `mysql` user group, and then add a `mysql` user to this group:

```
shell> groupadd mysql
shell> useradd -g mysql mysql
```

The syntax for `useradd` and `groupadd` may differ slightly on different versions of Unix, or they may have different names such as `adduser` and `addgroup`.

2. Change location to the directory containing the downloaded file, unpack the archive, and create a symlink to the `mysql` directory named `mysql`. Note that the actual file and directory names will vary according to the MySQL Cluster version number.

```
shell> cd /var/tmp
shell> tar -C /usr/local -xzf mysql-cluster-gpl-6.3.26-linux-i686-glibc23.tar.gz
shell> ln -s /usr/local/mysql-cluster-gpl-6.3.26-linux-i686-glibc23.tar.gz /usr/local/mysql
```

3. Change location to the `mysql` directory and run the supplied script for creating the system databases:

```
shell> cd mysql
shell> scripts/mysql_install_db --user=mysql
```

4. Set the necessary permissions for the MySQL server and data directories:

```
shell> chown -R root .
shell> chown -R mysql data
shell> chgrp -R mysql .
```

Note that the data directory on each machine hosting a data node is `/usr/local/mysql/data`. This piece of information is essential when configuring the management node. (See [Section 17.2.3, “MySQL Cluster Multi-Computer Configuration”](#).)

5. Copy the MySQL startup script to the appropriate directory, make it executable, and set it to start when the operating system is booted up:

```
shell> cp support-files/mysql.server /etc/rc.d/init.d/
shell> chmod +x /etc/rc.d/init.d/mysql.server
shell> chkconfig --add mysql.server
```

(The startup scripts directory may vary depending on your operating system and version — for example, in some Linux distributions, it is `/etc/init.d`.)

Here we use Red Hat's `chkconfig` for creating links to the startup scripts; use whatever means is appropriate for this purpose on your operating system and distribution, such as `update-rc.d` on Debian.

Remember that the preceding steps must be repeated on each machine where an SQL node is to reside.

SQL node installation — RPM files. On each machine to be used for hosting a cluster SQL node, install the **Server** RPM by executing the following command as the system root user, replacing the name shown for the RPM as necessary to match the name of the RPM downloaded from the MySQL AB web site:

```
shell> rpm -Uhv MySQL-Cluster-gpl-server-6.3.26-0.sles10.i586.rpm
```

This installs the MySQL server binary (`mysqld`) in the `/usr/sbin` directory, as well as all needed MySQL Server support files. It also installs the `mysql.server` and `mysqld_safe` startup scripts in `/usr/share/mysql` and `/usr/bin`, respectively. The RPM installer should take care of general configuration issues (such as creating the `mysql` user and group, if needed) automatically.

Note

To administer the SQL node (MySQL server), you should also install the **Client** RPM, as shown here:

```
shell> rpm -Uhv MySQL-Cluster-gpl-client-6.3.26-0.sles10.i586.rpm
```

This installs the `mysql` client program.

SQL node installation — building from source. If you compile MySQL with clustering support (for example, by using the `BUILD/compile-platform_name-max` script appropriate to your platform), and perform the default installation (using `make install` as the root user), `mysqld` is placed in `/usr/local/mysql/bin`. Follow the steps given in [Section 2.10, “MySQL Installation Using a Source Distribution”](#) to make `mysqld` ready for use. If you want to run multiple SQL nodes, you can use a copy of the same `mysqld` executable and its associated support files on several machines. The easiest way to do this is to copy the entire `/usr/local/mysql` directory and all directories and files contained within it to the other SQL node host or hosts, then repeat the steps from [Section 2.10, “MySQL Installation Using a Source Distribution”](#) on each machine. If you configure the build with a non-default `--prefix`, you need to adjust the directory accordingly.

Data node installation — RPM Files. On a computer that is to host a cluster data node it is necessary to install only the **NDB Cluster - Storage engine** RPM. To do so, copy this RPM to the data node host, and run the following command as the system root user, replacing the name shown for the RPM as necessary to match that of the RPM downloaded from the MySQL AB web site:

```
shell> rpm -Uhv MySQL-Cluster-gpl-storage-6.2.18-0.sles10.i586.rpm
```

The previous command installs the MySQL Cluster data node binary (`ndbd`) in the `/usr/sbin` directory.

Data node installation — building from source. The only executable required on a data node host is `ndbd` (`mysqld`, for example, does not have to be present on the host machine). By default when doing a source build, this file is placed in the directory `/usr/local/mysql/libexec`. For installing on multiple data node hosts, only `ndbd` need be copied to the other host machine or machines. (This assumes that all data node hosts use the same architecture and operating system; otherwise you may need to compile separately for each different platform.) `ndbd` need not be in any particular location on the host's file system, as long as the location is known.

Management node installation — .tar.gz binary. Installation of the management node does not require the `mysqld` binary. Only the MySQL Cluster management server (`ndb_mgmd`) is required; you most likely want to install the management client (`ndb_mgm`) as well. Both of these binaries also be found in the `.tar.gz` archive. Again, we assume that you have placed this archive in `/var/tmp`.

As system `root` (that is, after using `sudo`, `su root`, or your system's equivalent for temporarily assuming the system administrator account's privileges), perform the following steps to install `ndb_mgmd` and `ndb_mgm` on the Cluster management node host:

1. Change location to the `/var/tmp` directory, and extract the `ndb_mgm` and `ndb_mgmd` from the archive into a suitable directory such as `/usr/local/bin`:

```
shell> cd /var/tmp
shell> tar -zxvf mysql-5.1.34-ndb-6.3.26-linux-i686-glibc23.tar.gz
shell> cd mysql-5.1.34-ndb-6.3.26-linux-i686-glibc23
shell> cp bin/ndb_mgm* /usr/local/bin
```

(You can safely delete the directory created by unpacking the downloaded archive, and the files it contains, from `/var/tmp` once `ndb_mgm` and `ndb_mgmd` have been copied to the executables directory.)

2. Change location to the directory into which you copied the files, and then make both of them executable:

```
shell> cd /usr/local/bin
shell> chmod +x ndb_mgm*
```

Management node installation — RPM file. To install the MySQL Cluster management server, it is necessary only to use the **NDB Cluster - Storage engine management** RPM. Copy this RPM to the computer intended to host the management node, and then install it by running the following command as the system root user (replace the name shown for the RPM as necessary to match that of the **Storage engine management** RPM downloaded from the MySQL AB web site):

```
shell> rpm -Uhv MySQL-Cluster-gpl-management-6.3.26-0.sles10.i586.rpm
```

This installs the management server binary (`ndb_mgmd`) to the `/usr/sbin` directory.

You should also install the **NDB** management client, which is supplied by the **Storage engine basic tools** RPM. Copy this RPM to the same computer as the management node, and then install it by running the following command as the system root user (again, replace the name shown for the RPM as necessary to match that of the **Storage engine basic tools** RPM downloaded from the MySQL AB web site):

```
shell> rpm -Uhv MySQL-Cluster-gpl-tools-6.3.26-0.sles10.i586.rpm
```

The **Storage engine basic tools** RPM installs the MySQL Cluster management client (`ndb_mgm`) to the `/usr/bin` directory.

Note

You can also install the **Cluster storage engine extra tools** RPM, if you wish, as shown here:

```
shell> rpm -Uhv MySQL-Cluster-gpl-extra-6.3.26-0.sles10.i586.rpm
```

You may find the extra tools useful; however the **Cluster storage engine extra tools** RPM is *not* required to install a working MySQL Cluster.

Management node installation — building from source. When building from source and running the default `make install`, the management server binary (`ndb_mgmd`) is placed in `/usr/local/mysql/libexec`, while the management client binary (`ndb_mgm`) can be found in `/usr/local/mysql/bin`. Only `ndb_mgmd` is required to be present on a management node host; however, it is also a good idea to have `ndb_mgm` present on the same host machine. Neither of these executables requires a specific location on the host machine's file system.

In [Section 17.2.3, “MySQL Cluster Multi-Computer Configuration”](#), we create configuration files for all of the nodes in our example MySQL Cluster.

MySQL Cluster on Windows (*alpha*). In MySQL Cluster NDB 7.0, experimental support is added for Microsoft Windows platforms. To compile MySQL Cluster from source on Windows, you must configure the build using the `WITH_NDBCLUSTER_STORAGE_ENGINE` option before creating the Visual Studio project files. After running `make_win_bin_dist`, the MySQL Cluster binaries can be found in the `bin` directory of the resulting archive. For more information, see [Section 2.10.6, “Installing MySQL from Source on Windows”](#).

17.2.3. MySQL Cluster Multi-Computer Configuration

For our four-node, four-host MySQL Cluster, it is necessary to write four configuration files, one per node host.

- Each data node or SQL node requires a `my.cnf` file that provides two pieces of information: a *connectstring* that tells the node where to find the management node, and a line telling the MySQL server on this host (the machine hosting the data node) to enable the `NDBCLUSTER` storage engine.

For more information on connectstrings, see [Section 17.3.4.3, “The MySQL Cluster Connectstring”](#).

- The management node needs a `config.ini` file telling it how many replicas to maintain, how much memory to allocate for data and indexes on each data node, where to find the data nodes, where to save data to disk on each data node, and where to find any SQL nodes.

Configuring the Storage and SQL Nodes

The `my.cnf` file needed for the data nodes is fairly simple. The configuration file should be located in the `/etc` directory and can be edited using any text editor. (Create the file if it does not exist.) For example:

```
shell> vi /etc/my.cnf
```

Note

We show `vi` being used here to create the file, but any text editor should work just as well.

For each data node and SQL node in our example setup, `my.cnf` should look like this:

```
# Options for mysqld process:
[mysqld]
ndbcluster                # run NDB storage engine
ndb-connectstring=192.168.0.10 # location of management server

# Options for ndbd process:
[mysql_cluster]
ndb-connectstring=192.168.0.10 # location of management server
```

After entering the preceding information, save this file and exit the text editor. Do this for the machines hosting data node “A”, data node “B”, and the SQL node.

Important

Once you have started a `mysqld` process with the `NDBCLUSTER` and `ndb-connectstring` parameters in the `[mysqld]` in the `my.cnf` file as shown previously, you cannot execute any `CREATE TABLE` or `ALTER TABLE` statements without having actually started the cluster. Otherwise, these statements will fail with an error. *This is by design.*

Configuring the management node. The first step in configuring the management node is to create the directory in which the configuration file can be found and then to create the file itself. For example (running as `root`):

```
shell> mkdir /var/lib/mysql-cluster
shell> cd /var/lib/mysql-cluster
shell> vi config.ini
```

For our representative setup, the `config.ini` file should read as follows:

```
# Options affecting ndbd processes on all data nodes:
[ndbd default]
NoOfReplicas=2      # Number of replicas
DataMemory=80M     # How much memory to allocate for data storage
IndexMemory=18M    # How much memory to allocate for index storage
                  # For DataMemory and IndexMemory, we have used the
                  # default values. Since the "world" database takes up
                  # only about 500KB, this should be more than enough for
                  # this example Cluster setup.

# TCP/IP options:
[tcp default]
portnumber=2202    # This the default; however, you can use any port that is free
                  # for all the hosts in the cluster
                  # Note: It is recommended that you do not specify the port
                  # number at all and allow the default value to be used instead

# Management process options:
[ndb_mgmd]
hostname=192.168.0.10 # Hostname or IP address of management node
datadir=/var/lib/mysql-cluster # Directory for management node log files

# Options for data node "A":
[ndbd]
hostname=192.168.0.30 # (one [ndbd] section per data node)
                  # Hostname or IP address
datadir=/usr/local/mysql/data # Directory for this data node's data files

# Options for data node "B":
[ndbd]
hostname=192.168.0.40 # Hostname or IP address
datadir=/usr/local/mysql/data # Directory for this data node's data files

# SQL node options:
[mysqld]
hostname=192.168.0.20 # Hostname or IP address
                  # (additional mysqld connections can be
                  # specified for this node for various
                  # purposes such as running ndb_restore)
```

Note

The `world` database can be downloaded from <http://dev.mysql.com/doc/>, where it can be found listed under “Examples”.

After all the configuration files have been created and these minimal options have been specified, you are ready to proceed with starting the cluster and verifying that all processes are running. We discuss how this is done in [Section 17.2.4, “Initial Startup of MySQL Cluster”](#).

For more detailed information about the available MySQL Cluster configuration parameters and their uses, see [Section 17.3.4, “MySQL Cluster Configuration Files”](#), and [Section 17.3, “MySQL Cluster Configuration”](#). For configuration of MySQL Cluster as relates to making backups, see [Section 17.7.3.3, “Configuration for MySQL Cluster Backups”](#).

Note

The default port for Cluster management nodes is 1186; the default port for data nodes is 2202. However, the cluster can automatically allocate ports for data nodes from those that are already free.

17.2.4. Initial Startup of MySQL Cluster

Starting the cluster is not very difficult after it has been configured. Each cluster node process must be started separately, and on the host where it resides. The management node should be started first, followed by the data nodes, and then finally by any SQL nodes:

1. On the management host, issue the following command from the system shell to start the management node process:

```
shell> ndb_mgmd -f /var/lib/mysql-cluster/config.ini
```

Note

`ndb_mgmd` must be told where to find its configuration file, using the `-f` or `--config-file` option. (See [Section 17.6.4, “ndb_mgmd — The MySQL Cluster Management Server Daemon”](#), for details.)

For additional options which can be used with `ndb_mgmd`, see [Section 17.6.23, “Options Common to MySQL Cluster Programs”](#).

- On each of the data node hosts, run this command to start the `ndbd` process:

```
shell> ndbd
```

- If you used RPM files to install MySQL on the cluster host where the SQL node is to reside, you can (and should) use the supplied startup script to start the MySQL server process on the SQL node.

If all has gone well, and the cluster has been set up correctly, the cluster should now be operational. You can test this by invoking the `ndb_mgm` management node client. The output should look like that shown here, although you might see some slight differences in the output depending upon the exact version of MySQL that you are using:

```
shell> ndb_mgm
-- NDB Cluster -- Management Client --
ndb_mgm> SHOW
Connected to Management Server at: localhost:1186
Cluster Configuration
-----
[ndbd(NDB)] 2 node(s)
id=2 @192.168.0.30 (Version: 5.1.34-ndb-6.3.26, Nodegroup: 0, Master)
id=3 @192.168.0.40 (Version: 5.1.34-ndb-6.3.26, Nodegroup: 0)

[ndb_mgmd(MGM)] 1 node(s)
id=1 @192.168.0.10 (Version: 5.1.34-ndb-6.3.26)

[mysqld(API)] 1 node(s)
id=4 @192.168.0.20 (Version: 5.1.34-ndb-6.3.26)
```

The SQL node is referenced here as `[mysqld(API)]`, which reflects the fact that the `mysqld` process is acting as a MySQL Cluster API node.

Note

The IP address shown for a given MySQL Cluster SQL or other API node in the output of `SHOW` is the address used by the SQL or API node to connect to the cluster data nodes, and not to any management node.

You should now be ready to work with databases, tables, and data in MySQL Cluster. See [Section 17.2.5, “Loading Sample Data into MySQL Cluster and Performing Queries”](#), for a brief discussion.

17.2.5. Loading Sample Data into MySQL Cluster and Performing Queries

Working with data in MySQL Cluster is not much different from doing so in MySQL without Cluster. There are two points to keep in mind:

- For a table to be replicated in the cluster, it must use the `NDBCLUSTER` storage engine. To specify this, use the `ENGINE=NDBCLUSTER` or `ENGINE=NDB` option when creating the table:

```
CREATE TABLE tbl_name (col_name column_definitions) ENGINE=NDBCLUSTER;
```

Alternatively, for an existing table that uses a different storage engine, use `ALTER TABLE` to change the table to use `NDBCLUSTER`:

```
ALTER TABLE tbl_name ENGINE=NDBCLUSTER;
```

- Each `NDBCLUSTER` table *must* have a primary key. If no primary key is defined by the user when a table is created, the `NDBCLUSTER` storage engine automatically generates a hidden one.

Note

This hidden key takes up space just as does any other table index. It is not uncommon to encounter problems due to insufficient memory for accommodating these automatically created indexes.)

If you are importing tables from an existing database using the output of `mysqldump`, you can open the SQL script in a text editor and add the `ENGINE` option to any table creation statements, or replace any existing `ENGINE` (or `TYPE`) options. Suppose that you have the `world` sample database on another MySQL server that does not support MySQL Cluster, and you want to export the `City` table:

```
shell> mysqldump --add-drop-table world City > city_table.sql
```

The resulting `city_table.sql` file will contain this table creation statement (and the `INSERT` statements necessary to import

the table data):

```
DROP TABLE IF EXISTS `City`;
CREATE TABLE `City` (
  `ID` int(11) NOT NULL auto_increment,
  `Name` char(35) NOT NULL default '',
  `CountryCode` char(3) NOT NULL default '',
  `District` char(20) NOT NULL default '',
  `Population` int(11) NOT NULL default '0',
  PRIMARY KEY (`ID`)
) ENGINE=MyISAM DEFAULT CHARSET=latin1;

INSERT INTO `City` VALUES (1,'Kabul','AFG','Kabul',1780000);
INSERT INTO `City` VALUES (2,'Qandahar','AFG','Qandahar',237500);
INSERT INTO `City` VALUES (3,'Herat','AFG','Herat',186800);
(remaining INSERT statements omitted)
```

You need to make sure that MySQL uses the `NDBCLUSTER` storage engine for this table. There are two ways that this can be accomplished. One of these is to modify the table definition *before* importing it into the Cluster database. Using the `City` table as an example, modify the `ENGINE` option of the definition as follows:

```
DROP TABLE IF EXISTS `City`;
CREATE TABLE `City` (
  `ID` int(11) NOT NULL auto_increment,
  `Name` char(35) NOT NULL default '',
  `CountryCode` char(3) NOT NULL default '',
  `District` char(20) NOT NULL default '',
  `Population` int(11) NOT NULL default '0',
  PRIMARY KEY (`ID`)
) ENGINE=NDBCLUSTER DEFAULT CHARSET=latin1;

INSERT INTO `City` VALUES (1,'Kabul','AFG','Kabul',1780000);
INSERT INTO `City` VALUES (2,'Qandahar','AFG','Qandahar',237500);
INSERT INTO `City` VALUES (3,'Herat','AFG','Herat',186800);
(remaining INSERT statements omitted)
```

This must be done for the definition of each table that is to be part of the clustered database. The easiest way to accomplish this is to do a search-and-replace on the file that contains the definitions and replace all instances of `TYPE=engine_name` or `ENGINE=engine_name` with `ENGINE=NDBCLUSTER`. If you do not want to modify the file, you can use the unmodified file to create the tables, and then use `ALTER TABLE` to change their storage engine. The particulars are given later in this section.

Assuming that you have already created a database named `world` on the SQL node of the cluster, you can then use the `mysql` command-line client to read `city_table.sql`, and create and populate the corresponding table in the usual manner:

```
shell> mysql world < city_table.sql
```

It is very important to keep in mind that the preceding command must be executed on the host where the SQL node is running (in this case, on the machine with the IP address `192.168.0.20`).

To create a copy of the entire `world` database on the SQL node, use `mysqldump` on the non-cluster server to export the database to a file named `world.sql`; for example, in the `/tmp` directory. Then modify the table definitions as just described and import the file into the SQL node of the cluster like this:

```
shell> mysql world < /tmp/world.sql
```

If you save the file to a different location, adjust the preceding instructions accordingly.

Running `SELECT` queries on the SQL node is no different from running them on any other instance of a MySQL server. To run queries from the command line, you first need to log in to the MySQL Monitor in the usual way (specify the `root` password at the `Enter password:` prompt):

```
shell> mysql -u root -p
Enter password:
Welcome to the MySQL monitor.  Commands end with ; or \g.
Your MySQL connection id is 1 to server version: 5.1.34-ndb-6.2.18

Type 'help;' or '\h' for help. Type '\c' to clear the buffer.

mysql>
```

We simply use the MySQL server's `root` account and assume that you have followed the standard security precautions for installing a MySQL server, including setting a strong `root` password. For more information, see [Section 2.11.3, “Securing the Initial MySQL Accounts”](#).

It is worth taking into account that Cluster nodes do *not* make use of the MySQL privilege system when accessing one another. Setting or changing MySQL user accounts (including the `root` account) effects only applications that access the SQL node, not interaction between nodes. See [Section 17.8.2, “MySQL Cluster and MySQL Privileges”](#), for more information.

If you did not modify the `ENGINE` clauses in the table definitions prior to importing the SQL script, you should run the following statements at this point:

```
mysql> USE world;
mysql> ALTER TABLE City ENGINE=NDBCLUSTER;
mysql> ALTER TABLE Country ENGINE=NDBCLUSTER;
mysql> ALTER TABLE CountryLanguage ENGINE=NDBCLUSTER;
```

Selecting a database and running a `SELECT` query against a table in that database is also accomplished in the usual manner, as is exiting the MySQL Monitor:

```
mysql> USE world;
mysql> SELECT Name, Population FROM City ORDER BY Population DESC LIMIT 5;
+-----+-----+
| Name      | Population |
+-----+-----+
| Bombay    | 10500000  |
| Seoul     | 9981619   |
| São Paulo | 9968485   |
| Shanghai  | 9696300   |
| Jakarta   | 9604900   |
+-----+-----+
5 rows in set (0.34 sec)

mysql> \q
Bye

shell>
```

Applications that use MySQL can employ standard APIs to access `NDB` tables. It is important to remember that your application must access the SQL node, and not the management or data nodes. This brief example shows how we might execute the `SELECT` statement just shown by using the PHP 5.X `mysqli` extension running on a Web server elsewhere on the network:

```
<!DOCTYPE HTML PUBLIC "-//W3C//DTD HTML 4.01 Transitional//EN"
"http://www.w3.org/TR/html4/loose.dtd">
<html>
<head>
  <meta http-equiv="Content-Type"
        content="text/html; charset=iso-8859-1">
  <title>SIMPLE mysqli SELECT</title>
</head>
<body>
<?php
  # connect to SQL node:
  $link = new mysqli('192.168.0.20', 'root', 'root_password', 'world');
  # parameters for mysqli constructor are:
  #   host, user, password, database

  if( mysqli_connect_errno() )
    die("Connect failed: " . mysqli_connect_error());

  $query = "SELECT Name, Population
            FROM City
            ORDER BY Population DESC
            LIMIT 5";

  # if no errors...
  if( $result = $link->query($query) )
  {
?>
<table border="1" width="40%" cellpadding="4" cellspacing="1">
<tbody>
<tr>
  <th width="10%">City</th>
  <th>Population</th>
</tr>
<?
  # then display the results...
  while($row = $result->fetch_object())
    printf("<tr>\n  <td align=\"center\">%s</td><td>%d</td>\n</tr>\n",
          $row->Name, $row->Population);
?>
</tbody>
</table>
<?
  # ...and verify the number of rows that were retrieved
  printf("<p>Affected rows: %d</p>\n", $link->affected_rows);
  }
  else
    # otherwise, tell us what went wrong
    echo mysqli_error();

  # free the result set and the mysqli connection object
  $result->close();
  $link->close();
?>
</body>
</html>
```

We assume that the process running on the Web server can reach the IP address of the SQL node.

In a similar fashion, you can use the MySQL C API, Perl-DBI, Python-mysql, or MySQL AB's own Connectors to perform the tasks of data definition and manipulation just as you would normally with MySQL.

17.2.6. Safe Shutdown and Restart of MySQL Cluster

To shut down the cluster, enter the following command in a shell on the machine hosting the management node:

```
shell> ndb_mgm -e shutdown
```

The `-e` option here is used to pass a command to the `ndb_mgm` client from the shell. (See [Section 17.6.23, “Options Common to MySQL Cluster Programs”](#), for more information about this option.) The command causes the `ndb_mgm`, `ndb_mgmd`, and any `ndbd` processes to terminate gracefully. Any SQL nodes can be terminated using `mysqladmin shutdown` and other means.

To restart the cluster, run these commands:

- On the management host (192.168.0.10 in our example setup):

```
shell> ndb_mgmd -f /var/lib/mysql-cluster/config.ini
```

- On each of the data node hosts (192.168.0.30 and 192.168.0.40):

```
shell> ndbd
```

- On the SQL host (192.168.0.20):

```
shell> mysqld_safe &
```

In a production setting, it is usually not desirable to shut down the cluster completely. In many cases, even when making configuration changes, or performing upgrades to the cluster hardware or software (or both), which require shutting down individual host machines, it is possible to do so without shutting down the cluster as a whole by performing a *rolling restart* of the cluster. For more information about doing this, see [Section 17.5.1, “Performing a Rolling Restart of a MySQL Cluster”](#).

17.3. MySQL Cluster Configuration

A MySQL server that is part of a MySQL Cluster differs in one chief respect from a normal (non-clustered) MySQL server, in that it employs the `NDBCLUSTER` storage engine. This engine is also referred to simply as `NDB`, and the two forms of the name are synonymous.

To avoid unnecessary allocation of resources, the server is configured by default with the `NDB` storage engine disabled. To enable `NDB`, you must modify the server's `my.cnf` configuration file, or start the server with the `--ndbcluster` option.

For more information about `--ndbcluster` and other MySQL server options specific to MySQL Cluster, see [Section 17.4.2, “mysqld Command Options for MySQL Cluster”](#).

The MySQL server is a part of the cluster, so it also must know how to access an MGM node to obtain the cluster configuration data. The default behavior is to look for the MGM node on `localhost`. However, should you need to specify that its location is elsewhere, this can be done in `my.cnf` or on the MySQL server command line. Before the `NDB` storage engine can be used, at least one MGM node must be operational, as well as any desired data nodes.

17.3.1. Building MySQL Cluster from Source Code

`NDBCLUSTER`, the MySQL Cluster storage engine, is available in binary distributions for Linux, Mac OS X, and Solaris. We are working to make Cluster run on all operating systems supported by MySQL, including Windows. Beginning with MySQL Cluster NDB 6.4.0, there is experimental support for MySQL Cluster on Windows.

If you choose to build from a source tarball or one of the MySQL Cluster public development trees, be sure to use the `--with-ndbcluster` option when running `configure` (if building from source on Microsoft Windows platforms, use the `WITH_NDBCLUSTER_STORAGE_ENGINE` option with `configure.js`). You can also use the `BUILD/com-pile-pentium-max` build scripts provided for most Unix platforms. Note that this script includes OpenSSL, so you must either have or obtain OpenSSL to build successfully, or else modify `compile-pentium-max` to exclude this requirement. Of course, you can also just follow the standard instructions for compiling your own binaries, and then perform the usual tests and installation procedure. See [Section 2.10.3, “Installing from the Development Source Tree”](#).

`BUILD/compile-pentium-max` also includes OpenSSL, so you must either have or obtain OpenSSL to build successfully, or else modify `compile-pentium-max` to exclude this requirement. Of course, you can also just follow the standard instructions for compiling your own binaries, and then perform the usual tests and installation procedure. See [Section 2.10.3, “Installing from the Development Source Tree”](#).

You should also note that `compile-pentium-max` installs MySQL to the directory `/usr/local/mysql`, placing all MySQL Cluster executables, scripts, databases, and support files in subdirectories under this directory. If this is not what you desire, be sure to modify the script accordingly.

17.3.2. Installing MySQL Cluster Software

In the next few sections, we assume that you are already familiar with installing MySQL, and here we cover only the differences between configuring MySQL Cluster and configuring MySQL without clustering. (See [Chapter 2, *Installing and Upgrading MySQL*](#), if you require more information about the latter.)

You will find Cluster configuration easiest if you have already have all management and data nodes running first; this is likely to be the most time-consuming part of the configuration. Editing the `my.cnf` file is fairly straightforward, and this section will cover only any differences from configuring MySQL without clustering.

17.3.3. Quick Test Setup of MySQL Cluster

To familiarize you with the basics, we will describe the simplest possible configuration for a functional MySQL Cluster. After this, you should be able to design your desired setup from the information provided in the other relevant sections of this chapter.

First, you need to create a configuration directory such as `/var/lib/mysql-cluster`, by executing the following command as the system `root` user:

```
shell> mkdir /var/lib/mysql-cluster
```

In this directory, create a file named `config.ini` that contains the following information. Substitute appropriate values for `HostName` and `DataDir` as necessary for your system.

```
# file "config.ini" - showing minimal setup consisting of 1 data node,
# 1 management server, and 3 MySQL servers.
# The empty default sections are not required, and are shown only for
# the sake of completeness.
# Data nodes must provide a hostname but MySQL Servers are not required
# to do so.
# If you don't know the hostname for your machine, use localhost.
# The DataDir parameter also has a default value, but it is recommended to
# set it explicitly.
# Note: [db], [api], and [mgm] are aliases for [ndbd], [mysqld], and [ndb_mgmd],
# respectively. [db] is deprecated and should not be used in new installations.

[ndbd default]
NoOfReplicas= 1

[mysqld default]
[ndb_mgmd default]
[tcp default]

[ndb_mgmd]
HostName= myhost.example.com

[ndbd]
HostName= myhost.example.com
DataDir= /var/lib/mysql-cluster

[mysqld]
[mysqld]
[mysqld]
```

You can now start the `ndb_mgmd` management server. By default, it attempts to read the `config.ini` file in its current working directory, so change location into the directory where the file is located and then invoke `ndb_mgmd`:

```
shell> cd /var/lib/mysql-cluster
shell> ndb_mgmd
```

Then start a single data node by running `ndbd`:

```
shell> ndbd
```

For command-line options which can be used when starting `ndbd`, see [Section 17.6.23, “Options Common to MySQL Cluster Programs”](#).

By default, `ndbd` looks for the management server at `localhost` on port 1186.

Note

If you have installed MySQL from a binary tarball, you will need to specify the path of the `ndb_mgmd` and `ndbd` servers explicitly. (Normally, these will be found in `/usr/local/mysql/bin`.)

Finally, change location to the MySQL data directory (usually `/var/lib/mysql` or `/usr/local/mysql/data`), and make sure that the `my.cnf` file contains the option necessary to enable the NDB storage engine:

```
[mysqld]
ndbcluster
```

You can now start the MySQL server as usual:

```
shell> mysqld_safe --user=mysql &
```

Wait a moment to make sure the MySQL server is running properly. If you see the notice `mysql ended`, check the server's `.err` file to find out what went wrong.

If all has gone well so far, you now can start using the cluster. Connect to the server and verify that the `NDBCLUSTER` storage engine is enabled:

```
shell> mysql
Welcome to the MySQL monitor.  Commands end with ; or \g.
Your MySQL connection id is 1 to server version: 5.1.36

Type 'help;' or '\h' for help. Type '\c' to clear the buffer.

mysql> SHOW ENGINES\G
...
***** 12. row *****
Engine: NDBCLUSTER
Support: YES
Comment: Clustered, fault-tolerant, memory-based tables
***** 13. row *****
Engine: NDB
Support: YES
Comment: Alias for NDBCLUSTER
...
```

The row numbers shown in the preceding example output may be different from those shown on your system, depending upon how your server is configured.

Try to create an `NDBCLUSTER` table:

```
shell> mysql
mysql> USE test;
Database changed

mysql> CREATE TABLE ctest (i INT) ENGINE=NDBCLUSTER;
Query OK, 0 rows affected (0.09 sec)

mysql> SHOW CREATE TABLE ctest \G
***** 1. row *****
      Table: ctest
Create Table: CREATE TABLE `ctest` (
  `i` int(11) default NULL
) ENGINE=ndbcluster DEFAULT CHARSET=latin1
1 row in set (0.00 sec)
```

To check that your nodes were set up properly, start the management client:

```
shell> ndb_mgm
```

Use the `SHOW` command from within the management client to obtain a report on the cluster's status:

```
ndb_mgm> SHOW
Cluster Configuration
-----
[ndbd(NDB)] 1 node(s)
id=2 @127.0.0.1 (Version: 3.5.3, Nodegroup: 0, Master)

[ndb_mgmd(MGM)] 1 node(s)
id=1 @127.0.0.1 (Version: 3.5.3)

[mysqld(API)] 3 node(s)
id=3 @127.0.0.1 (Version: 3.5.3)
id=4 (not connected, accepting connect from any host)
id=5 (not connected, accepting connect from any host)
```

At this point, you have successfully set up a working MySQL Cluster. You can now store data in the cluster by using any table created with `ENGINE=NDBCLUSTER` or its alias `ENGINE=NDB`.

17.3.4. MySQL Cluster Configuration Files

Configuring MySQL Cluster requires working with two files:

- `my.cnf`: Specifies options for all MySQL Cluster executables. This file, with which you should be familiar with from previous work with MySQL, must be accessible by each executable running in the cluster.
- `config.ini`: This file, sometimes known as the *global configuration file*, is read only by the MySQL Cluster management server, which then distributes the information contained therein to all processes participating in the cluster. `config.ini` contains a description of each node involved in the cluster. This includes configuration parameters for data nodes and configuration parameters for connections between all nodes in the cluster. For a quick reference to the sections that can appear in this file, and what sorts of configuration parameters may be placed in each section, see [Sections of the config.ini File](#).

Caching of configuration data. Beginning with MySQL Cluster NDB 6.4.0, MySQL Cluster uses *stateful configuration*. The global configuration file is no longer read every time the management server is restarted. Instead, the management server caches the configuration the first time it is started, and thereafter, the global configuration file is read only when one of the following items is true:

- **The management server is started using `--initial` option.** In this case, the global configuration file is re-read, any existing cache files are deleted, and the management server creates a new configuration cache.
- **The management server is started using `--reload` option.** In this case, the management server compares its cache with the global configuration file. If they differ, the management server creates a new configuration cache; any existing configuration cache is preserved, but not used. If the management server's cache and the global configuration file contain the same configuration data, then the existing cache is used, and no new cache is created.
- **No configuration cache is found.** In this case, the management server reads the global configuration file and creates a cache containing the same configuration data as found in the file.

Configuration cache files. Beginning with MySQL Cluster 6.4.0, the management server by default creates configuration cache files in a directory named `mysql-cluster` in the MySQL installation directory. (If you build MySQL Cluster from source on a Unix system, the default location is `/usr/local/mysql-cluster`.) This can be overridden at run time by starting the management server with the `--configdir` option. Configuration cache files are binary files named according to the pattern `ndb_node_id_config.bin.seq_id`, where `node_id` is the management server's node ID in the cluster, and `seq_id` is a cache identifier. Cache files are numbered sequentially using `seq_id`, in the order in which they are created. The management server uses the latest cache file as determined by the `seq_id`.

Note

It is possible to roll back to a previous configuration by deleting later configuration cache files, or by renaming an earlier cache file so that it has a higher `seq_id`. However, since configuration cache files are written in a binary format, you should not attempt to edit their contents by hand.

For more information about the `--configdir`, `--initial`, and `--reload` options for the MySQL Cluster management server, see [Section 17.6.24.3, “Program Options for ndb_mgmd”](#).

We are continuously making improvements in Cluster configuration and attempting to simplify this process. Although we strive to maintain backward compatibility, there may be times when introduce an incompatible change. In such cases we will try to let Cluster users know in advance if a change is not backward compatible. If you find such a change and we have not documented it, please report it in the MySQL bugs database using the instructions given in [Section 1.6, “How to Report Bugs or Problems”](#).

17.3.4.1. MySQL Cluster Configuration — Basic Example

To support MySQL Cluster, you will need to update `my.cnf` as shown in the following example. You may also specify these parameters on the command line when invoking the executables.

Note

The options shown here should not be confused with those that are used in `config.ini` global configuration files. Global configuration options are discussed later in this section.

```
# my.cnf
# example additions to my.cnf for MySQL Cluster
# (valid in MySQL 5.1)
```

```
# enable ndbcluster storage engine, and provide connectstring for
# management server host (default port is 1186)
[mysqld]
ndbcluster
ndb-connectstring=ndb_mgmd.mysql.com

# provide connectstring for management server host (default port: 1186)
[ndbd]
connect-string=ndb_mgmd.mysql.com

# provide connectstring for management server host (default port: 1186)
[ndb_mgm]
connect-string=ndb_mgmd.mysql.com

# provide location of cluster configuration file
[ndb_mgmd]
config-file=/etc/config.ini
```

(For more information on connectstrings, see [Section 17.3.4.3, “The MySQL Cluster Connectstring”](#).)

```
# my.cnf
# example additions to my.cnf for MySQL Cluster
# (will work on all versions)

# enable ndbcluster storage engine, and provide connectstring for management
# server host to the default port 1186
[mysqld]
ndbcluster
ndb-connectstring=ndb_mgmd.mysql.com:1186
```

Important

Once you have started a `mysqld` process with the `NDBCLUSTER` and `ndb-connectstring` parameters in the `[mysqld]` in the `my.cnf` file as shown previously, you cannot execute any `CREATE TABLE` or `ALTER TABLE` statements without having actually started the cluster. Otherwise, these statements will fail with an error. *This is by design.*

You may also use a separate `[mysql_cluster]` section in the cluster `my.cnf` file for settings to be read and used by all executables:

```
# cluster-specific settings
[mysql_cluster]
ndb-connectstring=ndb_mgmd.mysql.com:1186
```

For additional `NDB` variables that can be set in the `my.cnf` file, see [Section 17.4.3, “MySQL Cluster System Variables”](#).

The MySQL Cluster global configuration file is named `config.ini` by default. It is read by `ndb_mgmd` at startup and can be placed anywhere. Its location and name are specified by using `--config-file=path_name` on the `ndb_mgmd` command line. If the configuration file is not specified, `ndb_mgmd` by default tries to read a file named `config.ini` located in the current working directory.

The global configuration file for MySQL Cluster uses INI format, which consists of sections preceded by section headings (surrounded by square brackets), followed by the appropriate parameter names and values. One deviation from the standard INI format is that the parameter name and value can be separated by a colon (“:”) as well as the equals sign (“=”); however, the equals sign is preferred. Another deviation is that sections are not uniquely identified by section name. Instead, unique sections (such as two different nodes of the same type) are identified by a unique ID specified as a parameter within the section.

Default values are defined for most parameters, and can also be specified in `config.ini`. (*Exception:* The `NoOfReplicas` configuration parameter has no default value, and must always be specified explicitly in the `[ndbd default]` section.) To create a default value section, simply add the word `default` to the section name. For example, an `[ndbd]` section contains parameters that apply to a particular data node, whereas an `[ndbd default]` section contains parameters that apply to all data nodes. Suppose that all data nodes should use the same data memory size. To configure them all, create an `[ndbd default]` section that contains a `DataMemory` line to specify the data memory size.

The global configuration file must define the computers and nodes involved in the cluster and on which computers these nodes are located. An example of a simple configuration file for a cluster consisting of one management server, two data nodes and two MySQL servers is shown here:

```
# file "config.ini" - 2 data nodes and 2 SQL nodes
# This file is placed in the startup directory of ndb_mgmd (the
# management server)
# The first MySQL Server can be started from any host. The second
# can be started only on the host mysqld_5.mysql.com

[ndbd default]
NoOfReplicas= 2
DataDir= /var/lib/mysql-cluster
```

```
[ndb_mgmd]
HostName= ndb_mgmd.mysql.com
DataDir= /var/lib/mysql-cluster

[ndbd]
HostName= ndbd_2.mysql.com

[ndbd]
HostName= ndbd_3.mysql.com

[mysqld]
[mysqld]
HostName= mysqld_5.mysql.com
```

Note

The preceding example is intended as a minimal starting configuration for purposes of familiarization with MySQL Cluster, and is almost certain not to be sufficient for production settings. See [Section 17.3.4.2, “Recommended Starting Configurations for MySQL Cluster NDB 6.2 and Later”](#), which provides more complete example starting configurations for use with MySQL Cluster NDB 6.2 and newer versions of MySQL Cluster.

Each node has its own section in the `config.ini` file. For example, this cluster has two data nodes, so the preceding configuration file contains two `[ndbd]` sections defining these nodes.

Note

Do not place comments on the same line as a section heading in the `config.ini` file; this causes the management server not to start because it cannot parse the configuration file in such cases.

Sections of the `config.ini` File

There are six different sections that you can use in the `config.ini` configuration file, as described in the following list:

- `[computer]`: Defines cluster hosts. This is not required to configure a viable MySQL Cluster, but it may be used as a convenience when setting up a large cluster. See [Section 17.3.4.4, “Defining Computers in a MySQL Cluster”](#), for more information.
- `[ndbd]`: Defines a cluster data node (`ndbd` process). See [Section 17.3.4.6, “Defining MySQL Cluster Data Nodes”](#), for details.
- `[mysqld]`: Defines the cluster’s MySQL server nodes (also called SQL or API nodes). For a discussion of SQL node configuration, see [Section 17.3.4.7, “Defining SQL and Other API Nodes in a MySQL Cluster”](#).
- `[mgm]` or `[ndb_mgmd]`: Defines a cluster management server (MGM) node. For information concerning the configuration of MGM nodes, see [Section 17.3.4.5, “Defining a MySQL Cluster Management Server”](#).
- `[tcp]`: Defines a TCP/IP connection between cluster nodes, with TCP/IP being the default connection protocol. Normally, `[tcp]` or `[tcp default]` sections are not required to set up a MySQL Cluster, as the cluster handles this automatically; however, it may be necessary in some situations to override the defaults provided by the cluster. See [Section 17.3.4.8, “MySQL Cluster TCP/IP Connections”](#), for information about available TCP/IP configuration parameters and how to use them. (You may also find [Section 17.3.4.9, “MySQL Cluster TCP/IP Connections Using Direct Connections”](#) to be of interest in some cases.)
- `[shm]`: Defines shared-memory connections between nodes. In MySQL 5.1, it is enabled by default, but should still be considered experimental. For a discussion of SHM interconnects, see [Section 17.3.4.10, “MySQL Cluster Shared-Memory Connections”](#).
- `[sci]`: Defines *Scalable Coherent Interface* connections between cluster data nodes. Such connections require software which, while freely available, is not part of the MySQL Cluster distribution, as well as specialised hardware. See [Section 17.3.4.11, “SCI Transport Connections in MySQL Cluster”](#) for detailed information about SCI interconnects.

You can define `default` values for each section. All Cluster parameter names are case-insensitive, which differs from parameters specified in `my.cnf` or `my.ini` files.

17.3.4.2. Recommended Starting Configurations for MySQL Cluster NDB 6.2 and Later

Achieving the best performance from a MySQL Cluster depends on a number of factors including the following:

- MySQL Cluster software version
- Numbers of data nodes and SQL nodes

- Hardware
- Operating system
- Amount of data to be stored
- Size and type of load under which the cluster is to operate

Therefore, obtaining an optimum configuration is likely to be an iterative process, the outcome of which can vary widely with the specifics of each MySQL Cluster deployment. Changes in configuration are also likely to be indicated when changes are made in the platform on which the cluster is run, or in applications that use the MySQL Cluster's data. For these reasons, it is not possible to offer a single configuration that is ideal for all usage scenarios. However, in this section, we provide recommended base configurations for MySQL Cluster NDB 6.2 and 6.3 that can serve as reasonable starting points.

Starting configuration for MySQL Cluster NDB 6.2. The following is a recommended starting point for configuring a cluster running MySQL Cluster NDB 6.2.

```
# TCP PARAMETERS

[tcp default]
SendBufferMemory=2M
ReceiveBufferMemory=2M

# Increasing the sizes of these 2 buffers beyond the default values
# helps prevent bottlenecks due to slow disk I/O.

# MANAGEMENT NODE PARAMETERS

[ndb_mgmd default]
DataDir=path/to/management/server/data/directory

# It is possible to use a different data directory for each management
# server, but for ease of administration it is preferable to be
# consistent.

[ndb_mgmd]
HostName=management-server-1-hostname
# Id=management-server-A-id

[ndb_mgmd]
HostName=management-server-2-hostname

# Using 2 management servers helps guarantee that there is always an
# arbitrator in the event of network partitioning, and so is
# recommended for high availability. Each management server must be
# identified by a HostName. You may for the sake of convenience specify
# a node ID for any management server, although one will be allocated
# for it automatically; if you do so, it must be in the range 1-255
# inclusive and must be unique among all IDs specified for cluster
# nodes.

# DATA NODE PARAMETERS

[ndbd default]
NoOfReplicas=2

# This parameter has no default value; it must always must be set
# explicitly. Using 2 replicas is recommended to guarantee
# availability of data; using only 1 replica does not provide any
# redundancy, which means that the failure of a single data node causes
# the entire cluster to shut down. We do not recommend using more than
# 2 replicas, since 2 is sufficient to provide high availability, and
# we do not currently test with greater values for this parameter.

LockPagesInMainMemory=1

# On Linux and Solaris systems, setting this parameter locks data node
# processes into memory. Doing so prevents them from swapping to disk,
# which can severely degrade cluster performance.

DataMemory=3072M
IndexMemory=384M

# The values provided for DataMemory and IndexMemory assume 4 GB RAM
# per data node. However, for best results, you should first calculate
# the memory that would be used based on the data you actually plan to
# store (you may find the ndb_size.pl utility helpful in estimating
# this), then allow an extra 20% over the calculated values. Naturally,
# you should ensure that each data node host has at least as much
# physical memory as the sum of these two values.

# ODirect=1

# Enabling this parameter causes NDBCLUSTER to try using O_DIRECT
# writes for local checkpoints and redo logs; this can reduce load on
# CPUs. We recommend doing so when using MySQL Cluster NDB 6.2.3 or
# newer on systems running Linux kernel 2.6 or later.

NoOfFragmentLogFiles=300
```

```

DataDir=path/to/data/node/data/directory
MaxNoOfConcurrentOperations=100000
TimeBetweenGlobalCheckpoints=1000
TimeBetweenEpochs=200
DiskCheckpointSpeed=10M
DiskCheckpointSpeedInRestart=100M
RedoBuffer=32M
# MaxNoOfLocalScans=64
MaxNoOfTables=1024
MaxNoOfOrderedIndexes=256

[ndbd]
HostName=data-node-A-hostname
# Id=data-node-A-id

[ndbd]
HostName=data-node-B-hostname
# Id=data-node-B-id

# You must have an [ndbd] section for every data node in the cluster;
# each of these sections must include a HostName. Each section may
# optionally include an Id for convenience, but in most cases, it is
# sufficient to allow the cluster to allocate node IDs dynamically. If
# you do specify the node ID for a data node, it must be in the range 1
# to 48 inclusive and must be unique among all IDs specified for
# cluster nodes.

# SQL NODE / API NODE PARAMETERS

[mysqld]
# HostName=SQL-node-1-hostname
# Id=sql-node-A-id

[mysqld]

[mysqld]

# Each API or SQL node that connects to the cluster requires a [mysqld]
# or [api] section of its own. Each such section defines a connection
# "slot"; you should have at least as many of these sections in the
# config.ini file as the total number of API nodes and SQL nodes that
# you wish to have connected to the cluster at any given time. There is
# no performance or other penalty for having extra slots available in
# case you find later that you want or need more API or SQL nodes to
# connect to the cluster at the same time.
# If no HostName is specified for a given [mysqld] or [api] section,
# then any API or SQL node may use that slot to connect to the
# cluster. You may wish to use an explicit HostName for one connection slot
# to guarantee that an API or SQL node from that host can always
# connect to the cluster. If you wish to prevent API or SQL nodes from
# connecting from other than a desired host or hosts, then use a
# HostName for every [mysqld] or [api] section in the config.ini file.
# You can if you wish define a node ID (Id parameter) for any API or
# SQL node, but this is not necessary; if you do so, it must be in the
# range 1 to 255 inclusive and must be unique among all IDs specified
# for cluster nodes.

```

Starting configuration for MySQL Cluster NDB 6.3. The following is a recommended starting point for configuring a cluster running MySQL Cluster NDB 6.3. It is similar to the recommendation for MySQL Cluster NDB 6.2, with the addition of parameters for better control of `NDBCLUSTER` process threads.

```

# TCP PARAMETERS

[tcp default]
SendBufferMemory=2M
ReceiveBufferMemory=2M

# Increasing the sizes of these 2 buffers beyond the default values
# helps prevent bottlenecks due to slow disk I/O.

# MANAGEMENT NODE PARAMETERS

[ndb_mgmd default]
DataDir=path/to/management/server/data/directory

# It is possible to use a different data directory for each management
# server, but for ease of administration it is preferable to be
# consistent.

[ndb_mgmd]
HostName=management-server-1-hostname
# Id=management-server-A-id

[ndb_mgmd]
HostName=management-server-2-hostname

# Using 2 management servers helps guarantee that there is always an
# arbitrator in the event of network partitioning, and so is
# recommended for high availability. Each management server must be
# identified by a HostName. You may for the sake of convenience specify
# a node ID for any management server, although one will be allocated
# for it automatically; if you do so, it must be in the range 1-255
# inclusive and must be unique among all IDs specified for cluster
# nodes.

```

```

# DATA NODE PARAMETERS

[ndbd default]
NoOfReplicas=2

# This parameter has no default value; it must always must be set
# explicitly. Using 2 replicas is recommended to guarantee
# availability of data; using only 1 replica does not provide any
# redundancy, which means that the failure of a single data node causes
# the entire cluster to shut down. We do not recommend using more than
# 2 replicas, since 2 is sufficient to provide high availability, and
# we do not currently test with greater values for this parameter.

LockPagesInMainMemory=1

# On Linux and Solaris systems, setting this parameter locks data node
# processes into memory. Doing so prevents them from swapping to disk,
# which can severely degrade cluster performance.

DataMemory=3072M
IndexMemory=384M

# The values provided for DataMemory and IndexMemory assume 4 GB RAM
# per data node. However, for best results, you should first calculate
# the memory that would be used based on the data you actually plan to
# store (you may find the ndb\_size.pl utility helpful in estimating
# this), then allow an extra 20% over the calculated values. Naturally,
# you should ensure that each data node host has at least as much
# physical memory as the sum of these two values.

# ODirect=1

# Enabling this parameter causes NDBCLUSTER to try using O_DIRECT
# writes for local checkpoints and redo logs; this can reduce load on
# CPUs. We recommend doing so when using MySQL Cluster NDB 6.2.3 or
# newer on systems running Linux kernel 2.6 or later.

# threads to specific CPUs

[ndbd]
HostName=data-node-B-hostname
# Id=data-node-B-id

LockExecuteThreadToCPU=1
LockMaintThreadsToCPU=0

# You must have an [ndbd] section for every data node in the cluster;
# each of these sections must include a HostName. Each section may
# optionally include an Id for convenience, but in most cases, it is
# sufficient to allow the cluster to allocate node IDs dynamically. If
# you do specify the node ID for a data node, it must be in the range 1
# to 48 inclusive and must be unique among all IDs specified for
# cluster nodes.

# SQL NODE / API NODE PARAMETERS

[mysqld]
# HostName=SQL-node-1-hostname
# Id=sql-node-A-id

[mysqld]

[mysqld]

```

```
# Each API or SQL node that connects to the cluster requires a [mysqld]
# or [api] section of its own. Each such section defines a connection
# "slot"; you should have at least as many of these sections in the
# config.ini file as the total number of API nodes and SQL nodes that
# you wish to have connected to the cluster at any given time. There is
# no performance or other penalty for having extra slots available in
# case you find later that you want or need more API or SQL nodes to
# connect to the cluster at the same time.
# If no HostName is specified for a given [mysqld] or [api] section,
# then any API or SQL node may use that slot to connect to the
# cluster. You may wish to use an explicit HostName for one connection slot
# to guarantee that an API or SQL node from that host can always
# connect to the cluster. If you wish to prevent API or SQL nodes from
# connecting from other than a desired host or hosts, then use a
# HostName for every [mysqld] or [api] section in the config.ini file.
# You can if you wish define a node ID (Id parameter) for any API or
# SQL node, but this is not necessary; if you do so, it must be in the
# range 1 to 255 inclusive and must be unique among all IDs specified
# for cluster nodes.
```

Recommended `my.cnf` options for SQL nodes. MySQL Servers acting as MySQL Cluster SQL nodes must always be started with the `--ndbcluster` and `--ndb-connectstring` options, either on the command line or in `my.cnf`. In addition, we recommend setting the following options for all `mysqld` processes in the cluster, unless your setup requires otherwise:

- `--ndb-use-exact-count=0`
- `--ndb-index-stat-enable=0`
- `--ndb-force-send=1`
- `--engine-condition-pushdown=1`

17.3.4.3. The MySQL Cluster Connectstring

With the exception of the MySQL Cluster management server (`ndb_mgmd`), each node that is part of a MySQL Cluster requires a *connectstring* that points to the management server's location. This connectstring is used in establishing a connection to the management server as well as in performing other tasks depending on the node's role in the cluster. The syntax for a connectstring is as follows:

```
[nodeid=node_id, ]host-definition[, host-definition[, ...]]
host-definition:
    host_name[:port_number]
```

`node_id` is an integer larger than 1 which identifies a node in `config.ini`. `host_name` is a string representing a valid Internet host name or IP address. `port_number` is an integer referring to a TCP/IP port number.

```
example 1 (long):    "nodeid=2,myhost1:1100,myhost2:1100,192.168.0.3:1200"
example 2 (short):  "myhost1"
```

`localhost:1186` is used as the default connectstring value if none is provided. If `port_num` is omitted from the connectstring, the default port is 1186. This port should always be available on the network because it has been assigned by IANA for this purpose (see <http://www.iana.org/assignments/port-numbers> for details).

By listing multiple host definitions, it is possible to designate several redundant management servers. A MySQL Cluster data or API node attempts to contact successive management servers on each host in the order specified, until a successful connection has been established.

Beginning with MySQL Cluster NDB 6.3.19, it is also possible in a connectstring to specify one or more bind addresses to be used by nodes having multiple network interfaces for connecting to management servers. A bind address consists of a hostname or network address and an optional port number. This enhanced syntax for connectstrings is shown here:

```
[nodeid=node_id, ]
[bind-address=host-definition, ]
host-definition[; bind-address=host-definition]
host-definition[; bind-address=host-definition]
[, ...]]
host-definition:
    host_name[:port_number]
```

If a single bind address is used in the connectstring *prior* to specifying any management hosts, then this address is used as the default for connecting to any of them (unless overridden for a given management server; see later in this section for an example). For example, the following connectstring causes the node to use `192.168.178.242` regardless of the management server to which it

connects:

```
bind-address=192.168.178.242, poseidon:1186, perch:1186
```

If a bind address is specified *following* a management host definition, then it is used only for connecting to that management node. Consider the following connectstring:

```
poseidon:1186;bind-address=localhost, perch:1186;bind-address=192.168.178.242
```

In this case, the node uses `localhost` to connect to the management server running on the host named `poseidon` and `192.168.178.242` to connect to the management server running on the host named `perch`.

You can specify a default bind address and then override this default for one or more specific management hosts. In the following example, `localhost` is used for connecting to the management server running on host `poseidon`; since `192.168.178.242` is specified first (before any management server definitions), it is the default bind address and so is used for connecting to the management servers on hosts `perch` and `orca`:

```
bind-address=192.168.178.242,poseidon:1186;bind-address=localhost,perch:1186,orca:2200
```

There are a number of different ways to specify the connectstring:

- Each executable has its own command-line option which enables specifying the management server at startup. (See the documentation for the respective executable.)
- It is also possible to set the connectstring for all nodes in the cluster at once by placing it in a `[mysql_cluster]` section in the management server's `my.cnf` file.
- For backward compatibility, two other options are available, using the same syntax:
 1. Set the `NDB_CONNECTSTRING` environment variable to contain the connectstring.
 2. Write the connectstring for each executable into a text file named `Ndb.cfg` and place this file in the executable's startup directory.

However, these are now deprecated and should not be used for new installations.

The recommended method for specifying the connectstring is to set it on the command line or in the `my.cnf` file for each executable.

The maximum length of a connectstring is 1024 characters.

17.3.4.4. Defining Computers in a MySQL Cluster

The `[computer]` section has no real significance other than serving as a way to avoid the need of defining host names for each node in the system. All parameters mentioned here are required.

- `Id`

This is an integer value, used to refer to the host computer elsewhere in the configuration file. This is not the same as the node ID.

- `HostName`

This is the computer's hostname or IP address.

17.3.4.5. Defining a MySQL Cluster Management Server

The `[ndb_mgmd]` section is used to configure the behavior of the management server. `[mgm]` can be used as an alias; the two section names are equivalent. All parameters in the following list are optional and assume their default values if omitted.

Note

If neither the `ExecuteOnComputer` nor the `HostName` parameter is present, the default value `localhost` will be assumed for both.

•

Id

Each node in the cluster has a unique identity. For a management node, this is represented by an integer value in the range 1 to 63 inclusive (previous to MySQL Cluster NDB 6.1.1), or in the range 1 to 255 inclusive (MySQL Cluster NDB 6.1.1 and later). This ID is used by all internal cluster messages for addressing the node, and so must be unique for each MySQL Cluster node, regardless of the type of node.

Note

Data node IDs must be less than 49, regardless of the MySQL Cluster version used. If you plan to deploy a large number of data nodes, it is a good idea to limit the node IDs for management nodes (and API nodes) to values greater than 48.

•

ExecuteOnComputer

This refers to the **Id** set for one of the computers defined in a `[computer]` section of the `config.ini` file.

•

PortNumber

This is the port number on which the management server listens for configuration requests and management commands.

•

HostName

Specifying this parameter defines the hostname of the computer on which the management node is to reside. To specify a host-name other than `localhost`, either this parameter or `ExecuteOnComputer` is required.

•

LogDestination

This parameter specifies where to send cluster logging information. There are three options in this regard — `CONSOLE`, `SYSLOG`, and `FILE` — with `FILE` being the default:

- `CONSOLE` outputs the log to `stdout`:

```
CONSOLE
```

- `SYSLOG` sends the log to a `syslog` facility, possible values being one of `auth`, `authpriv`, `cron`, `daemon`, `ftp`, `kern`, `lpr`, `mail`, `news`, `syslog`, `user`, `uucp`, `local0`, `local1`, `local2`, `local3`, `local4`, `local5`, `local6`, or `local7`.

Note

Not every facility is necessarily supported by every operating system.

```
SYSLOG:facility=syslog
```

- `FILE` pipes the cluster log output to a regular file on the same machine. The following values can be specified:

- `filename`: The name of the log file.
- `maxsize`: The maximum size (in bytes) to which the file can grow before logging rolls over to a new file. When this occurs, the old log file is renamed by appending `.N` to the file name, where `N` is the next number not yet used with this name.
- `maxfiles`: The maximum number of log files.

```
FILE:filename=cluster.log,maxsize=1000000,maxfiles=6
```

The default value for the `FILE` parameter is

```
FILE:filename=ndb_node_id_cluster.log,maxsize=1000000,maxfiles=6
```

where `node_id` is the ID of the node.

It is possible to specify multiple log destinations separated by semicolons as shown here:

```
CONSOLE;SYSLOG:facility=local0;FILE:filename=/var/log/mgmd
```

- **ArbitrationRank**

This parameter is used to define which nodes can act as arbitrators. Only management nodes and SQL nodes can be arbitrators. `ArbitrationRank` can take one of the following values:

- `0`: The node will never be used as an arbitrator.
- `1`: The node has high priority; that is, it will be preferred as an arbitrator over low-priority nodes.
- `2`: Indicates a low-priority node which be used as an arbitrator only if a node with a higher priority is not available for that purpose.

Normally, the management server should be configured as an arbitrator by setting its `ArbitrationRank` to 1 (the default value) and that of all SQL nodes to 0.

Beginning with MySQL 5.1.16 and MySQL Cluster NDB 6.1.3, it is possible to disable arbitration completely by setting `ArbitrationRank` to 0 on all management and SQL nodes.

- **ArbitrationDelay**

An integer value which causes the management server's responses to arbitration requests to be delayed by that number of milliseconds. By default, this value is 0; it is normally not necessary to change it.

- **DataDir**

This specifies the directory where output files from the management server will be placed. These files include cluster log files, process output files, and the daemon's process ID (PID) file. (For log files, this location can be overridden by setting the `FILE` parameter for `LogDestination` as discussed previously in this section.)

The default value for this parameter is the directory in which `ndb_mgmd` is located.

- **TotalSendBufferMemory**

This parameter is available beginning with MySQL Cluster NDB 6.4.0. It is used to determine the total amount of memory to allocate on this node for shared send buffer memory among all configured transporters.

If this parameter is set, its minimum allowed value is 256K; the maximum is 4294967039. For more detailed information about the behavior and use of `TotalSendBufferMemory` and configuring send buffer memory parameters in MySQL Cluster NDB 6.4.0 and later, see [Section 17.3.7, “Configuring MySQL Cluster Send Buffer Parameters”](#).

Note

After making changes in a management node's configuration, it is necessary to perform a rolling restart of the cluster in order for the new configuration to take effect.

To add new management servers to a running MySQL Cluster, it is also necessary to perform a rolling restart of all cluster nodes after modifying any existing `config.ini` files. For more information about issues arising when using multiple management nodes, see [Section 17.12.10, “Limitations Relating to Multiple MySQL Cluster Nodes”](#).

17.3.4.6. Defining MySQL Cluster Data Nodes

The `[ndbd]` and `[ndbd default]` sections are used to configure the behavior of the cluster's data nodes.

`[ndbd]` and `[ndbd default]` are always used as the section names whether you are using `ndbd` or (in MySQL Cluster NDB 6.4.0 and later) `ndbmt` binaries for the data node processes.

There are many parameters which control buffer sizes, pool sizes, timeouts, and so forth. The only mandatory parameters are:

- Either `ExecuteOnComputer` or `HostName`, which must be defined in the local `[ndbd]` section.
- The parameter `NoOfReplicas`, which must be defined in the `[ndbd default]` section, as it is common to all Cluster data nodes.

Most data node parameters are set in the `[ndbd default]` section. Only those parameters explicitly stated as being able to set

local values are allowed to be changed in the `[ndbd]` section. Where present, `HostName`, `Id` and `ExecuteOnComputer` must be defined in the local `[ndbd]` section, and not in any other section of `config.ini`. In other words, settings for these parameters are specific to one data node.

For those parameters affecting memory usage or buffer sizes, it is possible to use `K`, `M`, or `G` as a suffix to indicate units of 1024, 1024×1024, or 1024×1024×1024. (For example, `100K` means $100 \times 1024 = 102400$.) Parameter names and values are currently case-sensitive.

Information about configuration parameters specific to MySQL Cluster Disk Data tables can be found later in this section.

Beginning with MySQL Cluster NDB 6.4.0, all of these parameters also apply to `ndbmt` (the multi-threaded version of `ndbd`). An additional data node configuration parameter `MaxNoOfExecutionThreads` applies to `ndbmt` only, and has no effect when used with `ndbd`. For a description of this parameter and its use, see [Section 17.6.3, “ndbmt — The MySQL Cluster Data Node Daemon \(Multi-Threaded\)”](#).

Identifying data nodes. The `Id` value (that is, the data node identifier) can be allocated on the command line when the node is started or in the configuration file.

- `Id`

This is the node ID used as the address of the node for all cluster internal messages. For data nodes, this is an integer in the range 1 to 48 inclusive. Each node in the cluster must have a unique identifier.
- `ExecuteOnComputer`

This refers to the `Id` set for one of the computers defined in a `[computer]` section.
- `HostName`

Specifying this parameter defines the hostname of the computer on which the data node is to reside. To specify a hostname other than `localhost`, either this parameter or `ExecuteOnComputer` is required.
- `ServerPort` (*OBSOLETE*)

Each node in the cluster uses a port to connect to other nodes. This port is used also for non-TCP transporters in the connection setup phase. The default port is allocated dynamically in such a way as to ensure that no two nodes on the same computer receive the same port number, so it should not normally be necessary to specify a value for this parameter.
- `TcpBind_INADDR_ANY`

Setting this parameter to `TRUE` or `1` binds `IP_ADDR_ANY` so that connections can be made from anywhere (for autogenerated connections). The default is `FALSE` (`0`).

This parameter was added in MySQL Cluster NDB 6.2.0.
- `NodeGroup`

This parameter can be used to assign a data node to a specific node group. It is read only when the cluster is started for the first time, and cannot be used to reassign a data node to a different node group online. It is generally not desirable to use this parameter in the `[ndbd default]` section of the `config.ini` file, and care must be taken not to assign nodes to node groups in such a way that an invalid numbers of nodes are assigned to any node groups.

The `NodeGroup` parameter is chiefly intended for use in adding a new node group to a running MySQL Cluster without having to perform a rolling restart. For this purpose, you should set it to 65535 (the maximum value). You are not required to set a `NodeGroup` value for all cluster data nodes, only for those nodes which are to be started and added to the cluster as a new node group at a later time. For more information, see [Section 17.7.8.3, “Adding MySQL Cluster Data Nodes Online: Detailed Example”](#).

This parameter was added in MySQL Cluster NDB 6.4.0.
- `NoOfReplicas`

This global parameter can be set only in the `[ndbd default]` section, and defines the number of replicas for each table stored in the cluster. This parameter also specifies the size of node groups. A node group is a set of nodes all storing the same information.

Node groups are formed implicitly. The first node group is formed by the set of data nodes with the lowest node IDs, the next node group by the set of the next lowest node identities, and so on. By way of example, assume that we have 4 data nodes and that `NoOfReplicas` is set to 2. The four data nodes have node IDs 2, 3, 4 and 5. Then the first node group is formed from nodes 2 and 3, and the second node group by nodes 4 and 5. It is important to configure the cluster in such a manner that nodes in the same node groups are not placed on the same computer because a single hardware failure would cause the entire cluster to fail.

If no node IDs are provided, the order of the data nodes will be the determining factor for the node group. Whether or not explicit assignments are made, they can be viewed in the output of the management client's `SHOW` command.

There is no default value for `NoOfReplicas`; the maximum possible value is 4. Currently, only the values 1 and 2 are actually supported (see [Bug#18621](#)).

Important

Setting `NoOfReplicas` to 1 means that there is only a single copy of all Cluster data; in this case, the loss of a single data node causes the cluster to fail because there are no additional copies of the data stored by that node.

The value for this parameter must divide evenly into the number of data nodes in the cluster. For example, if there are two data nodes, then `NoOfReplicas` must be equal to either 1 or 2, since $2/3$ and $2/4$ both yield fractional values; if there are four data nodes, then `NoOfReplicas` must be equal to 1, 2, or 4.

- `DataDir`

This parameter specifies the directory where trace files, log files, pid files and error logs are placed.

The default is the data node process working directory.

- `FileSystemPath`

This parameter specifies the directory where all files created for metadata, REDO logs, UNDO logs (for Disk Data tables) and data files are placed. The default is the directory specified by `DataDir`.

Note

This directory must exist before the `ndbd` process is initiated.

The recommended directory hierarchy for MySQL Cluster includes `/var/lib/mysql-cluster`, under which a directory for the node's file system is created. The name of this subdirectory contains the node ID. For example, if the node ID is 2, this subdirectory is named `ndb_2_fs`.

- `BackupDataDir`

This parameter specifies the directory in which backups are placed. If omitted, the default backup location is the directory named `BACKUP` under the location specified by the `FileSystemPath` parameter. (See above.)

Data Memory, Index Memory, and String Memory

`DataMemory` and `IndexMemory` are `[ndbd]` parameters specifying the size of memory segments used to store the actual records and their indexes. In setting values for these, it is important to understand how `DataMemory` and `IndexMemory` are used, as they usually need to be updated to reflect actual usage by the cluster:

- `DataMemory`

This parameter defines the amount of space (in bytes) available for storing database records. The entire amount specified by this value is allocated in memory, so it is extremely important that the machine has sufficient physical memory to accommodate it.

The memory allocated by `DataMemory` is used to store both the actual records and indexes. There is a 16-byte overhead on each record; an additional amount for each record is incurred because it is stored in a 32KB page with 128 byte page overhead (see below). There is also a small amount wasted per page due to the fact that each record is stored in only one page.

For variable-size table attributes in MySQL 5.1, the data is stored on separate datapages, allocated from `DataMemory`. Variable-length records use a fixed-size part with an extra overhead of 4 bytes to reference the variable-size part. The variable-size

part has 2 bytes overhead plus 2 bytes per attribute.

The maximum record size is currently 8052 bytes.

The memory space defined by `DataMemory` is also used to store ordered indexes, which use about 10 bytes per record. Each table row is represented in the ordered index. A common error among users is to assume that all indexes are stored in the memory allocated by `IndexMemory`, but this is not the case: Only primary key and unique hash indexes use this memory; ordered indexes use the memory allocated by `DataMemory`. However, creating a primary key or unique hash index also creates an ordered index on the same keys, unless you specify `USING HASH` in the index creation statement. This can be verified by running `ndb_desc -d db_name table_name` in the management client.

The memory space allocated by `DataMemory` consists of 32KB pages, which are allocated to table fragments. Each table is normally partitioned into the same number of fragments as there are data nodes in the cluster. Thus, for each node, there are the same number of fragments as are set in `NoOfReplicas`.

In addition, due to the way in which new pages are allocated when the capacity of the current page is exhausted, there is an additional overhead of approximately 18.75%. When more `DataMemory` is required, more than one new page is allocated, according to the following formula:

```
number of new pages = FLOOR(number of current pages × 0.1875) + 1
```

For example, if 15 pages are currently allocated to a given table and an insert to this table requires additional storage space, the number of new pages allocated to the table is $FLOOR(15 \times 0.1875) + 1 = FLOOR(2.8125) + 1 = 2 + 1 = 3$. Now $15 + 3 = 18$ memory pages are allocated to the table. When the last of these 18 pages becomes full, $FLOOR(18 \times 0.1875) + 1 = FLOOR(3.3750) + 1 = 3 + 1 = 4$ new pages are allocated, so the total number of pages allocated to the table is now 22.

Note

The “18.75% + 1” overhead is no longer required beginning with MySQL Cluster NDB 6.2.3 and MySQL Cluster NDB 6.3.0.

Once a page has been allocated, it is currently not possible to return it to the pool of free pages, except by deleting the table. (This also means that `DataMemory` pages, once allocated to a given table, cannot be used by other tables.) Performing a node recovery also compresses the partition because all records are inserted into empty partitions from other live nodes.

The `DataMemory` memory space also contains UNDO information: For each update, a copy of the unaltered record is allocated in the `DataMemory`. There is also a reference to each copy in the ordered table indexes. Unique hash indexes are updated only when the unique index columns are updated, in which case a new entry in the index table is inserted and the old entry is deleted upon commit. For this reason, it is also necessary to allocate enough memory to handle the largest transactions performed by applications using the cluster. In any case, performing a few large transactions holds no advantage over using many smaller ones, for the following reasons:

- Large transactions are not any faster than smaller ones
- Large transactions increase the number of operations that are lost and must be repeated in event of transaction failure
- Large transactions use more memory

The default value for `DataMemory` is 80MB; the minimum is 1MB. There is no maximum size, but in reality the maximum size has to be adapted so that the process does not start swapping when the limit is reached. This limit is determined by the amount of physical RAM available on the machine and by the amount of memory that the operating system may commit to any one process. 32-bit operating systems are generally limited to 2–4GB per process; 64-bit operating systems can use more. For large databases, it may be preferable to use a 64-bit operating system for this reason.

IndexMemory

This parameter controls the amount of storage used for hash indexes in MySQL Cluster. Hash indexes are always used for primary key indexes, unique indexes, and unique constraints. Note that when defining a primary key and a unique index, two indexes will be created, one of which is a hash index used for all tuple accesses as well as lock handling. It is also used to enforce unique constraints.

The size of the hash index is 25 bytes per record, plus the size of the primary key. For primary keys larger than 32 bytes another 8 bytes is added.

The default value for `IndexMemory` is 18MB. The minimum is 1MB.

StringMemory

This parameter determines how much memory is allocated for strings such as table names, and is specified in an `[ndbd]` or `[ndbd default]` section of the `config.ini` file. A value between 0 and 100 inclusive is interpreted as a percent of the maximum default value, which is calculated based on a number of factors including the number of tables, maximum table name size, maximum size of `.FRM` files, `MaxNoOfTriggers`, maximum column name size, and maximum default column value. In general it is safe to assume that the maximum default value is approximately 5 MB for a MySQL Cluster having 1000 tables.

A value greater than 100 is interpreted as a number of bytes.

The default value is 5 — that is, 5 percent of the default maximum, or roughly 5 KB. (Note that this is a change from previous versions of MySQL Cluster.)

Under most circumstances, the default value should be sufficient, but when you have a great many Cluster tables (1000 or more), it is possible to get Error 773 `OUT OF STRING MEMORY, PLEASE MODIFY STRINGMEMORY CONFIG PARAMETER: PERMANENT ERROR: SCHEMA ERROR`, in which case you should increase this value. 25 (25 percent) is not excessive, and should prevent this error from recurring in all but the most extreme conditions.

The following example illustrates how memory is used for a table. Consider this table definition:

```
CREATE TABLE example (
  a INT NOT NULL,
  b INT NOT NULL,
  c INT NOT NULL,
  PRIMARY KEY (a),
  UNIQUE (b)
) ENGINE=NDBCLUSTER;
```

For each record, there are 12 bytes of data plus 12 bytes overhead. Having no nullable columns saves 4 bytes of overhead. In addition, we have two ordered indexes on columns `a` and `b` consuming roughly 10 bytes each per record. There is a primary key hash index on the base table using roughly 29 bytes per record. The unique constraint is implemented by a separate table with `b` as primary key and `a` as a column. This other table consumes an additional 29 bytes of index memory per record in the `example` table as well 8 bytes of record data plus 12 bytes of overhead.

Thus, for one million records, we need 58MB for index memory to handle the hash indexes for the primary key and the unique constraint. We also need 64MB for the records of the base table and the unique index table, plus the two ordered index tables.

You can see that hash indexes takes up a fair amount of memory space; however, they provide very fast access to the data in return. They are also used in MySQL Cluster to handle uniqueness constraints.

Currently, the only partitioning algorithm is hashing and ordered indexes are local to each node. Thus, ordered indexes cannot be used to handle uniqueness constraints in the general case.

An important point for both `IndexMemory` and `DataMemory` is that the total database size is the sum of all data memory and all index memory for each node group. Each node group is used to store replicated information, so if there are four nodes with two replicas, there will be two node groups. Thus, the total data memory available is $2 \times \text{DataMemory}$ for each data node.

It is highly recommended that `DataMemory` and `IndexMemory` be set to the same values for all nodes. Data distribution is even over all nodes in the cluster, so the maximum amount of space available for any node can be no greater than that of the smallest node in the cluster.

`DataMemory` and `IndexMemory` can be changed, but decreasing either of these can be risky; doing so can easily lead to a node or even an entire MySQL Cluster that is unable to restart due to there being insufficient memory space. Increasing these values should be acceptable, but it is recommended that such upgrades are performed in the same manner as a software upgrade, beginning with an update of the configuration file, and then restarting the management server followed by restarting each data node in turn.

Updates do not increase the amount of index memory used. Inserts take effect immediately; however, rows are not actually deleted until the transaction is committed.

Transaction parameters. The next three `[ndbd]` parameters that we discuss are important because they affect the number of parallel transactions and the sizes of transactions that can be handled by the system. `MaxNoOfConcurrentTransactions` sets the number of parallel transactions possible in a node. `MaxNoOfConcurrentOperations` sets the number of records that can be in update phase or locked simultaneously.

Both of these parameters (especially `MaxNoOfConcurrentOperations`) are likely targets for users setting specific values and not using the default value. The default value is set for systems using small transactions, to ensure that these do not use excessive memory.

- `MaxNoOfConcurrentTransactions`

Each cluster data node requires a transaction record for each active transaction in the cluster. The task of coordinating transactions is distributed among all of the data nodes. The total number of transaction records in the cluster is the number of transactions in any given node times the number of nodes in the cluster.

Transaction records are allocated to individual MySQL servers. Each connection to a MySQL server requires at least one transaction record, plus an additional transaction object per table accessed by that connection. This means that a reasonable minimum for this parameter is

```
MaxNoOfConcurrentTransactions =
  (maximum number of tables accessed in any single transaction + 1)
  * number of cluster SQL nodes
```

For example, suppose that there are 4 SQL nodes using the cluster. A single join involving 5 tables requires 6 transaction records; if there are 5 such joins in a transaction, then $5 * 6 = 30$ transaction records are required for this transaction, per MySQL server, or $30 * 4 = 120$ transaction records total.

This parameter must be set to the same value for all cluster data nodes. This is due to the fact that, when a data node fails, the oldest surviving node re-creates the transaction state of all transactions that were ongoing in the failed node.

Changing the value of `MaxNoOfConcurrentTransactions` requires a complete shutdown and restart of the cluster.

The default value is 4096.

• `MaxNoOfConcurrentOperations`

It is a good idea to adjust the value of this parameter according to the size and number of transactions. When performing transactions of only a few operations each and not involving a great many records, there is no need to set this parameter very high. When performing large transactions involving many records need to set this parameter higher.

Records are kept for each transaction updating cluster data, both in the transaction coordinator and in the nodes where the actual updates are performed. These records contain state information needed to find UNDO records for rollback, lock queues, and other purposes.

This parameter should be set to the number of records to be updated simultaneously in transactions, divided by the number of cluster data nodes. For example, in a cluster which has four data nodes and which is expected to handle 1,000,000 concurrent updates using transactions, you should set this value to $1000000 / 4 = 250000$.

Read queries which set locks also cause operation records to be created. Some extra space is allocated within individual nodes to accommodate cases where the distribution is not perfect over the nodes.

When queries make use of the unique hash index, there are actually two operation records used per record in the transaction. The first record represents the read in the index table and the second handles the operation on the base table.

The default value is 32768.

This parameter actually handles two values that can be configured separately. The first of these specifies how many operation records are to be placed with the transaction coordinator. The second part specifies how many operation records are to be local to the database.

A very large transaction performed on an eight-node cluster requires as many operation records in the transaction coordinator as there are reads, updates, and deletes involved in the transaction. However, the operation records of the are spread over all eight nodes. Thus, if it is necessary to configure the system for one very large transaction, it is a good idea to configure the two parts separately. `MaxNoOfConcurrentOperations` will always be used to calculate the number of operation records in the transaction coordinator portion of the node.

It is also important to have an idea of the memory requirements for operation records. These consume about 1KB per record.

• `MaxNoOfLocalOperations`

By default, this parameter is calculated as $1.1 \times \text{MaxNoOfConcurrentOperations}$. This fits systems with many simultaneous transactions, none of them being very large. If there is a need to handle one very large transaction at a time and there are many nodes, it is a good idea to override the default value by explicitly specifying this parameter.

Transaction temporary storage. The next set of `[ndbd]` parameters is used to determine temporary storage when executing a statement that is part of a Cluster transaction. All records are released when the statement is completed and the cluster is waiting for the commit or rollback.

The default values for these parameters are adequate for most situations. However, users with a need to support transactions in-

volving large numbers of rows or operations may need to increase these values to enable better parallelism in the system, whereas users whose applications require relatively small transactions can decrease the values to save memory.

- [MaxNoOfConcurrentIndexOperations](#)

For queries using a unique hash index, another temporary set of operation records is used during a query's execution phase. This parameter sets the size of that pool of records. Thus, this record is allocated only while executing a part of a query. As soon as this part has been executed, the record is released. The state needed to handle aborts and commits is handled by the normal operation records, where the pool size is set by the parameter [MaxNoOfConcurrentOperations](#).

The default value of this parameter is 8192. Only in rare cases of extremely high parallelism using unique hash indexes should it be necessary to increase this value. Using a smaller value is possible and can save memory if the DBA is certain that a high degree of parallelism is not required for the cluster.

- [MaxNoOfFiredTriggers](#)

The default value of [MaxNoOfFiredTriggers](#) is 4000, which is sufficient for most situations. In some cases it can even be decreased if the DBA feels certain the need for parallelism in the cluster is not high.

A record is created when an operation is performed that affects a unique hash index. Inserting or deleting a record in a table with unique hash indexes or updating a column that is part of a unique hash index fires an insert or a delete in the index table. The resulting record is used to represent this index table operation while waiting for the original operation that fired it to complete. This operation is short-lived but can still require a large number of records in its pool for situations with many parallel write operations on a base table containing a set of unique hash indexes.

- [TransactionBufferMemory](#)

The memory affected by this parameter is used for tracking operations fired when updating index tables and reading unique indexes. This memory is used to store the key and column information for these operations. It is only very rarely that the value for this parameter needs to be altered from the default.

The default value for [TransactionBufferMemory](#) is 1MB.

Normal read and write operations use a similar buffer, whose usage is even more short-lived. The compile-time parameter [ZATTRBUF_FILESIZE](#) (found in `ndb/src/kernel/blocks/Dbtc/Dbtc.hpp`) set to 4000×128 bytes (500KB). A similar buffer for key information, [ZDATABUF_FILESIZE](#) (also in `Dbtc.hpp`) contains $4000 \times 16 = 62.5$ KB of buffer space. `Dbtc` is the module that handles transaction coordination.

Scans and buffering. There are additional `[ndbd]` parameters in the `Dblqh` module (in `ndb/src/kernel/blocks/Dblqh/Dblqh.hpp`) that affect reads and updates. These include [ZATTRINBUF_FILESIZE](#), set by default to 10000×128 bytes (1250KB) and [ZDATABUF_FILE_SIZE](#), set by default to 10000×16 bytes (roughly 156KB) of buffer space. To date, there have been neither any reports from users nor any results from our own extensive tests suggesting that either of these compile-time limits should be increased.

- [MaxNoOfConcurrentScans](#)

This parameter is used to control the number of parallel scans that can be performed in the cluster. Each transaction coordinator can handle the number of parallel scans defined for this parameter. Each scan query is performed by scanning all partitions in parallel. Each partition scan uses a scan record in the node where the partition is located, the number of records being the value of this parameter times the number of nodes. The cluster should be able to sustain [MaxNoOfConcurrentScans](#) scans concurrently from all nodes in the cluster.

Scans are actually performed in two cases. The first of these cases occurs when no hash or ordered indexes exists to handle the query, in which case the query is executed by performing a full table scan. The second case is encountered when there is no hash index to support the query but there is an ordered index. Using the ordered index means executing a parallel range scan. The order is kept on the local partitions only, so it is necessary to perform the index scan on all partitions.

The default value of [MaxNoOfConcurrentScans](#) is 256. The maximum value is 500.

- [MaxNoOfLocalScans](#)

Specifies the number of local scan records if many scans are not fully parallelized. If the number of local scan records is not provided, it is calculated as the product of [MaxNoOfConcurrentScans](#) and the number of data nodes in the system. The

minimum value is 32.

- [BatchSizePerLocalScan](#)

This parameter is used to calculate the number of lock records used to handle concurrent scan operations.

The default value is 64; this value has a strong connection to the [ScanBatchSize](#) defined in the SQL nodes.

- [LongMessageBuffer](#)

This is an internal buffer used for passing messages within individual nodes and between nodes. Although it is highly unlikely that this would need to be changed, it is configurable. In MySQL Cluster NDB 6.4.3 and earlier, the default is 1MB; beginning with MySQL Cluster NDB 7.0.4, it is 4MB.

Memory Allocation

[MaxAllocate](#)

This is the maximum size of the memory unit to use when allocating memory for tables. In cases where NDB gives `OUT OF MEMORY` errors, but it is evident by examining the cluster logs or the output of `DUMP 1000` (see [DUMP 1000](#)) that all available memory has not yet been used, you can increase the value of this parameter (or [MaxNoOfTables](#), or both) in order to cause NDB to make sufficient memory available.

This parameter was introduced in MySQL 5.1.20, MySQL Cluster NDB 6.1.12 and MySQL Cluster NDB 6.2.3.

Logging and checkpointing

The following `[ndbd]` parameters control log and checkpoint behavior.

- [NoOfFragmentLogFiles](#)

This parameter sets the number of REDO log files for the node, and thus the amount of space allocated to REDO logging. Because the REDO log files are organized in a ring, it is extremely important that the first and last log files in the set (sometimes referred to as the “head” and “tail” log files, respectively) do not meet. When these approach one another too closely, the node begins aborting all transactions encompassing updates due to a lack of room for new log records.

A REDO log record is not removed until the required number of local checkpoints has been completed since that log record was inserted (prior to MySQL Cluster NDB 6.3.8, this was 3 local checkpoints; in later versions of MySQL Cluster, only 2 local checkpoints are necessary). Checkpointing frequency is determined by its own set of configuration parameters discussed elsewhere in this chapter.

How these parameters interact and proposals for how to configure them are discussed in [Section 17.3.6, “Configuring MySQL Cluster Parameters for Local Checkpoints”](#).

The default parameter value is 16, which by default means 16 sets of 4 16MB files for a total of 1024MB. Beginning with MySQL Cluster NDB 6.1.1, the size of the individual log files is configurable using the [FragmentLogFileSize](#) parameter; more information about this parameter can be found [here](#). In scenarios requiring a great many updates, the value for [NoOfFragmentLogFiles](#) may need to be set as high as 300 or even higher to provide sufficient space for REDO logs.

If the checkpointing is slow and there are so many writes to the database that the log files are full and the log tail cannot be cut without jeopardizing recovery, all updating transactions are aborted with internal error code 410 (`Out of log file space temporarily`). This condition prevails until a checkpoint has completed and the log tail can be moved forward.

Important

This parameter cannot be changed “on the fly”; you must restart the node using `--initial`. If you wish to change this value for all data nodes in a running cluster, you can do so via a rolling node restart (using `--initial` when starting each data node).

- [FragmentLogFileSize](#)

Setting this parameter allows you to control directly the size of redo log files. This can be useful in situations when MySQL Cluster is operating under a high load and it is unable to close fragment log files quickly enough before attempting to open new ones (only 2 fragment log files can be open at one time); increasing the size of the fragment log files gives the cluster more time before having to open each new fragment log file. The default value for this parameter is 16M. [FragmentLogFileSize](#)

was added in MySQL Cluster NDB 6.1.11.

For more information about fragment log files, see the description of the [NoOfFragmentLogFiles](#) parameter.

- [InitFragmentLogFiles](#)

By default, fragment log files are created sparsely when performing an initial start of a data node — that is, depending on the operating system and file system in use, not all bytes are necessarily written to disk. Beginning with MySQL Cluster NDB 6.3.19, it is possible to override this behavior and force all bytes to be written regardless of the platform and file system type being used by mean of this parameter.

[InitFragmentLogFiles](#) takes one of two values:

- [SPARSE](#). Fragment log files are created sparsely. This is the default value.
- [FULL](#). Force all bytes of the fragment log file to be written to disk.

Depending on your operating system and file system, setting [InitFragmentLogFiles=FULL](#) may help eliminate I/O errors on writes to the REDO log.

- [MaxNoOfOpenFiles](#)

This parameter sets a ceiling on how many internal threads to allocate for open files. *Any situation requiring a change in this parameter should be reported as a bug.*

The default value is 0. (Prior to MySQL 5.1.16, the default was 40.) However, the minimum value to which this parameter can be set is 20.

- [InitialNoOfOpenFiles](#)

This parameter sets the initial number of internal threads to allocate for open files.

The default value is 27.

- [MaxNoOfSavedMessages](#)

This parameter sets the maximum number of trace files that are kept before overwriting old ones. Trace files are generated when, for whatever reason, the node crashes.

The default is 25 trace files.

- [MaxLCPStartDelay](#)

In parallel data node recovery (supported in MySQL Cluster NDB 6.3.8 and later), only table data is actually copied and synchronized in parallel; synchronization of metadata such as dictionary and checkpoint information is done in a serial fashion. In addition, recovery of dictionary and checkpoint information cannot be executed in parallel with performing of local checkpoints. This means that, when starting or restarting many data nodes concurrently, data nodes may be forced to wait while a local checkpoint is performed, which can result in longer node recovery times.

Beginning with MySQL Cluster NDB 6.3.23 and MySQL Cluster NDB 6.4.3, it is possible to force a delay in the local checkpoint to allow more (and possibly all) data nodes to complete metadata synchronization; once each data node's metadata synchronization is complete, all of the data nodes can recover table data in parallel, even while the local checkpoint is being executed.

To force such a delay, you can set [MaxLCPStartDelay](#), which determines the number of seconds the cluster can wait to begin a local checkpoint while data nodes continue to synchronize metadata. This parameter should be set in the [\[ndbd default\]](#) section of the [config.ini](#) file, so that it is the same for all data nodes. The maximum value is 600; the default is 0.

Metadata objects. The next set of [\[ndbd\]](#) parameters defines pool sizes for metadata objects, used to define the maximum number of attributes, tables, indexes, and trigger objects used by indexes, events, and replication between clusters. Note that these act merely as “suggestions” to the cluster, and any that are not specified revert to the default values shown.

- [MaxNoOfAttributes](#)

Defines the number of attributes that can be defined in the cluster.

The default value is 1000, with the minimum possible value being 32. The maximum is 4294967039. Each attribute consumes around 200 bytes of storage per node due to the fact that all metadata is fully replicated on the servers.

When setting `MaxNoOfAttributes`, it is important to prepare in advance for any `ALTER TABLE` statements that you might want to perform in the future. This is due to the fact, during the execution of `ALTER TABLE` on a Cluster table, 3 times the number of attributes as in the original table are used, and a good practice is to allow double this amount. For example, if the MySQL Cluster table having the greatest number of attributes (`greatest_number_of_attributes`) has 100 attributes, a good starting point for the value of `MaxNoOfAttributes` would be $6 * \text{greatest_number_of_attributes} = 600$.

You should also estimate the average number of attributes per table and multiply this by `MaxNoOfTables`. If this value is larger than the value obtained in the previous paragraph, you should use the larger value instead.

Assuming that you can create all desired tables without any problems, you should also verify that this number is sufficient by trying an actual `ALTER TABLE` after configuring the parameter. If this is not successful, increase `MaxNoOfAttributes` by another multiple of `MaxNoOfTables` and test it again.

- `MaxNoOfTables`

A table object is allocated for each table, unique hash index, and ordered index. This parameter sets the maximum number of table objects for the cluster as a whole.

For each attribute that has a `BLOB` data type an extra table is used to store most of the `BLOB` data. These tables also must be taken into account when defining the total number of tables.

The default value of this parameter is 128. The minimum is 8 and the maximum is 1600. Each table object consumes approximately 20KB per node.

- `MaxNoOfOrderedIndexes`

For each ordered index in the cluster, an object is allocated describing what is being indexed and its storage segments. By default, each index so defined also defines an ordered index. Each unique index and primary key has both an ordered index and a hash index.

The default value of this parameter is 128. Each object consumes approximately 10KB of data per node.

- `MaxNoOfUniqueHashIndexes`

For each unique index that is not a primary key, a special table is allocated that maps the unique key to the primary key of the indexed table. By default, an ordered index is also defined for each unique index. To prevent this, you must specify the `USING HASH` option when defining the unique index.

The default value is 64. Each index consumes approximately 15KB per node.

- `MaxNoOfTriggers`

Internal update, insert, and delete triggers are allocated for each unique hash index. (This means that three triggers are created for each unique hash index.) However, an *ordered* index requires only a single trigger object. Backups also use three trigger objects for each normal table in the cluster.

Replication between clusters also makes use of internal triggers.

This parameter sets the maximum number of trigger objects in the cluster.

The default value is 768.

- `MaxNoOfIndexes`

This parameter is deprecated in MySQL 5.1; you should use `MaxNoOfOrderedIndexes` and `MaxNoOfUniqueHashIndexes` instead.

This parameter is used only by unique hash indexes. There needs to be one record in this pool for each unique hash index defined in the cluster.

The default value of this parameter is 128.

Boolean parameters. The behavior of data nodes is also affected by a set of [ndbd] parameters taking on boolean values. These parameters can each be specified as **TRUE** by setting them equal to **1** or **Y**, and as **FALSE** by setting them equal to **0** or **N**.

- [LockPagesInMainMemory](#)

For a number of operating systems, including Solaris and Linux, it is possible to lock a process into memory and so avoid any swapping to disk. This can be used to help guarantee the cluster's real-time characteristics.

Beginning with MySQL 5.1.15 and MySQL Cluster NDB 6.1.1, this parameter takes one of the integer values **0**, **1**, or **2**, which act as follows:

- **0**: Disables locking. This is the default value.
- **1**: Performs the lock after allocating memory for the process.
- **2**: Performs the lock before memory for the process is allocated.

Previously, this parameter was a Boolean. **0** or **false** was the default setting, and disabled locking. **1** or **true** enabled locking of the process after its memory was allocated.

Important

Beginning with MySQL 5.1.15 and MySQL Cluster NDB 6.1.1, it is no longer possible to use **true** or **false** for the value of this parameter; when upgrading from a previous version, you must change the value to **0**, **1**, or **2**.

- [StopOnError](#)

This parameter specifies whether an **ndbd** process should exit or perform an automatic restart when an error condition is encountered.

This feature is enabled by default.

- [Diskless](#)

It is possible to specify MySQL Cluster tables as *diskless*, meaning that tables are not checkpointed to disk and that no logging occurs. Such tables exist only in main memory. A consequence of using diskless tables is that neither the tables nor the records in those tables survive a crash. However, when operating in diskless mode, it is possible to run **ndbd** on a diskless computer.

Important

This feature causes the *entire* cluster to operate in diskless mode.

When this feature is enabled, Cluster online backup is disabled. In addition, a partial start of the cluster is not possible.

Diskless is disabled by default.

- [ODirect](#)

Enabling this parameter causes **NDB** to attempt using **O_DIRECT** writes for LCP, backups, and redo logs, often lowering **kswapd** and CPU usage. When using MySQL Cluster on Linux, we recommend that you enable **ODirect** if you are using a 2.6 or kernel.

This parameter was added in the following releases:

- MySQL 5.1.20
- MySQL Cluster NDB 6.1.11
- MySQL Cluster NDB 6.2.3
- MySQL Cluster NDB 6.3.0

ODirect is disabled by default.

- `RestartOnErrorInsert`

This feature is accessible only when building the debug version where it is possible to insert errors in the execution of individual blocks of code as part of testing.

This feature is disabled by default.

- `CompressedBackup`

Setting this parameter to `1` causes backup files to be compressed. The compression used is equivalent to `gzip --fast`, and can save 50% or more of the space required on the data node to store uncompressed backup files. Compressed backups can be enabled for individual data nodes, or for all data nodes (by setting this parameter in the `[ndbd default]` section of the `config.ini` file).

Important

You cannot restore a compressed backup to a cluster running a MySQL version that does not support this feature.

The default value is `0` (disabled).

This parameter was introduced in MySQL Cluster NDB 6.3.7.

- `CompressedLCP`

Setting this parameter to `1` causes local checkpoint files to be compressed. The compression used is equivalent to `gzip --fast`, and can save 50% or more of the space required on the data node to store uncompressed checkpoint files. Compressed LCPs can be enabled for individual data nodes, or for all data nodes (by setting this parameter in the `[ndbd default]` section of the `config.ini` file).

Important

You cannot restore a compressed local checkpoint to a cluster running a MySQL version that does not support this feature.

The default value is `0` (disabled).

This parameter was introduced in MySQL Cluster NDB 6.3.7.

Controlling Timeouts, Intervals, and Disk Paging

There are a number of `[ndbd]` parameters specifying timeouts and intervals between various actions in Cluster data nodes. Most of the timeout values are specified in milliseconds. Any exceptions to this are mentioned where applicable.

- `TimeBetweenWatchDogCheck`

To prevent the main thread from getting stuck in an endless loop at some point, a “watchdog” thread checks the main thread. This parameter specifies the number of milliseconds between checks. If the process remains in the same state after three checks, the watchdog thread terminates it.

This parameter can easily be changed for purposes of experimentation or to adapt to local conditions. It can be specified on a per-node basis although there seems to be little reason for doing so.

The default timeout is 6000 milliseconds (6 seconds).

- `TimeBetweenWatchDogCheckInitial`

This is similar to the `TimeBetweenWatchDogCheck` parameter, except that `TimeBetweenWatchDogCheckInitial` controls the amount of time that passes between execution checks inside a database node in the early start phases during which memory is allocated.

The default timeout is 6000 milliseconds (6 seconds).

This parameter was added in MySQL 5.1.20.

-

`StartPartialTimeout`

This parameter specifies how long the Cluster waits for all data nodes to come up before the cluster initialization routine is invoked. This timeout is used to avoid a partial Cluster startup whenever possible.

The default value is 30000 milliseconds (30 seconds). 0 disables the timeout, in which case the cluster may start only if all nodes are available.

- ### `StartPartitionedTimeout`

If the cluster is ready to start after waiting for `StartPartialTimeout` milliseconds but is still possibly in a partitioned state, the cluster waits until this timeout has also passed.

The default timeout is 60000 milliseconds (60 seconds).

- ### `StartFailureTimeout`

If a data node has not completed its startup sequence within the time specified by this parameter, the node startup fails. Setting this parameter to 0 (the default value) means that no data node timeout is applied.

For nonzero values, this parameter is measured in milliseconds. For data nodes containing extremely large amounts of data, this parameter should be increased. For example, in the case of a data node containing several gigabytes of data, a period as long as 10–15 minutes (that is, 600000 to 1000000 milliseconds) might be required to perform a node restart.

- ### `HeartbeatIntervalDbDb`

One of the primary methods of discovering failed nodes is by the use of heartbeats. This parameter states how often heartbeat signals are sent and how often to expect to receive them. After missing three heartbeat intervals in a row, the node is declared dead. Thus, the maximum time for discovering a failure through the heartbeat mechanism is four times the heartbeat interval.

The default heartbeat interval is 1500 milliseconds (1.5 seconds). This parameter must not be changed drastically and should not vary widely between nodes. If one node uses 5000 milliseconds and the node watching it uses 1000 milliseconds, obviously the node will be declared dead very quickly. This parameter can be changed during an online software upgrade, but only in small increments.

- ### `HeartbeatIntervalDbApi`

Each data node sends heartbeat signals to each MySQL server (SQL node) to ensure that it remains in contact. If a MySQL server fails to send a heartbeat in time it is declared “dead,” in which case all ongoing transactions are completed and all resources released. The SQL node cannot reconnect until all activities initiated by the previous MySQL instance have been completed. The three-heartbeat criteria for this determination are the same as described for `HeartbeatIntervalDbDb`.

The default interval is 1500 milliseconds (1.5 seconds). This interval can vary between individual data nodes because each data node watches the MySQL servers connected to it, independently of all other data nodes.

- ### `TimeBetweenLocalCheckpoints`

This parameter is an exception in that it does not specify a time to wait before starting a new local checkpoint; rather, it is used to ensure that local checkpoints are not performed in a cluster where relatively few updates are taking place. In most clusters with high update rates, it is likely that a new local checkpoint is started immediately after the previous one has been completed.

The size of all write operations executed since the start of the previous local checkpoints is added. This parameter is also exceptional in that it is specified as the base-2 logarithm of the number of 4-byte words, so that the default value 20 means 4MB (4×2^{20}) of write operations, 21 would mean 8MB, and so on up to a maximum value of 31, which equates to 8GB of write operations.

All the write operations in the cluster are added together. Setting `TimeBetweenLocalCheckpoints` to 6 or less means that local checkpoints will be executed continuously without pause, independent of the cluster's workload.

- ### `TimeBetweenGlobalCheckpoints`

When a transaction is committed, it is committed in main memory in all nodes on which the data is mirrored. However, transaction log records are not flushed to disk as part of the commit. The reasoning behind this behavior is that having the transaction safely committed on at least two autonomous host machines should meet reasonable standards for durability.

It is also important to ensure that even the worst of cases — a complete crash of the cluster — is handled properly. To guarantee that this happens, all transactions taking place within a given interval are put into a global checkpoint, which can be thought of as a set of committed transactions that has been flushed to disk. In other words, as part of the commit process, a transaction is placed in a global checkpoint group. Later, this group's log records are flushed to disk, and then the entire group of transactions is safely committed to disk on all computers in the cluster.

This parameter defines the interval between global checkpoints. The default is 2000 milliseconds.

- [TimeBetweenEpochs](#)

This parameter defines the interval between synchronisation epochs for MySQL Cluster Replication. The default value is 100 milliseconds.

[TimeBetweenEpochs](#) is part of the implementation of “micro-GCPs”, which can be used to improve the performance of MySQL Cluster Replication. This parameter was introduced in MySQL Cluster NDB 6.2.5 and MySQL Cluster NDB 6.3.2.

- [TimeBetweenEpochsTimeout](#)

This parameter defines a timeout for synchronisation epochs for MySQL Cluster Replication. If a node fails to participate in a global checkpoint within the time determined by this parameter, the node is shut down. The default value is 4000 milliseconds.

[TimeBetweenEpochsTimeout](#) is part of the implementation of “micro-GCPs”, which can be used to improve the performance of MySQL Cluster Replication. This parameter was introduced in MySQL Cluster NDB 6.2.7 and MySQL Cluster NDB 6.3.4.

- [MaxBufferedEpochs](#)

The number of unprocessed epochs by which a subscribing node can lag behind. Exceeding this number causes a lagging subscriber to be disconnected.

The default value of 100 is sufficient for most normal operations. If a subscribing node does lag enough to cause disconnections, it is usually due to network or scheduling issues with regard to processes or threads. (In rare circumstances, the problem may be due to a bug in the [NDB](#) client.) It may be desirable to set the value lower than the default when epochs are longer.

Disconnection prevents client issues from affecting the data node service, running out of memory to buffer data, and eventually shutting down. Instead, only the client is affected as a result of the disconnect (by, for example gap events in the binlog), forcing the client to reconnect or restart the process.

- [TimeBetweenInactiveTransactionAbortCheck](#)

Timeout handling is performed by checking a timer on each transaction once for every interval specified by this parameter. Thus, if this parameter is set to 1000 milliseconds, every transaction will be checked for timing out once per second.

The default value is 1000 milliseconds (1 second).

- [TransactionInactiveTimeout](#)

This parameter states the maximum time that is permitted to lapse between operations in the same transaction before the transaction is aborted.

The default for this parameter is zero (no timeout). For a real-time database that needs to ensure that no transaction keeps locks for too long, this parameter should be set to a relatively small value. The unit is milliseconds.

- [TransactionDeadlockDetectionTimeout](#)

When a node executes a query involving a transaction, the node waits for the other nodes in the cluster to respond before continuing. A failure to respond can occur for any of the following reasons:

- The node is “dead”
- The operation has entered a lock queue
- The node requested to perform the action could be heavily overloaded.

This timeout parameter states how long the transaction coordinator waits for query execution by another node before aborting

the transaction, and is important for both node failure handling and deadlock detection. In MySQL 5.1.10 and earlier versions, setting it too high could cause undesirable behavior in situations involving deadlocks and node failure. Beginning with MySQL 5.1.11, active transactions occurring during node failures are actively aborted by the MySQL Cluster Transaction Coordinator, and so high settings are no longer an issue with this parameter.

The default timeout value is 1200 milliseconds (1.2 seconds).

Prior to MySQL Cluster NDB versions 6.2.18, 6.3.24, and 7.0.5, the effective minimum for this parameter was 100 milliseconds. ([Bug#44099](#)) Beginning with these versions, the actual minimum is 50 milliseconds.

- [DiskSyncSize](#)

This is the maximum number of bytes to store before flushing data to a local checkpoint file. This is done in order to prevent write buffering, which can impede performance significantly. This parameter is *not* intended to take the place of [TimeBetweenLocalCheckpoints](#).

Note

When [ODirect](#) is enabled, it is not necessary to set [DiskSyncSize](#); in fact, in such cases its value is simply ignored.

The default value is 4M (4 megabytes).

This parameter was added in MySQL 5.1.12.

- [DiskCheckpointSpeed](#)

The amount of data, in bytes per second, that is sent to disk during a local checkpoint.

The default value is 10M (10 megabytes per second).

This parameter was added in MySQL 5.1.12.

- [DiskCheckpointSpeedInRestart](#)

The amount of data, in bytes per second, that is sent to disk during a local checkpoint as part of a restart operation.

The default value is 100M (100 megabytes per second).

This parameter was added in MySQL 5.1.12.

- [NoOfDiskPagesToDiskAfterRestartTUP](#)

When executing a local checkpoint, the algorithm flushes all data pages to disk. Merely doing so as quickly as possible without any moderation is likely to impose excessive loads on processors, networks, and disks. To control the write speed, this parameter specifies how many pages per 100 milliseconds are to be written. In this context, a “page” is defined as 8KB. This parameter is specified in units of 80KB per second, so setting [NoOfDiskPagesToDiskAfterRestartTUP](#) to a value of 20 entails writing 1.6MB in data pages to disk each second during a local checkpoint. This value includes the writing of UNDO log records for data pages. That is, this parameter handles the limitation of writes from data memory. (See the entry for [IndexMemory](#) for information about index pages.)

In short, this parameter specifies how quickly to execute local checkpoints. It operates in conjunction with [NoOfFragmentLogFiles](#), [DataMemory](#), and [IndexMemory](#).

For more information about the interaction between these parameters and possible strategies for choosing appropriate values for them, see [Section 17.3.6, “Configuring MySQL Cluster Parameters for Local Checkpoints”](#).

The default value is 40 (3.2MB of data pages per second).

Note

This parameter is deprecated as of MySQL 5.1.6. For MySQL 5.1.12 and later versions, use [DiskCheckpointSpeed](#) and [DiskSyncSize](#) instead.

- [NoOfDiskPagesToDiskAfterRestartACC](#)

This parameter uses the same units as `NoOfDiskPagesToDiskAfterRestartTUP` and acts in a similar fashion, but limits the speed of writing index pages from index memory.

The default value of this parameter is 20 (1.6MB of index memory pages per second).

Note

This parameter is deprecated as of MySQL 5.1.6. For MySQL 5.1.12 and later versions, use `DiskCheckpointSpeed` and `DiskSyncSize`.

`NoOfDiskPagesToDiskDuringRestartTUP`

This parameter is used in a fashion similar to `NoOfDiskPagesToDiskAfterRestartTUP` and `NoOfDiskPagesToDiskAfterRestartACC`, only it does so with regard to local checkpoints executed in the node when a node is restarting. A local checkpoint is always performed as part of all node restarts. During a node restart it is possible to write to disk at a higher speed than at other times, because fewer activities are being performed in the node.

This parameter covers pages written from data memory.

The default value is 40 (3.2MB per second).

Note

This parameter is deprecated as of MySQL 5.1.6. For MySQL 5.1.12 and later versions, use `DiskCheckpointSpeedInRestart` and `DiskSyncSize`.

`NoOfDiskPagesToDiskDuringRestartACC`

Controls the number of index memory pages that can be written to disk during the local checkpoint phase of a node restart.

As with `NoOfDiskPagesToDiskAfterRestartTUP` and `NoOfDiskPagesToDiskAfterRestartACC`, values for this parameter are expressed in terms of 8KB pages written per 100 milliseconds (80KB/second).

The default value is 20 (1.6MB per second).

Note

This parameter is deprecated as of MySQL 5.1.6. For MySQL 5.1.12 and later versions, use `DiskCheckpointSpeedInRestart` and `DiskSyncSize`.

`ArbitrationTimeout`

This parameter specifies how long data nodes wait for a response from the arbitrator to an arbitration message. If this is exceeded, the network is assumed to have split.

The default value is 1000 milliseconds (1 second).

Buffering and logging. Several `[ndbd]` configuration parameters enable the advanced user to have more control over the resources used by node processes and to adjust various buffer sizes at need.

These buffers are used as front ends to the file system when writing log records to disk. If the node is running in diskless mode, these parameters can be set to their minimum values without penalty due to the fact that disk writes are “faked” by the NDB storage engine's file system abstraction layer.

`UndoIndexBuffer`

The UNDO index buffer, whose size is set by this parameter, is used during local checkpoints. The NDB storage engine uses a recovery scheme based on checkpoint consistency in conjunction with an operational REDO log. To produce a consistent checkpoint without blocking the entire system for writes, UNDO logging is done while performing the local checkpoint. UNDO logging is activated on a single table fragment at a time. This optimization is possible because tables are stored entirely in main memory.

The UNDO index buffer is used for the updates on the primary key hash index. Inserts and deletes rearrange the hash index; the NDB storage engine writes UNDO log records that map all physical changes to an index page so that they can be undone at sys-

tem restart. It also logs all active insert operations for each fragment at the start of a local checkpoint.

Reads and updates set lock bits and update a header in the hash index entry. These changes are handled by the page-writing algorithm to ensure that these operations need no UNDO logging.

This buffer is 2MB by default. The minimum value is 1MB, which is sufficient for most applications. For applications doing extremely large or numerous inserts and deletes together with large transactions and large primary keys, it may be necessary to increase the size of this buffer. If this buffer is too small, the NDB storage engine issues internal error code 677 (`Index UNDO buffers overloaded`).

Important

It is not safe to decrease the value of this parameter during a rolling restart.

UndoDataBuffer

This parameter sets the size of the UNDO data buffer, which performs a function similar to that of the UNDO index buffer, except the UNDO data buffer is used with regard to data memory rather than index memory. This buffer is used during the local checkpoint phase of a fragment for inserts, deletes, and updates.

Because UNDO log entries tend to grow larger as more operations are logged, this buffer is also larger than its index memory counterpart, with a default value of 16MB.

This amount of memory may be unnecessarily large for some applications. In such cases, it is possible to decrease this size to a minimum of 1MB.

It is rarely necessary to increase the size of this buffer. If there is such a need, it is a good idea to check whether the disks can actually handle the load caused by database update activity. A lack of sufficient disk space cannot be overcome by increasing the size of this buffer.

If this buffer is too small and gets congested, the NDB storage engine issues internal error code 891 (`DATA UNDO BUFFERS OVERLOADED`).

Important

It is not safe to decrease the value of this parameter during a rolling restart.

RedoBuffer

All update activities also need to be logged. The REDO log makes it possible to replay these updates whenever the system is restarted. The NDB recovery algorithm uses a “fuzzy” checkpoint of the data together with the UNDO log, and then applies the REDO log to play back all changes up to the restoration point.

`RedoBuffer` sets the size of the buffer in which the REDO log is written. In MySQL Cluster NDB 6.4.3 and earlier, the default value is 8MB; beginning with MySQL Cluster NDB 7.0.4, the default is 32MB. The minimum value is 1MB.

If this buffer is too small, the NDB storage engine issues error code 1221 (`REDO log buffers overloaded`).

Important

It is not safe to decrease the value of this parameter during a rolling restart.

Controlling log messages. In managing the cluster, it is very important to be able to control the number of log messages sent for various event types to `stdout`. For each event category, there are 16 possible event levels (numbered 0 through 15). Setting event reporting for a given event category to level 15 means all event reports in that category are sent to `stdout`; setting it to 0 means that there will be no event reports made in that category.

By default, only the startup message is sent to `stdout`, with the remaining event reporting level defaults being set to 0. The reason for this is that these messages are also sent to the management server’s cluster log.

An analogous set of levels can be set for the management client to determine which event levels to record in the cluster log.

LogLevelStartup

The reporting level for events generated during startup of the process.

The default level is 1.

- [LogLevelShutdown](#)

The reporting level for events generated as part of graceful shutdown of a node.

The default level is 0.

- [LogLevelStatistic](#)

The reporting level for statistical events such as number of primary key reads, number of updates, number of inserts, information relating to buffer usage, and so on.

The default level is 0.

- [LogLevelCheckpoint](#)

The reporting level for events generated by local and global checkpoints.

The default level is 0.

- [LogLevelNodeRestart](#)

The reporting level for events generated during node restart.

The default level is 0.

- [LogLevelConnection](#)

The reporting level for events generated by connections between cluster nodes.

The default level is 0.

- [LogLevelError](#)

The reporting level for events generated by errors and warnings by the cluster as a whole. These errors do not cause any node failure but are still considered worth reporting.

The default level is 0.

- [LogLevelCongestion](#)

The reporting level for events generated by congestion. These errors do not cause node failure but are still considered worth reporting.

The default level is 0.

- [LogLevelInfo](#)

The reporting level for events generated for information about the general state of the cluster.

The default level is 0.

- [MemReportFrequency](#)

This parameter controls how often data node memory usage reports are recorded in the cluster log; it is an integer value representing the number of seconds between reports.

Each data node's data memory and index memory usage is logged as both a percentage and a number of 32 KB pages of the [DataMemory](#) and [IndexMemory](#), respectively, set in the `config.ini` file. For example, if [DataMemory](#) is equal to 100 MB, and a given data node is using 50 MB for data memory storage, the corresponding line in the cluster log might look like this:

```
2006-12-24 01:18:16 [MgmSrvr] INFO -- Node 2: Data usage is 50%(1280 32K pages of total 2560)
```

`MemReportFrequency` is not a required parameter. If used, it can be set for all cluster data nodes in the `[ndbd default]` section of `config.ini`, and can also be set or overridden for individual data nodes in the corresponding `[ndbd]` sections of the configuration file. The minimum value — which is also the default value — is 0, in which case memory reports are logged only when memory usage reaches certain percentages (80%, 90%, and 100%), as mentioned in the discussion of statistics events in [Section 17.7.4.2, “MySQL Cluster Log Events”](#).

This parameter was added in MySQL Cluster 5.1.16 and MySQL Cluster NDB 6.1.0.

Backup parameters. The `[ndbd]` parameters discussed in this section define memory buffers set aside for execution of online backups.

- `BackupDataBufferSize`

In creating a backup, there are two buffers used for sending data to the disk. The backup data buffer is used to fill in data recorded by scanning a node's tables. Once this buffer has been filled to the level specified as `BackupWriteSize` (see below), the pages are sent to disk. While flushing data to disk, the backup process can continue filling this buffer until it runs out of space. When this happens, the backup process pauses the scan and waits until some disk writes have completed freed up memory so that scanning may continue.

In MySQL Cluster NDB 6.4.3 and earlier, the default value is 2MB; in MySQL Cluster NDB 7.0.4 and later, it is 16MB.

- `BackupLogBufferSize`

The backup log buffer fulfills a role similar to that played by the backup data buffer, except that it is used for generating a log of all table writes made during execution of the backup. The same principles apply for writing these pages as with the backup data buffer, except that when there is no more space in the backup log buffer, the backup fails. For that reason, the size of the backup log buffer must be large enough to handle the load caused by write activities while the backup is being made. See [Section 17.7.3.3, “Configuration for MySQL Cluster Backups”](#).

The default value for this parameter should be sufficient for most applications. In fact, it is more likely for a backup failure to be caused by insufficient disk write speed than it is for the backup log buffer to become full. If the disk subsystem is not configured for the write load caused by applications, the cluster is unlikely to be able to perform the desired operations.

It is preferable to configure cluster nodes in such a manner that the processor becomes the bottleneck rather than the disks or the network connections.

In MySQL Cluster NDB 6.4.3 and earlier, the default value is 2MB; in MySQL Cluster NDB 7.0.4 and later, it is 16MB.

- `BackupMemory`

This parameter is simply the sum of `BackupDataBufferSize` and `BackupLogBufferSize`.

In MySQL Cluster NDB 6.4.3 and earlier, the default value was $2\text{MB} + 2\text{MB} = 4\text{MB}$; in MySQL Cluster NDB 7.0.4 and later, it is $16\text{MB} + 16\text{MB} = 32\text{MB}$.

Important

If `BackupDataBufferSize` and `BackupLogBufferSize` taken together exceed the default value for `BackupMemory`, then this parameter must be set explicitly in the `config.ini` file to their sum.

- `BackupReportFrequency`

This parameter controls how often backup status reports are issued in the management client during a backup, as well as how often such reports are written to the cluster log (provided cluster event logging is configured to allow it — see [Section 17.3.4.6, “Defining MySQL Cluster Data Nodes” \[1442\]](#)). `BackupReportFrequency` represents the time in seconds between backup status reports.

The default value is 0.

This parameter was added in MySQL Cluster NDB 6.2.3.

BackupWriteSize

This parameter specifies the default size of messages written to disk by the backup log and backup data buffers.

In MySQL Cluster 6.4.3 and earlier, the default value for this parameter was 32KB; beginning with MySQL Cluster NDB 7.0.4, it is 256KB.

BackupMaxWriteSize

This parameter specifies the maximum size of messages written to disk by the backup log and backup data buffers.

In MySQL Cluster 6.4.3 and earlier, the default value for this parameter was 256KB; beginning with MySQL Cluster NDB 7.0.4, it is 1MB.

Important

When specifying these parameters, the following relationships must hold true. Otherwise, the data node will be unable to start:

- `BackupDataBufferSize >= BackupWriteSize + 188KB`
- `BackupLogBufferSize >= BackupWriteSize + 16KB`
- `BackupMaxWriteSize >= BackupWriteSize`

Realtime Performance Parameters

The `[ndbd]` parameters discussed in this section are used in scheduling and locking of threads to specific CPUs on multiprocessor data node hosts. They were introduced in MySQL Cluster NDB 6.3.4.

LockExecuteThreadToCPU

Previous to MySQL Cluster NDB 7.0. This parameter specifies the ID of the CPU assigned to handle the `NDBCLUSTER` execution thread. The value of this parameter is an integer in the range 0 to 65535 (inclusive). The default is 65535.

MySQL Cluster NDB 7.0 and later (beginning with MySQL Cluster NDB 6.4.0). When used with `ndbd`, this parameter (now a string) specifies the ID of the CPU assigned to handle the `NDBCLUSTER` execution thread. When used with `ndbmt`, the value of this parameter is a comma-separated list of CPU IDs assigned to handle execution threads. Each CPU ID in the list should be an integer in the range 0 to 65535 (inclusive). The number of IDs specified should match the number of execution threads determined by `MaxNoOfExecutionThreads`. There is no default value.

LockMaintThreadsToCPU

This parameter specifies the ID of the CPU assigned to handle `NDBCLUSTER` maintenance threads.

The value of this parameter is an integer in the range 0 to 65535 (inclusive). This parameter was added in MySQL Cluster NDB 6.3.4. Prior to MySQL Cluster NDB 6.4.0, the default is 65535; in MySQL Cluster NDB 7.0 and later MySQL Cluster release series, there is no default value.

RealtimeScheduler

Setting this parameter to 1 enables real-time scheduling of `NDBCLUSTER` threads.

The default is 0 (scheduling disabled).

SchedulerExecutionTimer

This parameter specifies the time in microseconds for threads to be executed in the scheduler before being sent. Setting it to 0 minimizes the response time; to achieve higher throughput, you can increase the value at the expense of longer response times.

The default is 50 μ sec, which our testing shows to increase throughput slightly in high-load cases without materially delaying requests.

This parameter was added in MySQL Cluster NDB 6.3.4.

- [SchedulerSpinTimer](#)

This parameter specifies the time in microseconds for threads to be executed in the scheduler before sleeping.

The default value is 0.

Disk Data Configuration Parameters. Configuration parameters affecting Disk Data behavior include the following:

- [DiskPageBufferMemory](#)

This determines the amount of space used for caching pages on disk, and is set in the `[ndbd]` or `[ndbd default]` section of the `config.ini` file. It is measured in bytes. Each page takes up 32 KB. This means that Cluster Disk Data storage always uses $N * 32$ KB memory where N is some non-negative integer.

The default value for this parameter is `64M` (2000 pages of 32 KB each).

This parameter was added in MySQL 5.1.6.

- [SharedGlobalMemory](#)

This determines the amount of memory that is used for log buffers, disk operations (such as page requests and wait queues), and metadata for tablespaces, log file groups, `UNDO` files, and data files. It can be set in the `[ndbd]` or `[ndbd default]` section of the `config.ini` configuration file, and is measured in bytes.

The default value is `20M`.

This parameter was added in MySQL 5.1.6.

- [DiskIOThreadPool](#)

This parameter determines the number of unbound threads used for Disk Data file access. Currently, it applies to Disk Data I/O threads only, but we plan in the future to make the number of such threads configurable for in-memory data as well.

The optimum value for this parameter depends on your hardware and configuration, and includes these factors:

- **Physical distribution of Disk Data files.** You can obtain better performance by placing data files, undo log files, and the data node filesystem on separate physical disks. If you do this with some or all of these sets of files, then you can set `DiskIOThreadPool` higher to allow separate threads to handle the files on each disk.
- **Disk performance and types.** The number of threads that can be accommodated for Disk Data file handling is also dependent on the speed and throughput of the disks. Faster disks and higher throughput allow for more disk I/O threads. Our test results indicate that solid-state disk drives can handle many more disk I/O threads than conventional disks, and thus higher values for `DiskIOThreadPool`.

This parameter was added in MySQL Cluster NDB 6.4.0. Previous to MySQL Cluster NDB 6.4.3, it was named `ThreadPool`. The default value is 8

- **Disk Data filesystem parameters.** The parameters in the following list were added in MySQL Cluster NDB 6.2.17, 6.3.22, and 6.4.3 to make it easier to place MySQL Cluster Disk Data files in specific directories.

- [FileSystemPathDD](#)

If this parameter is specified, then MySQL Cluster Disk Data data files and undo log files are placed in the indicated directory. This can be overridden for data files, undo log files, or both, by specifying values for `FileSystemPathDataFiles`, `FileSystemPathUndoFiles`, or both, as explained for these parameters. It can also be overridden for data files by specifying a path in the `ADD DATAFILE` clause of a `CREATE TABLESPACE` or `ALTER TABLESPACE` statement, and for undo log files by specifying a path in the `ADD UNDOFILE` clause of a `CREATE LOGFILE GROUP` or `ALTER LOGFILE GROUP` statement. If `FileSystemPathDD` is not specified, then `FileSystemPath` is used.

If a `FileSystemPathDD` directory is specified for a given data node (including the case where the parameter is specified in the `[ndbd default]` section of the `config.ini` file), then starting that data node with `--initial` causes all files in the directory to be deleted.

- `FileSystemPathDataFiles`

If this parameter is specified, then MySQL Cluster Disk Data data files are placed in the indicated directory. This overrides any value set for `FileSystemPathDD`. This parameter can be overridden for a given data file by specifying a path in the `ADD DATAFILE` clause of a `CREATE TABLESPACE` or `ALTER TABLESPACE` statement used to create that data file. If `FileSystemPathDataFiles` is not specified, then `FileSystemPathDD` is used (or `FileSystemPath`, if `FileSystemPathDD` has also not been set).

If a `FileSystemPathDataFiles` directory is specified for a given data node (including the case where the parameter is specified in the `[ndbd default]` section of the `config.ini` file), then starting that data node with `--initial` causes all files in the directory to be deleted.

- `FileSystemPathUndoFiles`

If this parameter is specified, then MySQL Cluster Disk Data undo log files are placed in the indicated directory. This overrides any value set for `FileSystemPathDD`. This parameter can be overridden for a given data file by specifying a path in the `ADD UNDO` clause of a `CREATE LOGFILE GROUP` or `ALTER LOGFILE GROUP` statement used to create that data file. If `FileSystemPathUndoFiles` is not specified, then `FileSystemPathDD` is used (or `FileSystemPath`, if `FileSystemPathDD` has also not been set).

If a `FileSystemPathUndoFiles` directory is specified for a given data node (including the case where the parameter is specified in the `[ndbd default]` section of the `config.ini` file), then starting that data node with `--initial` causes all files in the directory to be deleted.

For more information, see [Section 17.10.1, “MySQL Cluster Disk Data Objects”](#).

- **Disk Data object creation parameters.** The next two parameters enable you — when starting the cluster for the first time — to cause a Disk Data log file group, tablespace, or both, to be created without the use of SQL statements.

- `InitialLogFileGroup`

This parameter can be used to specify a log file group that is created when performing an initial start of the cluster. `InitialLogFileGroup` is specified as shown here:

```
InitialLogFileGroup = [name=name;] [undobuffer_size=size;] file-specification-list
file-specification-list:
    file-specification[; file-specification[; ...]]
file-specification:
    filename:size
```

The `name` of the log file group is optional and defaults to `DEFAULT_LG`. The `undobuffer_size` is also optional; if omitted, it defaults to `256M` (256 megabytes). Each `file-specification` corresponds to an undo log file, and at least one must be specified in the `file-specification-list`. Undo log files are placed according to any values that have been set for `FileSystemPath`, `FileSystemPathDD`, and `FileSystemPathUndoFiles`, just as if they had been created as the result of a `CREATE LOGFILE GROUP` or `ALTER LOGFILE GROUP` statement.

Consider the following example:

```
InitialLogFileGroup = name=LG1; undobuffer_size=128M; undo1.log:250M; undo2.log:150M
```

This is equivalent to the following SQL statements:

```
CREATE LOGFILE GROUP LG1
  ADD UNDOFILE 'undo1.log'
  INITIAL_SIZE 250M
  UNDO_BUFFER_SIZE 128M
  ENGINE NDBCLUSTER;

ALTER LOGFILE GROUP LG1
  ADD UNDOFILE 'undo2.log'
  INITIAL_SIZE 150M
  ENGINE NDBCLUSTER;
```

This logfile group is created when the data nodes are started with `--initial`.

This parameter, if used, should always be set in the `[ndbd default]` section of the `config.ini` file. The behavior of a MySQL Cluster when different values are set on different data nodes is not defined.

- [InitialTablespace](#)

This parameter can be used to specify a MySQL Cluster Disk Data tablespace that is created when performing an initial start of the cluster. [InitialTablespace](#) is specified as shown here:

```
InitialTablespace = [name=name;] [extent_size=size;] [logfile_group=lg-name;] file-specification-list
```

The *name* of the tablespace is optional and defaults to `DEFAULT_TS`. The *extent_size* is also optional; it defaults to `1M` (1 megabyte). The *logfile_group* is also optional, and defaults to `DEFAULT_LG`. The *file-specification-list* uses the same syntax as shown with the [InitialLogfileGroup](#) parameter, the only difference being that each *file-specification* used with [InitialTablespace](#) corresponds to a data file. At least one must be specified in the *file-specification-list*. Data files are placed according to any values that have been set for [FileSystemPath](#), [FileSystemPathDD](#), and [FileSystemPathDataFiles](#), just as if they had been created as the result of a `CREATE TABLESPACE` or `ALTER TABLESPACE` statement.

For example, consider the following line specifying [InitialTablespace](#) in the `[ndbd default]` section of the `config.ini` file (as with [InitialLogfileGroup](#), this parameter should always be set in the `[ndbd default]` section, as the behavior of a MySQL Cluster when different values are set on different data nodes is not defined):

```
InitialTablespace = name=TS1; extent_size=8M; logfile_group=LG1; data1.dat:2G; data2.dat:4G
```

This is equivalent to the following SQL statements:

```
CREATE TABLESPACE TS1
  ADD DATAFILE 'data1.dat'
  USE LOGFILE GROUP LG1
  EXTENT_SIZE 8M
  INITIAL_SIZE 2G
  ENGINE NDBCLUSTER;

ALTER TABLESPACE TS1
  ADD UNDOFILE 'data2.dat'
  INITIAL_SIZE 4G
  ENGINE NDBCLUSTER;
```

This tablespace is created when the data nodes are started with `--initial`, and can be used whenever creating MySQL Cluster Disk Data tables thereafter.

Disk Data and GCP STOP errors. Errors encountered when using Disk Data tables such as `NODE NODEID KILLED THIS NODE BECAUSE GCP STOP WAS DETECTED` (error 2303) are often referred to as “CGP stop errors”. Such errors are usually due to slow disks and insufficient disk throughput. You can help prevent these errors from occurring by using faster disks, and by adjusting the cluster configuration as discussed here:

- **MySQL Cluster NDB 6.2 and 6.3.** When working with large amounts of data on disk under high load, the default value for [DiskPageBufferMemory](#) may not be large enough. In such cases, you should increase its value to include most of the memory available to the data nodes after accounting for index memory, data memory, internal buffers, and memory needed by the data node host operating system. You can use this formula as a guide:

```
DiskPageBufferMemory
= 0.8
  x (
    [total memory]
    - ([operating system memory] + [buffer memory] + DataMemory + IndexMemory)
  )
```

Once you have established that sufficient memory is reserved for [DataMemory](#), [IndexMemory](#), NDB internal buffers, and operating system overhead, it is possible (and sometimes desirable) to allocate more than the above amount of the remainder to [DiskPageBufferMemory](#).

- **MySQL Cluster NDB 6.4 and 7.X.** In addition to the considerations given for [DiskPageBufferMemory](#) as explained in the previous item, it is also very important that the [DiskIOThreadPool](#) configuration parameter be set correctly; having [DiskIOThreadPool](#) set too high is very likely to cause GCP stop errors ([Bug#37227](#)).

Parameters for configuring send buffer memory allocation (MySQL Cluster NDB 7.0). Beginning with MySQL Cluster NDB 6.4.0, send buffer memory is allocated dynamically from a memory pool shared between all transporters, which means that the size of the send buffer can be adjusted as necessary. (Previously, the NDB kernel used a fixed-size send buffer for every node in the cluster, which was allocated when the node started and could not be changed while the node was running.) The following data node configuration parameters were added in MySQL Cluster NDB 6.4.0 to permit the setting of limits on this memory allocation; this change is reflected by the addition of the configuration parameters [TotalSendBufferMemory](#), [ReservedSendBuffer-](#)

`Memory`, and `OverLoadLimit`, as well as a change in how the existing `SendBufferMemory` configuration parameter is used. For more information, see [Section 17.3.7, “Configuring MySQL Cluster Send Buffer Parameters”](#).

- `TotalSendBufferMemory`

This parameter is available beginning with MySQL Cluster NDB 6.4.0. It is used to determine the total amount of memory to allocate on this node for shared send buffer memory among all configured transporters.

If this parameter is set, its minimum allowed value is 256K; the maximum is 4294967039.

- `ReservedSendBufferMemory`

This optional parameter is available beginning with MySQL Cluster NDB 6.4.0. If set, it reserves an amount of memory (in bytes) for connections between data nodes, and that cannot be allocated for send buffers to be used for management or API nodes. This helps prevent API nodes from using excess send buffer memory and thereby causing communications failures in the NDB kernel.

If this parameter is set, its minimum allowed value is 256K; the maximum is 4294967039.

For more detailed information about the behavior and use of `TotalSendBufferMemory` and `ReservedSendBufferMemory`, and about configuring send buffer memory parameters in MySQL Cluster NDB 6.4.0 and later, see [Section 17.3.7, “Configuring MySQL Cluster Send Buffer Parameters”](#).

Note

Previous to MySQL Cluster NDB 7.0, to add new data nodes to a MySQL Cluster, it is necessary to shut down the cluster completely, update the `config.ini` file, and then restart the cluster (that is, you must perform a system restart). All data node processes must be started with the `--initial` option.

Beginning with MySQL Cluster NDB 7.0, it is possible to add new data node groups to a running cluster online. See [Section 17.7.8, “Adding MySQL Cluster Data Nodes Online”](#), for more information.

17.3.4.7. Defining SQL and Other API Nodes in a MySQL Cluster

The `[mysqld]` and `[api]` sections in the `config.ini` file define the behavior of the MySQL servers (SQL nodes) and other applications (API nodes) used to access cluster data. None of the parameters shown is required. If no computer or host name is provided, any host can use this SQL or API node.

Generally speaking, a `[mysqld]` section is used to indicate a MySQL server providing an SQL interface to the cluster, and an `[api]` section is used for applications other than `mysqld` processes accessing cluster data, but the two designations are actually synonymous; you can, for instance, list parameters for a MySQL server acting as an SQL node in an `[api]` section.

Note

For a discussion of MySQL server options for MySQL Cluster, see [Section 17.4.2, “mysqld Command Options for MySQL Cluster”](#); for information about MySQL server system variables relating to MySQL Cluster, see [Section 17.4.3, “MySQL Cluster System Variables”](#).

- `Id`

The `Id` is an integer value used to identify the node in all cluster internal messages. Prior to MySQL Cluster NDB 6.1.1, the permitted range of values for this parameter was 1 to 63 inclusive. Beginning with MySQL Cluster NDB 6.1.1, the permitted range is 1 to 255 inclusive. This value must be unique for each node in the cluster, regardless of the type of node.

Note

Data node IDs must be less than 49, regardless of the MySQL Cluster version used. If you plan to deploy a large number of data nodes, it is a good idea to limit the node IDs for API nodes (and management nodes) to values greater than 48.

- `ExecuteOnComputer`

This refers to the `Id` set for one of the computers (hosts) defined in a `[computer]` section of the configuration file.

- `HostName`

Specifying this parameter defines the hostname of the computer on which the SQL node (API node) is to reside. To specify a hostname, either this parameter or `ExecuteOnComputer` is required.

If no `HostName` or `ExecuteOnComputer` is specified in a given `[mysql]` or `[api]` section of the `config.ini` file, then an SQL or API node may connect using the corresponding “slot” from any host which can establish a network connection to the management server host machine. *This differs from the default behavior for data nodes, where `localhost` is assumed for `HostName` unless otherwise specified.*

- `ArbitrationRank`

This parameter defines which nodes can act as arbitrators. Both MGM nodes and SQL nodes can be arbitrators. A value of 0 means that the given node is never used as an arbitrator, a value of 1 gives the node high priority as an arbitrator, and a value of 2 gives it low priority. A normal configuration uses the management server as arbitrator, setting its `ArbitrationRank` to 1 (the default) and those for all SQL nodes to 0.

Beginning with MySQL 5.1.16 and MySQL Cluster NDB 6.1.3, it is possible to disable arbitration completely by setting `ArbitrationRank` to 0 on all management and SQL nodes.

- `ArbitrationDelay`

Setting this parameter to any other value than 0 (the default) means that responses by the arbitrator to arbitration requests will be delayed by the stated number of milliseconds. It is usually not necessary to change this value.

- `BatchByteSize`

For queries that are translated into full table scans or range scans on indexes, it is important for best performance to fetch records in properly sized batches. It is possible to set the proper size both in terms of number of records (`BatchSize`) and in terms of bytes (`BatchByteSize`). The actual batch size is limited by both parameters.

The speed at which queries are performed can vary by more than 40% depending upon how this parameter is set. In future releases, MySQL Server will make educated guesses on how to set parameters relating to batch size, based on the query type.

This parameter is measured in bytes and by default is equal to 32KB.

- `BatchSize`

This parameter is measured in number of records and is by default set to 64. The maximum size is 992.

- `MaxScanBatchSize`

The batch size is the size of each batch sent from each data node. Most scans are performed in parallel to protect the MySQL Server from receiving too much data from many nodes in parallel; this parameter sets a limit to the total batch size over all nodes.

The default value of this parameter is set to 256KB. Its maximum size is 16MB.

- `TotalSendBufferMemory`

This parameter is available beginning with MySQL Cluster NDB 6.4.0. It is used to determine the total amount of memory to allocate on this node for shared send buffer memory among all configured transporters.

If this parameter is set, its minimum allowed value is 256K; the maximum is 4294967039. For more detailed information about the behavior and use of `TotalSendBufferMemory` and configuring send buffer memory parameters in MySQL Cluster NDB 6.4.0 and later, see [Section 17.3.7, “Configuring MySQL Cluster Send Buffer Parameters”](#).

You can obtain some information from a MySQL server running as a Cluster SQL node using `SHOW STATUS` in the `mysql` client, as shown here:

```
mysql> SHOW STATUS LIKE 'ndb%';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| Ndb_cluster_node_id | 5 |
| Ndb_config_from_host | 192.168.0.112 |
| Ndb_config_from_port | 1186 |
| Ndb_number_of_storage_nodes | 4 |
+-----+-----+
```

```
+-----+
4 rows in set (0.02 sec)
```

For information about these Cluster system status variables, see [Section 5.1.6, “Server Status Variables”](#).

Note

To add new SQL or API nodes to the configuration of a running MySQL Cluster, it is necessary to perform a rolling restart of all cluster nodes after adding new `[mysqld]` or `[api]` sections to the `config.ini` file (or files, if you are using more than one management server). This must be done before the new SQL or API nodes can connect to the cluster.

It is *not* necessary to perform any restart of the cluster if new SQL or API nodes can employ previously unused API slots in the cluster configuration to connect to the cluster.

17.3.4.8. MySQL Cluster TCP/IP Connections

TCP/IP is the default transport mechanism for all connections between nodes in a MySQL Cluster. Normally it is not necessary to define TCP/IP connections; MySQL Cluster automatically sets up such connections for all data nodes, management nodes, and SQL or API nodes.

Note

For an exception to this rule, see [Section 17.3.4.9, “MySQL Cluster TCP/IP Connections Using Direct Connections”](#).

To override the default connection parameters, it is necessary to define a connection using one or more `[tcp]` sections in the `config.ini` file. Each `[tcp]` section explicitly defines a TCP/IP connection between two MySQL Cluster nodes, and must contain at a minimum the parameters `NodeId1` and `NodeId2`, as well as any connection parameters to override.

It is also possible to change the default values for these parameters by setting them in the `[tcp default]` section.

Important

Any `[tcp]` sections in the `config.ini` file should be listed *last*, following all other sections in the file. However, this is not required for a `[tcp default]` section. This requirement is a known issue with the way in which the `config.ini` file is read by the MySQL Cluster management server.

Connection parameters which can be set in `[tcp]` and `[tcp default]` sections of the `config.ini` file are listed here:

- `NodeId1, NodeId2`

To identify a connection between two nodes it is necessary to provide their node IDs in the `[tcp]` section of the configuration file. These are the same unique `Id` values for each of these nodes as described in [Section 17.3.4.7, “Defining SQL and Other API Nodes in a MySQL Cluster”](#).

- `OverloadLimit`

Beginning in MySQL Cluster NDB 6.4.0, this parameter can be used to determine the amount of unsent data that must be present in the send buffer before the connection is considered overloaded. See [Section 17.3.7, “Configuring MySQL Cluster Send Buffer Parameters”](#), for more information.

- `SendBufferMemory`

TCP transporters use a buffer to store all messages before performing the send call to the operating system. When this buffer reaches 64KB its contents are sent; these are also sent when a round of messages have been executed. To handle temporary overload situations it is also possible to define a bigger send buffer.

Prior to MySQL Cluster NDB 7.0, this parameter determined a fixed amount of memory allocated at startup for each configured TCP connection. Beginning with MySQL Cluster NDB 6.4.0, memory is not dedicated to each transporter. Instead, the value denotes the hard limit for how much memory (out of the total available memory — that is, `TotalSendBufferMemory`) that may be used by a single transporter. For more information about configuring dynamic transporter send buffer memory allocation in MySQL Cluster NDB 7.0 and later, see [Section 17.3.7, “Configuring MySQL Cluster Send Buffer Parameters”](#).

In MySQL Cluster NDB 6.4.3 and earlier, the default size of the send buffer was 256 KB; in MySQL Cluster NDB 7.0.4 and later, it is 2MB, which is the size recommended in most situations. The minimum size is 64 KB; the theoretical maximum is 4 GB.

-

SendSignalId

To be able to retrace a distributed message datagram, it is necessary to identify each message. When this parameter is set to **Y**, message IDs are transported over the network. This feature is disabled by default in production builds, and enabled in `-debug` builds.

•

Checksum

This parameter is a boolean parameter (enabled by setting it to **Y** or **1**, disabled by setting it to **N** or **0**). It is disabled by default. When it is enabled, checksums for all messages are calculated before they placed in the send buffer. This feature ensures that messages are not corrupted while waiting in the send buffer, or by the transport mechanism.

•

PortNumber (OBSOLETE)

This formerly specified the port number to be used for listening for connections from other nodes. This parameter should no longer be used.

•

ReceiveBufferMemory

Specifies the size of the buffer used when receiving data from the TCP/IP socket.

In MySQL Cluster NDB 6.4.3 and earlier, the default value of this parameter was 64 KB; beginning with MySQL Cluster NDB 7.0.4, 2MB is the default. The minimum possible value is 16KB; the theoretical maximum is 4GB.

17.3.4.9. MySQL Cluster TCP/IP Connections Using Direct Connections

Setting up a cluster using direct connections between data nodes requires specifying explicitly the crossover IP addresses of the data nodes so connected in the `[tcp]` section of the cluster `config.ini` file.

In the following example, we envision a cluster with at least four hosts, one each for a management server, an SQL node, and two data nodes. The cluster as a whole resides on the `172.23.72.*` subnet of a LAN. In addition to the usual network connections, the two data nodes are connected directly using a standard crossover cable, and communicate with one another directly using IP addresses in the `1.1.0.*` address range as shown:

```
# Management Server
[ndb_mgmd]
Id=1
HostName=172.23.72.20

# SQL Node
[mysqld]
Id=2
HostName=172.23.72.21

# Data Nodes
[ndbd]
Id=3
HostName=172.23.72.22

[ndbd]
Id=4
HostName=172.23.72.23

# TCP/IP Connections
[tcp]
NodeId1=3
NodeId2=4
HostName1=1.1.0.1
HostName2=1.1.0.2
```

The `HostName N` parameter, where N is an integer, is used only when specifying direct TCP/IP connections.

The use of direct connections between data nodes can improve the cluster's overall efficiency by allowing the data nodes to bypass an Ethernet device such as a switch, hub, or router, thus cutting down on the cluster's latency. It is important to note that to take the best advantage of direct connections in this fashion with more than two data nodes, you must have a direct connection between each data node and every other data node in the same node group.

17.3.4.10. MySQL Cluster Shared-Memory Connections

MySQL Cluster attempts to use the shared memory transporter and configure it automatically where possible. `[shm]` sections in the `config.ini` file explicitly define shared-memory connections between nodes in the cluster. When explicitly defining shared memory as the connection method, it is necessary to define at least `NodeId1`, `NodeId2` and `ShmKey`. All other parameters have

default values that should work well in most cases.

Important

SHM functionality is considered experimental only. It is not officially supported in any current MySQL Cluster release, and testing results indicate that SHM performance is not appreciably greater than when using TCP/IP for the transporter.

For these reasons, you must determine for yourself or by using our free resources (forums, mailing lists) whether SHM can be made to work correctly in your specific case.

- [NodeId1, NodeId2](#)
To identify a connection between two nodes it is necessary to provide node identifiers for each of them, as [NodeId1](#) and [NodeId2](#).
- [ShmKey](#)
When setting up shared memory segments, a node ID, expressed as an integer, is used to identify uniquely the shared memory segment to use for the communication. There is no default value.
- [ShmSize](#)
Each SHM connection has a shared memory segment where messages between nodes are placed by the sender and read by the reader. The size of this segment is defined by [ShmSize](#). The default value is 1MB.
- [SendSignalId](#)
To retrace the path of a distributed message, it is necessary to provide each message with a unique identifier. Setting this parameter to `Y` causes these message IDs to be transported over the network as well. This feature is disabled by default in production builds, and enabled in `-debug` builds.
- [Checksum](#)
This parameter is a boolean (`Y/N`) parameter which is disabled by default. When it is enabled, checksums for all messages are calculated before being placed in the send buffer.

This feature prevents messages from being corrupted while waiting in the send buffer. It also serves as a check against data being corrupted during transport.
- [SigNum](#)
When using the shared memory transporter, a process sends an operating system signal to the other process when there is new data available in the shared memory. Should that signal conflict with an existing signal, this parameter can be used to change it. This is a possibility when using SHM due to the fact that different operating systems use different signal numbers.

The default value of [SigNum](#) is 0; therefore, it must be set to avoid errors in the cluster log when using the shared memory transporter. Typically, this parameter is set to 10 in the `[shm default]` section of the `config.ini` file.

17.3.4.11. SCI Transport Connections in MySQL Cluster

`[sci]` sections in the `config.ini` file explicitly define SCI (Scalable Coherent Interface) connections between cluster nodes. Using SCI transporters in MySQL Cluster is supported only when the MySQL binaries are built using `--with-ndb-sci=/your/path/to/SCI`. The `path` should point to a directory that contains at a minimum `lib` and `include` directories containing SISI libraries and header files. (See [Section 17.11, “Using High-Speed Interconnects with MySQL Cluster”](#) for more information about SCI.)

In addition, SCI requires specialized hardware.

It is strongly recommended to use SCI Transporters only for communication between `ndbd` processes. Note also that using SCI Transporters means that the `ndbd` processes never sleep. For this reason, SCI Transporters should be used only on machines having at least two CPUs dedicated for use by `ndbd` processes. There should be at least one CPU per `ndbd` process, with at least one CPU left in reserve to handle operating system activities.

- `NodeId1, NodeId2`
To identify a connection between two nodes it is necessary to provide node identifiers for each of them, as `NodeId1` and `NodeId2`.
- `Host1SciId0`
This identifies the SCI node ID on the first Cluster node (identified by `NodeId1`).
- `Host1SciId1`
It is possible to set up SCI Transporters for failover between two SCI cards which then should use separate networks between the nodes. This identifies the node ID and the second SCI card to be used on the first node.
- `Host2SciId0`
This identifies the SCI node ID on the second Cluster node (identified by `NodeId2`).
- `Host2SciId1`
When using two SCI cards to provide failover, this parameter identifies the second SCI card to be used on the second node.
- `SharedBufferSize`
Each SCI transporter has a shared memory segment used for communication between the two nodes. Setting the size of this segment to the default value of 1MB should be sufficient for most applications. Using a smaller value can lead to problems when performing many parallel inserts; if the shared buffer is too small, this can also result in a crash of the `ndbd` process.
- `SendLimit`
A small buffer in front of the SCI media stores messages before transmitting them over the SCI network. By default, this is set to 8KB. Our benchmarks show that performance is best at 64KB but 16KB reaches within a few percent of this, and there was little if any advantage to increasing it beyond 8KB.
- `SendSignalId`
To trace a distributed message it is necessary to identify each message uniquely. When this parameter is set to `Y`, message IDs are transported over the network. This feature is disabled by default in production builds, and enabled in `-debug` builds.
- `Checksum`
This parameter is a boolean value, and is disabled by default. When `Checksum` is enabled, checksums are calculated for all messages before they are placed in the send buffer. This feature prevents messages from being corrupted while waiting in the send buffer. It also serves as a check against data being corrupted during transport.

17.3.5. Overview of MySQL Cluster Configuration Parameters

The next three sections provide summary tables of MySQL Cluster configuration parameters used in the `config.ini` file to govern the cluster's functioning. Each table lists the parameters for one of the Cluster node process types (`ndbd`, `ndb_mgmd`, and `mysqld`), and includes the parameter's type as well as its default, minimum, and maximum values as applicable.

It is also stated what type of restart is required (node restart or system restart) — and whether the restart must be done with `-initial` — to change the value of a given configuration parameter. This information is provided in each table's **Restart Type** column, which contains one of the values shown in this list:

- `N`: Node Restart
- `IN`: Initial Node Restart
- `S`: System Restart
- `IS`: Initial System Restart

When performing a node restart or an initial node restart, all of the cluster's data nodes must be restarted in turn (also referred to as a *rolling restart*). It is possible to update cluster configuration parameters marked **N** or **IN** online — that is, without shutting down the cluster — in this fashion. An initial node restart requires restarting each `ndbd` process with the `--initial` option.

A system restart requires a complete shutdown and restart of the entire cluster. An initial system restart requires taking a backup of the cluster, wiping the cluster file system after shutdown, and then restoring from the backup following the restart.

In any cluster restart, all of the cluster's management servers must be restarted in order for them to read the updated configuration parameter values.

Important

Values for numeric cluster parameters can generally be increased without any problems, although it is advisable to do so progressively, making such adjustments in relatively small increments. However, decreasing the values of such parameters — particularly those relating to memory usage and disk space — is not to be undertaken lightly, and it is recommended that you do so only following careful planning and testing. In addition, it is generally the case that parameters relating to memory and disk usage which can be raised using a simple node restart require an initial node restart to be lowered.

Because some of these parameters can be used for configuring more than one type of cluster node, they may appear in more than one of the tables.

Note

`4294967039` — which often appears as a maximum value in these tables — is defined in the `NDBCLUSTER` sources as `MAX_INT_RNIL` and is equal to `0xFFFFFFFF`, or $2^{32} - 2^8 - 1$.

17.3.5.1. MySQL Cluster Data Node Configuration Parameters

The following table provides information about parameters used in the `[ndbd]` or `[ndbd default]` sections of a `config.ini` file for configuring MySQL Cluster data nodes. For detailed descriptions and other additional information about each of these parameters, see [Section 17.3.4.6, “Defining MySQL Cluster Data Nodes”](#).

Beginning with MySQL Cluster NDB 6.4.0, these parameters also apply to `ndbmt_d`, which is a multi-threaded version of `ndbd`. For more information, see [Section 17.6.3, “ndbmt_d — The MySQL Cluster Data Node Daemon \(Multi-Threaded\)”](#).

Restart Type Column Values

- **N**: Node Restart
- **IN**: Initial Node Restart
- **S**: System Restart
- **IS**: Initial System Restart

See [Section 17.3.5, “Overview of MySQL Cluster Configuration Parameters”](#), for additional explanations of these abbreviations.

Table 17.1. MySQL Cluster Data Node Configuration Parameters

Parameter Name	Type / Units	Default Value	Minimum Value	Maximum Value	Restart Type
<code>ArbitrationTimeout</code>	mil- li- sec- onds	3000	10	4294967039	N

<code>TimeBetweenEpochsTimeout</code> (Added in MySQL Cluster NDB 6.2.7 and MySQL Cluster NDB 6.3.4)	milliseconds	4000	0	32000	N
<code>TimeBetweenGlobalCheckpoints</code>	milliseconds	2000	10	32000	N
<code>TimeBetweenInactiveTransactionAbortCheck</code>	milliseconds	1000	1000	4294967039	N
<code>TimeBetweenLocalCheckpoints</code>	integer (number of 4-byte words as a base-2 logarithm)	20 (= $4 * 2^{20} = 4\text{MB}$ write operations)	0	31	N
<code>TimeBetweenWatchDogCheck</code>	milliseconds	6000	70	4294967039	N
<code>TimeBetweenWatchDogCheckInitial</code> (added in MySQL 5.1.20)	milliseconds	6000	70	4294967039	N
<code>TotalSendBufferMemory</code> (added in MySQL Cluster NDB 6.4.0)	bytes	<i>None</i>	256K	4294967039	N
<code>TransactionBufferMemory</code>	bytes	1M	1K	4294967039	N
<code>TransactionDeadlockDetectionTimeout</code>	milliseconds	1200	50 (<i>Note:</i> Prior to MySQL Cluster NDB 6.2.18/6.3.24/7.0.5, 100 was the effective minimum.)	4294967039	N
<code>TransactionInactiveTimeout</code>	milliseconds	0	0	4294967039	N
<code>UndoDataBuffer</code> (<i>OBSOLETE</i>)	bytes	16M	1M	4294967039	N
<code>UndoIndexBuffer</code> (<i>OBSOLETE</i>)	bytes	2M	1M	4294967039	N

Note

To add new data nodes to a MySQL Cluster, it is necessary to shut down the cluster completely, update the `con-fig.ini` file, and then restart the cluster (that is, you must perform a system restart). All data node processes must be started with the `--initial` option.

Beginning in MySQL Cluster NDB 7.0, it is possible to add new data node groups to a running cluster online. For more information, see [Section 17.7.8, “Adding MySQL Cluster Data Nodes Online”](#).

17.3.5.2. MySQL Cluster Management Node Configuration Parameters

The following table provides information about parameters used in the `[ndb_mgmd]` or `[mgm]` sections of a `config.ini` file for configuring MySQL Cluster management nodes. For detailed descriptions and other additional information about each of these parameters, see [Section 17.3.4.5, “Defining a MySQL Cluster Management Server”](#).

Restart Type Column Values

- **N**: Node Restart
- **IN**: Initial Node Restart
- **S**: System Restart
- **IS**: Initial System Restart

See [Section 17.3.5, “Overview of MySQL Cluster Configuration Parameters”](#), for additional explanations of these abbreviations.

Table 17.2. MySQL Cluster Management Node Configuration Parameters

Parameter Name	Type / Units	Default Value	Minimum Value	Maximum Value	Restart Type
ArbitrationDelay	mil- li- seco nds	0	0	4294967039	N
ArbitrationRank	in- teger	1	0	2	N
DataDir	strin g	<code>./</code> (<code>ndb_mgmd</code> directory)	N/A	N/A	IN
ExecuteOnComputer	in- teger				
HostName	strin g	<code>localhost</code>	N/A	N/A	IN
Id	in- teger	<i>None</i>	1	(<i>MySQL Cluster NDB 6.1.0 and earlier:</i>) 63; (<i>MySQL Cluster NDB 6.1.1 and later:</i>) 255	IS
LogDestination	CON SOL E, SYS LOG, or FIL E	FILE (see Section 17.3.4.5, “Defining a MySQL Cluster Management Server”)	N/A	N/A	N
PortNumber	in- teger	1186	1	65535	S
TotalSendBufferMemory (added in MySQL Cluster NDB 6.4.0)	bytes	<i>None</i>	256K	4294967039	N

Note

After making changes in a management node's configuration, it is necessary to perform a rolling restart of the cluster in order for the new configuration to take effect. See [Section 17.3.4.5, “Defining a MySQL Cluster Management Server”](#), for more information.

To add new management servers to a running MySQL Cluster, it is also necessary perform a rolling restart of all cluster nodes after modifying any existing `config.ini` files. For more information about issues arising when using multiple management nodes, see [Section 17.12.10, “Limitations Relating to Multiple MySQL Cluster Nodes”](#).

17.3.5.3. MySQL Cluster SQL Node and API Node Configuration Parameters

The following table provides information about parameters used in the `[SQL]` and `[api]` sections of a `config.ini` file for configuring MySQL Cluster SQL nodes and API nodes. For detailed descriptions and other additional information about each of these parameters, see [Section 17.3.4.7, “Defining SQL and Other API Nodes in a MySQL Cluster”](#).

Note

For a discussion of MySQL server options for MySQL Cluster, see [Section 17.4.2, “mysqld Command Options for MySQL Cluster”](#); for information about MySQL server system variables relating to MySQL Cluster, see [Section 17.4.3, “MySQL Cluster System Variables”](#).

Restart Type Column Values

- **N**: Node Restart
- **IN**: Initial Node Restart
- **S**: System Restart
- **IS**: Initial System Restart

See [Section 17.3.5, “Overview of MySQL Cluster Configuration Parameters”](#), for additional explanations of these abbreviations.

Table 17.3. MySQL Cluster SQL Node and API Node Configuration Parameters

Parameter Name	Type / Units	Default Value	Minimum Value	Maximum Value	Restart Type
ArbitrationDelay	mil- li- seconds	0	0	4294967039	N
ArbitrationRank	in- teger	0	0	2	N
BatchByteSize	bytes	32K	1K	1M	N
BatchSize	in- teger	64	1	992	N
ExecuteOnComputer	in- teger				
HostName	string	<i>none</i>	N/A	N/A	IN
Id	in- teger	<i>None</i>	1	(MySQL Cluster NDB 6.1.0 and earlier:) 63; (MySQL Cluster NDB 6.1.1 and later:) 255	IS
MaxScanBatchSize	bytes	256K	32K	16M	N
TotalSendBufferMemory (added in MySQL Cluster NDB 6.4.0)	bytes	<i>None</i>	256K	4294967039	N

Note

To add new SQL or API nodes to the configuration of a running MySQL Cluster, it is necessary to perform a rolling restart of all cluster nodes after adding new `[mysqld]` or `[api]` sections to the `config.ini` file (or files, if you are using more than one management server). This must be done before the new SQL or API nodes can connect to the cluster.

It is *not* necessary to perform any restart of the cluster if new SQL or API nodes can employ previously unused API slots in the cluster configuration to connect to the cluster.

17.3.6. Configuring MySQL Cluster Parameters for Local Checkpoints

The parameters discussed in [Logging and Checkpointing](#) and in [Data Memory, Index Memory, and String Memory](#) that are used to configure local checkpoints for a MySQL Cluster do not exist in isolation, but rather are very much interdependent on each other. In this section, we illustrate how these parameters — including `DataMemory`, `IndexMemory`, `NoOfDiskPagesToDiskAfterRestartTUP`, `NoOfDiskPagesToDiskAfterRestartACC`, and `NoOfFragmentLogFiles` — relate to one another in a working Cluster.

Important

The parameters `NoOfDiskPagesToDiskAfterRestartTUP` and `NoOfDiskPagesToDiskAfterRestartACC` were deprecated in MySQL 5.1.6. From MySQL 5.1.6 through 5.1.11, disk writes during LCPs took place at the maximum speed possible. Beginning with MySQL 5.1.12, the speed and throughput for LCPs are controlled using the parameters `DiskSyncSize`, `DiskCheckpointSpeed`, and `DiskCheckpointSpeedInRestart`. See [Section 17.3.4.6, “Defining MySQL Cluster Data Nodes”](#).

In this example, we assume that our application performs the following numbers of types of operations per hour:

- 50000 selects
- 15000 inserts
- 15000 updates
- 15000 deletes

We also make the following assumptions about the data used in the application:

- We are working with a single table having 40 columns.
- Each column can hold up to 32 bytes of data.
- A typical `UPDATE` run by the application affects the values of 5 columns.
- No `NULL` values are inserted by the application.

A good starting point is to determine the amount of time that should elapse between local checkpoints (LCPs). It is worth noting that, in the event of a system restart, it takes 40-60 percent of this interval to execute the REDO log — for example, if the time between LCPs is 5 minutes (300 seconds), then it should take 2 to 3 minutes (120 to 180 seconds) for the REDO log to be read.

The maximum amount of data per node can be assumed to be the size of the `DataMemory` parameter. In this example, we assume that this is 2 GB. The `NoOfDiskPagesToDiskAfterRestartTUP` parameter represents the amount of data to be checkpointed per unit time — however, this parameter is actually expressed as the number of 8K memory pages to be checkpointed per 100 milliseconds. 2 GB per 300 seconds is approximately 6.8 MB per second, or 700 KB per 100 milliseconds, which works out to roughly 85 pages per 100 milliseconds.

Similarly, we can calculate `NoOfDiskPagesToDiskAfterRestartACC` in terms of the time for local checkpoints and the amount of memory required for indexes — that is, the `IndexMemory`. Assuming that we allow 512 MB for indexes, this works out to approximately 20 8-KB pages per 100 milliseconds for this parameter.

Next, we need to determine the number of REDO log files required — that is, fragment log files — the corresponding parameter being `NoOfFragmentLogFiles`. We need to make sure that there are sufficient REDO log files for keeping records for at least 3 local checkpoints (in MySQL Cluster NDB 6.3.8 and later, we need only allow for 2 local checkpoints). In a production setting, there are always uncertainties — for instance, we cannot be sure that disks always operate at top speed or with maximum throughput. For this reason, it is best to err on the side of caution, so we double our requirement and calculate a number of fragment log files which should be enough to keep records covering 6 local checkpoints (in MySQL Cluster NDB 6.3.8 and later, a number of fragment log files accommodating 4 local checkpoints should be sufficient).

It is also important to remember that the disk also handles writes to the REDO log, so if you find that the amount of data being written to disk as determined by the values of `NoOfDiskPagesToDiskAfterRestartACC` and `NoOfDiskPagesToDiskAfterRestartTUP` is approaching the amount of disk bandwidth available, you may wish to increase the time between local checkpoints.

Given 5 minutes (300 seconds) per local checkpoint, this means that we need to support writing log records at maximum speed for $6 * 300 = 1800$ seconds (*MySQL Cluster NDB 6.3.8 and later*: $4 * 300 = 1200$ seconds). The size of a REDO log record is 72 bytes plus 4 bytes per updated column value plus the maximum size of the updated column, and there is one REDO log record for each table record updated in a transaction, on each node where the data reside. Using the numbers of operations set out previously in this section, we derive the following:

- 50000 select operations per hour yields 0 log records (and thus 0 bytes), since `SELECT` statements are not recorded in the REDO log.
- 15000 `DELETE` statements per hour is approximately 5 delete operations per second. (Since we wish to be conservative in our estimate, we round up here and in the following calculations.) No columns are updated by deletes, so these statements consume only 5 operations * 72 bytes per operation = 360 bytes per second.
- 15000 `UPDATE` statements per hour is roughly the same as 5 updates per second. Each update uses 72 bytes, plus 4 bytes per column * 5 columns updated, plus 32 bytes per column * 5 columns — this works out to $72 + 20 + 160 = 252$ bytes per operation, and multiplying this by 5 operation per second yields 1260 bytes per second.
- 15000 `INSERT` statements per hour is equivalent to 5 insert operations per second. Each insert requires REDO log space of 72 bytes, plus 4 bytes per record * 40 columns, plus 32 bytes per column * 40 columns, which is $72 + 160 + 1280 = 1512$ bytes per operation. This times 5 operations per second yields 7560 bytes per second.

So the total number of REDO log bytes being written per second is approximately $0 + 360 + 1260 + 7560 = 9180$ bytes. Multiplied by 1800 seconds, this yields 16524000 bytes required for REDO logging, or approximately 15.75 MB. The unit used for `NoOfFragmentLogFiles` represents a set of 4 16-MB log files — that is, 64 MB. Thus, the minimum value (3) for this parameter is sufficient for the scenario envisioned in this example, since 3 times 64 = 192 MB, or about 12 times what is required; the default value of 8 (or 512 MB) is more than ample in this case.

17.3.7. Configuring MySQL Cluster Send Buffer Parameters

Formerly, the NDB kernel used a send buffer whose size was fixed at 2MB for every node in the cluster, which was allocated when the node started. Because the size of this buffer could not be changed after the cluster was started, it was necessary to make it large enough in advance to accommodate the maximum possible load on any transporter socket. However, this was an inefficient use of memory, since much of it often went unused, and could result in large amounts of resources being wasted when scaling up to many API nodes.

Beginning with MySQL Cluster NDB 7.0, this problem is solved by employing a unified send buffer whose memory is allocated dynamically from a pool shared by all transporters. This means that the size of the send buffer can be adjusted as necessary. Configuration of the unified send buffer can be accomplished by setting the following parameters:

- **TotalSendBufferMemory.** This parameter can be set for all types of MySQL Cluster nodes — that is, it can be set in the `[ndbd]`, `[mgm]`, and `[api]` (or `[mysql]`) sections of the `config.ini` file. It represents the total amount of memory (in bytes) to be allocated by each node for which it is set for use among all configured transporters. If set, its minimum is 256K; the maximum is 4294967039.

In order to be backward-compatible with existing configurations, this parameter takes as its default value the sum of the maximum send buffer sizes of all configured transporters, plus an additional 32KB (one page) per transporter. The maximum depends on the type of transporter, as shown in the following table:

Transporter	Maximum Send Buffer Size (bytes)
TCP	<code>SendBufferMemory</code> (default = 2M)
SCI	<code>SendLimit</code> (default = 8K) plus 16K
SHM	20K

This allows existing configurations to function in close to the same way as they did with MySQL Cluster NDB 6.3 and earlier, with the same amount of memory and send buffer space available to each transporter. However, memory that is unused by one transporter is not available to other transporters.

- **ReservedSendBufferMemory.** This optional data node parameter, if set, gives an amount of memory (in bytes) that is reserved for connections between data nodes; this memory is not allocated to send buffers used for communications with management servers or API nodes. This provides a way to protect the cluster against misbehaving API nodes that use excess send memory and thus cause failures in communications internally in the NDB kernel. If set, its the minimum permitted value for this parameters is 256K; the maximum is 4294967039.
- **OverloadLimit.** This parameter is used in the `config.ini` file `[tcp]` section, and denotes the amount of unsent data (in bytes) that must be present in the send buffer before the connection is considered overloaded. When such an overload condi-

tion occurs, transactions that affect the overloaded connection fail with NDB API Error 1218 (`SEND_BUFFERS_OVERLOADED_IN_NDB_KERNEL`) until the overload status passes. The default value is 0; there is no defined maximum value for this parameter.

- **SendBufferMemory.** In MySQL Cluster NDB 6.3 and earlier, this TCP configuration parameter represented the amount of memory allocated at startup for each configured TCP connection. Beginning with MySQL Cluster NDB 7.0, this value denotes a hard limit for how much memory (out of the total available — that is, `TotalSendBufferMemory`) that may be used by a single transporter. However, the sum of `TotalSendBufferMemory` for all configured transporters may be greater than `SendBufferMemory`. This is a way to save memory when many nodes are in use, as long as the maximum amount of memory is never required by all transporters at the same time.

17.4. MySQL Cluster Options and Variables

This section provides information about MySQL server options, server and status variables that are specific to MySQL Cluster. For general information on using these, and for other options and variables not specific to MySQL Cluster, see [Section 5.1, “The MySQL Server”](#).

For MySQL Cluster configuration parameters used in the cluster configuration file (usually named `config.ini`), see [Section 17.3, “MySQL Cluster Configuration”](#).

17.4.1. MySQL Cluster Server Option and Variable Reference

The following table provides a list of the command-line options, server and status variables applicable within `mysqld` when it is running as an SQL node in a MySQL Cluster. For a table showing *all* command-line options, server and status variables available for use with `mysqld`, see [Section 5.1.1, “Server Option and Variable Reference”](#).

Table 17.4. `mysqld` Command Options for MySQL Cluster

Name	Cmd-Line	Option file	System Var	Status Var	Var Scope	Dynamic
Handler_discover				Yes	Both	No
have_ndbcluster			Yes		Global	No
ndb_autoincrement_prefetch_sz	Yes	Yes	Yes		Both	Yes
ndb-batch-size	Yes	Yes	Yes		Global	No
ndb_cache_check_time	Yes	Yes	Yes		Global	Yes
ndb-cluster-connection-pool	Yes	Yes		Yes	Global	No
Ndb_cluster_node_id				Yes	Both	No
Ndb_config_from_host				Yes	Both	No
Ndb_config_from_port				Yes	Both	No
Ndb_conflict_fn_max				Yes	Global	No
Ndb_conflict_fn_old				Yes	Global	No
ndb-connectstring	Yes	Yes				
ndb_execute_count				Yes	Global	No
ndb_extra_logging	Yes	Yes	Yes		Global	Yes
ndb_force_send	Yes	Yes	Yes		Both	Yes
ndb_index_stat_cache_entries	Yes	Yes				
ndb_index_stat_enable	Yes	Yes				
ndb_index_stat_update_freq	Yes	Yes				
ndb_log_empty_epochs	Yes	Yes	Yes		Global	Yes
ndb_log_orig			Yes		Global	No
ndb-log-update-as-write	Yes	Yes	Yes		Global	Yes

ndbcluster	Yes	Yes				
skip-ndbcluster	Yes	Yes				
slave-allow-batching	Yes	Yes			Global	Yes
- Variable: <code>slave_allow_batching</code>			Yes		Global	Yes

17.4.2. `mysqld` Command Options for MySQL Cluster

This section provides descriptions of `mysqld` server options relating to MySQL Cluster. For information about `mysqld` options not specific to MySQL Cluster, and for general information about the use of options with `mysqld`, see [Section 5.1.2, “Server Command Options”](#).

For information about command-line options used with other MySQL Cluster processes (`ndbd`, `ndb_mgmd`, and `ndb_mgm`), see [Section 17.6.23, “Options Common to MySQL Cluster Programs”](#). For information about command-line options used with NDB utility programs (such as `ndb_desc`, `ndb_size.pl`, and `ndb_show_tables`), see [Section 17.6, “MySQL Cluster Programs”](#).

- `--ndb-batch-size=#`

Version Introduced	5.1.23-ndb-6.3.8	
Command Line Format	<code>--ndb-batch-size</code>	
Config File Format	<code>ndb-batch-size</code>	
Variable Name	<code>ndb_batch_size</code>	
Variable Scope	Global	
Dynamic Variable	No	
Value Set	Type	numeric
	Default	32768
	Range	0-31536000

This sets the size in bytes that is used for NDB transaction batches.

- `--ndb-cluster-connection-pool=#`

Version Introduced	5.1.19-ndb-6.2.2	
Command Line Format	<code>--ndb-cluster-connection-pool</code>	
Config File Format	<code>ndb-cluster-connection-pool</code>	
Variable Name	<code>ndb-cluster-connection-pool</code>	
Variable Scope	Global	
Dynamic Variable	No	
Value Set	Type	numeric
	Default	1
	Range	1-63

By setting this option to a value greater than 1 (the default), a `mysqld` process can use multiple connections to the cluster, effectively mimicking several SQL nodes. Each connection requires its own `[api]` or `[mysqld]` section in the cluster configuration (`config.ini`) file, and counts against the maximum number of API connections supported by the cluster.

For example, suppose that you have 2 cluster host computers, each running an SQL node whose `mysqld` process was started with `--ndb-cluster-connection-pool=4`; this means that the cluster must have 8 API slots available for these connections (instead of 2). All of these connections are set up when the SQL node connects to the cluster, and are allocated to threads in a round-robin fashion.

This option is useful only when running `mysqld` on host machines having multiple CPUs, multiple cores, or both. For best results, the value should be smaller than the total number of cores available on the host machine. Setting it to a value greater than this is likely to degrade performance severely.

Important

Because each SQL node using connection pooling occupies multiple API node slots — each slot having its own node ID in the cluster — you must *not* use a node ID as part of the cluster connect string when starting any `mysqld` process that employs connection pooling.

Setting a node ID in the connect string when using the `--ndb-cluster-connection-pool` option causes node ID allocation errors when the SQL node attempts to connect to the cluster.

This option was introduced in MySQL Cluster NDB 6.2.2. Beginning with MySQL Cluster NDB 6.2.16 and MySQL Cluster NDB 6.3.13, the value used for this option is available as a global status variable ([Bug#35573](#)).

- `--ndb-connectstring=connect_string`

Command Line Format	<code>--ndb-connectstring</code>	
Config File Format	<code>ndb-connectstring</code>	
Value Set	Type	<code>string</code>

When using the `NDBCLUSTER` storage engine, this option specifies the management server that distributes cluster configuration data. See [Section 17.3.4.3, “The MySQL Cluster Connectstring”](#), for syntax.

- `--ndbcluster`

Command Line Format	<code>--ndbcluster</code>	
Config File Format	<code>ndbcluster</code>	
Value Set	Type	<code>boolean</code>
	Default	<code>FALSE</code>

The `NDBCLUSTER` storage engine is necessary for using MySQL Cluster. If a `mysqld` binary includes support for the `NDB-CLUSTER` storage engine, the engine is disabled by default. Use the `--ndbcluster` option to enable it. Use `--skip-ndbcluster` to explicitly disable the engine.

- `--ndb-nodeid=#`

Version Introduced	5.1.15	
Command Line Format	<code>--ndb-nodeid=#</code>	
Config File Format	<code>ndb-nodeid</code>	
Variable Name	<code>Ndb_cluster_node_id</code>	
Variable Scope	Global	
Dynamic Variable	No	
Value Set (>= 5.1.5)	Type	<code>numeric</code>
	Range	<code>1-255</code>

Set this MySQL server's node ID in a MySQL Cluster. This can be used instead of specifying the node ID as part of the connectstring or in the `config.ini` file, or allowing the cluster to determine an arbitrary node ID. If you use this option, then `--ndb-nodeid` must be specified *before* `--ndb-connectstring`. If `--ndb-nodeid` is used *and* a node ID is specified

in the connectstring, then the MySQL server will not be able to connect to the cluster. In addition, if `--nodeid` is used, then either a matching node ID must be found in a `[mysqld]` or `[api]` section of `config.ini`, or there must be an “open” `[mysqld]` or `[api]` section in the file (that is, a section without an `Id` parameter specified).

Regardless of how the node ID is determined, its is shown as the value of the global status variable `Ndb_cluster_node_id` in the output of `SHOW STATUS`, and as `cluster_node_id` in the `connection` row of the output of `SHOW ENGINE NDBCLUSTER STATUS`.

For more information about node IDs for MySQL Cluster SQL nodes, see [Section 17.3.4.7, “Defining SQL and Other API Nodes in a MySQL Cluster”](#).

- `--skip-ndbcluster`

Command Line Format	<code>--skip-ndbcluster</code>
Config File Format	<code>skip-ndbcluster</code>

Disable the `NDBCLUSTER` storage engine. This is the default for binaries that were built with `NDBCLUSTER` storage engine support; the server allocates memory and other resources for this storage engine only if the `--ndbcluster` option is given explicitly. See [Section 17.3.3, “Quick Test Setup of MySQL Cluster”](#), for an example.

17.4.3. MySQL Cluster System Variables

This section provides detailed information about MySQL server system variables that are specific to MySQL Cluster and the `NDB` storage engine. For system variables not specific to MySQL Cluster, see [Section 5.1.3, “Server System Variables”](#). For general information on using system variables, see [Section 5.1.5, “Using System Variables”](#).

- `have_ndbcluster`

Variable Name	<code>have_ndbcluster</code>	
Variable Scope	Global	
Dynamic Variable	No	
Value Set	Type	<code>boolean</code>

`YES` if `mysqld` supports `NDBCLUSTER` tables. `DISABLED` if `--skip-ndbcluster` is used.

- `multi_range_count`

Command Line Format	<code>--multi_range_count=#</code>	
Config File Format	<code>multi_range_count</code>	
Option Sets Variable	Yes, <code>multi_range_count</code>	
Variable Name	<code>multi_range_count</code>	
Variable Scope	Both	
Dynamic Variable	Yes	
Value Set	Type	<code>numeric</code>
	Default	<code>256</code>
	Range	<code>1-4294967295</code>

The maximum number of ranges to send to a table handler at once during range selects. The default value is 256. Sending multiple ranges to a handler at once can improve the performance of certain selects dramatically. This is especially true for the `NDBCLUSTER` table handler, which needs to send the range requests to all nodes. Sending a batch of those requests at once reduces communication costs significantly.

This variable is deprecated in MySQL 5.1, and is no longer supported in MySQL 6.0, in which arbitrarily long lists of ranges can be processed.

- `ndb_autoincrement_prefetch_sz`

Command Line Format	<code>--ndb_autoincrement_prefetch_sz</code>
----------------------------	--

Config File Format	<code>ndb_autoincrement_prefetch_sz</code>	
Option Sets Variable	Yes, <code>ndb_autoincrement_prefetch_sz</code>	
Variable Name	<code>ndb_autoincrement_prefetch_sz</code>	
Variable Scope	Both	
Dynamic Variable	Yes	
Value Set (<= 5.1.22)	Type	numeric
	Default	32
	Range	1-256
Value Set (>= 5.1.23)	Type	numeric
	Default	1
	Range	1-256

Determines the probability of gaps in an autoincremented column. Set it to 1 to minimize this. Setting it to a high value for optimization — makes inserts faster, but decreases the likelihood that consecutive autoincrement numbers will be used in a batch of inserts. Default value: 32. Minimum value: 1.

Beginning with MySQL Cluster NDB 6.2.10, MySQL Cluster NDB 6.3.7, and MySQL 5.1.23, this variable affects the number of `AUTO_INCREMENT` IDs that are fetched between statements only. Within a statement, at least 32 IDs are now obtained at a time. The default value for `ndb_autoincrement_prefetch_sz` is now 1, to increase the speed of statements inserting single rows. (Bug#31956)

- `ndb_cache_check_time`

Command Line Format	<code>--ndb_cache_check_time</code>	
Config File Format	<code>ndb_cache_check_time</code>	
Option Sets Variable	Yes, <code>ndb_cache_check_time</code>	
Variable Name	<code>ndb_cache_check_time</code>	
Variable Scope	Global	
Dynamic Variable	Yes	
Value Set	Type	numeric
	Default	0

The number of milliseconds that elapse between checks of MySQL Cluster SQL nodes by the MySQL query cache. Setting this to 0 (the default and minimum value) means that the query cache checks for validation on every query.

The recommended maximum value for this variable is 1000, which means that the check is performed once per second. A larger value means that the check is performed and possibly invalidated due to updates on different SQL nodes less often. It is generally not desirable to set this to a value greater than 2000.

- `ndb_extra_logging`

Version Introduced	5.1.6	
Command Line Format	<code>ndb_extra_logging=#</code>	
Config File Format	<code>ndb_extra_logging</code>	
Variable Name	<code>ndb_extra_logging</code>	
Variable Scope	Global	
Dynamic Variable	Yes	
Value Set	Type	numeric
	Default	0

This variable can be used to enable recording in the MySQL error log of information specific to the NDB storage engine. It is normally of interest only when debugging NDB storage engine code.

The default value is 0, which means that the only NDB-specific information written to the MySQL error log relates to transaction handling. If the value is greater than 0 but less than 10, NDB table schema and connection events are also logged, as well as whether or not conflict resolution is in use, and other NDB errors and information. If the value is set to 10 or more, information about NDB internals, such as the progress of data distribution among cluster nodes, is also written to the MySQL error log.

This variable was added in MySQL 5.1.6.

- `ndb_force_send`

Command Line Format	<code>--ndb-force-send</code>	
Config File Format	<code>ndb_force_send</code>	
Option Sets Variable	Yes, <code>ndb_force_send</code>	
Variable Name	<code>ndb_force_send</code>	
Variable Scope	Both	
Dynamic Variable	Yes	
Value Set	Type	boolean
	Default	TRUE

Forces sending of buffers to NDB immediately, without waiting for other threads. Defaults to ON.

- `ndb_index_stat_cache_entries`

Version Removed	5.1.14	
Command Line Format	<code>--ndb_index_stat_cache_entries</code>	
Config File Format	<code>ndb_index_stat_cache_entries</code>	
Value Set	Type	numeric
	Default	32
	Range	0-4294967295

Sets the granularity of the statistics by determining the number of starting and ending keys to store in the statistics memory cache. Zero means no caching takes place; in this case, the data nodes are always queried directly. Default value: 32.

- `ndb_index_stat_enable`

Version Removed	5.1.19	
Command Line Format	<code>--ndb_index_stat_enable</code>	
Config File Format	<code>ndb_index_stat_enable</code>	
Value Set	Type	boolean
	Default	ON

Use NDB index statistics in query optimization. Defaults to ON.

- `ndb_index_stat_update_freq`

Version Removed	5.1.14	
Command Line Format	<code>--ndb_index_stat_update_freq</code>	
Config File Format	<code>ndb_index_stat_update_freq</code>	
Value Set	Type	numeric
	Default	20
	Range	0-4294967295

How often to query data nodes instead of the statistics cache. For example, a value of 20 (the default) means to direct every 20th query to the data nodes.

- `ndb_optimized_node_selection`

Command Line Format	<code>--ndb-optimized-node-selection</code>	
Config File Format	<code>ndb_optimized_node_selection</code>	
Value Set	Type	<code>boolean</code>
	Default	<code>ON</code>

Prior to MySQL Cluster NDB 6.3.4. Causes an SQL node to use the “closest” data node as transaction coordinator. Enabled by default. Set to `0` or `OFF` to disable, in which case the SQL node uses each data node in the cluster in succession. When this option is disabled each SQL thread attempts to use a given data node 8 times before proceeding to the next one.

Beginning with MySQL Cluster NDB 6.3.4. There are two forms of optimized node selection:

1. The SQL node uses *proximity* to determine the transaction coordinator; that is, the “closest” data node to the SQL node is chosen as the transaction coordinator. For this purpose, a data node having a shared memory connection with the SQL node is considered to be “closest” to the SQL node; the next closest (in order of decreasing proximity) are: TCP connection to `localhost`; SCI connection; TCP connection from a host other than `localhost`.
2. The SQL thread uses *distribution awareness* to select the data node. That is, the data node housing the cluster partition accessed by the first statement of a given transaction is used as the transaction coordinator for the entire transaction. (This is effective only if the first statement of the transaction accesses no more than one cluster partition.)

This option takes one of the integer values `0`, `1`, `2`, or `3`. `3` is the default. These values affect node selection as follows:

- `0`: Node selection is not optimized. Each data node is employed as the transaction coordinator 8 times before the SQL thread proceeds to the next data node. (This is the same “round-robin” behavior as caused by setting this option to `0` or `OFF` in previous versions of MySQL Cluster.)
- `1`: Proximity to the SQL node is used to determine the transaction coordinator. (This is the same behavior as caused by setting this option to `1` or `ON` in previous MySQL versions.)
- `2`: Distribution awareness is used to select the transaction coordinator. However, if the first statement of the transaction accesses more than one cluster partition, the SQL node reverts to the round-robin behavior seen when this option is set to `0`.
- `3`: If distribution awareness can be employed to determine the transaction coordinator, then it is used; otherwise proximity is used to select the transaction coordinator. (This is the default behavior in MySQL Cluster NDB 6.3.4 and later.)

Important

Beginning with MySQL Cluster NDB 6.3.4, it is no longer possible to set `-ndb_optimized_node_selection` to `ON` or `OFF`; attempting to do so causes `mysqld` to abort with an error.

- `ndb_report_thresh_binlog_epoch_slip`

Command Line Format	<code>--ndb_report_thresh_binlog_epoch_slip</code>	
Config File Format	<code>ndb_report_thresh_binlog_epoch_slip</code>	
Value Set	Type	<code>numeric</code>
	Default	<code>3</code>
	Range	<code>0-256</code>

This is a threshold on the number of epochs to be behind before reporting binlog status. For example, a value of `3` (the default) means that if the difference between which epoch has been received from the storage nodes and which epoch has been applied to the binlog is 3 or more, a status message will be sent to the cluster log.

- `ndb_report_thresh_binlog_mem_usage`

Command Line Format	<code>--ndb_report_thresh_binlog_mem_usage</code>	
Config File Format	<code>ndb_report_thresh_binlog_mem_usage</code>	
Value Set	Type	<code>numeric</code>
	Default	<code>10</code>
	Range	<code>0-10</code>

This is a threshold on the percentage of free memory remaining before reporting binlog status. For example, a value of `10` (the default) means that if the amount of available memory for receiving binlog data from the data nodes falls below 10%, a status message will be sent to the cluster log.

- `ndb_use_copying_alter_table`

Version Introduced	5.1.12
Variable Name	<code>ndb_use_copying_alter_table</code>
Variable Scope	Both
Dynamic Variable	No

Forces `NDB` to use copying of tables in the event of problems with online `ALTER TABLE` operations. The default value is `OFF`.

This variable was added in MySQL 5.1.12.

- `ndb_use_exact_count`

Variable Name	<code>ndb_use_exact_count</code>	
Variable Scope	Both	
Dynamic Variable	Yes	
Value Set	Type	<code>boolean</code>
	Default	<code>ON</code>

Forces `NDB` to use a count of records during `SELECT COUNT(*)` query planning to speed up this type of query. The default value is `ON`. For faster queries overall, disable this feature by setting the value of `ndb_use_exact_count` to `OFF`.

- `ndb_use_transactions`

Command Line Format	<code>--ndb_use_transactions</code>	
Config File Format	<code>ndb_use_transactions</code>	
Value Set	Type	<code>boolean</code>
	Default	<code>ON</code>

You can disable `NDB` transaction support by setting this variable's values to `OFF` (not recommended). The default is `ON`.

Note

The setting for this variable was not honored in MySQL Cluster NDB 6.4.3 and MySQL Cluster NDB 7.0.4. ([Bug#43236](#))

- `ndb_wait_connected`

Version Introduced	5.1.16-ndb-6.2.0	
Command Line Format	<code>ndb_wait_connected</code>	
Config File Format	<code>ndb_wait_connected</code>	
Option Sets Variable	Yes, <code>ndb_wait_connected</code>	
Variable Name	<code>ndb_wait_connected</code>	
Variable Scope		
Dynamic Variable	No	
Value Set	Type	<code>numeric</code>
	Default	<code>0</code>

This variable can be used to cause the MySQL server to wait a given period of time for connections to MySQL Cluster management and data nodes to be established before accepting MySQL client connections. The time is specified in seconds. The default value is `0`.

17.4.4. MySQL Cluster Status Variables

This section provides detailed information about MySQL server status variables that relate to MySQL Cluster and the [NDB](#) storage engine. For status variables not specific to MySQL Cluster, and for general information on using status variables, see [Section 5.1.6](#), “[Server Status Variables](#)”.

- [Handler_discover](#)

The MySQL server can ask the [NDBCLUSTER](#) storage engine if it knows about a table with a given name. This is called discovery. [Handler_discover](#) indicates the number of times that tables have been discovered via this mechanism.

- [Ndb_cluster_node_id](#)

If the server is acting as a MySQL Cluster node, then the value of this variable is its node ID in the cluster.

If the server is not part of a MySQL Cluster, then the value of this variable is 0.

- [Ndb_config_from_host](#)

If the server is part of a MySQL Cluster, the value of this variable is the host name or IP address of the Cluster management server from which it gets its configuration data.

If the server is not part of a MySQL Cluster, then the value of this variable is an empty string.

Prior to MySQL 5.1.12, this variable was named [Ndb_connected_host](#).

- [Ndb_config_from_port](#)

If the server is part of a MySQL Cluster, the value of this variable is the number of the port through which it is connected to the Cluster management server from which it gets its configuration data.

If the server is not part of a MySQL Cluster, then the value of this variable is 0.

Prior to MySQL 5.1.12, this variable was named [Ndb_connected_port](#).

- [Ndb_execute_count](#)

Provides the number of round trips to the [NDB](#) kernel made by operations. Added in MySQL Cluster NDB 6.3.6.

- [Ndb_number_of_data_nodes](#)

If the server is part of a MySQL Cluster, the value of this variable is the number of data nodes in the cluster.

If the server is not part of a MySQL Cluster, then the value of this variable is 0.

Prior to MySQL 5.1.12, this variable was named [Ndb_number_of_storage_nodes](#).

- [Slave_heartbeat_period](#)

Shows the replication heartbeat interval (in seconds) on a replication slave.

This variable was added in MySQL Cluster NDB 6.3.4.

- [Slave_received_heartbeats](#)

This counter increments with each replication heartbeat received by a replication slave since the last time that the slave was restarted or reset, or a [CHANGE MASTER TO](#) statement was issued.

This variable was added in MySQL Cluster NDB 6.3.4.

- [Ndb_pruned_scan_count](#)

This variable holds a count of the number of scans executed by [NDBCLUSTER](#) since the MySQL Cluster was last started where [NDBCLUSTER](#) was able to use partition pruning.

Using this variable together with [Ndb_scan_count](#) can be helpful in schema design to maximize the ability of the server to prune scans to a single table partition, thereby involving only a single data node.

This variable was added in MySQL Cluster NDB 6.3.25 and MySQL Cluster NDB 7.0.5.

- [Ndb_scan_count](#)

This variable holds a count of the total number of scans executed by `NDBCLUSTER` since the MySQL Cluster was last started.

This variable was added in MySQL Cluster NDB 6.3.25 and MySQL Cluster NDB 7.0.5.

17.5. Upgrading and Downgrading MySQL Cluster

This portion of the MySQL Cluster chapter covers upgrading and downgrading a MySQL Cluster from one MySQL release to another. It discusses different types of Cluster upgrades and downgrades, and provides a Cluster upgrade/downgrade compatibility matrix (see [Section 17.5.2, “MySQL Cluster 5.1 and MySQL Cluster NDB 6.x/7.x Upgrade and Downgrade Compatibility”](#)). You are expected already to be familiar with installing and configuring a MySQL Cluster prior to attempting an upgrade or downgrade. See [Section 17.3, “MySQL Cluster Configuration”](#).

For information about upgrading or downgrading between MySQL Cluster NDB releases, or between MySQL Cluster NDB releases and mainline MySQL releases, see the changelogs relating to MySQL Cluster NDB.

This section remains in development, and continues to be updated and expanded.

17.5.1. Performing a Rolling Restart of a MySQL Cluster

This section discusses how to perform a *rolling restart* of a MySQL Cluster installation, so called because it involves stopping and starting (or restarting) each node in turn, so that the cluster itself remains operational. This is often done as part of a *rolling upgrade* or *rolling downgrade*, where high availability of the cluster is mandatory and no downtime of the cluster as a whole is permissible. Where we refer to upgrades, the information provided here also generally applies to downgrades as well.

There are a number of reasons why a rolling restart might be desirable:

- **Cluster configuration change.** To make a change in the cluster's configuration, such as adding an SQL node to the cluster, or setting a configuration parameter to a new value.
- **Cluster software upgrade/downgrade.** To upgrade the cluster to a newer version of the MySQL Cluster software (or to downgrade it to an older version). This is usually referred to as a “rolling upgrade” (or “rolling downgrade”, when reverting to an older version of MySQL Cluster).
- **Change on node host.** To make changes in the hardware or operating system on which one or more cluster nodes are running
- **Cluster reset.** To reset the cluster because it has reached an undesirable state
- **Freeing of resources.** To allow memory allocated to a table by successive `INSERT` and `DELETE` operations to be freed for reuse by other Cluster tables

The process for performing a rolling restart may be generalised as follows:

1. Stop all cluster management nodes (`ndb_mgmd` processes), reconfigure them, then restart them
2. Stop, reconfigure, then restart each cluster data node (`ndbd` process) in turn
3. Stop, reconfigure, then restart each cluster SQL node (`mysqld` process) in turn

The specifics for implementing a particular rolling upgrade depend upon the actual changes being made. A more detailed view of the process is presented here:

RESTART TYPE:					
Cluster Configuration Change		Cluster Software Upgrade or Downgrade	Change on Node Host	Cluster Reset	
A. Management node (ndb_mgmd) processes...					
1. Stop all ndb_mgmd processes 2. Make changes in global configuration file(s) 3. Start all ndb_mgmd processes		1. Stop all ndb_mgmd processes 2. Replace each ndb_mgmd binary with new version 3. Start ndb_mgmd processes	1. Stop all ndb_mgmd processes 2. Make desired changes in hardware, operating system, or both 3. Start all ndb_mgmd processes	(OR)	
				1. Stop all ndb_mgmd processes 2. Start all ndb_mgmd processes	Restart all ndb_mgmd processes (optional)
B. For each data node (ndbd) process...					
(OR)		1. Stop ndbd 2. Replace ndbd binary with new version 3. Start ndbd	1. Stop ndbd 2. Make desired changes in hardware, operating system, or both 3. Start ndbd	(OR)	
1. Stop ndbd 2. Start ndbd	Restart ndbd			1. Stop ndbd 2. Start ndbd	Restart ndbd
C. For each SQL node (mysqld) process...					
(OR)		1. Stop mysqld 2. Replace mysqld binary with new version 3. Start mysqld	1. Stop mysqld 2. Make desired changes in hardware, operating system, or both 3. Start mysqld	(OR)	
1. Stop mysqld 2. Start mysqld	Restart mysqld			1. Stop mysqld 2. Start mysqld	Restart mysqld

In the previous diagram, **Stop** and **Start** steps indicate that the process must be stopped completely using a shell command (such as `kill` on most Unix systems) or the management client `STOP` command, then started again from a system shell by invoking the `ndbd` or `ndb_mgmd` executable as appropriate. **Restart** indicates the process may be restarted using the `ndb_mgm` management client `RESTART` command.

Important

When performing an upgrade or downgrade of the cluster software, you *must* upgrade or downgrade the management nodes *first*, then the data nodes, and finally the SQL nodes. Doing so in any other order may leave the cluster in an unusable state.

17.5.2. MySQL Cluster 5.1 and MySQL Cluster NDB 6.x/7.x Upgrade and Downgrade Compatibility

This section provides information about MySQL Cluster software and table file compatibility between MySQL 5.1 and MySQL Cluster NDB 6.x releases with regard to performing upgrades and downgrades.

Important

Only compatibility between MySQL versions with regard to [NDBCLUSTER](#) is taken into account in this section, and there are likely other issues to be considered. *As with any other MySQL software upgrade or downgrade, you are strongly encouraged to review the relevant portions of the MySQL Manual for the MySQL versions from which and to which you intend to migrate, before attempting an upgrade or downgrade of the MySQL Cluster software. See [Section 2.12.1, “Upgrading MySQL”](#).*

The following table shows Cluster upgrade and downgrade compatibility between different releases of MySQL 5.1:

Notes — MySQL 5.1.

- MySQL 5.1.3 was the first public release in this series.
- Direct upgrades or downgrades between MySQL Cluster 5.0 and 5.1 are not supported; you must dump all **NDBCLUSTER** tables using `mysqldump`, install the new version of the software, and then reload the tables from the dump.
- You cannot downgrade a MySQL 5.1.6 or later Cluster using Disk Data tables to MySQL 5.1.5 or earlier unless you convert all such tables to in-memory Cluster tables first.
- MySQL 5.1.8, MySQL 5.1.10, and MySQL 5.1.13 were not released.
- Online cluster upgrades and downgrades between MySQL 5.1.11 (or an earlier version) and 5.1.12 (or a later version) are not possible due to major changes in the cluster file system. In such cases, you must perform a backup or dump, upgrade (or downgrade) the software, start each data node with `--initial`, and then restore from the backup or dump. You can use **NDB** backup/restore or `mysqldump` for this purpose.
- Online downgrades from MySQL 5.1.14 or later to versions previous to 5.1.14 are not supported due to incompatible changes in the cluster system tables.
- Online upgrades from MySQL 5.1.17 and earlier to 5.1.18 and later are not supported for clusters using replication due to incompatible changes in the `mysql.ndb_apply_status` table. However, it should not be necessary to shut down the cluster entirely, if you follow this modified rolling restart procedure:
 1. Stop the management server, update the `ndb_mgmd` binary, then start it again. For multiple management servers, repeat this step for each management server in turn.
 2. For each data node in turn: Stop the data node, replace the `ndbd` binary with the new version, then restart the data node. It is not necessary to use `--initial` when restarting any of the data nodes.
 3. Stop *all* SQL nodes. Replace the `mysqld` binary with the new version for all SQL nodes, then restart them. It is not necessary to start them one at a time, but they must all be shut down at the same time before starting any of them again using the 5.1.18 (or later) `mysqld`. Otherwise — due to the fact that `mysql.ndb_apply_status` uses the **NDB** storage engine and is thus shared between all SQL nodes — there may be conflicts between MySQL servers using the old and new versions of the table.
You can find more information about the changes to `ndb_apply_status` in [Section 17.9.4, “MySQL Cluster Replication Schema and Tables”](#).
- The internal specifications for columns in **NDBCLUSTER** tables changed in MySQL 5.1.18 to allow compatibility with later MySQL Cluster releases that allow online adding and dropping of columns. *This change is not backward-compatible with earlier MySQL versions.*

In order to make tables created in MySQL 5.1.17 and earlier compatible with online adding and dropping of columns (available beginning with beginning with MySQL Cluster NDB 6.2.5 and MySQL Cluster NDB 6.3.3 — see [Section 12.1.7, “ALTER TABLE Syntax”](#), for more information), it is necessary to force MySQL 5.1.18 and later to convert the tables to the new format by following this procedure:

1. Back up all **NDBCLUSTER** tables.
2. Upgrade the MySQL Cluster software on all data, management, and SQL nodes.
3. Shut down the cluster completely (this includes all data, management, and API or SQL nodes).
4. Restart the cluster, starting all data nodes with the `--initial` option (to clear and rebuild the data node file systems).
5. Restore the **NDBCLUSTER** tables from backup.

This is not necessary for **NDBCLUSTER** tables created in MySQL 5.1.18 and later; such tables will automatically be compatible with online adding and dropping of columns (as implemented beginning with MySQL Cluster NDB 6.2.5 and MySQL Cluster NDB 6.3.2).

In order to minimise possible later difficulties, it is strongly advised that the procedure outlined above be followed as soon as possible after to upgrading from MySQL 5.1.17 or earlier to MySQL 5.1.18 or later.

Information about how this change effects users of MySQL Cluster NDB 6.x/7.0 is provided later in this section.

- MySQL Cluster is not supported in standard MySQL 5.1 releases, beginning with MySQL 5.1.25. If you are using MySQL Cluster in a standard MySQL 5.1 release, you should upgrade to the most recent MySQL Cluster NDB 6.2 or 6.3 release.

The following table shows Cluster upgrade and downgrade compatibility between different releases of MySQL Cluster NDB 6.x/7.0:

MySQL Cluster NDB 6.x/7.0				
NDB 6.1†		NDB 6.2	NDB 6.3	NDB 7.0
			6.3.25	
			6.3.24	
			6.3.23	
			6.3.22	
			6.3.21	
			6.3.20	
			6.3.19	
		6.2.19	6.3.18	
	6.1.18*	6.2.18	6.3.17	
	6.1.17	6.2.17	6.3.16	
	6.1.16	6.2.16	6.3.15	
	6.1.15	6.2.15	6.3.14	
	6.1.14	6.2.14	6.3.13	
	6.1.13	6.2.13	6.3.12*	
	6.1.12	6.2.12	6.3.11*	
	6.1.11	6.2.11	6.3.10	
	6.1.10	6.2.10	6.3.9	
	6.1.9	6.2.9	6.3.8	
	6.1.8	6.2.8	6.3.7	
	6.1.7	6.2.7	6.3.6	7.0.7
	6.1.6*	6.2.6	6.3.5	7.0.6
	6.1.5	6.2.5	6.3.4	7.0.5
	6.1.4	6.2.4	6.3.3	7.0.4
	6.1.3	6.2.3	6.3.2	6.4.3
	6.1.2	6.2.2	6.3.1	6.4.2
	6.1.1	6.2.1	6.3.0	6.4.1
	6.1.0	6.2.0		6.4.0

KEY:

- ↕ Online upgrades and downgrades possible
- ↑ Online downgrades not possible

* Unreleased or withdrawn following release.

† The NDB 6.1 series is no longer in production.

Notes — MySQL Cluster NDB 6.x/7.x.

- MySQL Cluster NDB 6.1 is no longer in production; if you are still using a MySQL Cluster NDB 6.1 release, you should upgrade to the most recent MySQL Cluster NDB 6.2 or 6.3 as soon as possible.
- It is not possible to upgrade from MySQL Cluster NDB 6.1.2 (or an older 6.1 release) directly to 6.1.4 or a newer NDB 6.1 release, or to downgrade from 6.1.4 (or a newer 6.1 release) directly to 6.1.2 or an older NDB 6.1 release; in either case, you must upgrade or downgrade to MySQL Cluster NDB 6.1.3 first.
- It is not possible to perform an online downgrade from MySQL Cluster NDB 6.1.8 (or a newer 6.1 release) to MySQL Cluster NDB 6.1.7 (or an older 6.1 release).
- MySQL Cluster NDB 6.1.6 and 6.1.18 were not released.
- It is not possible to perform an online upgrade or downgrade between MySQL Cluster NDB 6.2 and any previous release series (including mainline MySQL 5.1 and MySQL Cluster NDB 6.1); it is necessary to perform a dump and reload. However, it should be possible to perform online upgrades or downgrades between any MySQL Cluster NDB 6.2 release and any MySQL Cluster NDB 6.3 release up to and including 6.3.7.
- The internal specifications for columns in **NDB** tables changed in MySQL Cluster NDB 6.1.17 and 6.2.1 to allow compatibility with future MySQL Cluster releases that are expected to implement online adding and dropping of columns. This change is not backward-compatible with earlier MySQL or MySQL Cluster NDB 6.x versions.

In order to make tables created in earlier versions compatible with online adding and dropping of columns in later versions, it is necessary to force MySQL Cluster to convert the tables to the new format by following this procedure following an upgrade:

1. Upgrade the MySQL Cluster software on all data, management, and SQL nodes
2. Back up all **NDB** tables
3. Shut down the cluster (all data, management, and SQL nodes)
4. Restart the cluster, starting all data nodes with the `--initial` option (to clear and rebuild the data node file systems)
5. Restore the tables from backup

In order to minimise possible later difficulties, it is strongly advised that the procedure outlined above be followed as soon as possible after to upgrading between the versions indicated. The procedure is *not* necessary for **NDBCLUSTER** tables created in any of the following versions:

- MySQL Cluster NDB 6.1.8 or a later MySQL Cluster NDB 6.1 release
 - MySQL Cluster 6.2.1 or a later MySQL Cluster NDB 6.2 release
 - Any MySQL Cluster NDB 6.3 release
- Tables created in the listed versions (or later ones, as indicated) are already compatible with online adding and dropping of columns (as implemented beginning with MySQL Cluster NDB 6.2.5 and MySQL Cluster NDB 6.3.2).
- It was not possible to perform an online upgrade between any MySQL Cluster NDB 6.2 release and MySQL Cluster NDB 6.3.8 and later MySQL Cluster 6.3 releases. This issue was fixed in MySQL Cluster NDB 6.3.21. ([Bug#41435](#))
 - Online downgrades between MySQL Cluster NDB 6.2.5 and earlier releases are not supported.
 - Online downgrades between MySQL Cluster NDB 6.3.8 and earlier releases are not supported.
 - Online upgrades from any MySQL Cluster NDB 7.0 release up to and including MySQL Cluster NDB 7.0.4 (as well as all early releases numbered NDB 6.4.x) to MySQL Cluster NDB 7.0.5 or later are not possible. Upgrades to MySQL Cluster NDB 7.0.6 or later from MySQL Cluster NDB 6.3.8 or a later MySQL Cluster NDB 6.3 release, or from MySQL Cluster NDB 7.0.5 or later, are supported. ([Bug#44294](#))

17.6. MySQL Cluster Programs

Using and managing a MySQL Cluster requires several specialized programs, which we describe in this chapter. We discuss the purposes of these programs in a MySQL Cluster, how to use the programs, and what startup options are available for each of them.

These programs include the MySQL Cluster data, management, and SQL node process daemons (`ndbd`, `ndb_mgmd`, and `mysqld`) and the management client (`ndb_mgm`).

Other NDB utility, diagnostic, and example programs are included with the MySQL Cluster distribution. These include

`ndb_restore`, `ndb_show_tables`, and `ndb_config`). These programs are covered later in this chapter.

The last two sections of this chapter contain tables of options used, respectively, with `mysqld` and with the various NDB programs.

17.6.1. MySQL Server Usage for MySQL Cluster

`mysqld` is the traditional MySQL server process. To be used with MySQL Cluster, `mysqld` needs to be built with support for the `NDBCLUSTER` storage engine, as it is in the precompiled binaries available from <http://dev.mysql.com/downloads/>. If you build MySQL from source, you must invoke `configure` with the `--with-ndbcluster` option to enable `NDB Cluster` storage engine support.

If the `mysqld` binary has been built with Cluster support, the `NDBCLUSTER` storage engine is still disabled by default. You can use either of two possible options to enable this engine:

- Use `--ndbcluster` as a startup option on the command line when starting `mysqld`.
- Insert a line containing `NDBCLUSTER` in the `[mysqld]` section of your `my.cnf` file.

An easy way to verify that your server is running with the `NDBCLUSTER` storage engine enabled is to issue the `SHOW ENGINES` statement in the MySQL Monitor (`mysql`). You should see the value `YES` as the `Support` value in the row for `NDBCLUSTER`. If you see `NO` in this row or if there is no such row displayed in the output, you are not running an `NDB-enabled` version of MySQL. If you see `DISABLED` in this row, you need to enable it in either one of the two ways just described.

To read cluster configuration data, the MySQL server requires at a minimum three pieces of information:

- The MySQL server's own cluster node ID
- The host name or IP address for the management server (MGM node)
- The number of the TCP/IP port on which it can connect to the management server

Node IDs can be allocated dynamically, so it is not strictly necessary to specify them explicitly.

The `mysqld` parameter `ndb-connectstring` is used to specify the connectstring either on the command line when starting `mysqld` or in `my.cnf`. The connectstring contains the host name or IP address where the management server can be found, as well as the TCP/IP port it uses.

In the following example, `ndb_mgmd.mysql.com` is the host where the management server resides, and the management server listens for cluster messages on port 1186:

```
shell> mysqld --ndbcluster --ndb-connectstring=ndb_mgmd.mysql.com:1186
```

See [Section 17.3.4.3, “The MySQL Cluster Connectstring”](#), for more information on connectstrings.

Given this information, the MySQL server will be a full participant in the cluster. (We often refer to a `mysqld` process running in this manner as an SQL node.) It will be fully aware of all cluster data nodes as well as their status, and will establish connections to all data nodes. In this case, it is able to use any data node as a transaction coordinator and to read and update node data.

You can see in the `mysql` client whether a MySQL server is connected to the cluster using `SHOW PROCESSLIST`. If the MySQL server is connected to the cluster, and you have the `PROCESS` privilege, then the first row of the output is as shown here:

```
mysql> SHOW PROCESSLIST \G
***** 1. row *****
  Id: 1
  User: system user
  Host:
  db:
  Command: Daemon
  Time: 1
  State: Waiting for event from ndbcluster
  Info: NULL
```

Important

To participate in a MySQL Cluster, the `mysqld` process must be started with *both* the options `--ndbcluster` and `--ndb-connectstring` (or their equivalents in `my.cnf`). If `mysqld` is started with only the `--ndbcluster` option, or if it is unable to contact the cluster, it is not possible to work with `NDB` tables, *nor is it possible to create any new tables regardless of storage engine*. The latter restriction is a safety measure intended to prevent the creation

of tables having the same names as NDB tables while the SQL node is not connected to the cluster. If you wish to create tables using a different storage engine while the `mysqld` process is not participating in a MySQL Cluster, you must restart the server *without* the `--ndbcluster` option.

17.6.2. `ndbd` — The MySQL Cluster Data Node Daemon

`ndbd` is the process that is used to handle all the data in tables using the NDB Cluster storage engine. This is the process that empowers a data node to accomplish distributed transaction handling, node recovery, checkpointing to disk, online backup, and related tasks.

In a MySQL Cluster, a set of `ndbd` processes cooperate in handling data. These processes can execute on the same computer (host) or on different computers. The correspondences between data nodes and Cluster hosts is completely configurable.

The following list describes command options specific to the MySQL Cluster data node program `ndbd`.

Note

All of these options also apply to the multi-threaded version of this program — `ndbmt`, which is available in MySQL Cluster NDB 7.0 — and you may substitute “`ndbmt`” for “`ndbd`” wherever the latter occurs in this section.

For options common to all NDBCLUSTER programs, see [Section 17.6.23, “Options Common to MySQL Cluster Programs”](#).

- `--bind-address`

Version Introduced	5.1.12	
Command Line Format	<code>--bind-address=name</code>	
Value Set	Type	<code>string</code>
	Default	

Causes `ndbd` to bind to a specific network interface (host name or IP address). This option has no default value.

This option was added in MySQL 5.1.12.

- `--daemon, -d`

Command Line Format	<code>--daemon</code>	
Value Set	Type	<code>boolean</code>
	Default	<code>TRUE</code>

Instructs `ndbd` to execute as a daemon process. This is the default behavior. `--nodaemon` can be used to prevent the process from running as a daemon.

- `--initial`

Command Line Format	<code>--initial</code>	
Value Set	Type	<code>boolean</code>
	Default	<code>FALSE</code>

Instructs `ndbd` to perform an initial start. An initial start erases any files created for recovery purposes by earlier instances of `ndbd`. It also re-creates recovery log files. Note that on some operating systems this process can take a substantial amount of time.

An `--initial` start is to be used *only* when starting the `ndbd` process under very special circumstances; this is because this option causes all files to be removed from the Cluster file system and all redo log files to be re-created. These circumstances are listed here:

- When performing a software upgrade which has changed the contents of any files.
- When restarting the node with a new version of `ndbd`.
- As a measure of last resort when for some reason the node restart or system restart repeatedly fails. In this case, be aware

that this node can no longer be used to restore data due to the destruction of the data files.

Important

This option does *not* affect either of the following:

- Backup files that have already been created by the affected node
- MySQL Cluster Disk Data files (see [Section 17.10, “MySQL Cluster Disk Data Tables”](#)).

It is permissible to use this option when starting the cluster for the very first time (that is, before any data node files have been created); however, it is *not* necessary to do so.

- `--initial-start`

Version Introduced	5.1.11	
Command Line Format	<code>--initial-start</code>	
Value Set	Type	boolean
	Default	FALSE

This option is used when performing a partial initial start of the cluster. Each node should be started with this option, as well as `--nowait-nodes`.

For example, suppose you have a 4-node cluster whose data nodes have the IDs 2, 3, 4, and 5, and you wish to perform a partial initial start using only nodes 2, 4, and 5 — that is, omitting node 3:

```
ndbd --ndbd-nodeid=2 --nowait-nodes=3 --initial-start
ndbd --ndbd-nodeid=4 --nowait-nodes=3 --initial-start
ndbd --ndbd-nodeid=5 --nowait-nodes=3 --initial-start
```

This option was added in MySQL 5.1.11.

Important

Prior to MySQL 5.1.19, it was not possible to perform DDL operations involving Disk Data tables on a partially started cluster. (See [Bug#24631](#).)

- `--nowait-nodes=node_id_1[, node_id_2[, ...]]`

Version Introduced	5.1.11	
Command Line Format	<code>--nowait-nodes=list</code>	
Value Set	Type	string
	Default	

This option takes a list of data nodes which for which the cluster will not wait for before starting.

This can be used to start the cluster in a partitioned state. For example, to start the cluster with only half of the data nodes (nodes 2, 3, 4, and 5) running in a 4-node cluster, you can start each `ndbd` process with `--nowait-nodes=3,5`. In this case, the cluster starts as soon as nodes 2 and 4 connect, and does *not* wait `StartPartitionedTimeout` milliseconds for nodes 3 and 5 to connect as it would otherwise.

If you wanted to start up the same cluster as in the previous example without one `ndbd` — say, for example, that the host machine for node 3 has suffered a hardware failure — then start nodes 2, 4, and 5 with `--nowait-nodes=3`. Then the cluster will start as soon as nodes 2, 4, and 5 connect and will not wait for node 3 to start.

This option was added in MySQL 5.1.9.

- `--nodaemon`

Command Line Format	<code>--nodaemon</code>
----------------------------	-------------------------

Value Set	Type	boolean
	Default	FALSE

Instructs `ndbd` not to start as a daemon process. This is useful when `ndbd` is being debugged and you want output to be redirected to the screen.

- `--nostart, -n`

Command Line Format	<code>--nostart</code>	
Value Set	Type	boolean
	Default	FALSE

Instructs `ndbd` not to start automatically. When this option is used, `ndbd` connects to the management server, obtains configuration data from it, and initializes communication objects. However, it does not actually start the execution engine until specifically requested to do so by the management server. This can be accomplished by issuing the proper `START` command in the management client (see Section 17.7.2, “Commands in the MySQL Cluster Management Client”).

`ndbd` generates a set of log files which are placed in the directory specified by `DataDir` in the `config.ini` configuration file.

These log files are listed below. `node_id` is the node's unique identifier. Note that `node_id` represents the node's unique identifier. For example, `ndb_2_error.log` is the error log generated by the data node whose node ID is 2.

- `ndb_node_id_error.log` is a file containing records of all crashes which the referenced `ndbd` process has encountered. Each record in this file contains a brief error string and a reference to a trace file for this crash. A typical entry in this file might appear as shown here:

```
Date/Time: Saturday 30 July 2004 - 00:20:01
Type of error: error
Message: Internal program error (failed ndbrequire)
Fault ID: 2341
Problem data: DbtupFixAlloc.cpp
Object of reference: DBTUP (Line: 173)
ProgramName: NDB Kernel
ProcessID: 14909
TraceFile: ndb_2_trace.log.2
***EOM***
```

Listings of possible `ndbd` exit codes and messages generated when a data node process shuts down prematurely can be found in [ndbd Error Messages](#).

Important

The last entry in the error log file is not necessarily the newest one (nor is it likely to be). Entries in the error log are not listed in chronological order; rather, they correspond to the order of the trace files as determined in the `ndb_node_id_trace.log.next` file (see below). Error log entries are thus overwritten in a cyclical and not sequential fashion.

- `ndb_node_id_trace.log.trace_id` is a trace file describing exactly what happened just before the error occurred. This information is useful for analysis by the MySQL Cluster development team.
- It is possible to configure the number of these trace files that will be created before old files are overwritten. `trace_id` is a number which is incremented for each successive trace file.
- `ndb_node_id_trace.log.next` is the file that keeps track of the next trace file number to be assigned.
 - `ndb_node_id_out.log` is a file containing any data output by the `ndbd` process. This file is created only if `ndbd` is started as a daemon, which is the default behavior.
 - `ndb_node_id.pid` is a file containing the process ID of the `ndbd` process when started as a daemon. It also functions as a lock file to avoid the starting of nodes with the same identifier.
 - `ndb_node_id_signal.log` is a file used only in debug versions of `ndbd`, where it is possible to trace all incoming, out-

going, and internal messages with their data in the `ndbd` process.

It is recommended not to use a directory mounted through NFS because in some environments this can cause problems whereby the lock on the `.pid` file remains in effect even after the process has terminated.

To start `ndbd`, it may also be necessary to specify the host name of the management server and the port on which it is listening. Optionally, one may also specify the node ID that the process is to use.

```
shell> ndbd --connect-string="nodeid=2;host=ndb_mgmd.mysql.com:1186"
```

See [Section 17.3.4.3, “The MySQL Cluster Connectstring”](#), for additional information about this issue. [Section 17.6.2, “ndbd — The MySQL Cluster Data Node Daemon”](#), describes other options for `ndbd`.

When `ndbd` starts, it actually initiates two processes. The first of these is called the “angel process”; its only job is to discover when the execution process has been completed, and then to restart the `ndbd` process if it is configured to do so. Thus, if you attempt to kill `ndbd` via the Unix `kill` command, it is necessary to kill both processes, beginning with the angel process. The preferred method of terminating an `ndbd` process is to use the management client and stop the process from there.

The execution process uses one thread for reading, writing, and scanning data, as well as all other activities. This thread is implemented asynchronously so that it can easily handle thousands of concurrent actions. In addition, a watch-dog thread supervises the execution thread to make sure that it does not hang in an endless loop. A pool of threads handles file I/O, with each thread able to handle one open file. Threads can also be used for transporter connections by the transporters in the `ndbd` process. In a multi-processor system performing a large number of operations (including updates), the `ndbd` process can consume up to 2 CPUs if permitted to do so.

For a machine with many CPUs it is possible to use several `ndbd` processes which belong to different node groups; however, such a configuration is still considered experimental and is not supported for MySQL 5.1 in a production setting. See [Section 17.12, “Known Limitations of MySQL Cluster”](#).

17.6.3. `ndbmt` — The MySQL Cluster Data Node Daemon (Multi-Threaded)

`ndbmt` is a multi-threaded version of `ndbd`, the process that is used to handle all the data in tables using the `NDBCLUSTER` storage engine. `ndbmt` is intended for use on host computers having multiple CPU cores. Except where otherwise noted, `ndbmt` functions in the same way as `ndbd`; therefore, in this section, we concentrate on the ways in which `ndbmt` differs from `ndbd`, and you should consult [Section 17.6.2, “ndbd — The MySQL Cluster Data Node Daemon”](#), for additional information about running MySQL Cluster data nodes that apply to both the single-threaded and multi-threaded versions of the data node process.

Command-line options and configuration parameters used with `ndbd` also apply to `ndbmt`. For more information about these options and parameters, see [Section 17.6.2.4.2, “Program Options for ndbd and ndbmt”](#), and [Section 17.3.4.6, “Defining MySQL Cluster Data Nodes”](#), respectively.

`ndbmt` is also file system-compatible with `ndbd`. In other words, a data node running `ndbd` can be stopped, the binary replaced with `ndbmt`, and then restarted without any loss of data. (However, when doing this, you must make sure that `MaxNoOfExecutionThreads` is set to an appropriate value before restarting the node if you wish for `ndbmt` to run in multi-threaded fashion.) Similarly, an `ndbmt` binary can be replaced with `ndbd` simply by stopping the node and then starting `ndbd` in place of the multi-threaded binary. It is not necessary when switching between the two to start the data node binary using `--initial`.

Important

We do not currently recommend using `ndbmt` with MySQL Cluster Disk Data tables in production, due to known issues which we are working to fix in a future MySQL Cluster release. ([Bug#41915](#), [Bug#44915](#))

Using `ndbmt` differs from using `ndbd` in two key respects:

1. You must set an appropriate value for the `MaxNoOfExecutionThreads` configuration parameter in the `config.ini` file. If you do not do so, `ndbmt` runs in single-threaded mode — that is, it behaves like `ndbd`.
2. Trace files are generated by critical errors in `ndbmt` processes in a somewhat different fashion from how these are generated by `ndbd` failures.

These differences are discussed in more detail in the next few paragraphs.

Number of execution threads. The `MaxNoOfExecutionThreads` configuration parameter is used to determine the number of local query handler (LQH) threads spawned by `ndbmt`. Although this parameter is set in `[ndbd]` or `[ndbd default]` sections of the `config.ini` file, it is exclusive to `ndbmt` and does not apply to `ndbd`.

This parameter takes an integer value from 2 to 8 inclusive. Generally, you should set this to the number of CPU cores on the data

node host, as shown in the following table:

Number of Cores	Recommended <code>MaxNoOfExecutionThreads</code> Value
2	2
4	4
8 or more	8

(It is possible to set this parameter to other values within the permitted range, but these are automatically rounded as shown in the **Value Used** column of the next table in this section.)

The multi-threaded data node process always spawns at least 4 threads:

- 1 local query handler (LQH) thread
- 1 transaction coordinator (TC) thread
- 1 transporter thread
- 1 subscription manager (SUMA) thread

Setting this parameter to a value between 4 and 8 inclusive causes additional LQH threads to be used by `ndbmt_d` (up to a maximum of 4 LQH threads), as shown in the following table:

<code>config.ini</code> Value	Value Used	Number of LQH Threads Used
3	2	1
5 or 6	4	2
7	8	4

Setting this parameter outside the permitted range of values causes the management server to abort on startup with the error `ERROR LINE NUMBER: ILLEGAL VALUE VALUE FOR PARAMETER MAXNOOFEXECUTIONTHREADS`.

Note

In MySQL Cluster NDB 6.4.0, it is not possible to set `MaxNoOfExecutionThreads` to 2. You can safely use the value 3 instead (it is treated as 2 internally). This issue is resolved in MySQL Cluster NDB 6.4.1.

In MySQL Cluster NDB 6.4.0 through 6.4.3, the default value for this parameter was undefined, although the default behavior for `ndbmt_d` was to use 1 LQH thread, as though `MaxNoOfExecutionThreads` had been set to 2. Beginning with MySQL Cluster NDB 7.0.4, this parameter has an explicit default value of 2, thus guaranteeing this default behavior.

In MySQL Cluster NDB 7.0, it is not possible to cause `ndbmt_d` to use more than 1 TC thread, although we plan to introduce this capability in a future MySQL Cluster release series.

Like `ndbd`, `ndbmt_d` generates a set of log files which are placed in the directory specified by `DataDir` in the `config.ini` configuration file. Except for trace files, these are generated in the same way and have the same names as those generated by `ndbd`.

In the event of a critical error, `ndbmt_d` generates trace files describing what happened just prior to the error's occurrence. These files, which can be found in the data node's `DataDir`, are useful for analysis of problems by the MySQL Cluster Development and Support teams. One trace file is generated for each `ndbmt_d` thread. The names of these files follow the pattern `ndb_node_id_trace.log.trace_id_tthread_id`, where `node_id` is the data node's unique node ID in the cluster, `trace_id` is a trace sequence number, and `thread_id` is the thread ID. For example, in the event of the failure of an `ndbmt_d` process running as a MySQL Cluster data node having the node ID 3 and with `MaxNoOfExecutionThreads` equal to 4, four trace files are generated in the data node's data directory; if this is the first time this node has failed, then these files are named `ndb_3_trace.log.1_t1`, `ndb_3_trace.log.1_t2`, `ndb_3_trace.log.1_t3`, and `ndb_3_trace.log.1_t4`. Internally, these trace files follow the same format as `ndbd` trace files.

The `ndbd` exit codes and messages that are generated when a data node process shuts down prematurely are also used by `ndbmt_d`. See [ndbd Error Messages](#), for a listing of these.

Note

It is possible to use `ndbd` and `ndbmt_d` concurrently on different data nodes in the same MySQL Cluster. However,

such configurations have not been tested extensively; thus, we cannot not recommend doing so in a production setting at this time.

17.6.4. `ndb_mgmd` — The MySQL Cluster Management Server Daemon

The management server is the process that reads the cluster configuration file and distributes this information to all nodes in the cluster that request it. It also maintains a log of cluster activities. Management clients can connect to the management server and check the cluster's status.

The following list includes options that are specific to `ndb_mgmd`. For options common to all NDB programs, see [Section 17.6.23, “Options Common to MySQL Cluster Programs”](#).

- `--bind-address=host[:port]`

Version Introduced	5.1.22-ndb-6.3.2	
Command Line Format	<code>--bind-address</code>	
Value Set	Type	string
	Default	[none]

When specified, this option limits management server connections by management clients to clients at the specified host name or IP address (and possibly port, if this is also specified). In such cases, a management client attempting to connect to the management server from any other address fails with the error `UNABLE TO SETUP PORT: HOST:PORT!`

If the `port` is not specified, the management client attempts to use port 1186.

This option was added in MySQL Cluster NDB 6.2.5 and MySQL Cluster NDB 6.3.2.

- `--configdir=directory`

Version Introduced	5.1.30-ndb-6.4.0	
Command Line Format	<code>--configdir=directory</code>	
Value Set	Type	filename
	Default	<code>\$INSTALLDIR/mysql-cluster</code>

Beginning with MySQL Cluster NDB 6.4.0, configuration data is cached internally rather than being read from the cluster global configuration file each time the management server is started (see [Section 17.3.4, “MySQL Cluster Configuration Files”](#)). This option instructs the management server to its configuration cache in the `directory` indicated. By default, this is a directory named `mysql-cluster` in the MySQL installation directory — for example, if you compile and install MySQL Cluster on a Unix system using the default location, this is `/usr/local/mysql-cluster`.

This behavior can be overridden using the `--initial` or `--reload` option for `ndb_mgmd`. Each of these options is described elsewhere in this section.

This option is available beginning with MySQL Cluster NDB 6.4.0.

- `--config-file=filename, -f filename`

Command Line Format	<code>-c</code>	
Value Set	Type	filename
	Default	<code>./config.ini</code>

Instructs the management server as to which file it should use for its configuration file. By default, the management server looks for a file named `config.ini` in the same directory as the `ndb_mgmd` executable; otherwise the file name and location must be specified explicitly.

Beginning with MySQL Cluster NDB 6.4.0, this option is ignored unless the management server is forced to read the configuration file, either because `ndb_mgmd` was started with the `--reload` or `--initial` option, or because the management server could not find any configuration cache. See [Section 17.3.4, “MySQL Cluster Configuration Files”](#), for more information.

- `--daemon, -d`

Command Line Format	<code>--daemon</code>	
Value Set	Type	<code>boolean</code>
	Default	<code>TRUE</code>

Instructs `ndb_mgmd` to start as a daemon process. This is the default behavior.

- `--initial`

Version Introduced	5.1.30-ndb-6.4.0	
Command Line Format	<code>--initial</code>	
Value Set	Type	<code>boolean</code>
	Default	<code>FALSE</code>

Beginning with MySQL Cluster NDB 6.4.0, configuration data is cached internally rather than being read from the cluster global configuration file each time the management server is started (see [Section 17.3.4, “MySQL Cluster Configuration Files”](#)). Using this option overrides this behavior, by forcing the management server to delete any existing cache files, and then to re-read the configuration data from the cluster configuration file and to build a new cache.

This differs in two ways from the `--reload` option. First, `--reload` forces the server to check the configuration file against the cache and reload its data only if the contents of the file are different from the cache. Second, `--reload` does not delete any existing cache files.

If `ndb_mgmd` is invoked with `--initial` but cannot find a global configuration file, the management server cannot start.

This option was introduced in MySQL Cluster NDB 6.4.0.

- `--nodaemon`

Command Line Format	<code>--nodaemon</code>	
Value Set	Type	<code>boolean</code>
	Default	<code>FALSE</code>

Instructs `ndb_mgmd` not to start as a daemon process.

- `--print-full-config, -P`

Command Line Format	<code>--print-full-config</code>	
Value Set	Type	<code>boolean</code>
	Default	<code>FALSE</code>

Shows extended information regarding the configuration of the cluster. With this option on the command line the `ndb_mgmd` process prints information about the cluster setup including an extensive list of the cluster configuration sections as well as parameters and their values. Normally used together with the `--config-file (-f)` option.

- `--reload`

Version Introduced	5.1.30-ndb-6.4.0	
Command Line Format	<code>--reload</code>	
Value Set	Type	<code>boolean</code>
	Default	<code>FALSE</code>

Beginning with MySQL Cluster NDB 6.4.0, configuration data is stored internally rather than being read from the cluster global configuration file each time the management server is started (see [Section 17.3.4, “MySQL Cluster Configuration Files”](#)). Using this option forces the management server to check its internal data store against the cluster configuration file and to reload the configuration if it finds that the configuration file does not match the cache. Existing configuration cache files are preserved, but not used.

This differs in two ways from the `--initial` option. First, `--initial` causes all cache files to be deleted. Second, `--initial` forces the management server to re-read the global configuration file and construct a new cache.

If the management server cannot find a global configuration file, then the `--reload` option is ignored.

This option was introduced in MySQL Cluster NDB 6.4.0.

It is not strictly necessary to specify a connectstring when starting the management server. However, if you are using more than one management server, a connectstring should be provided and each node in the cluster should specify its node ID explicitly.

See [Section 17.3.4.3, “The MySQL Cluster Connectstring”](#), for information about using connectstrings. [Section 17.6.4, “ndb_mgmd — The MySQL Cluster Management Server Daemon”](#), describes other options for `ndb_mgmd`.

The following files are created or used by `ndb_mgmd` in its starting directory, and are placed in the `DataDir` as specified in the `config.ini` configuration file. In the list that follows, `node_id` is the unique node identifier.

- `config.ini` is the configuration file for the cluster as a whole. This file is created by the user and read by the management server. [Section 17.3, “MySQL Cluster Configuration”](#), discusses how to set up this file.
- `ndb_node_id_cluster.log` is the cluster events log file. Examples of such events include checkpoint startup and completion, node startup events, node failures, and levels of memory usage. A complete listing of cluster events with descriptions may be found in [Section 17.7, “Management of MySQL Cluster”](#).

When the size of the cluster log reaches one million bytes, the file is renamed to `ndb_node_id_cluster.log.seq_id`, where `seq_id` is the sequence number of the cluster log file. (For example: If files with the sequence numbers 1, 2, and 3 already exist, the next log file is named using the number 4.)

- `ndb_node_id_out.log` is the file used for `stdout` and `stderr` when running the management server as a daemon.
- `ndb_node_id.pid` is the process ID file used when running the management server as a daemon.

17.6.5. `ndb_mgm` — The MySQL Cluster Management Client

The `ndb_mgm` management client process is actually not needed to run the cluster. Its value lies in providing a set of commands for checking the cluster's status, starting backups, and performing other administrative functions. The management client accesses the management server using a C API. Advanced users can also employ this API for programming dedicated management processes to perform tasks similar to those performed by `ndb_mgm`.

To start the management client, it is necessary to supply the host name and port number of the management server:

```
shell> ndb_mgm [host_name [port_num]]
```

For example:

```
shell> ndb_mgm ndb_mgmd.mysql.com 1186
```

The default host name and port number are `localhost` and 1186, respectively.

The following list includes options that are specific to `ndb_mgm`. For options common to all NDB programs, see [Section 17.6.23, “Options Common to MySQL Cluster Programs”](#).

- `--try-reconnect=number`

Command Line Format	<code>--try-reconnect=#</code>	
Value Set	Type	<code>boolean</code>
	Default	<code>TRUE</code>

If the connection to the management server is broken, the node tries to reconnect to it every 5 seconds until it succeeds. By using this option, it is possible to limit the number of attempts to *number* before giving up and reporting an error instead.

Additional information about using `ndb_mgm` can be found in [Section 17.6.24.4, “Program Options for `ndb_mgm`”](#), and [Section 17.7.2, “Commands in the MySQL Cluster Management Client”](#).

17.6.6. `ndb_config` — Extract MySQL Cluster Configuration Information

This tool extracts current configuration information for data nodes, SQL nodes, and API nodes from a cluster management node (and possibly its `config.ini` file). Beginning with MySQL Cluster NDB 6.3.25 and MySQL Cluster NDB 7.0.6, it can also provide an offline dump (in text or XML format) of all configuration parameters which can be used, along with their default, maximum, and minimum values and other information (see the discussion of the `--configinfo` and `--xml` options later in this section).

Usage:

```
ndb_config options
```

The *options* available for this utility differ somewhat from those used with the other utilities, and so are listed in their entirety in the next section, followed by some examples.

Options:

- `--usage, --help, or -?`

Command Line Format	<code>--help</code>
----------------------------	---------------------

Causes `ndb_config` to print a list of available options, and then exit.

- `--version, -V`

Command Line Format	<code>-V</code>
----------------------------	-----------------

Causes `ndb_config` to print a version information string, and then exit.

- `--ndb-connectstring=connect_string`

Command Line Format	<code>--ndb-connectstring=name</code>	
Value Set	Type	string
	Default	localhost:1186

Specifies the connectstring to use in connecting to the management server. The format for the connectstring is the same as described in [Section 17.3.4.3, “The MySQL Cluster Connectstring”](#), and defaults to `localhost:1186`.

The use of `-c` as a short version for this option is supported for `ndb_config` beginning with MySQL 5.1.12.

- `--config-file=path-to-file`

Gives the path to the management server's configuration file (`config.ini`). This may be a relative or absolute path. If the management node resides on a different host from the one on which `ndb_config` is invoked, then an absolute path must be used.

- `--query=query-options, -q query-options`

Command Line Format	<code>--query=string</code>	
Value Set	Type	string
	Default	

This is a comma-delimited list of *query options* — that is, a list of one or more node attributes to be returned. These include `id`

(node ID), type (node type — that is, `ndbd`, `mysqld`, or `ndb_mgmd`), and any configuration parameters whose values are to be obtained.

For example, `--query=id,type,indexmemory,datamemory` would return the node ID, node type, `DataMemory`, and `IndexMemory` for each node.

Note

If a given parameter is not applicable to a certain type of node, then an empty string is returned for the corresponding value. See the examples later in this section for more information.

- `--host=hostname`

Command Line Format	<code>--host=name</code>	
Value Set	Type	<code>string</code>
	Default	

Specifies the host name of the node for which configuration information is to be obtained.

- `--id=node_id, --nodeid=node_id`

Command Line Format	<code>--ndb-nodeid=#</code>	
Value Set	Type	<code>numeric</code>
	Default	<code>0</code>

Used to specify the node ID of the node for which configuration information is to be obtained.

- `--nodes`

Command Line Format	<code>--nodes</code>	
Value Set	Type	<code>boolean</code>
	Default	<code>FALSE</code>

(Tells `ndb_config` to print information from parameters defined in `[ndbd]` sections only. Currently, using this option has no affect, since these are the only values checked, but it may become possible in future to query parameters set in `[tcp]` and other sections of cluster configuration files.)

- `--type=node_type`

Command Line Format	<code>--type=name</code>	
Value Set	Type	<code>enumeration</code>
	Default	
	Valid Values	<code>ndbd,mysqld,ndb_mgmd</code>

Filters results so that only configuration values applying to nodes of the specified `node_type` (`ndbd`, `mysqld`, or `ndb_mgmd`) are returned.

- `--fields=delimiter, -f delimiter`

Command Line Format	<code>--fields=string</code>	
Value Set	Type	<code>string</code>
	Default	

Specifies a `delimiter` string used to separate the fields in the result. The default is “,” (the comma character).

Note

If the *delimiter* contains spaces or escapes (such as `\n` for the linefeed character), then it must be quoted.

- `--rows=separator, -r separator`

Command Line Format	<code>--rows=string</code>	
Value Set	Type	<code>string</code>
	Default	

Specifies a *separator* string used to separate the rows in the result. The default is a space character.

Note

If the *separator* contains spaces or escapes (such as `\n` for the linefeed character), then it must be quoted.

- `--configinfo [--xml]`

Version Introduced	5.1.34-ndb-7.0.6	
Command Line Format	<code>--configinfo</code>	
Value Set	Type	<code>boolean</code>
	Default	<code>false</code>

Version Introduced	5.1.34-ndb-7.0.6	
Command Line Format	<code>--configinfo --xml</code>	
Value Set	Type	<code>boolean</code>
	Default	<code>false</code>

The `--configinfo` option, added in MySQL Cluster NDB 6.3.25 and MySQL Cluster NDB 7.0.6, causes `ndb_config` to dump a list of each MySQL Cluster configuration parameter supported by the MySQL Cluster distribution of which `ndb_config` is a part, including the following information:

- A brief description of each parameter's purpose, effects, and usage
- The section of the `config.ini` file where the parameter may be used
- The parameter's data type or unit of measurement
- Where applicable, the parameter's default, minimum, and maximum values
- A brief description of the parameter's purpose, effects, and usage
- MySQL Cluster release version and build information

By default, this output is in text format. Part of this output is shown here:

```
shell> ndb_config --configinfo
***** SYSTEM *****
Name (String)
Name of system (NDB Cluster)
MANDATORY

PrimaryMGMNode (Non-negative Integer)
Node id of Primary ndb_mgmd(MGM) node
Default: 0 (Min: 0, Max: 4294967039)

ConfigGenerationNumber (Non-negative Integer)
Configuration generation number
Default: 0 (Min: 0, Max: 4294967039)

***** DB *****

MaxNoOfSubscriptions (Non-negative Integer)
Max no of subscriptions (default 0 == MaxNoOfTables)
Default: 0 (Min: 0, Max: 4294967039)

MaxNoOfSubscribers (Non-negative Integer)
Max no of subscribers (default 0 == 2 * MaxNoOfTables)
```

```
Default: 0 (Min: 0, Max: 4294967039)
```

```
...
```

You can obtain the output as XML by using the `--xml` option (also available beginning with MySQL Cluster NDB 6.3.25 and MySQL Cluster NDB 7.0.6) in addition to `--configinfo`. A portion of the resulting output is shown in this example:

```
shell> ndb_config --configinfo --xml
```

```
<configvariables protocolversion="1" ndbversionstring="mysql-5.1.34 ndb-7.0.6"
  ndbversion="458758" ndbversionmajor="7" ndbversionminor="0"
  ndbversionbuild="6">
  <section name="SYSTEM">
    <param name="Name" comment="Name of system (NDB Cluster)" type="string"
      mandatory="true"/>
    <param name="PrimaryMGMNode" comment="Node id of Primary ndb_mgmd(MGM) node"
      type="unsigned" default="0" min="0" max="4294967039"/>
    <param name="ConfigGenerationNumber" comment="Configuration generation number"
      type="unsigned" default="0" min="0" max="4294967039"/>
  </section>
  <section name="NDBD">
    <param name="MaxNoOfSubscriptions" comment="Max no of subscriptions (default 0 == MaxNoOfTables)"
      type="unsigned" default="0" min="0" max="4294967039"/>
    <param name="MaxNoOfSubscribers" comment="Max no of subscribers (default 0 == 2 * MaxNoOfTables)"
      type="unsigned" default="0" min="0" max="4294967039"/>
    ...
  </section>
  ...
</configvariables>
```

Important

The `--xml` option can be used only with the `--configinfo` option. Using `--xml` without `--configinfo` fails with an error.

Unlike the options used with this program to obtain current configuration data, `--configinfo` and `--xml` use information obtained from the MySQL Cluster sources when `ndb_config` was compiled. For this reason, no connection to a running MySQL Cluster or access to a `config.ini` or `my.cnf` file is required for these two options.

Combining other `ndb_config` options (such as `--query` or `--type`) with `--configinfo` or `--xml` is not supported. If you attempt to do so, the usual (current) result is that all other options besides `--configinfo` or `--xml` are simply ignored. However, this behavior is not guaranteed and is subject to change at any time. In addition, since `ndb_config` when used with the `--configinfo` option does not access the MySQL Cluster or read any files, trying to specify additional options such as `--ndb-connectstring` or `--config-file` with `--configinfo` serves no purpose.

Examples:

1. To obtain the node ID and type of each node in the cluster:

```
shell> ./ndb_config --query=id,type --fields=':' --rows='\n'
1:ndbd
2:ndbd
3:ndbd
4:ndbd
5:ndb_mgmd
6:mysqlqld
7:mysqlqld
8:mysqlqld
9:mysqlqld
```

In this example, we used the `--fields` options to separate the ID and type of each node with a colon character (:), and the `--rows` options to place the values for each node on a new line in the output.

2. To produce a connectstring that can be used by data, SQL, and API nodes to connect to the management server:

```
shell> ./ndb_config --config-file=/usr/local/mysql/cluster-data/config.ini --query=hostname,portnumber --fields=: -
192.168.0.179:1186
```

3. This invocation of `ndb_config` checks only data nodes (using the `--type` option), and shows the values for each node's ID and host name, and its `DataMemory`, `IndexMemory`, and `DataDir` parameters:

```
shell> ./ndb_config --type=ndbd --query=id,host,datamemory,indexmemory,datadir -f ' : ' -r '\n'
1 : 192.168.0.193 : 83886080 : 18874368 : /usr/local/mysql/cluster-data
```

```
2 : 192.168.0.112 : 83886080 : 18874368 : /usr/local/mysql/cluster-data
3 : 192.168.0.176 : 83886080 : 18874368 : /usr/local/mysql/cluster-data
4 : 192.168.0.119 : 83886080 : 18874368 : /usr/local/mysql/cluster-data
```

In this example, we used the short options `-f` and `-r` for setting the field delimiter and row separator, respectively.

- To exclude results from any host except one in particular, use the `--host` option:

```
shell> ./ndb_config --host=192.168.0.176 -f : -r '\n' -q id,type
3:ndbd
5:ndb_mgmd
```

In this example, we also used the short form `-q` to determine the attributes to be queried.

Similarly, you can limit results to a node with a specific ID using the `--id` or `--nodeid` option.

17.6.7. `ndb_cpced` — Automate Testing for NDB Development

This utility is found in the `libexec` directory. It is part of an internal automated test framework used in testing and debugging MySQL Cluster. Because it can control processes on remote systems, it is not advisable to use `ndb_cpced` in a production cluster.

The source files for `ndb_cpced` may be found in the directory `storage/ndb/src/cw/cpced`, in the MySQL Cluster source tree.

17.6.8. `ndb_delete_all` — Delete All Rows from an NDB Table

`ndb_delete_all` deletes all rows from the given NDB table. In some cases, this can be much faster than `DELETE` or even `TRUNCATE`.

Usage:

```
ndb_delete_all -c connect_string tbl_name -d db_name
```

This deletes all rows from the table named `tbl_name` in the database named `db_name`. It is exactly equivalent to executing `TRUNCATE db_name.tbl_name` in MySQL.

Additional Options:

- `--transactional, -t`

Use of this option causes the delete operation to be performed as a single transaction.

Warning

With very large tables, using this option may cause the number of operations available to the cluster to be exceeded.

17.6.9. `ndb_desc` — Describe NDB Tables

`ndb_desc` provides a detailed description of one or more NDB tables.

Usage:

```
ndb_desc -c connect_string tbl_name -d db_name [-p]
```

Sample Output:

MySQL table creation and population statements:

```
USE test;

CREATE TABLE fish (
  id INT(11) NOT NULL AUTO_INCREMENT,
  name VARCHAR(20),

  PRIMARY KEY pk (id),
  UNIQUE KEY uk (name)
) ENGINE=NDBCLUSTER;

INSERT INTO fish VALUES
```

```
('','guppy'), ('','tuna'), ('','shark'),
('','manta ray'), ('','grouper'), ('','puffer');
```

Output from `ndb_desc`:

```
shell> ./ndb_desc -c localhost fish -d test -p
-- fish --
Version: 16777221
Fragment type: 5
K Value: 6
Min load factor: 78
Max load factor: 80
Temporary table: no
Number of attributes: 2
Number of primary keys: 1
Length of frm data: 268
Row Checksum: 1
Row GCI: 1
TableStatus: Retrieved
-- Attributes --
id Int PRIMARY KEY DISTRIBUTION KEY AT=FIXED ST=MEMORY
name Varchar(20;latin1_swedish_ci) NULL AT=SHORT_VAR ST=MEMORY

-- Indexes --
PRIMARY KEY(id) - UniqueHashIndex
uk(name) - OrderedIndex
PRIMARY(id) - OrderedIndex
uk$unique(name) - UniqueHashIndex

-- Per partition info --
Partition Row count Commit count Frag fixed memory Frag var sized memory
2          2          2          65536          327680
1          2          2          65536          327680
3          2          2          65536          327680

NDBT_ProgramExit: 0 - OK
```

Additional Options:

- `--extra-partition-info, -p`

Prints additional information about the table's partitions.

- Information about multiple tables can be obtained in a single invocation of `ndb_desc` by using their names, separated by spaces. All of the tables must be in the same database.

17.6.10. `ndb_drop_index` — Drop Index from an NDB Table

`ndb_drop_index` drops the specified index from an NDB table. *It is recommended that you use this utility only as an example for writing NDB API applications* — see the Warning later in this section for details.

Usage:

```
ndb_drop_index -c connect_string table_name index -d db_name
```

The statement shown above drops the index named `index` from the `table` in the `database`.

Additional Options: None that are specific to this application.

Warning

Operations performed on Cluster table indexes using the NDB API are not visible to MySQL and make the table unusable by a MySQL server. If you use this program to drop an index, then try to access the table from an SQL node, an error results, as shown here:

```
shell> ./ndb_drop_index -c localhost dogs ix -d ctest1
Dropping index dogs/idx...OK

NDBT_ProgramExit: 0 - OK

shell> ./mysql -u jon -p ctest1
Enter password: *****
Reading table information for completion of table and column names
You can turn off this feature to get a quicker startup with -A

Welcome to the MySQL monitor.  Commands end with ; or \g.
Your MySQL connection id is 7 to server version: 5.1.12-beta-20060817

Type 'help;' or '\h' for help. Type '\c' to clear the buffer.
```

```
mysql> SHOW TABLES;
+-----+
| Tables_in_ctest1 |
+-----+
| a                |
| bt1              |
| bt2              |
| dogs             |
| employees        |
| fish             |
+-----+
6 rows in set (0.00 sec)

mysql> SELECT * FROM dogs;
ERROR 1296 (HY000): GOT ERROR 4243 'INDEX NOT FOUND' FROM NDBCLUSTER
```

In such a case, your *only* option for making the table available to MySQL again is to drop the table and re-create it. You can use either the SQL statement `DROP TABLE` or the `ndb_drop_table` utility (see [Section 17.6.11, “ndb_drop_table — Drop an NDB Table”](#)) to drop the table.

17.6.11. `ndb_drop_table` — Drop an NDB Table

`ndb_drop_table` drops the specified NDB table. (If you try to use this on a table created with a storage engine other than NDB, it fails with the error `723: NO SUCH TABLE EXISTS.`) This operation is extremely fast — in some cases, it can be an order of magnitude faster than using `DROP TABLE` on an NDB table from MySQL.

Usage:

```
ndb_drop_table -c connect_string tbl_name -d db_name
```

Additional Options: None.

17.6.12. `ndb_error_reporter` — NDB Error-Reporting Utility

`ndb_error_reporter` creates an archive from data node and management node log files that can be used to help diagnose bugs or other problems with a cluster. *It is highly recommended that you make use of this utility when filing reports of bugs in MySQL Cluster.*

Usage:

```
ndb_error_reporter path/to/config-file [username] [--fs]
```

This utility is intended for use on a management node host, and requires the path to the management host configuration file (`config.ini`). Optionally, you can supply the name of a user that is able to access the cluster's data nodes via SSH, in order to copy the data node log files. `ndb_error_reporter` then includes all of these files in archive that is created in the same directory in which it is run. The archive is named `ndb_error_report_YYYYMMDDHHMMSS.tar.bz2`, where `YYYYMMDDHHMMSS` is a datetime string.

If the `--fs` is used, then the data node file systems are also copied to the management host and included in the archive that is produced by this script. As data node file systems can be extremely large even after being compressed, we ask that you please do *not* send archives created using this option to MySQL AB unless you are specifically requested to do so.

Command Line Format	<code>--fs</code>	
Value Set	Type	boolean
	Default	FALSE

17.6.13. `ndb_print_backup_file` — Print NDB Backup File Contents

`ndb_print_backup_file` obtains diagnostic information from a cluster backup file.

Usage:

```
ndb_print_backup_file file_name
```

file_name is the name of a cluster backup file. This can be any of the files (`.Data`, `.ctl`, or `.log` file) found in a cluster backup directory. These files are found in the data node's backup directory under the subdirectory `BACKUP-#`, where `#` is the sequence number for the backup. For more information about cluster backup files and their contents, see [Section 17.7.3.1, “MySQL Cluster Backup Concepts”](#).

Like `ndb_print_schema_file` and `ndb_print_sys_file` (and unlike most of the other NDB utilities that are intended to be run on a management server host or to connect to a management server) `ndb_print_backup_file` must be run on a cluster data node, since it accesses the data node file system directly. Because it does not make use of the management server, this utility can be used when the management server is not running, and even when the cluster has been completely shut down.

Additional Options: None.

17.6.14. `ndb_print_schema_file` — Print NDB Schema File Contents

`ndb_print_schema_file` obtains diagnostic information from a cluster schema file.

Usage:

```
ndb_print_schema_file file_name
```

file_name is the name of a cluster schema file. For more information about cluster schema files, see [Cluster Data Node FileSystemDir Files](#).

Like `ndb_print_backup_file` and `ndb_print_sys_file` (and unlike most of the other NDB utilities that are intended to be run on a management server host or to connect to a management server) `ndb_schema_backup_file` must be run on a cluster data node, since it accesses the data node file system directly. Because it does not make use of the management server, this utility can be used when the management server is not running, and even when the cluster has been completely shut down.

Additional Options: None.

17.6.15. `ndb_print_sys_file` — Print NDB System File Contents

`ndb_print_sys_file` obtains diagnostic information from a MySQL Cluster system file.

Usage:

```
ndb_print_sys_file file_name
```

file_name is the name of a cluster system file (sysfile). Cluster system files are located in a data node's data directory (`DataDir`); the path under this directory to system files matches the pattern `ndb_#_fs/D#/DBDIH/P#.sysfile`. In each case, the # represents a number (not necessarily the same number). For more information, see [Cluster Data Node FileSystemDir Files](#).

Like `ndb_print_backup_file` and `ndb_print_schema_file` (and unlike most of the other NDB utilities that are intended to be run on a management server host or to connect to a management server) `ndb_print_backup_file` must be run on a cluster data node, since it accesses the data node file system directly. Because it does not make use of the management server, this utility can be used when the management server is not running, and even when the cluster has been completely shut down.

Additional Options: None.

17.6.16. `ndbd_redo_log_reader` — Check and Print Content of Cluster Redo Log

Reads a redo log file, checking it for errors, printing its contents in a human-readable format, or both. `ndbd_redo_log_reader` is intended for use primarily by MySQL developers and support personnel in debugging and diagnosing problems.

This utility was made available as part of default builds beginning with MySQL Cluster NDB 6.1.3. It remains under development, and its syntax and behavior are subject to change in future releases. For this reason, it should be considered experimental at this time.

The C++ source files for `ndbd_redo_log_reader` can be found in the directory `/storage/ndb/src/kernel/blocks/dblqh/redoLogReader`.

Usage:

```
ndbd_redo_log_reader file_name [options]
```

file_name is the name of a cluster REDO log file. REDO log files are located in the numbered directories under the data node's data directory (`DataDir`); the path under this directory to the REDO log files matches the pattern `ndb_#_fs/D#/LCP/#/T#F#.Data`. In each case, the # represents a number (not necessarily the same number). For more information, see [Cluster Data Node FileSystemDir Files](#).

Additional Options:

Command Line Format	<code>-noprnt</code>	
Value Set	Type	boolean
	Default	FALSE

Command Line Format	<code>-nocheck</code>	
Value Set	Type	boolean
	Default	FALSE

The name of the file to be read may be followed by one or more of the options listed here:

- `-noprnt`: Do not print the contents of the log file.
- `-nocheck`: Do not check the log file for errors.

Like `ndb_print_backup_file` and `ndb_print_schema_file` (and unlike most of the NDB utilities that are intended to be run on a management server host or to connect to a management server) `ndbd_redo_log_reader` must be run on a cluster data node, since it accesses the data node file system directly. Because it does not make use of the management server, this utility can be used when the management server is not running, and even when the cluster has been completely shut down.

17.6.17. `ndb_restore` — Restore a MySQL Cluster Backup

The cluster restoration program is implemented as a separate command-line utility `ndb_restore`, which can normally be found in the MySQL `bin` directory. This program reads the files created as a result of the backup and inserts the stored information into the database.

`ndb_restore` must be executed once for each of the backup files that were created by the `START BACKUP` command used to create the backup (see Section 17.7.3.2, “Using The MySQL Cluster Management Client to Create a Backup”). This is equal to the number of data nodes in the cluster at the time that the backup was created.

Note

Before using `ndb_restore`, it is recommended that the cluster be running in single user mode, unless you are restoring multiple data nodes in parallel. See Section 17.7.6, “MySQL Cluster Single User Mode”, for more information about single user mode.

Typical options for this utility are shown here:

```
ndb_restore [-c connectstring] -n
node_id [-s] [-m] -b backup_id -r --backup_path=/path/to/backup/files [-e]
```

The `-c` option is used to specify a connectstring which tells `ndb_restore` where to locate the cluster management server. (See Section 17.3.4.3, “The MySQL Cluster Connectstring”, for information on connectstrings.) If this option is not used, then `ndb_restore` attempts to connect to a management server on `localhost:1186`. This utility acts as a cluster API node, and so requires a free connection “slot” to connect to the cluster management server. This means that there must be at least one `[api]` or `[mysqld]` section that can be used by it in the cluster `config.ini` file. It is a good idea to keep at least one empty `[api]` or `[mysqld]` section in `config.ini` that is not being used for a MySQL server or other application for this reason (see Section 17.3.4.7, “Defining SQL and Other API Nodes in a MySQL Cluster”).

You can verify that `ndb_restore` is connected to the cluster by using the `SHOW` command in the `ndb_mgm` management client. You can also accomplish this from a system shell, as shown here:

```
shell> ndb_mgm -e "SHOW"
```

`-n` is used to specify the node ID of the data node on which the backups were taken.

The first time you run the `ndb_restore` restoration program, you also need to restore the metadata. In other words, you must recreate the database tables — this can be done by running it with the `-m` option. Note that the cluster should have an empty database when starting to restore a backup. (In other words, you should start `ndbd` with `--initial` prior to performing the restore. You should also remove manually any Disk Data files present in the data node's `DataDir`.)

It is possible to restore data without restoring table metadata. Prior to MySQL 5.1.17, `ndb_restore` did not perform any checks of table schemas; if a table was altered between the time the backup was taken and when `ndb_restore` was run, `ndb_restore` would still attempt to restore the data to the altered table.

Beginning with MySQL 5.1.17, the default behavior is for `ndb_restore` to fail with an error if table data do not match the table schema; this can be overridden using the `--skip-table-check` or `-s` option. Prior to MySQL 5.1.21, if this option is used, then `ndb_restore` attempts to fit data into the existing table schema, but the result of restoring a backup to a table schema that does not match the original is unspecified.

Beginning with MySQL Cluster NDB 6.3.8, `ndb_restore` supports limited *attribute promotion* in much the same way that it is supported by MySQL replication; that is, data backed up from a column of a given type can generally be restored to a column using a “larger, similar” type. For example, data from a `CHAR(20)` column can be restored to a column declared as `VARCHAR(20)`, `VARCHAR(30)`, or `CHAR(30)`; data from a `MEDIUMINT` column can be restored to a column of type `INT` or `BIGINT`. See [Section 16.3.1.4.2, “Replication of Columns Having Different Data Types”](#), for a table of type conversions currently supported by attribute promotion.

Attribute promotion by `ndb_restore` must be enabled explicitly, as follows:

1. Prepare the table to which the backup is to be restored. `ndb_restore` cannot be used to re-create the table with a different definition from the original; this means that you must either create the table manually, or alter the columns which you wish to promote using `ALTER TABLE` after restoring the table metadata but before restoring the data.
2. Invoke `ndb_restore` with the `--promote-attributes` option (short form `-A`) when restoring the table data. Attribute promotion does not occur if this option is not used; instead, the restore operation fails with an error.

In addition to `--promote-attributes`, a `--preserve-trailing-spaces` option is also available for use with `ndb_restore` beginning with MySQL Cluster NDB 6.3.8. This option (short form `-R`) causes trailing spaces to be preserved when promoting a `CHAR` column to `VARCHAR` or a `BINARY` column to `VARBINARY`. Otherwise, any trailing spaces are dropped from column values when they are inserted into the new columns.

Note

Although you can promote `CHAR` columns to `VARCHAR` and `BINARY` columns to `VARBINARY`, you cannot promote `VARCHAR` columns to `CHAR` or `VARBINARY` columns to `BINARY`.

The `-b` option is used to specify the ID or sequence number of the backup, and is the same number shown by the management client in the `Backup backup_id completed` message displayed upon completion of a backup. (See [Section 17.7.3.2, “Using The MySQL Cluster Management Client to Create a Backup”](#).)

Important

When restoring cluster backups, you must be sure to restore all data nodes from backups having the same backup ID. Using files from different backups will at best result in restoring the cluster to an inconsistent state, and may fail altogether.

`-e` adds (or restores) epoch information to the cluster replication status table. This is useful for starting replication on a MySQL Cluster replication slave. When this option is used, the row in the `mysql.ndb_apply_status` having 0 in the `id` column is updated if it already exists; such a row is inserted if it does not already exist. (See [Section 17.9.9, “MySQL Cluster Backups With MySQL Cluster Replication”](#).)

The path to the backup directory is required; this is supplied to `ndb_restore` using the `--backup_path` option, and must include the subdirectory corresponding to the ID backup of the backup to be restored. For example, if the data node's `DataDir` is `/var/lib/mysql-cluster`, then the backup directory is `/var/lib/mysql-cluster/BACKUP`, and the backup files for the backup with the ID 3 can be found in `/var/lib/mysql-cluster/BACKUP/BACKUP-3`. The path may be absolute or relative to the directory in which the `ndb_restore` executable is located.

Note

Previous to MySQL 5.1.17 and MySQL Cluster NDB 6.1.5, the path to the backup directory was specified as shown here, with `backup_path=` being optional:

```
[backup_path=]/path/to/backup/files
```

Beginning with MySQL 5.1.17 and MySQL Cluster NDB 6.1.5, this syntax changed to `--backup_path=/path/to/backup/files`, to conform more closely with options used by other MySQL programs; `-backup_id` is required, and there is no short form for this option.

It is possible to restore a backup to a database with a different configuration than it was created from. For example, suppose that a

backup with backup ID 12, created in a cluster with two database nodes having the node IDs 2 and 3, is to be restored to a cluster with four nodes. Then `ndb_restore` must be run twice — once for each database node in the cluster where the backup was taken. However, `ndb_restore` cannot always restore backups made from a cluster running one version of MySQL to a cluster running a different MySQL version. See [Section 17.5.2, “MySQL Cluster 5.1 and MySQL Cluster NDB 6.x/7.x Upgrade and Downgrade Compatibility”](#), for more information.

Important

It is not possible to restore a backup made from a newer version of MySQL Cluster using an older version of `ndb_restore`. You can restore a backup made from a newer version of MySQL to an older cluster, but you must use a copy of `ndb_restore` from the newer MySQL Cluster version to do so.

For example, to restore a cluster backup taken from a cluster running MySQL Cluster NDB 6.2.15 to a cluster running MySQL 5.1.20, you must use a copy of `ndb_restore` from the MySQL Cluster NDB 6.2.15 distribution.

For more rapid restoration, the data may be restored in parallel, provided that there is a sufficient number of cluster connections available. That is, when restoring to multiple nodes in parallel, you must have an `[api]` or `[mysqld]` section in the cluster `config.ini` file available for each concurrent `ndb_restore` process. However, the data files must always be applied before the logs.

Formerly, when using `ndb_restore` to restore a backup made from a MySQL 5.0 cluster to a 5.1 cluster, `VARCHAR` columns were not resized and were recreated using the 5.0 fixed format. Beginning with MySQL 5.1.19, `ndb_restore` recreates such `VARCHAR` columns using MySQL Cluster 5.1's variable-width format. Also beginning with MySQL 5.1.19, this behavior can be overridden using the `--no-upgrade` option (short form: `-u`) when running `ndb_restore`.

Most of the options available for this program are shown in the following table:

Long Form	Short Form	Description	Default Value
<code>--backup-id</code>	<code>-b</code>	Backup sequence ID	<i>None</i>
<code>--backup_path</code> (added in MySQL 5.1.17 and MySQL Cluster NDB 6.1.5; previously this was <code>backup_path</code> — see Note in text)	<i>None</i>	Path to backup files	<i>None</i>
<code>--character-sets-dir</code>	<i>None</i>	Specify the directory where character set information can be found	<i>None</i>
<code>--connect</code> , <code>-connectstring</code> , or <code>-ndb-connectstring</code>	<code>-c</code> or <code>-C</code>	Set the connectstring in	<code>localhost:1186</code>

] format	
<code>--core-file</code>	<i>None</i>	Write a core file in the event of an error	<code>TRUE</code>
<code>--debug</code>	<code>-#</code>	Output debug log	<code>d:t:0,/tmp/ndb_restore.trace</code>
<code>-d</code> <code>-dont_ignore_systab_0</code>	<code>-f</code>	Do not ignore system table during restore — <i>EXPERIMENTAL; not for production use</i>	<code>FALSE</code>
<code>d</code> <code>b</code> <code>-</code> <code>l</code> <code>i</code> <code>s</code> <code>--exclude-databases=t</code>	<i>None</i>	Do not restore the indicated database or databases (added in MySQL Cluster NDB 6.3.22 and 6.4.3)	[N/A]
<code>tbl_</code> <code>--exclude-tables=list</code>	<i>None</i>	Do not restore the indicated table or tables; each table must be specified using <i>database.table</i> format (added in MySQL Cluster NDB 6.3.22 and 6.4.3)	[N/A]
<code>--help</code> or <code>--usage</code>	<code>-?</code>	Display help message with available options and current values, then exit	[N/A]
<code>d</code> <code>b</code> <code>-</code> <code>l</code> <code>i</code> <code>s</code> <code>--include-databases=t</code>	<i>None</i>	Restore only the indicated database or databases (added in MySQL Cluster NDB 6.3.22 and 6.4.3)	[N/A]
<code>tbl_</code> <code>--include-tables=list</code>	<i>None</i>	Restore only the indicated table or tables; each table must be specified using <i>database.table</i> format (added in MySQL Cluster NDB 6.3.22 and 6.4.3)	[N/A]
<code>--ndb-mgmd-host</code>	<i>None</i>	Set the host and port in <i>host[:port]</i> format for the management server to connect to; this is the same as <code>--connect</code> , <code>--connectstring</code> , or <code>--ndb-connectstring</code> , but without a way to specify the <i>nodeid</i>	<i>None</i>
<code>--ndb-nodegroup-map</code>	<code>-z</code>	Specifies a nodegroup map — <i>Syntax</i> : list of (<i>source_nodegroup</i> , <i>destination_nodegroup</i>)	<i>None</i>
<code>--ndb-nodeid</code>	<i>None</i>	Specify a node ID for the <code>ndb_restore</code> process	<code>0</code>
<code>-</code> <code>-</code> <code>ndb-optimized-node-selection</code>	<i>None</i>	Optimize selection of nodes for transactions	<code>TRUE</code>
<code>--ndb-shm</code>	<i>None</i>	Use shared memory connections when available	<code>FALSE</code>
<code>--no-binlog</code>	<i>None</i>	Do not write anything to <code>mysqld</code> binary logs (added in MySQL Cluster NDB 6.2.16 and 6.3.16)	<code>FALSE</code> (in other words, write to binary logs unless this option is used)
<code>-</code> <code>-</code> <code>no-restore-disk-objects</code>	<code>-d</code>	Do not restore Disk Data objects such as tablespaces and log file groups	<code>FALSE</code> (in other words, restore Disk Data objects unless this option is used)
<code>--no-upgrade</code>	<code>-u</code>	Do not re-create <code>VARIABLE</code> columns from a MySQL 5.0 Cluster backup as variable-width columns (added in MySQL 5.1.19)	<code>FALSE</code> (in other words, re-create <code>VARIABLE</code> columns from a MySQL 5.0 Cluster backup as variable-width columns unless this option is used)
<code>--nodeid</code>	<code>-n</code>	Use backup files from node with the specified ID	<code>0</code>

<code>--parallelism</code>	<code>-p</code>	Set from 1 to 1024 parallel transactions to be used during the restoration process	128
<code>--print</code>	<i>None</i>	Print metadata, data, and log to <code>stdout</code>	FALSE
<code>--print_data</code>	<i>None</i>	Print data to <code>stdout</code>	FALSE
<code>--print_log</code>	<i>None</i>	Print log to <code>stdout</code>	FALSE
<code>--print_meta</code>	<i>None</i>	Print metadata to <code>stdout</code>	FALSE
<code>--restore_data</code>	<code>-r</code>	Restore data and logs	FALSE
<code>--restore_epoch</code>	<code>-e</code>	Restore epoch data into the status table; the row in the <code>cluster.apply_status</code> having the <code>id 0</code> is inserted or updated as appropriate — this is convenient when starting up replication on a MySQL Cluster replication slave	FALSE
<code>--restore_meta</code>	<code>-m</code>	Restore table metadata	FALSE
<code>--skip-table-check</code>	<code>-s</code>	Do not check table schemas (Added in MySQL 5.1.17)	FALSE
<code>--version</code>	<code>-V</code>	Output version information and exit	[N/A]

Beginning with MySQL 5.1.18, several additional options are available for use with the `--print_data` option in generating data dumps, either to `stdout`, or to a file. These are similar to some of the options used with `mysqldump`, and are shown in the following table:

Long Form	Short Form	Description	Default Value
<code>--tab</code>	<code>-T</code>	Creates dumpfiles, one per table, each named <code>tbl_name.txt</code> . Takes as its argument the path to the directory where the files should be saved (required; use <code>.</code> for the current directory).	<i>None</i>
<code>--fields-enclosed-by</code>	<i>None</i>	String used to enclose all column values	<i>None</i>
<code>- - fields-option- ally-enclosed-by</code>	<i>None</i>	String used to enclose column values containing character data (such as <code>CHAR</code> , <code>VARCHAR</code> , <code>BINARY</code> , <code>TEXT</code> , or <code>ENUM</code>)	<i>None</i>
<code>- -fields-terminated-by</code>	<i>None</i>	String used to separate column values	<code>\t</code> (tab character)
<code>--hex</code>	<i>None</i>	Use hex format for binary values	[N/A]
<code>--lines-terminated-by</code>	<i>None</i>	String used to terminate each line	<code>\n</code> (linefeed character)
<code>--append</code>	<i>None</i>	When used with <code>--tab</code> , causes the data to be appended to existing files of the same name	[N/A]

Note

If a table has no explicit primary key, then the output generated when using the `--print` includes the table's hidden primary key.

Beginning with MySQL 5.1.18, it is possible to restore selected databases, or to restore selected tables from a given database using the syntax shown here:

```
ndb_restore other_options db_name_1 [db_name_2[, db_name_3][, ...] | tbl_name_1[, tbl_name_2][, ...]]
```

In other words, you can specify either of the following to be restored:

- All tables from one or more databases
- One or more tables from a single database

Beginning with MySQL Cluster NDB 6.3.22 and 6.4.3, you can (and should) use instead the options `--include-databases` and `--include-tables` for restoring only specific databases or tables, respectively. `--include-databases` takes a comma-delimited list of databases to be restored. `--include-tables` takes a comma-delimited list of tables (in `database.table` format) to be restored. You can use these two options together. For example, the following causes all tables in databases `db1` and `db2`, together with the tables `t1` and `t2` in database `db3`, to be restored (and no other databases or tables):

```
shell> ndb_restore [...] --include-databases=db1,db2 --include-tables=db3.t1,db3.t2
```

(For the sake of clarity and brevity, we have omitted other, possibly required, options in the example just shown.) When `--include-databases`, `--include-tables`, or both are used, only those databases or tables specified are restored; all other databases and tables are ignored by `ndb_restore`.

Also beginning with MySQL Cluster NDB 6.3.22 and 6.4.3, it is possible to exclude from being restored one or more databases, tables, or both using the `ndb_restore` options `--exclude-databases` and `--exclude-tables`. `--exclude-databases` takes a comma-delimited list of one or more databases which should not be restored. `--exclude-tables` takes a comma-delimited list of one or more tables, using `database.table` format, which should not be restored. You can use these two options together. For example, the following causes all tables in all databases *except for* databases `db1` and `db2`, along with the tables `t1` and `t2` in database `db3`, *not* to be restored:

```
shell> ndb_restore [...] --exclude-databases=db1,db2 --exclude-tables=db3.t1,db3.t2
```

(Again, we have omitted other possibly necessary options in the interest of clarity and brevity from the example just shown.)

You should not use `--include-databases` or `--include-tables` together with `--exclude-databases` or `--exclude-tables`, since `--include-databases` and `--include-tables` exclude all databases and tables not explicitly named. Similarly, `--exclude-databases` and `--exclude-tables` include all databases and tables not listed in the arguments to these options.

Error reporting. `ndb_restore` reports both temporary and permanent errors. In the case of temporary errors, it may be able to recover from them. Beginning with MySQL 5.1.12, it reports `Restore successful, but encountered temporary error, please look at configuration` in such cases.

Important

After using `ndb_restore` to initialize a MySQL Cluster for use in circular replication, binary logs on the SQL node acting as the replication slave are not automatically created, and you must cause them to be created manually. In order to cause the binary logs to be created, issue a `SHOW TABLES` statement on that SQL node before running `START SLAVE`.

This is a known issue with MySQL Cluster management, which we intend to address in a future release.

17.6.18. `ndb_select_all` — Print Rows from an NDB Table

`ndb_select_all` prints all rows from an NDB table to `stdout`.

Usage:

```
ndb_select_all -c connect_string tbl_name -d db_name [> file_name]
```

Additional Options:

- `--lock=lock_type, -l lock_type`

Employs a lock when reading the table. Possible values for `lock_type` are:

- `0`: Read lock
- `1`: Read lock with hold
- `2`: Exclusive read lock

There is no default value for this option.

- `--order=index_name, -o index_name`

Orders the output according to the index named `index_name`. Note that this is the name of an index, not of a column, and that the index must have been explicitly named when created.

- `--descending, -z`

Sorts the output in descending order. This option can be used only in conjunction with the `-o` (`--order`) option.

- `--header=FALSE`

Excludes column headers from the output.

- `--useHexFormat -x`

Causes all numeric values to be displayed in hexadecimal format. This does not affect the output of numerals contained in strings or datetime values.

- `--delimiter=character, -D character`

Causes the *character* to be used as a column delimiter. Only table data columns are separated by this delimiter.

The default delimiter is the tab character.

- `--disk`

Adds a disk reference column to the output. The column is non-empty only for Disk Data tables having non-indexed columns.

- `--rowid`

Adds a `ROWID` column providing information about the fragments in which rows are stored.

- `--gci`

Adds a column to the output showing the global checkpoint at which each row was last updated. See [Section 17.14](#), “MySQL Cluster Glossary”, and [Section 17.7.4.2](#), “MySQL Cluster Log Events”, for more information about checkpoints.

- `--tupscan, -t`

Scan the table in the order of the tuples.

- `--nodata`

Causes any table data to be omitted.

Sample Output:

Output from a MySQL `SELECT` statement:

```
mysql> SELECT * FROM ctest1.fish;
+----+-----+
| id | name |
+----+-----+
| 3  | shark|
| 6  | puffer|
| 2  | tuna |
| 4  | manta ray|
| 5  | grouper|
| 1  | guppy|
+----+-----+
6 rows in set (0.04 sec)
```

Output from the equivalent invocation of `ndb_select_all`:

```
shell> ./ndb_select_all -c localhost fish -d ctest1
id      name
3       [shark]
6       [puffer]
2       [tuna]
4       [manta ray]
5       [grouper]
1       [guppy]
6 rows returned
NDBT_ProgramExit: 0 - OK
```

Note that all string values are enclosed by square brackets (“[...]”) in the output of `ndb_select_all`. For a further example, consider the table created and populated as shown here:

```
CREATE TABLE dogs (
  id INT(11) NOT NULL AUTO_INCREMENT,
  name VARCHAR(25) NOT NULL,
  breed VARCHAR(50) NOT NULL,
  PRIMARY KEY pk (id),
  KEY ix (name)
)
TABLESPACE ts STORAGE DISK
ENGINE=NDBCLUSTER;
```

```
INSERT INTO dogs VALUES
  ('', 'Lassie', 'collie'),
  ('', 'Scooby-Doo', 'Great Dane'),
  ('', 'Rin-Tin-Tin', 'Alsatian'),
  ('', 'Rosscoe', 'Mutt');
```

This demonstrates the use of several additional `ndb_select_all` options:

```
shell> ./ndb_select_all -d ctest1 dogs -o ix -z --gci --disk
GCI      id name      breed      DISK_REF
834461   2 [Scooby-Doo] [Great Dane] [ m_file_no: 0 m_page: 98 m_page_idx: 0 ]
834478   4 [Rosscoe]     [Mutt]      [ m_file_no: 0 m_page: 98 m_page_idx: 16 ]
834463   3 [Rin-Tin-Tin] [Alsatian]  [ m_file_no: 0 m_page: 34 m_page_idx: 0 ]
835657   1 [Lassie]      [Collie]    [ m_file_no: 0 m_page: 66 m_page_idx: 0 ]
4 rows returned
NDBT_ProgramExit: 0 - OK
```

17.6.19. `ndb_select_count` — Print Row Counts for NDB Tables

`ndb_select_count` prints the number of rows in one or more NDB tables. With a single table, the result is equivalent to that obtained by using the MySQL statement `SELECT COUNT(*) FROM tbl_name`.

Usage:

```
ndb_select_count [-c connect_string] -ddb_name tbl_name[, tbl_name2[, ...]]
```

Additional Options: None that are specific to this application. However, you can obtain row counts from multiple tables in the same database by listing the table names separated by spaces when invoking this command, as shown under **Sample Output**.

Sample Output:

```
shell> ./ndb_select_count -c localhost -d ctest1 fish dogs
6 records in table fish
4 records in table dogs
NDBT_ProgramExit: 0 - OK
```

17.6.20. `ndb_show_tables` — Display List of NDB Tables

`ndb_show_tables` displays a list of all NDB database objects in the cluster. By default, this includes not only both user-created tables and NDB system tables, but NDB-specific indexes, internal triggers, and MySQL Cluster Disk Data objects as well.

Usage:

```
ndb_show_tables [-c connect_string]
```

Additional Options:

- `--loops, -l`

Specifies the number of times the utility should execute. This is 1 when this option is not specified, but if you do use the option, you must supply an integer argument for it.

- `--parsable, -p`

Using this option causes the output to be in a format suitable for use with `LOAD DATA INFILE`.

- `--type, -t`

Can be used to restrict the output to one type of object, specified by an integer type code as shown here:

- **1:** System table
- **2:** User-created table
- **3:** Unique hash index

Any other value causes all NDB database objects to be listed (the default).

- `--unqualified, -u`

If specified, this causes unqualified object names to be displayed.

Note

Only user-created Cluster tables may be accessed from MySQL; system tables such as `SYSTAB_0` are not visible to `mysqld`. However, you can examine the contents of system tables using NDB API applications such as `ndb_select_all` (see [Section 17.6.18, “ndb_select_all — Print Rows from an NDB Table”](#)).

17.6.21. `ndb_size.pl` — NDBCLUSTER Size Requirement Estimator

This is a Perl script that can be used to estimate the amount of space that would be required by a MySQL database if it were converted to use the `NDBCLUSTER` storage engine. Unlike the other utilities discussed in this section, it does not require access to a MySQL Cluster (in fact, there is no reason for it to do so). However, it does need to access the MySQL server on which the database to be tested resides.

Requirements:

- A running MySQL server. The server instance does not have to provide support for MySQL Cluster.
- A working installation of Perl.
- The `DBI` module, which can be obtained from CPAN if it is not already part of your Perl installation. (Many Linux and other operating system distributions provide their own packages for this library.)
- Previous to MySQL 5.1.18, `ndb_size.pl` also required the `HTML::Template` module and an associated template file `share/mysql/ndb_size.tpl`. Beginning with MySQL 5.1.18, `ndb_size.tpl` is no longer needed (or included).
- A MySQL user account having the necessary privileges. If you do not wish to use an existing account, then creating one using `GRANT USAGE ON db_name.*` — where `db_name` is the name of the database to be examined — is sufficient for this purpose.

`ndb_size.pl` can also be found in the MySQL sources in `storage/ndb/tools`. If this file is not present in your MySQL installation, you can obtain it from the [MySQL Forge project page](#).

Usage:

```
perl ndb_size.pl db_name|ALL] [--hostname=host[:port]] [--socket=socket] [--user=user] \
  [--password=password] [--help|-h] [--format=(html|text)] [--loadqueries=file_name] [--savequeries=file_name]
```

By default, this utility attempts to analyze all databases on the server. You can specify a single database using the `--database` option; the default behavior can be made explicit by using `ALL` for the name of the database. You can also exclude one or more databases by using the `--excludedbs` with a comma-separated list of the names of the databases to be skipped. Similarly, you can cause specific tables to be skipped by listing their names, separated by commas, following the optional `--excludetables` option. A host name (and possibly a port as well) can be specified using `--hostname`; the default is `localhost:3306`. If necessary, you can specify a socket; the default is `/var/lib/mysql.sock`. A MySQL user name and password can be specified the corresponding options shown. It also possible to control the format of the output using the `--format` option; this can take either of the values `html` or `text`, with `text` being the default. An example of the text output is shown here:

```
shell> ndb_size.pl --database=test --socket=/tmp/mysql.sock
ndb_size.pl report for database: 'test' (1 tables)
-----
Connected to: DBI:mysql:host=localhost:mysql_socket=/tmp/mysql.sock

Including information for versions: 4.1, 5.0, 5.1

test.t1

  NoOfTriggers     768        5        5        5

```

For debugging purposes, the Perl arrays containing the queries run by this script can be read from the file specified using `--savequeries`; a file containing such arrays to be read in during script execution can be specified using `--loadqueries`. Neither of these options has a default value.

To produce output in HTML format, use the `--format` option and redirect the output to a file, as shown in this example:

```
shell> ndb_size.pl --database=test --socket=/tmp/mysql.sock --format=html > ndb_size.html
```

(Without the redirection, the output is sent to `stdout`.) This figure shows a portion of the generated `ndb_size.html` output file, as viewed in a Web browser:

MySQL Cluster analysis for world

This is an automated analysis of the DBI:mysql:database=world;host=192.168.0.176 database for migration into MySQL Cluster. No warranty is made to the accuracy of the information.

This information should be valid for MySQL 4.1 and 5.0. Since 5.1 is not a final release yet, the numbers should be used as a guide only.

Parameter Settings

NOTE the configuration parameters below do not take into account system tables and other requirements.

Parameter	4.1	5.0	5.1
DataMemory (kb)	544	544	544
IndexMemory (kb)	192	136	136
MaxNoOfTables	3	3	3
MaxNoOfAttributes	24	24	24
MaxNoOfOrderedIndexes	3	3	3
MaxNoOfUniqueHashIndexes	3	3	3
MaxNoOfTriggers	12	12	12

Memory usage because of parameters

Usage is in kilobytes. Actual usage will vary as you should set the parameters larger than those listed in the table above.

Parameter	4.1	5.0	5.1
Attributes	5	5	5
Tables	60	60	60
OrderedIndexes	30	30	30
UniqueHashIndexes	45	45	45

CountryCode	char	3		4	4	4

Indexes

We assume that indexes are ORDERED (not created USING HASH). If order is not required, 10 bytes of data memory can be saved per row if the index is created USING HASH

Index	Type	Columns	4.1 IdxMem	5.0 IdxMem	5.1 IdxMem	4.1 DatMem	5.0 DatMem	5.1 DatMem
PRIMARY	BTREE	ID	29	25	25	10	10	10

DataMemory Usage

	4.1	5.0	5.1
Row Overhead	16	16	16
Column DataMemory/Row	68	68	68
Index DataMemory/Row	10	10	10
Total DataMemory/Row	94	94	94
Rows per 32 kb page	347	347	347
Current number of rows	4079	4079	4079
Total DataMemory (kb)	384	384	384

IndexMemory Usage

	4.1	5.0	5.1
IndexMemory/Row	29	25	25
Rows per 8kb page	282	327	327
Current number of rows	4079	4079	4079
Total IndexMemory (kb)	120	104	104

The output from this script includes:

- Minimum values for the `DataMemory`, `IndexMemory`, `MaxNoOfTables`, `MaxNoOfAttributes`, `MaxNoOfOrderedIndexes`, `MaxNoOfUniqueHashIndexes`, and `MaxNoOfTriggers` configuration parameters required to accommodate the tables analyzed.
- Memory requirements for all of the tables, attributes, ordered indexes, and unique hash indexes defined in the database.
- The `IndexMemory` and `DataMemory` required per table and table row.

Note

Prior to MySQL 5.1.23, MySQL Cluster NDB 6.2.5, and MySQL Cluster NDB 6.3.7, `ndb_size.pl` was invoked as shown here:

```
perl ndb_size.pl db_name hostname username password > file_name.html
```

For more information about this change, see [Bug#28683](#) and [Bug#28253](#).

17.6.22. `ndb_waiter` — Wait for MySQL Cluster to Reach a Given Status

`ndb_waiter` repeatedly (each 100 milliseconds) prints out the status of all cluster data nodes until either the cluster reaches a given status or the `--timeout` limit is exceeded, then exits. By default, it waits for the cluster to achieve `STARTED` status, in which all nodes have started and connected to the cluster. This can be overridden using the `--no-contact` and `--not-started` options (see [Additional Options](#)).

The node states reported by this utility are as follows:

- `NO_CONTACT`: The node cannot be contacted.
- `UNKNOWN`: The node can be contacted, but its status is not yet known. Usually, this means that the node has received a `START` or `RESTART` command from the management server, but has not yet acted on it.
- `NOT_STARTED`: The node has stopped, but remains in contact with the cluster. This is seen when restarting the node using the management client's `RESTART` command.
- `STARTING`: The node's `ndbd` process has started, but the node has not yet joined the cluster.
- `STARTED`: The node is operational, and has joined the cluster.
- `SHUTTING_DOWN`: The node is shutting down.
- `SINGLE_USER_MODE`: This is shown for all cluster data nodes when the cluster is in single user mode.

Usage:

```
ndb_waiter [-c connect_string]
```

Additional Options:

- `--no-contact, -n`

Instead of waiting for the `STARTED` state, `ndb_waiter` continues running until the cluster reaches `NO_CONTACT` status before exiting.

- `--not-started`

Instead of waiting for the `STARTED` state, `ndb_waiter` continues running until the cluster reaches `NOT_STARTED` status before exiting.

- `--timeout=seconds, -t seconds`

Time to wait. The program exits if the desired state is not achieved within this number of seconds. The default is 120 seconds (1200 reporting cycles).

Sample Output. Shown here is the output from `ndb_waiter` when run against a 4-node cluster in which two nodes have been shut down and then started again manually. Duplicate reports (indicated by "...") are omitted.

```
shell> ./ndb_waiter -c localhost

Connecting to mgmsrv at (localhost)
State node 1 STARTED
State node 2 NO_CONTACT
State node 3 STARTED
State node 4 NO_CONTACT
Waiting for cluster enter state STARTED

...

State node 1 STARTED
State node 2 UNKNOWN
State node 3 STARTED
State node 4 NO_CONTACT
Waiting for cluster enter state STARTED

...

State node 1 STARTED
State node 2 STARTING
State node 3 STARTED
State node 4 NO_CONTACT
Waiting for cluster enter state STARTED

...

State node 1 STARTED
State node 2 STARTING
State node 3 STARTED
State node 4 UNKNOWN
Waiting for cluster enter state STARTED

...

State node 1 STARTED
State node 2 STARTING
State node 3 STARTED
State node 4 STARTING
Waiting for cluster enter state STARTED

...

State node 1 STARTED
State node 2 STARTED
State node 3 STARTED
State node 4 STARTING
Waiting for cluster enter state STARTED

...

State node 1 STARTED
State node 2 STARTED
State node 3 STARTED
State node 4 STARTED
Waiting for cluster enter state STARTED

NDBT_ProgramExit: 0 - OK
```

Note

If no connectstring is specified, then `ndb_waiter` tries to connect to a management on `localhost`, and reports `Connecting to mgmsrv at (null)`.

17.6.23. Options Common to MySQL Cluster Programs

All MySQL Cluster programs (except for `mysqld`) take the options described in this section. Users of earlier MySQL Cluster versions should note that some of these options have been changed to make them consistent with one another as well as with `mysqld`. You can use the `--help` option with any MySQL Cluster program to view a list of the options which it supports.

The options in the following list are common to all MySQL Cluster executables.

For options specific to individual NDB programs, see [Section 17.6, “MySQL Cluster Programs”](#).

See [Section 17.4.2, “mysqld Command Options for MySQL Cluster”](#), for `mysqld` options relating to MySQL Cluster.

- `--help --usage, -?`

Command Line Format	<code>--help</code>
---------------------	---------------------

Prints a short list with descriptions of the available command options.

- `--character-sets-dir=name`

Command Line Format	<code>--character-sets-dir=name</code>	
Value Set	Type	<code>filename</code>
	Default	

Tells the program where to find character set information.

- `--connect-string=connect_string, -c connect_string`

Command Line Format	<code>--ndb-connectstring=name</code>	
Value Set	Type	<code>string</code>
	Default	<code>localhost:1186</code>

`connect_string` sets the connectstring to the management server as a command option.

```
shell> ndbd --connect-string="nodeid=2;host=ndb_mgmd.mysql.com:1186"
```

For more information, see [Section 17.3.4.3, “The MySQL Cluster Connectstring”](#).

- `--core-file`

Command Line Format	<code>--core-file</code>	
Value Set	Type	<code>boolean</code>
	Default	<code>FALSE</code>

Write a core file if the program dies. The name and location of the core file are system-dependent. (For MySQL Cluster programs nodes running on Linux, the default location is the program's working directory — for a data node, this is the node's `DataDir`.) For some systems, there may be restrictions or limitations; for example, it might be necessary to execute `ulimit -c unlimited` before starting the server. Consult your system documentation for detailed information.

If MySQL Cluster was built using the `--debug` option for `configure`, then `--core-file` is enabled by default. For regular builds, `--core-file` is disabled by default.

- `--debug[=options]`

Command Line Format	<code>--debug=options</code>
----------------------------	------------------------------

This option can be used only for versions compiled with debugging enabled. It is used to enable output from debug calls in the same manner as for the `mysqld` process.

- `--execute=command, -e command`

Command Line Format	<code>--execute=name</code>
----------------------------	-----------------------------

Can be used to send a command to a Cluster executable from the system shell. For example, either of the following:

```
shell> ndb_mgm -e "SHOW"
```

or

```
shell> ndb_mgm --execute="SHOW"
```

is equivalent to

```
ndb_mgm> SHOW
```

This is analogous to how the `--execute` or `-e` option works with the `mysql` command-line client. See [Section 4.2.3.1, “Using Options on the Command Line”](#).

- `--ndb-mgmd-host=host[:port]`

Can be used to set the host and port number of the management server to connect to.

- `--ndb-nodeid=#`

Sets this node's MySQL Cluster node ID. *The range of permitted values depends on the type of the node (data, management, or API) and the version of the MySQL Cluster software which is running on it.* See [Section 17.12.2, “Limits and Differences of MySQL Cluster from Standard MySQL Limits”](#), for more information.

- `--ndb-optimized-node-selection`

Command Line Format	<code>--ndb-optimized-node-selection</code>	
Value Set	Type	boolean
	Default	TRUE

Optimize selection of nodes for transactions. Enabled by default.

- `--version, -V`

Command Line Format	<code>-V</code>
----------------------------	-----------------

Prints the MySQL Cluster version number of the executable. The version number is relevant because not all versions can be used together, and the MySQL Cluster startup process verifies that the versions of the binaries being used can co-exist in the same cluster. This is also important when performing an online (rolling) software upgrade or downgrade of MySQL Cluster. (See [Section 17.5.1, “Performing a Rolling Restart of a MySQL Cluster”](#)).

17.6.24. Summary Tables of NDB Program Options

The next few sections contain summary tables providing basic information about command-line options used with MySQL Cluster programs.

17.6.24.1. Common Options for MySQL Cluster Programs

Table 17.5. `ndb_common` Option Reference

Format	Description	Introduc-tion	Deprec-ated	Removed
<code>-character-sets-dir=name</code>	Directory where character sets are			
<code>-ndb-connectstring=name</code>	Set connect string for connecting to <code>ndb_mgmd</code> . Syntax: <code>[nodeid=<id>][host=<hostname>[:<port>]</code> . Overrides specifying entries in <code>NDB_CONNECTSTRING</code> and <code>my.cnf</code>			
<code>--core-file</code>	Write core on errors (defaults to TRUE in debug builds)			
<code>--debug=options</code>	Enable output from debug calls. Can be used only for versions compiled with debugging enabled			
<code>--execute=name</code>	Execute command and exit			
<code>--help</code>	Display help message and exit			
<code>--ndb-mgmd-host=name</code>	Set host and port for connecting to <code>ndb_mgmd</code> . Syntax:			

Format	Description	Introduc- tion	Deprec- ated	Removed
	<hostname>[:<port>]. Overrides specifying entries in NDB_CONNECTSTRING and my.cnf			
- - ndb-optim- ized-node-selection	Select nodes for transactions in a more optimal way			
--ndb-nodeid=#	Set node id for this node			
-V	Output version information and exit			

For options specific to individual MySQL Cluster programs, see [Section 17.6.23, “Options Common to MySQL Cluster Programs”](#).

17.6.24.2. Program Options for `ndbd` and `ndbmt d`

Table 17.6. `ndbd` Option Reference

Format	Description	Introduc- tion	Deprec- ated	Removed
--bind-address=name	Local bind address	5.1.12		
--daemon	Start ndbd as daemon (default); override with --nodaemon			
--foreground	Run ndbd in foreground, provided for debugging purposes (implies --nodaemon)			
--initial	Perform initial start of ndbd, including cleaning the file system. Consult the documentation before using this option			
--initial-start	Perform partial initial start (requires --nowait-nodes)	5.1.11		
--nodaemon	Do not start ndbd as daemon; provided for testing purposes			
--nostart	Don't start ndbd immediately; ndbd waits for command to start from ndb_mgmd			
--nowait-nodes=list	Nodes that will not be waited for during start (comma-separated list of node IDs)	5.1.11		

For more information about `ndbd`, see [Section 17.6.2, “`ndbd` — The MySQL Cluster Data Node Daemon”](#). For options common to all MySQL Cluster programs, see [Section 17.6.23, “Options Common to MySQL Cluster Programs”](#).

17.6.24.3. Program Options for `ndb_mgmd`

Table 17.7. `ndb_mgmd` Option Reference

Format	Description	Introduc- tion	Deprec- ated	Removed
--bind-address	Local bind address	5.1.22-ndb-6.3.2		
-c	Specify the cluster configuration file; in NDB-6.4.0 and later, needs --reload or --initial to override configuration cache if present			
--configdir=directory	Specify the cluster management server's configuration cache directory	5.1.30-ndb-6.4.0		
--daemon	Run ndb_mgmd in daemon mode (default)			
--initial	Causes the management server reload its configuration data from the configuration file, bypassing the configuration cache	5.1.30-ndb-6.4.0		
--interactive	Run ndb_mgmd in interactive mode (not officially supported in production; for testing purposes only)			
--mycnf	Read cluster configuration data from the my.cnf file			
--no-nodeid-checks	Do not provide any node id checks			
--nodaemon	Do not run ndb_mgmd as a daemon			
--print-full-config	Print full configuration and exit			

Format	Description	Introduction	Deprecated	Removed
<code>--reload</code>	Causes the management server to compare the configuration file with its configuration cache	5.1.30-ndb-6.4.0		

For more information about `ndb_mgmd`, see [Section 17.6.4, “ndb_mgmd — The MySQL Cluster Management Server Daemon”](#). For options common to all MySQL Cluster programs, see [Section 17.6.23, “Options Common to MySQL Cluster Programs”](#).

17.6.24.4. Program Options for `ndb_mgm`

Table 17.8. `ndb_mgm` Option Reference

Format	Description	Introduction	Deprecated	Removed
<code>--try-reconnect=#</code>	Specify number of tries for connecting to <code>ndb_mgmd</code> (0 = infinite)			

For more information about `ndb_mgm`, see [Section 17.6.5, “ndb_mgm — The MySQL Cluster Management Client”](#). For options common to all MySQL Cluster programs, see [Section 17.6.23, “Options Common to MySQL Cluster Programs”](#).

17.6.24.5. Program Options for `ndbd_redo_log_reader`

Table 17.9. `ndbd_redo_log_reader` Option Reference

Format	Description	Introduction	Deprecated	Removed
<code>-nocheck</code>	Do not check records for errors			
<code>-noprint</code>	Do not print records			

For more information about `ndbd_redo_log_reader`, see [Section 17.6.16, “ndbd_redo_log_reader — Check and Print Content of Cluster Redo Log”](#). For options common to all MySQL Cluster programs, see [Section 17.6.23, “Options Common to MySQL Cluster Programs”](#).

17.6.24.6. Program Options for `ndb_config`

Table 17.10. `ndb_config` Option Reference

Format	Description	Introduction	Deprecated	Removed
<code>--configinfo</code>	Dumps information about all NDB configuration parameters in text format with default, maximum, and minimum values. Use with <code>--xml</code> to obtain XML output.	5.1.34-ndb-7.0.6		
<code>--connections</code>	Print connection information only			
<code>--fields=string</code>	Field separator			
<code>--host=name</code>	Specify host			
<code>--mycnf</code>	Read configuration data from <code>my.cnf</code> file			
<code>--nodeid</code>	Get configuration of node with this ID			
<code>--nodes</code>	Print node information only			
	Short form for <code>--ndb-connectstring</code>	5.1.12		
<code>--config-file=path</code>	Set the path to <code>config.ini</code> file			
<code>--query=string</code>	One or more query options (attributes)			
<code>--rows=string</code>	Row separator			
<code>--type=name</code>	Specify node type			
<code>--configinfo --xml</code>	Use with <code>--configinfo</code> to obtain a dump of all NDB configuration parameters in XML format with default, maximum, and minimum values.	5.1.34-ndb-7.0.6		

For more information about `ndb_config`, see [Section 17.6.6, “ndb_config — Extract MySQL Cluster Configuration Information”](#). For options common to all MySQL Cluster programs, see [Section 17.6.23, “Options Common to MySQL Cluster Programs”](#).

17.6.24.7. Program Options for `ndb_error_reporter`

Table 17.11. `ndb_error_reporter` Option Reference

Format	Description	Introduction	Deprecated	Removed
<code>--fs</code>	Include file system data in error report; can use a large amount of disk space			

For more information about `ndb_error_reporter`, see [Section 17.6.12, “ndb_error_reporter — NDB Error-Reporting Utility”](#). For options common to all MySQL Cluster programs, see [Section 17.6.23, “Options Common to MySQL Cluster Programs”](#).

17.6.24.8. Program Options for `ndb_restore`

Table 17.12. `ndb_restore` Option Reference

Format	Description	Introduction	Deprecated	Removed
<code>--append</code>	Append data to a tab-delimited file	5.1.18		
<code>--backup_path=path</code>	Path to backup files directory			
<code>--backupid=#</code>	Restore from the backup with the given ID			
<code>--connect</code>	Same as connectstring			
<code>--restore_data</code>	Restore table data and logs into NDB Cluster using the NDB API			
<code>--dont_ignore_systab_0</code>	Do not ignore system table during restore. Experimental only; not for production use			
<code>-ex-include-databases=db-list</code>	List of one or more databases to exclude (includes those not named)	5.1.32-ndb-6.4.3		
<code>-ex-include-tables=table-list</code>	List of one or more tables to exclude (includes those not named)	5.1.32-ndb-6.4.3		
<code>-fields-enclosed-by=char</code>	Fields are enclosed with the indicated character	5.1.18		
<code>-fields-optionally-enclosed-by</code>	Fields are optionally enclosed with the indicated character	5.1.18		
<code>-fields-terminated-by=char</code>	Fields are terminated by the indicated character	5.1.18		
<code>--hex</code>	Print binary types in hexadecimal format	5.1.18		
<code>-include-databases=db-list</code>	List of one or more databases to restore (excludes those not named)	5.1.32-ndb-6.4.3		
<code>-include-tables=table-list</code>	List of one or more tables to restore (excludes those not named)	5.1.32-ndb-6.4.3		
<code>-lines-terminated-by=char</code>	Lines are terminated by the indicated character	5.1.18		
<code>--restore_meta</code>	Restore metadata to NDB Cluster using the NDB API			
<code>-</code>	Nodegroup map for NDBCLUSTER storage engine. Syntax: list			

Format	Description	Introduction	Deprecated	Removed
- ndb-node- group-map=map	of (source_nodegroup, destination_nodegroup)			
--no-binlog	If a mysqld is connected and using binary logging, do not log the restored data	5.1.24-ndb-6.3.16		
--no-restore-disk-objects	Do not restore Disk Data objects such as tablespaces and log file groups			
--no-upgrade	Do not upgrade array type for varsize attributes which do not already resize VAR data, and do not change column attributes	5.1.19		
--nodeid=#	Back up files from node with this ID			
--parallelism=#	Number of parallel transactions during restoration of data			
- -preserve-trailing-spaces	Allow preservation of trailing spaces (including padding) when CHAR is promoted to VARCHAR or BINARY is promoted to VARBINARY	5.1.23-ndb-6.3.8		
--print	Print metadata, data and log to stdout (equivalent to - -print_meta --print_data --print_log)			
--print_data	Print data to stdout			
--print_log	Print to stdout			
--print_metadata	Print metadata to stdout			
--progress-frequency=#	Print status of restoration each given number of seconds	5.1.?		
--promote-attributes	Allow attributes to be promoted when restoring data from backup	5.1.23-ndb-6.3.8		
--restore_epoch	Restore epoch info into the status table. Convenient on a MySQL Cluster replication slave for starting replication. The row in mysql.ndb_apply_status with id 0 will be updated/inserted.			
--skip-table-check	Skip table structure check during restoring of data	5.1.17		
--tab=path	Creates tab separated a .txt file for each table in the given path	5.1.18		
--verbose=#	Control level of verbosity in output			

For more information about `ndb_restore`, see [Section 17.6.17, “ndb_restore — Restore a MySQL Cluster Backup”](#). For options common to all NDB programs, see [Section 17.6.23, “Options Common to MySQL Cluster Programs”](#).

17.6.24.9. Program Options for `ndb_show_tables`

Table 17.13. `ndb_show_tables` Option Reference

Format	Description	Introduction	Deprecated	Removed
--database=string	Specifies the database in which the table is found			
--loops=#	Number of times to repeat output			
--show-temp-status	Show table temporary flag			
--parsable	Return output suitable for MySQL LOAD DATA INFILE statement			
--type=#	Limit output to objects of this type			
--unqualified	Do not qualify table names			

For more information about `ndb_show_tables`, see [Section 17.6.20, “ndb_show_tables — Display List of NDB Tables”](#). For options common to all MySQL Cluster programs, see [Section 17.6.23, “Options Common to MySQL Cluster Programs”](#).

17.6.24.10. Program Options for `ndb_size.pl`

Table 17.14. `ndb_size.pl` Option Reference

Format	Description	Introduc- tion	Deprec- ated	Removed
<code>--database=dbname</code>	The database or databases to examine; accepts a comma-delimited list; the default is ALL (use all databases found on the server)			
<code>--excludedbs=db-list</code>	Skip any databases in a comma-separated list of databases			
<code>--excludetables=tbl-list</code>	Skip any tables in a comma-separated list of tables			
<code>--format=string</code>	Set output format (text or HTML)			
<code>--hostname[:port]</code>	Specify host and optional port as host[:port]			
<code>--loadqueries=file</code>	Loads all queries from the file specified; does not connect to a database			
<code>--password=string</code>	Specify a MySQL user password			
<code>--real_table_name=table</code>	Designates a table to handle unique index size calculations	5.1.22-ndb-6.2.5		
<code>--savequeries=file</code>	Saves all queries to the database into the file specified			
<code>--socket=file</code>	Specify a socket to connect to	5.1.22-ndb-6.2.5		
<code>--user=string</code>	Specify a MySQL user name			

For more information about `ndb_size.pl`, see [Section 17.6.21, “ndb_size.pl — NDBCLUSTER Size Requirement Estimator”](#). For options common to all MySQL Cluster programs, see [Section 17.6.23, “Options Common to MySQL Cluster Programs”](#).

17.7. Management of MySQL Cluster

Managing a MySQL Cluster involves a number of tasks, the first of which is to configure and start MySQL Cluster. This is covered in [Section 17.3, “MySQL Cluster Configuration”](#), and [Section 17.6, “MySQL Cluster Programs”](#).

The following sections cover the management of a running MySQL Cluster.

For information about security issues relating to management and deployment of a MySQL Cluster, see [Section 17.8, “MySQL Cluster Security Issues”](#).

There are essentially two methods of actively managing a running MySQL Cluster. The first of these is through the use of commands entered into the management client whereby cluster status can be checked, log levels changed, backups started and stopped, and nodes stopped and started. The second method involves studying the contents of the cluster log `ndb_node_id_cluster.log`; this is usually found in the management server's `DataDir` directory, but this location can be overridden using the `LogDestination` option — see [Section 17.3.4.5, “Defining a MySQL Cluster Management Server”](#), for details. (Recall that `node_id` represents the unique identifier of the node whose activity is being logged.) The cluster log contains event reports generated by `ndbd`. It is also possible to send cluster log entries to a Unix system log.

In addition, some aspects of the cluster's operation can be monitored from an SQL node using the `SHOW ENGINE NDB STATUS` statement. See [Section 12.5.5.16, “SHOW ENGINE Syntax”](#), for more information.

17.7.1. Summary of MySQL Cluster Start Phases

This section provides a simplified outline of the steps involved when MySQL Cluster data nodes are started. More complete information can be found in [MySQL Cluster Start Phases](#).

These phases are the same as those reported in the output from the `node_id STATUS` command in the management client. (See [Section 17.7.2, “Commands in the MySQL Cluster Management Client”](#), for more information about this command.)

Start types. There are several different startup types and modes, as shown here:

- **Initial Start.** The cluster starts with a clean file system on all data nodes. This occurs either when the cluster started for the very first time, or when all data nodes are restarted using the `--initial` option.

Note

Disk Data files are not removed when restarting a node using `--initial`.

- **System Restart.** The cluster starts and reads data stored in the data nodes. This occurs when the cluster has been shut down after having been in use, when it is desired for the cluster to resume operations from the point where it left off.

- **Node Restart.** This is the online restart of a cluster node while the cluster itself is running.
- **Initial Node Restart.** This is the same as a node restart, except that the node is reinitialized and started with a clean file system.

Setup and initialization (Phase -1). Prior to startup, each data node (`ndbd` process) must be initialized. Initialization consists of the following steps:

1. Obtain a node ID
2. Fetch configuration data
3. Allocate ports to be used for inter-node communications
4. Allocate memory according to settings obtained from the configuration file

When a data node or SQL node first connects to the management node, it reserves a cluster node ID. To make sure that no other node allocates the same node ID, this ID is retained until the node has managed to connect to the cluster and at least one `ndbd` reports that this node is connected. This retention of the node ID is guarded by the connection between the node in question and `ndb_mgmd`.

Normally, in the event of a problem with the node, the node disconnects from the management server, the socket used for the connection is closed, and the reserved node ID is freed. However, if a node is disconnected abruptly — for example, due to a hardware failure in one of the cluster hosts, or because of network issues — the normal closing of the socket by the operating system may not take place. In this case, the node ID continues to be reserved and not released until a TCP timeout occurs 10 or so minutes later.

To take care of this problem, you can use `PURGE STALE SESSIONS`. Running this statement forces all reserved node IDs to be checked; any that are not being used by nodes actually connected to the cluster are then freed.

Beginning with MySQL 5.1.11, timeout handling of node ID assignments is implemented. This performs the ID usage checks automatically after approximately 20 seconds, so that `PURGE STALE SESSIONS` should no longer be necessary in a normal Cluster start.

After each data node has been initialized, the cluster startup process can proceed. The stages which the cluster goes through during this process are listed here:

- **Phase 0.** The `NDBFS` and `NDBCNTR` blocks start (see [NDB Kernel Blocks](#)). The cluster file system is cleared, if the cluster was started with the `--initial` option.
- **Phase 1.** In this stage, all remaining `NDB` kernel blocks are started. Cluster connections are set up, inter-block communications are established, and Cluster heartbeats are started. In the case of a node restart, API node connections are also checked.

Note

When one or more nodes hang in Phase 1 while the remaining node or nodes hang in Phase 2, this often indicates network problems. One possible cause of such issues is one or more cluster hosts having multiple network interfaces. Another common source of problems causing this condition is the blocking of TCP/IP ports needed for communications between cluster nodes. In the latter case, this is often due to a misconfigured firewall.

- **Phase 2.** The `NDBCNTR` kernel block checks the states of all existing nodes. The master node is chosen, and the cluster schema file is initialized.
- **Phase 3.** The `DBLQH` and `DBTC` kernel blocks set up communications between them. The startup type is determined; if this is a restart, the `DBDIH` block obtains permission to perform the restart.
- **Phase 4.** For an initial start or initial node restart, the redo log files are created. The number of these files is equal to `NoOfFragmentLogFiles`.

For a system restart:

- Read schema or schemas.
- Read data from the local checkpoint.
- Apply all redo information until the latest restorable global checkpoint has been reached.

For a node restart, find the tail of the redo log.

- **Phase 5.** Most of the database-related portion of a data node start is performed during this phase. For an initial start or system restart, a local checkpoint is executed, followed by a global checkpoint. Periodic checks of memory usage begin during this phase, and any required node takeovers are performed.
- **Phase 6.** In this phase, node groups are defined and set up.
- **Phase 7.** The arbitrator node is selected and begins to function. The next backup ID is set, as is the backup disk write speed. Nodes reaching this start phase are marked as `Started`. It is now possible for API nodes (including SQL nodes) to connect to the cluster. `connect`.
- **Phase 8.** If this is a system restart, all indexes are rebuilt (by `DBDIH`).
- **Phase 9.** The node internal startup variables are reset.
- **Phase 100 (OBSOLETE).** Formerly, it was at this point during a node restart or initial node restart that API nodes could connect to the node and begin to receive events. Currently, this phase is empty.
- **Phase 101.** At this point in a node restart or initial node restart, event delivery is handed over to the node joining the cluster. The newly-joined node takes over responsibility for delivering its primary data to subscribers. This phase is also referred to as *SUMA handover phase*.

After this process is completed for an initial start or system restart, transaction handling is enabled. For a node restart or initial node restart, completion of the startup process means that the node may now act as a transaction coordinator.

17.7.2. Commands in the MySQL Cluster Management Client

In addition to the central configuration file, a cluster may also be controlled through a command-line interface available through the management client `ndb_mgm`. This is the primary administrative interface to a running cluster.

Commands for the event logs are given in [Section 17.7.4, “Event Reports Generated in MySQL Cluster”](#); commands for creating backups and restoring from them are provided in [Section 17.7.3, “Online Backup of MySQL Cluster”](#).

The management client has the following basic commands. In the listing that follows, `node_id` denotes either a database node ID or the keyword `ALL`, which indicates that the command should be applied to all of the cluster's data nodes.

- `HELP`
Displays information on all available commands.

- `SHOW`
Displays information on the cluster's status.

Note

In a cluster where multiple management nodes are in use, this command displays information only for data nodes that are actually connected to the current management server.

- `node_id START`
Brings online the data node identified by `node_id` (or all data nodes).
`ALL START` works on all data nodes only, and does not affect management nodes.

Important

To use this command to bring a data node online, the data node must have been started using `ndbd --nostream` or `ndbd -n`.

- `node_id STOP`
Stops the data or management node identified by `node_id`. Note that `ALL STOP` works to stop all data nodes only, and does not affect management nodes.
A node affected by this command disconnects from the cluster, and its associated `ndbd` or `ndb_mgmd` process terminates.

- `node_id RESTART [-n] [-i] [-a]`

Restarts the data node identified by `node_id` (or all data nodes).

Using the `-i` option with `RESTART` causes the data node to perform an initial restart; that is, the node's file system is deleted and recreated. The effect is the same as that obtained from stopping the data node process and then starting it again using `ndbd --initial` from the system shell. Note that backup files and Disk Data files are not removed when this option is used.

Using the `-n` option causes the data node process to be restarted, but the data node is not actually brought online until the appropriate `START` command is issued. The effect of this option is the same as that obtained from stopping the data node and then starting it again using `ndbd --nostream` or `ndbd -n` from the system shell.

Using the `-a` causes all current transactions relying on this node to be aborted. No GCP check is done when the node rejoins the cluster.

- `node_id STATUS`

Displays status information for the data node identified by `node_id` (or for all data nodes).

- `node_id REPORT report-type`

Displays a report of type `report-type` for the data node identified by `node_id`, or for all data nodes using `ALL`.

Currently, there are two accepted values for `report-type`:

- `BackupStatus` provides a status report on a cluster backup in progress
- `MemoryUsage` displays how much data memory and index memory is being used by each data node.

The `REPORT` command was introduced in MySQL Cluster NDB 6.2.3 and MySQL Cluster NDB 6.3.0.

- `ENTER SINGLE USER MODE node_id`

Enters single user mode, whereby only the MySQL server identified by the node ID `node_id` is allowed to access the database.

Important

Currently, it is not possible in for data nodes to join a MySQL Cluster while it is running in single user mode. (Bug#20395)

- `EXIT SINGLE USER MODE`

Exits single user mode, allowing all SQL nodes (that is, all running `mysqld` processes) to access the database.

Note

It is possible to use `EXIT SINGLE USER MODE` even when not in single user mode, although the command has no effect in this case.

- `QUIT, EXIT`

Terminates the management client.

This command does not affect any nodes connected to the cluster.

- `SHUTDOWN`

Shuts down all cluster data nodes and management nodes. To exit the management client after this has been done, use `EXIT` or `QUIT`.

This command does *not* shut down any SQL nodes or API nodes that are connected to the cluster.

- `CREATE NODEGROUP nodeid[, nodeid, ...]`

Creates a new MySQL Cluster node group and causes data nodes to join it.

This command is used after adding new data nodes online to a MySQL Cluster, and causes them to join a new node group and thus to begin participating fully in the cluster. The command takes as its sole parameter a comma-separated list of node IDs — these are the IDs of the nodes just added and started that are to join the new node group. The number of nodes must be the same as the number of nodes in each node group that is already part of the cluster (each MySQL Cluster node group must have the same number of nodes). In other words, if the MySQL Cluster has 2 node groups of 2 data nodes each, then the new node group must also have 2 data nodes.

The node group ID of the new node group created by this command is determined automatically, and always the next highest unused node group ID in the cluster; it is not possible to set it manually.

This command was introduced in MySQL Cluster NDB 6.4.0. For more information, see [Section 17.7.8, “Adding MySQL Cluster Data Nodes Online”](#).

- `DROP NODEGROUP nodegroup_id`

Drops the MySQL Cluster node group with the given *nodegroup_id*.

This command can be used to drop a node group from a MySQL Cluster. `DROP NODEGROUP` takes as its sole argument the node group ID of the node group to be dropped.

`DROP NODEGROUP` acts only to remove the data nodes in the effected node group from that node group. It does not stop data nodes, assign them to a different node group, or remove them from the cluster's configuration. A data node that does not belong to a node group is indicated in the output of the management client `SHOW` command with `no nodegroup` in place of the node group ID, like this (indicated using bold text):

```
id=3      @10.100.2.67  (5.1.34-ndb-7.0.7, no nodegroup)
```

Prior to MySQL Cluster NDB 7.0.4, the `SHOW` output was not updated correctly following `DROP NODEGROUP`. ([Bug#43413](#))

`DROP NODEGROUP` works only when all data nodes in the node group to be dropped are completely empty of any table data and table definitions. Since there is currently no way using `ndb_mgm` or in the `mysql` client to remove all data from a specific data node or node group, this means that the command succeeds only in the two following cases:

1. After issuing `CREATE NODEGROUP` in the `ndb_mgm` client, but before issuing any `ALTER ONLINE TABLE ... REORGANIZE PARTITION` statements in the `mysql` client.
2. After dropping all `NDBCLUSTER` tables using `DROP TABLE`.

`TRUNCATE` does not work for this purpose because this removes only the table data; the data nodes continue to store an `NDBCLUSTER` table's definition until a `DROP TABLE` statement is issued that causes the table metadata to be dropped.

`DROP NODEGROUP` was introduced in MySQL Cluster NDB 6.4.0. For more information, see [Section 17.7.8, “Adding MySQL Cluster Data Nodes Online”](#).

17.7.3. Online Backup of MySQL Cluster

This section describes how to create a backup and how to restore the database from a backup at a later time.

17.7.3.1. MySQL Cluster Backup Concepts

A backup is a snapshot of the database at a given time. The backup consists of three main parts:

- **Metadata.** The names and definitions of all database tables
- **Table records.** The data actually stored in the database tables at the time that the backup was made
- **Transaction log.** A sequential record telling how and when data was stored in the database

Each of these parts is saved on all nodes participating in the backup. During backup, each node saves these three parts into three files on disk:

- `BACKUP-backup_id.node_id.ctl`

A control file containing control information and metadata. Each node saves the same table definitions (for all tables in the cluster) to its own version of this file.

- `BACKUP-backup_id-0.node_id.data`

A data file containing the table records, which are saved on a per-fragment basis. That is, different nodes save different fragments during the backup. The file saved by each node starts with a header that states the tables to which the records belong. Following the list of records there is a footer containing a checksum for all records.

- `BACKUP-backup_id.node_id.log`

A log file containing records of committed transactions. Only transactions on tables stored in the backup are stored in the log. Nodes involved in the backup save different records because different nodes host different database fragments.

In the listing above, *backup_id* stands for the backup identifier and *node_id* is the unique identifier for the node creating the file.

17.7.3.2. Using The MySQL Cluster Management Client to Create a Backup

Before starting a backup, make sure that the cluster is properly configured for performing one. (See [Section 17.7.3.3, “Configuration for MySQL Cluster Backups”](#).)

The `START BACKUP` command is used to create a backup:

```
START BACKUP [backup_id] [wait_option] [snapshot_option]

wait_option:
WAIT {STARTED | COMPLETED} | NOWAIT

snapshot_option:
SNAPSHOTSTART | SNAPSHOTEND
```

Successive backups are automatically identified sequentially, so the *backup_id*, an integer greater than or equal to 1, is optional; if it is omitted, the next available value is used. If an existing *backup_id* value is used, the backup fails with the error `BACKUP FAILED: FILE ALREADY EXISTS`. If used, the *backup_id* must follow `START BACKUP` immediately, before any other options are used.

Prior to MySQL Cluster NDB 6.2.17, 6.3.23, and 6.4.3, backup IDs greater than 2147483648 (2^{31}) were not supported correctly. ([Bug#43042](#)) Beginning with these versions, the maximum possible backup ID is 4294967296 (2^{32}).

Note

Prior to MySQL Cluster NDB 7.0.5, when starting a backup using `ndb_mgm -e "START BACKUP"`, the *backup_id* was required. ([Bug#31754](#))

The *wait_option* can be used to determine when control is returned to the management client after a `START BACKUP` command is issued, as shown in the following list:

- If `NOWAIT` is specified, the management client displays a prompt immediately, as seen here:

```
ndb_mgm> START BACKUP NOWAIT
ndb_mgm>
```

In this case, the management client can be used even while it prints progress information from the backup process.

- With `WAIT STARTED` the management client waits until the backup has started before returning control to the user, as shown here:

```
ndb_mgm> START BACKUP WAIT STARTED
Waiting for started, this may take several minutes
Node 2: Backup 3 started from node 1
ndb_mgm>
```

- `WAIT COMPLETED` causes the management client to wait until the backup process is complete before returning control to the user.

`WAIT COMPLETED` is the default.

Beginning with MySQL Cluster NDB 6.4.0, a *snapshot_option* can be used to determine whether the backup matches the state of the cluster when `START BACKUP` was issued, or when it was completed. `SNAPSHOTSTART` causes the backup to match the state of the cluster when the backup began; `SNAPSHOTEND` causes the backup to reflect the state of the cluster when the backup was finished. `SNAPSHOTEND` is the default, and matches the behavior found in previous MySQL Cluster releases.

Note

If you use the `SNAPSHOTSTART` option with `START BACKUP`, and the `CompressedBackup` parameter is enabled, only the data and control files are compressed — the log file is not compressed.

If both a *wait_option* and a *snapshot_option* are used, they may be specified in either order. For example, all of the following commands are valid, assuming that there is no existing backup having 4 as its ID:

```
START BACKUP WAIT STARTED SNAPSHOTSTART
START BACKUP SNAPSHOTSTART WAIT STARTED
START BACKUP 4 WAIT COMPLETED SNAPSHOTSTART
START BACKUP SNAPSHOTEND WAIT COMPLETED
START BACKUP 4 NOWAIT SNAPSHOTSTART
```

The procedure for creating a backup consists of the following steps:

1. Start the management client (`ndb_mgm`), if it not running already.
2. Execute the `START BACKUP` command. This produces several lines of output indicating the progress of the backup, as shown here:

```
ndb_mgm> START BACKUP
Waiting for completed, this may take several minutes
Node 2: Backup 1 started from node 1
Node 2: Backup 1 started from node 1 completed
StartGCP: 177 StopGCP: 180
#Records: 7362 #LogRecords: 0
Data: 453648 bytes Log: 0 bytes
ndb_mgm>
```

3. When the backup has started the management client displays this message:

```
Backup backup_id started from node node_id
```

backup_id is the unique identifier for this particular backup. This identifier is saved in the cluster log, if it has not been configured otherwise. *node_id* is the identifier of the management server that is coordinating the backup with the data nodes. At this point in the backup process the cluster has received and processed the backup request. It does not mean that the backup has finished. An example of this statement is shown here:

```
Node 2: Backup 1 started from node 1
```

4. The management client indicates with a message like this one that the backup has started:

```
Backup backup_id started from node node_id completed
```

As is the case for the notification that the backup has started, *backup_id* is the unique identifier for this particular backup, and *node_id* is the node ID of the management server that is coordinating the backup with the data nodes. This output is accompanied by additional information including relevant global checkpoints, the number of records backed up, and the size of the data, as shown here:

```
Node 2: Backup 1 started from node 1 completed
StartGCP: 177 StopGCP: 180
#Records: 7362 #LogRecords: 0
Data: 453648 bytes Log: 0 bytes
```

It is also possible to perform a backup from the system shell by invoking `ndb_mgm` with the `-e` or `--execute` option, as shown in this example:

```
shell> ndb_mgm -e "START BACKUP 6 WAIT COMPLETED SNAPSHOTSTART"
```

When using `START BACKUP` in this way, you must specify the backup ID.

Cluster backups are created by default in the `BACKUP` subdirectory of the `DataDir` on each data node. This can be overridden for one or more data nodes individually, or for all cluster data nodes in the `config.ini` file using the `BackupDataDir` configuration parameter as discussed in [Identifying Data Nodes](#). The backup files created for a backup with a given `backup_id` are stored in a subdirectory named `BACKUP-backup_id` in the backup directory.

To abort a backup that is already in progress:

1. Start the management client.
2. Execute this command:

```
ndb_mgm> ABORT BACKUP backup_id
```

The number `backup_id` is the identifier of the backup that was included in the response of the management client when the backup was started (in the message `Backup backup_id started from node management_node_id`).

3. The management client will acknowledge the abort request with `Abort of backup backup_id ordered`.

Note

At this point, the management client has not yet received a response from the cluster data nodes to this request, and the backup has not yet actually been aborted.

4. After the backup has been aborted, the management client will report this fact in a manner similar to what is shown here:

```
Node 1: Backup 3 started from 5 has been aborted. Error: 1321 - Backup aborted by user request: Permanent error: U
Node 3: Backup 3 started from 5 has been aborted. Error: 1323 - 1323: Permanent error: Internal error
Node 2: Backup 3 started from 5 has been aborted. Error: 1323 - 1323: Permanent error: Internal error
Node 4: Backup 3 started from 5 has been aborted. Error: 1323 - 1323: Permanent error: Internal error
```

In this example, we have shown sample output for a cluster with 4 data nodes, where the sequence number of the backup to be aborted is 3, and the management node to which the cluster management client is connected has the node ID 5. The first node to complete its part in aborting the backup reports that the reason for the abort was due to a request by the user. (The remaining nodes report that the backup was aborted due to an unspecified internal error.)

Note

There is no guarantee that the cluster nodes respond to an `ABORT BACKUP` command in any particular order.

The `Backup backup_id started from node management_node_id has been aborted` messages mean that the backup has been terminated and that all files relating to this backup have been removed from the cluster file system.

It is also possible to abort a backup in progress from a system shell using this command:

```
shell> ndb_mgm -e "ABORT BACKUP backup_id"
```

Note

If there is no backup having the ID `backup_id` running when an `ABORT BACKUP` is issued, the management client makes no response, nor is it indicated in the cluster log that an invalid abort command was sent.

17.7.3.3. Configuration for MySQL Cluster Backups

Five configuration parameters are essential for backup:

- `BackupDataBufferSize`
The amount of memory used to buffer data before it is written to disk.
- `BackupLogBufferSize`
The amount of memory used to buffer log records before these are written to disk.
- `BackupMemory`

The total memory allocated in a database node for backups. This should be the sum of the memory allocated for the backup data buffer and the backup log buffer.

- `BackupWriteSize`
The default size of blocks written to disk. This applies for both the backup data buffer and the backup log buffer.
- `BackupMaxWriteSize`
The maximum size of blocks written to disk. This applies for both the backup data buffer and the backup log buffer.

More detailed information about these parameters can be found in [Backup Parameters](#).

17.7.3.4. MySQL Cluster Backup Troubleshooting

If an error code is returned when issuing a backup request, the most likely cause is insufficient memory or disk space. You should check that there is enough memory allocated for the backup.

Important

If you have set `BackupDataBufferSize` and `BackupLogBufferSize` and their sum is greater than 4MB, then you must also set `BackupMemory` as well. See [BackupMemory](#).

You should also make sure that there is sufficient space on the hard drive partition of the backup target.

NDB does not support repeatable reads, which can cause problems with the restoration process. Although the backup process is “hot”, restoring a MySQL Cluster from backup is not a 100% “hot” process. This is due to the fact that, for the duration of the restore process, running transactions get non-repeatable reads from the restored data. This means that the state of the data is inconsistent while the restore is in progress.

MySQL Enterprise

MySQL Enterprise subscribers will find more information about Cluster backup in the Knowledge Base article, [How Do I Backup my Cluster Database](#). Access to the MySQL Knowledge Base collection of articles is one of the advantages of subscribing to MySQL Enterprise. For more information, see <http://www.mysql.com/products/enterprise/advisors.html>.

17.7.4. Event Reports Generated in MySQL Cluster

In this section, we discuss the types of event logs provided by MySQL Cluster, and the types of events that are logged.

MySQL Cluster provides two types of event log:

- The *cluster log*, which includes events generated by all cluster nodes. The cluster log is the log recommended for most uses because it provides logging information for an entire cluster in a single location.

By default, the cluster log is saved to a file named `ndb_node_id_cluster.log`, (where `node_id` is the node ID of the management server) in the same directory where the `ndb_mgm` binary resides.

Cluster logging information can also be sent to `stdout` or a `syslog` facility in addition to or instead of being saved to a file, as determined by the values set for the `DataDir` and `LogDestination` configuration parameters. See [Section 17.3.4.5, “Defining a MySQL Cluster Management Server”](#), for more information about these parameters.

- *Node logs* are local to each node.

Output generated by node event logging is written to the file `ndb_node_id_out.log` (where `node_id` is the node's node ID) in the node's `DataDir`. Node event logs are generated for both management nodes and data nodes.

Node logs are intended to be used only during application development, or for debugging application code.

Both types of event logs can be set to log different subsets of events.

Each reportable event can be distinguished according to three different criteria:

- *Category*: This can be any one of the following values: `STARTUP`, `SHUTDOWN`, `STATISTICS`, `CHECKPOINT`, `NODERE-`

START, CONNECTION, ERROR, or INFO.

- *Priority*: This is represented by one of the numbers from 1 to 15 inclusive, where 1 indicates “most important” and 15 “least important.”
- *Severity Level*: This can be any one of the following values: ALERT, CRITICAL, ERROR, WARNING, INFO, or DEBUG.

Both the cluster log and the node log can be filtered on these properties.

The format used in the cluster log is as shown here:

```
2007-01-26 19:35:55 [MgmSrvr] INFO -- Node 1: Data usage is 2%(60 32K pages of total 2560)
2007-01-26 19:35:55 [MgmSrvr] INFO -- Node 1: Index usage is 1%(24 8K pages of total 2336)
2007-01-26 19:35:55 [MgmSrvr] INFO -- Node 1: Resource 0 min: 0 max: 639 curr: 0
2007-01-26 19:35:55 [MgmSrvr] INFO -- Node 2: Data usage is 2%(76 32K pages of total 2560)
2007-01-26 19:35:55 [MgmSrvr] INFO -- Node 2: Index usage is 1%(24 8K pages of total 2336)
2007-01-26 19:35:55 [MgmSrvr] INFO -- Node 2: Resource 0 min: 0 max: 639 curr: 0
2007-01-26 19:35:55 [MgmSrvr] INFO -- Node 3: Data usage is 2%(58 32K pages of total 2560)
2007-01-26 19:35:55 [MgmSrvr] INFO -- Node 3: Index usage is 1%(25 8K pages of total 2336)
2007-01-26 19:35:55 [MgmSrvr] INFO -- Node 3: Resource 0 min: 0 max: 639 curr: 0
2007-01-26 19:35:55 [MgmSrvr] INFO -- Node 4: Data usage is 2%(74 32K pages of total 2560)
2007-01-26 19:35:55 [MgmSrvr] INFO -- Node 4: Index usage is 1%(25 8K pages of total 2336)
2007-01-26 19:35:55 [MgmSrvr] INFO -- Node 4: Resource 0 min: 0 max: 639 curr: 0
2007-01-26 19:39:42 [MgmSrvr] INFO -- Node 4: Node 9 Connected
2007-01-26 19:39:42 [MgmSrvr] INFO -- Node 1: Node 9 Connected
2007-01-26 19:39:42 [MgmSrvr] INFO -- Node 1: Node 9: API version 5.1.15
2007-01-26 19:39:42 [MgmSrvr] INFO -- Node 2: Node 9 Connected
2007-01-26 19:39:42 [MgmSrvr] INFO -- Node 2: Node 9: API version 5.1.15
2007-01-26 19:39:42 [MgmSrvr] INFO -- Node 3: Node 9 Connected
2007-01-26 19:39:42 [MgmSrvr] INFO -- Node 3: Node 9: API version 5.1.15
2007-01-26 19:39:42 [MgmSrvr] INFO -- Node 4: Node 9: API version 5.1.15
2007-01-26 19:59:22 [MgmSrvr] ALERT -- Node 2: Node 7 Disconnected
2007-01-26 19:59:22 [MgmSrvr] ALERT -- Node 2: Node 7 Disconnected
```

Each line in the cluster log contains the following information:

- A timestamp in *YYYY-MM-DD HH:MM:SS* format.
- The type of node which is performing the logging. In the cluster log, this is always `[MgmSrvr]`.
- The severity of the event.
- The ID of the node reporting the event.
- A description of the event. The most common types of events to appear in the log are connections and disconnections between different nodes in the cluster, and when checkpoints occur. In some cases, the description may contain status information.

17.7.4.1. MySQL Cluster Logging Management Commands

The following management commands are related to the cluster log:

- `CLUSTERLOG ON`
Turns the cluster log on.
- `CLUSTERLOG OFF`
Turns the cluster log off.
- `CLUSTERLOG INFO`
Provides information about cluster log settings.
- `node_id CLUSTERLOG category=threshold`
Logs *category* events with priority less than or equal to *threshold* in the cluster log.
- `CLUSTERLOG FILTER severity_level`
Toggles cluster logging of events of the specified *severity_level*.

The following table describes the default setting (for all data nodes) of the cluster log category threshold. If an event has a priority

with a value lower than or equal to the priority threshold, it is reported in the cluster log.

Note that events are reported per data node, and that the threshold can be set to different values on different nodes.

Category	Default threshold (All data nodes)
STARTUP	7
SHUTDOWN	7
STATISTICS	7
CHECKPOINT	7
NODERESTART	7
CONNECTION	7
ERROR	15
INFO	7

The `STATISTICS` category can provide a great deal of useful data. See [Section 17.7.4.3, “Using `CLUSTERLOG STATISTICS` in the MySQL Cluster Management Client”](#), for more information.

Thresholds are used to filter events within each category. For example, a `STARTUP` event with a priority of 3 is not logged unless the threshold for `STARTUP` is set to 3 or higher. Only events with priority 3 or lower are sent if the threshold is 3.

The following table shows the event severity levels.

Note

These correspond to Unix `syslog` levels, except for `LOG_EMERG` and `LOG_NOTICE`, which are not used or mapped.

1	ALERT	A condition that should be corrected immediately, such as a corrupted system database
2	CRITICAL	Critical conditions, such as device errors or insufficient resources
3	ERROR	Conditions that should be corrected, such as configuration errors
4	WARNING	Conditions that are not errors, but that might require special handling
5	INFO	Informational messages
6	DEBUG	Debugging messages used for <code>NDBCLUSTER</code> development

Event severity levels can be turned on or off (using `CLUSTERLOG FILTER` — see above). If a severity level is turned on, then all events with a priority less than or equal to the category thresholds are logged. If the severity level is turned off then no events belonging to that severity level are logged.

Important

Cluster log levels are set on a per `ndb_mgmd`, per subscriber basis. This means that, in a MySQL Cluster with multiple management servers, using a `CLUSTERLOG` command in an instance of `ndb_mgm` connected to one management server affects only logs generated by that management server but not by any of the others. This also means that, should one of the management servers be restarted, only logs generated by that management server are affected by the resetting of log levels caused by the restart.

17.7.4.2. MySQL Cluster Log Events

An event report reported in the event logs has the following format:

```
datetime [string] severity -- message
```

For example:

```
09:19:30 2005-07-24 [NDB] INFO -- Node 4 Start phase 4 completed
```

This section discusses all reportable events, ordered by category and severity level within each category.

In the event descriptions, GCP and LCP mean “Global Checkpoint” and “Local Checkpoint”, respectively.

CONNECTION Events

These events are associated with connections between Cluster nodes.

Event	Priority	Severity Level	Description
data nodes connected	8	INFO	Data nodes connected
data nodes disconnected	8	INFO	Data nodes disconnected
Communication closed	8	INFO	SQL node or data node connection closed
Communication opened	8	INFO	SQL node or data node connection opened

CHECKPOINT Events

The logging messages shown here are associated with checkpoints.

Event	Priority	Severity Level	Description
LCP stopped in calc keep GCI	0	ALERT	LCP stopped
Local checkpoint fragment completed	11	INFO	LCP on a fragment has been completed
Global checkpoint completed	10	INFO	GCP finished
Global checkpoint started	9	INFO	Start of GCP: REDO log is written to disk
Local checkpoint completed	8	INFO	LCP completed normally
Local checkpoint started	7	INFO	Start of LCP: data written to disk

STARTUP Events

The following events are generated in response to the startup of a node or of the cluster and of its success or failure. They also provide information relating to the progress of the startup process, including information concerning logging activities.

Event	Priority	Severity Level	Description
Internal start signal received STTORY	15	INFO	Blocks received after completion of restart
New REDO log started	10	INFO	GCI keep <i>X</i> , newest restorable GCI <i>Y</i>
New log started	10	INFO	Log part <i>X</i> , start MB <i>Y</i> , stop MB <i>Z</i>
Node has been refused for inclusion in the cluster	8	INFO	Node cannot be included in cluster due to misconfiguration, inability to establish communication, or other problem
data node neighbors	8	INFO	Shows neighboring data nodes
data node start phase <i>X</i> completed	4	INFO	A data node start phase has been completed
Node has been successfully included into the cluster	3	INFO	Displays the node, managing node, and dynamic ID
data node start phases initiated	1	INFO	NDB Cluster nodes starting
data node all start phases completed	1	INFO	NDB Cluster nodes started
data node shutdown initiated	1	INFO	Shutdown of data node has commenced
data node shutdown aborted	1	INFO	Unable to shut down data node normally

NODERESTART Events

The following events are generated when restarting a node and relate to the success or failure of the node restart process.

Event	Priority	Severity Level	Description
Node failure phase completed	8	ALERT	Reports completion of node failure phases
Node has failed, node state was <i>X</i>	8	ALERT	Reports that a node has failed
Report arbitrator results	2	ALERT	There are eight different possible results for arbitration attempts:

			<ul style="list-style-type: none"> • Arbitration check failed — less than 1/2 nodes left • Arbitration check succeeded — node group majority • Arbitration check failed — missing node group • Network partitioning — arbitration required • Arbitration succeeded — affirmative response from node <i>X</i> • Arbitration failed - negative response from node <i>X</i> • Network partitioning - no arbitrator available • Network partitioning - no arbitrator configured
Completed copying a fragment	10	INFO	
Completed copying of dictionary information	8	INFO	
Completed copying distribution information	8	INFO	
Starting to copy fragments	8	INFO	
Completed copying all fragments	8	INFO	
GCP takeover started	7	INFO	
GCP takeover completed	7	INFO	
LCP takeover started	7	INFO	
LCP takeover completed (state = <i>X</i>)	7	INFO	
Report whether an arbitrator is found or not	6	INFO	<p>There are seven different possible outcomes when seeking an arbitrator:</p> <ul style="list-style-type: none"> • Management server restarts arbitration thread [state=<i>X</i>] • Prepare arbitrator node <i>X</i> [ticket=<i>Y</i>] • Receive arbitrator node <i>X</i> [ticket=<i>Y</i>] • Started arbitrator node <i>X</i> [ticket=<i>Y</i>] • Lost arbitrator node <i>X</i> - process failure [state=<i>Y</i>] • Lost arbitrator node <i>X</i> - process exit [state=<i>Y</i>] • Lost arbitrator node <i>X</i> <error msg> [state=<i>Y</i>]

STATISTICS Events

The following events are of a statistical nature. They provide information such as numbers of transactions and other operations, amount of data sent or received by individual nodes, and memory usage.

Event	Priority	Severity Level	Description
Report job scheduling statistics	9	INFO	Mean internal job scheduling statistics
Sent number of bytes	9	INFO	Mean number of bytes sent to node <i>X</i>
Received # of bytes	9	INFO	Mean number of bytes received from node <i>X</i>
Report transaction statistics	8	INFO	Numbers of: transactions, commits, reads, simple reads, writes, concurrent operations, attribute information, and aborts
Report operations	8	INFO	Number of operations
Report table create	7	INFO	

Memory usage	5	INFO	Data and index memory usage (80%, 90%, and 100%)
--------------	---	------	--

ERROR Events

These events relate to Cluster errors and warnings. The presence of one or more of these generally indicates that a major malfunction or failure has occurred.

Event	Priority	Severity	Description
Dead due to missed heartbeat	8	ALERT	Node <i>X</i> declared “dead” due to missed heartbeat
Transporter errors	2	ERROR	
Transporter warnings	8	WARNING	
Missed heartbeats	8	WARNING	Node <i>X</i> missed heartbeat # <i>Y</i>
General warning events	2	WARNING	

INFO Events

These events provide general information about the state of the cluster and activities associated with Cluster maintenance, such as logging and heartbeat transmission.

Event	Priority	Severity	Description
Sent heartbeat	12	INFO	Heartbeat sent to node <i>X</i>
Create log bytes	11	INFO	Log part, log file, MB
General information events	2	INFO	

17.7.4.3. Using `CLUSTERLOG STATISTICS` in the MySQL Cluster Management Client

The NDB management client's `CLUSTERLOG STATISTICS` command can provide a number of useful statistics in its output. Counters providing information about the state of the cluster are updated at 5-second reporting intervals by the transaction coordinator (TC) and the local query handler (LQH), and written to the cluster log.

Transaction coordinator statistics. Each transaction has one transaction coordinator, which is chosen by one of the following methods:

- In a round-robin fashion
- By communication proximity
- (*Beginning with MySQL Cluster NDB 6.3.4:*) By supplying a data placement hint when the transaction is started

Note

You can determine which TC selection method is used for transactions started from a given SQL node using the `ndb_optimized_node_selection` system variable.

All operations within the same transaction use the same transaction coordinator, which reports the following statistics:

- **Trans count.** This is the number transactions started in the last interval using this TC as the transaction coordinator. Any of these transactions may have committed, have been aborted, or remain uncommitted at the end of the reporting interval.

Note

Transactions do not migrate between TCs.

- **Commit count.** This is the number of transactions using this TC as the transaction coordinator that were committed in the last reporting interval. Because some transactions committed in this reporting interval may have started in a previous reporting interval, it is possible for `Commit count` to be greater than `Trans count`.
- **Read count.** This is the number of primary key read operations using this TC as the transaction coordinator that were started in the last reporting interval, including simple reads. This count also includes reads performed as part of unique index operations. A unique index read operation generates 2 primary key read operations — 1 for the hidden unique index table, and 1 for the table on which the read takes place.

- **Simple read count.** This is the number of simple read operations using this TC as the transaction coordinator that were started in the last reporting interval. This is a subset of `Read count`. Because the value of `Simple read count` is incremented at a different point in time from `Read count`, it can lag behind `Read count` slightly, so it is conceivable that `Simple read count` is not equal to `Read count` for a given reporting interval, even if all reads made during that time were in fact simple reads.
- **Write count.** This is the number of primary key write operations using this TC as the transaction coordinator that were started in the last reporting interval. This includes all inserts, updates, writes and deletes, as well as writes performed as part of unique index operations.

Note

A unique index update operation can generate multiple PK read and write operations on the index table and on the base table.

- **AttrInfoCount.** This is the number of 32-bit data words received in the last reporting interval for primary key operations using this TC as the transaction coordinator. For reads, this is proportional to the number of columns requested. For inserts and updates, this is proportional to the number of columns written, and the size of their data. For delete operations, this is usually zero. Unique index operations generate multiple PK operations and so increase this count. However, data words sent to describe the PK operation itself, and the key information sent, are *not* counted here. Attribute information sent to describe columns to read for scans, or to describe ScanFilters, is also not counted in `AttrInfoCount`.
- **Concurrent Operations.** This is the number of primary key or scan operations using this TC as the transaction coordinator that were started during the last reporting interval but that were not completed. Operations increment this counter when they are started and decrement it when they are completed; this occurs after the transaction commits. Dirty reads and writes — as well as failed operations — decrement this counter. The maximum value that `Concurrent Operations` can have is the maximum number of operations that a TC block can support; currently, this is $(2 * \text{MaxNoOfConcurrentOperations}) + 16 + \text{MaxNoOfConcurrentTransactions}$. (For more information about these configuration parameters, see the *Transaction Parameters* section of [Section 17.3.4.6, “Defining MySQL Cluster Data Nodes”](#).)
- **Abort count.** This is the number of transactions using this TC as the transaction coordinator that were aborted during the last reporting interval. Because some transactions that were aborted in the last reporting interval may have started in a previous reporting interval, `Abort count` can sometimes be greater than `Trans count`.
- **Scans.** This is the number of table scans using this TC as the transaction coordinator that were started during the last reporting interval. This does not include range scans (that is, ordered index scans).
- **Range scans.** This is the number of ordered index scans using this TC as the transaction coordinator that were started in the last reporting interval.

Local query handler statistics (`Operations`). There is 1 cluster event per local query handler block (that is, 1 per data node process). Operations are recorded in the LQH where the data they are operating on resides.

Note

A single transaction may operate on data stored in multiple LQH blocks.

The `Operations` statistic provides the number of local operations performed by this LQH block in the last reporting interval, and includes all types of read and write operations (insert, update, write, and delete operations). This also includes operations used to replicate writes — for example, in a 2-replica cluster, the write to the primary replica is recorded in the primary LQH, and the write to the backup will be recorded in the backup LQH. Unique key operations may result in multiple local operations; however, this does *not* include local operations generated as a result of a table scan or ordered index scan, which are not counted.

Process scheduler statistics. In addition to the statistics reported by the transaction coordinator and local query handler, each `nd-bd` process has a scheduler which also provides useful metrics relating to the performance of a MySQL Cluster. This scheduler runs in an infinite loop; during each loop the scheduler performs the following tasks:

1. Read any incoming messages from sockets into a job buffer.
2. Check whether there are any timed messages to be executed; if so, put these into the job buffer as well.
3. Execute (in a loop) any messages in the job buffer.
4. Send any distributed messages that were generated by executing the messages in the job buffer.
5. Wait for any new incoming messages.

Process scheduler statistics include the following:

- **Mean Loop Counter.** This is the number of loops executed in the third step from the preceding list. This statistic increases in size as the utilization of the TCP/IP buffer improves. You can use this to monitor changes in performance as you add new data node processes.
- **Mean send size and Mean receive size.** These statistics allow you to gauge the efficiency of, respectively writes and reads between nodes. The values are given in bytes. Higher values mean a lower cost per byte sent or received; the maximum value is 64K.

To cause all cluster log statistics to be logged, you can use the following command in the NDB management client:

```
ndb_mgm> ALL CLUSTERLOG STATISTICS=15
```

Note

Setting the threshold for `STATISTICS` to 15 causes the cluster log to become very verbose, and to grow quite rapidly in size, in direct proportion to the number of cluster nodes and the amount of activity in the MySQL Cluster.

For more information about MySQL Cluster management client commands relating to logging and reporting, see [Section 17.7.4.1, “MySQL Cluster Logging Management Commands”](#).

17.7.5. MySQL Cluster Log Messages

This section contains information about the messages written to the cluster log in response to different cluster log events. It provides additional, more specific information on NDB transporter errors.

17.7.5.1. MySQL Cluster — Messages in the Cluster Log

The following table lists the most common NDB cluster log messages. For information about the cluster log, log events, and event types, see [Section 17.7.4, “Event Reports Generated in MySQL Cluster”](#). These log messages also correspond to log event types in the MGM API; see [The Ndb_logevent_type Type](#), for related information of interest to Cluster API developers.

<p>Log Message. Node <i>mgm_node_id</i>: Node <i>data_node_id</i> Connected</p> <p>Description. The data node having node ID <i>node_id</i> has connected to the management server (node <i>mgm_node_id</i>).</p>	<p>Event Name. Connected</p> <p>Event Type. Connection</p> <p>Priority. 8</p> <p>Severity. INFO</p>
<p>Log Message. Node <i>mgm_node_id</i>: Node <i>data_node_id</i> Disconnected</p> <p>Description. The data node having node ID <i>data_node_id</i> has disconnected from the management server (node <i>mgm_node_id</i>).</p>	<p>Event Name. Disconnected</p> <p>Event Type. Connection</p> <p>Priority. 8</p> <p>Severity. ALERT</p>
<p>Log Message. Node <i>data_node_id</i>: Communication to Node <i>api_node_id</i> closed</p> <p>Description. The API node or SQL node having node ID <i>api_node_id</i> is no longer communicating with data node <i>data_node_id</i>.</p>	<p>Event Name. CommunicationClosed</p> <p>Event Type. Connection</p> <p>Priority. 8</p> <p>Severity. INFO</p>
<p>Log Message. Node <i>data_node_id</i>: Communication to Node <i>api_node_id</i> opened</p> <p>Description. The API node or SQL node having node ID <i>api_node_id</i> is now communicating with data node <i>data_node_id</i>.</p>	<p>Event Name. CommunicationOpened</p> <p>Event Type. Connection</p> <p>Priority. 8</p> <p>Severity. INFO</p>
<p>Log Message. Node <i>mgm_node_id</i>: Node <i>api_node_id</i>: API <i>version</i></p> <p>Description. The API node having node ID <i>api_node_id</i> has connected</p>	<p>Event Name. ConnectedApiVersion</p> <p>Event Type. Connection</p>

to management node <i>mgm_node_id</i> using NDB API version <i>version</i> (generally the same as the MySQL version number).	Priority. 8 Severity. INFO
Log Message. Node <i>node_id</i> : Global checkpoint <i>gci</i> started Description. A global checkpoint with the ID <i>gci</i> has been started; node <i>node_id</i> is the master responsible for this global checkpoint.	Event Name. GlobalCheckpointStarted Event Type. Checkpoint Priority. 9 Severity. INFO
Log Message. Node <i>node_id</i> : Global checkpoint <i>gci</i> completed Description. The global checkpoint having the ID <i>gci</i> has been completed; node <i>node_id</i> was the master responsible for this global checkpoint.	Event Name. GlobalCheckpointCompleted Event Type. Checkpoint Priority. 10 Severity. INFO
Log Message. Node <i>node_id</i> : Local checkpoint <i>lcp</i> started. Keep GCI = <i>current_gci</i> oldest restorable GCI = <i>old_gci</i> Description. The local checkpoint having sequence ID <i>lcp</i> has been started on node <i>node_id</i> . The most recent GCI that can be used has the index <i>current_gci</i> , and the oldest GCI from which the cluster can be restored has the index <i>old_gci</i> .	Event Name. LocalCheckpointStarted Event Type. Checkpoint Priority. 7 Severity. INFO
Log Message. Node <i>node_id</i> : Local checkpoint <i>lcp</i> completed Description. The local checkpoint having sequence ID <i>lcp</i> on node <i>node_id</i> has been completed.	Event Name. LocalCheckpointCompleted Event Type. Checkpoint Priority. 8 Severity. INFO
Log Message. Node <i>node_id</i> : Local Checkpoint stopped in CALCULATED_KEEP_GCI Description. The node was unable to determine the most recent usable GCI.	Event Name. LCPStoppedInCalcKeepGci Event Type. Checkpoint Priority. 0 Severity. ALERT
Log Message. Node <i>node_id</i> : Table ID = <i>table_id</i> , fragment ID = <i>fragment_id</i> has completed LCP on Node <i>node_id</i> maxGciStarted: <i>started_gci</i> maxGciCompleted: <i>completed_gci</i> Description. A table fragment has been checkpointed to disk on node <i>node_id</i> . The GCI in progress has the index <i>started_gci</i> , and the most recent GCI to have been completed has the index <i>completed_gci</i> .	Event Name. LCPFragmentCompleted Event Type. Checkpoint Priority. 11 Severity. INFO
Log Message. Node <i>node_id</i> : ACC Blocked <i>num_1</i> and TUP Blocked <i>num_2</i> times last second Description. Undo logging is blocked because the log buffer is close to overflowing.	Event Name. UndoLogBlocked Event Type. Checkpoint Priority. 7 Severity. INFO
Log Message. Node <i>node_id</i> : Start initiated <i>version</i> Description. Data node <i>node_id</i> , running NDB version <i>version</i> , is beginning its startup process.	Event Name. NDBStartStarted Event Type. StartUp

17.7.5.2. MySQL Cluster — NDB Transporter Errors

This section lists error codes, names, and messages that are written to the cluster log in the event of transporter errors.

Error Code	Error Name	Error Text
0x00	TE_NO_ERROR	NO ERROR
0x01	TE_ERROR_CLOSING_SOCKET	ERROR FOUND DURING CLOSING OF SOCKET
0x02	TE_ERROR_IN_SELECT_BEFORE_ACCEPT	ERROR FOUND BEFORE ACCEPT. THE TRANSPORTER WILL RETRY
0x03	TE_INVALID_MESSAGE_LENGTH	ERROR FOUND IN MESSAGE (INVALID MESSAGE LENGTH)
0x04	TE_INVALID_CHECKSUM	ERROR FOUND IN MESSAGE (CHECKSUM)
0x05	TE_COULD_NOT_CREATE_SOCKET	ERROR FOUND WHILE CREATING SOCKET(CAN'T CREATE SOCKET)
0x06	TE_COULD_NOT_BIND_SOCKET	ERROR FOUND WHILE BINDING SERVER SOCKET
0x07	TE_LISTEN_FAILED	ERROR FOUND WHILE LISTENING TO SERVER SOCKET
0x08	TE_ACCEPT_RETURN_ERROR	ERROR FOUND DURING ACCEPT(ACCEPT RETURN ERROR)
0x0b	TE_SHM_DISCONNECT	THE REMOTE NODE HAS DISCONNECTED
0x0c	TE_SHM_IPC_STAT	UNABLE TO CHECK SHM SEGMENT
0x0d	TE_SHM_UNABLE_TO_CREATE_SEGMENT	UNABLE TO CREATE SHM SEGMENT
0x0e	TE_SHM_UNABLE_TO_ATTACH_SEGMENT	UNABLE TO ATTACH SHM SEGMENT
0x0f	TE_SHM_UNABLE_TO_REMOVE_SEGMENT	UNABLE TO REMOVE SHM SEGMENT
0x10	TE_TOO_SMALL_SIGID	SIG ID TOO SMALL
0x11	TE_TOO_LARGE_SIGID	SIG ID TOO LARGE
0x12	TE_WAIT_STACK_FULL	WAIT STACK WAS FULL
0x13	TE_RECEIVE_BUFFER_FULL	RECEIVE BUFFER WAS FULL
0x14	TE_SIGNAL_LOST_SEND_BUFFER_FULL	SEND BUFFER WAS FULL, AND TRYING TO FORCE SEND FAILS
0x15	TE_SIGNAL_LOST	SEND FAILED FOR UNKNOWN REASON(SIGNAL LOST)
0x16	TE_SEND_BUFFER_FULL	THE SEND BUFFER WAS FULL, BUT SLEEPING FOR A WHILE SOLVED
0x0017	TE_SCI_LINK_ERROR	THERE IS NO LINK FROM THIS NODE TO THE SWITCH
0x18	TE_SCI_UNABLE_TO_START_SEQUENCE	COULD NOT START A SEQUENCE, BECAUSE SYSTEM RESOURCES ARE EXUMED OR NO SEQUENCE HAS BEEN CREATED
0x19	TE_SCI_UNABLE_TO_REMOVE_SEQUENCE	COULD NOT REMOVE A SEQUENCE
0x1a	TE_SCI_UNABLE_TO_CREATE_SEQUENCE	COULD NOT CREATE A SEQUENCE, BECAUSE SYSTEM RESOURCES ARE EXEMPTED. MUST REBOOT
0x1b	TE_SCI_UNRECOVERABLE_DATA_TFX_ERROR	TRIED TO SEND DATA ON REDUNDANT LINK BUT FAILED

Error Code	Error Name	Error Text
0x1c	TE_SCI_CANNOT_INIT_LOCALSEGMENT	CANNOT INITIALIZE LOCAL SEGMENT
0x1d	TE_SCI_CANNOT_MAP_REMOTESEGMENT	CANNOT MAP REMOTE SEGMENT
0x1e	TE_SCI_UNABLE_TO_UNMAP_SEGMENT	CANNOT FREE THE RESOURCES USED BY THIS SEGMENT (STEP 1)
0x1f	TE_SCI_UNABLE_TO_REMOVE_SEGMENT	CANNOT FREE THE RESOURCES USED BY THIS SEGMENT (STEP 2)
0x20	TE_SCI_UNABLE_TO_DISCONNECT_SEGMENT	CANNOT DISCONNECT FROM A REMOTE SEGMENT
0x21	TE_SHM_IPC_PERMANENT	SHM IPC PERMANENT ERROR
0x22	TE_SCI_UNABLE_TO_CLOSE_CHANNEL	UNABLE TO CLOSE THE SCI CHANNEL AND THE RESOURCES ALLOCATED

17.7.6. MySQL Cluster Single User Mode

Single user mode allows the database administrator to restrict access to the database system to a single API node, such as a MySQL server (SQL node) or an instance of `ndb_restore`. When entering single user mode, connections to all other API nodes are closed gracefully and all running transactions are aborted. No new transactions are permitted to start.

Once the cluster has entered single user mode, only the designated API node is granted access to the database.

You can use the `ALL STATUS` command to see when the cluster has entered single user mode.

Example:

```
ndb_mgm> ENTER SINGLE USER MODE 5
```

After this command has executed and the cluster has entered single user mode, the API node whose node ID is `5` becomes the cluster's only permitted user.

The node specified in the preceding command must be an API node; attempting to specify any other type of node will be rejected.

Note

When the preceding command is invoked, all transactions running on the designated node are aborted, the connection is closed, and the server must be restarted.

The command `EXIT SINGLE USER MODE` changes the state of the cluster's data nodes from single user mode to normal mode. API nodes — such as MySQL Servers — waiting for a connection (that is, waiting for the cluster to become ready and available), are again permitted to connect. The API node denoted as the single-user node continues to run (if still connected) during and after the state change.

Example:

```
ndb_mgm> EXIT SINGLE USER MODE
```

There are two recommended ways to handle a node failure when running in single user mode:

- Method 1:
 1. Finish all single user mode transactions
 2. Issue the `EXIT SINGLE USER MODE` command
 3. Restart the cluster's data nodes

- Method 2:

Restart database nodes prior to entering single user mode.

17.7.7. Quick Reference: MySQL Cluster SQL Statements

This section discusses several SQL statements that can prove useful in managing and monitoring a MySQL server that is connected to a MySQL Cluster, and in some cases provide information about the cluster itself.

- `SHOW ENGINE NDB STATUS, SHOW ENGINE NDBCLUSTER STATUS`

The output of this statement contains information about the server's connection to the cluster, creation and usage of MySQL Cluster objects, and binary logging for MySQL Cluster replication.

See [Section 12.5.5.16, “SHOW ENGINE Syntax”](#), for a usage example and more detailed information.

- `SHOW ENGINES`

This statement can be used to determine whether or not clustering support is enabled in the MySQL server, and if so, whether it is active.

See [Section 12.5.5.17, “SHOW ENGINES Syntax”](#), for more detailed information.

Note

In MySQL 5.1, this statement no longer supports a `LIKE` clause. However, you can use `LIKE` to filter queries against the `INFORMATION_SCHEMA.ENGINES`, as discussed in the next item.

- `SELECT * FROM INFORMATION_SCHEMA.ENGINES [WHERE ENGINE LIKE 'NDB%']`

This is the equivalent of `SHOW ENGINES`, but uses the `ENGINES` table of the `INFORMATION_SCHEMA` database (available beginning with MySQL 5.1.5). Unlike the case with the `SHOW ENGINES` statement, it is possible to filter the results using a `LIKE` clause, and to select specific columns to obtain information that may be of use in scripts. For example, the following query shows whether the server was built with `NDB` support and, if so, whether it is enabled:

```
mysql> SELECT SUPPORT FROM INFORMATION_SCHEMA.ENGINES
-> WHERE ENGINE LIKE 'NDB%';
+-----+
| support |
+-----+
| ENABLED |
+-----+
```

See [Section 20.18, “The INFORMATION_SCHEMA ENGINES Table”](#), for more information.

- `SHOW VARIABLES LIKE 'NDB%'`

This statement provides a list of most server system variables relating to the `NDB` storage engine, and their values, as shown here:

```
mysql> SHOW VARIABLES LIKE 'NDB%';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| ndb_autoincrement_prefetch_sz | 32 |
| ndb_cache_check_time | 0 |
| ndb_extra_logging | 0 |
| ndb_force_send | ON |
| ndb_index_stat_cache_entries | 32 |
| ndb_index_stat_enable | OFF |
| ndb_index_stat_update_freq | 20 |
| ndb_report_thresh_binlog_epoch_slip | 3 |
| ndb_report_thresh_binlog_mem_usage | 10 |
| ndb_use_copying_alter_table | OFF |
| ndb_use_exact_count | ON |
| ndb_use_transactions | ON |
+-----+-----+
```

See [Section 5.1.3, “Server System Variables”](#), for more information.

- `SELECT * FROM INFORMATION_SCHEMA.GLOBAL_VARIABLES WHERE VARIABLE_NAME LIKE 'NDB%';`

This statement is the equivalent of the `SHOW` command described in the previous item, and provides almost identical output, as shown here:

```
mysql> SELECT * FROM INFORMATION_SCHEMA.GLOBAL_VARIABLES
-> WHERE VARIABLE_NAME LIKE 'NDB%';
+-----+-----+
| VARIABLE_NAME | VARIABLE_VALUE |
+-----+-----+
```

NDB_AUTOINCREMENT_PREFETCH_SZ	32
NDB_CACHE_CHECK_TIME	0
NDB_EXTRA_LOGGING	0
NDB_FORCE_SEND	ON
NDB_INDEX_STAT_CACHE_ENTRIES	32
NDB_INDEX_STAT_ENABLE	OFF
NDB_INDEX_STAT_UPDATE_FREQ	20
NDB_REPORT_THRESH_BINLOG_EPOCH_SLIP	3
NDB_REPORT_THRESH_BINLOG_MEM_USAGE	10
NDB_USE_COPYING_ALTER_TABLE	OFF
NDB_USE_EXACT_COUNT	ON
NDB_USE_TRANSACTIONS	ON

Unlike the case with the `SHOW` command, it is possible to select individual columns. For example:

```
mysql> SELECT VARIABLE_VALUE
      -> FROM INFORMATION_SCHEMA.GLOBAL_VARIABLES
      -> WHERE VARIABLE_NAME = 'ndb_force_send';
```

VARIABLE_VALUE
ON

See Section 20.25, “The `INFORMATION_SCHEMA.GLOBAL_VARIABLES` and `SESSION_VARIABLES` Tables”, and Section 5.1.3, “Server System Variables”, for more information.

• `SHOW STATUS LIKE 'NDB%'`

This statement shows at a glance whether or not the MySQL server is acting as a cluster SQL node, and if so, it provides the MySQL server's cluster node ID, the host name and port for the cluster management server to which it is connected, and the number of data nodes in the cluster, as shown here:

```
mysql> SHOW STATUS LIKE 'NDB%';
```

Variable_name	Value
Ndb_cluster_node_id	10
Ndb_config_from_host	192.168.0.103
Ndb_config_from_port	1186
Ndb_number_of_data_nodes	4

If the MySQL server was built with clustering support, but it is not connected to a cluster, all rows in the output of this statement contain a zero or an empty string:

```
mysql> SHOW STATUS LIKE 'NDB%';
```

Variable_name	Value
Ndb_cluster_node_id	0
Ndb_config_from_host	
Ndb_config_from_port	0
Ndb_number_of_data_nodes	0

See also Section 12.5.5.37, “`SHOW STATUS` Syntax”.

• `SELECT * FROM INFORMATION_SCHEMA.GLOBAL_STATUS WHERE VARIABLE_NAME LIKE 'NDB%';`

Beginning with MySQL 5.1.12, this statement provides similar output to the `SHOW` command discussed in the previous item. However, unlike the case with `SHOW STATUS`, it is possible using the `SELECT` to extract values in SQL for use in scripts for monitoring and automation purposes.

See Section 20.24, “The `INFORMATION_SCHEMA.GLOBAL_STATUS` and `SESSION_STATUS` Tables”, for more information.

17.7.8. Adding MySQL Cluster Data Nodes Online

This section describes how to add MySQL Cluster data nodes “online” — that is, without needing to shut down the cluster completely and restart it as part of the process. This capability is available in MySQL Cluster NDB 7.0 (beginning with MySQL Cluster NDB 6.4.0) and later MySQL Cluster release series.

■ Important

Currently, you must add new data nodes to a MySQL Cluster as part of a new node group. In addition, it is not possible to change the number of replicas (or the number of nodes per node group) online.

17.7.8.1. Adding MySQL Cluster Data Nodes Online: General Issues

This section provides general information about the behavior of and current limitations in adding MySQL Cluster nodes online.

Redistribution of Data. The ability to add new nodes online includes a means to reorganize `NDBCLUSTER` table data and indexes so that they are distributed across all data nodes, including the new ones. Table reorganization of both in-memory and Disk Data tables is supported. This redistribution does not currently include unique indexes (only ordered indexes are redistributed) or `BLOB` table data, but we are working to add redistribution of these in the near future. The redistribution for `NDBCLUSTER` tables already existing before the new data nodes were added is not automatic, but can be accomplished using simple SQL statements in `mysql` or another MySQL client application. However, all data and indexes added to tables created after a new node group has been added are distributed automatically among all cluster data nodes, including those added as part of the new node group.

Partial starts. It is possible to add a new node group without all of the new data nodes being started. It is also possible to add a new node group to a degraded cluster — that is, a cluster that is only partially started, or where one or more data nodes are not running. In the latter case, the cluster must have enough nodes running to be viable before the new node group can be added.

Effects on ongoing operations. Normal DML operations using MySQL Cluster data are not prevented by the creation or addition of a new node group, or by table reorganization. However, it is not possible to perform DDL concurrently with table reorganization — that is, no other DDL statements can be issued while an `ALTER TABLE ... REORGANIZE PARTITION` statement is executing. In addition, during the execution of `ALTER TABLE ... REORGANIZE PARTITION` (or the execution of any other DDL statement), it is not possible to restart cluster data nodes.

Failure handling. Failures of data nodes during node group creation and table reorganization are handled as shown in the following table:

Failure occurs during:	Failure occurs in:		
	“Old” data nodes	“New” data nodes	System
Node group creation	<ul style="list-style-type: none"> • If a node other than the master fails: The creation of the node group is always rolled forward. • If the master fails: <ul style="list-style-type: none"> • If the internal commit point has been reached: The creation of the node group is rolled forward. • If the internal commit point has not yet been reached. The creation of the node group is rolled back 	<ul style="list-style-type: none"> • If a node other than the master fails: The creation of the node group is always rolled forward. • If the master fails: <ul style="list-style-type: none"> • If the internal commit point has been reached: The creation of the node group is rolled forward. • If the internal commit point has not yet been reached. The creation of the node group is rolled back 	<ul style="list-style-type: none"> • If the execution of <code>CREATE NODEGROUP</code> has reached the internal commit point: When restarted, the cluster includes the new node group. Otherwise it without. • If the execution of <code>CREATE NODEGROUP</code> has not yet reached the internal commit point: When restarted, the cluster does not include the new node group.
Table reorganization	<ul style="list-style-type: none"> • If a node other than the master fails: The table reorganization is always rolled forward. • If the master fails: <ul style="list-style-type: none"> • If the internal commit point has been reached: The table reorganization is rolled forward. • If the internal commit point has not yet been reached. The table re- 	<ul style="list-style-type: none"> • If a node other than the master fails: The table reorganization is always rolled forward. • If the master fails: <ul style="list-style-type: none"> • If the internal commit point has been reached: The table reorganization is rolled forward. • If the internal commit point has not yet been reached. The table re- 	<ul style="list-style-type: none"> • If the execution of an <code>ALTER ONLINE TABLE table REORGANIZE PARTITION</code> statement has reached the internal commit point: When the cluster is restarted, the data and indexes belonging to <code>table</code> are distributed using the “new” data nodes. • If the execution of an <code>ALTER ONLINE TABLE table REORGANIZE PARTITION</code> statement has not yet reached the in-

Failure occurs during:	Failure occurs in:		
	“Old” data nodes	“New” data nodes	System
	organization is rolled back.	organization is rolled back.	Internal commit point: When the cluster is restarted, the data and indexes belonging to <i>table</i> are distributed using only the “old” data nodes.

Dropping node groups. The `ndb_mgm` client supports a `DROP NODEGROUP` command, but it is possible to drop a node group only when no data nodes in the node group contain any data. Since there is currently no way to “empty” a specific data node or node group, this command works only the following two cases:

1. After issuing `CREATE NODEGROUP` in the `ndb_mgm` client, but before issuing any `ALTER ONLINE TABLE ... REORGANIZE PARTITION` statements in the `mysql` client.
2. After dropping all `NDBCLUSTER` tables using `DROP TABLE`.

`TRUNCATE` does not work for this purpose because the data nodes continue to store the table definitions.

17.7.8.2. Adding MySQL Cluster Data Nodes Online: Basic procedure

In this section, we list the basic steps required to add new data nodes to a MySQL Cluster. For a detailed example, see [Section 17.7.8.3, “Adding MySQL Cluster Data Nodes Online: Detailed Example”](#).

Note

Beginning with MySQL Cluster NDB 7.0.4, this procedure applies whether you are using `ndbd` or `ndbmt` binaries for the data node processes. Previously, this did not work with multi-threaded data nodes. ([Bug#43108](#))

Assuming that you already have a running MySQL Cluster, adding data nodes online requires the following steps:

1. Edit the cluster configuration `config.ini` file, adding new `[ndbd]` sections corresponding to the nodes to be added. In the case where the cluster uses multiple management servers, these changes need to be made to all `config.ini` files used by the management servers.
2. Perform a rolling restart of all MySQL Cluster management servers.

Important

All management servers must be restarted with the `--reload` or `--initial` option to force the reading of the new configuration.

3. Perform a rolling restart of all existing MySQL Cluster data nodes.

Note

It is not necessary to use `--initial` when restarting the existing data nodes.

4. Perform a rolling restart of any SQL or API nodes connected to the MySQL Cluster.
5. Perform an initial start of the new data nodes.

Note

The new data nodes may be started in any order, and can also be started concurrently, as long as they are started after the rolling restarts of all existing nodes have been completed and before proceeding to the next step.

6. Execute one or more `CREATE NODEGROUP` commands in the MySQL Cluster management client to create the new node group or node groups to which the new data nodes will belong.
7. Redistribute the cluster's data among all data nodes (including the new ones) by issuing an `ALTER ONLINE TABLE ... REORGANIZE PARTITION` statement in the `mysql` client for each `NDBCLUSTER` table.

Note

This needs to be done only for tables already existing at the time the new node group is added. Data in tables created after the new node group is added is distributed automatically; however, data added to any given table `tbl` that existed before the new nodes were added is not distributed using the new nodes until that table has been reorganized using `ALTER ONLINE TABLE tbl REORGANIZE PARTITION`.

8. Reclaim the space freed on the “old” nodes by issuing, for each `NDBCLUSTER` table, an `OPTIMIZE TABLE` statement in the `mysql` client.

17.7.8.3. Adding MySQL Cluster Data Nodes Online: Detailed Example

In this section we provide a detailed example illustrating how to add new MySQL Cluster data nodes online, starting with a MySQL Cluster having 2 data nodes in a single node group and concluding with a cluster having 4 data nodes in 2 node groups.

Starting configuration. For purposes of illustration, we assume a minimal configuration, and that the cluster uses a `con-fig.ini` file containing only the following information:

```
[ndbd default]
DataMemory = 100M
IndexMemory = 100M
NoOfReplicas = 2
DataDir = /usr/local/mysql/var/mysql-cluster

[ndbd]
Id = 1
HostName = 192.168.0.1

[ndbd]
Id = 2
HostName = 192.168.0.2

[mgm]
HostName = 192.168.0.10
Id = 10

[api]
Id=20
HostName = 192.168.0.20

[api]
Id=21
HostName = 192.168.0.21
```

We also assume that you have already started the cluster using the appropriate command line or `my.cnf` options, and that running `SHOW` in the management client produces output similar to what is shown here:

```
-- NDB Cluster -- Management Client --
ndb_mgm> SHOW
Connected to Management Server at: 192.168.0.10:1186
Cluster Configuration
-----
[ndbd(NDB)] 2 node(s)
id=1 @192.168.0.1 (5.1.34-ndb-7.0.7, Nodegroup: 0, Master)
id=2 @192.168.0.2 (5.1.34-ndb-7.0.7, Nodegroup: 0)

[ndb_mgmd(MGM)] 1 node(s)
id=10 @192.168.0.10 (5.1.34-ndb-7.0.7)

[mysqld(API)] 2 node(s)
id=20 @192.168.0.20 (5.1.34-ndb-7.0.7)
id=21 @192.168.0.21 (5.1.34-ndb-7.0.7)
```

Finally, we assume that the cluster contains a single `NDBCLUSTER` table created as shown here:

```
USE n;

CREATE TABLE ips (
  id BIGINT NOT NULL AUTO_INCREMENT PRIMARY KEY,
  country_code CHAR(2) NOT NULL,
  type CHAR(4) NOT NULL,
  ip_address varchar(15) NOT NULL,
  addresses BIGINT UNSIGNED DEFAULT NULL,
  date BIGINT UNSIGNED DEFAULT NULL
) ENGINE NDBCLUSTER;
```

The memory usage and related information shown later in this section was generated after inserting approximately 50000 rows into this table.

Note

In this example, we show the single-threaded `ndbd` being used for the data node processes. However — beginning

with MySQL Cluster NDB 7.0.4 ([Bug#43108](#)) — you can also apply this example if you are using the multi-threaded `ndbmtb` by substituting `ndbmtb` for `ndbd` wherever it appears in the steps that follow.

Step 1: Update configuration file. Open the cluster global configuration file in a text editor and add `[ndbd]` sections corresponding to the 2 new data nodes. (We give these data nodes IDs 3 and 4, and assume that they are to be run on host machines at addresses 192.168.0.3 and 192.168.0.4, respectively.) After you have added the new sections, the contents of the `config.ini` file should look like what is shown here, where the additions to the file are shown in bold type:

```
[ndbd default]
DataMemory = 100M
IndexMemory = 100M
NoOfReplicas = 2
DataDir = /usr/local/mysql/var/mysql-cluster

[ndbd]
Id = 1
HostName = 192.168.0.1

[ndbd]
Id = 2
HostName = 192.168.0.2

[ndbd]
Id = 3
HostName = 192.168.0.3

[ndbd]
Id = 4
HostName = 192.168.0.4

[mgm]
HostName = 192.168.0.10
Id = 10

[api]
Id=20
HostName = 192.168.0.20

[api]
Id=21
HostName = 192.168.0.21
```

Once you have made the necessary changes, save the file.

Step 2: Restart the management server. Restarting the cluster management server requires that you issue separate commands to stop the management server and then to start it again, as follows:

1. Stop the management server using the management client `STOP` command, as shown here:

```
ndb_mgm> 10 STOP
Node 10 has shut down.
Disconnecting to allow Management Server to shutdown

shell>
```

2. Because shutting down the management server causes the management client to terminate, you must start the management server from the system shell. For simplicity, we assume that `config.ini` is in the same directory as the management server binary, but in practice, you must supply the correct path to the configuration file. You must also supply the `--reload` or `--initial` option so that the management server reads the new configuration from the file rather than its configuration cache. If your shell's current directory is also the same as the directory where the management server binary is located, then you can invoke the management server as shown here:

```
shell> ndb_mgmd -f config.ini --reload
2008-12-08 17:29:23 [MgmSrvr] INFO -- NDB Cluster Management Server. 5.1.34-ndb-7.0.7
2008-12-08 17:29:23 [MgmSrvr] INFO -- Reading cluster configuration from 'config.ini'
```

If you check the output of `SHOW` in the management client after restarting the `ndb_mgm` process, you should now see something like this:

```
-- NDB Cluster -- Management Client --
ndb_mgm> SHOW
Connected to Management Server at: 192.168.0.10:1186
Cluster Configuration
-----
[ndbd(NDB)] 2 node(s)
id=1 @192.168.0.1 (5.1.34-ndb-7.0.7, Nodegroup: 0, Master)
id=2 @192.168.0.2 (5.1.34-ndb-7.0.7, Nodegroup: 0)
id=3 (not connected, accepting connect from 192.168.0.3)
id=4 (not connected, accepting connect from 192.168.0.4)

[ndb_mgmd(MGM)] 1 node(s)
id=10 @192.168.0.10 (5.1.34-ndb-7.0.7)

[mysqld(API)] 2 node(s)
id=20 @192.168.0.20 (5.1.34-ndb-7.0.7)
```

```
id=21 @192.168.0.21 (5.1.34-ndb-7.0.7)
```

Step 3: Perform a rolling restart of the existing data nodes. This step can be accomplished entirely within the cluster management client using the `RESTART` command, as shown here:

```
ndb_mgm> 1 RESTART
Node 1: Node shutdown initiated
Node 1: Node shutdown completed, restarting, no start.
Node 1 is being restarted

ndb_mgm> Node 1: Start initiated (version 7.0.7)
Node 1: Started (version 7.0.7)

ndb_mgm> 2 RESTART
Node 2: Node shutdown initiated
Node 2: Node shutdown completed, restarting, no start.
Node 2 is being restarted

ndb_mgm> Node 2: Start initiated (version 7.0.7)

ndb_mgm> Node 2: Started (version 7.0.7)
```

Important

After issuing each `X RESTART` command, wait until the management client reports `Node X: Started (version ...)` before proceeding any further.

Step 4: Perform a rolling restart of all cluster API nodes. Shut down and restart each MySQL server acting as an SQL node in the cluster using `mysqldadmin shutdown` followed by `mysqld_safe` (or another startup script). This should be similar to what is shown here, where `password` is the MySQL `root` password for a given MySQL server instance:

```
shell> mysqldadmin -uroot -ppassword shutdown
081208 20:19:56 mysqld_safe mysqld from pid file
/usr/local/mysql/var/tonfisk.pid ended
shell> mysqld_safe --ndbcluster --ndb-connectstring=192.168.0.10 &
081208 20:20:06 mysqld_safe Logging to '/usr/local/mysql/var/tonfisk.err'.
081208 20:20:06 mysqld_safe Starting mysqld daemon with databases
from /usr/local/mysql/var
```

Of course, the exact input and output depend on how and where MySQL is installed on the system, as well as which options you choose to start it (and whether or not some or all of these options are specified in a `my.cnf` file).

Step 5: Perform an initial start of the new data nodes. From a system shell on each of the hosts for the new data nodes, start the data nodes as shown here, using the `--initial` option:

```
shell> ndbd -c 192.168.0.10 --initial
```

Note

Unlike the case with restarting the existing data nodes, you can start the new data nodes concurrently; you do not need to wait for one to finish starting before starting the other.

Wait until both of the new data nodes have started before proceeding with the next step. Once the new data nodes have started, you can see in the output of the management client `SHOW` command that they do not yet belong to any node group (as indicated with bold type here):

```
ndb_mgm> SHOW
Connected to Management Server at: 192.168.0.10:1186
Cluster Configuration
-----
[ndbd(NDB)] 2 node(s)
id=1 @192.168.0.1 (5.1.34-ndb-7.0.7, Nodegroup: 0, Master)
id=2 @192.168.0.2 (5.1.34-ndb-7.0.7, Nodegroup: 0)
id=3 @192.168.0.3 (5.1.34-ndb-7.0.7, no nodegroup)
id=4 @192.168.0.4 (5.1.34-ndb-7.0.7, no nodegroup)

[ndb_mgmd(MGM)] 1 node(s)
id=10 @192.168.0.10 (5.1.34-ndb-7.0.7)

[mysqld(API)] 2 node(s)
id=20 @192.168.0.20 (5.1.34-ndb-7.0.7)
id=21 @192.168.0.21 (5.1.34-ndb-7.0.7)
```

Step 6: Create a new node group. You can do this by issuing a `CREATE NODEGROUP` command in the cluster management client. This command takes as its argument a comma-separated list of the node IDs of the data nodes to be included in the new node group, as shown here:

```
ndb_mgm> CREATE NODEGROUP 3,4
Nodegroup 1 created
```

By issuing `SHOW` again, you can verify that data nodes 3 and 4 have joined the new node group (again indicated in bold type):

```

ndb_mgm> SHOW
Connected to Management Server at: 192.168.0.10:1186
Cluster Configuration
-----
[ndbd(NDB)] 2 node(s)
id=1 @192.168.0.1 (5.1.34-ndb-7.0.7, Nodegroup: 0, Master)
id=2 @192.168.0.2 (5.1.34-ndb-7.0.7, Nodegroup: 0)
id=3 @192.168.0.3 (5.1.34-ndb-7.0.7, Nodegroup: 1)
id=4 @192.168.0.4 (5.1.34-ndb-7.0.7, Nodegroup: 1)

[ndb_mgmd(MGM)] 1 node(s)
id=10 @192.168.0.10 (5.1.34-ndb-7.0.7)

[mysqld(API)] 2 node(s)
id=20 @192.168.0.20 (5.1.34-ndb-7.0.7)
id=21 @192.168.0.21 (5.1.34-ndb-7.0.7)

```

Step 7: Redistribute cluster data. When a node group is created, existing data and indexes are not automatically distributed to the new node group's data nodes, as you can see by issuing the appropriate `REPORT` command in the management client:

```

ndb_mgm> ALL REPORT MEMORY

Node 1: Data usage is 5%(177 32K pages of total 3200)
Node 1: Index usage is 0%(108 8K pages of total 12832)
Node 2: Data usage is 5%(177 32K pages of total 3200)
Node 2: Index usage is 0%(108 8K pages of total 12832)
Node 3: Data usage is 0%(0 32K pages of total 3200)
Node 3: Index usage is 0%(0 8K pages of total 12832)
Node 4: Data usage is 0%(0 32K pages of total 3200)
Node 4: Index usage is 0%(0 8K pages of total 12832)

```

By using `ndb_desc` with the `-p` option, which causes the output to include partitioning information, you can see that the table still uses only 2 partitions (in the `Per partition info` section of the output, shown here in bold text):

```

shell> ndb_desc -c 192.168.0.10 -d n ips -p
-- ips --
Version: 1
Fragment type: 9
K Value: 6
Min load factor: 78
Max load factor: 80
Temporary table: no
Number of attributes: 6
Number of primary keys: 1
Length of frm data: 340
Row Checksum: 1
Row GCI: 1
SingleUserMode: 0
ForceVarPart: 1
FragmentCount: 2
TableStatus: Retrieved
-- Attributes --
id Bigint PRIMARY KEY DISTRIBUTION KEY AT=FIXED ST=MEMORY AUTO_INCR
country_code Char(2;latin1_swedish_ci) NOT NULL AT=FIXED ST=MEMORY
type Char(4;latin1_swedish_ci) NOT NULL AT=FIXED ST=MEMORY
ip_address Varchar(15;latin1_swedish_ci) NOT NULL AT=SHORT_VAR ST=MEMORY
addresses Bigunsigned NULL AT=FIXED ST=MEMORY
date Bigunsigned NULL AT=FIXED ST=MEMORY

-- Indexes --
PRIMARY KEY(id) - UniqueHashIndex
PRIMARY(id) - OrderedIndex

-- Per partition info --
Partition Row count Commit count Frag fixed memory Frag varsized memory
0 26086 26086 1572864 557056
1 26329 26329 1605632 557056

NDBT_ProgramExit: 0 - OK

```

You can cause the data to be redistributed among all of the data nodes by performing, for each `NDBCLUSTER` table, an `ALTER ONLINE TABLE ... REORGANIZE PARTITION` statement in the `mysql` client. After issuing the statement `ALTER ONLINE TABLE ips REORGANIZE PARTITION`, you can see using `ndb_desc` that the data for this table is now stored using 4 partitions, as shown here (with the relevant portions of the output in bold type):

```

shell> ndb_desc -c 192.168.0.10 -d n ips -p
-- ips --
Version: 16777217
Fragment type: 9
K Value: 6
Min load factor: 78
Max load factor: 80
Temporary table: no
Number of attributes: 6
Number of primary keys: 1
Length of frm data: 341
Row Checksum: 1
Row GCI: 1
SingleUserMode: 0
ForceVarPart: 1
FragmentCount: 4

```

```

TableStatus: Retrieved
-- Attributes --
id Bigint PRIMARY KEY DISTRIBUTION KEY AT=FIXED ST=MEMORY AUTO_INCR

0          12981      52296         1572864            557056
1          13236      52515         1605632            557056
2          13105      13105         819200             294912
3          13093      13093         819200             294912

NDBT_ProgramExit: 0 - OK

```

Note

Normally, `ALTER [ONLINE] TABLE table_name REORGANIZE PARTITION` is used with a list of partition identifiers and a set of partition definitions to create a new partitioning scheme for a table that has already been explicitly partitioned. Its use here to redistribute data onto a new MySQL Cluster node group is an exception in this regard; when used in this way, only the name of the table is used following the `TABLE` keyword, and no other keywords or identifiers follow `REORGANIZE PARTITION`.

Prior to MySQL Cluster NDB 6.4.3, `ALTER ONLINE TABLE ... REORGANIZE PARTITION` with no `partition_names INTO (partition_definitions)` option did not work correctly with Disk Data tables or with in-memory `NDBCLUSTER` tables having one or more disk-based columns. ([Bug#42549](#))

For more information, see [Section 12.1.7, “ALTER TABLE Syntax”](#).

Also, for each table, the `ALTER ONLINE TABLE` statement should be followed by an `OPTIMIZE TABLE` to reclaim wasted space. You can obtain a list of all `NDBCLUSTER` tables using the following query against the `INFORMATION_SCHEMA.TABLES` table:

```

SELECT TABLE_SCHEMA, TABLE_NAME
FROM INFORMATION_SCHEMA.TABLES
WHERE ENGINE = 'NDBCLUSTER';

```

Note

The `INFORMATION_SCHEMA.TABLES.ENGINE` value for a MySQL Cluster table is always `NDBCLUSTER`, regardless of whether the `CREATE TABLE` statement used to create the table (or `ALTER TABLE` statement used to convert an existing table from a different storage engine) used `NDB` or `NDBCLUSTER` in its `ENGINE` option.

You can see after performing these statements in the output of `ALL REPORT MEMORY` that the data and indexes are now redistributed between all cluster data nodes, as shown here:

```

ndb_mgm> ALL REPORT MEMORY

Node 1: Data usage is 5%(176 32K pages of total 3200)
Node 1: Index usage is 0%(76 8K pages of total 12832)
Node 2: Data usage is 5%(176 32K pages of total 3200)
Node 2: Index usage is 0%(76 8K pages of total 12832)
Node 3: Data usage is 2%(80 32K pages of total 3200)
Node 3: Index usage is 0%(51 8K pages of total 12832)
Node 4: Data usage is 2%(80 32K pages of total 3200)
Node 4: Index usage is 0%(50 8K pages of total 12832)

```

Note

Since only one DDL operation on `NDBCLUSTER` tables can be executed at a time, you must wait for each `ALTER ONLINE TABLE ... REORGANIZE PARTITION` statement to finish before issuing the next one.

It is not necessary to issue `ALTER ONLINE TABLE ... REORGANIZE PARTITION` statements for `NDBCLUSTER` tables created *after* the new data nodes have been added; data added to such tables is distributed among all data nodes automatically. However, in `NDBCLUSTER` tables that existed *prior to* the addition of the new nodes, neither existing nor new data is distributed using the new nodes until these tables have been reorganized using `ALTER ONLINE TABLE ... REORGANIZE PARTITION`.

Alternative procedure, without rolling restart. It is possible to avoid the need for a rolling restart by configuring the extra data nodes, but not starting them, when first starting the cluster. This can be accomplished by using the `NodeGroup` data node configuration parameter in the `config.ini` file, as shown here (note the section with bold text). We assume, as before, that you wish to start with two data nodes — nodes 1 and 2 — in one node group and later to expand the cluster to four data nodes, by adding a second node group consisting of nodes 3 and 4:

```
[ndbd default]
DataMemory = 100M
IndexMemory = 100M
NoOfReplicas = 2
DataDir = /usr/local/mysql/var/mysql-cluster

[ndbd]
Id = 1
HostName = 192.168.0.1

[ndbd]
Id = 2
HostName = 192.168.0.2

[ndbd]
Id = 3
HostName = 192.168.0.3
NodeGroup = 65535

[ndbd]
Id = 4
HostName = 192.168.0.4
NodeGroup = 65535

[mgm]
HostName = 192.168.0.10
Id = 10

[api]
Id=20
HostName = 192.168.0.20

[api]
Id=21
HostName = 192.168.0.21
```

In this case, you must perform the initial start of the cluster using the `--nowait` option with `ndbd` (or `ndbmt` in MySQL Cluster NDB 7.0.4 and later) for each of the data nodes that you wish to have online immediately, so that the cluster does not wait for the remaining nodes to start:

```
shell> ndbd -c 192.168.0.10 --initial --nowait=3,4
```

When you are ready to add the second nodegroup, you need only perform the following additional steps:

1. Start data nodes 3 and 4, invoking the data node process once for each new node:

```
shell> ndbd -c 192.168.0.10 --initial
```

2. Issue the appropriate `CREATE NODEGROUP` command in the management client:

```
ndb_mgm> CREATE NODEGROUP 3,4
```

3. In the `mysql` client, issue `ALTER ONLINE TABLE ... REORGANIZE PARTITION` and `OPTIMIZE TABLE` statements for each existing `NDBCLUSTER` table. (As noted elsewhere in this section, existing MySQL Cluster tables cannot use the new nodes for data distribution until this has been done.)

17.8. MySQL Cluster Security Issues

This section discusses security considerations to take into account when setting up and running MySQL Cluster.

Topics to be covered in this chapter include the following:

- MySQL Cluster and network security issues
- Configuration issues relating to running MySQL Cluster securely
- MySQL Cluster and the MySQL privilege system
- MySQL standard security procedures as applicable to MySQL Cluster

17.8.1. MySQL Cluster Security and Networking Issues

In this section, we discuss basic network security issues as they relate to MySQL Cluster. It is extremely important to remember that MySQL Cluster “out of the box” is not secure; you or your network administrator must take the proper steps to insure that your cluster cannot be compromised over the network.

Cluster communication protocols are inherently insecure, and no encryption or similar security measures are used in communications between nodes in the cluster. Because network speed and latency have a direct impact on the cluster's efficiency, it is also not advisable to employ SSL or other encryption to network connections between nodes, as such schemes will effectively slow communications.

It is also true that no authentication is used for controlling API node access to a MySQL Cluster. As with encryption, the overhead of imposing authentication requirements would have an adverse impact on Cluster performance.

In addition, there is no checking of the source IP address for either of the following when accessing the cluster:

- SQL or API nodes using “free slots” created by empty `[mysqld]` or `[api]` sections in the `config.ini` file

This means that, if there are any empty `[mysqld]` or `[api]` sections in the `config.ini` file, then any API nodes (including SQL nodes) that know the management server's host name (or IP address) and port can connect to the cluster and access its data without restriction. (See [Section 17.8.2, “MySQL Cluster and MySQL Privileges”](#), for more information about this and related issues.)

Note

You can exercise some control over SQL and API node access to the cluster by specifying a `HostName` parameter for all `[mysqld]` and `[api]` sections in the `config.ini` file. However, this also means that, should you wish to connect an API node to the cluster from a previously unused host, you need to add an `[api]` section containing its host name to the `config.ini` file.

More information is available [elsewhere in this chapter](#) about the `HostName` parameter. Also see [Section 17.3.3, “Quick Test Setup of MySQL Cluster”](#), for configuration examples using `HostName` with API nodes.

- Any `ndb_mgm` client

This means that any cluster management client that is given the management server's host name (or IP address) and port (if not the standard port) can connect to the cluster and execute any management client command. This includes commands such as `ALL STOP` and `SHUTDOWN`.

For these reasons, it is necessary to protect the cluster on the network level. The safest network configuration for Cluster is one which isolates connections between Cluster nodes from any other network communications. This can be accomplished by any of the following methods:

1. Keeping Cluster nodes on a network that is physically separate from any public networks. This option is the most dependable; however, it is the most expensive to implement.

We show an example of a MySQL Cluster setup using such a physically segregated network here:

This setup has two networks, one private (solid box) for the Cluster management servers and data nodes, and one public (dotted box) where the SQL nodes reside. (We show the management and data nodes connected using a gigabit switch since this provides the best performance.) Both networks are protected from the outside by a hardware firewall, sometimes also known as a *network-based firewall*.

This network setup is safest because no packets can reach the cluster's management or data nodes from outside the network — and none of the cluster's internal communications can reach the outside — without going through the SQL nodes, as long as the SQL nodes do not allow any packets to be forwarded. This means, of course, that all SQL nodes must be secured against hacking attempts.

Important

With regard to potential security vulnerabilities, an SQL node is no different from any other MySQL server. See [Section 5.3.2, “Making MySQL Secure Against Attackers”](#), for a description of techniques you can use to secure MySQL servers.

- Using one or more software firewalls (also known as *host-based firewalls*) to control which packets pass through to the cluster from portions of the network that do not require access to it. In this type of setup, a software firewall must be installed on every host in the cluster which might otherwise be accessible from outside the local network.

The host-based option is the least expensive to implement, but relies purely on software to provide protection and so is the most difficult to keep secure.

This type of network setup for MySQL Cluster is illustrated here:

Using this type of network setup means that there are two zones of MySQL Cluster hosts. Each cluster host must be able to communicate with all of the other machines in the cluster, but only those hosting SQL nodes (dotted box) can be permitted to have any contact with the outside, while those in the zone containing the data nodes and management nodes (solid box) must be isolated from any machines that are not part of the cluster. Applications using the cluster and user of those applications must *not* be permitted to have direct access to the management and data node hosts.

To accomplish this, you must set up software firewalls that limit the traffic to the type or types shown in the following table, according to the type of node that is running on each cluster host computer:

Type of Node to be Accessed	Traffic to Allow
SQL or API node	<ul style="list-style-type: none"> • It originates from the IP address of a management or data node (using any TCP or UDP port). • It originates from within the network in which the cluster resides and is on the port that your application is using.
Data node or Management node	<ul style="list-style-type: none"> • It originates from the IP address of a management or data node (using any TCP or UDP port). • It originates from the IP address of an SQL or API node.

Any traffic other than that shown in the table for a given node type should be denied.

The specifics of configuring a firewall vary from firewall application to firewall application, and are beyond the scope of this Manual. `iptables` is a very common and reliable firewall application, which is often used with `APF` as a front end to make configuration easier. You can (and should) consult the documentation for the software firewall that you employ, should you choose to implement a MySQL Cluster network setup of this type, or of a “mixed” type as discussed under the next item.

- It is also possible to employ a combination of the first two methods, using both hardware and software to secure the cluster — that is, using both network-based and host-based firewalls. This is between the first two schemes in terms of both security level and cost. This type of network setup keeps the cluster behind the hardware firewall, but allows incoming packets to travel beyond the router connecting all cluster hosts in order to reach the SQL nodes.

One possible network deployment of a MySQL Cluster using hardware and software firewalls in combination is shown here:

In this case, you can set the rules in the hardware firewall to deny any external traffic except to SQL nodes and API nodes, and then allow traffic to them only on the ports required by your application.

Whatever network configuration you use, remember that your objective from the viewpoint of keeping the cluster secure remains the same — to prevent any unessential traffic from reaching the cluster while ensuring the most efficient communication between the nodes in the cluster.

Because MySQL Cluster requires large numbers of ports to be open for communications between nodes, the recommended option is to use a segregated network. This represents the simplest way to prevent unwanted traffic from reaching the cluster.

Note

If you wish to administer a MySQL Cluster remotely (that is, from outside the local network), the recommended way to do this is to use `ssh` or another secure login shell to access an SQL node host. From this host, you can then run the management client to access the management server safely, from within the Cluster's own local network.

Even though it is possible to do so in theory, it is *not* recommended to use `ndb_mgm` to manage a Cluster directly from outside the local network on which the Cluster is running. Since neither authentication nor encryption takes place between the management client and the management server, this represents an extremely insecure means of managing the cluster, and is almost certain to be compromised sooner or later.

17.8.2. MySQL Cluster and MySQL Privileges

In this section, we discuss how the MySQL privilege system works in relation to MySQL Cluster and the implications of this for keeping a MySQL Cluster secure.

Standard MySQL privileges apply to MySQL Cluster tables. This includes all MySQL privilege types (`SELECT` privilege, `UPDATE` privilege, `DELETE` privilege, and so on) granted on the database, table, and column level. As with any other MySQL Server,

user and privilege information is stored in the `mysql` system database. The SQL statements used to grant and revoke privileges on NDB tables, databases containing such tables, and columns within such tables are identical in all respects with the `GRANT` and `REVOKE` statements used in connection with database objects involving any (other) MySQL storage engine. The same thing is true with respect to the `CREATE USER` and `DROP USER` statements.

It is important to keep in mind that the MySQL grant tables use the `MyISAM` storage engine. Because of this, those tables are not duplicated or shared among MySQL servers acting as SQL nodes in a MySQL Cluster. By way of example, suppose that two SQL nodes **A** and **B** are connected to the same MySQL Cluster, which has an NDB table named `mytable` in a database named `mydb`, and that you execute an SQL statement on server **A** that creates a new user `jon@localhost` and grants this user the `SELECT` privilege on that table:

```
mysql> GRANT SELECT ON mydb.mytable
-> TO jon@localhost IDENTIFIED BY 'mypass';
```

This user is *not* created on server **B**. In order for this to take place, the statement must also be run on server **B**. Similarly, statements run on server **A** and affecting the privileges of existing users on server **A** do not affect users on server **B** unless those statements are actually run on server **B** as well.

In other words, *changes in users and their privileges do not automatically propagate between SQL nodes*. Synchronization of privileges between SQL nodes must be done either manually or by scripting an application that periodically synchronizes the privilege tables on all SQL nodes in the cluster.

Conversely, because there is no way in MySQL to deny privileges (privileges can either be revoked or not granted in the first place, but not denied as such), there is no special protection for NDB tables on one SQL node from users that have privileges on another SQL node. The most far-reaching example of this is the MySQL `root` account, which can perform any action on any database object. In combination with empty `[mysqld]` or `[api]` sections of the `config.ini` file, this account can be especially dangerous. To understand why, consider the following scenario:

- The `config.ini` file contains at least one empty `[mysqld]` or `[api]` section. This means that the Cluster management server performs no checking of the host from which a MySQL Server (or other API node) accesses the MySQL Cluster.
- There is no firewall, or the firewall fails to protect against access to the Cluster from hosts external to the network.
- The host name or IP address of the Cluster's management server is known or can be determined from outside the network.

If these conditions are true, then anyone, anywhere can start a MySQL Server with `--ndbcluster - -ndb-connectstring=management_host` and access the Cluster. Using the MySQL `root` account, this person can then perform the following actions:

- Execute a `SHOW DATABASES` statement to obtain a list of all databases that exist in the cluster
- Execute a `SHOW TABLES FROM some_database` statement to obtain a list of all NDB tables in a given database
- Run any legal MySQL statements on any of those tables, such as:
 - `SELECT * FROM some_table` to read all the data from any table
 - `DELETE FROM some_table` to delete all the data from a table
 - `DESCRIBE some_table` or `SHOW CREATE TABLE some_table` to determine the table schema
 - `UPDATE some_table SET column1 = any_value1` to fill a table column with “garbage” data; this could actually cause much greater damage than simply deleting all the data

Even more insidious variations might include statements like these:

```
UPDATE some_table SET an_int_column = an_int_column + 1
```

or

```
UPDATE some_table SET a_varchar_column = REVERSE(a_varchar_column)
```

Such malicious statements are limited only by the imagination of the attacker.

The only tables that would be safe from this sort of mayhem would be those tables that were created using storage engines other than NDB, and so not visible to a “rogue” SQL node.

Note

A user who can log in as `root` can also access the `INFORMATION_SCHEMA` database and its tables, and so obtain information about databases, tables, stored routines, scheduled events, and any other database objects for which metadata is stored in `INFORMATION_SCHEMA`.

It is also a very good idea to use different passwords for the `root` accounts on different cluster SQL nodes.

In sum, you cannot have a safe MySQL Cluster if it is directly accessible from outside your local network.

Important

Never leave the MySQL root account password empty. This is just as true when running MySQL as a MySQL Cluster SQL node as it is when running it as a standalone (non-Cluster) MySQL Server, and should be done as part of the MySQL installation process before configuring the MySQL Server as an SQL node in a MySQL Cluster.

You should never convert the system tables in the `mysql` database to use the `NDB` storage engine. There are a number of reasons why you should not do this, but the most important reason is this: *Many of the SQL statements that affect `mysql` tables storing information about user privileges, stored routines, scheduled events, and other database objects cease to function if these tables are changed to use any storage engine other than `MyISAM`.* This is a consequence of various MySQL Server internals which are not expected to change in the foreseeable future.

If you need to synchronize `mysql` system tables between SQL nodes, you can use standard MySQL replication to do so, or employ a script to copy table entries between the MySQL servers.

Summary. The two most important points to remember regarding the MySQL privilege system with regard to MySQL Cluster are:

1. Users and privileges established on one SQL node do not automatically exist or take effect on other SQL nodes in the cluster. Conversely, removing a user or privilege on one SQL node in the cluster does not remove the user or privilege from any other SQL nodes.
2. Once a MySQL user is granted privileges on an `NDB` table from one SQL node in a MySQL Cluster, that user can “see” any data in that table regardless of the SQL node from which the data originated.

17.8.3. MySQL Cluster and MySQL Security Procedures

In this section, we discuss MySQL standard security procedures as they apply to running MySQL Cluster.

In general, any standard procedure for running MySQL securely also applies to running a MySQL Server as part of a MySQL Cluster. First and foremost, you should always run a MySQL Server as the `mysql` system user; this is no different from running MySQL in a standard (non-Cluster) environment. The `mysql` system account should be uniquely and clearly defined. Fortunately, this is the default behavior for a new MySQL installation. You can verify that the `mysqld` process is running as the system user `mysql` by using the system command such as the one shown here:

```
shell> ps aux | grep mysqld
root      10467  0.0  0.1   3616  1380 pts/3    S    11:53   0:00 \
/bin/sh ./mysqld_safe --ndbcluster --ndb-connectstring=localhost:1186
mysql     10512  0.2  2.5  58528 26636 pts/3    Sl   11:53   0:00 \
/usr/local/mysql/libexec/mysqld --basedir=/usr/local/mysql \
--datadir=/usr/local/mysql/var --user=mysql --ndbcluster \
--ndb-connectstring=localhost:1186 --pid-file=/usr/local/mysql/var/mothra.pid \
--log-error=/usr/local/mysql/var/mothra.err
jon       10579  0.0  0.0   2736   688 pts/0    S+   11:54   0:00 grep mysqld
```

If the `mysqld` process is running as any other user than `mysql`, you should immediately shut it down and restart it as the `mysql` user. If this user does not exist on the system, the `mysql` user account should be created, and this user should be part of the `mysql` user group; in this case, you should also make sure that the MySQL `DataDir` on this system is owned by the `mysql` user, and that the SQL node's `my.cnf` file includes `user=mysql` in the `[mysqld]` section. Alternatively, you can start the server with `-user=mysql` on the command line, but it is preferable to use the `my.cnf` option, since you might forget to use the command-line option and so have `mysqld` running as another user unintentionally. The `mysqld_safe` startup script forces MySQL to run as the `mysql` user.

Important

Never run `mysqld` as the system root user. Doing so means that potentially any file on the system can be read by MySQL, and thus — should MySQL be compromised — by an attacker.

As mentioned in the previous section (see [Section 17.8.2, “MySQL Cluster and MySQL Privileges”](#)), you should always set a root password for the MySQL Server as soon as you have it running. You should also delete the anonymous user account that is installed by default. You can accomplish these tasks via the following statements:

```
shell> mysql -u root
mysql> UPDATE mysql.user
```

```

-> SET Password=PASSWORD('secure_password')
-> WHERE User='root';

mysql> DELETE FROM mysql.user
-> WHERE User='';

mysql> FLUSH PRIVILEGES;

```

Be very careful when executing the `DELETE` statement not to omit the `WHERE` clause, or you risk deleting *all* MySQL users. Be sure to run the `FLUSH PRIVILEGES` statement as soon as you have modified the `mysql.user` table, so that the changes take immediate effect. Without `FLUSH PRIVILEGES`, the changes do not take effect until the next time that the server is restarted.

Note

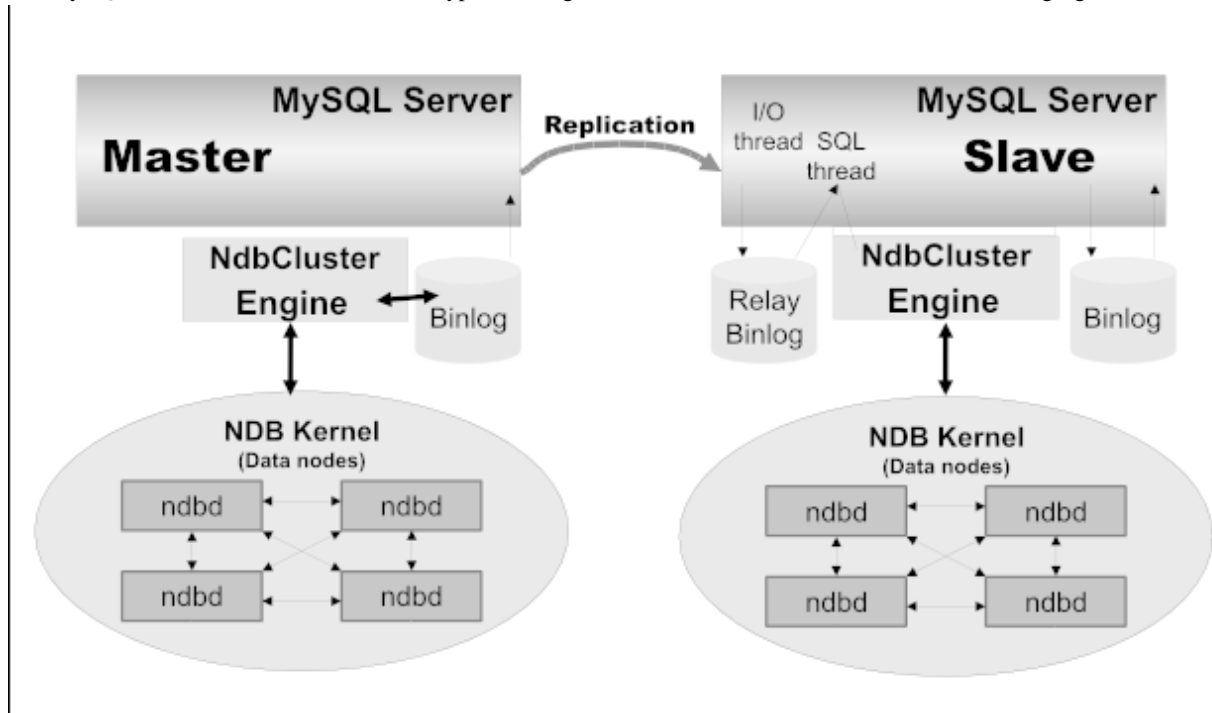

Many of the MySQL Cluster utilities such as `ndb_show_tables`, `ndb_desc`, and `ndb_select_all` also work without authentication and can reveal table names, schemas, and data. By default these are installed on Unix-style systems with the permissions `wxr-xr-x` (755), which means they can be executed by any user that can access the `mysql/bin` directory.

See [Section 17.6, “MySQL Cluster Programs”](#), for more information about these utilities.

17.9. MySQL Cluster Replication

Previous to MySQL 5.1.6, *asynchronous replication*, more usually referred to simply as “replication”, was not available when using MySQL Cluster. MySQL 5.1.6 introduces master-slave replication of this type for MySQL Cluster databases. This section explains how to set up and manage a configuration wherein one group of computers operating as a MySQL Cluster replicates to a second computer or group of computers. We assume some familiarity on the part of the reader with standard MySQL replication as discussed elsewhere in this Manual. (See [Chapter 16, Replication](#)).

Normal (non-clustered) replication involves a “master” server and a “slave” server, the master being the source of the operations and data to be replicated and the slave being the recipient of these. In MySQL Cluster, replication is conceptually very similar but can be more complex in practice, as it may be extended to cover a number of different configurations including replicating between two complete clusters. Although a MySQL Cluster itself depends on the `NDBCLUSTER` storage engine for clustering functionality, it is not necessary to use the Cluster storage engine on the slave. However, for maximum availability, it is possible to replicate from one MySQL Cluster to another, and it is this type of configuration that we discuss, as shown in the following figure:

In this scenario, the replication process is one in which successive states of a master cluster are logged and saved to a slave cluster. This process is accomplished by a special thread known as the NDB binlog injector thread, which runs on each MySQL server and produces a binary log (`binlog`). This thread ensures that all changes in the cluster producing the binary log — and not just those changes that are effected via the MySQL Server — are inserted into the binary log with the correct serialization order. We refer to the MySQL replication master and replication slave servers as replication servers or replication nodes, and the data flow or line of communication between them as a *replication channel*.

17.9.1. MySQL Cluster Replication — Abbreviations and Symbols

Throughout this section, we use the following abbreviations or symbols for referring to the master and slave clusters, and to processes and commands run on the clusters or cluster nodes:

Symbol or Abbreviation	Description (Refers to...)
<i>M</i>	The cluster serving as the (primary) replication master
<i>S</i>	The cluster acting as the (primary) replication slave
<code>shellM></code>	Shell command to be issued on the master cluster
<code>mysqlM></code>	MySQL client command issued on a single MySQL server running as an SQL node on the master cluster
<code>mysqlM*></code>	MySQL client command to be issued on all SQL nodes participating in the replication master cluster
<code>shellS></code>	Shell command to be issued on the slave cluster
<code>mysqlS></code>	MySQL client command issued on a single MySQL server running as an SQL node on the slave cluster
<code>mysqlS*></code>	MySQL client command to be issued on all SQL nodes participating in the replication slave cluster
<i>C</i>	Primary replication channel
<i>C'</i>	Secondary replication channel
<i>M'</i>	Secondary replication master
<i>S'</i>	Secondary replication slave

17.9.2. MySQL Cluster Replication — Assumptions and General Requirements

A replication channel requires two MySQL servers acting as replication servers (one each for the master and slave). For example, this means that in the case of a replication setup with two replication channels (to provide an extra channel for redundancy), there will be a total of four replication nodes, two per cluster.

Replication of a MySQL Cluster as described in this section and those following is dependent on row-based replication. This means that the replication master MySQL server must be started with `--binlog-format=ROW` or `--binlog-format=MIXED`, as described in [Section 17.9.6, “Starting MySQL Cluster Replication \(Single Replication Channel\)”](#). For general information about row-based replication, see [Section 16.1.2, “Replication Formats”](#).

Important

If you attempt to use MySQL Cluster Replication with `--binlog-format=STATEMENT`, replication fails to work properly because the `ndb_binlog_index` table on the master and the `epoch` column of the `ndb_apply_status` table on the slave are not updated (see [Section 17.9.4, “MySQL Cluster Replication Schema and Tables”](#)). Instead, only updates on the MySQL server acting as the replication master propagate to the slave, and no updates from any other SQL nodes on the master cluster are replicated.

In all MySQL Cluster NDB 6.x releases, the default value for the `--binlog-format` option is `MIXED`.

Each MySQL server used for replication in either cluster must be uniquely identified among all the MySQL replication servers participating in either cluster (you cannot have replication servers on both the master and slave clusters sharing the same ID). This can be done by starting each SQL node using the `--server-id=id` option, where `id` is a unique integer. Although it is not strictly necessary, we will assume for purposes of this discussion that all MySQL installations are the same version.

In any event, both MySQL servers involved in replication must be compatible with one another with respect to both the version of the replication protocol used and the SQL feature sets which they support; the simplest and easiest way to assure that this is the case is to use the same MySQL version for all servers involved. Note that in many cases it is not possible to replicate to a slave running a version of MySQL with a lower version number than that of the master — see [Section 16.3.2, “Replication Compatibility Between MySQL Versions”](#), for details.

We assume that the slave server or cluster is dedicated to replication of the master, and that no other data is being stored on it.

Note

It is possible to replicate a MySQL Cluster using statement-based replication. However, in this case, the following restrictions apply:

- All updates to data rows on the cluster acting as the master must be directed to a single MySQL server.

- It is not possible to replicate a cluster using multiple simultaneous MySQL replication processes.
- Only changes made at the SQL level are replicated.

These are in addition to the other limitations of statement-based replication as opposed to row-based replication; see [Section 16.1.2.1, “Comparison of Statement-Based and Row-Based Replication”](#), for more specific information concerning the differences between the two replication formats.

17.9.3. Known Issues in MySQL Cluster Replication

The following are known problems or issues when using replication with MySQL Cluster in MySQL 5.1:

- **Loss of master-slave connection.** Prior to MySQL 5.1.18, a MySQL Cluster replication slave `mysqld` had no way of detecting that the connection from the master had been interrupted (due to, for instance, the master going down or a network failure). For this reason, it was possible for the slave to become inconsistent with the master.

Beginning with MySQL 5.1.18, the master issues a “gap” event when connecting to the cluster. When the slave encounters a gap in the replication log, it stops with an error message. This message is available in the output of `SHOW SLAVE STATUS`, and indicates that the SQL thread has stopped due to an incident registered in the replication stream, and that manual intervention is required. In order to restart the slave, it is necessary to issue the following commands:

```
SET GLOBAL SQL_SLAVE_SKIP_COUNTER = 1;
START SLAVE;
```

The slave then resumes reading the master binlog from the point where the gap was recorded.

Important

If high availability is a requirement for the slave server or cluster, then it is still advisable to set up multiple replication lines, to monitor the master `mysqld` on the primary replication line, and to fail over to a secondary line if and as necessary. For information about implementing this type of setup, see [Section 17.9.7, “Using Two Replication Channels for MySQL Cluster Replication”](#), and [Section 17.9.8, “Implementing Failover with MySQL Cluster Replication”](#).

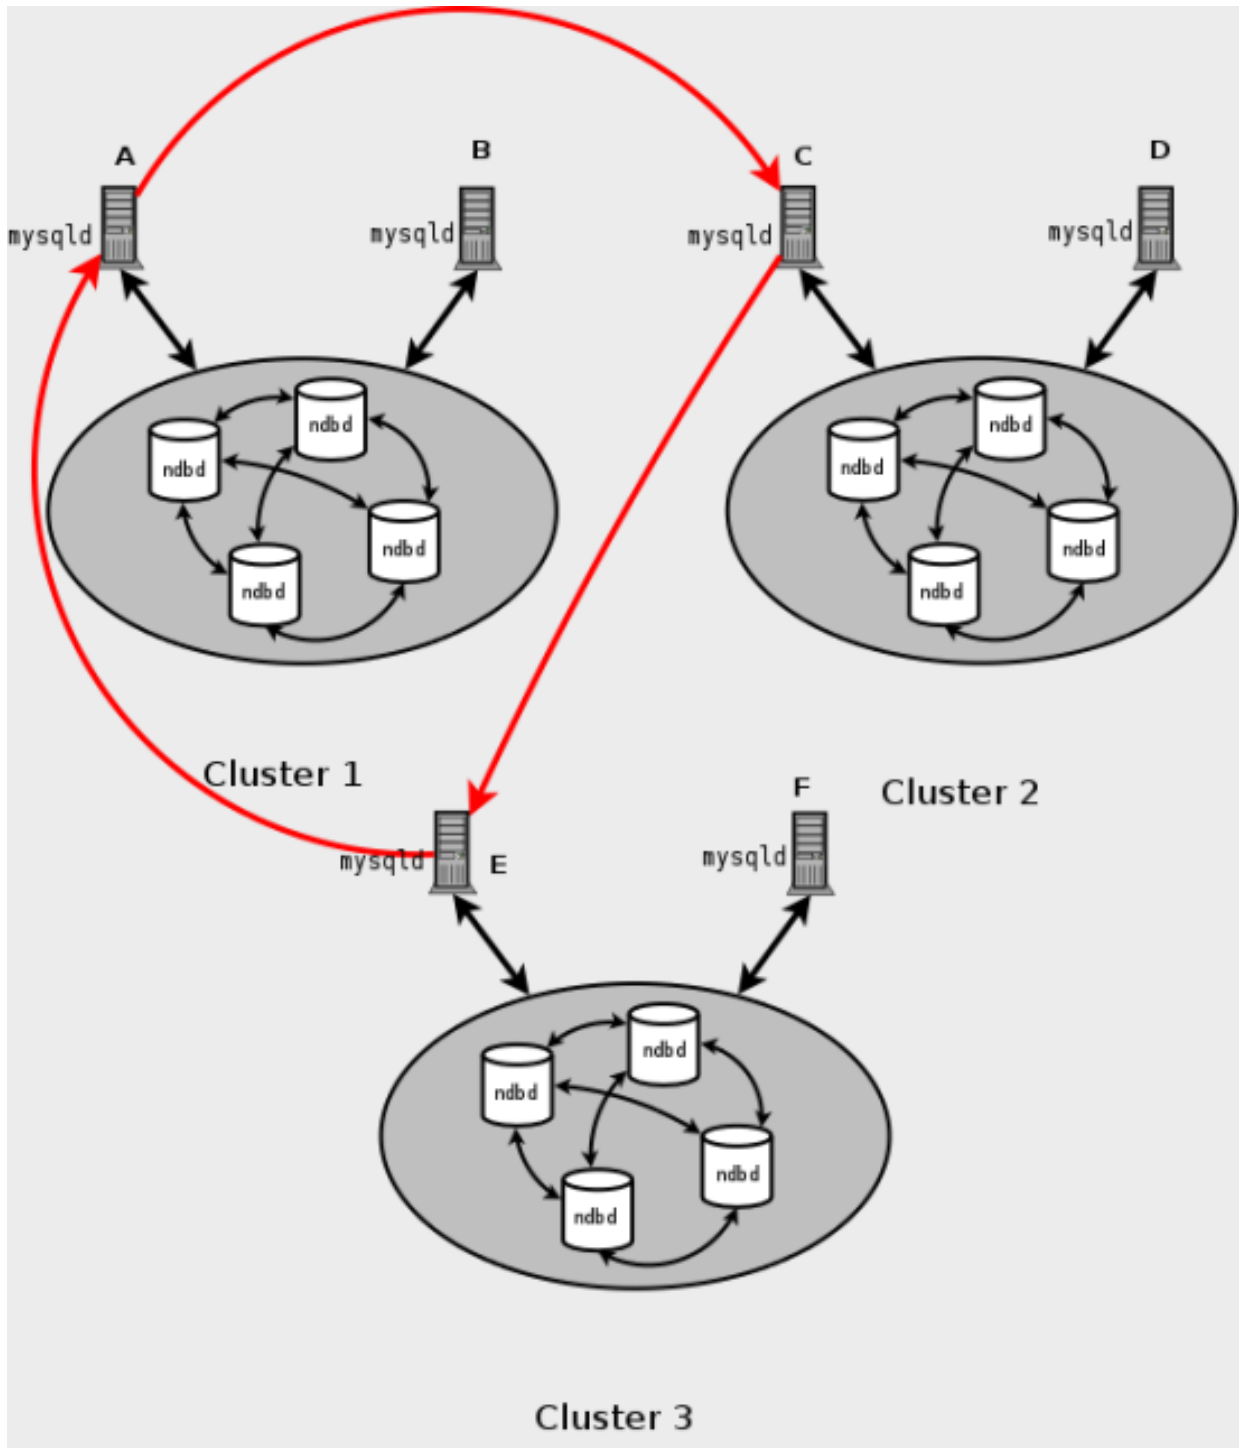

However, if you are replicating from a standalone MySQL server to a MySQL Cluster, one channel is usually sufficient.

- **Multi-byte character sets.** There are several known issues with regard to the use of multi-byte characters sets with MySQL Cluster Replication. See [Bug#27404](#) (fixed in MySQL 5.1.21), [Bug#29562](#), [Bug#29563](#), and [Bug#29564](#) for more information.
- **Circular replication.** Prior to MySQL 5.1.18, circular replication was not supported with MySQL Cluster replication, due to the fact that all log events created in a particular MySQL Cluster were wrongly tagged with the server ID of the MySQL server used as master and not with the server ID of the originating server.

Beginning with MySQL 5.1.18, this limitation is lifted, as discussed in the next few paragraphs, in which we consider the example of a replication setup involving three MySQL Clusters numbered 1, 2, and 3, in which Cluster 1 acts as the replication master for Cluster 2, Cluster 2 acts as the master for Cluster 3, and Cluster 3 acts as the master for Cluster 1. Each cluster has two SQL nodes, with SQL nodes A and B belonging to Cluster 1, SQL nodes C and D belonging to Cluster 2, and SQL nodes E and F belonging to Cluster 3.

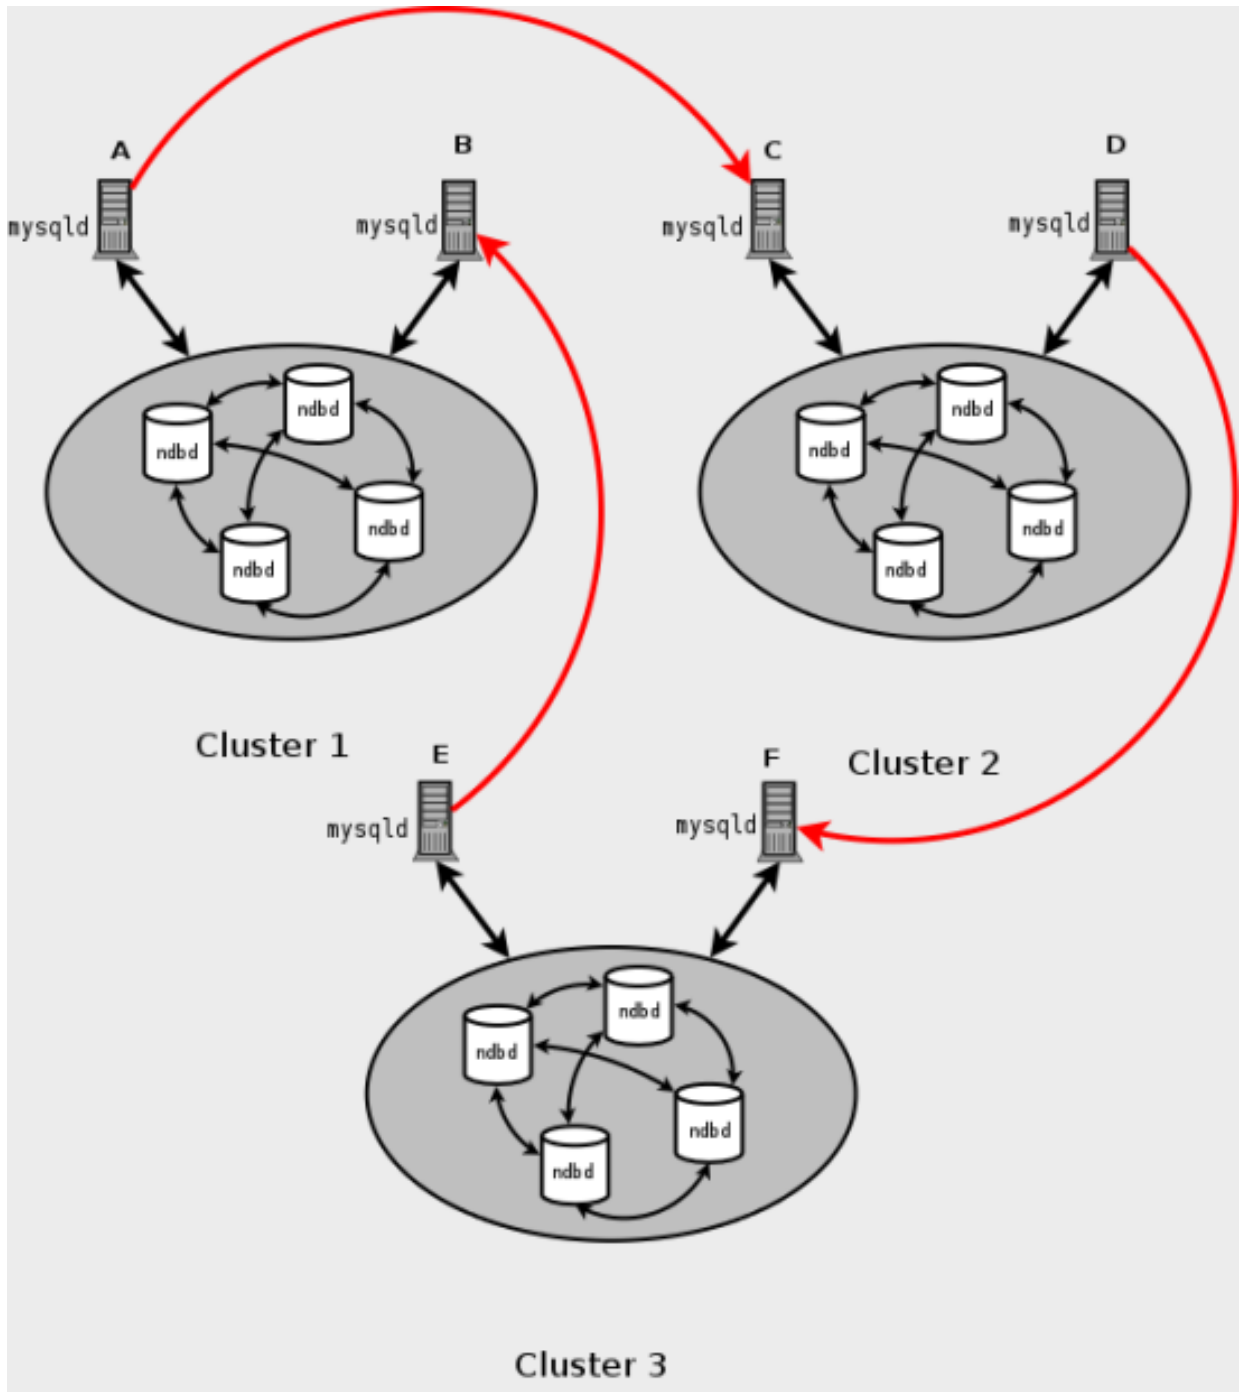

Circular replication using these clusters is supported as long as:

- the SQL nodes on all masters and slaves are the same
 - All SQL nodes acting as replication masters and slaves are started using the `--log-slave-updates` option
- This type of circular replication setup is shown in the following diagram:

In this scenario, SQL node A in Cluster 1 replicates to SQL node C in Cluster 2; SQL node C replicates to SQL node E in Cluster 3; SQL node E replicates to SQL node A. In other words, the replication line (indicated by the red arrows in the diagram) directly connects all SQL nodes used as replication masters and slaves.

It should also be possible to set up circular replication in which not all master SQL nodes are also slaves, as shown here:

In this case, different SQL nodes in each cluster are used as replication masters and slaves. However, you must *not* start any of the SQL nodes using `--log-slave-updates` (see the [description of this option](#) for more information). This type of circular replication scheme for MySQL Cluster, in which the line of replication (again indicated by the red arrows in the diagram) is discontinuous, should be possible, but it should be noted that it has not yet been thoroughly tested and must therefore still be considered experimental.

Important

Beginning with MySQL 5.1.24, you should execute the following statement before starting circular replication:

```
mysql> SET GLOBAL slave_exec_mode = 'IDEMPOTENT';
```

This is necessary to suppress duplicate-key and other errors that otherwise break circular replication of MySQL Cluster. `IDEMPOTENT` mode is also required for multi-master replication when using MySQL Cluster. ([Bug#31609](#))

See `slave_exec_mode`, for more information.

- **DDL statements.** The use of data definition statements, such as `CREATE TABLE`, `DROP TABLE`, and `ALTER TABLE`, are recorded in the binary log for only the MySQL server on which they are issued.
- **Cluster replication and primary keys.** In MySQL 5.1.6, only those NDB tables having explicit primary keys could be replicated. This limitation was lifted in MySQL 5.1.7. However, in the event of a node failure, errors in replication of NDB tables without primary keys can still occur, due to the possibility of duplicate rows being inserted in such cases. For this reason, it is highly recommended that all NDB tables being replicated have primary keys.
- **Restarting with `--initial`.** Restarting the cluster with the `--initial` option causes the sequence of GCI and epoch numbers to start over from 0. (This is generally true of MySQL Cluster and not limited to replication scenarios involving Cluster.) The MySQL servers involved in replication should in this case be restarted. After this, you should use the `RESET MASTER` and `RESET SLAVE` statements to clear the invalid `ndb_binlog_index` and `ndb_apply_status` tables, respectively.
- **`auto_increment_offset` and `auto_increment_increment` variables.** The use of the `auto_increment_offset` and `auto_increment_increment` server system variables is supported beginning with MySQL 5.1.20. Previously, these produced unpredictable results when used with NDB tables or MySQL Cluster replication.
- **Replication from NDBCLUSTER to other storage engines.** If you attempt to replicate from a MySQL Cluster to a slave that uses a storage engine that does not handle its own binary logging, the replication process aborts with the error `BINARY LOGGING NOT POSSIBLE ... STATEMENT CANNOT BE WRITTEN ATOMICALLY SINCE MORE THAN ONE ENGINE INVOLVED AND AT LEAST ONE ENGINE IS SELF-LOGGING` (Error 1595). It is possible to work around this issue in one of the following ways:
 - **Turn off binary logging on the slave.** This can be accomplished by setting `sql_log_bin = 0`.
 - **Change the storage engine used for the `mysql.ndb_apply_status` table.** Causing this table to use an engine that does not handle its own binary logging can also eliminate the conflict. This can be done by issuing a statement such as `ALTER TABLE mysql.ndb_apply_status ENGINE=MyISAM` on the slave. It is safe to do this when using a non-NDB storage engine on the slave, since you do not then need to worry about keeping multiple slave SQL nodes synchronized.
 - **Filter out changes to the `mysql.ndb_apply_status` table on the slave.** This can be done by starting the slave SQL node with the option `--replicate-ignore-table=mysql.ndb_apply_status`. If you need for other tables to be ignored by replication, you might wish to use an appropriate `--replicate-wild-ignore-table` option instead.

Important

You should *not* disable replication or binary logging of `mysql.ndb_apply_status` or change the storage engine used for this table when replicating from one MySQL Cluster to another. See *Replication and binary log filtering rules with replication between MySQL Clusters* elsewhere in this section for details.

When replicating from NDBCLUSTER to a non-transactional storage engine such as MyISAM, you may encounter unnecessary duplicate key errors when replicating `INSERT ... ON DUPLICATE KEY UPDATE` statements. You can suppress these in MySQL Cluster NDB 6.2 by using `--ndb-log-update-as-write=0`, which forces all columns from updated rows to be sent (and not just those that were updated). For MySQL Cluster NDB 6.3.3 and later, there are additional ways to determine whether or not an update to the row on the master should be applied on the slave `mysqld`; see [Section 17.9.11, “MySQL Cluster Replication Conflict Resolution”](#), for more information about these methods.

- **Replication and binary log filtering rules with replication between MySQL Clusters.** If you are using any of the options `--replicate-do-*`, `--replicate-ignore-*`, `--binlog-do-db`, or `--binlog-ignore-db` to filter databases or tables being replicated, care must be taken not to block replication or binary logging of the `mysql.ndb_apply_status`, which is required for replication between MySQL Clusters to operate properly. In particular, you must keep in mind the following:
 1. Using `--replicate-do-db=db_name` (and no other `--replicate-do-*` or `--replicate-ignore-*` options) means that *only* tables in database `db_name` are replicated. In this case, you should also use `--replicate-do-db=mysql`, `--binlog-do-db=mysql`, or `--replicate-do-table=mysql.ndb_apply_status` to insure that `mysql.ndb_apply_status` is populated on slaves.

Using `--binlog-do-db=db_name` (and no other `--binlog-do-db` options) means that changes *only* to tables in database `db_name` are written to the binary log. In this case, you should also use `--replicate-do-db=mysql`, `--binlog-do-db=mysql`, or `--replicate-do-table=mysql.ndb_apply_status` to insure that `mysql.ndb_apply_status` is populated on slaves.
 2. Using `--replicate-ignore-db=mysql` means that no tables in the `mysql` database are replicated. In this case, you should also use `--replicate-do-table=mysql.ndb_apply_status` to insure that `mysql.ndb_apply_status` is replicated.

Using `--binlog-ignore-db=mysql` means that no changes to tables in the `mysql` database are written to the binary

log. In this case, you should also use `--replicate-do-table=mysql.ndb_apply_status` to insure that `mysql.ndb_apply_status` is replicated.

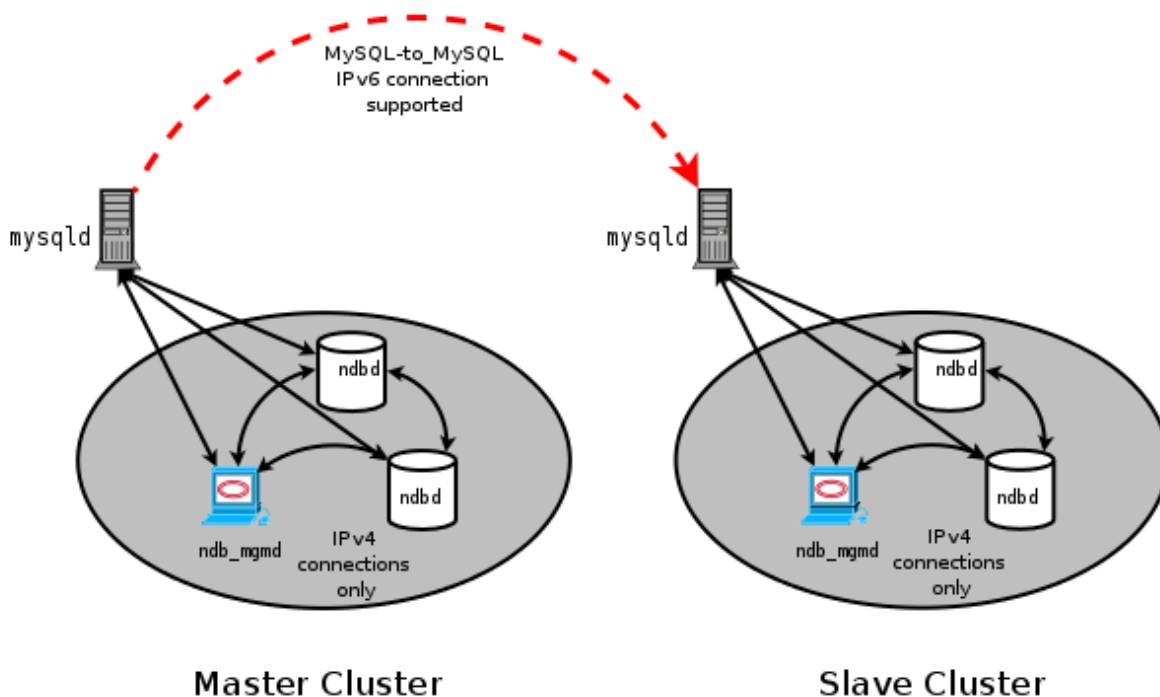

You should also remember that:

1. Each replication filtering rule requires its own `--replicate-do-*` or `--replicate-ignore-*` option, and that multiple rules cannot be expressed in a single replication filtering option. For information about these rules, see [Section 16.1.3, “Replication and Binary Logging Options and Variables”](#).
2. Each binary log filtering rule requires its own `--binlog-do-db` or `--binlog-ignore-db` option, and that multiple rules cannot be expressed in a single binary log filtering option. For information about these rules, see [Section 5.2.4, “The Binary Log”](#).

Note

If you are replicating a MySQL Cluster to a slave that uses a storage engine other than `NDBCLUSTER`, the considerations just given previously may not apply. See [Replication from `NDBCLUSTER` to other storage engines](#) elsewhere in this section for details.

- **MySQL Cluster Replication and IPv6.** Currently, the NDB API and MGM API do not support IPv6. However, beginning with MySQL Cluster NDB 6.4.1, MySQL Servers — including those acting as SQL nodes in a MySQL Cluster — can use IPv6 to contact other MySQL Servers. This means that you can replicate between MySQL Clusters using IPv6 to connect the master and slave SQL nodes as shown by the dotted arrow in the following diagram:

However, all connections originating *within* the MySQL Cluster — shown in the diagram by solid arrows — must use IPv4.

All MySQL Cluster data nodes, management servers, and management clients must be accessible from one another using IPv4. In addition, SQL nodes must use IPv4 to communicate with the cluster. There is not currently any support in the NDB and MGM APIs for IPv6, which means that any applications written using these APIs must also make all connections using IPv4.

17.9.4. MySQL Cluster Replication Schema and Tables

Replication in MySQL Cluster makes use of a number of dedicated tables in the `mysql` database on each MySQL Server instance acting as an SQL node in both the cluster being replicated and the replication slave (whether the slave is a single server or a cluster). These tables are created during the MySQL installation process by the `mysql_install_db` script, and include a table for storing the binary log's indexing data. Since the `ndb_binlog_index` table is local to each MySQL server and does not participate in clustering, it uses the `MyISAM` storage engine. This means that it must be created separately on each `mysqld` participating in the master cluster. (However, the binlog itself contains updates from all MySQL servers in the cluster to be replicated.) This table is defined as follows:

```
CREATE TABLE `ndb_binlog_index` (
  `Position` BIGINT(20) UNSIGNED NOT NULL,
  `File` VARCHAR(255) NOT NULL,
  `epoch` BIGINT(20) UNSIGNED NOT NULL,
  `inserts` BIGINT(20) UNSIGNED NOT NULL,
  `updates` BIGINT(20) UNSIGNED NOT NULL,
  `deletes` BIGINT(20) UNSIGNED NOT NULL,
  `schemaops` BIGINT(20) UNSIGNED NOT NULL,
  PRIMARY KEY (`epoch`)
) ENGINE=MYISAM DEFAULT CHARSET=latin1;
```

Important

Prior to MySQL 5.1.14, the `ndb_binlog_index` table was known as `binlog_index`, and was kept in a separate `cluster` database, which in MySQL 5.1.7 and earlier was known as the `cluster_replication` database. Similarly, the `ndb_apply_status` and `ndb_schema` tables were known as `apply_status` and `schema`, and were also found in the `cluster` (earlier `cluster_replication`) database. However, beginning with MySQL 5.1.14, all MySQL Cluster replication tables reside in the `mysql` system database.

Information about how this change affects upgrades from MySQL Cluster 5.1.13 and earlier to 5.1.14 and later versions can be found in [Section C.1.24, “Changes in MySQL 5.1.14 \(05 December 2006\)”](#).

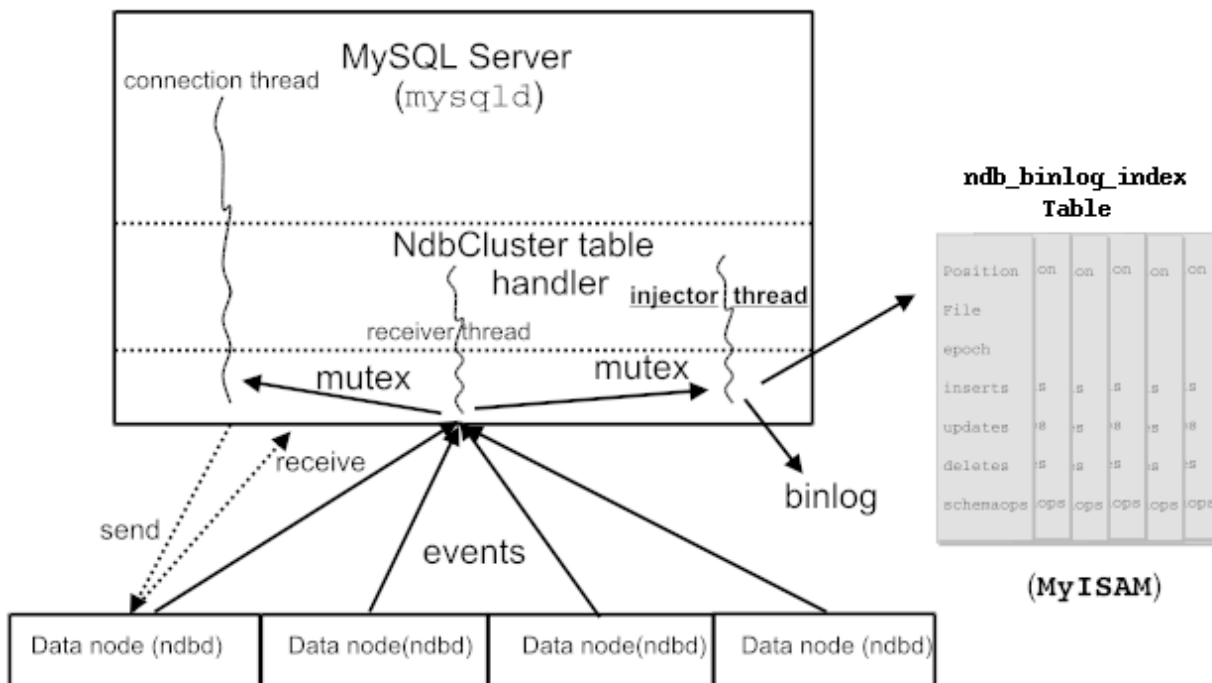

Beginning with MySQL Cluster NDB 6.3.2, this table has been changed to facilitate 3-way replication recovery. Two columns `orig_server_id` and `orig_epoch` have been added to this table; when `mysqld` is started with the `--ndb-log-orig` option, these columns store, respectively, the ID of the server on which the event originated and the epoch in which the event took place on the originating server. In addition, the table's primary key now includes these two columns. The modified table definition is shown here:

```
CREATE TABLE `ndb_binlog_index` (
  `Position` BIGINT(20) UNSIGNED NOT NULL,
  `File` VARCHAR(255) NOT NULL,
  `epoch` BIGINT(20) UNSIGNED NOT NULL,
  `inserts` INT(10) UNSIGNED NOT NULL,
  `updates` INT(10) UNSIGNED NOT NULL,
  `deletes` INT(10) UNSIGNED NOT NULL,
  `schemaops` INT(10) UNSIGNED NOT NULL,
  `orig_server_id` INT(10) UNSIGNED NOT NULL,
  `orig_epoch` BIGINT(20) UNSIGNED NOT NULL,
  `gci` INT(10) UNSIGNED NOT NULL,
  PRIMARY KEY (`epoch`, `orig_server_id`, `orig_epoch`)
) ENGINE=MyISAM DEFAULT CHARSET=latin1;
```

The `gci` column was added in MySQL Cluster NDB 6.2.6 and MySQL Cluster NDB 6.3.2.

The following figure shows the relationship of the MySQL Cluster replication master server, its binlog injector thread, and the `mysql.ndb_binlog_index` table.

MySQL Replication Between Clusters, Injecting into Binlog

An additional table, named `ndb_apply_status`, is used to keep a record of the operations that have been replicated from the master to the slave. Unlike the case with `ndb_binlog_index`, the data in this table is not specific to any one SQL node in the (slave) cluster, and so `ndb_apply_status` can use the `NDB Cluster` storage engine, as shown here:

```
CREATE TABLE `ndb_apply_status` (
  `server_id` INT(10) UNSIGNED NOT NULL,
  `epoch` BIGINT(20) UNSIGNED NOT NULL,
  `log_name` VARCHAR(255) CHARACTER SET latin1 COLLATE latin1_bin NOT NULL,
  `start_pos` BIGINT(20) UNSIGNED NOT NULL,
  `end_pos` BIGINT(20) UNSIGNED NOT NULL,
  PRIMARY KEY (`server_id`) USING HASH
) ENGINE=NDBCLUSTER DEFAULT CHARSET=latin1;
```

This table is populated only on slaves; on the master, no `DataMemory` is allocated to it. However, the table is populated *from* the master. For this reason, this table must be replicated and any replication filtering or binary log filtering rules that prevent this prevent replication between clusters from operating properly. For more information about potential problems arising from such filtering rules, see [Section 17.9.3, “Known Issues in MySQL Cluster Replication”](#).

The `log_name`, `start_pos`, and `end_pos` columns were added in MySQL 5.1.18.

Important

If you are using MySQL Cluster replication, see [Section 17.5.2, “MySQL Cluster 5.1 and MySQL Cluster NDB 6.x/7.x Upgrade and Downgrade Compatibility”](#) before upgrading to MySQL 5.1.18 or later from an earlier version.

The `ndb_binlog_index` and `ndb_apply_status` tables are created in the `mysql` database because they should not be replicated. No user intervention is normally required to create or maintain either of them. Both the `ndb_binlog_index` and the `ndb_apply_status` tables are maintained by the `NDB injector thread`. This keeps the master `mysqld` process updated to changes performed by the `NDB storage engine`. The `NDB binlog injector thread` receives events directly from the `NDB storage engine`. The `NDB injector` is responsible for capturing all the data events within the cluster, and ensures that all events which change, insert, or delete data are recorded in the `ndb_binlog_index` table. The slave I/O thread transfers the events from the master's binary log to the slave's relay log.

However, it is advisable to check for the existence and integrity of these tables as an initial step in preparing a MySQL Cluster for replication. It is possible to view event data recorded in the binary log by querying the `mysql.ndb_binlog_index` table dir-

ectly on the master. This can be also be accomplished using the `SHOW BINLOG EVENTS` statement on either the replication master or slave MySQL servers. (See [Section 12.5.5.3, “SHOW BINLOG EVENTS Syntax”](#).)

You can also obtain useful information from the output of `SHOW ENGINE NDB STATUS`.

The `ndb_schema` table is used to track schema changes made to NDB tables. It is defined as shown here:

```
CREATE TABLE ndb_schema (
  `db` VARBINARY(63) NOT NULL,
  `name` VARBINARY(63) NOT NULL,
  `slock` BINARY(32) NOT NULL,
  `query` BLOB NOT NULL,
  `node_id` INT UNSIGNED NOT NULL,
  `epoch` BIGINT UNSIGNED NOT NULL,
  `id` INT UNSIGNED NOT NULL,
  `version` INT UNSIGNED NOT NULL,
  `type` INT UNSIGNED NOT NULL,
  PRIMARY KEY USING HASH (db,name)
) ENGINE=NDB DEFAULT CHARSET=latin1;
```

Unlike the two tables previously mentioned in this section, the `ndb_schema` table is not visible either to MySQL `SHOW` statements, or in any `INFORMATION_SCHEMA` tables; however, it can be seen in the output of `ndb_show_tables`, as shown here:

```
shell> ndb_show_tables -t 2
id  type      state  logging database  schema  name
4   UserTable Online Yes   mysql     def     ndb_apply_status
5   UserTable Online Yes   ndbworld  def     City
6   UserTable Online Yes   ndbworld  def     Country
3   UserTable Online Yes   mysql     def     NDB$BLOB_2_3
7   UserTable Online Yes   ndbworld  def     CountryLanguage
2   UserTable Online Yes   mysql     def     ndb_schema

NDBT_ProgramExit: 0 - OK
```

It is also possible to `SELECT` from this table in `mysql` and other MySQL client applications, as shown here:

```
mysql> SELECT * FROM mysql.ndb_schema WHERE name='City' \G
***** 1. row *****
db: ndbworld
name: City
slock:
query: alter table City engine=ndb
node_id: 4
epoch: 0
id: 0
version: 0
type: 7
1 row in set (0.00 sec)
```

This can sometimes be useful when debugging applications.

Note

When performing schema changes on NDB tables, applications should wait until the `ALTER TABLE` statement has returned in the MySQL client connection that issued the statement before attempting to use the updated definition of the table.

The `ndb_schema` table was added in MySQL 5.1.8.

Beginning with MySQL 5.1.14, if either of the `ndb_apply_status` or `ndb_schema` tables does not exist on the slave, it is created by `ndb_restore`. ([Bug#14612](#))

Conflict resolution for MySQL Cluster Replication requires the presence of an additional `mysql.ndb_replication` table. Currently, this table must be created manually. For details, see [Section 17.9.11, “MySQL Cluster Replication Conflict Resolution”](#).

17.9.5. Preparing the MySQL Cluster for Replication

Preparing the MySQL Cluster for replication consists of the following steps:

1. Check all MySQL servers for version compatibility (see [Section 17.9.2, “MySQL Cluster Replication — Assumptions and General Requirements”](#)).
2. Create a slave account on the master Cluster with the appropriate privileges:

```
mysqlM> GRANT REPLICATION SLAVE
-> ON *.* TO 'slave_user'@'slave_host'
-> IDENTIFIED BY 'slave_password';
```

In the previous statement, `slave_user` is the slave account user name, `slave_host` is the host name or IP address of the

replication slave, and `slave_password` is the password to assign to this account.

For example, to create a slave user account with the name “`myslave`,” logging in from the host named “`rep-slave`,” and using the password “`53cr37`,” use the following `GRANT` statement:

```
mysqlM> GRANT REPLICATION SLAVE
-> ON *.* TO 'myslave'@'rep-slave'
-> IDENTIFIED BY '53cr37';
```

For security reasons, it is preferable to use a unique user account — not employed for any other purpose — for the replication slave account.

3. Configure the slave to use the master. Using the MySQL Monitor, this can be accomplished with the `CHANGE MASTER TO` statement:

```
mysqlS> CHANGE MASTER TO
-> MASTER_HOST='master_host',
-> MASTER_PORT=master_port,
-> MASTER_USER='slave_user',
-> MASTER_PASSWORD='slave_password';
```

In the previous statement, `master_host` is the host name or IP address of the replication master, `master_port` is the port for the slave to use for connecting to the master, `slave_user` is the user name set up for the slave on the master, and `slave_password` is the password set for that user account in the previous step.

For example, to tell the slave to replicate from the MySQL server whose host name is “`rep-master`,” using the replication slave account created in the previous step, use the following statement:

```
mysqlS> CHANGE MASTER TO
-> MASTER_HOST='rep-master'
-> MASTER_PORT=3306,
-> MASTER_USER='myslave'
-> MASTER_PASSWORD='53cr37';
```

For a complete list of clauses that can be used with this statement, see [Section 12.6.2.1, “CHANGE MASTER TO Syntax”](#).

You can also configure the slave to use the master by setting the corresponding startup options in the slave server’s `my.cnf` file. To configure the slave in the same way as the preceding example `CHANGE MASTER TO` statement, the following information would need to be included in the slave’s `my.cnf` file:

```
[mysqld]
master-host=rep-master
master-port=3306
master-user=myslave
master-password=53cr37
```

For additional options that can be set in `my.cnf` for replication slaves, see [Section 16.1.3, “Replication and Binary Logging Options and Variables”](#).

Note

To provide replication backup capability, you will also need to add an `ndb-connectstring` option to the slave’s `my.cnf` file prior to starting the replication process. See [Section 17.9.9, “MySQL Cluster Backups With MySQL Cluster Replication”](#), for details.

4. If the master cluster is already in use, you can create a backup of the master and load this onto the slave to cut down on the amount of time required for the slave to synchronize itself with the master. If the slave is also running MySQL Cluster, this can be accomplished using the backup and restore procedure described in [Section 17.9.9, “MySQL Cluster Backups With MySQL Cluster Replication”](#).

```
ndb-connectstring=management_host[:port]
```

In the event that you are *not* using MySQL Cluster on the replication slave, you can create a backup with this command on the replication master:

```
shellM> mysqldump --master-data=1
```

Then import the resulting data dump onto the slave by copying the dump file over to the slave. After this, you can use the `mysql` client to import the data from the dumpfile into the slave database as shown here, where `dump_file` is the name of the file that was generated using `mysqldump` on the master, and `db_name` is the name of the database to be replicated:

```
shellS> mysql -u root -p db_name < dump_file
```

For a complete list of options to use with `mysqldump`, see [Section 4.5.4, “mysqldump — A Database Backup Program”](#).

Note

If you copy the data to the slave in this fashion, you should make sure that the slave is started with the `--skip-slave-start` option on the command line, or else include `skip-slave-start` in the slave's `my.cnf` file to keep it from trying to connect to the master to begin replicating before all the data has been loaded. Once the data loading has completed, follow the additional steps outlined in the next two sections.

5. Ensure that each MySQL server acting as a replication master is configured with a unique server ID, and with binary logging enabled, using the row format. (See [Section 16.1.2, “Replication Formats”](#).) These options can be set either in the master server's `my.cnf` file, or on the command line when starting the master `mysqld` process. See [Section 17.9.6, “Starting MySQL Cluster Replication \(Single Replication Channel\)”](#), for information regarding the latter option.

17.9.6. Starting MySQL Cluster Replication (Single Replication Channel)

This section outlines the procedure for starting MySQL Cluster replication using a single replication channel.

1. Start the MySQL replication master server by issuing this command:

```
shellM> mysqld --ndbcluster --server-id=id \
--log-bin --binlog-format=ROW &
```

In the previous statement, `id` is this server's unique ID (see [Section 17.9.2, “MySQL Cluster Replication — Assumptions and General Requirements”](#)). This starts the server's `mysqld` process with binary logging enabled using the proper logging format.

Note

You can also start the master with `--binlog-format=MIXED`, in which case row-based replication is used automatically when replicating between clusters.

2. Start the MySQL replication slave server as shown here:

```
shellS> mysqld --ndbcluster --server-id=id &
```

In the previous statement, `id` is the slave server's unique ID. It is not necessary to enable logging on the replication slave.

Note

You should use the `--skip-slave-start` option with this command or else you should include `skip-slave-start` in the slave server's `my.cnf` file, unless you want replication to begin immediately. With the use of this option, the start of replication is delayed until the appropriate `START SLAVE` statement has been issued, as explained in Step 4 below.

3. It is necessary to synchronize the slave server with the master server's replication binlog. If binary logging has not previously been running on the master, run the following statement on the slave:

```
mysqlS> CHANGE MASTER TO
-> MASTER_LOG_FILE='',
-> MASTER_LOG_POS=4;
```

This instructs the slave to begin reading the master's binary log from the log's starting point. Otherwise — that is, if you are loading data from the master using a backup — see [Section 17.9.8, “Implementing Failover with MySQL Cluster Replication”](#), for information on how to obtain the correct values to use for `MASTER_LOG_FILE` and `MASTER_LOG_POS` in such cases.

4. Finally, you must instruct the slave to begin applying replication by issuing this command from the `mysql` client on the replication slave:

```
mysqlS> START SLAVE;
```

This also initiates the transmission of replication data from the master to the slave.

It is also possible to use two replication channels, in a manner similar to the procedure described in the next section; the differences

between this and using a single replication channel are covered in [Section 17.9.7, “Using Two Replication Channels for MySQL Cluster Replication”](#).

Beginning with MySQL Cluster NDB 6.2.3, it is possible to improve cluster replication performance by enabling *batched updates*. This can be accomplished by starting slave `mysqld` processes with the `--slave-allow-batching` option. Normally, updates are applied as soon as they are received. However, the use of batching causes updates to be applied in 32 KB batches, which can result in higher throughput and less CPU usage, particularly where individual updates are relatively small.

Note

Slave batching works on a per-epoch basis; updates belonging to more than one transaction can be sent as part of the same batch.

All outstanding updates are applied when the end of an epoch is reached, even if the updates total less than 32 KB.

Batching can be turned on and off at runtime. To activate it at runtime, you can use either of these two statements:

```
SET GLOBAL slave_allow_batching = 1;
SET GLOBAL slave_allow_batching = ON;
```

If a particular batch causes problems (such as a statement whose effects do not appear to be replicated correctly), slave batching can be deactivated using either of the following statements:

```
SET GLOBAL slave_allow_batching = 0;
SET GLOBAL slave_allow_batching = OFF;
```

You can check whether slave batching is currently being used by means of an appropriate `SHOW VARIABLES` statement, like this one:

```
mysql> SHOW VARIABLES LIKE 'slave%';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| slave_allow_batching | ON |
| slave_compressed_protocol | OFF |
| slave_load_tmpdir | /tmp |
| slave_net_timeout | 3600 |
| slave_skip_errors | OFF |
| slave_transaction_retries | 10 |
+-----+-----+
6 rows in set (0.00 sec)
```

17.9.7. Using Two Replication Channels for MySQL Cluster Replication

In a more complete example scenario, we envision two replication channels to provide redundancy and thereby guard against possible failure of a single replication channel. This requires a total of four replication servers, two masters for the master cluster and two slave servers for the slave cluster. For purposes of the discussion that follows, we assume that unique identifiers are assigned as shown here:

Server ID	Description
1	Master - primary replication channel (<i>M</i>)
2	Master - secondary replication channel (<i>M'</i>)
3	Slave - primary replication channel (<i>S</i>)
4	Slave - secondary replication channel (<i>S'</i>)

Setting up replication with two channels is not radically different from setting up a single replication channel. First, the `mysqld` processes for the primary and secondary replication masters must be started, followed by those for the primary and secondary slaves. Then the replication processes may be initiated by issuing the `START SLAVE` statement on each of the slaves. The commands and the order in which they need to be issued are shown here:

1. Start the primary replication master:

```
shellM> mysqld --ndbcluster --server-id=1 \
--log-bin --binlog-format=row &
```

2. Start the secondary replication master:

```
shellM'> mysqld --ndbcluster --server-id=2 \
--log-bin --binlog-format=row &
```

3. Start the primary replication slave server:

```
shellS> mysqld --ndbcluster --server-id=3 \
             --skip-slave-start &
```

4. Start the secondary replication slave:

```
shellS'> mysqld --ndbcluster --server-id=4 \
            --skip-slave-start &
```

5. Finally, initiate replication on the primary channel by executing the `START SLAVE` statement on the primary slave as shown here:

```
mysqlS> START SLAVE;
```

Warning

Only the primary channel is to be started at this point. The secondary replication channel is to be started only in the event that the primary replication channel fails, as described in [Section 17.9.8, “Implementing Failover with MySQL Cluster Replication”](#). Running multiple replication channels simultaneously can result in unwanted duplicate records being created on the replication slaves.

As mentioned previously, it is not necessary to enable binary logging on replication slaves.

17.9.8. Implementing Failover with MySQL Cluster Replication

In the event that the primary Cluster replication process fails, it is possible to switch over to the secondary replication channel. The following procedure describes the steps required to accomplish this.

1. Obtain the time of the most recent global checkpoint (GCP). That is, you need to determine the most recent epoch from the `ndb_apply_status` table on the slave cluster, which can be found using the following query:

```
mysqlS'> SELECT @latest:=MAX(epoch)
-> FROM mysql.ndb_apply_status;
```

2. Using the information obtained from the query shown in Step 1, obtain the corresponding records from the `ndb_binlog_index` table on the master cluster as shown here:

```
mysqlM'> SELECT
-> @file:=SUBSTRING_INDEX(File, '/', -1),
-> @pos:=Position
-> FROM mysql.ndb_binlog_index
-> WHERE epoch > @latest
-> ORDER BY epoch ASC LIMIT 1;
```

These are the records saved on the master since the failure of the primary replication channel. We have employed a user variable `@latest` here to represent the value obtained in Step 1. Of course, it is not possible for one `mysqld` instance to access user variables set on another server instance directly. These values must be “plugged in” to the second query manually or in application code.

3. Now it is possible to synchronize the secondary channel by running the following query on the secondary slave server:

```
mysqlS'> CHANGE MASTER TO
-> MASTER_LOG_FILE=@file',
-> MASTER_LOG_POS=@pos;
```

Again we have employed user variables (in this case `@file` and `@pos`) to represent the values obtained in Step 2 and applied in Step 3; in practice these values must be inserted manually or using application code that can access both of the servers involved.

Note

`@file` is a string value such as `'/var/log/mysql/replication-master-bin.00001'`, and so must be quoted when used in SQL or application code. However, the value represented by `@pos` must *not* be quoted. Although MySQL normally attempts to convert strings to numbers, this case is an exception.

4. You can now initiate replication on the secondary channel by issuing the appropriate command on the secondary slave

```
mysqld:
```

```
mysqlS' > START SLAVE;
```

Once the secondary replication channel is active, you can investigate the failure of the primary and effect repairs. The precise actions required to do this will depend upon the reasons for which the primary channel failed.

Warning

The secondary replication channel is to be started only if and when the primary replication channel has failed. Running multiple replication channels simultaneously can result in unwanted duplicate records being created on the replication slaves.

If the failure is limited to a single server, it should (in theory) be possible to replicate from *M* to *S'*, or from *M'* to *S*; however, this has not yet been tested.

17.9.9. MySQL Cluster Backups With MySQL Cluster Replication

This section discusses making backups and restoring from them using MySQL Cluster replication. We assume that the replication servers have already been configured as covered previously (see [Section 17.9.5, “Preparing the MySQL Cluster for Replication”](#), and the sections immediately following). This having been done, the procedure for making a backup and then restoring from it is as follows:

1. There are two different methods by which the backup may be started.
 - **Method A.** This method requires that the cluster backup process was previously enabled on the master server, prior to starting the replication process. This can be done by including the following line in a `[mysql_cluster]` section in the `my.cnf` file, where `management_host` is the IP address or host name of the NDB management server for the master cluster, and `port` is the management server's port number:

```
ndb-connectstring=management_host[:port]
```

Note

The port number needs to be specified only if the default port (1186) is not being used. See [Section 17.2.3, “MySQL Cluster Multi-Computer Configuration”](#), for more information about ports and port allocation in MySQL Cluster. In this case, the backup can be started by executing this statement on the replication master:

```
shellM> ndb_mgm -e "START BACKUP"
```

- **Method B.** If the `my.cnf` file does not specify where to find the management host, you can start the backup process by passing this information to the NDB management client as part of the `START BACKUP` command. This can be done as shown here, where `management_host` and `port` are the host name and port number of the management server:

```
shellM> ndb_mgm management_host:port -e "START BACKUP"
```

In our scenario as outlined earlier (see [Section 17.9.5, “Preparing the MySQL Cluster for Replication”](#)), this would be executed as follows:

```
shellM> ndb_mgm rep-master:1186 -e "START BACKUP"
```

2. Copy the cluster backup files to the slave that is being brought on line. Each system running an `ndbd` process for the master cluster will have cluster backup files located on it, and *all* of these files must be copied to the slave to ensure a successful restore. The backup files can be copied into any directory on the computer where the slave management host resides, so long as the MySQL and NDB binaries have read permissions in that directory. In this case, we will assume that these files have been copied into the directory `/var/BACKUPS/BACKUP-1`.

It is not necessary that the slave cluster have the same number of `ndbd` processes (data nodes) as the master; however, it is highly recommended this number be the same. It *is* necessary that the slave be started with the `--skip-slave-start` option, to prevent premature startup of the replication process.

3. Create any databases on the slave cluster that are present on the master cluster that are to be replicated to the slave.

Important

A `CREATE DATABASE` (or `CREATE SCHEMA`) statement corresponding to each database to be replicated must be executed on each SQL node in the slave cluster.

- Reset the slave cluster using this statement in the MySQL Monitor:

```
mysqlS> RESET SLAVE;
```

It is important to make sure that the slave's `apply_status` table does not contain any records prior to running the restore process. You can accomplish this by running this SQL statement on the slave:

```
mysqlS> DELETE FROM mysql.ndb_apply_status;
```

- You can now start the cluster restoration process on the replication slave using the `ndb_restore` command for each backup file in turn. For the first of these, it is necessary to include the `-m` option to restore the cluster metadata:

```
shellS> ndb_restore -c slave_host:port -n node-id \
  -b backup-id -m -r dir
```

`dir` is the path to the directory where the backup files have been placed on the replication slave. For the `ndb_restore` commands corresponding to the remaining backup files, the `-m` option should *not* be used.

For restoring from a master cluster with four data nodes (as shown in the figure in [Section 17.9, “MySQL Cluster Replication”](#)) where the backup files have been copied to the directory `/var/BACKUPS/BACKUP-1`, the proper sequence of commands to be executed on the slave might look like this:

```
shellS> ndb_restore -c rep-slave:1186 -n 2 -b 1 -m \
  -r ./var/BACKUPS/BACKUP-1
shellS> ndb_restore -c rep-slave:1186 -n 3 -b 1 \
  -r ./var/BACKUPS/BACKUP-1
shellS> ndb_restore -c rep-slave:1186 -n 4 -b 1 \
  -r ./var/BACKUPS/BACKUP-1
shellS> ndb_restore -c rep-slave:1186 -n 5 -b 1 -e \
  -r ./var/BACKUPS/BACKUP-1
```

Important

The `-e` (or `--restore-epoch`) option in the final invocation of `ndb_restore` in this example is required in order that the epoch is written to the slave `mysql.ndb_apply_status`. Without this information, the slave will not be able to synchronize properly with the master. (See [Section 17.6.17, “ndb_restore — Restore a MySQL Cluster Backup”](#).)

- Now you need to obtain the most recent epoch from the `ndb_apply_status` table on the slave (as discussed in [Section 17.9.8, “Implementing Failover with MySQL Cluster Replication”](#)):

```
mysqlS> SELECT @latest:=MAX(epoch)
  FROM mysql.ndb_apply_status;
```

- Using `@latest` as the epoch value obtained in the previous step, you can obtain the correct starting position `@pos` in the correct binary log file `@file` from the master's `mysql.ndb_binlog_index` table using the query shown here:

```
mysqlM> SELECT
  ->   @file:=SUBSTRING_INDEX(File, '/', -1),
  ->   @pos:=Position
  -> FROM mysql.ndb_binlog_index
  -> WHERE epoch > @latest
  -> ORDER BY epoch ASC LIMIT 1;
```

In the event that there is currently no replication traffic, you can get this information by running `SHOW MASTER STATUS` on the master and using the value in the `Position` column for the file whose name has the suffix with the greatest value for all files shown in the `File` column. However, in this case, you must determine this and supply it in the next step manually or by parsing the output with a script.

- Using the values obtained in the previous step, you can now issue the appropriate `CHANGE MASTER TO` statement in the slave's `mysql` client:

```
mysqlS> CHANGE MASTER TO
  ->   MASTER_LOG_FILE=@file',
  ->   MASTER_LOG_POS=@pos;
```

- Now that the slave “knows” from what point in which `binlog` file to start reading data from the master, you can cause the slave to begin replicating with this standard MySQL statement:

```
mysqlS> START SLAVE;
```

To perform a backup and restore on a second replication channel, it is necessary only to repeat these steps, substituting the host names and IDs of the secondary master and slave for those of the primary master and slave replication servers where appropriate, and running the preceding statements on them.

For additional information on performing Cluster backups and restoring Cluster from backups, see [Section 17.7.3, “Online Backup of MySQL Cluster”](#).

17.9.9.1. MySQL Cluster Replication — Automating Synchronization of the Replication Slave to the Master Binary Log

It is possible to automate much of the process described in the previous section (see [Section 17.9.9, “MySQL Cluster Backups With MySQL Cluster Replication”](#)). The following Perl script `reset-slave.pl` serves as an example of how you can do this.

```
#!/user/bin/perl -w

                        MASTER_LOG_FILE='$binlog',
                        MASTER_LOG_POS=$binpos;")
    or die "Prepare to CHANGE MASTER error: ", $dbhS->errstr;

  $sth->execute
    or die "CHANGE MASTER on slave error: ", $sth->errstr;
  $sth->finish;
}

```

```
print "\tSlave has been updated. You may now start the slave.\n";
}
# end reset-slave.pl
```

17.9.10. MySQL Cluster Replication — Multi-Master and Circular Replication

Beginning with MySQL 5.1.18, it is possible to use MySQL Cluster in multi-master replication, including circular replication between a number of MySQL Clusters.

Note

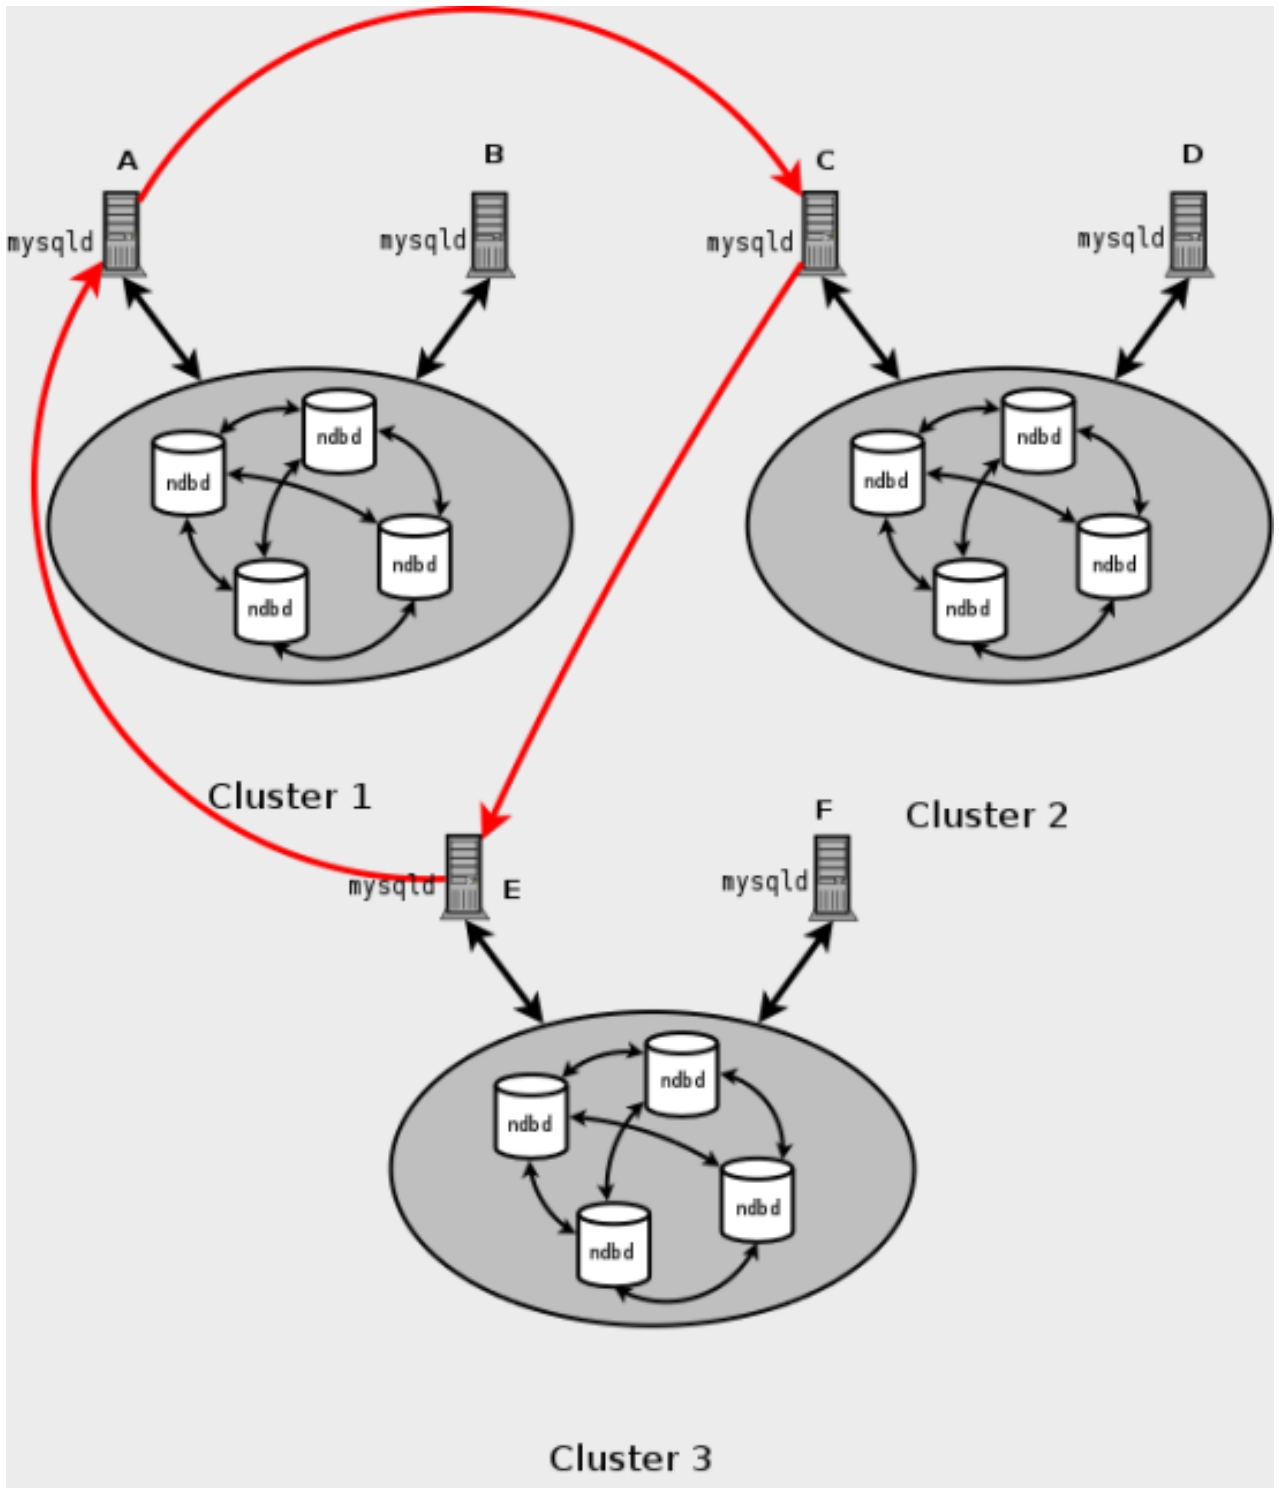

Prior to MySQL 5.1.18, multi-master replication including circular replication was not supported with MySQL Cluster replication. This was because log events created in a particular MySQL Cluster were wrongly tagged with the server ID of the master rather than the server ID of the originating server.

Circular replication example. In the next few paragraphs we consider the example of a replication setup involving three MySQL Clusters numbered 1, 2, and 3, in which Cluster 1 acts as the replication master for Cluster 2, Cluster 2 acts as the master for Cluster 3, and Cluster 3 acts as the master for Cluster 1. Each cluster has two SQL nodes, with SQL nodes A and B belonging to Cluster 1, SQL nodes C and D belonging to Cluster 2, and SQL nodes E and F belonging to Cluster 3.

Circular replication using these clusters is supported as long as:

- The SQL nodes on all masters and slaves are the same
- All SQL nodes acting as replication masters and slaves are started using the `--log-slave-updates` option

This type of circular replication setup is shown in the following diagram:

In this scenario, SQL node A in Cluster 1 replicates to SQL node C in Cluster 2; SQL node C replicates to SQL node E in Cluster 3; SQL node E replicates to SQL node A. In other words, the replication line (indicated by the red arrows in the diagram) directly connects all SQL nodes used as replication masters and slaves.

It is also possible to set up circular replication in such a way that not all master SQL nodes are also slaves, as shown here:

In this case, different SQL nodes in each cluster are used as replication masters and slaves. However, you must *not* start any of the SQL nodes using `--log-slave-updates` (see the [description of this option](#) for more information). This type of circular replication scheme for MySQL Cluster, in which the line of replication (again indicated by the red arrows in the diagram) is discontinuous, should be possible, but it should be noted that it has not yet been thoroughly tested and must therefore still be considered experimental.

Important

Beginning with MySQL 5.1.24, you should execute the following statement before starting circular replication:

```
mysql> SET GLOBAL SLAVE_EXEC_MODE = 'IDEMPOTENT';
```

This is necessary to suppress duplicate-key and other errors that otherwise break circular replication in MySQL Cluster. `IDEMPOTENT` mode is also required for multi-master replication when using MySQL Cluster. ([Bug#31609](#))

See [slave_exec_mode](#), for more information.

Using NDB-native backup and restore to initialize a slave MySQL Cluster. When setting up circular replication, it is possible to initialize the slave cluster by using the management client `BACKUP` command on one MySQL Cluster to create a backup and then applying this backup on another MySQL Cluster using `ndb_restore`. However, this does not automatically create binary logs on the second MySQL Cluster's SQL node acting as the replication slave. In order to cause the binary logs to be created, you must issue a `SHOW TABLES` statement on that SQL node; this should be done prior to running `START SLAVE`.

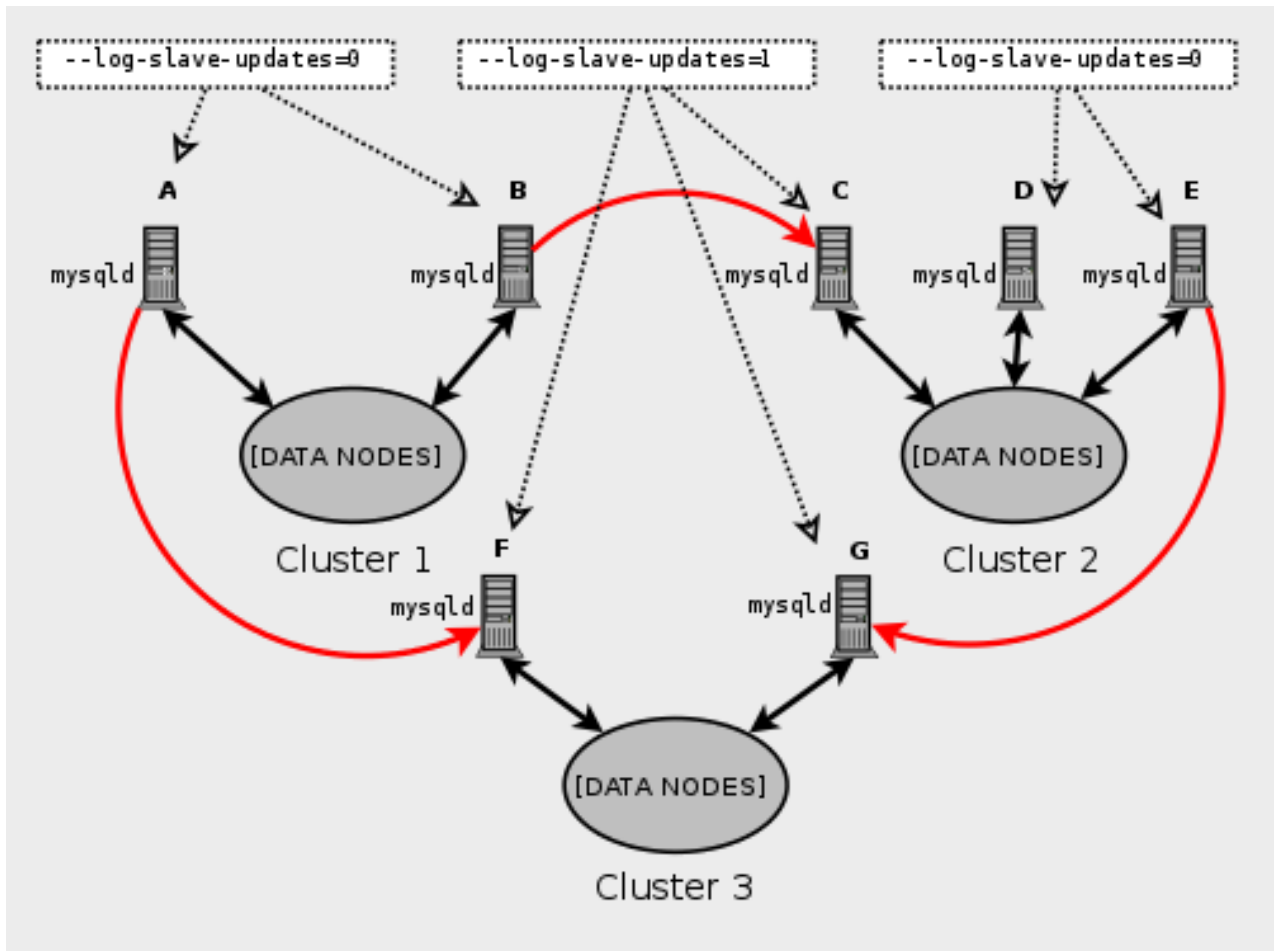

This is a known issue which we intend to address in a future release.

Multi-master failover example. In this section, we discuss failover in a multi-master MySQL Cluster replication setup with three MySQL Clusters having server IDs 1, 2, and 3. In this scenario, Cluster 1 replicates to Clusters 2 and 3; Cluster 2 also replicates to Cluster 3. This relationship is shown here:

In other words, data replicates from Cluster 1 to Cluster 3 via 2 different routes: directly, and by way of Cluster 2.

Not all MySQL servers taking part in multi-master replication must act as both master and slave, and a given MySQL Cluster might use different SQL nodes for different replication channels. Such a case is shown here:

MySQL servers acting as replication slaves must be run with the `--log-slave-updates` option. Which `mysqld` processes require this option is also shown in the preceding diagram.

Note

Using the `--log-slave-updates` option has no effect on servers not being run as replication slaves.

The need for failover arises when one of the replicating clusters goes down. In this example, we consider the case where Cluster 1 is lost to service, and so Cluster 3 loses 2 sources of updates from Cluster 1. Because replication between MySQL Clusters is asynchronous, there is no guarantee that Cluster 3's updates originating directly from Cluster 1 are more recent than those received via Cluster 2. You can handle this by ensuring that Cluster 3 catches up to Cluster 2 with regard to updates from Cluster 1. In terms of MySQL servers, this means that you need to replicate any outstanding updates from MySQL server C to server F.

On server C, perform the following queries:

```
mysqlC> SELECT @latest:=MAX(epoch)
-> FROM mysql.ndb_apply_status
-> WHERE server_id=1;

mysqlC> SELECT
-> @file:=SUBSTRING_INDEX(File, '/', -1),
-> @pos:=Position
-> FROM mysql.ndb_binlog_index
-> WHERE orig_epoch >= @latest
-> AND orig_server_id = 1
-> ORDER BY epoch ASC LIMIT 1;
```

Copy over the values for `@file` and `@pos` manually from server C to server F (or have your application perform the equivalent). Then, on server F, execute the following `CHANGE MASTER TO` statement:

```
mysqlF> CHANGE MASTER TO
-> MASTER_HOST = 'serverC',
-> MASTER_LOG_FILE=@file',
-> MASTER_LOG_POS=@pos;
```

Once this has been done, you can issue a `START SLAVE` statement on MySQL server F, and any missing updates originating from server B will be replicated to server F.

17.9.11. MySQL Cluster Replication Conflict Resolution

When using a replication setup involving multiple masters (including circular replication), it is possible that different masters may try to update the same row on the slave with different data. Conflict resolution in MySQL Cluster Replication provides a means of resolving such conflicts by allowing a user defined resolution column to be used to determine whether or not an update to the row on a given master should be applied on the slave. (This column is sometimes referred to as a “timestamp” column, even though this column’s type cannot be `TIMESTAMP`, as explained later in this section.) Different methods can be used to compare resolution column values on the slave when conflicts occur, as explained later in this section; the method used can be set on a per-table basis.

Important

Conflict resolution as described in this section is always applied on a row-by-row basis rather than a transactional basis. In addition, it is the application’s responsibility to ensure that the resolution column is correctly populated with relevant values, so that the resolution function can make the appropriate choice when determining whether to apply an update.

Requirements. Preparations for conflict resolution must be made on both the master and the slave:

- On the master writing the binlogs, you must determine which columns are sent (all columns or only those that have been updated). This is done for the MySQL Server as a whole by applying the `mysqld` startup option `--ndb-log-updated-only` (described later in this section) or on a per-table basis by entries in the `mysql.ndb_replication` table.
- On the slave, you must determine which type of conflict resolution to apply (“latest timestamp wins”, “same timestamp wins”, or none). This is done using the `mysql.ndb_replication` system table, on a per-table basis.

If only some but not all columns are sent, then the master and slave can diverge.

Note

We refer to the column used for determining updates as a “timestamp” column, but the data type of this column is never `TIMESTAMP`; rather, its data type should be `INT` (`INTEGER`) or `BIGINT`. This column should be `UNSIGNED` and `NOT NULL`.

Master column control. We can see update operations in terms of “before” and “after” images — that is, the states of the table before and after the update is applied. Normally, when updating a table with a primary key, the “before” image is not of great interest; however, when we need to determine on a per-update basis whether or not to use the updated values on a replication slave, we need to make sure that both images are written to the master’s binary log. This is done with the `--ndb-log-update-as-write` option for `mysqld`, as described later in this section.

Important

Whether logging of complete rows or of updated columns only is done is decided when the MySQL server is started, and cannot be changed online; you must either restart `mysqld`, or start a new `mysqld` instance with different logging options.

Logging full or partial rows (`--ndb-log-updated-only` option). For purposes of conflict resolution, there are two basic methods of logging rows, as determined by the setting of the `--ndb-log-updated-only` option for `mysqld`:

- Log complete rows
- Log only column data that has been updated — that is, column data whose value has been set, regardless of whether or not this value was actually changed.

It is more efficient to log updated columns only; however, if you need to log full rows, you can do so by setting `--ndb-log-updated-only` to `0` or `OFF`.

Logging changed data as updates (`--ndb-log-update-as-write` option). Either of these logging methods can be configured to be done with or without the “before” image as determined by the setting of another MySQL Server option `--ndb-log-update-as-write`. Because conflict resolution is done in the MySQL Server’s update handler, it is necessary to control logging on the master such that updates are updates and not writes; that is, such that updates are treated as changes in existing rows rather than the writing of new rows (even though these replace existing rows). This option is turned on by default; to turn it off, start the server with `--ndb-log-update-as-write=0` or `--ndb-log-update-as-write=OFF`.

Conflict resolution control. Conflict resolution is usually enabled on the server where conflicts can occur. Like logging method selection, it is enabled by entries in the `mysql.ndb_replication` table.

The `ndb_replication` system table. To enable conflict resolution, it is necessary to create an `ndb_replication` table in the `mysql` system database on the master, the slave, or both, depending on the conflict resolution type and method to be employed. This table is used to control logging and conflict resolution functions on a per-table basis, and has one row per table involved in

replication. `ndb_replication` is created and filled with control information on the server where the conflict is to be resolved. In a simple master-slave setup where data can also be changed locally on the slave this will typically be the slave. In a more complex master-master (2-way) replication schema this will usually be all of the masters involved. Each row in `mysql.ndb_replication` corresponds to a table being replicated, and specifies how to log and resolve conflicts (that is, which conflict resolution function, if any, to use) for that table. The definition of the `mysql.ndb_replication` table is shown here:

```
CREATE TABLE mysql.ndb_replication (
  db VARBINARY(63),
  table_name VARBINARY(63),
  server_id INT UNSIGNED,
  binlog_type INT UNSIGNED,
  conflict_fn VARBINARY(128),
  PRIMARY KEY USING HASH (db, table_name, server_id)
) ENGINE=NDB
PARTITION BY KEY(db,table_name);
```

The columns in this table are described in the following list:

- **db.** The name of the database containing the table to be replicated.
- **table_name.** The name of the table to be replicated.
- **server_id.** The unique server ID of the MySQL instance (SQL node) where the table resides.
- **binlog_type.** The type of binary logging to be employed. This is determined as shown in the following table:

Value	Internal Value	Description
0	<code>NBT_DEFAULT</code>	Use server default
1	<code>NBT_NO_LOGGING</code>	Do not log this table in the binary log
2	<code>NBT_UPDATED_ONLY</code>	Only updated attributes are logged
3	<code>NBT_FULL</code>	Log full row, even if not updated (MySQL server default behavior)
4	<code>NBT_USE_UPDATE</code>	(For generating <code>NBT_UPDATED_ONLY_USE_UPDATE</code> and <code>NBT_FULL_USE_UPDATE</code> values only — not intended for separate use)
5	<i>[Not used]</i>	---
6	<code>NBT_UPDATED_ONLY_USE_UPDATE</code> (equal to <code>NBT_UPDATED_ONLY</code> <code>NBT_USE_UPDATE</code>)	Use updated attributes, even if values are unchanged
7	<code>NBT_FULL_USE_UPDATE</code> (equal to <code>NBT_FULL</code> <code>NBT_USE_UPDATE</code>)	Use full row, even if values are unchanged

- **conflict_fn.** The conflict resolution function to be applied. This function must be specified as one of the following:
 - **NDB\$MAX(column_name).** If the “timestamp” column value for a given row coming from the master is higher than that on the slave, it is applied; otherwise it is not applied on the slave. This is illustrated by the following pseudocode:

```
if (master_new_column_value > slave_current_column_value)
  perform_update();
```

This function can be used for “greatest timestamp wins” conflict resolution. This type of conflict resolution ensures that, in the event of a conflict, the version of the row that was most recently updated is the version that persists.

Important

The column value from the master’s “after” image is used by this function.

This conflict resolution function is available beginning with MySQL Cluster NDB 6.3.0.

- **NDB\$OLD(column_name).** If the value of `column_name` is the same on both the master and the slave, then the update is applied; otherwise, the update is not applied on the slave and an exception is written to the log. This is illustrated by the following pseudocode:

```
if (master_old_column_value == slave_current_column_value)
  perform_update();
else
  log_exception();
```

This function can be used for “same value wins” conflict resolution. This type of conflict resolution ensures that updates are not applied on the slave from the wrong master.

Important

The column value from the master's “before” image is used by this function.

This conflict resolution function is available beginning with MySQL Cluster NDB 6.3.4.

- **NULL**: Indicates that conflict resolution is not to be used for the corresponding table

Status information. Beginning with MySQL Cluster NDB 6.3.3, a server status variable `Ndb_conflict_fn_max` provides a count of the number of times that a row was not applied on the current SQL node due to “greatest timestamp wins” conflict resolution since the last time that `mysqld` was started.

Beginning with MySQL Cluster NDB 6.3.4, the number of times that a row was not applied as the result of “same timestamp wins” conflict resolution on a given `mysqld` since the last time it was restarted is given by the global status variable `Ndb_conflict_fn_old`. In addition to incrementing `Ndb_conflict_fn_old`, the primary key of the row that was not used is inserted into an *exceptions table*, as explained later in this section.

Additional requirements for “Same timestamp wins” conflict resolution. To use the `NDB$OLD()` conflict resolution function, it is also necessary to create an exceptions table corresponding to each `NDB` table for which this type of conflict resolution is to be employed. The name of this table is that of the table for which “same timestamp wins” conflict resolution is to be applied, with the string `$EX` appended. (For example, if the name of the original table is `mytable`, the name of the corresponding exception table name should be `mytable$EX`.) This table is created as follows:

```
CREATE TABLE original_table$EX (
  server_id INT UNSIGNED,
  master_server_id INT UNSIGNED,
  master_epoch BIGINT UNSIGNED,
  count INT UNSIGNED,
  original_table_pk_columns,
  [additional_columns,]
  PRIMARY KEY(server_id, master_server_id, master_epoch, count)
) ENGINE=NDB;
```

The first four columns are required. Following these columns, the columns making up the original table's primary key should be copied in the order in which they are used to define the primary key of the original table.

Note

The names of the first four columns and the columns matching the original table's primary key columns are not critical; however, we suggest for reasons of clarity and consistency, that you use the names shown here for the `server_id`, `master_server_id`, `master_epoch`, and `count` columns, and that you use the same names as in the original table for the columns matching those in the original table's primary key.

The data types for the columns duplicating the primary key columns of the original table should be the same as for (or larger than) the original columns.

Additional columns may optionally be defined following these columns, but not before any of them; any such extra columns cannot be `NOT NULL`. The exception table's primary key must be defined as shown. The exception table must use the `NDB` storage engine. An example of use for `NDB$OLD()` and an exception table is given later in this section.

Important

The `mysql.ndb_replication` table is read when a data table is set up for replication, so the row corresponding to a table to be replicated must be inserted into `mysql.ndb_replication` *before* the table to be replicated is created.

Examples. The following examples assume that you have already a working MySQL Cluster replication setup, as described in Section 17.9.5, “Preparing the MySQL Cluster for Replication”, and Section 17.9.6, “Starting MySQL Cluster Replication (Single Replication Channel)”.

- **`NDB$MAX()` example.** Suppose you wish to enable “greatest timestamp wins” conflict resolution on table `test.t1`, using column `mycol` as the “timestamp”. This can be done using the following steps:
 1. Make sure that you have started the master `mysqld` with `--ndb-log-update-as-write=OFF`.
 2. On the master, perform this `INSERT` statement:

```
INSERT INTO mysql.ndb_replication
VALUES ('test', 't1', 0, NULL, 'NDB$MAX(mycol)');
```

Inserting a 0 into the `server_id` indicates that all SQL nodes accessing this table should use conflict resolution. If you want to use conflict resolution on a specific `mysqld` only, use the actual server ID.

Inserting `NULL` into the `binlog_type` column has the same effect as inserting 0 (`NBT_DEFAULT`); the server default is used.

3. Create the `test.t1` table:

```
CREATE TABLE test.t1 (
  columns
  mycol INT UNSIGNED,
  columns
) ENGINE=NDB;
```

Now, when updates are done on this table, conflict resolution will be applied, and the version of the row having the greatest value for `mycol` will be written to the slave.

Note

Other `binlog_type` options — such as `NBT_UPDATED_ONLY_USE_UPDATE` should be used in order to control logging on the master via the `ndb_replication` table rather than by using command-line options.

- **NDB\$OLD() example.** Suppose an `NDB` table such as the one defined here is being replicated, and you wish to enable “same timestamp wins” conflict resolution for updates to this table:

```
CREATE TABLE test.t2 (
  a INT UNSIGNED NOT NULL,
  b CHAR(25) NOT NULL,
  columns,
  mycol INT UNSIGNED NOT NULL,
  columns,
  PRIMARY KEY pk (a, b)
) ENGINE=NDB;
```

The following steps are required, in the order shown:

1. First — and *prior* to creating `test.t2` — you must insert a row into the `mysql.ndb_replication` table, as shown here:

```
INSERT INTO mysql.ndb_replication
VALUES ('test', 't2', 0, NULL, 'NDB$OLD(mycol)');
```

Possible values for the `binlog_type` column are shown earlier in this section. The value `'NDB$OLD(mycol)'` should be inserted into the `conflict_fn` column.

2. Create an appropriate exceptions table for `test.t2`. The table creation statement shown here includes all required columns; any additional columns must be declared following these columns, and before the definition of the table's primary key.

```
CREATE TABLE test.t2$EX (
  server_id SMALLINT UNSIGNED,
  master_server_id INT UNSIGNED,
  master_epoch BIGINT UNSIGNED,
  count BIGINT UNSIGNED,
  a INT UNSIGNED NOT NULL,
  b CHAR(25) NOT NULL,
  [additional_columns,]
  PRIMARY KEY(server_id, master_server_id, master_epoch, count)
) ENGINE=NDB;
```

3. Create the table `test.t2` as shown previously.

These steps must be followed for every table for which you wish to perform conflict resolution using `NDB$OLD()`. For each such table, there must be a corresponding row in `mysql.ndb_replication`, and there must be an exceptions table in the same database as the table being replicated.

17.10. MySQL Cluster Disk Data Tables

Beginning with MySQL 5.1.6, it is possible to store the non-indexed columns of `NDB` tables on disk, rather than in RAM as with previous versions of MySQL Cluster.

As part of implementing MySQL Cluster Disk Data work, a number of improvements were made in MySQL Cluster for the effi-

cient handling of very large amounts (terabytes) of data during node recovery and restart. These include a “no-steal” algorithm for synchronising a starting node with very large data sets. For more information, see the paper [Recovery Principles of MySQL Cluster 5.1](#), by MySQL Cluster developers Mikael Ronström and Jonas Oreland.

MySQL Cluster Disk Data performance can be influenced by a number of configuration parameters. For information about these parameters and their effects, see [MySQL Cluster Disk Data configuration parameters](#) and [MySQL Cluster Disk Data storage and GCP STOP errors](#).

The performance of a MySQL Cluster that uses Disk Data storage can also be greatly improved by separating data node file systems from undo log files and tablespace data files, which can be done using symbolic links. For more information, see [Section 17.10.2, “Using Symbolic Links with Disk Data Objects”](#).

17.10.1. MySQL Cluster Disk Data Objects

MySQL Cluster Disk Data storage is implemented using a number of *Disk Data objects*. These include the following:

- *Tablespaces* act as containers for other Disk Data objects.
- *Undo log files* undo information required for rolling back transactions.
- One or more undo log files are assigned to a *log file group*, which is then assigned to a tablespace.
- *Data files* store Disk Data table data. A data file is assigned directly to a tablespace.

Undo log files and data files are actual files in the filesystem of each data node; by default they are placed in `ndb_node_id_fs` in the `DataDir` specified in the MySQL Cluster `config.ini` file, and where `node_id` is the data node's node ID. It is possible to place these elsewhere by specifying either an absolute or relative path as part of the filename when creating the undo log or data file. Statements that create these files are shown later in this section.

MySQL Cluster tablespaces and log file groups are not implemented as files.

Important

Although not all Disk Data objects are implemented as files, they all share the same namespace. This means that *each Disk Data object* must be uniquely named (and not merely each Disk Data object of a given type). For example, you cannot have a tablespace and a log file group both named `dd1`.

Assuming that you have already set up a MySQL Cluster with all nodes (including management and SQL nodes) running MySQL 5.1.6 or newer, the basic steps for creating a Cluster table on disk are as follows:

1. Create a log file group, and assign one or more undo log files to it (an undo log file is also sometimes referred to as an *undofile*).

Note

In MySQL 5.1 and later, undo log files are necessary only for Disk Data tables. They are no longer used for `NDB-CLUSTER` tables that are stored only in memory.

2. Create a tablespace; assign the log file group, as well as one or more data files, to the tablespace.
3. Create a Disk Data table that uses this tablespace for data storage.

Each of these tasks can be accomplished using SQL statements in the `mysql` client or other MySQL client application, as shown in the example that follows.

1. We create a log file group named `lg_1` using `CREATE LOGFILE GROUP`. This log file group is to be made up of two undo log files, which we name `undo_1.log` and `undo_2.log`, whose initial sizes are 16 MB and 12 MB, respectively. (The default initial size for an undo log file is 128 MB.) Optionally, you can also specify a size for the log file group's undo buffer, or allow it to assume the default value of 8 MB. In this example, we set the UNDO buffer's size at 2 MB. A log file group must be created with an undo log file; so we add `undo_1.log` to `lg_1` in this `CREATE LOGFILE GROUP` statement:

```
CREATE LOGFILE GROUP lg_1
  ADD UNDOFILE 'undo_1.log'
  INITIAL_SIZE 16M
  UNDO_BUFFER_SIZE 2M
  ENGINE NDBCLUSTER;
```

To add `undo_2.log` to the log file group, use the following `ALTER LOGFILE GROUP` statement:

```
ALTER LOGFILE GROUP lg_1
  ADD UNDOFILE 'undo_2.log'
  INITIAL_SIZE 12M
  ENGINE NDBCLUSTER;
```

Some items of note:

- The `.log` file extension used here is not required. We use it merely to make the log files easily recognisable.
- Every `CREATE LOGFILE GROUP` and `ALTER LOGFILE GROUP` statement must include an `ENGINE` clause. In MySQL 5.1, the permitted values for this clause are `NDBCLUSTER` and `NDB`.

Important

In MySQL 5.1.8 and later, there can exist only one log file group in the same MySQL Cluster at any given time.

- When you add an undo log file to a log file group using `ADD UNDOFILE 'filename'`, a file with the name `filename` is created in the `ndb_node_id_fs` directory within the `DataDir` of each data node in the cluster, where `node_id` is the node ID of the data node. Each undo log file is of the size specified in the SQL statement. For example, if a MySQL Cluster has 4 data nodes, then the `ALTER LOGFILE GROUP` statement just shown creates 4 undo log files, 1 each on in the data directory of each of the 4 data nodes; each of these files is named `undo_2.log` and each file is 12 MB in size.
- `UNDO_BUFFER_SIZE` is limited by the amount of system memory available.
- For more information about the `CREATE LOGFILE GROUP` statement, see [Section 12.1.14, “CREATE LOGFILE GROUP Syntax”](#). For more information about `ALTER LOGFILE GROUP`, see [Section 12.1.3, “ALTER LOGFILE GROUP Syntax”](#).

2.

Now we can create a tablespace, which contains files to be used by MySQL Cluster Disk Data tables for storing their data. A tablespace is also associated with a particular log file group. When creating a new tablespace, you must specify the log file group which it is to use for undo logging; you must also specify a data file. You can add more data files to the tablespace after the tablespace is created; it is also possible to drop data files from a tablespace (an example of dropping data files is provided later in this section).

Assume that we wish to create a tablespace named `ts_1` which uses `lg_1` as its log file group. This tablespace is to contain two data files named `data_1.dat` and `data_2.dat`, whose initial sizes are 32 MB and 48 MB, respectively. (The default value for `INITIAL_SIZE` is 128 MB.) We can do this using two SQL statements, as shown here:

```
CREATE TABLESPACE ts_1
  ADD DATAFILE 'data_1.dat'
  USE LOGFILE GROUP lg_1
  INITIAL_SIZE 32M
  ENGINE NDBCLUSTER;

ALTER TABLESPACE ts_1
  ADD DATAFILE 'data_2.dat'
  INITIAL_SIZE 48M
  ENGINE NDBCLUSTER;
```

The `CREATE TABLESPACE` statement creates a tablespace `ts_1` with the data file `data_1.dat`, and associates `ts_1` with log file group `lg_1`. The `ALTER TABLESPACE` adds the second data file (`data_2.dat`).

Some items of note:

- As is the case with the `.log` file extension used in this example for undo log files, there is no special significance for the `.dat` file extension; it is used merely for easy recognition of data files.
- When you add a data file to a tablespace using `ADD DATAFILE 'filename'`, a file with the name `filename` is created in the `ndb_node_id_fs` directory within the `DataDir` of each data node in the cluster, where `node_id` is the node ID of the data node. Each data file is of the size specified in the SQL statement. For example, if a MySQL Cluster has 4 data nodes, then the `ALTER TABLESPACE` statement just shown creates 4 data files, 1 each on in the data directory of each of the 4 data nodes; each of these files is named `data_2.dat` and each file is 48 MB in size.
- All `CREATE TABLESPACE` and `ALTER TABLESPACE` statements must contain an `ENGINE` clause; only tables using the same storage engine as the tablespace can be created in the tablespace. In MySQL 5.1, the only permitted values for this clause are `NDBCLUSTER` and `NDB`.

- For more information about the `CREATE TABLESPACE` and `ALTER TABLESPACE` statements, see [Section 12.1.18, “CREATE TABLESPACE Syntax”](#), and [Section 12.1.8, “ALTER TABLESPACE Syntax”](#).

3.

Now it is possible to create a table whose non-indexed columns are stored on disk in the tablespace `ts_1`:

```
CREATE TABLE dt_1 (
  member_id INT UNSIGNED NOT NULL AUTO_INCREMENT PRIMARY KEY,
  last_name VARCHAR(50) NOT NULL,
  first_name VARCHAR(50) NOT NULL,
  dob DATE NOT NULL,
  joined DATE NOT NULL,
  INDEX(last_name, first_name)
)
TABLESPACE ts_1 STORAGE DISK
ENGINE NDBCLUSTER;
```

The `TABLESPACE ... STORAGE DISK` option tells the `NDBCLUSTER` storage engine to use tablespace `ts_1` for disk data storage.

Note

Beginning with MySQL Cluster NDB 6.2.5 and MySQL Cluster NDB 6.3.2, it is also possible to specify whether an individual column is stored on disk or in memory by using a `STORAGE` clause as part of the column's definition in a `CREATE TABLE` or `ALTER TABLE` statement. `STORAGE DISK` causes the column to be stored on disk, and `STORAGE MEMORY` causes in-memory storage to be used. See [Section 12.1.17, “CREATE TABLE Syntax”](#), for more information.

Once table `ts_1` has been created as shown, you can perform `INSERT`, `SELECT`, `UPDATE`, and `DELETE` statements on it just as you would with any other MySQL table.

For table `dt_1` as it has been defined here, only the `dob` and `joined` columns are stored on disk. This is because there are indexes on the `id`, `last_name`, and `first_name` columns, and so data belonging to these columns is stored in RAM. In MySQL 5.1, only non-indexed columns can be held on disk; indexes and indexed column data continue to be stored in memory. This tradeoff between the use of indexes and conservation of RAM is something you must keep in mind as you design Disk Data tables.

Performance note. The performance of a cluster using Disk Data storage is greatly improved if Disk Data files are kept on a separate physical disk from the data node file system. This must be done for each data node in the cluster to derive any noticeable benefit.

You may use absolute and relative file system paths with `ADD UNDOFILE` and `ADD DATAFILE`. Relative paths are calculated relative to the data node's data directory. You may also use symbolic links; see [Section 17.10.2, “Using Symbolic Links with Disk Data Objects”](#), for more information and examples.

A log file group, a tablespace, and any Disk Data tables using these must be created in a particular order. The same is true for dropping any of these objects:

- A log file group cannot be dropped as long as any tablespaces are using it.
- A tablespace cannot be dropped as long as it contains any data files.
- You cannot drop any data files from a tablespace as long as there remain any tables which are using the tablespace.
- Beginning with MySQL 5.1.12, it is no longer possible to drop files created in association with a different tablespace than the one with which the files were created. ([Bug#20053](#))

For example, to drop all the objects created so far in this section, you would use the following statements:

```
mysql> DROP TABLE dt_1;

mysql> ALTER TABLESPACE ts_1
-> DROP DATAFILE 'data_2.dat'
-> ENGINE NDBCLUSTER;

mysql> ALTER TABLESPACE ts_1
-> DROP DATAFILE 'data_1.dat'
-> ENGINE NDBCLUSTER;

mysql> DROP TABLESPACE ts_1
-> ENGINE NDBCLUSTER;

mysql> DROP LOGFILE GROUP lg_1
```

```
-> ENGINE NDBCLUSTER;
```

These statements must be performed in the order shown, except that the two `ALTER TABLESPACE ... DROP DATAFILE` statements may be executed in either order.

You can obtain information about data files used by Disk Data tables by querying the `FILES` table in the `INFORMATION_SCHEMA` database. An extra “NULL row” was added to this table in MySQL 5.1.14 for providing additional information about undo log files. For more information and examples of use, see [Section 20.21, “The INFORMATION_SCHEMA FILES Table”](#).

17.10.2. Using Symbolic Links with Disk Data Objects

The performance of a MySQL Cluster that uses Disk Data storage can be greatly improved by separating data node file systems from undo log files and tablespace data files and placing these on different disks. While there is currently no direct support for this in MySQL Cluster, it is possible to achieve this separation using symbolic links.

Each data node in the cluster creates a file system in the directory named `ndb_node_id_fs` under the data node's `DataDir` as defined in the `config.ini` file. In this example, we assume that each data node host has 3 disks, aliased as `/data0`, `/data1`, and `/data2`, and that the cluster's `config.ini` includes the following:

```
[ndb default]
DataDir= /data0
```

Our objective is to place all Disk Data log files in `/data1`, and all Disk Data data files in `/data2`, on each data node host.

Note

In this example, we assume that the cluster's data node hosts are all using Linux operating systems. For other platforms, you may need to substitute your operating system's commands for those shown here.

To accomplish this, perform the following steps:

- Under the data node file system create symbolic links pointing to the other drives:

```
shell> cd /data0/ndb_2_fs
shell> ls
D1 D10 D11 D2 D8 D9 LCP
shell> ln -s /data0 dnlogs
shell> ln -s /data1 dndata
```

You should now have two symbolic links:

```
shell> ls -l --hide=D*
lrwxrwxrwx 1 user group 30 2007-03-19 13:58 dndata -> /data1
lrwxrwxrwx 1 user group 30 2007-03-19 13:59 dnlogs -> /data2
```

We show this only for the data node with node ID 2; however, you must do this for *each* data node.

- Now, in the `mysql` client, create a log file group and tablespace using the symbolic links, as shown here:

```
mysql> CREATE LOGFILE GROUP lg1
-> ADD UNDOFILE 'dnlogs/undo1.log'
-> INITIAL_SIZE 150M
-> UNDO_BUFFER_SIZE = 1M
-> ENGINE=NDBCLUSTER;

mysql> CREATE TABLESPACE ts1
-> ADD DATAFILE 'dndata/data1.log'
-> USE LOGFILE GROUP lg1
-> INITIAL_SIZE 1G
-> ENGINE=NDBCLUSTER;
```

Verify that the files were created and placed correctly as shown here:

```
shell> cd /data1
shell> ls -l
total 2099304
-rw-rw-r-- 1 user group 157286400 2007-03-19 14:02 undo1.dat

shell> cd /data2
shell> ls -l
total 2099304
-rw-rw-r-- 1 user group 1073741824 2007-03-19 14:02 data1.dat
```

- If you are running multiple data nodes on one host, you must take care to avoid having them try to use the same space for Disk Data files. You can make this easier by creating a symbolic link in each data node filesystem. Suppose you are using `/data0` for both data node filesystems, but you wish to have the Disk Data files for both nodes on `/data1`. In this case, you can do

something similar to what is shown here:

```
shell> cd /data0
shell> ln -s ndb_2_fs/dd /data1/dn2
shell> ln -s ndb_3_fs/dd /data1/dn3
shell> ls -l --hide=D* ndb_2_fs
lrwxrwxrwx 1 user group 30 2007-03-19 14:22 dd -> /data1/dn2
shell> ls -l --hide=D* ndb_3_fs
lrwxrwxrwx 1 user group 30 2007-03-19 14:22 dd -> /data1/dn3
```

Now you can create a logfile group and tablespace using the symbolic link, like this:

```
mysql> CREATE LOGFILE GROUP lg1
-> ADD UNDOFILE 'dd/undo1.log'
-> INITIAL_SIZE 150M
-> UNDO_BUFFER_SIZE = 1M
-> ENGINE=NDBCLUSTER;

mysql> CREATE TABLESPACE ts1
-> ADD DATAFILE 'dd/data1.log'
-> USE LOGFILE GROUP lg1
-> INITIAL_SIZE 1G
-> ENGINE=NDBCLUSTER;
```

Verify that the files were created and placed correctly as shown here:

```
shell> cd /data1
shell> ls
dn2          dn3
shell> ls dn2
undo1.log    data1.log
shell> ls dn3
undo1.log    data1.log
```

17.10.3. MySQL Cluster Disk Data Storage Requirements

The following items apply to Disk Data storage requirements:

- Variable-length columns of Disk Data tables take up a fixed amount of space. For each row, this is equal to the space required to store the largest possible value for that column.

For general information about calculating these values, see [Section 10.5, “Data Type Storage Requirements”](#).

You can obtain an estimate the amount of space available in data files and undo log files by querying the `INFORMATION_SCHEMA.FILES` table. For more information and examples, see [Section 20.21, “The INFORMATION_SCHEMA FILES Table”](#).

Note

The `OPTIMIZE TABLE` statement does not have any effect on Disk Data tables.

- In a Disk Data table, the first 256 bytes of a `TEXT` or `BLOB` column are stored in memory; only the remainder is stored on disk.
- Each row in a Disk Data table uses 8 bytes in memory to point to the data stored on disk. This means that, in some cases, converting an in-memory column to the disk-based format can actually result in greater memory usage. For example, converting a `CHAR(4)` column from memory-based to disk-based format increases the amount of `DataMemory` used per row from 4 to 8 bytes.

Important

Starting the cluster with the `--initial` option does *not* remove Disk Data files. You must remove these manually prior to performing an initial restart of the cluster.

17.11. Using High-Speed Interconnects with MySQL Cluster

Even before design of `NDBCLUSTER` began in 1996, it was evident that one of the major problems to be encountered in building parallel databases would be communication between the nodes in the network. For this reason, `NDBCLUSTER` was designed from the very beginning to allow for the use of a number of different data transport mechanisms. In this Manual, we use the term *transporter* for these.

The MySQL Cluster codebase includes support for four different transporters:

- *TCP/IP using 100 Mbps or gigabit Ethernet*, as discussed in [Section 17.3.4.8, “MySQL Cluster TCP/IP Connections”](#).
- *Direct (machine-to-machine) TCP/IP*; although this transporter uses the same TCP/IP protocol as mentioned in the previous item, it requires setting up the hardware differently and is configured differently as well. For this reason, it is considered a separate transport mechanism for MySQL Cluster. See [Section 17.3.4.9, “MySQL Cluster TCP/IP Connections Using Direct Connections”](#), for details.
- *Shared memory (SHM)*. For more information about SHM, see [Section 17.3.4.10, “MySQL Cluster Shared-Memory Connections”](#).
- *Scalable Coherent Interface (SCI)*, as described in the next section of this chapter, [Section 17.3.4.11, “SCI Transport Connections in MySQL Cluster”](#).

Most users today employ TCP/IP over Ethernet because it is ubiquitous. TCP/IP is also by far the best-tested transporter for use with MySQL Cluster.

We are working to make sure that communication with the `ndbd` process is made in “chunks” that are as large as possible because this benefits all types of data transmission.

For users who desire it, it is also possible to use cluster interconnects to enhance performance even further. There are two ways to achieve this: Either a custom transporter can be designed to handle this case, or you can use socket implementations that bypass the TCP/IP stack to one extent or another. We have experimented with both of these techniques using the SCI (Scalable Coherent Interface) technology developed by [Dolphin Interconnect Solutions](#).

17.11.1. Configuring MySQL Cluster to use SCI Sockets

It is possible employing Scalable Coherent Interface (SCI) technology to achieve a significant increase in connection speeds and throughput between MySQL Cluster data and SQL nodes. To use SCI, it is necessary to obtain and install Dolphin SCI network cards and to use the drivers and other software supplied by Dolphin. You can get information on obtaining these, from [Dolphin Interconnect Solutions](#). SCI SuperSocket or SCI Transporter support is available for 32-bit and 64-bit Linux, Solaris, Windows, and other platforms. See the Dolphin documentation referenced later in this section for more detailed information regarding platforms supported for SCI.

Note

Prior to MySQL 5.1.20, there were issues with building MySQL Cluster with SCI support (see [Bug#25470](#)), but these have been resolved due to work contributed by Dolphin. SCI Sockets are now correctly supported for MySQL Cluster hosts running recent versions of Linux using the `-max` builds, and versions of MySQL Cluster with SCI Transporter support can be built using either of `compile-amd64-max-sci` or `compile-pentium64-max-sci`. Both of these build scripts can be found in the `BUILD` directory of the MySQL Cluster source trees; it should not be difficult to adapt them for other platforms. Generally, all that is necessary is to compile MySQL Cluster with SCI Transporter support is to configure the MySQL Cluster build using `--with-ndb-sci=/opt/DIS`.

Once you have acquired the required Dolphin hardware and software, you can obtain detailed information on how to adapt a MySQL Cluster configured for normal TCP/IP communication to use SCI from the *Dolphin Express for MySQL Installation and Reference Guide*, available for download at http://docsrva.mysql.com/public/DIS_install_guide_book.pdf (PDF file, 94 pages, 753 KB). This document provides instructions for installing the SCI hardware and software, as well as information concerning network topology and configuration.

17.11.2. MySQL Cluster Interconnects and Performance

The `ndbd` process has a number of simple constructs which are used to access the data in a MySQL Cluster. We have created a very simple benchmark to check the performance of each of these and the effects which various interconnects have on their performance.

There are four access methods:

- **Primary key access.** This is access of a record through its primary key. In the simplest case, only one record is accessed at a time, which means that the full cost of setting up a number of TCP/IP messages and a number of costs for context switching are borne by this single request. In the case where multiple primary key accesses are sent in one batch, those accesses share the cost of setting up the necessary TCP/IP messages and context switches. If the TCP/IP messages are for different destinations, additional TCP/IP messages need to be set up.
- **Unique key access.** Unique key accesses are similar to primary key accesses, except that a unique key access is executed as a read on an index table followed by a primary key access on the table. However, only one request is sent from the MySQL Server, and the read of the index table is handled by `ndbd`. Such requests also benefit from batching.

- **Full table scan.** When no indexes exist for a lookup on a table, a full table scan is performed. This is sent as a single request to the `ndbd` process, which then divides the table scan into a set of parallel scans on all cluster `ndbd` processes. In future versions of MySQL Cluster, an SQL node will be able to filter some of these scans.
- **Range scan using ordered index**

When an ordered index is used, it performs a scan in the same manner as the full table scan, except that it scans only those records which are in the range used by the query transmitted by the MySQL server (SQL node). All partitions are scanned in parallel when all bound index attributes include all attributes in the partitioning key.

With benchmarks developed internally by MySQL for testing simple and batched primary and unique key accesses, we have found that using SCI sockets improves performance by approximately 100% over TCP/IP, except in rare instances when communication performance is not an issue. This can occur when scan filters make up most of processing time or when very large batches of primary key accesses are achieved. In that case, the CPU processing in the `ndbd` processes becomes a fairly large part of the overhead.

Using the SCI transporter instead of SCI Sockets is only of interest in communicating between `ndbd` processes. Using the SCI transporter is also only of interest if a CPU can be dedicated to the `ndbd` process because the SCI transporter ensures that this process will never go to sleep. It is also important to ensure that the `ndbd` process priority is set in such a way that the process does not lose priority due to running for an extended period of time, as can be done by locking processes to CPUs in Linux 2.6. If such a configuration is possible, the `ndbd` process will benefit by 10–70% as compared with using SCI sockets. (The larger figures will be seen when performing updates and probably on parallel scan operations as well.)

There are several other optimized socket implementations for computer clusters, including Myrinet, Gigabit Ethernet, Infiniband and the VIA interface. However, we have tested MySQL Cluster so far only with SCI sockets. See [Section 17.11.1, “Configuring MySQL Cluster to use SCI Sockets”](#), for information on how to set up SCI sockets using ordinary TCP/IP for MySQL Cluster.

17.12. Known Limitations of MySQL Cluster

In the sections that follow, we discuss known limitations in current releases of MySQL Cluster as compared with the features available when using the `MyISAM` and `InnoDB` storage engines. If you check the “Cluster” category in the MySQL bugs database at <http://bugs.mysql.com>, you can find known bugs in the following categories under “MySQL Server:” in the MySQL bugs database at <http://bugs.mysql.com>, which we intend to correct in upcoming releases of MySQL Cluster:

- Cluster
- Cluster Direct API (NDBAPI)
- Cluster Disk Data
- Cluster Replication

This information is intended to be complete with respect to the conditions just set forth. You can report any discrepancies that you encounter to the MySQL bugs database using the instructions given in [Section 1.6, “How to Report Bugs or Problems”](#). If we do not plan to fix the problem in MySQL 5.1, we will add it to the list.

See [Section 17.12.11, “Previous MySQL Cluster Issues Resolved in MySQL 5.1 and MySQL Cluster NDB 6.x”](#) for a list of issues in MySQL Cluster in MySQL 5.0 that have been resolved in the current version.

Note

Limitations and other issues specific to MySQL Cluster Replication are described in [Section 17.9.3, “Known Issues in MySQL Cluster Replication”](#).

17.12.1. Non-Compliance with SQL Syntax in MySQL Cluster

Some SQL statements relating to certain MySQL features produce errors when used with `NDB` tables, as described in the following list:

- **Temporary tables.** Temporary tables are not supported. Trying either to create a temporary table that uses the `NDB` storage engine or to alter an existing temporary table to use `NDB` fails with the error `TABLE STORAGE ENGINE 'NDBCLUSTER' DOES NOT SUPPORT THE CREATE OPTION 'TEMPORARY'`.
- **Indexes and keys in `NDB` tables.** Keys and indexes on MySQL Cluster tables are subject to the following limitations:
 - **TEXT and BLOB columns.** You cannot create indexes on `NDB` table columns that use any of the `TEXT` or `BLOB` data types.

- **FULLTEXT indexes.** The NDB storage engine does not support FULLTEXT indexes, which are possible for MyISAM tables only.
However, you can create indexes on VARCHAR columns of NDB tables.
- **BIT columns.** A BIT column cannot be a primary key, unique key, or index, nor can it be part of a composite primary key, unique key, or index.
- **AUTO_INCREMENT columns.** Like other MySQL storage engines, the NDB storage engine can handle a maximum of one AUTO_INCREMENT column per table. However, in the case of a Cluster table with no explicit primary key, an AUTO_INCREMENT column is automatically defined and used as a “hidden” primary key. For this reason, you cannot define a table that has an explicit AUTO_INCREMENT column unless that column is also declared using the PRIMARY KEY option. Attempting to create a table with an AUTO_INCREMENT column that is not the table's primary key, and using the NDB storage engine, fails with an error.
- **MySQL Cluster and geometry data types.** Geometry datatypes (WKT and WKB) are supported in NDB tables in MySQL 5.1. However, spatial indexes are not supported.

- **Creating NDBCLUSTER tables with user-defined partitioning.** Support for user-defined partitioning for MySQL Cluster in MySQL 5.1 is restricted to [LINEAR] KEY partitioning. Beginning with MySQL 5.1.12, using any other partitioning type with ENGINE=NDB or ENGINE=NDBCLUSTER in a CREATE TABLE statement results in an error.

Default partitioning scheme. As of MySQL 5.1.6, all MySQL Cluster tables are by default partitioned by KEY using the table's primary key as the partitioning key. If no primary key is explicitly set for the table, the “hidden” primary key automatically created by the NDBCLUSTER storage engine is used instead. For additional discussion of these and related issues, see [Section 18.2.4, “KEY Partitioning”](#).

Beginning with MySQL Cluster NDB 6.2.18, MySQL Cluster NDB 6.3.25, and MySQL Cluster NDB 7.0.6, CREATE TABLE and ALTER TABLE statements that would cause a user-partitioned NDBCLUSTER table not to meet either or both of the following two requirements are disallowed, and fail with an error ([Bug#40709](#)):

1. The table must have an explicit primary key.
2. All columns listed in the table's partitioning expression must be part of the primary key.

Exception. If a user-partitioned NDBCLUSTER table is created using an empty column-list (that is, using PARTITION BY [LINEAR] KEY ()), then no explicit primary key is required.

Maximum number of partitions for NDBCLUSTER tables. The maximum number of partitions that can be defined for a NDBCLUSTER table when employing user-defined partitioning is 8 per node group. (See [Section 17.1.2, “MySQL Cluster Nodes, Node Groups, Replicas, and Partitions”](#), for more information about MySQL Cluster node groups.)

DROP PARTITION not supported. It is not possible to drop partitions from NDB tables using ALTER TABLE ... DROP PARTITION. The other partitioning extensions to ALTER TABLE — ADD PARTITION, REORGANIZE PARTITION, and COALESCE PARTITION — are supported for Cluster tables, but use copying and so are not optimized. See [Section 18.3.1, “Management of RANGE and LIST Partitions”](#) and [Section 12.1.7, “ALTER TABLE Syntax”](#).

- **Row-based replication.** When using row-based replication with MySQL Cluster, binary logging cannot be disabled. That is, the NDB storage engine ignores the value of sql_log_bin. ([Bug#16680](#))

17.12.2. Limits and Differences of MySQL Cluster from Standard MySQL Limits

In this section, we list limits found in MySQL Cluster that either differ from limits found in, or that are not found in, standard MySQL.

- **Memory usage and recovery.** Memory consumed when data is inserted into an NDB table is not automatically recovered when deleted, as it is with other storage engines. Instead, the following rules hold true:
 - A DELETE statement on an NDB table makes the memory formerly used by the deleted rows available for re-use by inserts on the same table only. This memory cannot be used by other NDB tables.
 - A DROP TABLE or TRUNCATE operation on an NDB table frees the memory that was used by this table for re-use by any NDB table, either by the same table or by another NDB table.

Note

Recall that `TRUNCATE` drops and re-creates the table. See [Section 12.2.10, “TRUNCATE Syntax”](#).

Memory freed by `DELETE` operations but still allocated to a specific table can also be made available for general re-use by performing a rolling restart of the cluster. See [Section 17.5.1, “Performing a Rolling Restart of a MySQL Cluster”](#).

Beginning with MySQL Cluster NDB 6.3.7, this limitation can be overcome using `OPTIMIZE TABLE`. See [Section 17.12.11, “Previous MySQL Cluster Issues Resolved in MySQL 5.1 and MySQL Cluster NDB 6.x”](#), for more information.

- **Limits imposed by the cluster's configuration.** A number of hard limits exist which are configurable, but available main memory in the cluster sets limits. See the complete list of configuration parameters in [Section 17.3.4, “MySQL Cluster Configuration Files”](#). Most configuration parameters can be upgraded online. These hard limits include:

- Database memory size and index memory size (`DataMemory` and `IndexMemory`, respectively).

`DataMemory` is allocated as 32KB pages. As each `DataMemory` page is used, it is assigned to a specific table; once allocated, this memory cannot be freed except by dropping the table.

See [Section 17.3.4.6, “Defining MySQL Cluster Data Nodes”](#), for further information about `DataMemory` and `IndexMemory`.

- The maximum number of operations that can be performed per transaction is set using the configuration parameters `MaxNoOfConcurrentOperations` and `MaxNoOfLocalOperations`.

Note

Bulk loading, `TRUNCATE TABLE`, and `ALTER TABLE` are handled as special cases by running multiple transactions, and so are not subject to this limitation.

- Different limits related to tables and indexes. For example, the maximum number of ordered indexes per table is determined by `MaxNoOfOrderedIndexes`.
- **Node and data object maximums.** The following limits apply to numbers of cluster nodes and metadata objects:
 - The maximum number of data nodes is 48.

A data node must have a node ID in the range of 1 to 48, inclusive. (Previous to MySQL Cluster NDB 6.1.1, management and API nodes were restricted to the range 1 to 63 inclusive as a node ID; starting with MySQL Cluster NDB 6.1.1, management and API nodes may use node IDs in the range 1 to 255, inclusive.)
 - Prior to MySQL Cluster NDB 6.1.1, the total maximum number of nodes in a MySQL Cluster was 63. Beginning with MySQL Cluster NDB 6.1.1, the total maximum number of nodes in a MySQL Cluster is 255. In either case, this number includes all SQL nodes (MySQL Servers), API nodes (applications accessing the cluster other than MySQL servers), data nodes, and management servers.
 - The maximum number of metadata objects in current versions of MySQL Cluster is 20320. This limit is hard-coded. See [Section 17.12.11, “Previous MySQL Cluster Issues Resolved in MySQL 5.1 and MySQL Cluster NDB 6.x”](#), for more information.

17.12.3. Limits Relating to Transaction Handling in MySQL Cluster

A number of limitations exist in MySQL Cluster with regard to the handling of transactions. These include the following:

- **Transaction isolation level.** The `NDBCLUSTER` storage engine supports only the `READ COMMITTED` transaction isolation level. (`InnoDB`, for example, supports `READ COMMITTED`, `READ UNCOMMITTED`, `REPEATABLE READ`, and `SERIALIZABLE`.) See [Section 17.7.3.4, “MySQL Cluster Backup Troubleshooting”](#), for information on how this can affect backing up and restoring Cluster databases.)

Important

If a `SELECT` from a Cluster table includes a `BLOB` or `TEXT` column, the `READ COMMITTED` transaction isolation level is converted to a read with read lock. This is done to guarantee consistency, due to the fact that parts of the values stored in columns of these types are actually read from a separate table.

- **Transactions and memory usage.** As noted elsewhere in this chapter, MySQL Cluster does not handle large transactions well; it is better to perform a number of small transactions with a few operations each than to attempt a single large transaction

containing a great many operations. Among other considerations, large transactions require very large amounts of memory. Because of this, the transactional behaviour of a number of MySQL statements is effected as described in the following list:

- **TRUNCATE** is not transactional when used on **NDB** tables. If a **TRUNCATE** fails to empty the table, then it must be re-run until it is successful.
- **DELETE FROM** (even with no **WHERE** clause) *is* transactional. For tables containing a great many rows, you may find that performance is improved by using several **DELETE FROM ... LIMIT ...** statements to “chunk” the delete operation. If your objective is to empty the table, then you may wish to use **TRUNCATE** instead.
- **LOAD DATA statements.** **LOAD DATA INFILE** is not transactional when used on **NDB** tables.

Important

When executing a **LOAD DATA INFILE** statement, the **NDB** engine performs commits at irregular intervals that enable better utilization of the communication network. It is not possible to know ahead of time when such commits take place.

LOAD DATA FROM MASTER is not supported in MySQL Cluster.

- **ALTER TABLE and transactions.** When copying an **NDB** table as part of an **ALTER TABLE**, the creation of the copy is non-transactional. (In any case, this operation is rolled back when the copy is deleted.)
- **Transactions and the COUNT() function.** When using MySQL Cluster Replication, it is not possible to guarantee the transactional consistency of the **COUNT()** function on the slave. In other words, when performing on the master a series of statements (**INSERT**, **DELETE**, or both) that changes the number of rows in a table within a single transaction, executing **SELECT COUNT(*) FROM table** queries on the slave may yield intermediate results. This is due to the fact that **SELECT COUNT(...)** may perform dirty reads, and is not a bug in the **NDB** storage engine. (See [Bug#31321](#) for more information.)

17.12.4. MySQL Cluster Error Handling

Starting, stopping, or restarting a node may give rise to temporary errors causing some transactions to fail. These include the following cases:

- **Temporary errors.** When first starting a node, it is possible that you may see Error 1204 **TEMPORARY FAILURE, DISTRIBUTION CHANGED** and similar temporary errors.
- **Errors due to node failure.** The stopping or failure of any data node can result in a number of different node failure errors. (However, there should be no aborted transactions when performing a planned shutdown of the cluster.)

In either of these cases, any errors that are generated must be handled within the application. This should be done by retrying the transaction.

See also [Section 17.12.2, “Limits and Differences of MySQL Cluster from Standard MySQL Limits”](#).

17.12.5. Limits Associated with Database Objects in MySQL Cluster

Some database objects such as tables and indexes have different limitations when using the **NDBCLUSTER** storage engine:

- **Identifiers.** Database names, table names and attribute names cannot be as long in **NDB** tables as when using other table handlers. Attribute names are truncated to 31 characters, and if not unique after truncation give rise to errors. Database names and table names can total a maximum of 122 characters. In other words, the maximum length for an **NDB** table name is 122 characters, less the number of characters in the name of the database of which that table is a part.
- **Table names containing special characters.** **NDB** tables whose names contain characters other than letters, numbers, dashes, and underscores and which are created on one SQL node were not always discovered correctly by other SQL nodes. ([Bug#31470](#))

Note

This issue was fixed in MySQL 5.1.23, MySQL Cluster NDB 6.2.7, and MySQL Cluster NDB 6.3.4.

- **Number of database objects.** The maximum number of *all* **NDB** database objects in a single MySQL Cluster — including databases, tables, and indexes — is limited to 20320.
- **Attributes per table.** The maximum number of attributes (that is, columns and indexes) per table is limited to 128.

- **Attributes per key.** The maximum number of attributes per key is 32.
- **Row size.** The maximum permitted size of any one row is 8KB. Note that each `BLOB` or `TEXT` column contributes $256 + 8 = 264$ bytes towards this total.

17.12.6. Unsupported or Missing Features in MySQL Cluster

A number of features supported by other storage engines are not supported for `NDB` tables. Trying to use any of these features in MySQL Cluster does not cause errors in or of itself; however, errors may occur in applications that expects the features to be supported or enforced:

- **Foreign key constraints.** The foreign key construct is ignored, just as it is in `MyISAM` tables.
- **OPTIMIZE operations.** `OPTIMIZE` operations are not supported.

Beginning with MySQL Cluster NDB 6.3.7, this limitation has been lifted. See [Section 17.12.11, “Previous MySQL Cluster Issues Resolved in MySQL 5.1 and MySQL Cluster NDB 6.x”](#), for more information.

- **LOAD TABLE ... FROM MASTER.** `LOAD TABLE ... FROM MASTER` is not supported.
- **Savepoints and rollbacks.** Savepoints and rollbacks to savepoints are ignored as in `MyISAM`.
- **Durability of commits.** There are no durable commits on disk. Commits are replicated, but there is no guarantee that logs are flushed to disk on commit.
- **Replication.** Statement-based replication is not supported. Use `--binlog-format=ROW` (or `--binlog-format=MIXED`) when setting up cluster replication. See [Section 17.9, “MySQL Cluster Replication”](#), for more information.

Note

See [Section 17.12.3, “Limits Relating to Transaction Handling in MySQL Cluster”](#), for more information relating to limitations on transaction handling in `NDB`.

17.12.7. Limitations Relating to Performance in MySQL Cluster

The following performance issues are specific to or especially pronounced in MySQL Cluster:

- **Range scans.** There are query performance issues due to sequential access to the `NDB` storage engine; it is also relatively more expensive to do many range scans than it is with either `MyISAM` or `InnoDB`.
- **Reliability of Records in range.** The `Records in range` statistic is available but is not completely tested or officially supported. This may result in non-optimal query plans in some cases. If necessary, you can employ `USE INDEX` or `FORCE INDEX` to alter the execution plan. See [Section 12.2.8.2, “Index Hint Syntax”](#), for more information on how to do this.
- **Unique hash indexes.** Unique hash indexes created with `USING HASH` cannot be used for accessing a table if `NULL` is given as part of the key.

17.12.8. Issues Exclusive to MySQL Cluster

The following are limitations specific to the `NDBCLUSTER` storage engine:

- **Machine architecture.** All machines used in the cluster must have the same architecture. That is, all machines hosting nodes must be either big-endian or little-endian, and you cannot use a mixture of both. For example, you cannot have a management node running on a PowerPC which directs a data node that is running on an x86 machine. This restriction does not apply to machines simply running `mysql` or other clients that may be accessing the cluster's SQL nodes.
- **Adding and dropping of data nodes.** Online adding or dropping of data nodes is not currently possible. In such cases, the entire cluster must be restarted.
- **Binary logging.** MySQL Cluster has the following limitations or restrictions with regard to binary logging:
 - `sql_log_bin` has no effect on data operations; however, it is supported for schema operations.
 - MySQL Cluster cannot produce a binlog for tables having `BLOB` columns but no primary key.

- Only the following schema operations are logged in a cluster binlog which is *not* on the `mysqld` executing the statement:
 - `CREATE TABLE`
 - `ALTER TABLE`
 - `DROP TABLE`
 - `CREATE DATABASE / CREATE SCHEMA`
 - `DROP DATABASE / DROP SCHEMA`
 - `CREATE TABLESPACE`
 - `ALTER TABLESPACE`
 - `DROP TABLESPACE`
 - `CREATE LOGFILE GROUP`
 - `ALTER LOGFILE GROUP`
 - `DROP LOGFILE GROUP`

See also [Section 17.12.10, “Limitations Relating to Multiple MySQL Cluster Nodes”](#).

17.12.9. Limitations Relating to MySQL Cluster Disk Data Storage

- Disk data objects are subject to the following maximums:
 - Maximum number of tablespaces: 2^{32} (4294967296)
 - Maximum number of data files per tablespace: 2^{16} (65535)
 - The theoretical maximum number of extents per tablespace data file is 2^{16} (65525); however, for practical purposes, the recommended maximum number of extents per data file is 2^8 (32768).
 - Maximum data file size: The theoretical limit is 64G; however, in MySQL 5.1, the practical upper limit is 32G. This is equivalent to 32768 extents of 1M each.

The minimum and maximum possible sizes of extents for tablespace data files are 32K and 2G, respectively. See [Section 12.1.18, “CREATE TABLESPACE Syntax”](#), for more information.

- Use of Disk Data tables is not supported when running the cluster in diskless mode. Beginning with MySQL 5.1.12, it is disallowed altogether. ([Bug#20008](#))

17.12.10. Limitations Relating to Multiple MySQL Cluster Nodes

Multiple SQL nodes. The following are issues relating to the use of multiple MySQL servers as MySQL Cluster SQL nodes, and are specific to the `NDBCLUSTER` storage engine:

- **No distributed table locks.** A `LOCK TABLES` works only for the SQL node on which the lock is issued; no other SQL node in the cluster “sees” this lock. This is also true for a lock issued by any statement that locks tables as part of its operations. (See next item for an example.)
- **ALTER TABLE operations.** `ALTER TABLE` is not fully locking when running multiple MySQL servers (SQL nodes). (As discussed in the previous item, MySQL Cluster does not support distributed table locks.)

Multiple management nodes. When using multiple management servers:

- You must give nodes explicit IDs in connectstrings because automatic allocation of node IDs does not work across multiple management servers.
- You must take extreme care to have the same configurations for all management servers. No special checks for this are performed by the cluster.

Multiple network addresses. Multiple network addresses per data node are not supported. Use of these is liable to cause problems: In the event of a data node failure, an SQL node waits for confirmation that the data node went down but never receives it because another route to that data node remains open. This can effectively make the cluster inoperable.

Note

It is possible to use multiple network hardware *interfaces* (such as Ethernet cards) for a single data node, but these must be bound to the same address. This also means that it is not possible to use more than one `[tcp]` section per connection in the `config.ini` file. See [Section 17.3.4.8, “MySQL Cluster TCP/IP Connections”](#), for more information.

17.12.11. Previous MySQL Cluster Issues Resolved in MySQL 5.1 and MySQL Cluster NDB 6.x

A number of limitations and related issues existing in earlier versions of MySQL Cluster have been resolved:

- **Variable-length column support.** The `NDBCLUSTER` storage engine now supports variable-length column types for in-memory tables.

Previously, for example, any Cluster table having one or more `VARCHAR` fields which contained only relatively small values, much more memory and disk space were required when using the `NDBCLUSTER` storage engine than would have been the case for the same table and data using the `MyISAM` engine. In other words, in the case of a `VARCHAR` column, such a column required the same amount of storage as a `CHAR` column of the same size. In MySQL 5.1, this is no longer the case for in-memory tables, where storage requirements for variable-length column types such as `VARCHAR` and `BINARY` are comparable to those for these column types when used in `MyISAM` tables (see [Section 10.5, “Data Type Storage Requirements”](#)).

Important

For MySQL Cluster Disk Data tables, the fixed-width limitation continues to apply. See [Section 17.10, “MySQL Cluster Disk Data Tables”](#).

- **Replication with MySQL Cluster.** It is now possible to use MySQL replication with Cluster databases. For details, see [Section 17.9, “MySQL Cluster Replication”](#).
 - **Circular Replication.** Circular replication is also supported with MySQL Cluster, beginning with MySQL 5.1.18. See [Section 17.9.10, “MySQL Cluster Replication — Multi-Master and Circular Replication”](#).
- **auto_increment_increment and auto_increment_offset.** The `auto_increment_increment` and `auto_increment_offset` server system variables are supported for Cluster replication beginning with MySQL 5.1.20, MySQL Cluster NDB 6.2.5, and MySQL Cluster 6.3.2.
- **Database autodiscovery and online schema changes.** Autodiscovery of databases is now supported for multiple MySQL servers accessing the same MySQL Cluster. Formerly, autodiscovery in MySQL Cluster 5.1 and MySQL Cluster NDB 6.x releases required that a given `mysqld` was already running and connected to the cluster at the time that the database was created on a different `mysqld` — in other words, when a `mysqld` process connected to the cluster after a database named `db_name` was created, it was necessary to issue a `CREATE DATABASE db_name` or `CREATE SCHEMA db_name` statement on the “new” MySQL server when it first accessed that MySQL Cluster. Beginning with MySQL Cluster NDB 6.2.16 and MySQL Cluster NDB 6.3.18, such a `CREATE` statement is no longer required. ([Bug#39612](#))

This also means that online schema changes in `NDB` tables are now possible. That is, the result of operations such as `ALTER TABLE` and `CREATE INDEX` performed on one SQL node in the cluster are now visible to the cluster's other SQL nodes without any additional action being taken.
- **Backup and restore between architectures.** Beginning with MySQL 5.1.10, it is possible to perform a Cluster backup and restore between different architectures. Previously — for example — you could not back up a cluster running on a big-endian platform and then restore from that backup to a cluster running on a little-endian system. ([Bug#19255](#))
- **Character set directory.** Beginning with MySQL 5.1.10, it is possible to install MySQL with Cluster support to a non-default location and change the search path for font description files using either the `--basedir` or `--character-sets-dir` options. (Previously, `ndbd` in MySQL 5.1 searched only the default path — typically `/usr/local/mysql/share/mysql/charsets` — for character sets.)
- **Multiple management servers.** In MySQL 5.1 (including all MySQL Cluster NDB 6.x versions), it is no longer necessary, when running multiple management servers, to restart all the cluster's data nodes to enable the management nodes to see one another.

Also, when using multiple management servers and starting concurrently several API nodes (possibly including one or more SQL nodes) whose connectstrings listed the management servers in different order, it was possible for 2 API nodes to be assigned the same node ID. This issue is resolved in MySQL Cluster NDB 6.2.17, 6.3.23, and 6.4.3. ([Bug#42973](#))

- **Multiple data node processes per host.** Beginning with MySQL Cluster NDB 6.2.0, you can use multiple data node processes on a single host. (In MySQL Cluster NDB 6.1, MySQL 5.1, and earlier release series, we did not support production MySQL Cluster deployments in which more than one `ndbd` process was run on a single physical machine.)
- **Length of `CREATE TABLE` statements.** `CREATE TABLE` statements may be no more than 4096 characters in length. *This limitation affects MySQL 5.1.6, 5.1.7, and 5.1.8 only.* (See [Bug#17813](#))
- **IGNORE and REPLACE functionality.** In MySQL 5.1.7 and earlier, `INSERT IGNORE`, `UPDATE IGNORE`, and `REPLACE` were supported only for primary keys, but not for unique keys. It was possible to work around this issue by removing the constraint, then dropping the unique index, performing any inserts, and then adding the unique index again.

This limitation was removed for `INSERT IGNORE` and `REPLACE` in MySQL 5.1.8. (See [Bug#17431](#).)

- **AUTO_INCREMENT columns.** In MySQL 5.1.10 and earlier versions, the maximum number of tables having `AUTO_INCREMENT` columns — including those belonging to hidden primary keys — was 2048.

This limitation was lifted in MySQL 5.1.11.

- **Maximum number of cluster nodes.** Prior to MySQL Cluster NDB 6.1.1, the total maximum number of nodes in a MySQL Cluster was 63, including all SQL nodes (MySQL Servers), API nodes (applications accessing the cluster other than MySQL servers), data nodes, and management servers.

Starting with MySQL Cluster NDB 6.1.1, the total maximum number of nodes in a MySQL Cluster is 255, including all SQL nodes (MySQL Servers), API nodes (applications accessing the cluster other than MySQL servers), data nodes, and management servers. The total number of data nodes and management nodes beginning with this version is 63, of which up to 48 can be data nodes.

Note

The limitation that a data node cannot have a node ID greater than 49 continues to apply.

- **Recovery of memory from deleted rows.** Beginning with MySQL Cluster NDB 6.3.7, memory can be reclaimed from an `NDB` table for reuse with any `NDB` table by employing `OPTIMIZE TABLE`, subject to the following limitations:
 - Only in-memory tables are supported; the `OPTIMIZE TABLE` statement still has no effect on MySQL Cluster Disk Data tables.
 - Only variable-length columns (such as those declared as `VARCHAR`, `TEXT`, or `BLOB`) are supported.

However, you can force columns defined using fixed-length data types (such as `CHAR`) to be dynamic using the `ROW_FORMAT` or `COLUMN_FORMAT` option with a `CREATE TABLE` or `ALTER TABLE` statement.

See [Section 12.1.17, “CREATE TABLE Syntax”](#), and [Section 12.1.7, “ALTER TABLE Syntax”](#), for information on these options.

You can regulate the effects of `OPTIMIZE` on performance by adjusting the value of the global system variable `ndb_optimization_delay`, which sets the number of milliseconds to wait between batches of rows being processed by `OPTIMIZE`. The default value is 10 milliseconds. It is possible to set a lower value (to a minimum of 0), but not recommended. The maximum is 100000 milliseconds (that is, 100 seconds).

- **Rollbacks.** Prior to MySQL Cluster NDB 6.3.19, the `NDBCLUSTER` storage engine did not support partial transactions or partial rollbacks of transactions. A duplicate key or similar error aborted the entire transaction, and subsequent statements raised `ERROR 1296 (HY000): GOT ERROR 4350 'TRANSACTION ALREADY ABORTED' FROM NDBCLUSTER`. In such cases, it was necessary to issue an explicit `ROLLBACK` and retry the entire transaction.

Beginning with MySQL Cluster NDB 6.3.19, this limitation has been removed, and the behavior of `NDBCLUSTER` is now in line with that of other transactional storage engines such as `InnoDB` which can roll back individual statements. ([Bug#32656](#))

- **Number of tables.** Previously, the maximum number of `NDBCLUSTER` tables in a single MySQL Cluster was 1792, but this is no longer the case in MySQL 5.1 (including MySQL Cluster NDB 6.x). However, the number of tables is still included in the total maximum number of `NDBCLUSTER` database objects (20320). (See [Section 17.12.5, “Limits Associated with Database Objects in MySQL Cluster”](#).)
- **DDL operations.** Beginning with MySQL Cluster NDB 6.4.0, DDL operations (such as `CREATE TABLE` or `ALTER TABLE`) are protected from data node failures. Previously, if a data node failed while trying to perform one of these, the data dictionary became locked and no further DDL statements could be executed without restarting the cluster ([Bug#36718](#)).

17.13. MySQL Cluster Development Roadmap

In this section, we discuss changes in the implementation of MySQL Cluster in MySQL 5.1 and MySQL Cluster NDB 6.x as compared to MySQL 5.0.

We also discuss our roadmap for further improvements to MySQL Cluster planned for MySQL Cluster NDB 7.0 and later.

There are a number of significant changes in the implementation of the `NDBCLUSTER` storage engine in mainline MySQL 5.1 releases up to and including MySQL 5.1.23 as compared to that in MySQL 5.0; MySQL Cluster NDB makes further changes and improvements in MySQL Cluster in addition to these. The changes and features most likely to be of interest are shown in the following table:

MySQL 5.1 (through 5.1.23)
MySQL Cluster Replication
Disk Data storage
Variable-size columns
User-defined partitioning
Autodiscovery of table schema changes
Online adding and dropping of indexes

MySQL Cluster NDB 6.1
Greater number of cluster nodes
Disabling of arbitration
Additional <code>DUMP</code> commands
Faster Disk Data backups
Batched slave updates

MySQL Cluster NDB 6.2
Improved backup status reporting (<code>BackupReportFrequency</code> , <code>REPORT BackupStatus</code>)
Multiple connections per SQL node
Data access with <code>NdbRecord</code> (NDB API)
<code>REPORT MemoryUsage</code> command
Memory allocation improvements
Management client connection control
Micro-GCPs
Online <code>ADD COLUMN</code> ; improved online index creation

MySQL Cluster NDB 6.3
Conflict detection and resolution for multi-master replication
Compressed backups and local checkpoints
Support for <code>OPTIMIZE TABLE</code>
Parallel data node recovery
Enhanced transaction coordinator selection
Improved SQL statement performance metrics
Transaction batching
<code>ndb_restore</code> attribute promotion
Support for <code>epoll</code> (Linux only)
Distribution awareness
NDB thread locks; realtime extensions for multiple CPUs

MySQL Cluster NDB 7.0
Multi-threaded data nodes (<code>ndbmt.d</code> data node daemon)
Online addition of data nodes; online data redistribution
MySQL on Windows (alpha; source releases only)
Configuration cache
Backup snapshots (<code>START BACKUP ... SNAPSHOTSTART</code> , <code>START BACKUP ... SNAPSHOTEND</code> commands)
IPv6 support for geo-replication
Protected DDL operations
Dynamic buffering for NDB transporters
<code>NDB\$INFO</code> meta-information database (in development)

17.13.1. Features Added in MySQL 5.1 Cluster

A number of new features for MySQL Cluster have been implemented in MySQL 5.1 through MySQL 5.1.23, when support for MySQL Cluster was moved to MySQL Cluster NDB. All of the features in the following list are also available in all MySQL Cluster NDB (6.1 and later) releases.

- Integration of MySQL Cluster into MySQL Replication.** MySQL Cluster Replication makes it possible to replicate from one MySQL Cluster to another. Updates on any SQL node (MySQL server) in the cluster acting as the master are replicated to the slave cluster; the state of the slave side remains consistent with the cluster acting as the master. This is sometimes referred to as *asynchronous replication* between clusters, providing *geographic redundancy*. It is also possible to replicate from a MySQL Cluster acting as the master to a standalone MySQL server acting as the slave, or from a standalone MySQL master server to a slave cluster; in either of these cases, the standalone MySQL server uses a storage engine other than `NDB-CLUSTER`. Multi-master replication setups such as circular replication are also supported.

See [Section 17.9, “MySQL Cluster Replication”](#).

- Support for storage of rows on disk.** Storage of `NDBCLUSTER` table data on disk is now supported. Indexed columns, including the primary key hash index, must still be stored in RAM; however, all other columns can be stored on disk.

See [Section 17.10, “MySQL Cluster Disk Data Tables”](#).

- Variable-size columns.** In MySQL 5.0, an `NDBCLUSTER` table column defined as `VARCHAR(255)` used 260 bytes of storage independent of what was stored in any particular record. In MySQL 5.1 Cluster tables, only the portion of the column actually taken up by the record is stored. This makes possible a significant reduction in space requirements for such columns as compared to previous release series — by a factor of up to 5 in many cases.
- User-defined partitioning.** Users can define partitions based on columns that are part of the primary key. It is possible to partition `NDB` tables based on `KEY` and `LINEAR KEY` schemes. This feature is also available for many other MySQL storage engines, which support additional partitioning types that are not available with `NDBCLUSTER` tables.

For additional general information about user-defined partitioning in MySQL 5.1, see [Chapter 18, Partitioning](#). Specifics of partitioning types are discussed in [Section 18.2, “Partition Types”](#).

The MySQL Server can also determine whether it is possible to “prune away” some of the partitions from the `WHERE` clause, which can greatly speed up some queries. See [Section 18.4, “Partition Pruning”](#), for information about designing tables and queries to take advantage of partition pruning.

- Autodiscovery of table schema changes.** In MySQL 5.0, it was necessary to issue a `FLUSH TABLES` statement or a “dummy” `SELECT` in order for new `NDBCLUSTER` tables or changes made to schemas of existing `NDBCLUSTER` tables on one SQL node to be visible on the cluster’s other SQL nodes. In MySQL 5.1, this is no longer necessary; new Cluster tables and changes in the definitions of existing `NDBCLUSTER` tables made on one SQL node are immediately visible to all SQL nodes connected to the cluster.

Note

When creating a new database, it is still necessary in MySQL 5.1 to issue a `CREATE DATABASE` or `CREATE SCHEMA` statement on each SQL node in the cluster.

- Distribution awareness (NDB API).** *Distribution awareness* is a mechanism by which the best data node is automatically selected to be queried for information. (Conceptually, it is similar in some ways to partition pruning (see [Section 18.4, “Partition Pruning”](#))). To take advantage of distribution awareness, you should do the following:

1. Determine which table column is most likely to be used for finding matching records.
2. Make this column part of the table's primary key.
3. Explicitly partition the table by `KEY`, using this column as the table's partitioning key. Following these steps causes records with the same value for the partitioning column to be stored on the same partition (that is, in the same node group). When reading data, transactions are begun on the data node actually having the desired rows instead of this node being determined by the usual round-robin mechanism.

Important

In order to see a measureable impact on performance, the cluster must have at least four data nodes, since, with only two data nodes, both data nodes have exactly the same data. Using distribution awareness can yield performance increase of as great as 45% when using four data nodes, and possibly more when using a greater number of data nodes.

Note

In mainline MySQL 5.1 releases, distribution awareness was supported only when using the NDB API; support was added for SQL and API nodes in MySQL Cluster NDB 6.3 (see [Section 17.13.4, “Features Added in MySQL Cluster NDB 6.3”](#), which includes an example showing how to create a table in order to take advantage of distribution awareness).

See [Section 17.12.11, “Previous MySQL Cluster Issues Resolved in MySQL 5.1 and MySQL Cluster NDB 6.x”](#), for more information.

17.13.2. Features Added in MySQL Cluster NDB 6.1

The following list provides an overview of significant feature additions and changes made in MySQL Cluster NDB 6.1. All of the changes in this list are also available in MySQL Cluster NDB 6.2 and 6.3 releases. For detailed information about all changes made in MySQL Cluster NDB 6.1, see [Section 17.15.4, “Changes in MySQL Cluster NDB 6.1”](#).

- **Increased number of cluster nodes.** The maximum number of all nodes in a MySQL Cluster has been increased to 255. For more information, see [Section 17.12.10, “Limitations Relating to Multiple MySQL Cluster Nodes”](#).
- **Disabling arbitration.** It is now possible to disable arbitration by setting `ArbitrationRank=0` on all cluster management and SQL nodes. For more information, see [Defining the Management Server: `ArbitrationRank`](#) and [Defining SQL and Other API Nodes: `ArbitrationRank`](#).
- **Additional DUMP commands.** New management client DUMP commands provide help with tracking transactions, scan operations, and locks. See [Section 17.7.2, “Commands in the MySQL Cluster Management Client”](#), and [DUMP Commands](#), for more information.
- **Faster Disk Data backups.** Improvements in backups of Disk Data tables can yield a 10 to 15% increase in backup speed of Disk Data tables.
- **Batched slave updates.** Batching of updates on cluster replication slaves, enabled using the `--slave-allow-batching` option for `mysqld`, increases replication efficiency. For more information, see [Section 17.9.6, “Starting MySQL Cluster Replication \(Single Replication Channel\)”](#).

17.13.3. Features Added in MySQL Cluster NDB 6.2

The following list provides an overview of significant feature additions and changes made in MySQL Cluster NDB 6.2. All of the changes in this list are also available in MySQL Cluster NDB 6.3. For more detailed information about all feature changes and bugfixes made in MySQL Cluster NDB 6.2, see [Section 17.15.3, “Changes in MySQL Cluster NDB 6.2”](#).

- **Enhanced backup status reporting.** Backup status reporting has been improved, aided in part by the introduction of a `BackupReportFrequency` configuration parameter; see [Defining Data Nodes: `BackupReportFrequency`](#), for more information.
- **Multiple cluster connections per SQL node.** A single MySQL server acting as a MySQL Cluster SQL node can employ multiple connections to the cluster using the `--ndb-cluster-connection-pool` startup option for `mysqld`. This option is described in [MySQL Cluster-Related Command Options for `mysqld`: `--ndb-cluster-connection-pool` option](#).
- **New data access interface.** The `NdbRecord` interface provides a new and simplified data handler for use in NDB API ap-

plications. See [The NdbRecord Interface](#), for more information.

- **New reporting commands.** The new management client `REPORT BackupStatus` and `REPORT MemoryUsage` commands provide better access to information about the status of MySQL Cluster backups and how much memory is being used by MySQL Cluster for data and index storage. See [Section 17.7.2, “Commands in the MySQL Cluster Management Client”](#), for more information about the `REPORT` commands. In addition, in-progress status reporting is provided by the `ndb_restore` utility; see [Section 17.6.17, “ndb_restore — Restore a MySQL Cluster Backup”](#).
- **Improved memory allocation and configuration.** Memory is now allocated by the NDB kernel to tables on a page-by-page basis, which significantly reduces the memory overhead required for maintaining NDBCLUSTER tables. In addition, the `MaxAllocate` configuration parameter now makes it possible to set the maximum size of the allocation unit used for table memory; for more information about this configuration parameter, see [Defining Data Nodes: MaxAllocate](#).
- **Choice of fixed-width or variable-width columns.** You can control whether fixed-width or variable-width storage is used for a given column of an NDB table by employing of the `COLUMN_FORMAT` specifier as part of the column's definition in a `CREATE TABLE` or `ALTER TABLE` statement. In addition, the ability to control whether a given column of an NDB table is stored in memory or on disk, using the `STORAGE` specifier as part of the column's definition in a `CREATE TABLE` or `ALTER TABLE` statement. For more information, see [Section 12.1.17, “CREATE TABLE Syntax”](#), and [Section 12.1.7, “ALTER TABLE Syntax”](#).
- **Controlling management client connections.** The `--bind-address` cluster management server startup option makes it possible to restrict management client connections to `ndb_mgmd` to a single host (IP address or host name) and port, which can make MySQL Cluster management operations more secure. For more information about this option, see [Section 17.6.24.3, “Program Options for ndb_mgmd”](#).
- **Micro-GCPs.** Due to a change in the protocol for handling of global checkpoints (GCPs handled in this manner sometimes being referred to as “micro-GCPs”), it is now possible to control how often the GCI number is updated, and how often global checkpoints are written to disk, using the `TimeBetweenEpochs` configuration parameter. This improves the reliability and performance of MySQL Cluster Replication. For more information, see [Defining Data Nodes: TimeBetweenEpochs](#) and [Defining Data Nodes: TimeBetweenEpochsTimeout](#).
- **Core online schema change support.** Support for the online `ALTER TABLE` operations `ADD COLUMN`, `ADD INDEX`, and `DROP INDEX` is available. When the `ONLINE` keyword is used, the `ALTER TABLE` is non-copying, which means that indexes do not have to be re-created, which provides these benefits:
 - Single user mode is no longer required for `ALTER TABLE` operations that can be performed online.
 - Transactions can continue during `ALTER TABLE` operations that can be performed online.
 - Tables being altered online are not locked against access by other SQL nodes.

However, such tables are locked against other operations on the *same* SQL node for the duration of the `ALTER TABLE`. We are working to overcome this limitation in a future MySQL Cluster release.

Online `CREATE INDEX` and `DROP INDEX` statements are also supported. Online changes can be suppressed using the `OFFLINE` key word. See [Section 12.1.7, “ALTER TABLE Syntax”](#), [Section 12.1.13, “CREATE INDEX Syntax”](#), and [Section 12.1.24, “DROP INDEX Syntax”](#), for more detailed information.
- **mysql.ndb_binlog_index improvements.** More information has been added to the `mysql.ndb_binlog_index` table so that it is possible to determine which originating epochs have been applied inside an epoch. This is particularly useful for 3-way replication. See [Section 17.9.4, “MySQL Cluster Replication Schema and Tables”](#), for more information.
- **Epoch lag control.** The `MaxBufferedEpochs` data node configuration parameter provides a means to control the maximum number of unprocessed epochs by which a subscribing node can lag. Subscribers which exceed this number are disconnected and forced to reconnect. For a discussion of this configuration parameter, see [Defining Data Nodes: MaxBufferedEpochs](#).
- **Fully automatic database discovery.** It is no longer a requirement for database autodiscovery that an SQL node already be connected to the cluster at the time that a database is created on another SQL node, or for a `CREATE DATABASE` or `CREATE SCHEMA` statement to be issued on the new SQL node after it joins the cluster.
- **Multiple data node processes per host.** In earlier MySQL Cluster release series, we did not support MySQL Cluster deployments in production where more than one `ndbd` process was run on a single physical machine. However, beginning with MySQL Cluster NDB 6.2.0, you can use multiple data node processes on a single host.

Note

A multi-threaded version of `ndbd` tailored for use on hosts with multiple CPUs or cores was introduced in MySQL Cluster NDB 7.0. See [Section 17.13.5, “Features Added in MySQL Cluster NDB 7.0”](#), and [Section 17.6.3, “ndbmt.d — The MySQL Cluster Data Node Daemon \(Multi-Threaded\)”](#), for more information.

- **Improved Disk Data filesystem configuration.** As of MySQL Cluster NDB 6.2.17, you can specify default locations for MySQL Cluster Disk Data data files and undo log files using the data node configuration parameters `FileSystemPathDD`, `FileSystemPathDataFiles`, and `FileSystemPathUndoFiles`. For more information, see [Disk Data filesystem parameters](#).
- **Automatic creation of Disk Data log file groups and tablespaces.** Beginning with MySQL Cluster NDB 6.2.17, using the data node configuration parameters `InitialLogFileGroup` and `InitialTablespace`, you can cause the creation of a MySQL Cluster Disk Data log file group, tablespace, or both, when the cluster is first started. When using these parameters, no SQL statements are required to create these Disk Data objects. For more information, see [Disk Data object creation parameters](#).

17.13.4. Features Added in MySQL Cluster NDB 6.3

The following list provides an overview of significant feature additions and changes first made in MySQL Cluster NDB 6.3. For more detailed information about all feature changes and bugfixes made in MySQL Cluster NDB 6.3, see [Section 17.15.2, “Changes in MySQL Cluster NDB 6.3”](#).

- **Conflict detection and resolution.** It is now possible to detect and resolve conflicts that arise in multi-master replication scenarios, such as circular replication, when different masters may try to update the same row on the slave with different data. Both “greatest timestamp wins” and “same timestamp wins” scenarios are supported. For more information, see [Section 17.9.11, “MySQL Cluster Replication Conflict Resolution”](#).
- **Recovery of “one master, many slaves” replication setups.** Recovery of multi-way replication setups (“one master, many slaves”) is now supported via the `--ndb-log-orig` server option and changes in the `mysql.ndb_binlog_index` table. See [Section 17.9.4, “MySQL Cluster Replication Schema and Tables”](#), for more information.
- **Enhanced selection options for transaction coordinator.** New values and behaviors are introduced for `-ndb_optimized_node_selection` allowing for greater flexibility when an SQL node chooses a transaction coordinator. For more information, see the description of `ndb_optimized_node_selection` in [Section 17.4.3, “MySQL Cluster System Variables”](#).
- **Replication heartbeats.** Replication heartbeats facilitate the task of monitoring and detecting failures in master-slave connections in real time. This feature is implemented via a new `MASTER_HEARTBEAT_PERIOD = value` clause for the `CHANGE MASTER TO` statement and the addition of two status variables `Slave_heartbeat_period` and `Slave_received_heartbeats`. For more information, see [Section 12.6.2.1, “CHANGE MASTER TO Syntax”](#).
- **NDB thread locks.** It is possible to lock NDB execution threads and maintenance threads (such as file system and other operating system threads) to specific CPUs on multiprocessor data node hosts, and to leverage real-time scheduling.
- **Improved performance of updates using primary keys or unique keys.** The number of unnecessary reads when performing a primary key or unique key update has been greatly reduced. Since it is seldom necessary to read a record prior to an update, this can yield a considerable improvement in performance. In addition, primary key columns are no longer written to when not needed during update operations.
- **Batching improvements.** Support of batched `DELETE` and `UPDATE` operations has been significantly improved. Batching of `UPDATE WHERE . . .` and multiple `DELETE` operations is also now implemented.
- **Improved SQL statement performance metrics.** The `Ndb_execute_count` system status variable measures the number of round trips made by SQL statements to the NDB kernel, providing an improved metric for determining efficiency with which statements are executed. For more information, see [MySQL Cluster Status Variables: Ndb_execute_count](#).
- **Compressed LCPs and backups.** Compressed local checkpoints and backups can save 50% or more of the disk space used by uncompressed LCPs and backups. These can be enabled using the two new data node configuration parameters `CompressedLCP` and `CompressedBackup`, respectively. See [MySQL Cluster Status Variables: CompressedBackup](#), and [MySQL Cluster Status Variables: CompressedLCP](#), for more information about these parameters.
- **OPTIMIZE TABLE support with NDBCLUSTER tables.** `OPTIMIZE TABLE` is supported for dynamic columns of in-memory NDB tables. In such cases, it is no longer necessary to drop (and possibly to re-create) a table, or to perform a rolling restart, in order to recover memory from deleted rows for general re-use by Cluster. The performance of `OPTIMIZE` on Cluster tables can be tuned by adjusting the value of the `ndb_optimization_delay` system variable, which controls the number of milliseconds to wait between processing batches of rows by `OPTIMIZE TABLE`. In addition, `OPTIMIZE TABLE` on an NDBCLUSTER table can be interrupted by, for example, killing the SQL thread performing the `OPTIMIZE` operation.
- **Batching of transactions.** It is possible to cause statements occurring within the same transaction to be run as a batch by setting the session variable `transaction_allow_batching` to 1 or ON. To use this feature, `autocommit` must be set to 0 or OFF. Batch sizes can be controlled using the `--ndb-batch-size` option for `mysqld`. For more information, see [Section 17.4.2, “mysqld Command Options for MySQL Cluster”](#), and [Section 17.4.3, “MySQL Cluster System Variables”](#).

- **Attribute promotion with `ndb_restore`.** It is possible using `ndb_restore` to restore data reliably from a column of a given type to a column that uses a “larger” type. This is sometimes referred to as *attribute promotion*. For example, MySQL Cluster backup data that originated in a `SMALLINT` column can be restored to a `MEDIUMINT`, `INT`, or `BIGINT` column. See [Section 17.6.17, “ndb_restore — Restore a MySQL Cluster Backup”](#), for more information.
- **Parallel data node recovery.** Recovery of multiple data nodes can now be done in parallel, rather than sequentially. In other words, several data nodes can be restored concurrently, which can often result in much faster recovery times than when they are restored one at a time.
- **Increased local checkpoint efficiency.** Only 2 local checkpoints are stored, rather than 3, lowering disk space requirements and the size and number of redo log files.
- **NDBCLUSTER table persistence control.** Persistence of NDB tables can be controlled using the session variables `ndb_table_temporary` and `ndb_table_no_logging`. `ndb_table_no_logging` causes NDB tables not to be checkpointed to disk; `ndb_table_temporary` does the same, and in addition, no schema files are created. See [Section 17.4.1, “MySQL Cluster Server Option and Variable Reference”](#).
- **Epoll support (Linux only).** *Epoll* is an improved method for handling file descriptors, which is more efficient than scanning to determine whether a file descriptor has data to be read. (The term *epoll* is specific to Linux and equivalent functionality is known by other names on other platforms such as Solaris and FreeBSD.) Currently, MySQL Cluster supports this functionality on Linux only.
- **Distribution awareness (SQL nodes).** In MySQL Cluster NDB 6.3, SQL nodes can take advantage of [distribution awareness](#). Here we provide a brief example showing how to design a table to make a given class of queries distribution-aware. Suppose an NDBCLUSTER table `t1` has the following schema:

```
CREATE TABLE t1 (
  userid INT NOT NULL,
  serviceid INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
  data VARCHAR(255)
) ENGINE=NDBCLUSTER;
```

Suppose further that most of the queries to be used in our application test values of the `userid` column of this table. The form of such a query looks something like this:

```
SELECT columns FROM t1
WHERE userid relation value;
```

In this query, `relation` represents some relational operator, such as `=`, `<`, `>`, and so on. Queries using `IN` and a list of values can also be used:

```
SELECT columns FROM t1
WHERE userid IN value_list;
```

In order to make use of distribution awareness, we need to make the `userid` column part of the table's primary key, then explicitly partition the table with this column being used as the partitioning key. (Recall that for a partitioned table having one or more unique keys, all columns of the table's partitioning key must also be part of all of the unique keys — for more information and examples, see [Section 18.5.1, “Partitioning Keys, Primary Keys, and Unique Keys”](#).) In other words, the table schema should be equivalent to the following `CREATE TABLE` statement:

```
CREATE TABLE t1 (
  userid INT NOT NULL,
  serviceid INT NOT NULL AUTO_INCREMENT,
  data VARCHAR(255),
  PRIMARY KEY p (userid,serviceid)
) ENGINE=NDBCLUSTER
PARTITION BY KEY(userid);
```

When the table is partitioned in this way, all rows having the same `userid` value are found on the same node group, and the MySQL Server can immediately select the optimal node to use as the transaction coordinator.

- **Realtime extensions for multiple CPUs.** When running MySQL Cluster data nodes on hosts with multiple processors, the realtime extensions make it possible to give priority to the data node process and control on which CPU cores it should operate. This can be done using the data node configuration parameters `RealtimeScheduler`, `SchedulerExecutionTimer` and `SchedulerSpinTimer`. Doing so properly can significantly lower response times and make them much more predictable response. For more information about using these parameters, see [Defining Data Nodes: Realtime Performance Parameters](#)
- **Fully automatic database discovery.** It is no longer a requirement for database autodiscovery that an SQL node already be connected to the cluster at the time that a database is created on another SQL node, or for a `CREATE DATABASE` or `CREATE SCHEMA` statement to be issued on the new SQL node after it joins the cluster.
- **Restoring specific tables and databases from a MySQL Cluster backup.** It is now possible exercise more fine-grained control when restoring a MySQL Cluster from backup using `ndb_restore`. You can restore only specified tables or databases, or exclude specific tables or databases from being restored, using the new `ndb_restore` options `--include-tables`, `--include-databases`, `--exclude-tables`, and `--exclude-databases`. For more information about these options, see [Section 17.6.17, “ndb_restore — Restore a MySQL Cluster Backup”](#).

- **Improved Disk Data filesystem configuration.** As of MySQL Cluster NDB 6.3.22, you can specify default locations for MySQL Cluster Disk Data data files and undo log files using the data node configuration parameters `FileSystemPathDD`, `FileSystemPathDataFiles`, and `FileSystemPathUndoFiles`. For more information, see [Disk Data filesystem parameters](#).
- **Automatic creation of Disk Data log file groups and tablespaces.** Beginning with MySQL Cluster NDB 6.3.22, using the data node configuration parameters `InitialLogFileGroup` and `InitialTablespace`, you can cause the creation of a MySQL Cluster Disk Data log file group, tablespace, or both, when the cluster is first started. When using these parameters, no SQL statements are required to create these Disk Data objects. For more information, see [Disk Data object creation parameters](#).
- **Configuration parameter data dumps.** Starting with MySQL Cluster NDB 6.3.25, the `ndb_config` utility supports a `--configinfo` option that causes it to dump a list of all configuration parameters supported by the cluster, along with brief descriptions, information about the parameters' default and allowed values, and the sections of the `config.ini` file in which the parameters apply. An additional `--xml` switch causes `ndb_config` to use XML rather than plaintext output. Using `ndb_config --configinfo` or `ndb_config --configinfo --xml` requires no access to a running MySQL Cluster, any other programs, or any files. For more information and examples, see [Section 17.6.6, “ndb_config — Extract MySQL Cluster Configuration Information”](#).

17.13.5. Features Added in MySQL Cluster NDB 7.0

The following list provides an overview of significant feature additions and changes made in or planned for MySQL Cluster NDB 7.0. For more detailed information about all feature changes and bugfixes made in MySQL Cluster NDB 7.0, see [Section 17.15.1, “Changes in MySQL Cluster NDB 7.0”](#).

Important

Early development versions of MySQL Cluster NDB 7.0 were known as “MySQL Cluster NDB 6.4”, and the first four releases in this series were identified as MySQL Cluster NDB 6.4.0 through 6.4.3. Any information relating to these MySQL Cluster NDB 6.4.x releases appearing in this documentation apply to MySQL Cluster NDB 7.0.

MySQL Cluster NDB 7.0.4 is the fifth MySQL Cluster NDB 7.0 release; it is the successor to MySQL Cluster NDB 6.4.3.

- **MySQL Cluster on Windows (*alpha*).** MySQL Cluster is now available on an experimental basis for Windows operating systems. Features and behavior comparable to those found on platforms that are already supported — such as Linux and Solaris — are planned for MySQL Cluster on Windows. Currently, you must build from source, although we intend to start making Windows binaries available in the near future. To enable MySQL Cluster support on Windows, you must configure the build using the `WITH_NDBCLUSTER_STORAGE_ENGINE` option. For more information, see [Section 2.10.6, “Installing MySQL from Source on Windows”](#).
- **Ability to add nodes and node groups online.** Beginning with MySQL Cluster NDB 6.4.0, it is possible to add new node groups (and thus new data nodes) to a running MySQL Cluster without shutting down and reloading the cluster. As part of enabling this feature, a new command `CREATE NODEGROUP` has been added to the cluster management client and the functionality of the `ALTER ONLINE TABLE ... REORGANIZE PARTITION` SQL statement has been extended. For more information, see [Section 17.7.8, “Adding MySQL Cluster Data Nodes Online”](#).
- **Data node multithreading support.** Beginning with MySQL Cluster NDB 6.4.0, a multithreaded version of the data node daemon, named `ndbmt_d`, is available for use on data node hosts with multiple CPU cores. This binary is built automatically when compiling with MySQL Cluster support; no additional options other than those needed to provide MySQL Cluster support are needed when configuring the build. In most respects, `ndbmt_d` functions in the same way as `ndbd`, and can use the same command-line options and configuration parameters. In addition, the new `MaxNoOfExecutionThreads` configuration parameter can be used to determine the number of data node process threads for `ndbmt_d`. For more information, see [Section 17.6.3, “ndbmt_d — The MySQL Cluster Data Node Daemon \(Multi-Threaded\)”](#).

Note

Disk Data tables are not yet supported for use with `ndbmt_d`.

- **Configuration cache.** Formerly, MySQL Cluster configuration was stateless — that is, configuration information was reloaded from the cluster's global configuration file (usually `config.ini`) each time `ndb_mgmd` was started. Beginning with MySQL Cluster NDB 6.4.0, the cluster's configuration is cached internally, and the global configuration file is no longer automatically re-read when the management server is restarted. This behavior can be controlled via the three new management server options `--configdir`, `--initial`, and `--reload`. For more information about this change, see [Section 17.3.4, “MySQL Cluster Configuration Files”](#). For more information about the new management server options, see [Section 17.6.24.3, “Program Options for ndb_mgmd”](#).
- **Snapshot options for backups.** Beginning with MySQL Cluster NDB 6.4.0, you can determine when performing a cluster

backup whether the backup matches the state of the data when the backup was started or when it was completed, using the new options `SNAPSHOTSTART` and `SNAPSHOTEND` for the management client's `START BACKUP` command. See [Section 17.7.3.2, “Using The MySQL Cluster Management Client to Create a Backup”](#), for more information.

- Dynamic NDB transporter send buffer memory allocation.** Previously, the NDB kernel used a fixed-size send buffer for every data node in the cluster, which was allocated when the node started. Because the size of this buffer could not be changed after the cluster was started, it was necessary to make it large enough in advance to accommodate the maximum possible load on any transporter socket. However, this was an inefficient use of memory, since much of it often went unused. Beginning with MySQL Cluster NDB 6.4.0, send buffer memory is allocated dynamically from a memory pool shared between all transporters, which means that the size of the send buffer can be adjusted as necessary. This change is reflected by the addition of the configuration parameters `TotalSendBufferMemory`, `ReservedSendBufferMemory`, and `OverLoadLimit`, as well as a change in how the existing `SendBufferMemory` configuration parameter is used. For more information, see [Section 17.3.7, “Configuring MySQL Cluster Send Buffer Parameters”](#).
- Robust DDL operations.** Beginning with MySQL Cluster NDB 6.4.0, DDL operations (such as `CREATE TABLE` or `ALTER TABLE`) are protected from data node failures; in the event of a data node failure, such operations are now rolled back gracefully. Previously, if a data node failed while trying to perform a DDL operation, the MySQL Cluster data dictionary became locked and no further DDL statements could be executed without restarting the cluster.
- IPv6 support in MySQL Cluster Replication.** Beginning with MySQL Cluster NDB 6.4.1, IPv6 networking is supported between MySQL Cluster SQL nodes, which makes it possible to replicate between instances of MySQL Cluster using IPv6 addresses. However, IPv6 is supported only for direct connections between MySQL servers; all connections *within* an individual MySQL Cluster must use IPv4. For more information, see [Section 17.9.3, “Known Issues in MySQL Cluster Replication”](#).
- Restoring specific tables and databases from a MySQL Cluster backup.** It is now possible to exercise more fine-grained control when restoring a MySQL Cluster from backup using `ndb_restore`. You can restore only specified tables or databases, or exclude specific tables or databases from being restored, using the new `ndb_restore` options `--include-tables`, `--include-databases`, `--exclude-tables`, and `--exclude-databases`. For more information about these options, see [Section 17.6.17, “ndb_restore — Restore a MySQL Cluster Backup”](#).
- Improved Disk Data filesystem configuration.** As of MySQL Cluster NDB 6.4.3, you can specify default locations for MySQL Cluster Disk Data data files and undo log files using the data node configuration parameters `FileSystemPathDD`, `FileSystemPathDataFiles`, and `FileSystemPathUndoFiles`. For more information, see [Disk Data filesystem parameters](#).
- Automatic creation of Disk Data log file groups and tablespaces.** Beginning with MySQL Cluster NDB 6.4.3, using the data node configuration parameters `InitialLogFileGroup` and `InitialTablespace`, you can cause the creation of a MySQL Cluster Disk Data log file group, tablespace, or both, when the cluster is first started. When using these parameters, no SQL statements are required to create these Disk Data objects. For more information, see [Disk Data object creation parameters](#).
- Improved internal message passing and record handling.** MySQL Cluster NDB 7.0 contains 2 changes that optimize the use of network connections by addressing the size and number of messages passed between data nodes, and between data nodes and API nodes, which can increase MySQL Cluster and application performance:
 - Packed reads.** Formerly, each read request signal contained a list of columns to be retrieved, each of these column identifiers using 4 bytes within the message. This meant that the message size increased as the number of columns being fetched increased. In addition, in the response from the data node, each column result was packed to a 4-byte boundary, which resulted in wasted space. In MySQL Cluster NDB 7.0, messaging for read operations is optimized in both directions, using a bitmap in the read request to specify the columns to be fetched. Where many fields are requested, this can result in a significant message size reduction as compared with the old method. In addition, the 4-byte packing in responses is no longer used, which means that smaller fields consume less space.
 - Long signal transactions.** This enhancement reduces the number of messages and signals that are sent to data nodes for complex requests. Prior to MySQL Cluster NDB 7.0, there was a 100 byte limit on the size of the request signal, which meant that complex requests had to be split up between multiple messages prior to transmission, then reassembled on the receiving end. In addition to actual payload data, each message required its own operating system and protocol overhead such as header information. This often wasted network bandwidth and data node CPU. The maximum size of the message is now 32 KB, which is sufficient to accommodate most queries.

Both of these optimizations are internal to the NDB API, and so is transparent to applications; this is true whether an application uses the NDB API directly or does so indirectly through an SQL node.

- Configuration parameter data dumps.** Starting with MySQL Cluster NDB 7.0.6, the `ndb_config` utility supports a `--configinfo` option that causes it to dump a list of all configuration parameters supported by the cluster, along with brief descriptions, information about the parameters' default and allowed values, and the sections of the `config.ini` file in which the parameters apply. An additional `--xml` switch causes `ndb_config` to use XML rather than plaintext output. Using `ndb_config --configinfo` or `ndb_config --configinfo --xml` requires no access to a running MySQL Cluster, any other programs, or any files. For more information and examples, see [Section 17.6.6, “ndb_config — Extract MySQL Cluster Configuration Information”](#).

17.13.6. Features Planned for MySQL Cluster NDB 7.1 and Later

The following improvements to MySQL Cluster are planned for MySQL Cluster NDB 7.1 and later release series.

Important

These features are in planning or early development phase. Timing, availability, and implementation details are not guaranteed, and are subject to change at any time without notice.

- **NDB\$INFO meta-information database.** This feature is intended to make it possible to obtain real-time characteristics of a MySQL Cluster by issuing queries from the `mysql` client or other MySQL client applications. `NDB$INFO` is a database which is planned for MySQL Cluster NDB 7.1 to provide metadata specific to MySQL Cluster similar to that provided by the `INFORMATION_SCHEMA` database for the standard MySQL Server. This would eliminate much of the need to read log files, issue `DUMP` commands, or parse the output of `ndb_config` in order to get configuration and status information from a running MySQL Cluster.

17.14. MySQL Cluster Glossary

The following terms are useful to an understanding of MySQL Cluster or have specialized meanings when used in relation to it.

- **Cluster.** In its generic sense, a cluster is a set of computers functioning as a unit and working together to accomplish a single task.

NDBCLUSTER. This is the storage engine used in MySQL to implement data storage, retrieval, and management distributed among several computers.

MySQL Cluster. This refers to a group of computers working together using the `NDB` storage engine to support a distributed MySQL database in a *shared-nothing architecture* using *in-memory storage*.

- **Configuration files.** Text files containing directives and information regarding the cluster, its hosts, and its nodes. These are read by the cluster's management nodes when the cluster is started. See [Section 17.3.4, “MySQL Cluster Configuration Files”](#), for details.
- **Backup.** A complete copy of all cluster data, transactions and logs, saved to disk or other long-term storage.
- **Restore.** Returning the cluster to a previous state, as stored in a backup.
- **Checkpoint.** Generally speaking, when data is saved to disk, it is said that a checkpoint has been reached. More specific to Cluster, it is a point in time where all committed transactions are stored on disk. With regard to the `NDB` storage engine, there are two types of checkpoints which work together to ensure that a consistent view of the cluster's data is maintained:
 - **Local Checkpoint (LCP).** This is a checkpoint that is specific to a single node; however, LCP's take place for all nodes in the cluster more or less concurrently. An LCP involves saving all of a node's data to disk, and so usually occurs every few minutes. The precise interval varies, and depends upon the amount of data stored by the node, the level of cluster activity, and other factors.
 - **Global Checkpoint (GCP).** A GCP occurs every few seconds, when transactions for all nodes are synchronized and the redo-log is flushed to disk.
- **Cluster host.** A computer making up part of a MySQL Cluster. A cluster has both a *physical* structure and a *logical* structure. Physically, the cluster consists of a number of computers, known as *cluster hosts* (or more simply as *hosts*). See also **Node** and **Node group** below.
- **Node.** This refers to a logical or functional unit of MySQL Cluster, and is sometimes also referred to as a *cluster node*. In the context of MySQL Cluster, we use the term “node” to indicate a *process* rather than a physical component of the cluster. There are three node types required to implement a working MySQL Cluster:
 - **Management nodes.** Manages the other nodes within the MySQL Cluster. It provides configuration data to the other nodes; starts and stops nodes; handles network partitioning; creates backups and restores from them, and so forth.
 - **SQL nodes.** Instances of MySQL Server which serve as front ends to data kept in the cluster's **data nodes**. Clients desiring to store, retrieve, or update data can access an SQL node just as they would any other MySQL Server, employing the usual MySQL authentication methods and APIs; the underlying distribution of data between node groups is transparent to users and applications. SQL nodes access the cluster's databases as a whole without regard to the data's distribution across different data nodes or cluster hosts.
 - **Data nodes.** These nodes store the actual data. Table data fragments are stored in a set of node groups; each node group

stores a different subset of the table data. Each of the nodes making up a node group stores a replica of the fragment for which that node group is responsible. Currently, a single cluster can support up to 48 data nodes total.

It is possible for more than one node to co-exist on a single machine. (In fact, it is even possible to set up a complete cluster on one machine, although one would almost certainly *not* want to do this in a production environment.) It may be helpful to remember that, when working with MySQL Cluster, the term *host* refers to a physical component of the cluster whereas a *node* is a logical or functional component (that is, a process).

Note Regarding Terms. In older versions of the MySQL Cluster documentation, data nodes were sometimes referred to as “database nodes”. The term “storage nodes” has also been used. In addition, SQL nodes were sometimes known as “client nodes”. This older terminology has been deprecated to minimize confusion, and for this reason should be avoided. They are also often referred to as “API nodes” — an SQL node is actually an API node that provides an SQL interface to the cluster.

- **Node group.** A set of data nodes. All data nodes in a node group contain the same data (fragments), and all nodes in a single group should reside on different hosts. It is possible to control which nodes belong to which node groups.

For more information, see [Section 17.1.2, “MySQL Cluster Nodes, Node Groups, Replicas, and Partitions”](#).

- **Node failure.** MySQL Cluster is not solely dependent upon the functioning of any single node making up the cluster; the cluster can continue to run if one or more nodes fail. The precise number of node failures that a given cluster can tolerate depends upon the number of nodes and the cluster's configuration.
- **Node restart.** The process of restarting a failed cluster node.
- **Initial node restart.** The process of starting a cluster node with its file system removed. This is sometimes used in the course of software upgrades and in other special circumstances.
- **System crash (or system failure).** This can occur when so many cluster nodes have failed that the cluster's state can no longer be guaranteed.
- **System restart.** The process of restarting the cluster and reinitializing its state from disk logs and checkpoints. This is required after either a planned or an unplanned shutdown of the cluster.
- **Fragment.** A portion of a database table; in the **NDB** storage engine, a table is broken up into and stored as a number of fragments. A fragment is sometimes also called a “partition”; however, “fragment” is the preferred term. Tables are fragmented in MySQL Cluster in order to facilitate load balancing between machines and nodes.
- **Replica.** Under the **NDB** storage engine, each table fragment has number of replicas stored on other data nodes in order to provide redundancy. Currently, there may be up four replicas per fragment.
- **Transporter.** A protocol providing data transfer between nodes. MySQL Cluster currently supports four different types of transporter connections:
 - **TCP/IP.** This is, of course, the familiar network protocol that underlies HTTP, FTP (and so on) on the Internet. TCP/IP can be used for both local and remote connections.
 - **SCI.** Scalable Coherent Interface is a high-speed protocol used in building multiprocessor systems and parallel-processing applications. Use of SCI with MySQL Cluster requires specialized hardware, as discussed in [Section 17.11.1, “Configuring MySQL Cluster to use SCI Sockets”](#). For a basic introduction to SCI, see [this essay at dolphins.com](#).
 - **SHM.** Unix-style **shared memory** segments. Where supported, SHM is used automatically to connect nodes running on the same host. The [Unix man page for shmop\(2\)](#) is a good place to begin obtaining additional information about this topic.

Note

The cluster transporter is internal to the cluster. Applications using MySQL Cluster communicate with SQL nodes just as they do with any other version of MySQL Server (via TCP/IP, or through the use of Unix socket files or Windows named pipes). Queries can be sent and results retrieved using the standard MySQL client APIs.

- **NDB.** This stands for **Network Database**, and refers to the storage engine used to enable MySQL Cluster. The **NDB** storage engine supports all the usual MySQL data types and SQL statements, and is **ACID**-compliant. This engine also provides full support for transactions (commits and rollbacks).
- **Shared-nothing architecture.** The ideal architecture for a MySQL Cluster. In a true shared-nothing setup, each node runs on a separate host. The advantage such an arrangement is that there no single host or node can act as single point of failure or as a performance bottle neck for the system as a whole.
- **In-memory storage.** All data stored in each data node is kept in memory on the node's host computer. For each data node in the cluster, you must have available an amount of RAM equal to the size of the database times the number of replicas, divided by the number of data nodes. Thus, if the database takes up 1GB of memory, and you want to set up the cluster with four rep-

licas and eight data nodes, a minimum of 500MB memory will be required per node. Note that this is in addition to any requirements for the operating system and any other applications that might be running on the host.

In MySQL 5.1 and MySQL Cluster NDB 6.x, it is also possible to create *Disk Data* tables where non-indexed columns are stored on disk, thus reducing the memory footprint required by the cluster. Note that indexes and indexed column data are still stored in RAM. See [Section 17.10, “MySQL Cluster Disk Data Tables”](#).

- **Table.** As is usual in the context of a relational database, the term “table” denotes a set of identically structured records. In MySQL Cluster, a database table is stored in a data node as a set of fragments, each of which is replicated on additional data nodes. The set of data nodes replicating the same fragment or set of fragments is referred to as a *node group*.
- **Cluster programs.** These are command-line programs used in running, configuring, and administering MySQL Cluster. They include both server daemons:

- `ndbd`:

The data node daemon (runs a data node process)

- `ndb_mgmd`:

The management server daemon (runs a management server process)

and client programs:

- `ndb_mgm`:

The management client (provides an interface for executing management commands)

- `ndb_waiter`:

Used to verify status of all nodes in a cluster

- `ndb_restore`:

Restores cluster data from backup

For more about these programs and their uses, see [Section 17.6, “MySQL Cluster Programs”](#).

- **Event log.** MySQL Cluster logs events by category (startup, shutdown, errors, checkpoints, and so on), priority, and severity. A complete listing of all reportable events may be found in [Section 17.7.4, “Event Reports Generated in MySQL Cluster”](#). Event logs are of two types:
 - **Cluster log.** Keeps a record of all desired reportable events for the cluster as a whole.
 - **Node log.** A separate log which is also kept for each individual node.

Under normal circumstances, it is necessary and sufficient to keep and examine only the cluster log. The node logs need be consulted only for application development and debugging purposes.

- **Angel process.** When a data node is started, `ndbd` actually starts two processes. One of these is known as the “angel” process; its purpose is to check to make sure that the main `ndbd` process continues to run, and to restart the main process if it should stop for any reason.
- **Watchdog thread.** Each `ndbd` process has an internal *watchdog thread* which monitors the main worker thread, ensuring forward progress and a timely response to cluster protocols such as the cluster heartbeat. If the `ndbd` process is not being woken up promptly by the operating system when its sleep time expires, **INFO** and **WARNING** events, which are identifiable because they contain “Watchdog:...”, are written to the cluster log. Such messages are usually a symptom of an overloaded system; you should see what else is running on the system, and whether the `ndbd` process is being swapped out to disk. If `ndbd` cannot wake up regularly then it cannot respond to heartbeat messages on time, and other nodes eventually consider it “dead” due to the missed heartbeats, causing it to be excluded from the cluster.

17.15. Changes in MySQL Cluster NDB 6.X and 7.X

This section contains changelog information for MySQL Cluster releases that use versions 6.1, 6.2, 6.3, and 7.0 of the **NDB-CLUSTER** storage engine.

Note

Version 7.0 of the **NDBCLUSTER** storage engine was previously known as “NDB 6.4”. For more information, see

■ Section 17.15.1, “Changes in MySQL Cluster NDB 7.0”.

Each MySQL Cluster release is based on a mainline MySQL 5.1 release and a particular version of the `NDBCLUSTER` storage engine, as shown in the version string returned by executing `SELECT VERSION()` in the `mysql` client, or by executing the `ndb_mgm` client `SHOW` or `STATUS` command; for more information, see [Chapter 17, MySQL Cluster NDB 6.X/7.X](#).

For general information about features added in MySQL Cluster, see [Section 17.13, “MySQL Cluster Development Roadmap”](#). For a complete list of all bugfixes and feature changes in MySQL Cluster, please refer to the changelog section for each individual MySQL Cluster release.

An overview of features added in MySQL 5.1 not specific to MySQL Cluster can be found here: [Section 1.4.1, “What Is New in MySQL 5.1”](#). For a complete list of all bugfixes and features changes made in MySQL 5.1 that are not specific to MySQL Cluster, see [Section C.1, “Changes in release 5.1.x \(Production\)”](#).

17.15.1. Changes in MySQL Cluster NDB 7.0

This section contains change history information for MySQL Cluster releases based on version 7.0 of the `NDBCLUSTER` storage engine.

Important

Previously, version 7.0 of `NDBCLUSTER` was known as version 6.4, and early development versions of MySQL Cluster NDB 7.0 were known as “MySQL Cluster 6.4”. The first four releases in this series were identified using NDB 6.4.x version numbers (NDB 6.4.0 through NDB 6.4.3).

MySQL Cluster NDB 7.0.4 is the fifth release in this series. All future MySQL Cluster NDB 7.0 releases will use NDB 7.0.x version numbers.

Users running MySQL Cluster NDB 6.4.3 should upgrade to MySQL Cluster NDB 7.0.4 (or a later MySQL Cluster NDB 7.0 release).

For an overview of new features added in MySQL Cluster NDB 7.0, see [Section 17.13.5, “Features Added in MySQL Cluster NDB 7.0”](#).

When upgrading to a MySQL Cluster NDB 7.0 release from earlier MySQL Cluster releases, you should be aware of the following issues:

- It is not currently possible to perform an online upgrade to MySQL Cluster NDB 7.0 from an earlier MySQL Cluster release.
- You cannot run a MySQL Cluster using a mix of MySQL Cluster NDB 7.0 and earlier binaries; all MySQL Cluster executables must be replaced with the MySQL Cluster NDB 7.0 versions.
- NDB API applications built against previous MySQL Cluster versions must be recompiled against against the MySQL Cluster NDB 7.0 sources.

17.15.1.1. Changes in MySQL Cluster NDB 7.0.7 (5.1.34-ndb-7.0.7) (Not yet released)

This release incorporates new features in the `NDBCLUSTER` storage engine and fixes recently discovered bugs in MySQL Cluster NDB 7.0.6.

Obtaining MySQL Cluster NDB 7.0.7. The latest MySQL Cluster NDB 7.0 binaries for supported platforms can be obtained from <http://dev.mysql.com/downloads/cluster/7.0.html>. Source code for the latest MySQL Cluster NDB 7.0 release can be obtained from the same location. You can also access the MySQL Cluster NDB 7.0 development source tree at <https://code.launchpad.net/~mysql/mysql-server/mysql-cluster-7.0>.

This release also incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.1, 6.2, 6.3, and 7.0 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.34 (see [Section C.1.3, “Changes in MySQL 5.1.34 \(02 April 2009\)”](#)).

Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Bugs fixed:

- **Disk Data: Partitioning:** An `NDBCLUSTER` table created with a very large value for the `MAX_ROWS` option could — if this table was dropped and a new table with fewer partitions, but having the same table ID, was created — cause `ndbd` to crash when

performing a system restart. This was because the server attempted to examine each partition whether or not it actually existed. (Bug#45154)

17.15.1.2. Changes in MySQL Cluster NDB 7.0.6 (5.1.34-ndb-7.0.6) (Not yet released)

This release incorporates new features in the `NDBCLUSTER` storage engine and fixes recently discovered bugs in MySQL Cluster NDB 7.0.5.

Obtaining MySQL Cluster NDB 7.0.5. The latest MySQL Cluster NDB 7.0 binaries for supported platforms can be obtained from <http://dev.mysql.com/downloads/cluster/7.0.html>. Source code for the latest MySQL Cluster NDB 7.0 release can be obtained from the same location. You can also access the MySQL Cluster NDB 7.0 development source tree at <https://code.launchpad.net/~mysql/mysql-server/mysql-cluster-7.0>.

This release also incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.1, 6.2, 6.3, and 7.0 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.34 (see [Section C.1.3](#), “Changes in MySQL 5.1.34 (02 April 2009)”).

Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Functionality added or changed:

- The `ndb_config` utility program can now provide an offline dump of all MySQL Cluster configuration parameters including information such as default and permitted values, brief description, and applicable section of the `config.ini` file. A dump in text format is produced when running `ndb_config` with the new `--configinfo` option, and in XML format when the options `--configinfo --xml` are used together. For more information and examples, see [Section 17.6.6](#), “`ndb_config` — Extract MySQL Cluster Configuration Information”.

Bugs fixed:

- Important Change: Partitioning:** User-defined partitioning of an `NDBCLUSTER` table without any primary key sometimes failed, and could cause `mysqld` to crash.

Now, if you wish to create an `NDBCLUSTER` table with user-defined partitioning, the table must have an explicit primary key, and all columns listed in the partitioning expression must be part of the primary key. The hidden primary key used by the `NDBCLUSTER` storage engine is not sufficient for this purpose. However, if the list of columns is empty (that is, the table is defined using `PARTITION BY [LINEAR] KEY()`), then no explicit primary key is required.

This change does not effect the partitioning of tables using any storage engine other than `NDBCLUSTER`. (Bug#40709)

- Important Note:** It was not possible to perform an online upgrade from any MySQL Cluster NDB 6.x release to MySQL Cluster NDB 7.0.5 or any to earlier MySQL Cluster NDB 7.0 release.

With this fix, it is possible in MySQL Cluster NDB 7.0.6 and later to perform online upgrades from MySQL Cluster NDB 6.3.8 and later MySQL Cluster NDB 6.3 releases, or from MySQL Cluster NDB 7.0.5 or later MySQL Cluster NDB 7.0 releases. Online upgrades to MySQL Cluster NDB 7.0 releases previous to MySQL Cluster NDB 7.0.6 from earlier MySQL Cluster releases remain unsupported; online upgrades from MySQL Cluster NDB 7.0 releases previous to MySQL Cluster NDB 7.0.5 (including NDB 6.4.x beta releases) to later MySQL Cluster NDB 7.0 releases also remain unsupported. (Bug#44294)

- An internal NDB API buffer was not properly initialized. (Bug#44977)
- When a data node had written its GCI marker to the first page of a megabyte, and that node was later killed during restart after having processed that page (marker) but before completing a LCP, the data node could fail with filesystem errors. (Bug#44952)

See also [Bug#42564](#).

- When restarting a data nodes, management and API nodes reconnecting to it failed to re-use existing ports that had already been dynamically allocated for communications with that data node. (Bug#44866)
- When `ndb_config` could not find the file referenced by the `--config-file` option, it tried to read `my.cnf` instead, then failed with a misleading error message. (Bug#44846)
- When a data node was down so long that its most recent local checkpoint depended on a global checkpoint that was no longer restorable, it was possible for it to be unable to use optimized node recovery when being restarted later. (Bug#44844)

See also [Bug#26913](#).

- Online upgrades to MySQL Cluster NDB 7.0 from a MySQL Cluster NDB 6.3 release could fail due to changes in the handling of key lengths and unique indexes during node recovery. ([Bug#44827](#))
- Use of `__builtin_expect()` had the side effect that compiler warnings about misuse of `=` (assignment) instead of `==` in comparisons were lost when building in debug mode. This is no longer employed when configuring the build with the `--with-debug` option. ([Bug#44570](#))

See also [Bug#44567](#).

- Inspection of the code revealed that several assignment operators (`=`) were used in place of comparison operators (`==`) in `Db-dihMain.cpp`. ([Bug#44567](#))

See also [Bug#44570](#).

- When using large numbers of configuration parameters, the management server took an excessive amount of time (several minutes or more) to load these from the configuration cache when starting. This problem occurred when there were more than 32 configuration parameters specified, and became progressively worse with each additional multiple of 32 configuration parameters. ([Bug#44488](#))
- Building the MySQL Cluster NDB 7.0 tree failed when using the `icc` compiler. ([Bug#44310](#))
- SSL connections to SQL nodes failed on big-endian platforms. ([Bug#44295](#))
- Signals providing node state information (`NODE_STATE_REP` and `CHANGE_NODE_STATE_REQ`) were not propagated to all blocks of `ndbmt.d`. This could cause the following problems:
 - Inconsistent redo logs when performing a graceful shutdown;
 - Data nodes crashing when later restarting the cluster, data nodes needing to perform node recovery during the system restart, or both.

([Bug#44291](#))

See also [Bug#42564](#).

- An NDB internal timing function did not work correctly on Windows and could cause `mysqld` to fail on some AMD processors, or when running inside a virtual machine. ([Bug#44276](#))
- It was possible for NDB API applications to insert corrupt data into the database, which could subsequently lead to data node crashes. Now, stricter checking is enforced on input data for inserts and updates. ([Bug#44132](#))
- `ndb_restore` failed when trying to restore data on a big-endian machine from a backup file created on a little-endian machine. ([Bug#44069](#))
- Repeated starting and stopping of data nodes could cause `ndb_mgmd` to fail. This issue was observed on Solaris/SPARC. ([Bug#43974](#))
- A number of incorrectly formatted output strings in the source code caused compiler warnings. ([Bug#43878](#))
- When trying to use a data node with an older version of the management server, the data node crashed on startup. ([Bug#43699](#))
- In some cases, data node restarts during a system restart could fail due to insufficient redo log space. ([Bug#43156](#))
- `NDBCLUSTER` did not build correctly on Solaris 9 platforms. ([Bug#39080](#))

See also [Bug#39036](#), [Bug#39038](#).

- The output of `ndbd --help` did not provide clear information about the program's `--initial` and `--initial-start` options. ([Bug#28905](#))
- It was theoretically possible for the value of a nonexistent column to be read as `NULL`, rather than causing an error. ([Bug#27843](#))
- **Disk Data:** During a checkpoint, restore points are created for both the on-disk and in-memory parts of a Disk Data table. Under certain rare conditions, the in-memory restore point could include or exclude a row that should have been in the snapshot. This would later later lead to a crash during or following recovery.

This issue was somewhat more likely to be encountered when using `ndbmt.d`. ([Bug#41915](#))

- **Disk Data:** This fix supercedes and improves on an earlier fix made for this bug in MySQL 5.1.18. ([Bug#24521](#))
- **Cluster Replication:** A failure when setting up replication events could lead to subsequent data node failures. ([Bug#44915](#))

17.15.1.3. Changes in MySQL Cluster NDB 7.0.5 (5.1.32-ndb-7.0.5) (20 April 2009)

This *General Availability* (GA) release incorporates new features in the `NDBCLUSTER` storage engine and fixes recently discovered bugs in MySQL Cluster NDB 7.0.4.

Obtaining MySQL Cluster NDB 7.0.5. The latest MySQL Cluster NDB 7.0 binaries for supported platforms can be obtained from <http://dev.mysql.com/downloads/cluster/7.0.html>. Source code for the latest MySQL Cluster NDB 7.0 release can be obtained from the same location. You can also access the MySQL Cluster NDB 7.0 development source tree at <https://code.launchpad.net/~mysql/mysql-server/mysql-cluster-7.0>.

This release also incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.1, 6.2, 6.3, and 6.4 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.32 (see [Section C.1.5](#), “Changes in MySQL 5.1.32 (14 February 2009)”).

Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Functionality added or changed:

- Two new server status variables `Ndb_scan_count` and `Ndb_pruned_scan_count` have been introduced. `Ndb_scan_count` gives the number of scans executed since the cluster was last started. `Ndb_pruned_scan_count` gives the number of scans for which `NDBCLUSTER` was able to use partition pruning. Together, these variables can be used to help determine in the MySQL server whether table scans are pruned by `NDBCLUSTER`. ([Bug#44153](#))

Bugs fixed:

- **Important Note:** Due to problem discovered after the code freeze for this release, it is not possible to perform an online upgrade from any MySQL Cluster NDB 6.x release to MySQL Cluster NDB 7.0.5 or any earlier MySQL Cluster NDB 7.0 release.

This issue is fixed in MySQL Cluster NDB 7.0.6 and later for upgrades from MySQL Cluster NDB 6.3.8 and later MySQL Cluster NDB 6.3 releases, or from MySQL Cluster NDB 7.0.5. ([Bug#44294](#))

- **Cluster Replication:** If data node failed during an event creation operation, there was a slight risk that a surviving data node could send an invalid table reference back to NDB, causing the operation to fail with a false Error 723 (`NO SUCH TABLE`). This could take place when a data node failed as a `mysqld` process was setting up MySQL Cluster Replication. ([Bug#43754](#))
- **Cluster API:** The following issues occurred when performing an online (rolling) upgrade of a cluster to a version of MySQL Cluster that supports configuration caching from a version that does not:
 1. When using multiple management servers, after upgrading and restarting one `ndb_mgmd`, any remaining management servers using the previous version of `ndb_mgmd` could not synchronize their configuration data.
 2. The MGM API `ndb_mgm_get_configuration()` function failed to obtain configuration data. ([Bug#43641](#))

If the number of fragments per table rises above a certain threshold, the `DBDIH` kernel block's on-disk table-definition grows large enough to occupy 2 pages. However, in MySQL Cluster NDB 7.0 (including MySQL Cluster NDB 6.4 releases), only 1 page was actually written, causing table definitions stored on disk to be incomplete.

This issue was not observed in MySQL Cluster release series prior to MySQL Cluster NDB 7.0. ([Bug#44135](#))

- `TransactionDeadlockDetectionTimeout` values less than 100 were treated as 100. This could cause scans to time out unexpectedly. ([Bug#44099](#))
- The file `ndberror.c` contained a C++-style comment, which caused builds to fail with some C compilers. ([Bug#44036](#))
- A race condition could occur when a data node failed to restart just before being included in the next global checkpoint. This could cause other data nodes to fail. ([Bug#43888](#))

- The setting for `ndb_use_transactions` was ignored. This issue was only known to occur in MySQL Cluster NDB 6.4.3 and MySQL Cluster NDB 7.0.4. (Bug#43236)
- When a data node process had been killed after allocating a node ID, but before making contact with any other data node processes, it was not possible to restart it due to a node ID allocation failure.

This issue could effect either `ndbd` or `ndbmt_d` processes. (Bug#43224)

This regression was introduced by Bug#42973.

- `ndb_restore` crashed when trying to restore a backup made to a MySQL Cluster running on a platform having different endianness from that on which the original backup was taken. (Bug#39540)
- PID files for the data and management node daemons were not removed following a normal shutdown. (Bug#37225)
- `ndb_restore --print_data` did not handle `DECIMAL` columns correctly. (Bug#37171)
- Invoking the management client `START BACKUP` command from the system shell (for example, as `ndb_mgm -e "START BACKUP"`) did not work correctly, unless the backup ID was included when the command was invoked.

Now, the backup ID is no longer required in such cases, and the backup ID that is automatically generated is printed to stdout, similar to how this is done when invoking `START BACKUP` within the management client. (Bug#31754)

- When aborting an operation involving both an insert and a delete, the insert and delete were aborted separately. This was because the transaction coordinator did not know that the operations affected on same row, and, in the case of a committed-read (tuple or index) scan, the abort of the insert was performed first, then the row was examined after the insert was aborted but before the delete was aborted. In some cases, this would leave the row in a inconsistent state. This could occur when a local checkpoint was performed during a backup. This issue did not affect primary key operations or scans that used locks (these are serialized).

After this fix, for ordered indexes, all operations that follow the operation to be aborted are now also aborted.

- **Disk Data:** When using multi-threaded data nodes, `DROP TABLE` statements on Disk Data tables could hang. (Bug#43825)
- **Disk Data:** This fix completes one that was made for this issue in MySQL Cluster NDB-7.0.4, which did not rectify the problem in all cases. (Bug#43632)
- **Cluster Replication:** When creating or altering a table an `NdbEventOperation` is created by the `mysqld` process to monitor the table for subsequent logging in the binlog. If this happened during a node restart there was a chance that the reference count on this event operation object could be incorrect, which could lead to an assert in debug MySQL Cluster builds. (Bug#43752)
- **Cluster API:** If the largest offset of a `RecordSpecification` used for an `NdbRecord` object was for the `NULL` bits (and thus not a column), this offset was not taken into account when calculating the size used for the `RecordSpecification`. This meant that the space for the `NULL` bits could be overwritten by key or other information. (Bug#43891)
- **Cluster API:** `BIT` columns created using the native NDB API format that were not created as nullable could still sometimes be overwritten, or cause other columns to be overwritten.

This issue did not effect tables having `BIT` columns created using the `mysqld` format (always used by MySQL Cluster SQL nodes). (Bug#43802)

17.15.1.4. Changes in MySQL Cluster NDB 7.0.4 (5.1.32-ndb-7.0.4) (18 March 2008)

This is a new Beta development release, incorporating new features in the `NDBCLUSTER` storage engine and fixing recently discovered bugs in MySQL Cluster NDB 6.4.3. All feature additions and bugfixes that were made in MySQL Cluster releases having NDB 6.4.x release numbers are included in MySQL Cluster 7.0.4.

Important

MySQL Cluster NDB 7.0.4 is the successor to MySQL Cluster NDB 6.4.3. Users running MySQL Cluster NDB 6.4.3 should upgrade to MySQL Cluster NDB 7.0.4 or a later 7.0.x release.

Obtaining MySQL Cluster NDB 7.0.4. MySQL Cluster NDB 7.0.4 is a source-only release. You can obtain the source code from ftp://ftp.mysql.com/pub/mysql/download/cluster_telco/mysql-5.1.32-ndb-7.0.4/.

This Beta release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.1, 6.2, 6.3, and 6.4 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.32 (see [Section C.1.5, “Changes in MySQL 5.1.32 \(14 February 2009\)”](#)).

Note

This Beta release, as any other pre-production release, should not be installed on *production* level systems or systems with critical data. Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Functionality added or changed:

- **Important Change:** The default values for a number of MySQL Cluster configuration parameters relating to memory usage and buffering have changed. These parameters include `RedoBuffer`, `LongMessageBuffer`, `BackupMemory`, `BackupDataBufferSize`, `BackupLogBufferSize`, `BackupWriteSize`, `BackupMaxWriteSize`, `SendBufferMemory` (when applied to TCP transporters), and `ReceiveBufferMemory`.

For more information, see [Section 17.3, “MySQL Cluster Configuration”](#).

- When restoring from backup, `ndb_restore` now reports the last global checkpoint reached when the backup was taken. (Bug#37384)

Bugs fixed:

- **Cluster API:** Partition pruning did not work correctly for queries involving multiple range scans.

As part of the fix for this issue, several improvements have been made in the NDB API, including the addition of a new `NdbScanOperation::getPruned()` method, a new variant of `NdbIndexScanOperation::setBound()`, and a new `Ndb::PartitionSpec` data structure. For more information about these changes, see `NdbScanOperation::getPruned()`, `NdbIndexScanOperation::setBound()`, and [The PartitionSpec Structure](#). (Bug#37934)

- `TimeBetweenLocalCheckpoints` was measured from the end of one local checkpoint to the beginning of the next, rather than from the beginning of one LCP to the beginning of the next. This meant that the time spent performing the LCP was not taken into account when determining the `TimeBetweenLocalCheckpoints` interval, so that LCPs were not started often enough, possibly causing data nodes to run out of redo log space prematurely. (Bug#43567)
- The management server failed to start correctly in daemon mode. (Bug#43559)
- Following a `DROP NODEGROUP` command, the output of `SHOW` in the `ndb_mgm` cliently was not updated to reflect the fact that the data nodes affected by this command were no longer part of a node group. (Bug#43413)
- Using indexes containing variable-sized columns could lead to internal errors when the indexes were being built. (Bug#43226)
- When using `ndbmttd`, multiple data node failures caused the remaining data nodes to fail as well. (Bug#43109)
- It was not possible to add new data nodes to the cluster online using multi-threaded data node processes (`ndbmttd`). (Bug#43108)
- Some queries using combinations of logical and comparison operators on an indexed column in the `WHERE` clause could fail with the error `GOT ERROR 4541 'INDEXBOUND HAS NO BOUND INFORMATION' FROM NDBCLUSTER`. (Bug#42857)
- **Disk Data:** When using multi-threaded data nodes, dropping a Disk Data table followed by a data node restart led to a crash. (Bug#43632)
- **Disk Data:** When using `ndbmttd`, repeated high-volume inserts (on the order of 10000 rows inserted at a time) on a Disk Data table would eventually lead to a data node crash. (Bug#41398)
- **Disk Data:** When a log file group had an undo log file whose size was too small, restarting data nodes failed with `READ UNDERFLOW` errors.

As a result of this fix, the minimum allowed `INTIAL_SIZE` for an undo log file is now `1M` (1 megabyte). (Bug#29574)

- **Cluster API:** The default `NdbRecord` structures created by `NdbDictionary` could have overlapping null bits and data fields. (Bug#43590)
- **Cluster API:** When performing insert or write operations, `NdbRecord` allows key columns to be specified in both the key record and in the attribute record. Only one key column value for each key column should be sent to the NDB kernel, but this was not guaranteed. This is now ensured as follows: For insert and write operations, key column values are taken from the key record; for scan takeover update operations, key column values are taken from the attribute record. (Bug#42238)
- **Cluster API:** Ordered index scans using `NdbRecord` formerly expressed a `BoundEQ` range as separate lower and upper bounds, resulting in 2 copies of the column values being sent to the NDB kernel.

Now, when a range is specified by `NdbScanOperation::setBound()`, the passed pointers, key lengths, and inclusive bits are compared, and only one copy of the equal key columns is sent to the kernel. This makes such operations more efficient, as half the amount of `KeyInfo` is now sent for a `BoundEQ` range as before. (Bug#38793)

17.15.1.5. Changes in MySQL Cluster NDB 6.4.3 (5.1.32-ndb-6.4.3) (23 February 2009)

This is a new Beta development release, incorporating new features in the `NDBCLUSTER` storage engine and fixing recently discovered bugs in MySQL Cluster NDB 6.4.2.

Important

The successor version to MySQL Cluster NDB 6.4.3 is MySQL Cluster NDB 7.0.4. See [Section 17.15.1.4, “Changes in MySQL Cluster NDB 7.0.4 \(5.1.32-ndb-7.0.4\) \(18 March 2008\)”](#).

Obtaining MySQL Cluster NDB 6.4.3. MySQL Cluster NDB 6.4.3 is a source-only release. You can obtain the source code from ftp://ftp.mysql.com/pub/mysql/download/cluster_telco/mysql-5.1.32-ndb-6.4.3/.

This Beta release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.1, 6.2, 6.3, and 6.4 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.32 (see [Section C.1.5, “Changes in MySQL 5.1.32 \(14 February 2009\)”](#)).

Note

This Beta release, as any other pre-production release, should not be installed on *production* level systems or systems with critical data. Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Functionality added or changed:

- **Important Change: Replication:** `RESET MASTER` and `RESET SLAVE` now reset the values shown for `Last_IO_Error`, `Last_IO_Errno`, `Last_SQL_Error`, and `Last_SQL_Errno` in the output of `SHOW SLAVE STATUS`. (Bug#34654)
- A new data node configuration parameter `MaxLCPStartDelay` has been introduced to facilitate parallel node recovery by causing a local checkpoint to be delayed while recovering nodes are synchronizing data dictionaries and other meta-information. For more information about this parameter, see [Section 17.3.4.6, “Defining MySQL Cluster Data Nodes”](#). (Bug#43053)
- New options are introduced for `ndb_restore` for determining which tables or databases should be restored:
 - `--include-tables` and `--include-databases` can be used to restore specific tables or databases.
 - `--exclude-tables` and `--exclude-databases` can be used to exclude the specified tables or databases from being restored.

For more information about these options, see [Section 17.6.17, “ndb_restore — Restore a MySQL Cluster Backup”](#). (Bug#40429)

- **Disk Data:** It is now possible to specify default locations for Disk Data data files and undo log files, either together or separately, using the data node configuration parameters `FileSystemPathDD`, `FileSystemPathDataFiles`, and `FileSystemPathUndoFiles`. For information about these configuration parameters, see [Disk Data filesystem parameters](#).

It is also now possible to specify a log file group, tablespace, or both, that is created when the cluster is started, using the `InitialLogFileGroup` and `InitialTablespace` data node configuration parameters. For information about these configuration parameters, see [Disk Data object creation parameters](#).

Bugs fixed:

- **Important Note:** It is not possible in this release to install the `InnoDB` plugin if `InnoDB` support has been compiled into `mysqld`. (Bug#42610)
This regression was introduced by [Bug#29263](#).
- **Packaging:** Packages for MySQL Cluster were missing the `libndbclient.so` and `libndbclient.a` files. (Bug#42278)
- **Partitioning:** Executing `ALTER TABLE ... REORGANIZE PARTITION` on an `NDBCLUSTER` table having only one partition caused `mysqld` to crash. (Bug#41945)

See also [Bug#40389](#).

- Backup IDs greater than 2^{31} were not handled correctly, causing negative values to be used in backup directory names and printouts. ([Bug#43042](#))
- When using `ndbmt_d`, NDB kernel threads could hang while trying to start the data nodes with `LockPagesInMainMemory` set to 1. ([Bug#43021](#))
- When using multiple management servers and starting several API nodes (possibly including one or more SQL nodes) whose connectstrings listed the management servers in different order, it was possible for 2 API nodes to be assigned the same node ID. When this happened it was possible for an API node not to get fully connected, consequently producing a number of errors whose cause was not easily recognizable. ([Bug#42973](#))
- When using multi-threaded data nodes, `IndexMemory`, `MaxNoOfLocalOperations`, and `MaxNoOfLocalScans` were effectively multiplied by the number of local query handlers in use by each `ndbmt_d` instance. ([Bug#42765](#))

See also [Bug#42215](#).

- `ndb_error_reporter` worked correctly only with GNU `tar`. (With other versions of `tar`, it produced empty archives.) ([Bug#42753](#))
- Triggers on `NDBCLUSTER` tables caused such tables to become locked. ([Bug#42751](#))

See also [Bug#16229](#), [Bug#18135](#).

- When performing more than 32 index or tuple scans on a single fragment, the scans could be left hanging. This caused unnecessary timeouts, and in addition could possibly lead to a hang of an LCP. ([Bug#42559](#))
- A data node failure that occurred between calls to `NdbIndexScanOperation::readTuples(SF_OrderBy)` and `NdbTransaction::Execute()` was not correctly handled; a subsequent call to `nextResult()` caused a null pointer to be dereferenced, leading to a segfault in `mysqld`. ([Bug#42545](#))
- If the cluster configuration cache file was larger than 32K, the management server would not start. ([Bug#42543](#))
- Issuing `SHOW GLOBAL STATUS LIKE 'NDB%'` before `mysqld` had connected to the cluster caused a segmentation fault. ([Bug#42458](#))
- When using `ndbmt_d` for all data nodes, repeated failures of one data node during DML operations caused other data nodes to fail. ([Bug#42450](#))
- Data node failures that occurred before all data nodes had connected to the cluster were not handled correctly, leading to additional data node failures. ([Bug#42422](#))
- When using multi-threaded data nodes, their `DataMemory` and `IndexMemory` usage as reported was multiplied by the number of local query handlers (worker threads), making it appear that much more memory was being used than was actually the case. ([Bug#42215](#))

See also [Bug#42765](#).

- Given a MySQL Cluster containing no data (that is, whose data nodes had all been started using `--initial`, and into which no data had yet been imported) and having an empty backup directory, executing `START BACKUP` with a user-specified backup ID caused the data nodes to crash. ([Bug#41031](#))
- In some cases, NDB did not check correctly whether tables had changed before trying to use the query cache. This could result in a crash of the debug MySQL server. ([Bug#40464](#))
- **Disk Data:** It was not possible to add an in-memory column online to a table that used a table-level or column-level `STORAGE DISK` option. The same issue prevented `ALTER ONLINE TABLE ... REORGANIZE PARTITION` from working on Disk Data tables. ([Bug#42549](#))
- **Disk Data:** Repeated insert and delete operations on disk-based tables could lead to failures in the NDB Tablespace Manager (TSMAN kernel block). ([Bug#40344](#))
- **Disk Data:** Creating a Disk Data tablespace with a very large extent size caused the data nodes to fail. The issue was observed when using extent sizes of 100 MB and larger. ([Bug#39096](#))
- **Disk Data:** Trying to execute a `CREATE LOGFILE GROUP` statement using a value greater than 150M for `UNDO_BUFFER_SIZE` caused data nodes to crash.

As a result of this fix, the upper limit for `UNDO_BUFFER_SIZE` is now 600M; attempting to set a higher value now fails

gracefully with an error. ([Bug#34102](#))

- **Disk Data:** When attempting to create a tablespace that already existed, the error message returned was `TABLE OR INDEX WITH GIVEN NAME ALREADY EXISTS`. ([Bug#32662](#))
- **Disk Data:** Using a path or filename longer than 128 characters for Disk Data undo log files and tablespace data files caused a number of issues, including failures of `CREATE LOGFILE GROUP`, `ALTER LOGFILE GROUP`, `CREATE TABLESPACE`, and `ALTER TABLESPACE` statements, as well as crashes of management nodes and data nodes.

With this fix, the maximum length for path and file names used for Disk Data undo log files and tablespace data files is now the same as the maximum for the operating system. ([Bug#31769](#), [Bug#31770](#), [Bug#31772](#))

- **Disk Data:** Attempting to perform a system restart of the cluster where there existed a logfile group without and undo log files caused the data nodes to crash.

Note

While issuing a `CREATE LOGFILE GROUP` statement without an `ADD UNDOFILE` option fails with an error in the MySQL server, this situation could arise if an SQL node failed during the execution of a valid `CREATE LOGFILE GROUP` statement; it is also possible to create a logfile group without any undo log files using the NDB API.

([Bug#17614](#))

- **Cluster Replication:** Being disconnected from the cluster while setting up the binary log caused `mysqld` to hang or crash. ([Bug#43045](#))
- **Cluster Replication:** Primary key updates on `MyISAM` and `InnoDB` tables failed to replicate to `NDBCLUSTER` tables. ([Bug#42921](#))
- **Cluster API:** Some error messages from `ndb_mgmd` contained newline (`\n`) characters. This could break the MGM API protocol, which uses the newline as a line separator. ([Bug#43104](#))
- **Cluster API:** When using an ordered index scan without putting all key columns in the read mask, this invalid use of the NDB API went undetected, which resulted in the use of uninitialized memory. ([Bug#42591](#))

17.15.1.6. Changes in MySQL Cluster NDB 6.4.2 (5.1.31-ndb-6.4.2) (28 January 2009)

This is a new Beta development release, incorporating new features in the `NDBCLUSTER` storage engine and fixing recently discovered bugs in MySQL Cluster NDB 6.4.1.

Obtaining MySQL Cluster NDB 6.4.2. MySQL Cluster NDB 6.4.2 is a source-only release. You can obtain the source code from ftp://ftp.mysql.com/pub/mysql/download/cluster_telco/mysql-5.1.31-ndb-6.4.2/.

This Beta release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.1, 6.2, 6.3, and 6.4 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.31 (see [Section C.1.7](#), “Changes in MySQL 5.1.31 (19 January 2009)”).

Note

This Beta release, as any other pre-production release, should not be installed on *production* level systems or systems with critical data. Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Bugs fixed:

- Connections using IPv6 were not handled correctly by `mysqld`. ([Bug#42413](#))
See also [Bug#42412](#), [Bug#38247](#).
- When a cluster backup failed with Error 1304 (Node `node_id1`: Backup request from `node_id2` failed to start), no clear reason for the failure was provided.
As part of this fix, MySQL Cluster now retries backups in the event of sequence errors. ([Bug#42354](#))
See also [Bug#22698](#).
- Issuing `SHOW ENGINE NDBCLUSTER STATUS` on an SQL node before the management server had connected to the cluster caused `mysqld` to crash. ([Bug#42264](#))

- When using `ndbmttd`, setting `MaxNoOfThreads` to a value higher than the actual number of cores available and with insufficient `SharedGlobalMemory` caused the data nodes to crash.

The fix for this issue changes the behavior of `ndbmttd` such that its internal job buffers no longer rely on `SharedGlobalMemory`. (Bug#42254)

17.15.1.7. Changes in MySQL Cluster NDB 6.4.1 (5.1.31-ndb-6.4.1) (21 January 2009)

This is a new Beta development release, incorporating new features in the `NDBCLUSTER` storage engine and fixing recently discovered bugs in MySQL Cluster NDB 6.4.0.

Obtaining MySQL Cluster NDB 6.4.1. MySQL Cluster NDB 6.4.1 is a source-only release. You can obtain the source code from ftp://ftp.mysql.com/pub/mysql/download/cluster_telco/mysql-5.1.31-ndb-6.4.1/.

This Beta release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.1, 6.2, 6.3, and 6.4 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.31 (see [Section C.1.7](#), “Changes in MySQL 5.1.31 (19 January 2009)”).

Note

This Beta release, as any other pre-production release, should not be installed on *production* level systems or systems with critical data. Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Functionality added or changed:

- **Important Change:** Formerly, when the management server failed to create a transporter for a data node connection, `net_write_timeout` seconds elapsed before the data node was actually allowed to disconnect. Now in such cases the disconnection occurs immediately. (Bug#41965)

See also [Bug#41713](#).

- Formerly, when using MySQL Cluster Replication, records for “empty” epochs — that is, epochs in which no changes to `NDBCLUSTER` data or tables took place — were inserted into the `ndb_apply_status` and `ndb_binlog_index` tables on the slave even when `--log-slave-updates` was disabled. Beginning with MySQL Cluster NDB 6.2.16 and MySQL Cluster NDB 6.3.13 this was changed so that these “empty” epochs were no longer logged. However, it is now possible to re-enable the older behavior (and cause “empty” epochs to be logged) by using the `--ndb-log-empty-epochs` option. For more information, see [Section 16.1.3.3](#), “Replication Slave Options and Variables”.

See also [Bug#37472](#).

- **Cluster Replication:** IPv6 networking is now supported between MySQL Cluster SQL nodes. This means that it is now possible to replicate between instances of MySQL Cluster using IPv6 addresses.

Important

Currently, other MySQL Cluster processes (`ndbd`, `ndbmttd`, `ndb_mgmd`, and `ndb_mgm`) do not support IPv6 connections. This means that all MySQL Cluster data nodes, management servers, and management clients must connect to and be accessible from one another using IPv4. In addition, SQL nodes must use IPv4 to communicate with the cluster. There is also not yet any support in the NDB and MGM APIs for IPv6, which means that applications written using the MySQL Cluster APIs must make connections using IPv4. For more information, see [Section 17.9.3](#), “Known Issues in MySQL Cluster Replication”.

Bugs fixed:

- A maximum of 11 `TUP` scans were allowed in parallel. (Bug#42084)
- The management server could hang after attempting to halt it with the `STOP` command in the management client. (Bug#42056)

See also [Bug#40922](#).

- When using `ndbmttd`, one thread could flood another thread, which would cause the system to stop with a `JOB BUFFER FULL` condition (currently implemented as an abort). This could be caused by committing or aborting a large transaction (50000 rows or more) on a single data node running `ndbmttd`. To prevent this from happening, the number of signals that can be accepted by the system threads is calculated before executing them, and only executing them if sufficient space is found. (Bug#42052)
- MySQL Cluster would not compile when using `libwrap`. This issue was known to occur only in MySQL Cluster NDB 6.4.0.

(Bug#41918)

- Trying to execute an `ALTER ONLINE TABLE ... ADD COLUMN` statement while inserting rows into the table caused `mysqld` to crash. (Bug#41905)
- When a data node connects to the management server, the node sends its node ID and transporter type; the management server then verifies that there is a transporter set up for that node and that it is in the correct state, and then sends back an acknowledgement to the connecting node. If the transporter was not in the correct state, no reply was sent back to the connecting node, which would then hang until a read timeout occurred (60 seconds). Now, if the transporter is not in the correct state, the management server acknowledges this promptly, and the node immediately disconnects. (Bug#41713)

See also Bug#41965.

- Issuing `EXIT` in the management client sometimes caused the client to hang. (Bug#40922)
- In the event that a MySQL Cluster backup failed due to file permissions issues, conflicting reports were issued in the management client. (Bug#34526)
- If all data nodes were shut down, MySQL clients were unable to access `NDBCLUSTER` tables and data even after the data nodes were restarted, unless the MySQL clients themselves were restarted. (Bug#33626)

17.15.1.8. Changes in MySQL Cluster NDB 6.4.0 (5.1.30-ndb-6.4.0) (22 December 2008)

This is a new Beta development release, incorporating new features in the `NDBCLUSTER` storage engine and fixing recently discovered bugs in previous MySQL Cluster releases.

Obtaining MySQL Cluster NDB 6.4.0. MySQL Cluster NDB 6.4.0 is a source-only release. You can obtain the source code from ftp://ftp.mysql.com/pub/mysql/download/cluster_telco/mysql-5.1.30-ndb-6.4.0/.

This Beta release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.1, 6.2, and 6.3 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.30 (see [Section C.1.8](#), “Changes in MySQL 5.1.30 (14 November 2008 General Availability)”).

Note

This Beta release, as any other pre-production release, should not be installed on *production* level systems or systems with critical data. Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Functionality added or changed:

- **Important Change:** MySQL Cluster now caches its configuration data. This means that, by default, the management server only reads the global configuration file (usually named `config.ini`) the first time that it is started, and does not automatically re-read this file when restarted. This behavior can be controlled using new management server options (`-config-dir`, `--initial`, and `--reload`) that have been added for this purpose. For more information, see [Section 17.3.4](#), “MySQL Cluster Configuration Files”, and [Section 17.6.24.3](#), “Program Options for `ndb_mgmd`”.
- It is now possible while in Single User Mode to restart all data nodes using `ALL RESTART` in the management client. Restarting of individual nodes while in Single User Mode remains disallowed. (Bug#31056)
- It is now possible to add data nodes to a MySQL Cluster online — that is, to a running MySQL Cluster without shutting it down.

For information about the procedure for adding data nodes online, see [Section 17.7.8](#), “Adding MySQL Cluster Data Nodes Online”.

- A multi-threaded version of the MySQL Cluster data node daemon is now available. The multi-threaded `ndbmt.d` binary is similar to `ndbd` and functions in much the same way, but is intended for use on machines with multiple CPU cores.

For more information, see [Section 17.6.3](#), “`ndbmt.d` — The MySQL Cluster Data Node Daemon (Multi-Threaded)”.

- It is now possible when performing a cluster backup to determine whether the backup matches the state of the data when the backup began or when it ended, using the new `START BACKUP` options `SNAPSHOTSTART` and `SNAPSHOTEND` in the management client. See [Section 17.7.3.2](#), “Using The MySQL Cluster Management Client to Create a Backup”, for more information.

Bugs fixed:

- API nodes disconnected too aggressively from cluster when data nodes were being restarted. This could sometimes lead to the API node being unable to access the cluster at all during a rolling restart. ([Bug#41462](#))
- When long signal buffer exhaustion in the `ndbd` process resulted in a signal being dropped, the usual handling mechanism did not take fragmented signals into account. This could result in a crash of the data node because the fragmented signal handling mechanism was not able to work with the missing fragments. ([Bug#39235](#))
- The failure of a master node during a DDL operation caused the cluster to be unavailable for further DDL operations until it was restarted; failures of non-master nodes during DLL operations caused the cluster to become completely inaccessible. ([Bug#36718](#))
- Status messages shown in the management client when restarting a management node were inappropriate and misleading. Now, when restarting a management node, the messages displayed are as follows, where `node_id` is the management node's node ID:

```
ndb_mgm> node_id RESTART
Shutting down MGM node node_id for restart
Node node_id is being restarted
ndb_mgm>
```

([Bug#29275](#))

- A data node failure when `NoOfReplicas` was greater than 2 caused all cluster SQL nodes to crash. ([Bug#18621](#))
- **Partitioning:** A query on a user-partitioned table caused MySQL to crash, where the query had the following characteristics:
 - The query's `WHERE` clause referenced an indexed column that was also in the partitioning key.
 - The query's `WHERE` clause included a value found in the partition.
 - The query's `WHERE` clause used the `<` or `<>` operators to compare with the indexed column's value with a constant.
 - The query used an `ORDER BY` clause, and the same indexed column was used in the `ORDER BY` clause.
 - The `ORDER BY` clause used an explicit or implicit `ASC` sort priority.

Two examples of such a query are given here, where `a` represents an indexed column used in the table's partitioning key:

1.

```
SELECT * FROM table WHERE a < constant ORDER BY a;
```

2.

```
SELECT * FROM table WHERE a <> constant ORDER BY a;
```

([Bug#40954](#))

This regression was introduced by [Bug#30573](#), [Bug#33257](#), [Bug#33555](#).

17.15.2. Changes in MySQL Cluster NDB 6.3

This section contains change history information for MySQL Cluster releases based on version 6.3 of the `NDBCLUSTER` storage engine.

For an overview of new features added in MySQL Cluster NDB 6.3, see [Section 17.13.4, "Features Added in MySQL Cluster NDB 6.3"](#).

17.15.2.1. Changes in MySQL Cluster NDB 6.3.26 (5.1.34-ndb-6.3.26) (Not yet released)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.3 release.

This release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.3 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.34 (see [Section C.1.3, "Changes in MySQL 5.1.34 \(02 April 2009\)"](#)).

Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Bugs fixed:

- An internal NDB API buffer was not properly initialized. ([Bug#44977](#))
- When a data node had written its GCI marker to the first page of a megabyte, and that node was later killed during restart after having processed that page (marker) but before completing a LCP, the data node could fail with filesystem errors. ([Bug#44952](#))

See also [Bug#42564](#).

- **Disk Data: Partitioning:** An `NDBCLUSTER` table created with a very large value for the `MAX_ROWS` option could — if this table was dropped and a new table with fewer partitions, but having the same table ID, was created — cause `ndbd` to crash when performing a system restart. This was because the server attempted to examine each partition whether or not it actually existed. ([Bug#45154](#))
- **Disk Data:** During a checkpoint, restore points are created for both the on-disk and in-memory parts of a Disk Data table. Under certain rare conditions, the in-memory restore point could include or exclude a row that should have been in the snapshot. This would later lead to a crash during or following recovery. ([Bug#41915](#))

17.15.2.2. Changes in MySQL Cluster NDB 6.3.25 (5.1.34-ndb-6.3.25) (25 May 2009)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.3 release.

This release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.3 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.34 (see [Section C.1.3, “Changes in MySQL 5.1.34 \(02 April 2009\)”](#)).

Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Functionality added or changed:

- Two new server status variables `Ndb_scan_count` and `Ndb_pruned_scan_count` have been introduced. `Ndb_scan_count` gives the number of scans executed since the cluster was last started. `Ndb_pruned_scan_count` gives the number of scans for which `NDBCLUSTER` was able to use partition pruning. Together, these variables can be used to help determine in the MySQL server whether table scans are pruned by `NDBCLUSTER`. ([Bug#44153](#))
- The `ndb_config` utility program can now provide an offline dump of all MySQL Cluster configuration parameters including information such as default and permitted values, brief description, and applicable section of the `config.ini` file. A dump in text format is produced when running `ndb_config` with the new `--configinfo` option, and in XML format when the options `--configinfo --xml` are used together. For more information and examples, see [Section 17.6.6, “ndb_config — Extract MySQL Cluster Configuration Information”](#).

Bugs fixed:

- **Important Change: Partitioning:** User-defined partitioning of an `NDBCLUSTER` table without any primary key sometimes failed, and could cause `mysqld` to crash.

Now, if you wish to create an `NDBCLUSTER` table with user-defined partitioning, the table must have an explicit primary key, and all columns listed in the partitioning expression must be part of the primary key. The hidden primary key used by the `NDBCLUSTER` storage engine is not sufficient for this purpose. However, if the list of columns is empty (that is, the table is defined using `PARTITION BY [LINEAR] KEY()`), then no explicit primary key is required.

This change does not effect the partitioning of tables using any storage engine other than `NDBCLUSTER`. ([Bug#40709](#))

- When `ndb_config` could not find the file referenced by the `--config-file` option, it tried to read `my.cnf` instead, then failed with a misleading error message. ([Bug#44846](#))
- When a data node was down so long that its most recent local checkpoint depended on a global checkpoint that was no longer restorable, it was possible for it to be unable to use optimized node recovery when being restarted later. ([Bug#44844](#))

See also [Bug#26913](#).

- Inspection of the code revealed that several assignment operators (`=`) were used in place of comparison operators (`==`) in `Db-dihMain.cpp`. ([Bug#44567](#))

See also [Bug#44570](#).

- It was possible for NDB API applications to insert corrupt data into the database, which could subsequently lead to data node crashes. Now, stricter checking is enforced on input data for inserts and updates. ([Bug#44132](#))
- `ndb_restore` failed when trying to restore data on a big-endian machine from a backup file created on a little-endian machine. ([Bug#44069](#))
- The file `ndberror.c` contained a C++-style comment, which caused builds to fail with some C compilers. ([Bug#44036](#))
- When trying to use a data node with an older version of the management server, the data node crashed on startup. ([Bug#43699](#))
- In some cases, data node restarts during a system restart could fail due to insufficient redo log space. ([Bug#43156](#))
- `NDBCLUSTER` did not build correctly on Solaris 9 platforms. ([Bug#39080](#))

See also [Bug#39036](#), [Bug#39038](#).

- `ndb_restore --print_data` did not handle `DECIMAL` columns correctly. ([Bug#37171](#))
- The output of `ndbd --help` did not provide clear information about the program's `--initial` and `--initial-start` options. ([Bug#28905](#))
- It was theoretically possible for the value of a nonexistent column to be read as `NULL`, rather than causing an error. ([Bug#27843](#))
- **Disk Data:** This fix supercedes and improves on an earlier fix made for this bug in MySQL 5.1.18. ([Bug#24521](#))
- **Cluster Replication:** A failure when setting up replication events could lead to subsequent data node failures. ([Bug#44915](#))

17.15.2.3. Changes in MySQL Cluster NDB 6.3.24 (5.1.32-ndb-6.3.24) (09 April 2009)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.3 release.

This is a source-only release. You can obtain the GPL source code for MySQL Cluster NDB 6.3.24 from ftp://ftp.mysql.com/pub/mysql/download/cluster_telco/mysql-5.1.32-ndb-6.3.24/.

This release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.3 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.32 (see [Section C.1.5](#), “Changes in MySQL 5.1.32 (14 February 2009)”).

Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Bugs fixed:

- **Cluster Replication:** If data node failed during an event creation operation, there was a slight risk that a surviving data node could send an invalid table reference back to NDB, causing the operation to fail with a false Error 723 (`NO SUCH TABLE`). This could take place when a data node failed as a `mysqld` process was setting up MySQL Cluster Replication. ([Bug#43754](#))
- **Cluster API:** Partition pruning did not work correctly for queries involving multiple range scans.

As part of the fix for this issue, several improvements have been made in the NDB API, including the addition of a new `NdbScanOperation::getPruned()` method, a new variant of `NdbIndexScanOperation::setBound()`, and a new `Ndb::PartitionSpec` data structure. For more information about these changes, see `NdbScanOperation::getPruned()`, `NdbIndexScanOperation::setBound()`, and [The PartitionSpec Structure](#). ([Bug#37934](#))

- `TransactionDeadlockDetectionTimeout` values less than 100 were treated as 100. This could cause scans to time out unexpectedly. ([Bug#44099](#))
- A race condition could occur when a data node failed to restart just before being included in the next global checkpoint. This could cause other data nodes to fail. ([Bug#43888](#))
- `TimeBetweenLocalCheckpoints` was measured from the end of one local checkpoint to the beginning of the next, rather than from the beginning of one LCP to the beginning of the next. This meant that the time spent performing the LCP was not taken into account when determining the `TimeBetweenLocalCheckpoints` interval, so that LCPs were not started often

enough, possibly causing data nodes to run out of redo log space prematurely. (Bug#43567)

- Using indexes containing variable-sized columns could lead to internal errors when the indexes were being built. (Bug#43226)
- When a data node process had been killed after allocating a node ID, but before making contact with any other data node processes, it was not possible to restart it due to a node ID allocation failure.

This issue could effect either `ndbd` or `ndbmt` processes. (Bug#43224)

This regression was introduced by Bug#42973.

- Some queries using combinations of logical and comparison operators on an indexed column in the `WHERE` clause could fail with the error `GOT ERROR 4541 'INDEXBOUND HAS NO BOUND INFORMATION' FROM NDBCLUSTER`. (Bug#42857)
- `ndb_restore` crashed when trying to restore a backup made to a MySQL Cluster running on a platform having different endianness from that on which the original backup was taken. (Bug#39540)
- When aborting an operation involving both an insert and a delete, the insert and delete were aborted separately. This was because the transaction coordinator did not know that the operations affected on same row, and, in the case of a committed-read (tuple or index) scan, the abort of the insert was performed first, then the row was examined after the insert was aborted but before the delete was aborted. In some cases, this would leave the row in a inconsistent state. This could occur when a local checkpoint was performed during a backup. This issue did not affect primary key operations or scans that used locks (these are serialized).

After this fix, for ordered indexes, all operations that follow the operation to be aborted are now also aborted.

- **Disk Data:** When a log file group had an undo log file whose size was too small, restarting data nodes failed with `READ UNDERFLOW` errors.

As a result of this fix, the minimum allowed `INITIAL_SIZE` for an undo log file is now `1M` (1 megabyte). (Bug#29574)

- **Cluster Replication:** When creating or altering a table an `NdbEventOperation` is created by the `mysqld` process to monitor the table for subsequent logging in the binlog. If this happened during a node restart there was a chance that the reference count on this event operation object could be incorrect, which could lead to an assert in debug MySQL Cluster builds. (Bug#43752)
- **Cluster API:** If the largest offset of a `RecordSpecification` used for an `NdbRecord` object was for the `NULL` bits (and thus not a column), this offset was not taken into account when calculating the size used for the `RecordSpecification`. This meant that the space for the `NULL` bits could be overwritten by key or other information. (Bug#43891)
- **Cluster API:** `BIT` columns created using the native NDB API format that were not created as nullable could still sometimes be overwritten, or cause other columns to be overwritten.

This issue did not effect tables having `BIT` columns created using the `mysqld` format (always used by MySQL Cluster SQL nodes). (Bug#43802)

- **Cluster API:** The default `NdbRecord` structures created by `NdbDictionary` could have overlapping null bits and data fields. (Bug#43590)
- **Cluster API:** When performing insert or write operations, `NdbRecord` allows key columns to be specified in both the key record and in the attribute record. Only one key column value for each key column should be sent to the NDB kernel, but this was not guaranteed. This is now ensured as follows: For insert and write operations, key column values are taken from the key record; for scan takeover update operations, key column values are taken from the attribute record. (Bug#42238)
- **Cluster API:** Ordered index scans using `NdbRecord` formerly expressed a `BoundEQ` range as separate lower and upper bounds, resulting in 2 copies of the column values being sent to the NDB kernel.

Now, when a range is specified by `NdbScanOperation::setBound()`, the passed pointers, key lengths, and inclusive bits are compared, and only one copy of the equal key columns is sent to the kernel. This makes such operations more efficient, as half the amount of `KeyInfo` is now sent for a `BoundEQ` range as before. (Bug#38793)

17.15.2.4. Changes in MySQL Cluster NDB 6.3.23 (5.1.32-ndb-6.3.23) (24 February 2009)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.3 release.

This is a source-only release. You can obtain the GPL source code for MySQL Cluster NDB 6.3.23 from ftp://ftp.mysql.com/pub/mysql/download/cluster_telco/mysql-5.1.32-ndb-6.3.23/.

This release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.3 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.32 (see Section C.1.5, “Changes in MySQL 5.1.32”).

(14 February 2009”).

Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Functionality added or changed:

- **Important Change: Replication:** `RESET MASTER` and `RESET SLAVE` now reset the values shown for `Last_IO_Error`, `Last_IO_Errno`, `Last_SQL_Error`, and `Last_SQL_Errno` in the output of `SHOW SLAVE STATUS`. (Bug#34654)
- A new data node configuration parameter `MaxLCPStartDelay` has been introduced to facilitate parallel node recovery by causing a local checkpoint to be delayed while recovering nodes are synchronizing data dictionaries and other meta-information. For more information about this parameter, see Section 17.3.4.6, “Defining MySQL Cluster Data Nodes”. (Bug#43053)

Bugs fixed:

- **Packaging:** Packages for MySQL Cluster were missing the `libndbclient.so` and `libndbclient.a` files. (Bug#42278)
- **Partitioning:** Executing `ALTER TABLE ... REORGANIZE PARTITION` on an `NDBCLUSTER` table having only one partition caused `mysqld` to crash. (Bug#41945)

See also Bug#40389.

- Backup IDs greater than 2^{31} were not handled correctly, causing negative values to be used in backup directory names and printouts. (Bug#43042)
- When using `ndbmttd`, NDB kernel threads could hang while trying to start the data nodes with `LockPagesInMainMemory` set to 1. (Bug#43021)
- When using multiple management servers and starting several API nodes (possibly including one or more SQL nodes) whose connectstrings listed the management servers in different order, it was possible for 2 API nodes to be assigned the same node ID. When this happened it was possible for an API node not to get fully connected, consequently producing a number of errors whose cause was not easily recognizable. (Bug#42973)
- `ndb_error_reporter` worked correctly only with GNU `tar`. (With other versions of `tar`, it produced empty archives.) (Bug#42753)
- Triggers on `NDBCLUSTER` tables caused such tables to become locked. (Bug#42751)

See also Bug#16229, Bug#18135.

- Given a MySQL Cluster containing no data (that is, whose data nodes had all been started using `--initial`, and into which no data had yet been imported) and having an empty backup directory, executing `START BACKUP` with a user-specified backup ID caused the data nodes to crash. (Bug#41031)
- In some cases, NDB did not check correctly whether tables had changed before trying to use the query cache. This could result in a crash of the debug MySQL server. (Bug#40464)
- **Disk Data:** It was not possible to add an in-memory column online to a table that used a table-level or column-level `STORAGE DISK` option. The same issue prevented `ALTER ONLINE TABLE ... REORGANIZE PARTITION` from working on Disk Data tables. (Bug#42549)
- **Disk Data:** Creating a Disk Data tablespace with a very large extent size caused the data nodes to fail. The issue was observed when using extent sizes of 100 MB and larger. (Bug#39096)
- **Disk Data:** Trying to execute a `CREATE LOGFILE GROUP` statement using a value greater than 150M for `UNDO_BUFFER_SIZE` caused data nodes to crash.

As a result of this fix, the upper limit for `UNDO_BUFFER_SIZE` is now 600M; attempting to set a higher value now fails gracefully with an error. (Bug#34102)

- **Disk Data:** When attempting to create a tablespace that already existed, the error message returned was `TABLE OR INDEX WITH GIVEN NAME ALREADY EXISTS`. (Bug#32662)
- **Disk Data:** Using a path or filename longer than 128 characters for Disk Data undo log files and tablespace data files caused a number of issues, including failures of `CREATE LOGFILE GROUP`, `ALTER LOGFILE GROUP`, `CREATE TABLESPACE`,

and `ALTER TABLESPACE` statements, as well as crashes of management nodes and data nodes.

With this fix, the maximum length for path and file names used for Disk Data undo log files and tablespace data files is now the same as the maximum for the operating system. ([Bug#31769](#), [Bug#31770](#), [Bug#31772](#))

- **Disk Data:** Attempting to perform a system restart of the cluster where there existed a logfile group without and undo log files caused the data nodes to crash.

Note

While issuing a `CREATE LOGFILE GROUP` statement without an `ADD UNDOFILE` option fails with an error in the MySQL server, this situation could arise if an SQL node failed during the execution of a valid `CREATE LOGFILE GROUP` statement; it is also possible to create a logfile group without any undo log files using the NDB API.

([Bug#17614](#))

- **Cluster Replication:** Being disconnected from the cluster while setting up the binary log caused `mysqld` to hang or crash. ([Bug#43045](#))
- **Cluster Replication:** Primary key updates on `MyISAM` and `InnoDB` tables failed to replicate to `NDBCLUSTER` tables. ([Bug#42921](#))
- **Cluster API:** Some error messages from `ndb_mgmd` contained newline (`\n`) characters. This could break the MGM API protocol, which uses the newline as a line separator. ([Bug#43104](#))
- **Cluster API:** When using an ordered index scan without putting all key columns in the read mask, this invalid use of the NDB API went undetected, which resulted in the use of uninitialized memory. ([Bug#42591](#))

17.15.2.5. Changes in MySQL Cluster NDB 6.3.22 (5.1.31-ndb-6.3.22) (09 February 2009)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.3 release.

This is a source-only release. You can obtain the GPL source code for MySQL Cluster NDB 6.3.22 from ftp://ftp.mysql.com/pub/mysql/download/cluster_telco/mysql-5.1.31-ndb-6.3.22/.

This release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.3 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.31 (see [Section C.1.7](#), “Changes in MySQL 5.1.31 (19 January 2009)”).

Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Functionality added or changed:

- New options are introduced for `ndb_restore` for determining which tables or databases should be restored:
 - `--include-tables` and `--include-databases` can be used to restore specific tables or databases.
 - `--exclude-tables` and `--exclude-databases` can be used to exclude the specified tables or databases from being restored.

For more information about these options, see [Section 17.6.17](#), “`ndb_restore` — Restore a MySQL Cluster Backup”. ([Bug#40429](#))

Bugs fixed:

- When performing more than 32 index or tuple scans on a single fragment, the scans could be left hanging. This caused unnecessary timeouts, and in addition could possibly lead to a hang of an LCP. ([Bug#42559](#))
- A data node failure that occurred between calls to `NdbIndexScanOperation::readTuples(SF_OrderBy)` and `NdbTransaction::Execute()` was not correctly handled; a subsequent call to `nextResult()` caused a null pointer to be dereferenced, leading to a segfault in `mysqld`. ([Bug#42545](#))
- Issuing `SHOW GLOBAL STATUS LIKE 'NDB%'` before `mysqld` had connected to the cluster caused a segmentation fault. ([Bug#42458](#))

- Data node failures that occurred before all data nodes had connected to the cluster were not handled correctly, leading to additional data node failures. ([Bug#42422](#))
- When a cluster backup failed with Error 1304 (Node `node_id1`: Backup request from `node_id2` failed to start), no clear reason for the failure was provided.

As part of this fix, MySQL Cluster now retries backups in the event of sequence errors. ([Bug#42354](#))

See also [Bug#22698](#).

- Issuing `SHOW ENGINE NDBCLUSTER STATUS` on an SQL node before the management server had connected to the cluster caused `mysqld` to crash. ([Bug#42264](#))

17.15.2.6. Changes in MySQL Cluster NDB 6.3.21 (5.1.31-ndb-6.3.21) (19 January 2009)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.3 release.

Note

MySQL Cluster NDB 6.3.21 was withdrawn due to issues discovered after its release.

This release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.3 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.31 (see [Section C.1.7, “Changes in MySQL 5.1.31 \(19 January 2009\)”](#)).

Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Functionality added or changed:

- **Important Change:** Formerly, when the management server failed to create a transporter for a data node connection, `net_write_timeout` seconds elapsed before the data node was actually allowed to disconnect. Now in such cases the disconnection occurs immediately. ([Bug#41965](#))
- See also [Bug#41713](#).
- It is now possible while in Single User Mode to restart all data nodes using `ALL RESTART` in the management client. Restarting of individual nodes while in Single User Mode remains disallowed. ([Bug#31056](#))
 - Formerly, when using MySQL Cluster Replication, records for “empty” epochs — that is, epochs in which no changes to `NDB-CLUSTER` data or tables took place — were inserted into the `ndb_apply_status` and `ndb_binlog_index` tables on the slave even when `--log-slave-updates` was disabled. Beginning with MySQL Cluster NDB 6.2.16 and MySQL Cluster NDB 6.3.13 this was changed so that these “empty” epochs were no longer logged. However, it is now possible to re-enable the older behavior (and cause “empty” epochs to be logged) by using the `--ndb-log-empty-epochs` option. For more information, see [Section 16.1.3.3, “Replication Slave Options and Variables”](#).

See also [Bug#37472](#).

Bugs fixed:

- A maximum of 11 `TUP` scans were allowed in parallel. ([Bug#42084](#))
- Trying to execute an `ALTER ONLINE TABLE ... ADD COLUMN` statement while inserting rows into the table caused `mysqld` to crash. ([Bug#41905](#))
- If the master node failed during a global checkpoint, it was possible in some circumstances for the new master to use an incorrect value for the global checkpoint index. This could occur only when the cluster used more than one node group. ([Bug#41469](#))
- API nodes disconnected too aggressively from cluster when data nodes were being restarted. This could sometimes lead to the API node being unable to access the cluster at all during a rolling restart. ([Bug#41462](#))
- It was not possible to perform online upgrades from a MySQL Cluster NDB 6.2 release to MySQL Cluster NDB 6.3.8 or a later MySQL Cluster NDB 6.3 release. ([Bug#41435](#))

- Cluster log files were opened twice by internal log-handling code, resulting in a resource leak. (Bug#41362)
- An abort path in the `DBLQH` kernel block failed to release a commit acknowledgement marker. This meant that, during node failure handling, the local query handler could be added multiple times to the marker record which could lead to additional node failures due an array overflow. (Bug#41296)
- During node failure handling (of a data node other than the master), there was a chance that the master was waiting for a `GCP_NODEFINISHED` signal from the failed node after having received it from all other data nodes. If this occurred while the failed node had a transaction that was still being committed in the current epoch, the master node could crash in the `DBTC` kernel block when discovering that a transaction actually belonged to an epoch which was already completed. (Bug#41295)
- Issuing `EXIT` in the management client sometimes caused the client to hang. (Bug#40922)
- In the event that a MySQL Cluster backup failed due to file permissions issues, conflicting reports were issued in the management client. (Bug#34526)
- If all data nodes were shut down, MySQL clients were unable to access `NDBCLUSTER` tables and data even after the data nodes were restarted, unless the MySQL clients themselves were restarted. (Bug#33626)
- **Disk Data:** Starting a cluster under load such that Disk Data tables used most of the undo buffer could cause data node failures. The fix for this bug also corrected an issue in the `LGMAN` kernel block where the amount of free space left in the undo buffer was miscalculated, causing buffer overruns. This could cause records in the buffer to be overwritten, leading to problems when restarting data nodes. (Bug#28077)
- **Cluster Replication:** Sometimes, when using the `--ndb_log_orig` option, the `orig_epoch` and `orig_server_id` columns of the `ndb_binlog_index` table on the slave contained the ID and epoch of the local server instead. (Bug#41601)
- **Cluster API:** `mgmapi.h` contained constructs which only worked in C++, but not in C. (Bug#27004)

17.15.2.7. Changes in MySQL Cluster NDB 6.3.20 (5.1.30-ndb-6.3.20) (17 December 2008)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.3 release.

Obtaining MySQL Cluster NDB 6.3.20. You can download MySQL Cluster NDB 6.3.20 source code and binaries for supported platforms from <http://dev.mysql.com/downloads/cluster>.

This release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.3 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.30 (see [Section C.1.8, “Changes in MySQL 5.1.30 \(14 November 2008 General Availability\)”](#)).

Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Bugs fixed:

- If a transaction was aborted during the handling of a data node failure, this could lead to the later handling of an API node failure not being completed. (Bug#41214)
- Issuing `SHOW TABLES` repeatedly could cause `NDBCLUSTER` tables to be dropped. (Bug#40854)
- Statements of the form `UPDATE ... ORDER BY ... LIMIT` run against `NDBCLUSTER` tables failed to update all matching rows, or failed with the error `CAN'T FIND RECORD IN 'TABLE_NAME'`. (Bug#40081)
- Start phase reporting was inconsistent between the management client and the cluster log. (Bug#39667)
- Status messages shown in the management client when restarting a management node were inappropriate and misleading. Now, when restarting a management node, the messages displayed are as follows, where `node_id` is the management node's node ID:

```
ndb_mgm> node_id RESTART
Shutting down MGM node node_id for restart
Node node_id is being restarted
ndb_mgm>
```

(Bug#29275)

- **Partitioning:** This bug was introduced in MySQL Cluster NDB 6.3.19. ([Bug#40954](#))

This regression was introduced by [Bug#30573](#), [Bug#33257](#), [Bug#33555](#).

- **Replication:** Issuing the statement `CHANGE MASTER TO ... MASTER_HEARTBEAT_PERIOD = period` using a value for *period* outside the permitted range caused the slave to crash. ([Bug#39077](#))
- **Disk Data:** This improves on a previous fix for this issue that was made in MySQL Cluster 6.3.8. ([Bug#37116](#))

See also [Bug#29186](#).

- **Cluster API:** When creating a scan using an `NdbScanFilter` object, it was possible to specify conditions against a `BIT` column, but the correct rows were not returned when the scan was executed.

As part of this fix, 4 new comparison operators have been implemented for use with scans on `BIT` columns:

- `COL_AND_MASK_EQ_MASK`
- `COL_AND_MASK_NE_MASK`
- `COL_AND_MASK_EQ_ZERO`
- `COL_AND_MASK_NE_ZERO`

For more information about these operators, see [The `NdbScanFilter::BinaryCondition` Type](#).

Equivalent methods are now also defined for `NdbInterpretedCode`; for more information, see [NdbInterpretedCode Bitwise Comparison Operations](#). ([Bug#40535](#))

17.15.2.8. Changes in MySQL Cluster NDB 6.3.19 (5.1.29-ndb-6.3.19) (21 November 2008)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.3 release.

This release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.3 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.29 (see [Section C.1.9](#), “Changes in MySQL 5.1.29 (11 October 2008)”).

Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Functionality added or changed:

- **Cluster API: Important Change:** MGM API applications exited without raising any errors if the connection to the management server was lost. The fix for this issue includes two changes:
 1. The MGM API now provides its own `SIGPIPE` handler to catch the “broken pipe” error that occurs when writing to a closed or reset socket. This means that MGM API now behaves the same as NDB API in this regard.
 2. A new function `ndb_mgm_set_ignore_sigpipe()` has been added to the MGM API. This function makes it possible to bypass the `SIGPIPE` handler provided by the MGM API. ([Bug#40498](#))
- **Cluster Replication: Important Note:** This release of MySQL Cluster derives in part from MySQL 5.1.29, where the default value for the `--binlog-format` option changed to `STATEMENT`. That change does *not* affect this or future MySQL Cluster NDB 6.x releases, where the default value for this option remains `MIXED`, since MySQL Cluster Replication does not work with the statement-based format. ([Bug#40586](#))
- When performing an initial start of a data node, fragment log files were always created sparsely — that is, not all bytes were written. Now it is possible to override this behavior using the new `InitFragmentLogFiles` configuration parameter. ([Bug#40847](#))

Bugs fixed:

- **Cluster API:** Failed operations on `BLOB` and `TEXT` columns were not always reported correctly to the originating SQL node. Such errors were sometimes reported as being due to timeouts, when the actual problem was a transporter overload due to in-

sufficient buffer space. ([Bug#39867](#), [Bug#39879](#))

- Undo logs and data files were created in 32K increments. Now these files are created in 512K increments, resulting in shorter creation times. ([Bug#40815](#))
- Redo log creation was very slow on some platforms, causing MySQL Cluster to start more slowly than necessary with some combinations of hardware and operating system. This was due to all write operations being synchronized to disk while creating a redo log file. Now this synchronization occurs only after the redo log has been created. ([Bug#40734](#))
- Transaction failures took longer to handle than was necessary.

When a data node acting as transaction coordinator (TC) failed, the surviving data nodes did not inform the API node initiating the transaction of this until the failure had been processed by all protocols. However, the API node needed only to know about failure handling by the transaction protocol — that is, it needed to be informed only about the TC takeover process. Now, API nodes (including MySQL servers acting as cluster SQL nodes) are informed as soon as the TC takeover is complete, so that it can carry on operating more quickly. ([Bug#40697](#))

- It was theoretically possible for stale data to be read from `NDBCLUSTER` tables when the transaction isolation level was set to `ReadCommitted`. ([Bug#40543](#))
- The `LockExecuteThreadToCPU` and `LockMaintThreadsToCPU` parameters did not work on Solaris. ([Bug#40521](#))
- `SET SESSION ndb_optimized_node_selection = 1` failed with an invalid warning message. ([Bug#40457](#))
- A restarting data node could fail with an error in the `DBDIH` kernel block when a local or global checkpoint was started or triggered just as the node made a request for data from another data node. ([Bug#40370](#))
- Restoring a MySQL Cluster from a dump made using `mysqldump` failed due to a spurious error: `CAN'T EXECUTE THE GIVEN COMMAND BECAUSE YOU HAVE ACTIVE LOCKED TABLES OR AN ACTIVE TRANSACTION`. ([Bug#40346](#))
- `O_DIRECT` was incorrectly disabled when making MySQL Cluster backups. ([Bug#40205](#))
- Heavy DDL usage caused the `mysqld` processes to hang due to a timeout error (NDB error code 266). ([Bug#39885](#))
- Executing `EXPLAIN SELECT` on an `NDBCLUSTER` table could cause `mysqld` to crash. ([Bug#39872](#))
- Events logged after setting `ALL CLUSTERLOG STATISTICS=15` in the management client did not always include the node ID of the reporting node. ([Bug#39839](#))
- The MySQL Query Cache did not function correctly with `NDBCLUSTER` tables containing `TEXT` columns. ([Bug#39295](#))
- A segfault in `Logger::Log` caused `ndbd` to hang indefinitely. This fix improves on an earlier one for this issue, first made in MySQL Cluster NDB 6.2.16 and MySQL Cluster NDB 6.3.17. ([Bug#39180](#))

See also [Bug#38609](#).

- Memory leaks could occur in handling of strings used for storing cluster metadata and providing output to users. ([Bug#38662](#))
- A duplicate key error raised when inserting into an `NDBCLUSTER` table caused the current transaction to abort, after which any SQL statement other than a `ROLLBACK` failed. With this fix, the `NDBCLUSTER` storage engine now supports rollback of individual statements in such cases, and it is no longer necessary to issue an explicit `ROLLBACK` and then retry the entire transaction. ([Bug#32656](#))
- Error messages for `NDBCLUSTER` error codes 1224 and 1227 were missing. ([Bug#28496](#))
- **Partitioning:** Dropping or creating an index on a partitioned table managed by the `InnoDB` Plugin locked the table. ([Bug#37453](#))
- **Disk Data:** Issuing concurrent `CREATE TABLESPACE`, `ALTER TABLESPACE`, `CREATE LOGFILE GROUP`, or `ALTER LOGFILE GROUP` statements on separate SQL nodes caused a resource leak that led to data node crashes when these statements were used again later. ([Bug#40921](#))
- **Disk Data:** Disk-based variable-length columns were not always handled like their memory-based equivalents, which could potentially lead to a crash of cluster data nodes. ([Bug#39645](#))
- **Disk Data:** `O_SYNC` was incorrectly disabled on platforms that do not support `O_DIRECT`. This issue was noted on Solaris but could have affected other platforms not having `O_DIRECT` capability. ([Bug#34638](#))
- **Cluster API:** The MGM API reset error codes on management server handles before checking them. This meant that calling an MGM API function with a null handle caused applications to crash. ([Bug#40455](#))

- **Cluster API:** It was not always possible to access parent objects directly from `NdbBlob`, `NdbOperation`, and `NdbScanOperation` objects. To alleviate this problem, a new `getNdbOperation()` method has been added to `NdbBlob` and new `getNdbTransaction()` methods have been added to `NdbOperation` and `NdbScanOperation`. In addition, a const variant of `NdbOperation::getErrorLine()` is now also available. (Bug#40242)
- **Cluster API:** `NdbScanOperation::getBlobHandle()` failed when used with incorrect column names or numbers. (Bug#40241)
- **Cluster API:** The MGM API function `ndb_mgm_listen_event()` ignored bind addresses.
As part of this fix, it is now possible to specify bind addresses in connectstrings. See Section 17.3.4.3, “The MySQL Cluster Connectstring”, for more information. (Bug#38473)
- **Cluster API:** The NDB API example programs included in MySQL Cluster source distributions failed to compile. (Bug#37491)

See also Bug#40238.

17.15.2.9. Changes in MySQL Cluster NDB 6.3.18 (5.1.28-ndb-6.3.18) (03 October 2008)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.3 release.

Obtaining MySQL Cluster NDB 6.3. You can download the latest MySQL Cluster NDB 6.3 source code and binaries for supported platforms from <http://dev.mysql.com/downloads/cluster>.

This release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.3 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.28 (see Section C.1.10, “Changes in MySQL 5.1.28 (28 August 2008)”).

Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Functionality added or changed:

- It is no longer a requirement for database autodiscovery that an SQL node already be connected to the cluster at the time that a database is created on another SQL node. It is no longer necessary to issue `CREATE DATABASE` (or `CREATE SCHEMA`) statements on an SQL node joining the cluster after a database is created in order for the new SQL node to see the database and any `NDCLUSTER` tables that it contains. (Bug#39612)

Bugs fixed:

- When a transaction included a multi-row insert to an `NDBCLUSTER` table that caused a constraint violation, the transaction failed to roll back. (Bug#395638)
- Starting the MySQL Server with the `--ndbcluster` option plus an invalid command-line option (for example, using `mysqld --ndbcluster --foobar`) caused it to hang while shutting down the binlog thread. (Bug#39635)
- Dropping and then re-creating a database on one SQL node caused other SQL nodes to hang. (Bug#39613)
- Setting a low value of `MaxNoOfLocalScans` (< 100) and performing a large number of (certain) scans could cause the Transaction Coordinator to run out of scan fragment records, and then crash. Now when this resource is exhausted, the cluster returns Error 291 (`OUT OF SCANFRAG RECORDS IN TC (INCREASE MAXNOOFLOCALSCANS)`) instead. (Bug#39549)
- Creating a unique index on an `NDBCLUSTER` table caused a memory leak in the `NDB` subscription manager (`SUMA`) which could lead to `mysqld` hanging, due to the fact that the resource shortage was not reported back to the `NDB` kernel correctly. (Bug#39518)

See also Bug#39450.

- Embedded `libmysqld` with `NDB` did not drop table events. (Bug#39450)
- Unique identifiers in tables having no primary key were not cached. This fix has been observed to increase the efficiency of `INSERT` operations on such tables by as much as 50%. (Bug#39267)
- When restarting a data node, an excessively long shutdown message could cause the node process to crash. (Bug#38580)

- After a forced shutdown and initial restart of the cluster, it was possible for SQL nodes to retain `.FRM` files corresponding to `NDBCLUSTER` tables that had been dropped, and thus to be unaware that these tables no longer existed. In such cases, attempting to re-create the tables using `CREATE TABLE IF NOT EXISTS` could fail with a spurious `TABLE ... DOESN'T EXIST` error. (Bug#37921)
- A statement of the form `DELETE FROM table WHERE primary_key=value` or `UPDATE table WHERE primary_key=value` where there was no row whose primary key column had the stated `value` appeared to succeed, with the server reporting that 1 row had been changed.
This issue was only known to affect MySQL Cluster NDB 6.3.11 and later NDB 6.3 versions. (Bug#37153)
- **Cluster Replication:** In some cases, dropping a database on the master could cause table logging to fail on the slave, or, when using a debug build, could cause the slave `mysqld` to fail completely. (Bug#39404)
- **Cluster API:** Passing a value greater than 65535 to `NdbInterpretedCode::add_val()` and `NdbInterpretedCode::sub_val()` caused these methods to have no effect. (Bug#39536)

17.15.2.10. Changes in MySQL Cluster NDB 6.3.17 (5.1.27-ndb-6.3.17) (28 August 2008)

This is a new release, fixing recently discovered bugs in previous MySQL Cluster NDB 6.3 releases.

Obtaining MySQL Cluster NDB 6.3. Previously, MySQL Cluster NDB 6.3 releases were source-only releases which required compiling and installing using the instructions found in [Section 2.10, “MySQL Installation Using a Source Distribution”](#), and in [Section 17.3.1, “Building MySQL Cluster from Source Code”](#). Beginning with MySQL Cluster NDB 6.3.17, binaries built from NDB 6.3 sources are also available. You can download the latest MySQL Cluster NDB 6.2 source code and binaries for supported platforms from <http://dev.mysql.com/downloads/cluster>.

This release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.3 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.27 (see [Section C.1.11, “Changes in MySQL 5.1.27 \(Not released\)”](#)).

Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Bugs fixed:

- **Packaging:** Support for the `InnoDB` storage engine was missing from the GPL source releases. An updated GPL source tarball `mysql-5.1.27-ndb-6.3.17-innodb.tar.gz` which includes code for building `InnoDB` can be found on [the MySQL FTP site](#).
- `MgmtSrvr::allocNodeId()` left a mutex locked following an `AMBIGUITY FOR NODE IF %D` error. (Bug#39158)
- An invalid path specification caused `mysql-test-run.pl` to fail. (Bug#39026)
- During transactional coordinator takeover (directly after node failure), the LQH finding an operation in the `LOG_COMMIT` state sent an `LQH_TRANS_CONF` signal twice, causing the TC to fail. (Bug#38930)
- An invalid memory access caused the management server to crash on Solaris Sparc platforms. (Bug#38628)
- A segfault in `Logger::Log` caused `ndbd` to hang indefinitely. (Bug#38609)
- `ndb_mgmd` failed to start on older Linux distributions (2.4 kernels) that did not support e-polling. (Bug#38592)
- `ndb_mgmd` sometimes performed unnecessary network I/O with the client. This in combination with other factors led to long-running threads that were attempting to write to clients that no longer existed. (Bug#38563)
- `ndb_restore` failed with a floating point exception due to a division by zero error when trying to restore certain data files. (Bug#38520)
- A failed connection to the management server could cause a resource leak in `ndb_mgmd`. (Bug#38424)
- Failure to parse configuration parameters could cause a memory leak in the NDB log parser. (Bug#38380)
- Renaming an `NDBCLUSTER` table on one SQL node, caused a trigger on this table to be deleted on another SQL node. (Bug#36658)
- Attempting to add a `UNIQUE INDEX` twice to an `NDBCLUSTER` table, then deleting rows from the table could cause the

MySQL Server to crash. (Bug#35599)

- `ndb_restore` failed when a single table was specified. (Bug#33801)
- `GCP_COMMIT` did not wait for transaction takeover during node failure. This could cause `GCP_SAVE_REQ` to be executed too early. This could also cause (very rarely) replication to skip rows. (Bug#30780)
- **Cluster Replication:** During a parallel node restart, the starting nodes could (sometimes) incorrectly synchronize subscriptions among themselves. Instead, this synchronization now takes place only among nodes that have actually (completely) started. (Bug#38767)
- **Cluster API:** Support for Multi-Range Read index scans using the old API (using, for example, `NdbIndexScanOperation::setBound()` or `NdbIndexScanOperation::end_of_bound()`) were dropped in MySQL Cluster NDB 6.2. This functionality is restored in MySQL Cluster NDB 6.3 beginning with 6.3.17, but remains unavailable in MySQL Cluster NDB 6.2. Both MySQL Cluster NDB 6.2 and 6.3 support Multi-Range Read scans via the `NdbRecord` API. (Bug#38791)
- **Cluster API:** The `NdbScanOperation::readTuples()` method could be called multiple times without error. (Bug#38717)
- **Cluster API:** Certain Multi-Range Read scans involving `IS NULL` and `IS NOT NULL` comparisons failed with an error in the NDB local query handler. (Bug#38204)
- **Cluster API:** Problems with the public headers prevented NDB applications from being built with warnings turned on. (Bug#38177)
- **Cluster API:** Creating an `NdbScanFilter` object using an `NdbScanOperation` object that had not yet had its `readTuples()` method called resulted in a crash when later attempting to use the `NdbScanFilter`. (Bug#37986)
- **Cluster API:** Executing an `NdbRecord` interpreted delete created with an `ANYVALUE` option caused the transaction to abort. (Bug#37672)

17.15.2.11. Changes in MySQL Cluster NDB 6.3.16 (5.1.24-ndb-6.3.16) (27 June 2008)

This is a new source release, fixing recently discovered bugs in previous MySQL Cluster NDB 6.3 releases.

Obtaining MySQL Cluster NDB 6.3. This is a source-only release, which you must compile and install using the instructions found in Section 2.10, “MySQL Installation Using a Source Distribution”, and in Section 17.3.1, “Building MySQL Cluster from Source Code”. You can download the GPL source tarball from the MySQL FTP site at ftp://ftp.mysql.com/pub/mysql/download/cluster_telco/.

This release incorporates all bugfixes and changes made in the previous MySQL Cluster NDB 6.3 release, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.24 (see Section C.1.14, “Changes in MySQL 5.1.24 (08 April 2008)”).

Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Functionality added or changed:

- Event buffer lag reports are now written to the cluster log. (Bug#37427)
- Added the `--no-binlog` option for `ndb_restore`. When used, this option prevents information being written to SQL node binary logs from the restoration of a cluster backup. (Bug#30452)

Bugs fixed:

- **Cluster API:** Changing the system time on data nodes could cause MGM API applications to hang and the data nodes to crash. (Bug#35607)
- Failure of a data node could sometimes cause `mysqld` to crash. (Bug#37628)
- `DELETE ... WHERE unique_index_column=value` deleted the wrong row from the table. (Bug#37516)
- If subscription was terminated while a node was down, the epoch was not properly acknowledged by that node. (Bug#37442)

- `libmysqld` failed to wait for the cluster binlog thread to terminate before exiting. (Bug#37429)
- In rare circumstances, a connection followed by a disconnection could give rise to a “stale” connection where the connection still existed but was not seen by the transporter. (Bug#37338)
- Queries against `NDBCLUSTER` tables were cached only if `autocommit` was in use. (Bug#36692)
- **Cluster Replication:** Data was written to the binlog with `--log-slave-updates` disabled. (Bug#37472)
- **Cluster API:** When some operations succeeded and some failed following a call to `NdbTransaction::execute(Commit, AO_IgnoreOnError)`, a race condition could cause spurious occurrences of NDB API Error 4011 (`INTERNAL ERROR`). (Bug#37158)
- **Cluster API:** Creating a table on an SQL node, then starting an NDB API application that listened for events from this table, then dropping the table from an SQL node, prevented data node restarts. (Bug#32949, Bug#37279)
- **Cluster API:** A buffer overrun in `NdbBlob::setValue()` caused erroneous results on Mac OS X. (Bug#31284)

17.15.2.12. Changes in MySQL Cluster NDB 6.3.15 (5.1.24-ndb-6.3.15) (30 May 2008)

This is a new source release, fixing recently discovered bugs in previous MySQL Cluster NDB 6.3 releases.

Obtaining MySQL Cluster NDB 6.3. This is a source-only release, which you must compile and install using the instructions found in Section 2.10, “MySQL Installation Using a Source Distribution”, and in Section 17.3.1, “Building MySQL Cluster from Source Code”. You can download the GPL source tarball from the MySQL FTP site at ftp://ftp.mysql.com/pub/mysql/download/cluster_telco/.

This release incorporates all bugfixes and changes made in the previous MySQL Cluster NDB 6.3 release, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.24 (see Section C.1.14, “Changes in MySQL 5.1.24 (08 April 2008)”).

Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Bugs fixed:

- In certain rare situations, `ndb_size.pl` could fail with the error `CAN'T USE STRING ("VALUE") AS A HASH REF WHILE "STRICT REFS" IN USE`. (Bug#43022)
- Under some circumstances, a failed `CREATE TABLE` could mean that subsequent `CREATE TABLE` statements caused node failures. (Bug#37092)
- A fail attempt to create an `NDB` table could in some cases lead to resource leaks or cluster failures. (Bug#37072)
- Attempting to create a native backup of `NDB` tables having a large number of `NULL` columns and data could lead to node failures. (Bug#37039)
- Checking of API node connections was not efficiently handled. (Bug#36843)
- Attempting to delete a non-existent row from a table containing a `TEXT` or `BLOB` column within a transaction caused the transaction to fail. (Bug#36756)

See also Bug#36851.

- If the combined total of tables and indexes in the cluster was greater than 4096, issuing `START BACKUP` caused data nodes to fail. (Bug#36044)
- Where column values to be compared in a query were of the `VARCHAR` or `VARBINARY` types, `NDBCLUSTER` passed a value padded to the full size of the column, which caused unnecessary data to be sent to the data nodes. This also had the effect of wasting CPU and network bandwidth, and causing condition pushdown to be disabled where it could (and should) otherwise have been applied. (Bug#35393)
- When dropping a table failed for any reason (such as when in single user mode) then the corresponding `.ndb` file was still removed.
- **Replication:** When flushing tables, there was a slight chance that the flush occurred between the processing of one table map event and the next. Since the tables were opened one by one, subsequent locking of tables would cause the slave to crash. This

problem was observed when replicating `NDBCLUSTER` or `InnoDB` tables, when executing multi-table updates, and when a trigger or a stored routine performed an (additional) insert on a table so that two tables were effectively being inserted into in the same statement. (Bug#36197)

- **Cluster API:** Ordered index scans were not pruned correctly where a partitioning key was specified with an EQ-bound. (Bug#36950)
 - **Cluster API:** When an insert operation involving `BLOB` data was attempted on a row which already existed, no duplicate key error was correctly reported and the transaction is incorrectly aborted. In some cases, the existing row could also become corrupted. (Bug#36851)
- See also Bug#26756.
- **Cluster API:** `NdbApi.hpp` depended on `ndb_global.h`, which was not actually installed, causing the compilation of programs that used `NdbApi.hpp` to fail. (Bug#35853)

17.15.2.13. Changes in MySQL Cluster NDB 6.3.14 (5.1.24-ndb-6.3.14) (11 May 2008)

This is a new source release, fixing recently discovered bugs in previous MySQL Cluster NDB 6.3 releases.

Obtaining MySQL Cluster NDB 6.3. This is a source-only release, which you must compile and install using the instructions found in Section 2.10, “MySQL Installation Using a Source Distribution”, and in Section 17.3.1, “Building MySQL Cluster from Source Code”. You can download the GPL source tarball from the MySQL FTP site at ftp://ftp.mysql.com/pub/mysql/download/cluster_telco/.

This release incorporates all bugfixes and changes made in the previous MySQL Cluster NDB 6.3 release, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.24 (see Section C.1.14, “Changes in MySQL 5.1.24 (08 April 2008)”).

Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Bugs fixed:

- `SET GLOBAL ndb_extra_logging` caused `mysqld` to crash. (Bug#36547)
- A race condition caused by a failure in `epoll` handling could cause data nodes to fail. (Bug#36537)
- Under certain rare circumstances, the failure of the new master node while attempting a node takeover would cause takeover errors to repeat without being resolved. (Bug#36199, Bug#36246, Bug#36247, Bug#36276)
- When more than one SQL node connected to the cluster at the same time, creation of the `mysql.ndb_schema` table failed on one of them with an explicit `TABLE EXISTS` error, which was not necessary. (Bug#35943)
- `mysqld` failed to start after running `mysql_upgrade`. (Bug#35708)
- Notification of a cascading master node failures could sometimes not be transmitted correctly (that is, transmission of the `NF_COMPLETE` signal could fail), leading to transactions hanging and timing out (NDB error 4012), scans hanging, and failure of the management server process. (Bug#32645)
- If an API node disconnected and then reconnected during Start Phase 8, then the connection could be “blocked” — that is, the `QMGR` kernel block failed to detect that the API node was in fact connected to the cluster, causing issues with the NDB Subscription Manager (SUMA).
- NDB error 1427 (`API NODE DIED, WHEN SUB_START_REQ REACHED NODE`) was incorrectly classified as a schema error rather than a temporary error.
- **Cluster Replication:** Performing `SELECT ... FROM mysql.ndb_apply_status` before the `mysqld` process had connected to the cluster failed, and caused this table never to be created. (Bug#36123)
- **Cluster API:** Accessing the debug version of `libndbclient` via `dlopen()` resulted in a segmentation fault. (Bug#35927)
- **Cluster API:** Attempting to pass a non-existent column name to the `equal()` and `setValue()` methods of `NdbOperation` caused NDB API applications to crash. Now the column name is checked, and an error is returned in the event that the column is not found. (Bug#33747)
- **Cluster API:** Relocation errors were encountered when trying to compile NDB API applications on a number of platforms, in-

cluding 64-bit Linux. As a result, `libmysys`, `libmystrings`, and `libdbug` have been changed from normal libraries to “noinst” `libtool` helper libraries. They are no longer installed as separate libraries; instead, all necessary symbols from these are added directly to `libndbclient`. This means that NDB API programs now need to be linked only using `-lndbclient`. (Bug#29791)

17.15.2.14. Changes in MySQL Cluster NDB 6.3.13 (5.1.24-ndb-6.3.13) (10 April 2008)

This is a new source release, fixing recently discovered bugs in previous MySQL Cluster NDB 6.3 releases.

Obtaining MySQL Cluster NDB 6.3. This is a source-only release, which you must compile and install using the instructions found in Section 2.10, “MySQL Installation Using a Source Distribution”, and in Section 17.3.1, “Building MySQL Cluster from Source Code”. You can download the GPL source tarball from the MySQL FTP site at ftp://ftp.mysql.com/pub/mysql/download/cluster_telco/.

This release incorporates all bugfixes and changes made in the previous MySQL Cluster NDB 6.3 release, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.24 (see Section C.1.14, “Changes in MySQL 5.1.24 (08 April 2008)”).

Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Functionality added or changed:

- The `ndbd` and `ndb_mgmd` man pages have been reclassified from volume 1 to volume 8. (Bug#34642)

Bugs fixed:

- **Important Change:** `mysqld_safe` now traps Signal 13 (`SIGPIPE`) so that this signal no longer kills the MySQL server process. (Bug#33984)
- Node or system restarts could fail due an uninitialized variable in the `DTUP` kernel block. This issue was found in MySQL Cluster NDB 6.3.11. (Bug#35797)
- If an error occurred while executing a statement involving a `BLOB` or `TEXT` column of an `NDB` table, a memory leak could result. (Bug#35593)
- It was not possible to determine the value used for the `--ndb-cluster-connection-pool` option in the `mysql` client. Now this value is reported as a system status variable. (Bug#35573)
- The `ndb_waiter` utility wrongly calculated timeouts. (Bug#35435)
- A `SELECT` on a table with a non-indexed, large `VARCHAR` column which resulted in condition pushdown on this column could cause `mysqld` to crash. (Bug#35413)
- `ndb_restore` incorrectly handled some datatypes when applying log files from backups. (Bug#35343)
- In some circumstances, a stopped data node was handled incorrectly, leading to redo log space being exhausted following an initial restart of the node, or an initial or partial restart of the cluster (the wrong CGI might be used in such cases). This could happen, for example, when a node was stopped following the creation of a new table, but before a new LCP could be executed. (Bug#35241)
- `SELECT ... LIKE ...` queries yielded incorrect results when used on `NDB` tables. As part of this fix, condition pushdown of such queries has been disabled; re-enabling it is expected to be done as part of a later, permanent fix for this issue. (Bug#35185)
- `ndb_mgmd` reported errors to `STDOUT` rather than to `STDERR`. (Bug#35169)
- Nested Multi-Range Read scans failed when the second Multi-Range Read released the first read's unprocessed operations, sometimes leading to an SQL node crash. (Bug#35137)
- In some situations, a problem with synchronizing checkpoints between nodes could cause a system restart or a node restart to fail with `ERROR 630 DURING RESTORE OF TX`. (Bug#34756)
- A node failure during an initial node restart followed by another node start could cause the master data node to fail, because it incorrectly gave the node permission to start even if the invalidated node's LCP was still running. (Bug#34702)

- When a secondary index on a `DECIMAL` column was used to retrieve data from an `NDB` table, no results were returned even if the target table had a matched value in the column that was defined with the secondary index. (Bug#34515)
- An `UPDATE` on an `NDB` table that set a new value for a unique key column could cause subsequent queries to fail. (Bug#34208)
- If a data node in one node group was placed in the “not started” state (using `node_id RESTART -n`), it was not possible to stop a data node in a different node group. (Bug#34201)
- Numerous `NDBCLUSTER` test failures occurred in builds compiled using `icc` on IA64 platforms. (Bug#31239)
- If a `START BACKUP` command was issued while `ndb_restore` was running, the backup being restored could be overwritten. (Bug#26498)
- `REPLACE` statements did not work correctly with `NDBCLUSTER` tables when all columns were not explicitly listed. (Bug#22045)
- `CREATE TABLE` and `ALTER TABLE` statements using `ENGINE=NDB` or `ENGINE=NDBCLUSTER` caused `mysqld` to fail on Solaris 10 for x86 platforms. (Bug#19911)
- **Replication:** A `CHANGE MASTER TO` statement with no `MASTER_HEARTBEAT_PERIOD` option failed to reset the heartbeat period to its default value. (Bug#34686)
- **Cluster Replication:** In some cases, when updating only one or some columns in a table, the complete row was written to the binary log instead of only the updated column or columns, even when `ndb_log_updated_only` was set to 1. (Bug#35208)
- **Cluster Replication:** Enabling the `ndb_wait_connected` system variable caused the server to wait for a partial connection plus an additional 3 seconds for a complete connection to the cluster. This could lead to issues with setting up the binary log. (Bug#34757)
- **Cluster API:** Closing a scan before it was executed caused the application to segfault. (Bug#36375)
- **Cluster API:** Using `NDB` API applications from older MySQL Cluster versions with `libndbclient` from newer ones caused the cluster to fail. (Bug#36124)
- **Cluster API:** Some ordered index scans could return tuples out of order. (Bug#35908)
- **Cluster API:** Scans having no bounds set were handled incorrectly. (Bug#35876)
- **Cluster API:** `NdbScanFilter::getNdbOperation()`, which was inadvertently removed in MySQL Cluster NDB 6.3.11, has been restored. (Bug#35854)
- Enabling the `read_only` system variable while autocommit mode was enabled caused `SELECT` statements for transactional storage engines to fail. (Bug#35732)
- Executing a `FLUSH PRIVILEGES` statement after creating a temporary table in the `mysql` database with the same name as one of the MySQL system tables caused the server to crash.

Note

While it is possible to shadow a system table in this way, the temporary table exists only for the current user and connection, and does not effect any user privileges. (Bug#33275)

17.15.2.15. Changes in MySQL Cluster NDB 6.3.12 (5.1.23-ndb-6.3.12) (05 April 2008)

MySQL Cluster NDB 6.3.12 was pulled due to issues discovered shortly after its release, and is no longer available. Users of MySQL Cluster NDB 6.3.10 and earlier MySQL Cluster NDB 6.3 releases should upgrade to MySQL Cluster NDB 6.3.13 or later.

For information about bugfixes and feature enhancements that were originally scheduled to appear for the first time in this release, see [Section 17.15.2.14, “Changes in MySQL Cluster NDB 6.3.13 \(5.1.24-ndb-6.3.13\) \(10 April 2008\)”](#).

17.15.2.16. Changes in MySQL Cluster NDB 6.3.11 (5.1.23-ndb-6.3.11) (28 March 2008)

This release was pulled due to issues discovered shortly after its release, and is no longer available. Users of MySQL Cluster NDB 6.3.10 and earlier MySQL Cluster NDB 6.3 releases should upgrade to MySQL Cluster NDB 6.3.13 or later.

For information about bugfixes and feature enhancements that were originally scheduled to appear for the first time in this release, see [Section 17.15.2.14, “Changes in MySQL Cluster NDB 6.3.13 \(5.1.24-ndb-6.3.13\) \(10 April 2008\)”](#).

17.15.2.17. Changes in MySQL Cluster NDB 6.3.10 (5.1.23-ndb-6.3.10) (17 February 2008)

This is a new Beta development release, fixing recently discovered bugs in previous MySQL Cluster NDB 6.3 releases.

Obtaining MySQL Cluster NDB 6.3. This is a source-only release, which you must compile and install using the instructions found in [Section 2.10, “MySQL Installation Using a Source Distribution”](#), and in [Section 17.3.1, “Building MySQL Cluster from Source Code”](#). You can download the GPL source tarball from the MySQL FTP site at ftp://ftp.mysql.com/pub/mysql/download/cluster_telco/.

This Beta release incorporates all bugfixes and changes made in the previous MySQL Cluster NDB 6.3 release, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.23 (see [Section C.1.15, “Changes in MySQL 5.1.23 \(29 January 2008\)”](#)).

Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Bugs fixed:

- Due to the reduction of the number of local checkpoints from 3 to 2 in MySQL Cluster NDB 6.3.8, a data node using ndbd from MySQL Cluster NDB 6.3.8 or later started using a file system from an earlier version could incorrectly invalidate local checkpoints too early during the startup process, causing the node to fail. ([Bug#34596](#))

17.15.2.18. Changes in MySQL Cluster NDB 6.3.9 (5.1.23-ndb-6.3.9) (12 February 2008)

This is a new Beta development release, fixing recently discovered bugs in previous MySQL Cluster NDB 6.3 releases.

Obtaining MySQL Cluster NDB 6.3. This is a source-only release, which you must compile and install using the instructions found in [Section 2.10, “MySQL Installation Using a Source Distribution”](#), and in [Section 17.3.1, “Building MySQL Cluster from Source Code”](#). You can download the GPL source tarball from the MySQL FTP site at ftp://ftp.mysql.com/pub/mysql/download/cluster_telco/.

This Beta release incorporates all bugfixes and changes made in the previous MySQL Cluster NDB 6.3 release, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.23 (see [Section C.1.15, “Changes in MySQL 5.1.23 \(29 January 2008\)”](#)).

Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Functionality added or changed:

- Beginning with this version, MySQL Cluster NDB 6.3.x releases once again include the [InnoDB](#) storage engine. In order to enable [InnoDB](#), you must configure the build using `--with-innodb`.

Bugs fixed:

- Cluster failures could sometimes occur when performing more than three parallel takeovers during node restarts or system restarts. This affected MySQL Cluster NDB 6.3.x releases only. ([Bug#34445](#))
- Upgrades of a cluster using while a [DataMemory](#) setting in excess of 16 GB caused data nodes to fail. ([Bug#34378](#))
- Performing many SQL statements on [NDB](#) tables while in `autocommit` mode caused a memory leak in `mysqld`. ([Bug#34275](#))
- In certain rare circumstances, a race condition could occur between an aborted insert and a delete leading a data node crash. ([Bug#34260](#))
- Multi-table updates using ordered indexes during handling of node failures could cause other data nodes to fail. ([Bug#34216](#))
- When configured with [NDB](#) support, MySQL failed to compile using `gcc` 4.3 on 64bit FreeBSD systems. ([Bug#34169](#))
- The failure of a DDL statement could sometimes lead to node failures when attempting to execute subsequent DDL statements. ([Bug#34160](#))

- Extremely long `SELECT` statements (where the text of the statement was in excess of 50000 characters) against NDB tables returned empty results. (Bug#34107)
- When configured with NDB support, MySQL failed to compile on 64bit FreeBSD systems. (Bug#34046)
- Statements executing multiple inserts performed poorly on NDB tables having `AUTO_INCREMENT` columns. (Bug#33534)
- The `ndb_waiter` utility polled `ndb_mgmd` excessively when obtaining the status of cluster data nodes. (Bug#32025)
See also Bug#32023.
- Transaction atomicity was sometimes not preserved between reads and inserts under high loads. (Bug#31477)
- Having tables with a great many columns could cause Cluster backups to fail. (Bug#30172)
- **Cluster Replication: Disk Data:** Statements violating unique keys on Disk Data tables (such as attempting to insert `NULL` into a `NOT NULL` column) could cause data nodes to fail. When the statement was executed from the binlog, this could also result in failure of the slave cluster. (Bug#34118)
- **Disk Data:** Updating in-memory columns of one or more rows of Disk Data table, followed by deletion of these rows and re-insertion of them, caused data node failures. (Bug#33619)
- **Cluster Replication:** Setting `--replicate-ignore-db=mysql` caused the `mysql.ndb_apply_status` table not to be replicated, breaking Cluster Replication. (Bug#28170)

17.15.2.19. Changes in MySQL Cluster NDB 6.3.8 (5.1.23-ndb-6.3.8) (29 January 2008)

This is a new Beta development release, fixing recently discovered bugs in previous MySQL Cluster NDB 6.3 releases.

Obtaining MySQL Cluster NDB 6.3. This is a source-only release, which you must compile and install using the instructions found in Section 2.10, “MySQL Installation Using a Source Distribution”, and in Section 17.3.1, “Building MySQL Cluster from Source Code”. You can download the GPL source tarball from the MySQL FTP site at ftp://ftp.mysql.com/pub/mysql/download/cluster_telco/.

This Beta release incorporates all bugfixes and changes made in the previous MySQL Cluster NDB 6.3 release, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.23 (see Section C.1.15, “Changes in MySQL 5.1.23 (29 January 2008)”).

Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Functionality added or changed:

- **Cluster API: Important Change:** Because `NDB_LE_MemoryUsage.page_size_kb` shows memory page sizes in bytes rather than kilobytes, it has been renamed to `page_size_bytes`. The name `page_size_kb` is now deprecated and thus subject to removal in a future release, although it currently remains supported for reasons of backward compatibility. See [The Ndb_logevent_type Type](#), for more information about `NDB_LE_MemoryUsage`. (Bug#30271)
- `ndb_restore` now supports basic *attribute promotion*; that is, data from a column of a given type can be restored to a column using a “larger” type. For example, Cluster backup data taken from a `SMALLINT` column can be restored to a `MEDIUMINT`, `INT`, or `BIGINT` column.

For more information, see Section 17.6.17, “`ndb_restore` — Restore a MySQL Cluster Backup”.

- Now only 2 local checkpoints are stored, rather than 3 as in previous MySQL Cluster versions. This lowers disk space requirements and reduces the size and number of redo log files needed.
- The `mysqld` option `--ndb-batch-size` has been added. This allows for controlling the size of batches used for running transactions.
- Node recovery can now be done in parallel, rather than sequentially, which can result in much faster recovery times.
- Persistence of NDB tables can now be controlled using the session variables `ndb_table_temporary` and `ndb_table_no_logging`. `ndb_table_no_logging` causes NDB tables not to be checkpointed to disk; `ndb_table_temporary` does the same, and in addition, no schema files are created.
- `OPTIMIZE TABLE` can now be interrupted. This can be done, for example, by killing the SQL thread performing the `OPTIM-`

IZE operation.

Bugs fixed:

- **Disk Data: Important Change:** It is no longer possible on 32-bit systems to issue statements appearing to create Disk Data log files or data files greater than 4 GB in size. (Trying to create log files or data files larger than 4 GB on 32-bit systems led to unrecoverable data node failures; such statements now fail with NDB error 1515.) (Bug#29186)
- **Replication:** The code implementing heartbeats did not check for possible errors in some circumstances; this kept the dump thread hanging while waiting for heartbeats loop even though the slave was no longer connected. (Bug#33332)
- High numbers of insert operations, delete operations, or both could cause NDB error 899 (`ROWID ALREADY ALLOCATED`) to occur unnecessarily. (Bug#34033)
- A periodic failure to flush the send buffer by the NDB TCP transporter could cause a unnecessary delay of 10 ms between operations. (Bug#34005)
- `DROP TABLE` did not free all data memory. This bug was observed in MySQL Cluster NDB 6.3.7 only. (Bug#33802)
- A race condition could occur (very rarely) when the release of a GCI was followed by a data node failure. (Bug#33793)
- Some tuple scans caused the wrong memory page to be accessed, leading to invalid results. This issue could affect both in-memory and Disk Data tables. (Bug#33739)
- A failure to initialize an internal variable led to sporadic crashes during cluster testing. (Bug#33715)
- The server failed to reject properly the creation of an NDB table having an unindexed `AUTO_INCREMENT` column. (Bug#30417)
- Issuing an `INSERT ... ON DUPLICATE KEY UPDATE` concurrently with or following a `TRUNCATE` statement on an NDB table failed with NDB error 4350 `TRANSACTION ALREADY ABORTED`. (Bug#29851)
- The Cluster backup process could not detect when there was no more disk space and instead continued to run until killed manually. Now the backup fails with an appropriate error when disk space is exhausted. (Bug#28647)
- It was possible in `config.ini` to define cluster nodes having node IDs greater than the maximum allowed value. (Bug#28298)
- Under some circumstances, a recovering data node did not use its own data, instead copying data from another node even when this was not required. This in effect bypassed the optimized node recovery protocol and caused recovery times to be unnecessarily long. (Bug#26913)
- **Cluster Replication:** Consecutive DDL statements involving tables (`CREATE TABLE`, `ALTER TABLE`, and `DROP TABLE`) could be executed so quickly that previous DDL statements upon which they depended were not yet written in the binary log. For example, if `DROP TABLE foo` was issued immediately following `CREATE TABLE foo`, the `DROP` statement could fail because the `CREATE` had not yet been recorded. (Bug#34006)
- **Cluster Replication:** `ndb_restore -e` restored excessively large values to the `ndb_apply_status` table's `epoch` column when restoring to a MySQL Cluster version supporting Micro-GCPs from an older version that did not support these.

A workaround when restoring to MySQL Cluster releases supporting micro-GCPs previous to MySQL Cluster NDB 6.3.8 is to perform a 32-bit shift on the `epoch` column values to reduce them to their proper size. (Bug#33406)

- **Cluster API:** Transactions containing inserts or reads would hang during `NdbTransaction::execute()` calls made from NDB API applications built against a MySQL Cluster version that did not support micro-GCPs accessing a later version that supported micro-GCPs. This issue was observed while upgrading from MySQL Cluster NDB 6.1.23 to MySQL Cluster NDB 6.2.10 when the API application built against the earlier version attempted to access a data node already running the later version, even after disabling micro-GCPs by setting `TimeBetweenEpochs` equal to 0. (Bug#33895)
- **Cluster API:** When reading a `BIT(64)` value using `NdbOperation::getValue()`, 12 bytes were written to the buffer rather than the expected 8 bytes. (Bug#33750)

17.15.2.20. Changes in MySQL Cluster NDB 6.3.7 (5.1.23-ndb-6.3.7) (19 December 2007)

This is a new Beta development release, fixing recently discovered bugs in previous MySQL Cluster NDB 6.3 releases.

Obtaining MySQL Cluster NDB 6.3. This is a source-only release, which you must compile and install using the instructions

found in [Section 2.10, “MySQL Installation Using a Source Distribution”](#), and in [Section 17.3.1, “Building MySQL Cluster from Source Code”](#). You can download the GPL source tarball from the MySQL FTP site at ftp://ftp.mysql.com/pub/mysql/download/cluster_telco/.

This Beta release incorporates all bugfixes and changes made in the previous MySQL Cluster NDB 6.3 release, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.23 (see [Section C.1.15, “Changes in MySQL 5.1.23 \(29 January 2008\)”](#)).

Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Functionality added or changed:

- Compressed local checkpoints and backups are now supported, resulting in a space savings of 50% or more over uncompressed LCPs and backups. Compression of these can be enabled in the `config.ini` file using the two new data node configuration parameters `CompressedLCP` and `CompressedBackup`, respectively.
- `OPTIMIZE TABLE` is now supported for `NDBCLUSTER` tables, subject to the following limitations:
 - Only in-memory tables are supported. `OPTIMIZE` still has no effect on Disk Data tables.
 - Only variable-length columns are supported. However, you can force columns defined using fixed-length data types to be dynamic using the `ROW_FORMAT` or `COLUMN_FORMAT` option with a `CREATE TABLE` or `ALTER TABLE` statement.

Memory reclaimed from an `NDB` table using `OPTIMIZE` is generally available to the cluster, and not confined to the table from which it was recovered, unlike the case with memory freed using `DELETE`.

The performance of `OPTIMIZE` on `NDB` tables can be regulated by adjusting the value of the `ndb_optimization_delay` system variable.

- It is now possible to cause statements occurring within the same transaction to be run as a batch by setting the session variable `transaction_allow_batching` to `1` or `ON`.

Note

To use this feature, autocommit must be disabled.

Bugs fixed:

- Partitioning:** When partition pruning on an `NDB` table resulted in an ordered index scan spanning only one partition, any descending flag for the scan was wrongly discarded, causing `ORDER BY DESC` to be treated as `ORDER BY ASC, MAX()` to be handled incorrectly, and similar problems. (Bug#33061)
- When all data and SQL nodes in the cluster were shut down abnormally (that is, other than by using `STOP` in the cluster management client), `ndb_mgm` used excessive amounts of CPU. (Bug#33237)
- When using micro-GCPs, if a node failed while preparing for a global checkpoint, the master node would use the wrong GCI. (Bug#32922)
- Under some conditions, performing an `ALTER TABLE` on an `NDBCLUSTER` table failed with a `TABLE IS FULL` error, even when only 25% of `DataMemory` was in use and the result should have been a table using less memory (for example, changing a `VARCHAR(100)` column to `VARCHAR(80)`). (Bug#32670)
- Cluster Replication: Replication:** Where a table being replicated had a `TEXT` or `BLOB` column, an `UPDATE` on the master that did not refer explicitly to this column in the `WHERE` clause stopped the SQL thread on the slave with `ERROR IN WRITE_ROWS EVENT: ROW APPLICATION FAILED. GOT ERROR 4288 'BLOB HANDLE FOR COLUMN NOT AVAILABLE' FROM NDB-CLUSTER`. (Bug#30674)
- Cluster Replication:** Creating the `mysql.ndb_replication` table with the wrong number of columns for the primary key caused `mysqld` to crash. Now a `CREATE TABLE [mysql.]ndb_replication` statement that is invalid for this reason fails with the error `BAD SCHEMA FOR MYSQL.NDB_REPLICATION TABLE. MESSAGE: WRONG NUMBER OF PRIMARY KEYS, EXPECTED NUMBER`. (Bug#33159)

17.15.2.21. Changes in MySQL Cluster NDB 6.3.6 (5.1.22-ndb-6.3.6) (08 November 2007)

This is a new Beta development release, fixing recently discovered bugs in previous MySQL Cluster NDB 6.3 releases.

Obtaining MySQL Cluster NDB 6.3. This is a source-only release, which you must compile and install using the instructions found in [Section 2.10, “MySQL Installation Using a Source Distribution”](#), and in [Section 17.3.1, “Building MySQL Cluster from Source Code”](#). You can download the GPL source tarball from the MySQL FTP site at ftp://ftp.mysql.com/pub/mysql/download/cluster_telco/.

This Beta release incorporates all bugfixes and changes made in the previous MySQL Cluster NDB 6.3 release, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.22 (see [Section C.1.16, “Changes in MySQL 5.1.22 \(24 September 2007 Release Candidate\)”](#)).

Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Functionality added or changed:

- **Important Note:** MySQL Cluster NDB 6.2 and 6.3 source archives are now available in separate commercial and GPL versions. Due to licensing concerns, previous MySQL Cluster NDB 6.2 and 6.3 source archives were removed from the FTP site.
- Unnecessary reads when performing a primary key or unique key update have been reduced, and in some cases, eliminated. (It is almost never necessary to read a record prior to an update, the lone exception to this being when a primary key is updated, since this requires a delete followed by an insert, which must be prepared by reading the record.) Depending on the number of primary key and unique key lookups that are performed per transaction, this can yield a considerable improvement in performance.
- Batched operations are now better supported for `DELETE` and `UPDATE`. (`UPDATE WHERE . . .` and multiple `DELETE`.)
- Introduced the `Ndb_execute_count` status variable, which measures the number of round trips made by queries to the NDB kernel.

Bugs fixed:

- An insert or update with combined range and equality constraints failed when run against an NDB table with the error `GOT UNKNOWN ERROR FROM NDB`. An example of such a statement would be `UPDATE t1 SET b = 5 WHERE a IN (7,8) OR a >= 10;` ([Bug#31874](#))
- An error with an `if` statement in `sql/ha_ndbcluster.cc` could potentially lead to an infinite loop in case of failure when working with `AUTO_INCREMENT` columns in NDB tables. ([Bug#31810](#))
- The NDB storage engine code was not safe for strict-alias optimization in `gcc` 4.2.1. ([Bug#31761](#))
- `ndb_restore` displayed incorrect backup file version information. This meant (for example) that, when attempting to restore a backup made from a MySQL 5.1.22 cluster to a MySQL Cluster NDB 6.3.3 cluster, the restore process failed with the error `RESTORE PROGRAM OLDER THAN BACKUP VERSION. NOT SUPPORTED. USE NEW RESTORE PROGRAM`. ([Bug#31723](#))
- Following an upgrade, `ndb_mgmd` would fail with an `ArbitrationError`. ([Bug#31690](#))
- The NDB management client command `node_id REPORT MEMORY` provided no output when `node_id` was the node ID of a management or API node. Now, when this occurs, the management client responds with `Node node_id: is not a data node`. ([Bug#29485](#))
- Performing `DELETE` operations after a data node had been shut down could lead to inconsistent data following a restart of the node. ([Bug#26450](#))
- `UPDATE IGNORE` could sometimes fail on NDB tables due to the use of uninitialized data when checking for duplicate keys to be ignored. ([Bug#25817](#))
- **Cluster Replication: Replication:** Slave batching did not work correctly with `UPDATE` statements. ([Bug#31787](#))
- **Cluster Replication: Replication:** A node failure during replication could lead to buckets out of order; now active subscribers are checked for, rather than empty buckets. ([Bug#31701](#))
- **Cluster Replication:** Updates performed unnecessary writes to the primary keys of the rows being updated. ([Bug#31841](#))
- **Cluster Replication:** When the master `mysqld` crashed or was restarted, no `LOST_EVENTS` entry was made in the binlog. ([Bug#31484](#))

See also [Bug#21494](#).

17.15.2.22. Changes in MySQL Cluster NDB 6.3.5 (5.1.22-ndb-6.3.5) (17 October 2007)

This is a new Beta development release, fixing recently discovered bugs in previous MySQL Cluster NDB 6.3 releases.

Obtaining MySQL Cluster NDB 6.3. This is a source-only release, which you must compile and install using the instructions found in [Section 2.10, “MySQL Installation Using a Source Distribution”](#), and in [Section 17.3.1, “Building MySQL Cluster from Source Code”](#). You can download the GPL source tarball from the MySQL FTP site at ftp://ftp.mysql.com/pub/mysql/download/cluster_telco/.

This Beta release incorporates all bugfixes and changes made in the previous MySQL Cluster NDB 6.3 release, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.22 (see [Section C.1.16, “Changes in MySQL 5.1.22 \(24 September 2007 Release Candidate\)”](#)).

Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Bugs fixed:

- A query against a table with `TEXT` or `BLOB` columns that would return more than a certain amount of data failed with `ERROR 4350 'TRANSACTION ALREADY ABORTED' FROM NDBCLUSTER`. ([Bug#31482](#))

This regression was introduced by [Bug#29102](#).

- **Cluster Replication:** In some cases, not all tables were properly initialized before the binary log thread was started. ([Bug#31618](#))

17.15.2.23. Changes in MySQL Cluster NDB 6.3.4 (5.1.22-ndb-6.3.4) (15 October 2007)

This is a new Beta development release, fixing recently discovered bugs in previous MySQL Cluster NDB 6.3 releases.

Obtaining MySQL Cluster NDB 6.3. This is a source-only release, which you must compile and install using the instructions found in [Section 2.10, “MySQL Installation Using a Source Distribution”](#), and in [Section 17.3.1, “Building MySQL Cluster from Source Code”](#). You can download the GPL source tarball from the MySQL FTP site at ftp://ftp.mysql.com/pub/mysql/download/cluster_telco/.

This Beta release incorporates all bugfixes and changes made in the previous MySQL Cluster NDB 6.3 release, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.22 (see [Section C.1.16, “Changes in MySQL 5.1.22 \(24 September 2007 Release Candidate\)”](#)).

Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Functionality added or changed:

- **Incompatible Change:** The `--ndb_optimized_node_selection` startup option for `mysqld` now allows a wider range of values and corresponding behaviors for SQL nodes when selecting a transaction coordinator.

You should be aware that the default value and behavior as well as the value type used for this option have changed, and that you may need to update the setting used for this option in your `my.cnf` file prior to upgrading `mysqld`. See [Section 5.1.3, “Server System Variables”](#), for more information.

- **Cluster Replication: Replication:** A replication heartbeat mechanism has been added to facilitate monitoring. This provides an alternative to checking log files, making it possible to detect in real time when a slave has failed.

Configuration of heartbeats is done via a new `MASTER_HEARTBEAT_PERIOD = interval` clause for the `CHANGE MASTER TO` statement (see [Section 12.6.2.1, “CHANGE MASTER TO Syntax”](#)); monitoring can be done by checking the values of the status variables `Slave_heartbeat_period` and `Slave_received_heartbeats` (see [Section 5.1.6, “Server Status Variables”](#)).

The addition of replication heartbeats addresses a number of issues:

- Relay logs were rotated every `slave_net_timeout` seconds even if no statements were being replicated.

- `SHOW SLAVE STATUS` displayed an incorrect value for `seconds_behind_master` following a `FLUSH LOGS` statement.
- Replication master-slave connections used `slave_net_timeout` for connection timeouts. (Bug#20435, Bug#29309, Bug#30932)
- **Replication:** On MySQL replication slaves having multiple network interfaces, it is now possible to set which interface to use for connecting to the master. This can be done by using either the `mysqld` startup option `--master-bind` or the `MAS-TER_BIND='interface'` clause in a `CHANGE MASTER TO` statement. (Bug#25939)
- **Cluster Replication:** A new configuration parameter `TimeBetweenEpochsTimeout` allows a timeout to be set for time between epochs. For more information, see Section 17.3.4.6, “Defining MySQL Cluster Data Nodes”. (Bug#31276)
- **Cluster Replication:** Support for a new conflict resolution function `NDB$OLD()` has been added for handling simultaneous updates in multi-master and circular replication setups. A new status variable `Ndb_conflict_fn_old` tracks the number of times that updates are prevented from being applied due to this type of conflict resolution. See Section 17.9.11, “MySQL Cluster Replication Conflict Resolution”, for more information.
- Additional checks were implemented to catch unsupported online `ALTER TABLE` operations. Currently it is not possible to reorder columns or to change the storage engine used for a table via online `ALTER TABLE`.
Some redundant checks made during online creation of indexes were removed.
- A `--bind-address` option has been added to a number of MySQL client programs: `mysql`, `mysqldump`, `mysqladmin`, `mysqlbinlog`, `mysqlcheck`, `mysqlimport`, and `mysqlshow`. This is for use on a computer having multiple network interfaces, and allows you to choose which interface is used to connect to the MySQL server.

Bugs fixed:

- It was possible in some cases for a node group to be “lost” due to missed local checkpoints following a system restart. (Bug#31525)
- NDB tables having names containing non-alphanumeric characters (such as “ \$ ”) were not discovered correctly. (Bug#31470)
- A node failure during a local checkpoint could lead to a subsequent failure of the cluster during a system restart. (Bug#31257)
- A cluster restart could sometimes fail due to an issue with table IDs. (Bug#30975)
- Transaction timeouts were not handled well in some circumstances, leading to excessive number of transactions being aborted unnecessarily. (Bug#30379)
- In some cases, the cluster management server logged entries multiple times following a restart of `mgmd`. (Bug#29565)
- `ndb_mgm --help` did not display any information about the `-a` option. (Bug#29509)
- An interpreted program of sufficient size and complexity could cause all cluster data nodes to shut down due to buffer overruns. (Bug#29390)
- The cluster log was formatted inconsistently and contained extraneous newline characters. (Bug#25064)
- A transaction was not aborted following the failure of statement. (Bug#31320)
- Online `ALTER` operations involving a column whose data type has an implicit default value left behind temporary `.frm` files, causing subsequent `DROP DATABASE` statements to fail. (Bug#31097)
- Errors could sometimes occur during an online `ADD COLUMN` under load. (Bug#31082)
- Transactions were committed prematurely when `LOCK TABLE` and `SET autocommit = 0` were used together. (Bug#30996)
- The `mysqld_safe` script contained a syntax error. (Bug#30624)

17.15.2.24. Changes in MySQL Cluster NDB 6.3.3 (5.1.22-ndb-6.3.3) (20 September 2007)

This is a new Beta development release, fixing recently discovered bugs in previous MySQL Cluster NDB 6.3 releases.

Obtaining MySQL Cluster NDB 6.3. This is a source-only release, which you must compile and install using the instructions

found in [Section 2.10, “MySQL Installation Using a Source Distribution”](#), and in [Section 17.3.1, “Building MySQL Cluster from Source Code”](#). You can download the GPL source tarball from the MySQL FTP site at ftp://ftp.mysql.com/pub/mysql/download/cluster_telco/.

This Beta release incorporates all bugfixes and changes made in the previous MySQL Cluster NDB 6.3 release, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.22 (see [Section C.1.16, “Changes in MySQL 5.1.22 \(24 September 2007 Release Candidate\)”](#)).

Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Functionality added or changed:

- Mapping of `NDB` error codes to MySQL storage engine error codes has been improved. ([Bug#28423](#))
- **Cluster Replication: Replication:** A server status variable `ndb_conflict_fn_max` now provides a count of the number of times that conflict resolution for MySQL Cluster Replication has been applied.

See [Section 17.9.11, “MySQL Cluster Replication Conflict Resolution”](#), for more information.

Bugs fixed:

- **Partitioning:** `EXPLAIN PARTITIONS` reported partition usage by queries on `NDB` tables according to the standard MySQL hash function than the hash function used in the `NDB` storage engine. ([Bug#29550](#))
- Attempting to restore a backup made on a cluster host using one endian to a machine using the other endian could cause the cluster to fail. ([Bug#29674](#))
- The description of the `--print` option provided in the output from `ndb_restore --help` was incorrect. ([Bug#27683](#))
- Restoring a backup made on a cluster host using one endian to a machine using the other endian failed for `BLOB` and `DATE-TIME` columns. ([Bug#27543](#), [Bug#30024](#))
- Errors could sometimes occur during an online `ADD COLUMN` under load. ([Bug#31082](#))

17.15.2.25. Changes in MySQL Cluster NDB 6.3.2 (5.1.22-ndb-6.3.2) (07 September 2007)

This is a new Beta development release, fixing recently discovered bugs in previous MySQL Cluster NDB 6.3 releases.

Obtaining MySQL Cluster NDB 6.3. This is a source-only release, which you must compile and install using the instructions found in [Section 2.10, “MySQL Installation Using a Source Distribution”](#), and in [Section 17.3.1, “Building MySQL Cluster from Source Code”](#). You can download the GPL source tarball from the MySQL FTP site at ftp://ftp.mysql.com/pub/mysql/download/cluster_telco/.

This Beta release incorporates all bugfixes and changes made in the previous MySQL Cluster NDB 6.3 release, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.22 (see [Section C.1.16, “Changes in MySQL 5.1.22 \(24 September 2007 Release Candidate\)”](#)).

Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Functionality added or changed:

- Online `ADD COLUMN`, `ADD INDEX`, and `DROP INDEX` operations can now be performed explicitly for `NDB` tables, as well as online renaming of tables and columns for `NDB` and `MyISAM` tables — that is, without copying or locking of the affected tables — using `ALTER ONLINE TABLE`.

Indexes can also be created and dropped online using `CREATE INDEX` and `DROP INDEX`, respectively, using the `ONLINE` keyword.

You can force operations that would otherwise be performed online to be done offline using the `OFFLINE` keyword.

See [Section 12.1.7, “ALTER TABLE Syntax”](#), [Section 12.1.13, “CREATE INDEX Syntax”](#), and [Section 12.1.24, “DROP IN-](#)

[DEX Syntax](#)”, for more information.

- It is now possible to control whether fixed-width or variable-width storage is used for a given column of an NDB table by means of the `COLUMN_FORMAT` specifier as part of the column's definition in a `CREATE TABLE` or `ALTER TABLE` statement.

It is also possible to control whether a given column of an NDB table is stored in memory or on disk, using the `STORAGE` specifier as part of the column's definition in a `CREATE TABLE` or `ALTER TABLE` statement.

For permitted values and other information about `COLUMN_FORMAT` and `STORAGE`, see [Section 12.1.17, “CREATE TABLE Syntax”](#).

- A new cluster management server startup option `--bind-address` makes it possible to restrict management client connections to `ndb_mgmd` to a single host and port. For more information, see [Section 17.6.24.3, “Program Options for ndb_mgmd”](#).
- **Cluster Replication:** Multi-way replication failover and recovery for NDB is facilitated with the introduction of the `-ndb-log-orig` option. When `mysqld` is started with this option, the originating server ID and epoch of each binlog event is recorded in the `mysql.ndb_binlog_index` table, which now contains two additional columns `orig_server_id` and `orig_epoch` for storing this information. In such cases, a single epoch on a slave may be represented by multiple rows in the slave's `ndb_binlog_index` table, one for each epoch as it originated from a master.
- **Cluster Replication:** The protocol for handling global checkpoints has been changed. It is now possible to control how often the GCI number is updated, and how often global checkpoints are written to disk, using the `TimeBetweenEpochs` configuration parameter. This improves the reliability and performance of MySQL Cluster Replication.

GCPs handled using the new protocol are sometimes referred to as “micro-GCPs”.

For more information, see [TimeBetweenEpochs](#) .

Bugs fixed:

- When an NDB event was left behind but the corresponding table was later recreated and received a new table ID, the event could not be dropped. ([Bug#30877](#))
- An insufficiently descriptive and potentially misleading Error 4006 (`CONNECT FAILURE - OUT OF CONNECTION OBJECTS...`) was produced when either of the following two conditions occurred:
 1. There were no more transaction records in the transaction coordinator
 2. An NDB object in the NDB API was initialized with insufficient parallelism
 Separate error messages are now generated for each of these two cases. ([Bug#11313](#))
- For micro-GCPs, the assignment of “fake” CGI events no longer cause buckets to be sent out of order. Now, when assigning a GCI to a non-GCI event (that is, creating a pseudo-GCI or “fake” CGI), the GCI that is to arrive is always initiated, even if no known GCI exists, which could occur in the event of a node failure. ([Bug#30884](#))

17.15.2.26. Changes in MySQL Cluster NDB 6.3.1 (5.1.19-ndb-6.3.1) (04 July 2007)

This is a new Beta development release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.3 release.

Obtaining MySQL Cluster NDB 6.3. This is a source-only release, which you must compile and install using the instructions found in [Section 2.10, “MySQL Installation Using a Source Distribution”](#), and in [Section 17.3.1, “Building MySQL Cluster from Source Code”](#). You can download the GPL source tarball from the MySQL FTP site at ftp://ftp.mysql.com/pub/mysql/download/cluster_telco/.

This Beta release incorporates all bugfixes and changes made in the previous MySQL Cluster NDB 6.3 release, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.19 (see [Section C.1.19, “Changes in MySQL 5.1.19 \(25 May 2007\)”](#)).

Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Bugs fixed:

- Batching of transactions was not handled correctly in some cases. ([Bug#29525](#))

17.15.2.27. Changes in MySQL Cluster NDB 6.3.0 (5.1.19-ndb-6.3.0) (02 July 2007)

This is the first development release for MySQL Cluster NDB 6.3, based on version 6.3 of the `NDBCLUSTER` storage engine.

Obtaining MySQL Cluster NDB 6.3. This is a source-only release, which you must compile and install using the instructions found in [Section 2.10, “MySQL Installation Using a Source Distribution”](#), and in [Section 17.3.1, “Building MySQL Cluster from Source Code”](#). You can download the GPL source tarball from the MySQL FTP site at ftp://ftp.mysql.com/pub/mysql/download/cluster_telco/.

This Beta release incorporates all bugfixes and feature changes made in previous MySQL Cluster releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.19 (see [Section C.1.19, “Changes in MySQL 5.1.19 \(25 May 2007\)”](#)).

Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Functionality added or changed:

- Reporting functionality has been significantly enhanced in this release:
 - A new configuration parameter `BackupReportFrequency` now makes it possible to cause the management client to provide status reports at regular intervals as well as for such reports to be written to the cluster log (depending on cluster event logging levels). See [Section 17.3.4.6, “Defining MySQL Cluster Data Nodes”](#), for more information about this parameter.
 - A new `REPORT` command has been added in the cluster management client. `REPORT BackupStatus` allows you to obtain a backup status report at any time during a backup. `REPORT MemoryUsage` reports the current data memory and index memory used by each data node. For more about the `REPORT` command, see [Section 17.7.2, “Commands in the MySQL Cluster Management Client”](#).
 - `ndb_restore` now provides running reports of its progress when restoring a backup. In addition, a complete report status report on the backup is written to the cluster log.
- A new configuration parameter `ODirect` causes `NDB` to attempt using `O_DIRECT` writes for LCP, backups, and redo logs, often lowering CPU usage.
- **Cluster Replication:** This release implements conflict resolution, which makes it possible to determine on a per-table basis whether or not an update to a given row on the master should be applied on the slave. For more information, see [Section 17.9.11, “MySQL Cluster Replication Conflict Resolution”](#).

17.15.3. Changes in MySQL Cluster NDB 6.2

This section contains change history information for MySQL Cluster releases based on version 6.2 of the `NDBCLUSTER` storage engine.

For an overview of new features added in MySQL Cluster NDB 6.2, see [Section 17.13.3, “Features Added in MySQL Cluster NDB 6.2”](#).

17.15.3.1. Changes in MySQL Cluster NDB 6.2.18 (5.1.34-ndb-6.2.18) (Not yet released)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.2 release.

This release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.2 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.32 (see [Section C.1.5, “Changes in MySQL 5.1.32 \(14 February 2009\)”](#)).

Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Bugs fixed:

- **Important Change: Partitioning:** User-defined partitioning of an `NDBCLUSTER` table without any primary key sometimes failed, and could cause `mysqld` to crash.

Now, if you wish to create an `NDBCLUSTER` table with user-defined partitioning, the table must have an explicit primary key, and all columns listed in the partitioning expression must be part of the primary key. The hidden primary key used by the `NDBCLUSTER` storage engine is not sufficient for this purpose. However, if the list of columns is empty (that is, the table is defined using `PARTITION BY [LINEAR] KEY()`), then no explicit primary key is required.

This change does not effect the partitioning of tables using any storage engine other than `NDBCLUSTER`. (Bug#40709)

- An internal NDB API buffer was not properly initialized. (Bug#44977)
- When a data node had written its GCI marker to the first page of a megabyte, and that node was later killed during restart after having processed that page (marker) but before completing a LCP, the data node could fail with filesystem errors. (Bug#44952)

See also Bug#42564.

- Inspection of the code revealed that several assignment operators (`=`) were used in place of comparison operators (`==`) in `Db-dihMain.cpp`. (Bug#44567)

See also Bug#44570.

- It was possible for NDB API applications to insert corrupt data into the database, which could subsequently lead to data node crashes. Now, stricter checking is enforced on input data for inserts and updates. (Bug#44132)
- `TransactionDeadlockDetectionTimeout` values less than 100 were treated as 100. This could cause scans to time out unexpectedly. (Bug#44099)
- The file `ndberror.c` contained a C++-style comment, which caused builds to fail with some C compilers. (Bug#44036)
- A race condition could occur when a data node failed to restart just before being included in the next global checkpoint. This could cause other data nodes to fail. (Bug#43888)
- When trying to use a data node with an older version of the management server, the data node crashed on startup. (Bug#43699)
- Using indexes containing variable-sized columns could lead to internal errors when the indexes were being built. (Bug#43226)
- In some cases, data node restarts during a system restart could fail due to insufficient redo log space. (Bug#43156)
- Some queries using combinations of logical and comparison operators on an indexed column in the `WHERE` clause could fail with the error `GOT ERROR 4541 'INDEXBOUND HAS NO BOUND INFORMATION' FROM NDBCLUSTER`. (Bug#42857)
- `ndb_restore --print_data` did not handle `DECIMAL` columns correctly. (Bug#37171)
- The output of `ndbd --help` did not provide clear information about the program's `--initial` and `--initial-start` options. (Bug#28905)
- It was theoretically possible for the value of a nonexistent column to be read as `NULL`, rather than causing an error. (Bug#27843)
- When aborting an operation involving both an insert and a delete, the insert and delete were aborted separately. This was because the transaction coordinator did not know that the operations affected on same row, and, in the case of a committed-read (tuple or index) scan, the abort of the insert was performed first, then the row was examined after the insert was aborted but before the delete was aborted. In some cases, this would leave the row in a inconsistent state. This could occur when a local checkpoint was performed during a backup. This issue did not affect primary key operations or scans that used locks (these are serialized).

After this fix, for ordered indexes, all operations that follow the operation to be aborted are now also aborted.

- **Disk Data: Partitioning:** An `NDBCLUSTER` table created with a very large value for the `MAX_ROWS` option could — if this table was dropped and a new table with fewer partitions, but having the same table ID, was created — cause `ndbd` to crash when performing a system restart. This was because the server attempted to examine each partition whether or not it actually existed. (Bug#45154)
- **Disk Data:** During a checkpoint, restore points are created for both the on-disk and in-memory parts of a Disk Data table. Under certain rare conditions, the in-memory restore point could include or exclude a row that should have been in the snapshot. This would later later lead to a crash during or following recovery. (Bug#41915)
- **Disk Data:** When a log file group had an undo log file whose size was too small, restarting data nodes failed with `READ UNDERFLOW` errors.

As a result of this fix, the minimum allowed `INTIAL_SIZE` for an undo log file is now `1M` (1 megabyte). (Bug#29574)

- **Disk Data:** This fix supercedes and improves on an earlier fix made for this bug in MySQL 5.1.18. ([Bug#24521](#))
- **Cluster Replication:** A failure when setting up replication events could lead to subsequent data node failures. ([Bug#44915](#))
- **Cluster API:** If the largest offset of a `RecordSpecification` used for an `NdbRecord` object was for the `NULL` bits (and thus not a column), this offset was not taken into account when calculating the size used for the `RecordSpecification`. This meant that the space for the `NULL` bits could be overwritten by key or other information. ([Bug#43891](#))
- **Cluster API:** The default `NdbRecord` structures created by `NdbDictionary` could have overlapping null bits and data fields. ([Bug#43590](#))
- **Cluster API:** When performing insert or write operations, `NdbRecord` allows key columns to be specified in both the key record and in the attribute record. Only one key column value for each key column should be sent to the NDB kernel, but this was not guaranteed. This is now ensured as follows: For insert and write operations, key column values are taken from the key record; for scan takeover update operations, key column values are taken from the attribute record. ([Bug#42238](#))
- **Cluster API:** Ordered index scans using `NdbRecord` formerly expressed a `BoundEQ` range as separate lower and upper bounds, resulting in 2 copies of the column values being sent to the NDB kernel.

Now, when a range is specified by `NdbScanOperation::setBound()`, the passed pointers, key lengths, and inclusive bits are compared, and only one copy of the equal key columns is sent to the kernel. This makes such operations more efficient, as half the amount of `KeyInfo` is now sent for a `BoundEQ` range as before. ([Bug#38793](#))

17.15.3.2. Changes in MySQL Cluster NDB 6.2.17 (5.1.32-ndb-6.2.17) (Not yet released)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.2 release.

This release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.2 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.32 (see [Section C.1.5, “Changes in MySQL 5.1.32 \(14 February 2009\)”](#)).

Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Functionality added or changed:

- **Important Change:** Formerly, when the management server failed to create a transporter for a data node connection, `net_write_timeout` seconds elapsed before the data node was actually allowed to disconnect. Now in such cases the disconnection occurs immediately. ([Bug#41965](#))
See also [Bug#41713](#).
- **Important Change: Replication:** `RESET MASTER` and `RESET SLAVE` now reset the values shown for `Last_IO_Error`, `Last_IO_Errno`, `Last_SQL_Error`, and `Last_SQL_Errno` in the output of `SHOW SLAVE STATUS`. ([Bug#34654](#))
- **Cluster Replication: Important Note:** This release of MySQL Cluster derives in part from MySQL 5.1.29, where the default value for the `--binlog-format` option changed to `STATEMENT`. That change does *not* affect this or future MySQL Cluster NDB 6.x releases, where the default value for this option remains `MIXED`, since MySQL Cluster Replication does not work with the statement-based format. ([Bug#40586](#))
- **Disk Data:** It is now possible to specify default locations for Disk Data data files and undo log files, either together or separately, using the data node configuration parameters `FileSystemPathDD`, `FileSystemPathDataFiles`, and `FileSystemPathUndoFiles`. For information about these configuration parameters, see [Disk Data filesystem parameters](#).

It is also now possible to specify a log file group, tablespace, or both, that is created when the cluster is started, using the `InitialLogFileGroup` and `InitialTablespace` data node configuration parameters. For information about these configuration parameters, see [Disk Data object creation parameters](#).

Bugs fixed:

- **Packaging:** Packages for MySQL Cluster were missing the `libndbclient.so` and `libndbclient.a` files. ([Bug#42278](#))
- **Partitioning:** Executing `ALTER TABLE ... REORGANIZE PARTITION` on an `NDBCLUSTER` table having only one partition caused `mysqld` to crash. ([Bug#41945](#))

See also [Bug#40389](#).

- **Cluster API:** Failed operations on `BLOB` and `TEXT` columns were not always reported correctly to the originating SQL node. Such errors were sometimes reported as being due to timeouts, when the actual problem was a transporter overload due to insufficient buffer space. ([Bug#39867](#), [Bug#39879](#))
- Backup IDs greater than 2^{31} were not handled correctly, causing negative values to be used in backup directory names and printouts. ([Bug#43042](#))
- When using `ndbmttd`, NDB kernel threads could hang while trying to start the data nodes with `LockPagesInMainMemory` set to 1. ([Bug#43021](#))
- When using multiple management servers and starting several API nodes (possibly including one or more SQL nodes) whose connectstrings listed the management servers in different order, it was possible for 2 API nodes to be assigned the same node ID. When this happened it was possible for an API node not to get fully connected, consequently producing a number of errors whose cause was not easily recognizable. ([Bug#42973](#))
- `ndb_error_reporter` worked correctly only with GNU `tar`. (With other versions of `tar`, it produced empty archives.) ([Bug#42753](#))
- Triggers on `NDBCLUSTER` tables caused such tables to become locked. ([Bug#42751](#))

See also [Bug#16229](#), [Bug#18135](#).

- When performing more than 32 index or tuple scans on a single fragment, the scans could be left hanging. This caused unnecessary timeouts, and in addition could possibly lead to a hang of an LCP. ([Bug#42559](#))
- A data node failure that occurred between calls to `NdbIndexScanOperation::readTuples(SF_OrderBy)` and `NdbTransaction::Execute()` was not correctly handled; a subsequent call to `nextResult()` caused a null pointer to be dereferenced, leading to a segfault in `mysqld`. ([Bug#42545](#))
- Issuing `SHOW GLOBAL STATUS LIKE 'NDB%'` before `mysqld` had connected to the cluster caused a segmentation fault. ([Bug#42458](#))
- Data node failures that occurred before all data nodes had connected to the cluster were not handled correctly, leading to additional data node failures. ([Bug#42422](#))
- When a cluster backup failed with Error 1304 (Node `node_id1`: Backup request from `node_id2` failed to start), no clear reason for the failure was provided.

As part of this fix, MySQL Cluster now retries backups in the event of sequence errors. ([Bug#42354](#))

See also [Bug#22698](#).

- Issuing `SHOW ENGINE NDBCLUSTER STATUS` on an SQL node before the management server had connected to the cluster caused `mysqld` to crash. ([Bug#42264](#))
- A maximum of 11 `TUP` scans were allowed in parallel. ([Bug#42084](#))
- Trying to execute an `ALTER ONLINE TABLE ... ADD COLUMN` statement while inserting rows into the table caused `mysqld` to crash. ([Bug#41905](#))
- If the master node failed during a global checkpoint, it was possible in some circumstances for the new master to use an incorrect value for the global checkpoint index. This could occur only when the cluster used more than one node group. ([Bug#41469](#))
- API nodes disconnected too aggressively from cluster when data nodes were being restarted. This could sometimes lead to the API node being unable to access the cluster at all during a rolling restart. ([Bug#41462](#))
- An abort path in the `DBLQH` kernel block failed to release a commit acknowledgement marker. This meant that, during node failure handling, the local query handler could be added multiple times to the marker record which could lead to additional node failures due an array overflow. ([Bug#41296](#))
- During node failure handling (of a data node other than the master), there was a chance that the master was waiting for a `GCP_NODEFINISHED` signal from the failed node after having received it from all other data nodes. If this occurred while the failed node had a transaction that was still being committed in the current epoch, the master node could crash in the `DBTC` kernel block when discovering that a transaction actually belonged to an epoch which was already completed. ([Bug#41295](#))
- If a transaction was aborted during the handling of a data node failure, this could lead to the later handling of an API node failure not being completed. ([Bug#41214](#))

- Given a MySQL Cluster containing no data (that is, whose data nodes had all been started using `--initial`, and into which no data had yet been imported) and having an empty backup directory, executing `START BACKUP` with a user-specified backup ID caused the data nodes to crash. (Bug#41031)
- Issuing `EXIT` in the management client sometimes caused the client to hang. (Bug#40922)
- Redo log creation was very slow on some platforms, causing MySQL Cluster to start more slowly than necessary with some combinations of hardware and operating system. This was due to all write operations being synchronized to disk while creating a redo log file. Now this synchronization occurs only after the redo log has been created. (Bug#40734)
- Transaction failures took longer to handle than was necessary.

When a data node acting as transaction coordinator (TC) failed, the surviving data nodes did not inform the API node initiating the transaction of this until the failure had been processed by all protocols. However, the API node needed only to know about failure handling by the transaction protocol — that is, it needed to be informed only about the TC takeover process. Now, API nodes (including MySQL servers acting as cluster SQL nodes) are informed as soon as the TC takeover is complete, so that it can carry on operating more quickly. (Bug#40697)

- It was theoretically possible for stale data to be read from `NDBCLUSTER` tables when the transaction isolation level was set to `ReadCommitted`. (Bug#40543)
- In some cases, `NDB` did not check correctly whether tables had changed before trying to use the query cache. This could result in a crash of the debug MySQL server. (Bug#40464)
- Restoring a MySQL Cluster from a dump made using `mysqldump` failed due to a spurious error: `CAN'T EXECUTE THE GIVEN COMMAND BECAUSE YOU HAVE ACTIVE LOCKED TABLES OR AN ACTIVE TRANSACTION`. (Bug#40346)
- `O_DIRECT` was incorrectly disabled when making MySQL Cluster backups. (Bug#40205)
- Events logged after setting `ALL CLUSTERLOG STATISTICS=15` in the management client did not always include the node ID of the reporting node. (Bug#39839)
- Start phase reporting was inconsistent between the management client and the cluster log. (Bug#39667)
- The MySQL Query Cache did not function correctly with `NDBCLUSTER` tables containing `TEXT` columns. (Bug#39295)
- A segfault in `Logger::Log` caused `ndbd` to hang indefinitely. This fix improves on an earlier one for this issue, first made in MySQL Cluster NDB 6.2.16 and MySQL Cluster NDB 6.3.17. (Bug#39180)

See also Bug#38609.

- Memory leaks could occur in handling of strings used for storing cluster metadata and providing output to users. (Bug#38662)
- In the event that a MySQL Cluster backup failed due to file permissions issues, conflicting reports were issued in the management client. (Bug#34526)
- A duplicate key error raised when inserting into an `NDBCLUSTER` table caused the current transaction to abort, after which any SQL statement other than a `ROLLBACK` failed. With this fix, the `NDBCLUSTER` storage engine now supports rollback of individual statements in such cases, and it is no longer necessary to issue an explicit `ROLLBACK` and then retry the entire transaction. (Bug#32656)
- Error messages for `NDBCLUSTER` error codes 1224 and 1227 were missing. (Bug#28496)
- **Partitioning:** A query on a user-partitioned table caused MySQL to crash, where the query had the following characteristics:
 - The query's `WHERE` clause referenced an indexed column that was also in the partitioning key.
 - The query's `WHERE` clause included a value found in the partition.
 - The query's `WHERE` clause used the `<` or `<>` operators to compare with the indexed column's value with a constant.
 - The query used an `ORDER BY` clause, and the same indexed column was used in the `ORDER BY` clause.
 - The `ORDER BY` clause used an explicit or implicit `ASC` sort priority.

Two examples of such a query are given here, where `a` represents an indexed column used in the table's partitioning key:

1.

```
SELECT * FROM table WHERE a < constant ORDER BY a;
```

2.

```
SELECT * FROM table WHERE a <> constant ORDER BY a;
```

([Bug#40954](#))

This regression was introduced by [Bug#30573](#), [Bug#33257](#), [Bug#33555](#).

- **Partitioning:** Dropping or creating an index on a partitioned table managed by the `InnoDB` Plugin locked the table. ([Bug#37453](#))
 - **Disk Data:** It was not possible to add an in-memory column online to a table that used a table-level or column-level `STORAGE DISK` option. The same issue prevented `ALTER ONLINE TABLE ... REORGANIZE PARTITION` from working on Disk Data tables. ([Bug#42549](#))
 - **Disk Data:** Issuing concurrent `CREATE TABLESPACE`, `ALTER TABLESPACE`, `CREATE LOGFILE GROUP`, or `ALTER LOGFILE GROUP` statements on separate SQL nodes caused a resource leak that led to data node crashes when these statements were used again later. ([Bug#40921](#))
 - **Disk Data:** Disk-based variable-length columns were not always handled like their memory-based equivalents, which could potentially lead to a crash of cluster data nodes. ([Bug#39645](#))
 - **Disk Data:** Creating a Disk Data tablespace with a very large extent size caused the data nodes to fail. The issue was observed when using extent sizes of 100 MB and larger. ([Bug#39096](#))
 - **Disk Data:** Creation of a tablespace data file whose size was greater than 4 GB failed silently on 32-bit platforms. ([Bug#37116](#))
- See also [Bug#29186](#).
- **Disk Data:** `O_SYNC` was incorrectly disabled on platforms that do not support `O_DIRECT`. This issue was noted on Solaris but could have affected other platforms not having `O_DIRECT` capability. ([Bug#34638](#))
 - **Disk Data:** Trying to execute a `CREATE LOGFILE GROUP` statement using a value greater than 150M for `UNDO_BUFFER_SIZE` caused data nodes to crash.

As a result of this fix, the upper limit for `UNDO_BUFFER_SIZE` is now 600M; attempting to set a higher value now fails gracefully with an error. ([Bug#34102](#))

- **Disk Data:** When attempting to create a tablespace that already existed, the error message returned was `TABLE OR INDEX WITH GIVEN NAME ALREADY EXISTS`. ([Bug#32662](#))
- **Disk Data:** Using a path or filename longer than 128 characters for Disk Data undo log files and tablespace data files caused a number of issues, including failures of `CREATE LOGFILE GROUP`, `ALTER LOGFILE GROUP`, `CREATE TABLESPACE`, and `ALTER TABLESPACE` statements, as well as crashes of management nodes and data nodes.

With this fix, the maximum length for path and file names used for Disk Data undo log files and tablespace data files is now the same as the maximum for the operating system. ([Bug#31769](#), [Bug#31770](#), [Bug#31772](#))

- **Disk Data:** Starting a cluster under load such that Disk Data tables used most of the undo buffer could cause data node failures.

The fix for this bug also corrected an issue in the `LGMAN` kernel block where the amount of free space left in the undo buffer was miscalculated, causing buffer overruns. This could cause records in the buffer to be overwritten, leading to problems when restarting data nodes. ([Bug#28077](#))

- **Disk Data:** Attempting to perform a system restart of the cluster where there existed a logfile group without and undo log files caused the data nodes to crash.

Note

While issuing a `CREATE LOGFILE GROUP` statement without an `ADD UNDOFILE` option fails with an error in the MySQL server, this situation could arise if an SQL node failed during the execution of a valid `CREATE LOGFILE GROUP` statement; it is also possible to create a logfile group without any undo log files using the NDB API.

([Bug#17614](#))

- **Cluster Replication:** Sometimes, when using the `--ndb_log_orig` option, the `orig_epoch` and `orig_server_id` columns of the `ndb_binlog_index` table on the slave contained the ID and epoch of the local server instead. ([Bug#41601](#))
- **Cluster API:** Some error messages from `ndb_mgmd` contained newline (`\n`) characters. This could break the MGM API protocol, which uses the newline as a line separator. ([Bug#43104](#))

- **Cluster API:** When using an ordered index scan without putting all key columns in the read mask, this invalid use of the NDB API went undetected, which resulted in the use of uninitialized memory. (Bug#42591)
 - **Cluster API:** The MGM API reset error codes on management server handles before checking them. This meant that calling an MGM API function with a null handle caused applications to crash. (Bug#40455)
 - **Cluster API:** It was not always possible to access parent objects directly from `NdbBlob`, `NdbOperation`, and `NdbScanOperation` objects. To alleviate this problem, a new `getNdbOperation()` method has been added to `NdbBlob` and new `getNdbTransaction()` methods have been added to `NdbOperation` and `NdbScanOperation`. In addition, a const variant of `NdbOperation::getErrorLine()` is now also available. (Bug#40242)
 - **Cluster API:** `NdbScanOperation::getBlobHandle()` failed when used with incorrect column names or numbers. (Bug#40241)
 - **Cluster API:** The NDB API example programs included in MySQL Cluster source distributions failed to compile. (Bug#37491)
- See also Bug#40238.
- **Cluster API:** `mgmapi.h` contained constructs which only worked in C++, but not in C. (Bug#27004)

17.15.3.3. Changes in MySQL Cluster NDB 6.2.16 (5.1.28-ndb-6.2.16) (08 October 2008)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.2 release.

Obtaining MySQL Cluster NDB 6.2. You can download the latest MySQL Cluster NDB 6.2 source code and binaries for supported platforms from ftp://ftp.mysql.com/pub/mysql/download/cluster_telco/mysql-5.1.28-ndb-6.2.16.

This release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.2 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.28 (see [Section C.1.10, “Changes in MySQL 5.1.28 \(28 August 2008\)”](#)).

Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Functionality added or changed:

- It is no longer a requirement for database autodiscovery that an SQL node already be connected to the cluster at the time that a database is created on another SQL node. It is no longer necessary to issue `CREATE DATABASE` (or `CREATE SCHEMA`) statements on an SQL node joining the cluster after a database is created in order for the new SQL node to see the database and any `NDBCLUSTER` tables that it contains. (Bug#39612)

Bugs fixed:

- Heavy DDL usage caused the `mysqld` processes to hang due to a timeout error (NDB error code 266). (Bug#39885)
- Executing `EXPLAIN SELECT` on an `NDBCLUSTER` table could cause `mysqld` to crash. (Bug#39872)
- Starting the MySQL Server with the `--ndbcluster` option plus an invalid command-line option (for example, using `mysqld --ndbcluster --foobar`) caused it to hang while shutting down the binlog thread. (Bug#39635)
- Dropping and then re-creating a database on one SQL node caused other SQL nodes to hang. (Bug#39613)
- Setting a low value of `MaxNoOfLocalScans` (< 100) and performing a large number of (certain) scans could cause the Transaction Coordinator to run out of scan fragment records, and then crash. Now when this resource is exhausted, the cluster returns Error 291 (`OUT OF SCANFRAG RECORDS IN TC (INCREASE MAXNOOFLOCALSCANS)`) instead. (Bug#39549)
- Creating a unique index on an `NDBCLUSTER` table caused a memory leak in the NDB subscription manager (`SUMA`) which could lead to `mysqld` hanging, due to the fact that the resource shortage was not reported back to the NDB kernel correctly. (Bug#39518)

See also Bug#39450.

- Unique identifiers in tables having no primary key were not cached. This fix has been observed to increase the efficiency of `INSERT` operations on such tables by as much as 50%. (Bug#39267)

- `MgmtSrvr::allocNodeId()` left a mutex locked following an `AMBIGUITY FOR NODE IF %D` error. (Bug#39158)
- An invalid path specification caused `mysql-test-run.pl` to fail. (Bug#39026)
- During transactional coordinator takeover (directly after node failure), the LQH finding an operation in the `LOG_COMMIT` state sent an `LQH_TRANS_CONF` signal twice, causing the TC to fail. (Bug#38930)
- An invalid memory access caused the management server to crash on Solaris Sparc platforms. (Bug#38628)
- A segfault in `Logger::Log` caused `ndbd` to hang indefinitely. (Bug#38609)
- `ndb_mgmd` failed to start on older Linux distributions (2.4 kernels) that did not support e-polling. (Bug#38592)
- When restarting a data node, an excessively long shutdown message could cause the node process to crash. (Bug#38580)
- `ndb_mgmd` sometimes performed unnecessary network I/O with the client. This in combination with other factors led to long-running threads that were attempting to write to clients that no longer existed. (Bug#38563)
- `ndb_restore` failed with a floating point exception due to a division by zero error when trying to restore certain data files. (Bug#38520)
- A failed connection to the management server could cause a resource leak in `ndb_mgmd`. (Bug#38424)
- Failure to parse configuration parameters could cause a memory leak in the NDB log parser. (Bug#38380)
- After a forced shutdown and initial restart of the cluster, it was possible for SQL nodes to retain `.FRM` files corresponding to `NDBCLUSTER` tables that had been dropped, and thus to be unaware that these tables no longer existed. In such cases, attempting to re-create the tables using `CREATE TABLE IF NOT EXISTS` could fail with a spurious `TABLE ... DOESN'T EXIST` error. (Bug#37921)
- Renaming an `NDBCLUSTER` table on one SQL node, caused a trigger on this table to be deleted on another SQL node. (Bug#36658)
- Attempting to add a `UNIQUE INDEX` twice to an `NDBCLUSTER` table, then deleting rows from the table could cause the MySQL Server to crash. (Bug#35599)
- `ndb_restore` failed when a single table was specified. (Bug#33801)
- `GCP_COMMIT` did not wait for transaction takeover during node failure. This could cause `GCP_SAVE_REQ` to be executed too early. This could also cause (very rarely) replication to skip rows. (Bug#30780)
- **Cluster Replication:** In some cases, dropping a database on the master could cause table logging to fail on the slave, or, when using a debug build, could cause the slave `mysqld` to fail completely. (Bug#39404)
- **Cluster Replication:** During a parallel node restart, the starting nodes could (sometimes) incorrectly synchronize subscriptions among themselves. Instead, this synchronization now takes place only among nodes that have actually (completely) started. (Bug#38767)
- **Cluster Replication:** Data was written to the binlog with `--log-slave-updates` disabled. (Bug#37472)
- **Cluster API:** Passing a value greater than 65535 to `NdbInterpretedCode::add_val()` and `NdbInterpretedCode::sub_val()` caused these methods to have no effect. (Bug#39536)
- **Cluster API:** The `NdbScanOperation::readTuples()` method could be called multiple times without error. (Bug#38717)
- **Cluster API:** Certain Multi-Range Read scans involving `IS NULL` and `IS NOT NULL` comparisons failed with an error in the NDB local query handler. (Bug#38204)
- **Cluster API:** Problems with the public headers prevented NDB applications from being built with warnings turned on. (Bug#38177)
- **Cluster API:** Creating an `NdbScanFilter` object using an `NdbScanOperation` object that had not yet had its `readTuples()` method called resulted in a crash when later attempting to use the `NdbScanFilter`. (Bug#37986)
- **Cluster API:** Executing an `NdbRecord` interpreted delete created with an `ANYVALUE` option caused the transaction to abort. (Bug#37672)
- **Cluster API:** Accessing the debug version of `libndbclient` via `dlopen()` resulted in a segmentation fault. (Bug#35927)

17.15.3.4. Changes in MySQL Cluster NDB 6.2.15 (5.1.23-ndb-6.2.15) (22 May 2008)

This is re-release of MySQL Cluster NDB 6.2.14 providing binaries for supported platforms. For more information, see [Section 17.15.3.5, “Changes in MySQL Cluster NDB 6.2.14 \(5.1.23-ndb-6.2.14\) \(05 March 2008\)”](#).

Obtaining MySQL Cluster NDB 6.2. You can download the latest MySQL Cluster NDB 6.2 source code and binaries for supported platforms from <http://dev.mysql.com/downloads/cluster>.

17.15.3.5. Changes in MySQL Cluster NDB 6.2.14 (5.1.23-ndb-6.2.14) (05 March 2008)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.2 release.

Obtaining MySQL Cluster NDB 6.2. You can download the latest MySQL Cluster NDB 6.2 source code and binaries for supported platforms from <http://dev.mysql.com/downloads/cluster>.

This release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.2 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.23 (see [Section C.1.15, “Changes in MySQL 5.1.23 \(29 January 2008\)”](#)).

Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Functionality added or changed:

- Added the `MaxBufferedEpochs` data node configuration parameter, which controls the maximum number of unprocessed epochs by which a subscribing node can lag. Subscribers which exceed this number are disconnected and forced to reconnect. See [Section 17.3.4.6, “Defining MySQL Cluster Data Nodes”](#), for more information.
- **Replication:** Introduced the `slave_exec_mode` system variable to control whether idempotent or strict mode is used for replication conflict resolution. Idempotent mode suppresses duplicate-key, no-key-found, and some other errors, and is needed for circular replication, multi-master replication, and some other complex replication setups when using MySQL Cluster. Strict mode is the default. ([Bug#31609](#))
- **Cluster Replication:** `RESET MASTER` now uses `TRUNCATE` rather than `DELETE` to clear the `mysql.ndb_binlog_index` table. This improves the performance of the statement and is less likely to leave the table in a fragmented state. ([Bug#34356](#))
- Formerly, when the MySQL server crashed, the generated stack dump was numeric and required external tools to properly resolve the names of functions. This is not very helpful to users having a limited knowledge of debugging techniques. In addition, the generated stack trace contained only the names of functions and was formatted differently for each platform due to different stack layouts.

Now it is possible to take advantage of newer versions of the GNU C Library provide a set of functions to obtain and manipulate stack traces from within the program. On systems that use the ELF binary format, the stack trace contains important information such as the shared object where the call was generated, an offset into the function, and the actual return address. Having the function name also makes possible the name demangling of C++ functions.

The library generates meaningful stack traces on the following platforms: i386, x86_64, PowerPC, IA64, Alpha, and S390. On other platforms, a numeric stack trace is still produced, and the use of the `resolve_stack_dump` utility is still required. ([Bug#31891](#))

- `mysqltest` now has `mkdir` and `rmdir` commands for creating and removing directories. ([Bug#31004](#))
- Added the `Uptime_since_flush_status` status variable, which indicates the number of seconds since the most recent `FLUSH STATUS` statement. (Community contribution by Jeremy Cole) ([Bug#24822](#))

Bugs fixed:

- **Incompatible Change:** The `UPDATE` statement allowed `NULL` to be assigned to `NOT NULL` columns (the implicit default value for the column data type was assigned). This was changed so that an error occurs.

This change was reverted, because the original report was determined not to be a bug: Assigning `NULL` to a `NOT NULL` column in an `UPDATE` statement should produce an error only in strict SQL mode and set the column to the implicit default with a warning otherwise, which was the original behavior. See [Section 10.1.4, “Data Type Default Values”](#), and [Bug#39265](#).

[Bug#33699](#))

- **Important Change: Replication:** When the master crashed during an update on a transactional table while in `autocommit` mode, the slave failed. This fix causes every transaction (including `autocommit` transactions) to be recorded in the binlog as starting with a `BEGIN` and ending with a `COMMIT` or `ROLLBACK`. ([Bug#26395](#))
- **Replication: Important Note:** Network timeouts between the master and the slave could result in corruption of the relay log. This fix rectifies a long-standing replication issue when using unreliable networks, including replication over wide area networks such as the Internet. If you experience reliability issues and see many `YOU HAVE AN ERROR IN YOUR SQL SYNTAX` errors on replication slaves, we strongly recommend that you upgrade to a MySQL version which includes this fix. ([Bug#26489](#))
- **Replication:** When the Windows version of `mysqlbinlog` read 4.1 binlogs containing `LOAD DATA INFILE` statements, it output backslashes as path separators, causing problems for client programs expecting forward slashes. In such cases, it now converts `\\` to `/` in directory paths. ([Bug#34355](#))
- **Replication:** `SHOW SLAVE STATUS` failed when slave I/O was about to terminate. ([Bug#34305](#))
- **Replication:** `mysqlbinlog` from a 5.1 or later MySQL distribution could not read binary logs generated by a 4.1 server when the logs contained `LOAD DATA INFILE` statements. ([Bug#34141](#))

This regression was introduced by [Bug#32407](#).

- **Replication:** A `CREATE USER`, `DROP USER`, or `RENAME USER` statement that fails on the master, or that is a duplicate of any of these statements, is no longer written to the binlog; previously, either of these occurrences could cause the slave to fail. ([Bug#33862](#))

See also [Bug#29749](#).

- **Replication:** `mysqlbinlog` failed to release all of its memory after terminating abnormally. ([Bug#33247](#))
- **Replication:** The error message generated due to lack of a default value for an extra column was not sufficiently informative. ([Bug#32971](#))
- **Replication:** When a user variable was used inside an `INSERT` statement, the corresponding binlog event was not written to the binlog correctly. ([Bug#32580](#))
- **Replication:** When using row-based replication, deletes from a table with a foreign key constraint failed on the slave. ([Bug#32468](#))
- **Replication:** SQL statements containing comments using `--` syntax were not replayable by `mysqlbinlog`, even though such statements replicated correctly. ([Bug#32205](#))
- **Replication:** When using row-based replication from a master running MySQL 5.1.21 or earlier to a slave running 5.1.22 or later, updates of integer columns failed on the slave with `ERROR IN UNKNOWN EVENT: ROW APPLICATION FAILED`. ([Bug#31583](#))

This regression was introduced by [Bug#21842](#).

- **Replication:** Replicating write, update, or delete events from a master running MySQL 5.1.15 or earlier to a slave running 5.1.16 or later caused the slave to crash. ([Bug#31581](#))
- **Replication:** When using row-based replication, the slave stopped when attempting to delete non-existent rows from a slave table without a primary key. In addition, no error was reported when this occurred. ([Bug#31552](#))
- **Replication:** Issuing a `DROP VIEW` statement caused replication to fail if the view did not actually exist. ([Bug#30998](#))
- **Replication:** Replication of `LOAD DATA INFILE` could fail when `read_buffer_size` was larger than `max_allowed_packet`. ([Bug#30435](#))
- **Replication:** Replication crashed with the NDB storage engine when `mysqld` was started with `-character-set-server=ucs2`. ([Bug#29562](#))
- **Replication:** Setting `server_id` did not update its value for the current session. ([Bug#28908](#))
- **Replication:** Some older servers wrote events to the binary log using different numbering from what is currently used, even though the file format number in the file is the same. Slaves running MySQL 5.1.18 and later could not read these binary logs properly. Binary logs from these older versions now are recognized and event numbers are mapped to the current numbering so that they can be interpreted properly. ([Bug#27779](#), [Bug#32434](#))

This regression was introduced by [Bug#22583](#).

- **Cluster Replication:** Enabling the `ndb_wait_connected` system variable caused the server to wait for a partial connection plus an additional 3 seconds for a complete connection to the cluster. This could lead to issues with setting up the binary log. (Bug#34757)
- **Cluster API:** Closing a scan before it was executed caused the application to segfault. (Bug#36375)
- **Cluster API:** Using NDB API applications from older MySQL Cluster versions with `libndbclient` from newer ones caused the cluster to fail. (Bug#36124)
- **Cluster API:** Scans having no bounds set were handled incorrectly. (Bug#35876)
- Use of stored functions in the `WHERE` clause for `SHOW OPEN TABLES` caused a server crash. (Bug#34166)
- Large unsigned integers were improperly handled for prepared statements, resulting in truncation or conversion to negative numbers. (Bug#33798)
- The server crashed when executing a query that had a subquery containing an equality `X=Y` where `Y` referred to a named select list expression from the parent select. The server crashed when trying to use the `X=Y` equality for `ref`-based access. (Bug#33794)
- `ORDER BY ... DESC` sorts could produce misordered results. (Bug#33697)
- The server could crash when `REPEAT` or another control instruction was used in conjunction with labels and a `LEAVE` instruction. (Bug#33618)
- `SET GLOBAL myisam_max_sort_file_size=DEFAULT` set `myisam_max_sort_file_size` to an incorrect value. (Bug#33382)
See also Bug#31177.
- Granting the `UPDATE` privilege on one column of a view caused the server to crash. (Bug#33201)
- For `DECIMAL` columns used with the `ROUND(X,D)` or `TRUNCATE(X,D)` function with a non-constant value of `D`, adding an `ORDER BY` for the function result produced misordered output. (Bug#33143)
See also Bug#33402, Bug#30617.
- The `SHOW ENGINE INNODB STATUS` and `SHOW ENGINE INNODB MUTEX` statements incorrectly required the `SUPER` privilege rather than the `PROCESS` privilege. (Bug#32710)
- Tables in the `mysql` database that stored the current `sql_mode` value as part of stored program definitions were not updated with newer mode values (`NO_ENGINE_SUBSTITUTION`, `PAD_CHAR_TO_FULL_LENGTH`). This causes various problems defining stored programs if those modes were included in the current `sql_mode` value. (Bug#32633)
- `ROUND(X,D)` or `TRUNCATE(X,D)` for non-constant values of `D` could crash the server if these functions were used in an `ORDER BY` that was resolved using `filesort`. (Bug#30889)
- Resetting the query cache by issuing a `SET GLOBAL query_cache_size=0` statement caused the server to crash if it concurrently was saving a new result set to the query cache. (Bug#30887)
- The `Table_locks_waited` waited variable was not incremented in the cases that a lock had to be waited for but the waiting thread was killed or the request was aborted. (Bug#30331)
- The `Com_create_function` status variable was not incremented properly. (Bug#30252)
- `mysqld` displayed the `--enable-pstack` option in its help message even if MySQL was configured without `-with-pstack`. (Bug#29836)
- Views were treated as insertable even if some base table columns with no default value were omitted from the view definition. (This is contrary to the condition for insertability that a view must contain all columns in the base table that do not have a default value.) (Bug#29477)
- Previously, the parser accepted the ODBC `{ OJ ... LEFT OUTER JOIN ... }` syntax for writing left outer joins. The parser now allows `{ OJ ... }` to be used to write other types of joins, such as `INNER JOIN` or `RIGHT OUTER JOIN`. This helps with compatibility with some third-party applications, but is not official ODBC syntax. (Bug#28317)
- The parser rules for the `SHOW PROFILE` statement were revised to work with older versions of `bison`. (Bug#27433)
- `resolveip` failed to produce correct results for host names that begin with a digit. (Bug#27427)
- `mysqlcheck -A -r` did not correctly identify all tables that needed repairing. (Bug#25347)

- `InnoDB` exhibited thread thrashing with more than 50 concurrent connections under an update-intensive workload. (Bug#22868)
- Warnings for deprecated syntax constructs used in stored routines make sense to report only when the routine is being created, but they were also being reported when the routine was parsed for loading into the execution cache. Now they are reported only at routine creation time. (Bug#21801)
- `CREATE . . . SELECT` did not always set `DEFAULT` column values in the new table. (Bug#21380)
- If a `SELECT` calls a stored function in a transaction, and a statement within the function fails, that statement should roll back. Furthermore, if `ROLLBACK` is executed after that, the entire transaction should be rolled back. Before this fix, the failed statement did not roll back when it failed (even though it might ultimately get rolled back by a `ROLLBACK` later that rolls back the entire transaction). (Bug#12713)

See also Bug#34655.

17.15.3.6. Changes in MySQL Cluster NDB 6.2.13 (5.1.23-ndb-6.2.13) (22 February 2008)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.2 release.

Obtaining MySQL Cluster NDB 6.2. You can download the latest MySQL Cluster NDB 6.2 source code and binaries for supported platforms from <http://dev.mysql.com/downloads/cluster>.

This release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.2 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.23 (see [Section C.1.15, “Changes in MySQL 5.1.23 \(29 January 2008\)”](#)).

Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Bugs fixed:

- A node failure during an initial node restart followed by another node start could cause the master data node to fail, because it incorrectly gave the node permission to start even if the invalidated node's LCP was still running. (Bug#34702)

17.15.3.7. Changes in MySQL Cluster NDB 6.2.12 (5.1.23-ndb-6.2.12) (12 February 2008)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.2 release.

Obtaining MySQL Cluster NDB 6.2. You can download the latest MySQL Cluster NDB 6.2 source code and binaries for supported platforms from <http://dev.mysql.com/downloads/cluster>.

This release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.2 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.23 (see [Section C.1.15, “Changes in MySQL 5.1.23 \(29 January 2008\)”](#)).

Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Functionality added or changed:

- Beginning with this version, MySQL Cluster NDB 6.3.x releases once again include the `InnoDB` storage engine. In order to enable `InnoDB`, you must configure the build using `--with-innodb`.

Bugs fixed:

- Upgrades of a cluster using while a `DataMemory` setting in excess of 16 GB caused data nodes to fail. (Bug#34378)
- Performing many SQL statements on NDB tables while in `autocommit` mode caused a memory leak in `mysqld`. (Bug#34275)

- In certain rare circumstances, a race condition could occur between an aborted insert and a delete leading a data node crash. (Bug#34260)
- Multi-table updates using ordered indexes during handling of node failures could cause other data nodes to fail. (Bug#34216)
- When configured with NDB support, MySQL failed to compile using gcc 4.3 on 64bit FreeBSD systems. (Bug#34169)
- The failure of a DDL statement could sometimes lead to node failures when attempting to execute subsequent DDL statements. (Bug#34160)
- Extremely long SELECT statements (where the text of the statement was in excess of 50000 characters) against NDB tables returned empty results. (Bug#34107)
- Statements executing multiple inserts performed poorly on NDB tables having AUTO_INCREMENT columns. (Bug#33534)
- The `ndb_waiter` utility polled `ndb_mgmd` excessively when obtaining the status of cluster data nodes. (Bug#32025)
See also Bug#32023.
- Transaction atomicity was sometimes not preserved between reads and inserts under high loads. (Bug#31477)
- Having tables with a great many columns could cause Cluster backups to fail. (Bug#30172)
- **Cluster Replication: Disk Data:** Statements violating unique keys on Disk Data tables (such as attempting to insert NULL into a NOT NULL column) could cause data nodes to fail. When the statement was executed from the binlog, this could also result in failure of the slave cluster. (Bug#34118)
- **Disk Data:** Updating in-memory columns of one or more rows of Disk Data table, followed by deletion of these rows and reinsertion of them, caused data node failures. (Bug#33619)
- **Cluster Replication:** Setting `--replicate-ignore-db=mysql` caused the `mysql.ndb_apply_status` table not to be replicated, breaking Cluster Replication. (Bug#28170)

17.15.3.8. Changes in MySQL Cluster NDB 6.2.11 (5.1.23-ndb-6.2.11) (28 January 2008)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.2 release.

Obtaining MySQL Cluster NDB 6.2. You can download the latest MySQL Cluster NDB 6.2 source code and binaries for supported platforms from <http://dev.mysql.com/downloads/cluster>.

This release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.2 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.23 (see Section C.1.15, “Changes in MySQL 5.1.23 (29 January 2008)”).

Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Functionality added or changed:

- **Cluster API: Important Change:** Because `NDB_LE_MemoryUsage.page_size_kb` shows memory page sizes in bytes rather than kilobytes, it has been renamed to `page_size_bytes`. The name `page_size_kb` is now deprecated and thus subject to removal in a future release, although it currently remains supported for reasons of backward compatibility. See [The Ndb_logevent_type Type](#), for more information about `NDB_LE_MemoryUsage`. (Bug#30271)

Bugs fixed:

- High numbers of insert operations, delete operations, or both could cause NDB error 899 (`ROWID ALREADY ALLOCATED`) to occur unnecessarily. (Bug#34033)
- A periodic failure to flush the send buffer by the NDB TCP transporter could cause a unnecessary delay of 10 ms between operations. (Bug#34005)
- A race condition could occur (very rarely) when the release of a GCI was followed by a data node failure. (Bug#33793)
- Some tuple scans caused the wrong memory page to be accessed, leading to invalid results. This issue could affect both in-

memory and Disk Data tables. (Bug#33739)

- The server failed to reject properly the creation of an NDB table having an unindexed `AUTO_INCREMENT` column. (Bug#30417)
- Issuing an `INSERT ... ON DUPLICATE KEY UPDATE` concurrently with or following a `TRUNCATE` statement on an NDB table failed with NDB error 4350 `TRANSACTION ALREADY ABORTED`. (Bug#29851)
- The Cluster backup process could not detect when there was no more disk space and instead continued to run until killed manually. Now the backup fails with an appropriate error when disk space is exhausted. (Bug#28647)
- It was possible in `config.ini` to define cluster nodes having node IDs greater than the maximum allowed value. (Bug#28298)
- **Cluster Replication:** `ndb_restore -e` restored excessively large values to the `ndb_apply_status` table's `epoch` column when restoring to a MySQL Cluster version supporting Micro-GCPs from an older version that did not support these. A workaround when restoring to MySQL Cluster releases supporting micro-GCPs previous to MySQL Cluster NDB 6.3.8 is to perform a 32-bit shift on the `epoch` column values to reduce them to their proper size. (Bug#33406)
- **Cluster API:** Transactions containing inserts or reads would hang during `NdbTransaction::execute()` calls made from NDB API applications built against a MySQL Cluster version that did not support micro-GCPs accessing a later version that supported micro-GCPs. This issue was observed while upgrading from MySQL Cluster NDB 6.1.23 to MySQL Cluster NDB 6.2.10 when the API application built against the earlier version attempted to access a data node already running the later version, even after disabling micro-GCPs by setting `TimeBetweenEpochs` equal to 0. (Bug#33895)
- **Cluster API:** When reading a `BIT(64)` value using `NdbOperation::getValue()`, 12 bytes were written to the buffer rather than the expected 8 bytes. (Bug#33750)

17.15.3.9. Changes in MySQL Cluster NDB 6.2.10 (5.1.23-ndb-6.2.10) (19 December 2007)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.2 release.

Obtaining MySQL Cluster NDB 6.2. You can download the latest MySQL Cluster NDB 6.2 source code and binaries for supported platforms from <http://dev.mysql.com/downloads/cluster>.

This Beta release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.2 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.23 (see [Section C.1.15, “Changes in MySQL 5.1.23 \(29 January 2008\)”](#)).

Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Bugs fixed:

- **Partitioning:** When partition pruning on an NDB table resulted in an ordered index scan spanning only one partition, any descending flag for the scan was wrongly discarded, causing `ORDER BY DESC` to be treated as `ORDER BY ASC, MAX()` to be handled incorrectly, and similar problems. (Bug#33061)
- When all data and SQL nodes in the cluster were shut down abnormally (that is, other than by using `STOP` in the cluster management client), `ndb_mgm` used excessive amounts of CPU. (Bug#33237)
- When using micro-GCPs, if a node failed while preparing for a global checkpoint, the master node would use the wrong GCI. (Bug#32922)
- Under some conditions, performing an `ALTER TABLE` on an `NDBCLUSTER` table failed with a `TABLE IS FULL` error, even when only 25% of `DataMemory` was in use and the result should have been a table using less memory (for example, changing a `VARCHAR(100)` column to `VARCHAR(80)`). (Bug#32670)

17.15.3.10. Changes in MySQL Cluster NDB 6.2.9 (5.1.22-ndb-6.2.9) (22 November 2007)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.2 release.

Obtaining MySQL Cluster NDB 6.2. You can download the latest MySQL Cluster NDB 6.2 source code and binaries for supported platforms from <http://dev.mysql.com/downloads/cluster>.

This Beta release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.2 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.22 (see [Section C.1.16, “Changes in MySQL 5.1.22 \(24 September 2007 Release Candidate\)”](#)).

Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Functionality added or changed:

- Added the `ndb_mgm` client command `DUMP 8011`, which dumps all subscribers to the cluster log. See `DUMP 8011`, for more information.

Bugs fixed:

- A local checkpoint could sometimes be started before the previous LCP was restorable from a global checkpoint. ([Bug#32519](#))
- High numbers of API nodes on a slow or congested network could cause connection negotiation to time out prematurely, leading to the following issues:
 - Excessive retries
 - Excessive CPU usage
 - Partially connected API nodes ([Bug#32359](#))
- The failure of a master node could lead to subsequent failures in local checkpointing. ([Bug#32160](#))
- Adding a new `TINYTEXT` column to an NDB table which used `COLUMN_FORMAT = DYNAMIC`, and when binary logging was enabled, caused all cluster `mysqld` processes to crash. ([Bug#30213](#))
- After adding a new column of one of the `TEXT` or `BLOB` types to an NDB table which used `COLUMN_FORMAT = DYNAMIC`, it was no longer possible to access or drop the table using SQL. ([Bug#30205](#))
- A restart of the cluster failed when more than 1 REDO phase was in use. ([Bug#22696](#))
- **Cluster Replication: Replication:** Where a table being replicated had a `TEXT` or `BLOB` column, an `UPDATE` on the master that did not refer explicitly to this column in the `WHERE` clause stopped the SQL thread on the slave with `ERROR IN WRITE_ROWS EVENT: ROW APPLICATION FAILED. GOT ERROR 4288 'BLOB HANDLE FOR COLUMN NOT AVAILABLE' FROM NDB-CLUSTER`. ([Bug#30674](#))
- **Cluster Replication:** Under certain conditions, the slave stopped processing relay logs. This resulted in the logs never being cleared and the slave eventually running out of disk space. ([Bug#31958](#))

17.15.3.11. Changes in MySQL Cluster NDB 6.2.8 (5.1.22-ndb-6.2.8) (08 November 2007)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.2 release.

Obtaining MySQL Cluster NDB 6.2. You can download the latest MySQL Cluster NDB 6.2 source code and binaries for supported platforms from <http://dev.mysql.com/downloads/cluster>.

This Beta release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.2 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.22 (see [Section C.1.16, “Changes in MySQL 5.1.22 \(24 September 2007 Release Candidate\)”](#)).

Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Functionality added or changed:

- **Important Note:** MySQL Cluster NDB 6.2 and 6.3 source archives are now available in separate commercial and GPL versions. Due to licensing concerns, previous MySQL Cluster NDB 6.2 and 6.3 source archives were removed from the FTP site.

Bugs fixed:

- In a cluster running in diskless mode and with arbitration disabled, the failure of a data node during an insert operation caused other data node to fail. (Bug#31980)
- An insert or update with combined range and equality constraints failed when run against an NDB table with the error `GOT UNKNOWN ERROR FROM NDB`. An example of such a statement would be `UPDATE t1 SET b = 5 WHERE a IN (7,8) OR a >= 10;`. (Bug#31874)
- An error with an `if` statement in `sql/ha_ndbcluster.cc` could potentially lead to an infinite loop in case of failure when working with `AUTO_INCREMENT` columns in NDB tables. (Bug#31810)
- The NDB storage engine code was not safe for strict-alias optimization in `gcc` 4.2.1. (Bug#31761)
- Following an upgrade, `ndb_mgmd` would fail with an `ArbitrationError`. (Bug#31690)
- The NDB management client command `node_id REPORT MEMORY` provided no output when `node_id` was the node ID of a management or API node. Now, when this occurs, the management client responds with `Node node_id: is not a data node`. (Bug#29485)
- Performing `DELETE` operations after a data node had been shut down could lead to inconsistent data following a restart of the node. (Bug#26450)
- `UPDATE IGNORE` could sometimes fail on NDB tables due to the use of uninitialized data when checking for duplicate keys to be ignored. (Bug#25817)
- **Cluster Replication: Replication:** A node failure during replication could lead to buckets out of order; now active subscribers are checked for, rather than empty buckets. (Bug#31701)
- **Cluster Replication:** When the master `mysqld` crashed or was restarted, no `LOST_EVENTS` entry was made in the binlog. (Bug#31484)

See also Bug#21494.

17.15.3.12. Changes in MySQL Cluster NDB 6.2.7 (5.1.22-ndb-6.2.7) (10 October 2007)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.2 release.

Obtaining MySQL Cluster NDB 6.2. You can download the latest MySQL Cluster NDB 6.2 source code and binaries for supported platforms from <http://dev.mysql.com/downloads/cluster>.

This Beta release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.2 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.22 (see [Section C.1.16, “Changes in MySQL 5.1.22 \(24 September 2007 Release Candidate\)”](#)).

Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Functionality added or changed:

- **Cluster Replication:** A new configuration parameter `TimeBetweenEpochsTimeout` allows a timeout to be set for time between epochs. For more information, see [Section 17.3.4.6, “Defining MySQL Cluster Data Nodes”](#). (Bug#31276)
- Additional checks were implemented to catch unsupported online `ALTER TABLE` operations. Currently it is not possible to re-order columns or to change the storage engine used for a table via online `ALTER TABLE`.

Some redundant checks made during online creation of indexes were removed.

Bugs fixed:

- It was possible in some cases for a node group to be “lost” due to missed local checkpoints following a system restart. (Bug#31525)
- NDB tables having names containing non-alphanumeric characters (such as “\$”) were not discovered correctly. (Bug#31470)

- A node failure during a local checkpoint could lead to a subsequent failure of the cluster during a system restart. (Bug#31257)
- A cluster restart could sometimes fail due to an issue with table IDs. (Bug#30975)
- Transaction timeouts were not handled well in some circumstances, leading to excessive number of transactions being aborted unnecessarily. (Bug#30379)
- In some cases, the cluster management server logged entries multiple times following a restart of `mgmd`. (Bug#29565)
- `ndb_mgm --help` did not display any information about the `-a` option. (Bug#29509)
- The cluster log was formatted inconsistently and contained extraneous newline characters. (Bug#25064)
- Online `ALTER` operations involving a column whose data type has an implicit default value left behind temporary `.frm` files, causing subsequent `DROP DATABASE` statements to fail. (Bug#31097)
- Transactions were committed prematurely when `LOCK TABLE` and `SET autocommit = 0` were used together. (Bug#30996)
- The `mysqld_safe` script contained a syntax error. (Bug#30624)

17.15.3.13. Changes in MySQL Cluster NDB 6.2.6 (5.1.22-ndb-6.2.6) (20 September 2007)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.2 release.

Obtaining MySQL Cluster NDB 6.2. You can download the latest MySQL Cluster NDB 6.2 source code and binaries for supported platforms from <http://dev.mysql.com/downloads/cluster>.

This Beta release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.2 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.22 (see [Section C.1.16, “Changes in MySQL 5.1.22 \(24 September 2007 Release Candidate\)”](#)).

Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Functionality added or changed:

- Mapping of `NDB` error codes to MySQL storage engine error codes has been improved. (Bug#28423)

Bugs fixed:

- **Partitioning:** `EXPLAIN PARTITIONS` reported partition usage by queries on `NDB` tables according to the standard MySQL hash function than the hash function used in the `NDB` storage engine. (Bug#29550)
- When an `NDB` event was left behind but the corresponding table was later recreated and received a new table ID, the event could not be dropped. (Bug#30877)
- Attempting to restore a backup made on a cluster host using one endian to a machine using the other endian could cause the cluster to fail. (Bug#29674)
- The description of the `--print` option provided in the output from `ndb_restore --help` was incorrect. (Bug#27683)
- Restoring a backup made on a cluster host using one endian to a machine using the other endian failed for `BLOB` and `DATE-TIME` columns. (Bug#27543, Bug#30024)
- An insufficiently descriptive and potentially misleading Error 4006 (`CONNECT FAILURE - OUT OF CONNECTION OBJECTS...`) was produced when either of the following two conditions occurred:
 1. There were no more transaction records in the transaction coordinator
 2. An `NDB` object in the `NDB` API was initialized with insufficient parallelism
 Separate error messages are now generated for each of these two cases. (Bug#11313)
- For micro-GCPs, the assignment of “fake” CGI events no longer cause buckets to be sent out of order. Now, when assigning a GCI to a non-GCI event (that is, creating a pseudo-GCI or “fake” CGI), the GCI that is to arrive is always initiated, even if no

known GCI exists, which could occur in the event of a node failure. ([Bug#30884](#))

17.15.3.14. Changes in MySQL Cluster NDB 6.2.5 (5.1.22-ndb-6.2.5) (06 September 2007)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.2 release.

Obtaining MySQL Cluster NDB 6.2. You can download the latest MySQL Cluster NDB 6.2 source code and binaries for supported platforms from <http://dev.mysql.com/downloads/cluster>.

This Beta release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.2 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.22 (see [Section C.1.16](#), “Changes in MySQL 5.1.22 (24 September 2007 Release Candidate)”).

Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Functionality added or changed:

- The following improvements have been made in the `ndb_size.pl` utility:
 - The script can now be used with multiple databases; lists of databases and tables can also be excluded from analysis.
 - Schema name information has been added to index table calculations.
 - The database name is now an optional parameter, the exclusion of which causes all databases to be examined.
 - If selecting from `INFORMATION_SCHEMA` fails, the script now attempts to fall back to `SHOW TABLES`.
 - A `--real_table_name` option has been added; this designates a table to handle unique index size calculations.
 - The report title has been amended to cover cases where more than one database is being analyzed.

Support for a `--socket` option was also added.

For more information, see [Section 17.6.21](#), “`ndb_size.pl` — NDBCLUSTER Size Requirement Estimator”. ([Bug#28683](#), [Bug#28253](#))

- Online `ADD COLUMN`, `ADD INDEX`, and `DROP INDEX` operations can now be performed explicitly for `NDB` tables, as well as online renaming of tables and columns for `NDB` and `MyISAM` tables — that is, without copying or locking of the affected tables — using `ALTER ONLINE TABLE`.

Indexes can also be created and dropped online using `CREATE INDEX` and `DROP INDEX`, respectively, using the `ONLINE` keyword.

You can force operations that would otherwise be performed online to be done offline using the `OFFLINE` keyword.

See [Section 12.1.7](#), “`ALTER TABLE Syntax`”, [Section 12.1.13](#), “`CREATE INDEX Syntax`”, and [Section 12.1.24](#), “`DROP INDEX Syntax`”, for more information.

- It is now possible to control whether fixed-width or variable-width storage is used for a given column of an `NDB` table by means of the `COLUMN_FORMAT` specifier as part of the column's definition in a `CREATE TABLE` or `ALTER TABLE` statement.

It is also possible to control whether a given column of an `NDB` table is stored in memory or on disk, using the `STORAGE` specifier as part of the column's definition in a `CREATE TABLE` or `ALTER TABLE` statement.

For permitted values and other information about `COLUMN_FORMAT` and `STORAGE`, see [Section 12.1.17](#), “`CREATE TABLE Syntax`”.

- A new cluster management server startup option `--bind-address` makes it possible to restrict management client connections to `ndb_mgmd` to a single host and port. For more information, see [Section 17.6.24.3](#), “Program Options for `ndb_mgmd`”.
- **Cluster Replication:** The protocol for handling global checkpoints has been changed. It is now possible to control how often the GCI number is updated, and how often global checkpoints are written to disk, using the `TimeBetweenEpochs` configuration parameter. This improves the reliability and performance of MySQL Cluster Replication.

GCPs handled using the new protocol are sometimes referred to as “micro-GCPs”.

For more information, see [TimeBetweenEpochs](#) .

Bugs fixed:

- When handling `BLOB` columns, the addition of read locks to the lock queue was not handled correctly. (Bug#30764)
- Discovery of `NDB` tables did not work correctly with `INFORMATION_SCHEMA`. (Bug#30667)
- A file system close operation could fail during a node or system restart. (Bug#30646)
- Using the `--ndb-cluster-connection-pool` option for `mysqld` caused DDL statements to be executed twice. (Bug#30598)
- `ndb_size.pl` failed on tables with `FLOAT` columns whose definitions included commas (for example, `FLOAT(6,2)`). (Bug#29228)
- Reads on `BLOB` columns were not locked when they needed to be to guarantee consistency. (Bug#29102)

See also [Bug#31482](#).

- A query using joins between several large tables and requiring unique index lookups failed to complete, eventually returning `UNKNOWN ERROR` after a very long period of time. This occurred due to inadequate handling of instances where the Transaction Coordinator ran out of `TransactionBufferMemory`, when the cluster should have returned NDB error code 4012 (`REQUEST NDBD TIME-OUT`). (Bug#28804)
- An attempt to perform a `SELECT ... FROM INFORMATION_SCHEMA.TABLES` whose result included information about `NDB` tables for which the user had no privileges crashed the MySQL Server on which the query was performed. (Bug#26793)
- **Cluster Replication:** Cluster replication did not handle large `VARCHAR` columns correctly. (Bug#29904)
- **Cluster Replication:** An issue with the `mysql.ndb_apply_status` table could cause `NDB` schema autodiscovery to fail in certain rare circumstances. (Bug#20872)
- **Cluster API:** A call to `CHECK_TIMEDOUT_RET()` in `mgmapi.cpp` should have been a call to `DBG_CHECK_TIMEDOUT_RET()`. (Bug#30681)

17.15.3.15. Changes in MySQL Cluster NDB 6.2.4 (5.1.19-ndb-6.2.4) (04 July 2007)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.2 release.

Obtaining MySQL Cluster NDB 6.2. You can download the latest MySQL Cluster NDB 6.2 source code and binaries for supported platforms from <http://dev.mysql.com/downloads/cluster>.

This Beta release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.2 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.19 (see [Section C.1.19, “Changes in MySQL 5.1.19 \(25 May 2007\)”](#)).

Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Bugs fixed:

- When restarting a data node, queries could hang during that node's start phase 5, and continue only after the node had entered phase 6. (Bug#29364)
- Replica redo logs were inconsistently handled during a system restart. (Bug#29354)
- **Disk Data:** Performing Disk Data schema operations during a node restart could cause forced shutdowns of other data nodes. (Bug#29501)
- **Disk Data:** Disk data meta-information that existed in `ndbd` might not be visible to `mysqld`. (Bug#28720)
- **Disk Data:** The number of free extents was incorrectly reported for some tablespaces. (Bug#28642)

- Batching of transactions was not handled correctly in some cases. ([Bug#29525](#))

17.15.3.16. Changes in MySQL Cluster NDB 6.2.3 (5.1.19-ndb-6.2.3) (02 July 2007)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.2 release.

Obtaining MySQL Cluster NDB 6.2. You can download the latest MySQL Cluster NDB 6.2 source code and binaries for supported platforms from <http://dev.mysql.com/downloads/cluster>.

This Beta release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.2 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.18 (see [Section C.1.20, “Changes in MySQL 5.1.18 \(08 May 2007\)”](#)).

Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Bugs fixed:

- When restarting a data node, queries could hang during that node's start phase 5, and continue only after the node had entered phase 6. ([Bug#29364](#))
- Replica redo logs were inconsistently handled during a system restart. ([Bug#29354](#))
- **Disk Data:** Performing Disk Data schema operations during a node restart could cause forced shutdowns of other data nodes. ([Bug#29501](#))
- **Disk Data:** Disk data meta-information that existed in `ndbd` might not be visible to `mysqld`. ([Bug#28720](#))
- **Disk Data:** The number of free extents was incorrectly reported for some tablespaces. ([Bug#28642](#))
- Batching of transactions was not handled correctly in some cases. ([Bug#29525](#))

17.15.3.17. Changes in MySQL Cluster NDB 6.2.2 (5.1.18-ndb-6.2.2) (07 May 2007)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.2 release.

Obtaining MySQL Cluster NDB 6.2. You can download the latest MySQL Cluster NDB 6.2 source code and binaries for supported platforms from <http://dev.mysql.com/downloads/cluster>.

This Beta release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.2 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.18 (see [Section C.1.20, “Changes in MySQL 5.1.18 \(08 May 2007\)”](#)).

Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Functionality added or changed:

- New cluster management client `DUMP` commands were added to aid in tracking transactions, scan operations, and locks. See `DUMP 2350`, `DUMP 2352`, and `DUMP 2550`, for more information.
- Added the `mysqld` option `--ndb-cluster-connection-pool` that allows a single MySQL server to use multiple connections to the cluster. This allows for scaling out using multiple MySQL clients per SQL node instead of or in addition to using multiple SQL nodes with the cluster.

For more information about this option, see [Section 17.4, “MySQL Cluster Options and Variables”](#).

17.15.3.18. Changes in MySQL Cluster NDB 6.2.1 (5.1.18-ndb-6.2.1) (30 April 2007)

This is a Beta development release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.2 release.

Obtaining MySQL Cluster NDB 6.2. You can download the latest MySQL Cluster NDB 6.2 source code and binaries for supported platforms from <http://dev.mysql.com/downloads/cluster>.

This Beta release incorporates all bugfixes and changes made in the previous MySQL Cluster NDB 6.2 release, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.18 (see [Section C.1.20, “Changes in MySQL 5.1.18 \(08 May 2007\)”](#)).

Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Bugs fixed:

- Multiple operations involving deletes followed by reads were not handled correctly.

Note

This issue could also affect MySQL Cluster Replication.

([Bug#28276](#))

- **Cluster API:** Using `NdbBlob::writeData()` to write data in the middle of an existing blob value (that is, updating the value) could overwrite some data past the end of the data to be changed. ([Bug#27018](#))
- Incorrect handling of fragmentation in a node takeover during a restart could cause stale data to be copied to the starting node, leading eventually to failure of the node. ([Bug#27434](#))
- An incorrect assertion was made when sending a `TCKEYFAILREF` or `TCKEYCONF` message to a failed data node. ([Bug#26814](#))

17.15.3.19. Changes in MySQL Cluster NDB 6.2.0 (5.1.16-ndb-6.2.0) (03 March 2007)

This is the first MySQL Cluster NDB 6.2 development release, based on version 6.2 of the `NDBCLUSTER` storage engine.

Obtaining MySQL Cluster NDB 6.2. You can download the latest MySQL Cluster NDB 6.2 source code and binaries for supported platforms from <http://dev.mysql.com/downloads/cluster>.

This Beta release incorporates bugfixes and changes made in previous MySQL Cluster releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.16 (see [Section C.1.22, “Changes in MySQL 5.1.16 \(26 February 2007\)”](#)).

Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Functionality added or changed:

- An `ndb_wait_connected` system variable has been added for `mysqld`. It causes `mysqld` wait a specified amount of time to be connected to the cluster before accepting client connections. For more information, see [Section 17.4.3, “MySQL Cluster System Variables”](#).
- **Cluster API:** The `Ndb::startTransaction()` method now provides an alternative interface for starting a transaction. See `Ndb::startTransaction()`, for more information.
- **Cluster API:** Methods were added to the `Ndb_cluster_connection` class to facilitate iterating over existing `NDB` objects. See `ndb_cluster_connection::get_next_ndb_object()`, for more information.
- It is now possible to disable arbitration by setting `ArbitrationRank` equal to 0 on all nodes.
- A new `TcpBind_INADDR_ANY` configuration parameter allows data nodes node to bind `INADDR_ANY` instead of a host name or IP address in the `config.ini` file.
- Memory allocation has been improved on 32-bit architectures that enables using close to 3GB for `DataMemory` and `IndexMemory` combined.

17.15.4. Changes in MySQL Cluster NDB 6.1

This section contains change history information for MySQL Cluster releases based on version 6.1 of the `NDBCLUSTER` storage engine.

For an overview of features that were added in MySQL Cluster NDB 6.1, see [Section 17.13.2, “Features Added in MySQL Cluster NDB 6.1”](#).

Note

MySQL Cluster NDB 6.1 is no longer being developed or maintained, and the information presented in the next few sections should be considered to be of historical interest only. If you are using MySQL Cluster NDB 6.1, you should upgrade as soon as possible to the most recent version of MySQL Cluster NDB 6.2 or later MySQL Cluster release series.

17.15.4.1. Changes in MySQL Cluster NDB 6.1.23 (5.1.15-ndb-6.1.23) (20 November 2007)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.1 release.

MySQL Cluster NDB 6.1 no longer in development. MySQL Cluster NDB 6.1 (formerly known as “MySQL Cluster Carrier Grade Edition 6.1.x”) is no longer being developed or maintained; if you are using a MySQL Cluster NDB 6.1 release, you should consider upgrading to MySQL Cluster NDB 6.2 or 6.3.

This Beta release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.1 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.15 (see [Section C.1.23, “Changes in MySQL 5.1.15 \(25 January 2007\)”](#)).

Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Bugs fixed:

- The `NDB` storage engine code was not safe for strict-alias optimization in `gcc` 4.2.1. ([Bug#31761](#))
- **Cluster Replication:** Under certain conditions, the slave stopped processing relay logs. This resulted in the logs never being cleared and the slave eventually running out of disk space. ([Bug#31958](#))

17.15.4.2. Changes in MySQL Cluster NDB 6.1.22 (5.1.15-ndb-6.1.22) (19 October 2007)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.1 release.

MySQL Cluster NDB 6.1 no longer in development. MySQL Cluster NDB 6.1 (formerly known as “MySQL Cluster Carrier Grade Edition 6.1.x”) is no longer being developed or maintained; if you are using a MySQL Cluster NDB 6.1 release, you should consider upgrading to MySQL Cluster NDB 6.2 or 6.3.

This Beta release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.1 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.15 (see [Section C.1.23, “Changes in MySQL 5.1.15 \(25 January 2007\)”](#)).

Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Bugs fixed:

- It was possible in some cases for a node group to be “lost” due to missed local checkpoints following a system restart. ([Bug#31525](#))
- **Cluster Replication: Replication:** A node failure during replication could lead to buckets out of order; now active subscribers are checked for, rather than empty buckets. ([Bug#31701](#))

17.15.4.3. Changes in MySQL Cluster NDB 6.1.21 (5.1.15-ndb-6.1.21) (01 October 2007)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.1 release.

MySQL Cluster NDB 6.1 no longer in development. MySQL Cluster NDB 6.1 (formerly known as “MySQL Cluster Carrier Grade Edition 6.1.x”) is no longer being developed or maintained; if you are using a MySQL Cluster NDB 6.1 release, you should consider upgrading to MySQL Cluster NDB 6.2 or 6.3.

This Beta release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.1 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.15 (see [Section C.1.23, “Changes in MySQL 5.1.15 \(25 January 2007\)”](#)).

Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Bugs fixed:

- A node failure during a local checkpoint could lead to a subsequent failure of the cluster during a system restart. ([Bug#31257](#))
- A cluster restart could sometimes fail due to an issue with table IDs. ([Bug#30975](#))

17.15.4.4. Changes in MySQL Cluster NDB 6.1.20 (5.1.15-ndb-6.1.20) (14 September 2007)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.1 release.

MySQL Cluster NDB 6.1 no longer in development. MySQL Cluster NDB 6.1 (formerly known as “MySQL Cluster Carrier Grade Edition 6.1.x”) is no longer being developed or maintained; if you are using a MySQL Cluster NDB 6.1 release, you should consider upgrading to MySQL Cluster NDB 6.2 or 6.3.

This Beta release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.1 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.15 (see [Section C.1.23, “Changes in MySQL 5.1.15 \(25 January 2007\)”](#)).

Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Bugs fixed:

- **Cluster Replication: Replication:** Incorrect handling of `INSERT` plus `DELETE` operations with regard to local checkpoints caused data node failures in multi-master replication setups. ([Bug#30914](#))

17.15.4.5. Changes in MySQL Cluster NDB 6.1.19 (5.1.15-ndb-6.1.19) (01 August 2007)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.1 release.

MySQL Cluster NDB 6.1 no longer in development. MySQL Cluster NDB 6.1 (formerly known as “MySQL Cluster Carrier Grade Edition 6.1.x”) is no longer being developed or maintained; if you are using a MySQL Cluster NDB 6.1 release, you should consider upgrading to MySQL Cluster NDB 6.2 or 6.3.

This Beta release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.1 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.15 (see [Section C.1.23, “Changes in MySQL 5.1.15 \(25 January 2007\)”](#)).

Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Functionality added or changed:

- Whenever a TCP send buffer is over 80% full, temporary error 1218 (`SEND BUFFERS OVERLOADED IN NDB KERNEL`) is now returned. See [SendBufferMemory](#) for more information.

- An **INFO** event is now sent if the time between global checkpoints is excessive, or if **DUMP 7901** is issued in the management client.

17.15.4.6. Changes in MySQL Cluster NDB 6.1.18 (5.1.15-ndb-6.1.18) (Not released)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.1 release.

MySQL Cluster NDB 6.1 no longer in development. MySQL Cluster NDB 6.1 (formerly known as “MySQL Cluster Carrier Grade Edition 6.1.x”) is no longer being developed or maintained; if you are using a MySQL Cluster NDB 6.1 release, you should consider upgrading to MySQL Cluster NDB 6.2 or 6.3.

This Beta release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.1 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.15 (see [Section C.1.23, “Changes in MySQL 5.1.15 \(25 January 2007\)”](#)).

Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Bugs fixed:

- When restarting a data node, queries could hang during that node's start phase 5, and continue only after the node had entered phase 6. ([Bug#29364](#))
- **Replication:** Storage engine error conditions in row-based replication were not correctly reported to the user. ([Bug#29570](#))
- **Disk Data:** Disk data meta-information that existed in `ndbd` might not be visible to `mysqld`. ([Bug#28720](#))
- **Disk Data:** The number of free extents was incorrectly reported for some tablespaces. ([Bug#28642](#))

17.15.4.7. Changes in MySQL Cluster NDB 6.1.17 (5.1.15-ndb-6.1.17) (03 July 2007)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.1 release.

MySQL Cluster NDB 6.1 no longer in development. MySQL Cluster NDB 6.1 (formerly known as “MySQL Cluster Carrier Grade Edition 6.1.x”) is no longer being developed or maintained; if you are using a MySQL Cluster NDB 6.1 release, you should consider upgrading to MySQL Cluster NDB 6.2 or 6.3.

This Beta release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.1 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.15 (see [Section C.1.23, “Changes in MySQL 5.1.15 \(25 January 2007\)”](#)).

Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Functionality added or changed:

- **Cluster Replication: Replication:** Batching of updates on cluster replication slaves, enabled using the `-slave-allow-batching` option for `mysqld`.

Bugs fixed:

- Replica redo logs were inconsistently handled during a system restart. ([Bug#29354](#))

17.15.4.8. Changes in MySQL Cluster NDB 6.1.16 (5.1.15-ndb-6.1.16) (29 June 2007)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.1 release.

MySQL Cluster NDB 6.1 no longer in development. MySQL Cluster NDB 6.1 (formerly known as “MySQL Cluster Carrier Grade Edition 6.1.x”) is no longer being developed or maintained; if you are using a MySQL Cluster NDB 6.1 release, you should

consider upgrading to MySQL Cluster NDB 6.2 or 6.3.

This Beta release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.1 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.15 (see [Section C.1.23, “Changes in MySQL 5.1.15 \(25 January 2007\)”](#)).

Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Bugs fixed:

- When a node failed to respond to a `COPY_GCI` signal as part of a global checkpoint, the master node was killed instead of the node that actually failed. ([Bug#29331](#))
- An invalid comparison made during `REDO` validation that could lead to an `ERROR WHILE READING REDO LOG` condition. ([Bug#29118](#))
- The wrong data pages were sometimes invalidated following a global checkpoint. ([Bug#29067](#))
- If at least 2 files were involved in `REDO` invalidation, then file 0 of page 0 was not updated and so pointed to an invalid part of the redo log. ([Bug#29057](#))
- **Disk Data:** When dropping a page, the stack's bottom entry could sometime be left “cold” rather than “hot”, violating the rules for stack pruning. ([Bug#29176](#))

17.15.4.9. Changes in MySQL Cluster NDB 6.1.15 (5.1.15-ndb-6.1.15) (20 June 2007)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.1 release.

MySQL Cluster NDB 6.1 no longer in development. MySQL Cluster NDB 6.1 (formerly known as “MySQL Cluster Carrier Grade Edition 6.1.x”) is no longer being developed or maintained; if you are using a MySQL Cluster NDB 6.1 release, you should consider upgrading to MySQL Cluster NDB 6.2 or 6.3.

This Beta release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.1 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.15 (see [Section C.1.23, “Changes in MySQL 5.1.15 \(25 January 2007\)”](#)).

Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Bugs fixed:

- Memory corruption could occur due to a problem in the `DBTUP` kernel block. ([Bug#29229](#))

17.15.4.10. Changes in MySQL Cluster NDB 6.1.14 (5.1.15-ndb-6.1.14) (19 June 2007)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.1 release.

MySQL Cluster NDB 6.1 no longer in development. MySQL Cluster NDB 6.1 (formerly known as “MySQL Cluster Carrier Grade Edition 6.1.x”) is no longer being developed or maintained; if you are using a MySQL Cluster NDB 6.1 release, you should consider upgrading to MySQL Cluster NDB 6.2 or 6.3.

This Beta release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.1 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.15 (see [Section C.1.23, “Changes in MySQL 5.1.15 \(25 January 2007\)”](#)).

Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Bugs fixed:

- In the event that two data nodes in the same node group and participating in a GCP crashed before they had written their respective `P0.sysfile` files, `QMGR` could refuse to start, issuing an invalid `INSUFFICIENT_NODES_FOR_RESTART` error instead. (Bug#29167)

17.15.4.11. Changes in MySQL Cluster NDB 6.1.13 (5.1.15-ndb-6.1.13) (15 June 2007)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.1 release.

MySQL Cluster NDB 6.1 no longer in development. MySQL Cluster NDB 6.1 (formerly known as “MySQL Cluster Carrier Grade Edition 6.1.x”) is no longer being developed or maintained; if you are using a MySQL Cluster NDB 6.1 release, you should consider upgrading to MySQL Cluster NDB 6.2 or 6.3.

This Beta release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.1 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.15 (see [Section C.1.23, “Changes in MySQL 5.1.15 \(25 January 2007\)”](#)).

Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Functionality added or changed:

- Read ahead was implemented for backups of Disk Data tables, resulting in a 10 to 15% increase in backup speed of Disk Data tables. (Bug#29099)

Bugs fixed:

- **Cluster API:** `NdbApi.hpp` depended on `ndb_global.h`, which was not actually installed, causing the compilation of programs that used `NdbApi.hpp` to fail. (Bug#35853)

17.15.4.12. Changes in MySQL Cluster NDB 6.1.12 (5.1.15-ndb-6.1.12) (13 June 2007)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.1 release.

MySQL Cluster NDB 6.1 no longer in development. MySQL Cluster NDB 6.1 (formerly known as “MySQL Cluster Carrier Grade Edition 6.1.x”) is no longer being developed or maintained; if you are using a MySQL Cluster NDB 6.1 release, you should consider upgrading to MySQL Cluster NDB 6.2 or 6.3.

This Beta release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.1 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.15 (see [Section C.1.23, “Changes in MySQL 5.1.15 \(25 January 2007\)”](#)).

Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Functionality added or changed:

- New cluster management client `DUMP` commands were added to aid in tracking transactions, scan operations, and locks. See `DUMP 2350`, `DUMP 2352`, and `DUMP 2550`.
- Backup dump output was extended to provide more information.

Bugs fixed:

- It is now possible to set the maximum size of the allocation unit for table memory using the `MaxAllocate` configuration parameter. (Bug#29044)

17.15.4.13. Changes in MySQL Cluster NDB 6.1.11 (5.1.15-ndb-6.1.11) (06 June 2007)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.1 release.

MySQL Cluster NDB 6.1 no longer in development. MySQL Cluster NDB 6.1 (formerly known as “MySQL Cluster Carrier Grade Edition 6.1.x”) is no longer being developed or maintained; if you are using a MySQL Cluster NDB 6.1 release, you should consider upgrading to MySQL Cluster NDB 6.2 or 6.3.

This Beta release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.1 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.15 (see [Section C.1.23, “Changes in MySQL 5.1.15 \(25 January 2007\)”](#)).

Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Functionality added or changed:

- **Important Change:** The `TimeBetweenWatchdogCheckInitial` configuration parameter was added to allow setting of a separate watchdog timeout for memory allocation during startup of the data nodes. See [Section 17.3.4.6, “Defining MySQL Cluster Data Nodes”](#), for more information. (Bug#28899)
- A new configuration parameter `ODirect` causes NDB to attempt using `O_DIRECT` writes for LCP, backups, and redo logs, often lowering CPU usage.
- It is now possible to set the size of redo log files (fragment log files) using the `FragmentLogFileSize` configuration parameter.

Bugs fixed:

- Having large amounts of memory locked caused swapping to disk. (Bug#28751)
- LCP files were not removed following an initial system restart. (Bug#28726)
- **Disk Data:** Repeated `INSERT` and `DELETE` operations on a Disk Data table having one or more large `VARCHAR` columns could cause data nodes to fail. (Bug#20612)

17.15.4.14. Changes in MySQL Cluster NDB 6.1.10 (5.1.15-ndb-6.1.10) (30 May 2007)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.1 release.

MySQL Cluster NDB 6.1 no longer in development. MySQL Cluster NDB 6.1 (formerly known as “MySQL Cluster Carrier Grade Edition 6.1.x”) is no longer being developed or maintained; if you are using a MySQL Cluster NDB 6.1 release, you should consider upgrading to MySQL Cluster NDB 6.2 or 6.3.

This Beta release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.1 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.15 (see [Section C.1.23, “Changes in MySQL 5.1.15 \(25 January 2007\)”](#)).

Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Functionality added or changed:

- A new `times` printout was added in the `ndbd` watchdog thread.
- Some unneeded printouts in the `ndbd` out file were removed.
- The names of some log and other files were changed to avoid issues with the `tar` command's 99-character file name limit.

Bugs fixed:

- A regression in the heartbeat monitoring code could lead to node failure under high load. This issue affected MySQL 5.1.19 and

MySQL Cluster NDB 6.1.10 only. (Bug#28783)

- A corrupt schema file could cause a `FILE ALREADY OPEN` error. (Bug#28770)
- Setting `InitialNoOpenFiles` equal to `MaxNoOfOpenFiles` caused an error. This was due to the fact that the actual value of `MaxNoOfOpenFiles` as used by the cluster was offset by 1 from the value set in `config.ini`. (Bug#28749)
- A race condition could result when non-master nodes (in addition to the master node) tried to update active status due to a local checkpoint (that is, between `NODE_FAILREP` and `COPY_GCIREQ` events). Now only the master updates the active status. (Bug#28717)
- A fast global checkpoint under high load with high usage of the redo buffer caused data nodes to fail. (Bug#28653)
- **Disk Data:** When loading data into a cluster following a version upgrade, the data nodes could forcibly shut down due to page and buffer management failures (that is, `ndbrequire` failures in `PGMAN`). (Bug#28525)

17.15.4.15. Changes in MySQL Cluster NDB 6.1.9 (5.1.15-ndb-6.1.9) (24 May 2007)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.1 release.

MySQL Cluster NDB 6.1 no longer in development. MySQL Cluster NDB 6.1 (formerly known as “MySQL Cluster Carrier Grade Edition 6.1.x”) is no longer being developed or maintained; if you are using a MySQL Cluster NDB 6.1 release, you should consider upgrading to MySQL Cluster NDB 6.2 or 6.3.

This Beta release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.1 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.15 (see [Section C.1.23, “Changes in MySQL 5.1.15 \(25 January 2007\)”](#)).

Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Bugs fixed:

- When an API node sent more than 1024 signals in a single batch, `NDB` would process only the first 1024 of these, and then hang. (Bug#28443)
- **Disk Data:** The cluster backup process scanned in `ACC` index order, which had bad effects for disk data. (Bug#28593)

17.15.4.16. Changes in MySQL Cluster NDB 6.1.8 (5.1.15-ndb-6.1.8) (05 May 2007)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.1 release.

MySQL Cluster NDB 6.1 no longer in development. MySQL Cluster NDB 6.1 (formerly known as “MySQL Cluster Carrier Grade Edition 6.1.x”) is no longer being developed or maintained; if you are using a MySQL Cluster NDB 6.1 release, you should consider upgrading to MySQL Cluster NDB 6.2 or 6.3.

This Beta release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.1 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.15 (see [Section C.1.23, “Changes in MySQL 5.1.15 \(25 January 2007\)”](#)).

Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Bugs fixed:

- Local checkpoint files relating to dropped `NDB` tables were not removed. (Bug#28348)
- Repeated insertion of data generated by `mysqldump` into `NDB` tables could eventually lead to failure of the cluster. (Bug#27437)
- **Disk Data:** Extremely large inserts into Disk Data tables could lead to data node failure in some circumstances. (Bug#27942)
- **Cluster API:** In a multi-operation transaction, a delete operation followed by the insertion of an implicit `NULL` failed to over-

write an existing value. (Bug#20535)

- Setting `MaxNoOfTables` very low and relative to `DataMemory` caused `OUT OF MEMORY IN NDB KERNEL` errors when inserting relatively small amounts of data into NDB tables. (Bug#24173)

17.15.4.17. Changes in MySQL Cluster NDB 6.1.7 (5.1.15-ndb-6.1.7) (05 May 2007)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.1 release.

MySQL Cluster NDB 6.1 no longer in development. MySQL Cluster NDB 6.1 (formerly known as “MySQL Cluster Carrier Grade Edition 6.1.x”) is no longer being developed or maintained; if you are using a MySQL Cluster NDB 6.1 release, you should consider upgrading to MySQL Cluster NDB 6.2 or 6.3.

This Beta release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.1 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.15 (see Section C.1.23, “Changes in MySQL 5.1.15 (25 January 2007)”).

Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Functionality added or changed:

- **Cluster Replication: Incompatible Change:** The schema for the `ndb_apply_status` table in the `mysql` system database has changed. When upgrading to this release from a previous MySQL Cluster NDB 6.x or mainline MySQL 5.1 release, you must drop the `mysql.ndb_apply_status` table, then restart the server in order for the table to be re-created with the new schema.

See Section 17.9.4, “MySQL Cluster Replication Schema and Tables”, for additional information.

Bugs fixed:

- The cluster waited 30 seconds instead of 30 milliseconds before reading table statistics. (Bug#28093)
- Under certain rare circumstances, `ndbd` could get caught in an infinite loop when one transaction took a read lock and then a second transaction attempted to obtain a write lock on the same tuple in the lock queue. (Bug#28073)
- Under some circumstances, a node restart could fail to update the Global Checkpoint Index (GCI). (Bug#28023)
- An `INSERT` followed by a delete `DELETE` on the same NDB table caused a memory leak. (Bug#27756)

This regression was introduced by Bug#20612.

- Under certain rare circumstances performing a `DROP TABLE` or `TRUNCATE` on an NDB table could cause a node failure or forced cluster shutdown. (Bug#27581)
- Memory usage of a `mysqld` process grew even while idle. (Bug#27560)
- Performing a delete followed by an insert during a local checkpoint could cause a `ROWID ALREADY ALLOCATED` error. (Bug#27205)
- **Cluster Replication: Disk Data:** An issue with replication of Disk Data tables could in some cases lead to node failure. (Bug#28161)
- **Disk Data:** Changes to a Disk Data table made as part of a transaction could not be seen by the client performing the changes until the transaction had been committed. (Bug#27757)
- **Disk Data:** When restarting a data node following the creation of a large number of Disk Data objects (approximately 200 such objects), the cluster could not assign a node ID to the restarting node. (Bug#25741)
- **Disk Data:** Changing a column specification or issuing a `TRUNCATE` statement on a Disk Data table caused the table to become an in-memory table.

This fix supersedes an incomplete fix that was made for this issue in MySQL 5.1.15. (Bug#24667, Bug#25296)

- **Cluster Replication:** Some queries that updated multiple tables were not backed up correctly. (Bug#27748)

- **Cluster Replication:** It was possible for API nodes to begin interacting with the cluster subscription manager before they were fully connected to the cluster. (Bug#27728)
- **Cluster Replication:** Under very high loads, checkpoints could be read or written with checkpoint indexes out of order. (Bug#27651)
- **Cluster API:** An issue with the way in which the `NdbDictionary::Dictionary::listEvents()` method freed resources could sometimes lead to memory corruption. (Bug#27663)
- `mysqldump` could not dump log tables. (Bug#26121)
- The `--with-readline` option for `configure` did not work for commercial source packages, but no error message was printed to that effect. Now a message is printed. (Bug#25530)

17.15.4.18. Changes in MySQL Cluster NDB 6.1.6 (5.1.15-ndb-6.1.6) (Not released)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.1 release.

MySQL Cluster NDB 6.1 no longer in development. MySQL Cluster NDB 6.1 (formerly known as “MySQL Cluster Carrier Grade Edition 6.1.x”) is no longer being developed or maintained; if you are using a MySQL Cluster NDB 6.1 release, you should consider upgrading to MySQL Cluster NDB 6.2 or 6.3.

This Beta release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.1 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.15 (see [Section C.1.23, “Changes in MySQL 5.1.15 \(25 January 2007\)”](#)).

Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Functionality added or changed:

- **Cluster Replication: Incompatible Change:** The schema for the `ndb_apply_status` table in the `mysql` system database has changed. When upgrading to this release from a previous MySQL Cluster NDB 6.x or mainline MySQL 5.1 release, you must drop the `mysql.ndb_apply_status` table, then restart the server in order for the table to be re-created with the new schema.

See [Section 17.9.4, “MySQL Cluster Replication Schema and Tables”](#), for additional information.

Bugs fixed:

- A data node failing while another data node was restarting could leave the cluster in an inconsistent state. In certain rare cases, this could lead to a race condition and the eventual forced shutdown of the cluster. (Bug#27466)
- It was not possible to set `LockPagesInMainMemory` equal to 0. (Bug#27291)
- A race condition could sometimes occur if the node acting as master failed while node IDs were still being allocated during startup. (Bug#27286)
- When a data node was taking over as the master node, a race condition could sometimes occur as the node was assuming responsibility for handling of global checkpoints. (Bug#27283)
- `mysqld` could crash shortly after a data node failure following certain DML operations. (Bug#27169)
- The same failed request from an API node could be handled by the cluster multiple times, resulting in reduced performance. (Bug#27087)
- The failure of a data node while restarting could cause other data nodes to hang or crash. (Bug#27003)
- `mysqld` processes would sometimes crash under high load.

Note

This fix improves on and replaces a fix for this bug that was made in MySQL Cluster NDB 6.1.5.

(Bug#26825)

- **Disk Data:** `DROP INDEX` on a Disk Data table did not always move data from memory into the tablespace. (Bug#25877)
- **Cluster Replication:** Trying to replicate a large number of frequent updates with a relatively small relay log (`max-relay-log-size` set to 1M or less) could cause the slave to crash. (Bug#27529)
- **Cluster API:** An issue with the way in which the `NdbDictionary::Dictionary::listEvents()` method freed resources could sometimes lead to memory corruption. (Bug#27663)
- **Cluster API:** A delete operation using a scan followed by an insert using a scan could cause a data node to fail. (Bug#27203)

17.15.4.19. Changes in MySQL Cluster NDB 6.1.5 (5.1.15-ndb-6.1.5) (15 March 2007)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.1 release.

MySQL Cluster NDB 6.1 no longer in development. MySQL Cluster NDB 6.1 (formerly known as “MySQL Cluster Carrier Grade Edition 6.1.x”) is no longer being developed or maintained; if you are using a MySQL Cluster NDB 6.1 release, you should consider upgrading to MySQL Cluster NDB 6.2 or 6.3.

This Beta release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.1 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.15 (see Section C.1.23, “Changes in MySQL 5.1.15 (25 January 2007)”).

Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Functionality added or changed:

- **Cluster Replication: Incompatible Change:** The schema for the `ndb_apply_status` table in the `mysql` system database has changed. When upgrading to this release from a previous MySQL Cluster NDB 6.x or mainline MySQL 5.1 release, you must drop the `mysql.ndb_apply_status` table, then restart the server in order for the table to be re-created with the new schema.

See Section 17.9.4, “MySQL Cluster Replication Schema and Tables”, for additional information.

Bugs fixed:

- Creating a table on one SQL node while in single user mode caused other SQL nodes to crash. (Bug#26997)
- `mysqld` processes would sometimes crash under high load.

Note

This fix was reverted in MySQL Cluster NDB 6.1.6.

(Bug#26825)

- An infinite loop in an internal logging function could cause trace logs to fill up with `UNKNOWN SIGNAL TYPE` error messages and thus grow to unreasonable sizes. (Bug#26720)
- **Disk Data:** When creating a log file group, setting `INITIAL_SIZE` to less than `UNDO_BUFFER_SIZE` caused data nodes to crash. (Bug#25743)

17.15.4.20. Changes in MySQL Cluster NDB 6.1.4 (5.1.15-ndb-6.1.4) (09 March 2007)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.1 release.

MySQL Cluster NDB 6.1 no longer in development. MySQL Cluster NDB 6.1 (formerly known as “MySQL Cluster Carrier Grade Edition 6.1.x”) is no longer being developed or maintained; if you are using a MySQL Cluster NDB 6.1 release, you should consider upgrading to MySQL Cluster NDB 6.2 or 6.3.

This Beta release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.1 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.15 (see Section C.1.23, “Changes in MySQL 5.1.15 (25 January 2007)”).

Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Functionality added or changed:

- An `ndb_wait_connected` system variable has been added for `mysqld`. It causes `mysqld` wait a specified amount of time to be connected to the cluster before accepting client connections. For more information, see [Section 17.4.3, “MySQL Cluster System Variables”](#).
- **Cluster API:** It is now possible to specify the transaction coordinator when starting a transaction. See `Ndb::startTransaction()`, for more information.
- **Cluster API:** It is now possible to iterate over all existing NDB objects using three new methods of the `Ndb_cluster_connection` class:
 - `lock_ndb_objects()`
 - `get_next_ndb_object()`
 - `unlock_ndb_objects()`
 For more information about these methods and their use, see `ndb_cluster_connection::get_next_ndb_object()`, in the MySQL Cluster API Guide.
- Data node memory allocation has been improved. On 32-bit platforms, it should now be possible to use close to 3GB RAM for `IndexMemory` and `DataMemory` combined.

Bugs fixed:

- Using only the `--print_data` option (and no other options) with `ndb_restore` caused `ndb_restore` to fail. ([Bug#26741](#))
This regression was introduced by [Bug#14612](#).
- An inadvertent use of unaligned data caused `ndb_restore` to fail on some 64-bit platforms, including Sparc and Itanium-2. ([Bug#26739](#))
- Assigning a node ID greater than 63 to an SQL node caused an out of bounds error in `mysqld`. It should now be possible to assign to SQL nodes node IDs up to 255. ([Bug#26663](#))

17.15.4.21. Changes in MySQL Cluster NDB 6.1.3 (5.1.15-ndb-6.1.3) (25 February 2007)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.1 release.

MySQL Cluster NDB 6.1 no longer in development. MySQL Cluster NDB 6.1 (formerly known as “MySQL Cluster Carrier Grade Edition 6.1.x”) is no longer being developed or maintained; if you are using a MySQL Cluster NDB 6.1 release, you should consider upgrading to MySQL Cluster NDB 6.2 or 6.3.

This Beta release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.1 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.15 (see [Section C.1.23, “Changes in MySQL 5.1.15 \(25 January 2007\)”](#)).

Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Functionality added or changed:

- The `ndbd_redo_log_reader` utility is now part of the default build. For more information, see [Section 17.6.16, “ndbd_redo_log_reader — Check and Print Content of Cluster Redo Log”](#).
- The `ndb_show_tables` utility now displays information about table events. See [Section 17.6.20, “ndb_show_tables — Display List of NDB Tables”](#), for more information.

- **Cluster API:** A new `listEvents()` method has been added to the `Dictionary` class. See `Dictionary::listEvents()`, for more information.
- It is now possible to disable arbitration by setting `ArbitrationRank = 0` on all management and SQL nodes.

Bugs fixed:

- An invalid pointer was returned following a `FSCLOSECONF` signal when accessing the REDO logs during a node restart or system restart. (Bug#26515)
- The `InvalidUndoBufferSize` error used the same error code (763) as the `IncompatibleVersions` error. `InvalidUndoBufferSize` now uses its own error code (779). (Bug#26490)
- The failure of a data node when restarting it with `--initial` could lead to failures of subsequent data node restarts. (Bug#26481)
- Takeover for local checkpointing due to multiple failures of master nodes was sometimes incorrectly handled. (Bug#26457)
- The `LockPagesInMainMemory` parameter was not read until after distributed communication had already started between cluster nodes. When the value of this parameter was 1, this could sometimes result in data node failure due to missed heartbeats. (Bug#26454)
- Under some circumstances, following the restart of a management node, all data nodes would connect to it normally, but some of them subsequently failed to log any events to the management node. (Bug#26293)
- No appropriate error message was provided when there was insufficient REDO log file space for the cluster to start. (Bug#25801)
- A memory allocation failure in `SUMA` (the cluster Subscription Manager) could cause the cluster to crash. (Bug#25239)
- The message `ERROR 0 IN READAUTOINCREMENTVALUE(): NO ERROR` was written to the error log whenever `SHOW TABLE STATUS` was performed on a Cluster table that did not have an `AUTO_INCREMENT` column.

Note

This improves on and supersedes an earlier fix that was made for this issue in MySQL 5.1.12.

(Bug#21033)

- **Disk Data:** A memory overflow could occur with tables having a large amount of data stored on disk, or with queries using a very high degree of parallelism on Disk Data tables. (Bug#26514)
- **Disk Data:** Use of a tablespace whose `INITIAL_SIZE` was greater than 1 GB could cause the cluster to crash. (Bug#26487)

17.15.4.22. Changes in MySQL Cluster NDB 6.1.2 (5.1.15-ndb-6.1.2) (07 February 2007)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.1 release.

MySQL Cluster NDB 6.1 no longer in development. MySQL Cluster NDB 6.1 (formerly known as “MySQL Cluster Carrier Grade Edition 6.1.x”) is no longer being developed or maintained; if you are using a MySQL Cluster NDB 6.1 release, you should consider upgrading to MySQL Cluster NDB 6.2 or 6.3.

This Beta release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.1 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.15 (see [Section C.1.23, “Changes in MySQL 5.1.15 \(25 January 2007\)”](#)).

Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Bugs fixed:

- Using node IDs greater than 48 could sometimes lead to incorrect memory access and a subsequent forced shutdown of the cluster. (Bug#26267)

17.15.4.23. Changes in MySQL Cluster NDB 6.1.1 (5.1.15-ndb-6.1.1) (01 February 2007)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.1 release.

MySQL Cluster NDB 6.1 no longer in development. MySQL Cluster NDB 6.1 (formerly known as “MySQL Cluster Carrier Grade Edition 6.1.x”) is no longer being developed or maintained; if you are using a MySQL Cluster NDB 6.1 release, you should consider upgrading to MySQL Cluster NDB 6.2 or 6.3.

This Beta release incorporates all bugfixes and changes made in the previous MySQL Cluster NDB 6.1 release, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.15 (see [Section C.1.23, “Changes in MySQL 5.1.15 \(25 January 2007\)”](#)).

Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Functionality added or changed:

- A single cluster can now support up to 255 API nodes, including MySQL servers acting as SQL nodes. See [Section 17.12.8, “Issues Exclusive to MySQL Cluster”](#), for more information.

Bugs fixed:

- A memory leak could cause problems during a node or cluster shutdown or failure. ([Bug#25997](#))
- **Cluster API: Disk Data:** A delete and a read performed in the same operation could cause one or more data nodes to crash. This could occur when the operation affected more than 5 columns concurrently, or when one or more of the columns was of the `VARCHAR` type and was stored on disk. ([Bug#25794](#))
- An element could sometimes be inserted twice into the hash table, causing a data node to crash. ([Bug#25286](#))

17.15.4.24. Changes in MySQL Cluster NDB 6.1.0 (5.1.14-ndb-6.1.0) (20 December 2006)

This is the first MySQL Cluster NDB 6.1 release, incorporating new features and bugfixes made for the `NDBCLUSTER` storage engine made since branching from MySQL 5.1.14 standard (see [Section C.1.24, “Changes in MySQL 5.1.14 \(05 December 2006\)”](#)).

MySQL Cluster NDB 6.1 no longer in development. MySQL Cluster NDB 6.1 (formerly known as “MySQL Cluster Carrier Grade Edition 6.1.x”) is no longer being developed or maintained; if you are using a MySQL Cluster NDB 6.1 release, you should consider upgrading to MySQL Cluster NDB 6.2 or 6.3.

Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Functionality added or changed:

- A new configuration parameter `MemReportFrequency` allows for additional control of data node memory usage. Previously, only warnings at predetermined percentages of memory allocation were given; setting this parameter allows for that behavior to be overridden. For more information, see [Section 17.3.4.6, “Defining MySQL Cluster Data Nodes”](#).

Bugs fixed:

- When a data node was shut down using the management client `STOP` command, a connection event (`NDB_LE_Connected`) was logged instead of a disconnection event (`NDB_LE_Disconnected`). ([Bug#22773](#))
- `SELECT` statements with a `BLOB` or `TEXT` column in the selected column list and a `WHERE` condition including a primary key lookup on a `VARCHAR` primary key produced empty result sets. ([Bug#19956](#))
- **Disk Data:** `MEDIUMTEXT` columns of Disk Data tables were stored in memory rather than on disk, even if the columns were not indexed. ([Bug#25001](#))
- **Disk Data:** Performing a node restart with a newly dropped Disk Data table could lead to failure of the node during the restart.

([Bug#24917](#))

- **Disk Data:** When restoring from backup a cluster containing any Disk Data tables with hidden primary keys, a node failure resulted which could lead to a crash of the cluster. ([Bug#24166](#))
- **Disk Data:** Repeated `CREATE`, `DROP`, or `TRUNCATE` in various combinations with system restarts between these operations could lead to the eventual failure of a system restart. ([Bug#21948](#))
- **Disk Data:** Extents that should have been available for re-use following a `DROP TABLE` operation were not actually made available again until after the cluster had performed a local checkpoint. ([Bug#17605](#))
- **Cluster API:** Invoking the `NdbTransaction::execute()` method using execution type `Commit` and abort option `AO_IgnoreError` could lead to a crash of the transaction coordinator (DBTC). ([Bug#25090](#))
- **Cluster API:** A unique index lookup on a non-existent tuple could lead to a data node timeout (error 4012). ([Bug#25059](#))
- **Cluster API:** When using the `NdbTransaction::execute()` method, a very long timeout (greater than 5 minutes) could result if the last data node being polled was disconnected from the cluster. ([Bug#24949](#))
- **Cluster API:** Due to an error in the computation of table fragment arrays, some transactions were not executed from the correct starting point. ([Bug#24914](#))
- Under certain rare circumstances, local checkpoints were not performed properly, leading to an inability to restart one or more data nodes. ([Bug#24664](#))

17.16. Unified Changelogs — MySQL Cluster NDB 6.X and 7.X

This section contains unified changelog information for each MySQL Cluster release series (NDB 6.1, NDB 6.2, NDB 6.3, and NDB 7.0).

For general information about features added in MySQL Cluster, see [Section 17.13, “MySQL Cluster Development Roadmap”](#). For release-specific MySQL Cluster changelogs, see [Section 17.15, “Changes in MySQL Cluster NDB 6.X and 7.X”](#).

An overview of features added in MySQL 5.1 not specific to MySQL Cluster can be found here: [Section 1.4.1, “What Is New in MySQL 5.1”](#). For a complete list of all bugfixes and features changes made in MySQL 5.1 that are not specific to MySQL Cluster, see [Section C.1, “Changes in release 5.1.x \(Production\)”](#).

17.16.1. Unified Changelog — MySQL Cluster NDB 7.0.x

This section contains unified change history highlights for all MySQL Cluster releases based on version 7.0 of the `NDBCLUSTER` storage engine through MySQL Cluster NDB 7.0.7. Included are all changelog entries in the categories *MySQL Cluster*, *Disk Data*, and *Cluster API*.

Early MySQL Cluster NDB 7.0 releases tagged “NDB 6.4.x” are also included in this listing.

For an overview of features that were added added in MySQL Cluster NDB 7.0, see [Section 17.13.5, “Features Added in MySQL Cluster NDB 7.0”](#).

- [Changes in MySQL Cluster NDB 7.0.7 \(5.1.34-ndb-7.0.7\)](#)
- [Changes in MySQL Cluster NDB 7.0.6 \(5.1.34-ndb-7.0.6\)](#)
- [Changes in MySQL Cluster NDB 7.0.5 \(5.1.32-ndb-7.0.5\)](#)
- [Changes in MySQL Cluster NDB 7.0.4 \(5.1.32-ndb-7.0.4\)](#)
- [Changes in MySQL Cluster NDB 6.4.3 \(5.1.32-ndb-6.4.3\)](#)
- [Changes in MySQL Cluster NDB 6.4.2 \(5.1.31-ndb-6.4.2\)](#)
- [Changes in MySQL Cluster NDB 6.4.1 \(5.1.31-ndb-6.4.1\)](#)
- [Changes in MySQL Cluster NDB 6.4.0 \(5.1.30-ndb-6.4.0\)](#)

Changes in MySQL Cluster NDB 7.0.7 (5.1.34-ndb-7.0.7)

Bugs fixed:

- **Disk Data: Partitioning:** An `NDBCLUSTER` table created with a very large value for the `MAX_ROWS` option could — if this table was dropped and a new table with fewer partitions, but having the same table ID, was created — cause `ndbd` to crash when performing a system restart. This was because the server attempted to examine each partition whether or not it actually existed. (Bug#45154)

Changes in MySQL Cluster NDB 7.0.6 (5.1.34-ndb-7.0.6)

Functionality added or changed:

- The `ndb_config` utility program can now provide an offline dump of all MySQL Cluster configuration parameters including information such as default and permitted values, brief description, and applicable section of the `config.ini` file. A dump in text format is produced when running `ndb_config` with the new `--configinfo` option, and in XML format when the options `--configinfo --xml` are used together. For more information and examples, see Section 17.6.6, “`ndb_config` — Extract MySQL Cluster Configuration Information”.

Bugs fixed:

- **Important Change: Partitioning:** User-defined partitioning of an `NDBCLUSTER` table without any primary key sometimes failed, and could cause `mysqld` to crash.

Now, if you wish to create an `NDBCLUSTER` table with user-defined partitioning, the table must have an explicit primary key, and all columns listed in the partitioning expression must be part of the primary key. The hidden primary key used by the `NDBCLUSTER` storage engine is not sufficient for this purpose. However, if the list of columns is empty (that is, the table is defined using `PARTITION BY [LINEAR] KEY()`), then no explicit primary key is required.

This change does not effect the partitioning of tables using any storage engine other than `NDBCLUSTER`. (Bug#40709)

- **Important Note:** It was not possible to perform an online upgrade from any MySQL Cluster NDB 6.x release to MySQL Cluster NDB 7.0.5 or any to earlier MySQL Cluster NDB 7.0 release.

With this fix, it is possible in MySQL Cluster NDB 7.0.6 and later to perform online upgrades from MySQL Cluster NDB 6.3.8 and later MySQL Cluster NDB 6.3 releases, or from MySQL Cluster NDB 7.0.5 or later MySQL Cluster NDB 7.0 releases. Online upgrades to MySQL Cluster NDB 7.0 releases previous to MySQL Cluster NDB 7.0.6 from earlier MySQL Cluster releases remain unsupported; online upgrades from MySQL Cluster NDB 7.0 releases previous to MySQL Cluster NDB 7.0.5 (including NDB 6.4.x beta releases) to later MySQL Cluster NDB 7.0 releases also remain unsupported. (Bug#44294)

- An internal NDB API buffer was not properly initialized. (Bug#44977)
- When a data node had written its GCI marker to the first page of a megabyte, and that node was later killed during restart after having processed that page (marker) but before completing a LCP, the data node could fail with filesystem errors. (Bug#44952)

See also Bug#42564.

- When restarting a data nodes, management and API nodes reconnecting to it failed to re-use existing ports that had already been dynamically allocated for communications with that data node. (Bug#44866)
- When `ndb_config` could not find the file referenced by the `--config-file` option, it tried to read `my.cnf` instead, then failed with a misleading error message. (Bug#44846)
- When a data node was down so long that its most recent local checkpoint depended on a global checkpoint that was no longer restorable, it was possible for it to be unable to use optimized node recovery when being restarted later. (Bug#44844)

See also Bug#26913.

- Online upgrades to MySQL Cluster NDB 7.0 from a MySQL Cluster NDB 6.3 release could fail due to changes in the handling of key lengths and unique indexes during node recovery. (Bug#44827)
- Use of `__builtin_expect()` had the side effect that compiler warnings about misuse of `=` (assignment) instead of `==` in comparisons were lost when building in debug mode. This is no longer employed when configuring the build with the `-with-debug` option. (Bug#44570)

See also Bug#44567.

- Inspection of the code revealed that several assignment operators (`=`) were used in place of comparison operators (`==`) in `Db-dihMain.cpp`. (Bug#44567)

See also Bug#44570.

- When using large numbers of configuration parameters, the management server took an excessive amount of time (several minutes or more) to load these from the configuration cache when starting. This problem occurred when there were more than 32 configuration parameters specified, and became progressively worse with each additional multiple of 32 configuration parameters. ([Bug#44488](#))
- Building the MySQL Cluster NDB 7.0 tree failed when using the `icc` compiler. ([Bug#44310](#))
- SSL connections to SQL nodes failed on big-endian platforms. ([Bug#44295](#))
- Signals providing node state information (`NODE_STATE_REP` and `CHANGE_NODE_STATE_REQ`) were not propagated to all blocks of `ndbmt.d`. This could cause the following problems:
 - Inconsistent redo logs when performing a graceful shutdown;
 - Data nodes crashing when later restarting the cluster, data nodes needing to perform node recovery during the system restart, or both.

([Bug#44291](#))

See also [Bug#42564](#).

- An NDB internal timing function did not work correctly on Windows and could cause `mysqld` to fail on some AMD processors, or when running inside a virtual machine. ([Bug#44276](#))
 - It was possible for NDB API applications to insert corrupt data into the database, which could subsequently lead to data node crashes. Now, stricter checking is enforced on input data for inserts and updates. ([Bug#44132](#))
 - `ndb_restore` failed when trying to restore data on a big-endian machine from a backup file created on a little-endian machine. ([Bug#44069](#))
 - Repeated starting and stopping of data nodes could cause `ndb_mgmd` to fail. This issue was observed on Solaris/SPARC. ([Bug#43974](#))
 - A number of incorrectly formatted output strings in the source code caused compiler warnings. ([Bug#43878](#))
 - When trying to use a data node with an older version of the management server, the data node crashed on startup. ([Bug#43699](#))
 - In some cases, data node restarts during a system restart could fail due to insufficient redo log space. ([Bug#43156](#))
 - `NDBCLUSTER` did not build correctly on Solaris 9 platforms. ([Bug#39080](#))
- See also [Bug#39036](#), [Bug#39038](#).
- The output of `ndbd --help` did not provide clear information about the program's `--initial` and `--initial-start` options. ([Bug#28905](#))
 - It was theoretically possible for the value of a nonexistent column to be read as `NULL`, rather than causing an error. ([Bug#27843](#))
 - **Disk Data:** During a checkpoint, restore points are created for both the on-disk and in-memory parts of a Disk Data table. Under certain rare conditions, the in-memory restore point could include or exclude a row that should have been in the snapshot. This would later lead to a crash during or following recovery.

This issue was somewhat more likely to be encountered when using `ndbmt.d`. ([Bug#41915](#))

- **Disk Data:** This fix supercedes and improves on an earlier fix made for this bug in MySQL 5.1.18. ([Bug#24521](#))

Changes in MySQL Cluster NDB 7.0.5 (5.1.32-ndb-7.0.5)

Functionality added or changed:

- Two new server status variables `Ndb_scan_count` and `Ndb_pruned_scan_count` have been introduced. `Ndb_scan_count` gives the number of scans executed since the cluster was last started. `Ndb_pruned_scan_count` gives the number of scans for which `NDBCLUSTER` was able to use partition pruning. Together, these variables can be used to help determine in the MySQL server whether table scans are pruned by `NDBCLUSTER`. ([Bug#44153](#))

Bugs fixed:

- **Important Note:** Due to problem discovered after the code freeze for this release, it is not possible to perform an online upgrade from any MySQL Cluster NDB 6.x release to MySQL Cluster NDB 7.0.5 or any earlier MySQL Cluster NDB 7.0 release.

This issue is fixed in MySQL Cluster NDB 7.0.6 and later for upgrades from MySQL Cluster NDB 6.3.8 and later MySQL Cluster NDB 6.3 releases, or from MySQL Cluster NDB 7.0.5. ([Bug#44294](#))

- **Cluster Replication:** If data node failed during an event creation operation, there was a slight risk that a surviving data node could send an invalid table reference back to NDB, causing the operation to fail with a false Error 723 (`NO SUCH TABLE`). This could take place when a data node failed as a `mysqld` process was setting up MySQL Cluster Replication. ([Bug#43754](#))
- **Cluster API:** The following issues occurred when performing an online (rolling) upgrade of a cluster to a version of MySQL Cluster that supports configuration caching from a version that does not:

1. When using multiple management servers, after upgrading and restarting one `ndb_mgmd`, any remaining management servers using the previous version of `ndb_mgmd` could not synchronize their configuration data.
2. The MGM API `ndb_mgm_get_configuration()` function failed to obtain configuration data.

([Bug#43641](#))

- **Cluster API:** The following issues occurred when performing an online (rolling) upgrade of a cluster to a version of MySQL Cluster that supports configuration caching from a version that does not:

1. When using multiple management servers, after upgrading and restarting one `ndb_mgmd`, any remaining management servers using the previous version of `ndb_mgmd` could not synchronize their configuration data.
2. The MGM API `ndb_mgm_get_configuration()` function failed to obtain configuration data.

([Bug#43641](#))

- If the number of fragments per table rises above a certain threshold, the `DBDIIH` kernel block's on-disk table-definition grows large enough to occupy 2 pages. However, in MySQL Cluster NDB 7.0 (including MySQL Cluster NDB 6.4 releases), only 1 page was actually written, causing table definitions stored on disk to be incomplete.

This issue was not observed in MySQL Cluster release series prior to MySQL Cluster NDB 7.0. ([Bug#44135](#))

- `TransactionDeadlockDetectionTimeout` values less than 100 were treated as 100. This could cause scans to time out unexpectedly. ([Bug#44099](#))
- The file `ndberror.c` contained a C++-style comment, which caused builds to fail with some C compilers. ([Bug#44036](#))
- A race condition could occur when a data node failed to restart just before being included in the next global checkpoint. This could cause other data nodes to fail. ([Bug#43888](#))
- The setting for `ndb_use_transactions` was ignored. This issue was only known to occur in MySQL Cluster NDB 6.4.3 and MySQL Cluster NDB 7.0.4. ([Bug#43236](#))
- When a data node process had been killed after allocating a node ID, but before making contact with any other data node processes, it was not possible to restart it due to a node ID allocation failure.

This issue could effect either `ndbd` or `ndbmt_d` processes. ([Bug#43224](#))

This regression was introduced by [Bug#42973](#).

- `ndb_restore` crashed when trying to restore a backup made to a MySQL Cluster running on a platform having different endianness from that on which the original backup was taken. ([Bug#39540](#))
- PID files for the data and management node daemons were not removed following a normal shutdown. ([Bug#37225](#))
- `ndb_restore --print_data` did not handle `DECIMAL` columns correctly. ([Bug#37171](#))
- Invoking the management client `START BACKUP` command from the system shell (for example, as `ndb_mgm -e "START BACKUP"`) did not work correctly, unless the backup ID was included when the command was invoked.

Now, the backup ID is no longer required in such cases, and the backup ID that is automatically generated is printed to stdout, similar to how this is done when invoking `START BACKUP` within the management client. ([Bug#31754](#))

- When aborting an operation involving both an insert and a delete, the insert and delete were aborted separately. This was because the transaction coordinator did not know that the operations affected on same row, and, in the case of a committed-read (tuple or index) scan, the abort of the insert was performed first, then the row was examined after the insert was aborted but be-

fore the delete was aborted. In some cases, this would leave the row in a inconsistent state. This could occur when a local checkpoint was performed during a backup. This issue did not affect primary key operations or scans that used locks (these are serialized).

After this fix, for ordered indexes, all operations that follow the operation to be aborted are now also aborted.

- **Disk Data:** When using multi-threaded data nodes, `DROP TABLE` statements on Disk Data tables could hang. (Bug#43825)
- **Disk Data:** This fix completes one that was made for this issue in MySQL Cluster NDB-7.0.4, which did not rectify the problem in all cases. (Bug#43632)
- **Cluster API:** If the largest offset of a `RecordSpecification` used for an `NdbRecord` object was for the `NULL` bits (and thus not a column), this offset was not taken into account when calculating the size used for the `RecordSpecification`. This meant that the space for the `NULL` bits could be overwritten by key or other information. (Bug#43891)
- **Cluster API:** `BIT` columns created using the native NDB API format that were not created as nullable could still sometimes be overwritten, or cause other columns to be overwritten.

This issue did not effect tables having `BIT` columns created using the `mysqld` format (always used by MySQL Cluster SQL nodes). (Bug#43802)

Changes in MySQL Cluster NDB 7.0.4 (5.1.32-ndb-7.0.4)

Functionality added or changed:

- **Important Change:** The default values for a number of MySQL Cluster configuration parameters relating to memory usage and buffering have changed. These parameters include `RedoBuffer`, `LongMessageBuffer`, `BackupMemory`, `BackupDataBufferSize`, `BackupLogBufferSize`, `BackupWriteSize`, `BackupMaxWriteSize`, `SendBufferMemory` (when applied to TCP transporters), and `ReceiveBufferMemory`.

For more information, see [Section 17.3, “MySQL Cluster Configuration”](#).

- When restoring from backup, `ndb_restore` now reports the last global checkpoint reached when the backup was taken. (Bug#37384)

Bugs fixed:

- **Cluster API:** Partition pruning did not work correctly for queries involving multiple range scans.
As part of the fix for this issue, several improvements have been made in the NDB API, including the addition of a new `NdbScanOperation::getPruned()` method, a new variant of `NdbIndexScanOperation::setBound()`, and a new `Ndb::PartitionSpec` data structure. For more information about these changes, see `NdbScanOperation::getPruned()`, `NdbIndexScanOperation::setBound`, and [The PartitionSpec Structure](#). (Bug#37934)
- **Cluster API:** Partition pruning did not work correctly for queries involving multiple range scans.
As part of the fix for this issue, several improvements have been made in the NDB API, including the addition of a new `NdbScanOperation::getPruned()` method, a new variant of `NdbIndexScanOperation::setBound()`, and a new `Ndb::PartitionSpec` data structure. For more information about these changes, see `NdbScanOperation::getPruned()`, `NdbIndexScanOperation::setBound`, and [The PartitionSpec Structure](#). (Bug#37934)
- `TimeBetweenLocalCheckpoints` was measured from the end of one local checkpoint to the beginning of the next, rather than from the beginning of one LCP to the beginning of the next. This meant that the time spent performing the LCP was not taken into account when determining the `TimeBetweenLocalCheckpoints` interval, so that LCPs were not started often enough, possibly causing data nodes to run out of redo log space prematurely. (Bug#43567)
- The management server failed to start correctly in daemon mode. (Bug#43559)
- Following a `DROP NODEGROUP` command, the output of `SHOW` in the `ndb_mgm` cliently was not updated to reflect the fact that the data nodes affected by this command were no longer part of a node group. (Bug#43413)
- Using indexes containing variable-sized columns could lead to internal errors when the indexes were being built. (Bug#43226)
- When using `ndbmt_d`, multiple data node failures caused the remaining data nodes to fail as well. (Bug#43109)
- It was not possible to add new data nodes to the cluster online using multi-threaded data node processes (`ndbmt_d`). (Bug#43108)

- Some queries using combinations of logical and comparison operators on an indexed column in the `WHERE` clause could fail with the error `GOT ERROR 4541 'INDEXBOUND HAS NO BOUND INFORMATION' FROM NDBCLUSTER`. (Bug#42857)
- **Disk Data:** When using multi-threaded data nodes, dropping a Disk Data table followed by a data node restart led to a crash. (Bug#43632)
- **Disk Data:** When using `ndbmt`, repeated high-volume inserts (on the order of 10000 rows inserted at a time) on a Disk Data table would eventually lead to a data node crash. (Bug#41398)
- **Disk Data:** When a log file group had an undo log file whose size was too small, restarting data nodes failed with `READ UNDERFLOW` errors.
As a result of this fix, the minimum allowed `INITIAL_SIZE` for an undo log file is now `1M` (1 megabyte). (Bug#29574)
- **Cluster API:** The default `NdbRecord` structures created by `NdbDictionary` could have overlapping null bits and data fields. (Bug#43590)
- **Cluster API:** When performing insert or write operations, `NdbRecord` allows key columns to be specified in both the key record and in the attribute record. Only one key column value for each key column should be sent to the NDB kernel, but this was not guaranteed. This is now ensured as follows: For insert and write operations, key column values are taken from the key record; for scan takeover update operations, key column values are taken from the attribute record. (Bug#42238)
- **Cluster API:** Ordered index scans using `NdbRecord` formerly expressed a `BoundEQ` range as separate lower and upper bounds, resulting in 2 copies of the column values being sent to the NDB kernel.
Now, when a range is specified by `NdbScanOperation::setBound()`, the passed pointers, key lengths, and inclusive bits are compared, and only one copy of the equal key columns is sent to the kernel. This makes such operations more efficient, as half the amount of `KeyInfo` is now sent for a `BoundEQ` range as before. (Bug#38793)

Changes in MySQL Cluster NDB 6.4.3 (5.1.32-ndb-6.4.3)

Functionality added or changed:

- A new data node configuration parameter `MaxLCPStartDelay` has been introduced to facilitate parallel node recovery by causing a local checkpoint to be delayed while recovering nodes are synchronizing data dictionaries and other meta-information. For more information about this parameter, see [Section 17.3.4.6, “Defining MySQL Cluster Data Nodes”](#). (Bug#43053)
- New options are introduced for `ndb_restore` for determining which tables or databases should be restored:
 - `--include-tables` and `--include-databases` can be used to restore specific tables or databases.
 - `--exclude-tables` and `--exclude-databases` can be used to exclude the specified tables or databases from being restored.

For more information about these options, see [Section 17.6.17, “ndb_restore — Restore a MySQL Cluster Backup”](#). (Bug#40429)

- **Disk Data:** It is now possible to specify default locations for Disk Data data files and undo log files, either together or separately, using the data node configuration parameters `FileSystemPathDD`, `FileSystemPathDataFiles`, and `FileSystemPathUndoFiles`. For information about these configuration parameters, see [Disk Data filesystem parameters](#).
It is also now possible to specify a log file group, tablespace, or both, that is created when the cluster is started, using the `InitialLogFileGroup` and `InitialTablespace` data node configuration parameters. For information about these configuration parameters, see [Disk Data object creation parameters](#).

Bugs fixed:

- **Important Note:** It is not possible in this release to install the `InnoDB` plugin if `InnoDB` support has been compiled into `mysqld`. (Bug#42610)
This regression was introduced by [Bug#29263](#).
- **Packaging:** Packages for MySQL Cluster were missing the `libndbclient.so` and `libndbclient.a` files. (Bug#42278)
- **Partitioning:** Executing `ALTER TABLE ... REORGANIZE PARTITION` on an `NDBCLUSTER` table having only one partition caused `mysqld` to crash. (Bug#41945)

See also [Bug#40389](#).

- Backup IDs greater than 2^{31} were not handled correctly, causing negative values to be used in backup directory names and printouts. ([Bug#43042](#))
- When using `ndbmt_d`, NDB kernel threads could hang while trying to start the data nodes with `LockPagesInMainMemory` set to 1. ([Bug#43021](#))
- When using multiple management servers and starting several API nodes (possibly including one or more SQL nodes) whose connectstrings listed the management servers in different order, it was possible for 2 API nodes to be assigned the same node ID. When this happened it was possible for an API node not to get fully connected, consequently producing a number of errors whose cause was not easily recognizable. ([Bug#42973](#))
- When using multi-threaded data nodes, `IndexMemory`, `MaxNoOfLocalOperations`, and `MaxNoOfLocalScans` were effectively multiplied by the number of local query handlers in use by each `ndbmt_d` instance. ([Bug#42765](#))

See also [Bug#42215](#).

- `ndb_error_reporter` worked correctly only with GNU `tar`. (With other versions of `tar`, it produced empty archives.) ([Bug#42753](#))
- Triggers on `NDBCLUSTER` tables caused such tables to become locked. ([Bug#42751](#))

See also [Bug#16229](#), [Bug#18135](#).

- When performing more than 32 index or tuple scans on a single fragment, the scans could be left hanging. This caused unnecessary timeouts, and in addition could possibly lead to a hang of an LCP. ([Bug#42559](#))
- A data node failure that occurred between calls to `NdbIndexScanOperation::readTuples(SF_OrderBy)` and `NdbTransaction::Execute()` was not correctly handled; a subsequent call to `nextResult()` caused a null pointer to be dereferenced, leading to a segfault in `mysqld`. ([Bug#42545](#))
- If the cluster configuration cache file was larger than 32K, the management server would not start. ([Bug#42543](#))
- Issuing `SHOW GLOBAL STATUS LIKE 'NDB%'` before `mysqld` had connected to the cluster caused a segmentation fault. ([Bug#42458](#))
- When using `ndbmt_d` for all data nodes, repeated failures of one data node during DML operations caused other data nodes to fail. ([Bug#42450](#))
- Data node failures that occurred before all data nodes had connected to the cluster were not handled correctly, leading to additional data node failures. ([Bug#42422](#))
- When using multi-threaded data nodes, their `DataMemory` and `IndexMemory` usage as reported was multiplied by the number of local query handlers (worker threads), making it appear that much more memory was being used than was actually the case. ([Bug#42215](#))

See also [Bug#42765](#).

- Given a MySQL Cluster containing no data (that is, whose data nodes had all been started using `--initial`, and into which no data had yet been imported) and having an empty backup directory, executing `START BACKUP` with a user-specified backup ID caused the data nodes to crash. ([Bug#41031](#))
- In some cases, NDB did not check correctly whether tables had changed before trying to use the query cache. This could result in a crash of the debug MySQL server. ([Bug#40464](#))
- **Disk Data:** It was not possible to add an in-memory column online to a table that used a table-level or column-level `STORAGE DISK` option. The same issue prevented `ALTER ONLINE TABLE ... REORGANIZE PARTITION` from working on Disk Data tables. ([Bug#42549](#))
- **Disk Data:** Repeated insert and delete operations on disk-based tables could lead to failures in the NDB Tablespace Manager (TSMAN kernel block). ([Bug#40344](#))
- **Disk Data:** Creating a Disk Data tablespace with a very large extent size caused the data nodes to fail. The issue was observed when using extent sizes of 100 MB and larger. ([Bug#39096](#))
- **Disk Data:** Trying to execute a `CREATE LOGFILE GROUP` statement using a value greater than 150M for `UNDO_BUFFER_SIZE` caused data nodes to crash.

As a result of this fix, the upper limit for `UNDO_BUFFER_SIZE` is now 600M; attempting to set a higher value now fails

gracefully with an error. ([Bug#34102](#))

- **Disk Data:** When attempting to create a tablespace that already existed, the error message returned was `TABLE OR INDEX WITH GIVEN NAME ALREADY EXISTS`. ([Bug#32662](#))
- **Disk Data:** Using a path or filename longer than 128 characters for Disk Data undo log files and tablespace data files caused a number of issues, including failures of `CREATE LOGFILE GROUP`, `ALTER LOGFILE GROUP`, `CREATE TABLESPACE`, and `ALTER TABLESPACE` statements, as well as crashes of management nodes and data nodes.

With this fix, the maximum length for path and file names used for Disk Data undo log files and tablespace data files is now the same as the maximum for the operating system. ([Bug#31769](#), [Bug#31770](#), [Bug#31772](#))

- **Disk Data:** Attempting to perform a system restart of the cluster where there existed a logfile group without and undo log files caused the data nodes to crash.

Note

While issuing a `CREATE LOGFILE GROUP` statement without an `ADD UNDOFILE` option fails with an error in the MySQL server, this situation could arise if an SQL node failed during the execution of a valid `CREATE LOGFILE GROUP` statement; it is also possible to create a logfile group without any undo log files using the NDB API.

([Bug#17614](#))

- **Cluster API:** Some error messages from `ndb_mgmd` contained newline (`\n`) characters. This could break the MGM API protocol, which uses the newline as a line separator. ([Bug#43104](#))
- **Cluster API:** When using an ordered index scan without putting all key columns in the read mask, this invalid use of the NDB API went undetected, which resulted in the use of uninitialized memory. ([Bug#42591](#))

Changes in MySQL Cluster NDB 6.4.2 (5.1.31-ndb-6.4.2)

Bugs fixed:

- Connections using IPv6 were not handled correctly by `mysqld`. ([Bug#42413](#))
See also [Bug#42412](#), [Bug#38247](#).
- When a cluster backup failed with Error 1304 (Node `node_id1`: Backup request from `node_id2` failed to start), no clear reason for the failure was provided.
As part of this fix, MySQL Cluster now retries backups in the event of sequence errors. ([Bug#42354](#))
See also [Bug#22698](#).
- Issuing `SHOW ENGINE NDBCLUSTER STATUS` on an SQL node before the management server had connected to the cluster caused `mysqld` to crash. ([Bug#42264](#))
- When using `ndbmttd`, setting `MaxNoOfThreads` to a value higher than the actual number of cores available and with insufficient `SharedGlobalMemory` caused the data nodes to crash.
The fix for this issue changes the behavior of `ndbmttd` such that its internal job buffers no longer rely on `SharedGlobalMemory`. ([Bug#42254](#))

Changes in MySQL Cluster NDB 6.4.1 (5.1.31-ndb-6.4.1)

Functionality added or changed:

- **Important Change:** Formerly, when the management server failed to create a transporter for a data node connection, `net_write_timeout` seconds elapsed before the data node was actually allowed to disconnect. Now in such cases the disconnection occurs immediately. ([Bug#41965](#))
See also [Bug#41713](#).
- Formerly, when using MySQL Cluster Replication, records for “empty” epochs — that is, epochs in which no changes to `NDB-CLUSTER` data or tables took place — were inserted into the `ndb_apply_status` and `ndb_binlog_index` tables on the slave even when `--log-slave-updates` was disabled. Beginning with MySQL Cluster NDB 6.2.16 and MySQL Cluster NDB 6.3.13 this was changed so that these “empty” epochs were no longer logged. However, it is now possible to re-enable the

older behavior (and cause “empty” epochs to be logged) by using the `--ndb-log-empty-epochs` option. For more information, see [Section 16.1.3.3, “Replication Slave Options and Variables”](#).

See also [Bug#37472](#).

Bugs fixed:

- A maximum of 11 `TUP` scans were allowed in parallel. ([Bug#42084](#))
- The management server could hang after attempting to halt it with the `STOP` command in the management client. ([Bug#42056](#))

See also [Bug#40922](#).

- When using `ndbmt.d`, one thread could flood another thread, which would cause the system to stop with a `JOB BUFFER FULL` condition (currently implemented as an abort). This could be caused by committing or aborting a large transaction (50000 rows or more) on a single data node running `ndbmt.d`. To prevent this from happening, the number of signals that can be accepted by the system threads is calculated before executing them, and only executing them if sufficient space is found. ([Bug#42052](#))
- MySQL Cluster would not compile when using `libwrap`. This issue was known to occur only in MySQL Cluster NDB 6.4.0. ([Bug#41918](#))
- Trying to execute an `ALTER ONLINE TABLE ... ADD COLUMN` statement while inserting rows into the table caused `mysqld` to crash. ([Bug#41905](#))
- When a data node connects to the management server, the node sends its node ID and transporter type; the management server then verifies that there is a transporter set up for that node and that it is in the correct state, and then sends back an acknowledgement to the connecting node. If the transporter was not in the correct state, no reply was sent back to the connecting node, which would then hang until a read timeout occurred (60 seconds). Now, if the transporter is not in the correct state, the management server acknowledges this promptly, and the node immediately disconnects. ([Bug#41713](#))

See also [Bug#41965](#).

- Issuing `EXIT` in the management client sometimes caused the client to hang. ([Bug#40922](#))
- In the event that a MySQL Cluster backup failed due to file permissions issues, conflicting reports were issued in the management client. ([Bug#34526](#))
- If all data nodes were shut down, MySQL clients were unable to access `NDBCLUSTER` tables and data even after the data nodes were restarted, unless the MySQL clients themselves were restarted. ([Bug#33626](#))

Changes in MySQL Cluster NDB 6.4.0 (5.1.30-ndb-6.4.0)

Functionality added or changed:

- **Important Change:** MySQL Cluster now caches its configuration data. This means that, by default, the management server only reads the global configuration file (usually named `config.ini`) the first time that it is started, and does not automatically re-read the this file when restarted. This behavior can be controlled using new management server options (`--config-dir`, `--initial`, and `--reload`) that have been added for this purpose. For more information, see [Section 17.3.4, “MySQL Cluster Configuration Files”](#), and [Section 17.6.24.3, “Program Options for ndb_mgmd”](#).
- It is now possible while in Single User Mode to restart all data nodes using `ALL RESTART` in the management client. Restarting of individual nodes while in Single User Mode remains disallowed. ([Bug#31056](#))
- It is now possible to add data nodes to a MySQL Cluster online — that is, to a running MySQL Cluster without shutting it down.

For information about the procedure for adding data nodes online, see [Section 17.7.8, “Adding MySQL Cluster Data Nodes Online”](#).

- A multi-threaded version of the MySQL Cluster data node daemon is now available. The multi-threaded `ndbmt.d` binary is similar to `ndbd` and functions in much the same way, but is intended for use on machines with multiple CPU cores.

For more information, see [Section 17.6.3, “ndbmt.d — The MySQL Cluster Data Node Daemon \(Multi-Threaded\)”](#).

- It is now possible when performing a cluster backup to determine whether the backup matches the state of the data when the backup began or when it ended, using the new `START BACKUP` options `SNAPSHOTSTART` and `SNAPSHOTEND` in the management client. See [Section 17.7.3.2, “Using The MySQL Cluster Management Client to Create a Backup”](#), for more informa-

tion.

Bugs fixed:

- API nodes disconnected too aggressively from cluster when data nodes were being restarted. This could sometimes lead to the API node being unable to access the cluster at all during a rolling restart. ([Bug#41462](#))
- When long signal buffer exhaustion in the `ndbd` process resulted in a signal being dropped, the usual handling mechanism did not take fragmented signals into account. This could result in a crash of the data node because the fragmented signal handling mechanism was not able to work with the missing fragments. ([Bug#39235](#))
- The failure of a master node during a DDL operation caused the cluster to be unavailable for further DDL operations until it was restarted; failures of non-master nodes during DLL operations caused the cluster to become completely inaccessible. ([Bug#36718](#))
- Status messages shown in the management client when restarting a management node were inappropriate and misleading. Now, when restarting a management node, the messages displayed are as follows, where `node_id` is the management node's node ID:

```
ndb_mgm> node_id RESTART
Shutting down MGM node node_id for restart
Node node_id is being restarted
ndb_mgm>
```

([Bug#29275](#))

- A data node failure when `NoOfReplicas` was greater than 2 caused all cluster SQL nodes to crash. ([Bug#18621](#))

17.16.2. Unified Changelog — MySQL Cluster NDB 6.3.x

This section contains unified change history highlights for all MySQL Cluster releases based on version 6.3 of the `NDBCLUSTER` storage engine through MySQL Cluster NDB 6.3.26. Included are all changelog entries in the categories *MySQL Cluster*, *Disk Data*, and *Cluster API*.

For an overview of features that were added added in MySQL Cluster NDB 6.3, see [Section 17.13.4, “Features Added in MySQL Cluster NDB 6.3”](#).

- [Changes in MySQL Cluster NDB 6.3.26 \(5.1.34-ndb-6.3.26\)](#)
- [Changes in MySQL Cluster NDB 6.3.25 \(5.1.34-ndb-6.3.25\)](#)

- [Changes in MySQL Cluster NDB 6.3.0 \(5.1.19-ndb-6.3.0\)](#)

Changes in MySQL Cluster NDB 6.3.26 (5.1.34-ndb-6.3.26)

Bugs fixed:

- An internal NDB API buffer was not properly initialized. ([Bug#44977](#))
- When a data node had written its GCI marker to the first page of a megabyte, and that node was later killed during restart after having processed that page (marker) but before completing a LCP, the data node could fail with filesystem errors. ([Bug#44952](#))

See also [Bug#42564](#).

- **Disk Data: Partitioning:** An `NDBCLUSTER` table created with a very large value for the `MAX_ROWS` option could — if this table was dropped and a new table with fewer partitions, but having the same table ID, was created — cause `ndbd` to crash when performing a system restart. This was because the server attempted to examine each partition whether or not it actually existed. ([Bug#45154](#))
- **Disk Data:** During a checkpoint, restore points are created for both the on-disk and in-memory parts of a Disk Data table. Under certain rare conditions, the in-memory restore point could include or exclude a row that should have been in the snapshot. This would later later lead to a crash during or following recovery. ([Bug#41915](#))

Changes in MySQL Cluster NDB 6.3.25 (5.1.34-ndb-6.3.25)

Functionality added or changed:

- Two new server status variables `Ndb_scan_count` and `Ndb_pruned_scan_count` have been introduced. `Ndb_scan_count` gives the number of scans executed since the cluster was last started. `Ndb_pruned_scan_count` gives the number of scans for which `NDBCLUSTER` was able to use partition pruning. Together, these variables can be used to help determine in the MySQL server whether table scans are pruned by `NDBCLUSTER`. ([Bug#44153](#))
- The `ndb_config` utility program can now provide an offline dump of all MySQL Cluster configuration parameters including information such as default and permitted values, brief description, and applicable section of the `config.ini` file. A dump in text format is produced when running `ndb_config` with the new `--configinfo` option, and in XML format when the options `--configinfo --xml` are used together. For more information and examples, see [Section 17.6.6, “ndb_config — Extract MySQL Cluster Configuration Information”](#).

Bugs fixed:

- **Important Change: Partitioning:** User-defined partitioning of an `NDBCLUSTER` table without any primary key sometimes failed, and could cause `mysqld` to crash.

Now, if you wish to create an `NDBCLUSTER` table with user-defined partitioning, the table must have an explicit primary key, and all columns listed in the partitioning expression must be part of the primary key. The hidden primary key used by the `NDBCLUSTER` storage engine is not sufficient for this purpose. However, if the list of columns is empty (that is, the table is defined using `PARTITION BY [LINEAR] KEY()`), then no explicit primary key is required.

This change does not effect the partitioning of tables using any storage engine other than `NDBCLUSTER`. ([Bug#40709](#))

- When `ndb_config` could not find the file referenced by the `--config-file` option, it tried to read `my.cnf` instead, then

failed with a misleading error message. ([Bug#44846](#))

- When a data node was down so long that its most recent local checkpoint depended on a global checkpoint that was no longer restorable, it was possible for it to be unable to use optimized node recovery when being restarted later. ([Bug#44844](#))

See also [Bug#26913](#).

- Inspection of the code revealed that several assignment operators (=) were used in place of comparison operators (==) in `Db-dihMain.cpp`. ([Bug#44567](#))

See also [Bug#44570](#).

- It was possible for NDB API applications to insert corrupt data into the database, which could subsequently lead to data node crashes. Now, stricter checking is enforced on input data for inserts and updates. ([Bug#44132](#))
- `ndb_restore` failed when trying to restore data on a big-endian machine from a backup file created on a little-endian machine. ([Bug#44069](#))
- The file `ndberror.c` contained a C++-style comment, which caused builds to fail with some C compilers. ([Bug#44036](#))
- When trying to use a data node with an older version of the management server, the data node crashed on startup. ([Bug#43699](#))
- In some cases, data node restarts during a system restart could fail due to insufficient redo log space. ([Bug#43156](#))
- `NDBCLUSTER` did not build correctly on Solaris 9 platforms. ([Bug#39080](#))

See also [Bug#39036](#), [Bug#39038](#).

- `ndb_restore --print_data` did not handle `DECIMAL` columns correctly. ([Bug#37171](#))
- The output of `ndbd --help` did not provide clear information about the program's `--initial` and `--initial-start` options. ([Bug#28905](#))
- It was theoretically possible for the value of a nonexistent column to be read as `NULL`, rather than causing an error. ([Bug#27843](#))
- **Disk Data:** This fix supercedes and improves on an earlier fix made for this bug in MySQL 5.1.18. ([Bug#24521](#))

Changes in MySQL Cluster NDB 6.3.24 (5.1.32-ndb-6.3.24)

Bugs fixed:

- **Cluster Replication:** If data node failed during an event creation operation, there was a slight risk that a surviving data node could send an invalid table reference back to NDB, causing the operation to fail with a false Error 723 (`NO SUCH TABLE`). This could take place when a data node failed as a `mysqld` process was setting up MySQL Cluster Replication. ([Bug#43754](#))

- **Cluster API:** Partition pruning did not work correctly for queries involving multiple range scans.

As part of the fix for this issue, several improvements have been made in the NDB API, including the addition of a new `NdbScanOperation::getPruned()` method, a new variant of `NdbIndexScanOperation::setBound()`, and a new `Ndb::PartitionSpec` data structure. For more information about these changes, see `NdbScanOperation::getPruned()`, `NdbIndexScanOperation::setBound()`, and [The PartitionSpec Structure](#). ([Bug#37934](#))

- **Cluster API:** Partition pruning did not work correctly for queries involving multiple range scans.

As part of the fix for this issue, several improvements have been made in the NDB API, including the addition of a new `NdbScanOperation::getPruned()` method, a new variant of `NdbIndexScanOperation::setBound()`, and a new `Ndb::PartitionSpec` data structure. For more information about these changes, see `NdbScanOperation::getPruned()`, `NdbIndexScanOperation::setBound()`, and [The PartitionSpec Structure](#). ([Bug#37934](#))

- `TransactionDeadlockDetectionTimeout` values less than 100 were treated as 100. This could cause scans to time out unexpectedly. ([Bug#44099](#))
- A race condition could occur when a data node failed to restart just before being included in the next global checkpoint. This could cause other data nodes to fail. ([Bug#43888](#))
- `TimeBetweenLocalCheckpoints` was measured from the end of one local checkpoint to the beginning of the next, rather than from the beginning of one LCP to the beginning of the next. This meant that the time spent performing the LCP was not taken into account when determining the `TimeBetweenLocalCheckpoints` interval, so that LCPs were not started often

enough, possibly causing data nodes to run out of redo log space prematurely. (Bug#43567)

- Using indexes containing variable-sized columns could lead to internal errors when the indexes were being built. (Bug#43226)
- When a data node process had been killed after allocating a node ID, but before making contact with any other data node processes, it was not possible to restart it due to a node ID allocation failure.

This issue could effect either `ndbd` or `ndbmt` processes. (Bug#43224)

This regression was introduced by Bug#42973.

- Some queries using combinations of logical and comparison operators on an indexed column in the `WHERE` clause could fail with the error `GOT ERROR 4541 'INDEXBOUND HAS NO BOUND INFORMATION' FROM NDBCLUSTER`. (Bug#42857)
- `ndb_restore` crashed when trying to restore a backup made to a MySQL Cluster running on a platform having different endianness from that on which the original backup was taken. (Bug#39540)
- When aborting an operation involving both an insert and a delete, the insert and delete were aborted separately. This was because the transaction coordinator did not know that the operations affected on same row, and, in the case of a committed-read (tuple or index) scan, the abort of the insert was performed first, then the row was examined after the insert was aborted but before the delete was aborted. In some cases, this would leave the row in a inconsistent state. This could occur when a local checkpoint was performed during a backup. This issue did not affect primary key operations or scans that used locks (these are serialized).

After this fix, for ordered indexes, all operations that follow the operation to be aborted are now also aborted.

- **Disk Data:** When a log file group had an undo log file whose size was too small, restarting data nodes failed with `READ UNDERFLOW` errors.

As a result of this fix, the minimum allowed `INITIAL_SIZE` for an undo log file is now `1M` (1 megabyte). (Bug#29574)

- **Cluster API:** If the largest offset of a `RecordSpecification` used for an `NdbRecord` object was for the `NULL` bits (and thus not a column), this offset was not taken into account when calculating the size used for the `RecordSpecification`. This meant that the space for the `NULL` bits could be overwritten by key or other information. (Bug#43891)
- **Cluster API:** `BIT` columns created using the native NDB API format that were not created as nullable could still sometimes be overwritten, or cause other columns to be overwritten.

This issue did not effect tables having `BIT` columns created using the `mysqld` format (always used by MySQL Cluster SQL nodes). (Bug#43802)

- **Cluster API:** The default `NdbRecord` structures created by `NdbDictionary` could have overlapping null bits and data fields. (Bug#43590)
- **Cluster API:** When performing insert or write operations, `NdbRecord` allows key columns to be specified in both the key record and in the attribute record. Only one key column value for each key column should be sent to the NDB kernel, but this was not guaranteed. This is now ensured as follows: For insert and write operations, key column values are taken from the key record; for scan takeover update operations, key column values are taken from the attribute record. (Bug#42238)
- **Cluster API:** Ordered index scans using `NdbRecord` formerly expressed a `BoundEQ` range as separate lower and upper bounds, resulting in 2 copies of the column values being sent to the NDB kernel.

Now, when a range is specified by `NdbScanOperation::setBound()`, the passed pointers, key lengths, and inclusive bits are compared, and only one copy of the equal key columns is sent to the kernel. This makes such operations more efficient, as half the amount of `KeyInfo` is now sent for a `BoundEQ` range as before. (Bug#38793)

Changes in MySQL Cluster NDB 6.3.23 (5.1.32-ndb-6.3.23)

Functionality added or changed:

- A new data node configuration parameter `MaxLCPStartDelay` has been introduced to facilitate parallel node recovery by causing a local checkpoint to be delayed while recovering nodes are synchronizing data dictionaries and other meta-information. For more information about this parameter, see Section 17.3.4.6, “Defining MySQL Cluster Data Nodes”. (Bug#43053)

Bugs fixed:

- **Packaging:** Packages for MySQL Cluster were missing the `libndbclient.so` and `libndbclient.a` files. (Bug#42278)
- **Partitioning:** Executing `ALTER TABLE ... REORGANIZE PARTITION` on an `NDBCLUSTER` table having only one partition caused `mysqld` to crash. (Bug#41945)

See also Bug#40389.

- Backup IDs greater than 2^{31} were not handled correctly, causing negative values to be used in backup directory names and printouts. (Bug#43042)
- When using `ndbmttd`, NDB kernel threads could hang while trying to start the data nodes with `LockPagesInMainMemory` set to 1. (Bug#43021)
- When using multiple management servers and starting several API nodes (possibly including one or more SQL nodes) whose connectstrings listed the management servers in different order, it was possible for 2 API nodes to be assigned the same node ID. When this happened it was possible for an API node not to get fully connected, consequently producing a number of errors whose cause was not easily recognizable. (Bug#42973)
- `ndb_error_reporter` worked correctly only with GNU `tar`. (With other versions of `tar`, it produced empty archives.) (Bug#42753)
- Triggers on `NDBCLUSTER` tables caused such tables to become locked. (Bug#42751)

See also Bug#16229, Bug#18135.

- Given a MySQL Cluster containing no data (that is, whose data nodes had all been started using `--initial`, and into which no data had yet been imported) and having an empty backup directory, executing `START BACKUP` with a user-specified backup ID caused the data nodes to crash. (Bug#41031)
- In some cases, NDB did not check correctly whether tables had changed before trying to use the query cache. This could result in a crash of the debug MySQL server. (Bug#40464)
- **Disk Data:** It was not possible to add an in-memory column online to a table that used a table-level or column-level `STORAGE DISK` option. The same issue prevented `ALTER ONLINE TABLE ... REORGANIZE PARTITION` from working on Disk Data tables. (Bug#42549)
- **Disk Data:** Creating a Disk Data tablespace with a very large extent size caused the data nodes to fail. The issue was observed when using extent sizes of 100 MB and larger. (Bug#39096)
- **Disk Data:** Trying to execute a `CREATE LOGFILE GROUP` statement using a value greater than 150M for `UNDO_BUFFER_SIZE` caused data nodes to crash.

As a result of this fix, the upper limit for `UNDO_BUFFER_SIZE` is now 600M; attempting to set a higher value now fails gracefully with an error. (Bug#34102)

- **Disk Data:** When attempting to create a tablespace that already existed, the error message returned was `TABLE OR INDEX WITH GIVEN NAME ALREADY EXISTS`. (Bug#32662)
- **Disk Data:** Using a path or filename longer than 128 characters for Disk Data undo log files and tablespace data files caused a number of issues, including failures of `CREATE LOGFILE GROUP`, `ALTER LOGFILE GROUP`, `CREATE TABLESPACE`, and `ALTER TABLESPACE` statements, as well as crashes of management nodes and data nodes.

With this fix, the maximum length for path and file names used for Disk Data undo log files and tablespace data files is now the same as the maximum for the operating system. (Bug#31769, Bug#31770, Bug#31772)

- **Disk Data:** Attempting to perform a system restart of the cluster where there existed a logfile group without and undo log files caused the data nodes to crash.

Note

While issuing a `CREATE LOGFILE GROUP` statement without an `ADD UNDOFILE` option fails with an error in the MySQL server, this situation could arise if an SQL node failed during the execution of a valid `CREATE LOGFILE GROUP` statement; it is also possible to create a logfile group without any undo log files using the NDB API.

(Bug#17614)

- **Cluster API:** Some error messages from `ndb_mgmd` contained newline (`\n`) characters. This could break the MGM API protocol, which uses the newline as a line separator. (Bug#43104)
- **Cluster API:** When using an ordered index scan without putting all key columns in the read mask, this invalid use of the NDB API went undetected, which resulted in the use of uninitialized memory. (Bug#42591)

Changes in MySQL Cluster NDB 6.3.22 (5.1.31-ndb-6.3.22)

Functionality added or changed:

- New options are introduced for `ndb_restore` for determining which tables or databases should be restored:
 - `--include-tables` and `--include-databases` can be used to restore specific tables or databases.
 - `--exclude-tables` and `--exclude-databases` can be used to exclude the specified tables or databases from being restored.

For more information about these options, see [Section 17.6.17, “ndb_restore — Restore a MySQL Cluster Backup”](#). (Bug#40429)

Bugs fixed:

- When performing more than 32 index or tuple scans on a single fragment, the scans could be left hanging. This caused unnecessary timeouts, and in addition could possibly lead to a hang of an LCP. (Bug#42559)
- A data node failure that occurred between calls to `NdbIndexScanOperation::readTuples(SF_OrderBy)` and `NdbTransaction::Execute()` was not correctly handled; a subsequent call to `nextResult()` caused a null pointer to be dereferenced, leading to a segfault in `mysqld`. (Bug#42545)
- Issuing `SHOW GLOBAL STATUS LIKE 'NDB%'` before `mysqld` had connected to the cluster caused a segmentation fault. (Bug#42458)
- Data node failures that occurred before all data nodes had connected to the cluster were not handled correctly, leading to additional data node failures. (Bug#42422)
- When a cluster backup failed with Error 1304 (Node `node_id1`: Backup request from `node_id2` failed to start), no clear reason for the failure was provided.

As part of this fix, MySQL Cluster now retries backups in the event of sequence errors. (Bug#42354)

See also [Bug#22698](#).

- Issuing `SHOW ENGINE NDBCLUSTER STATUS` on an SQL node before the management server had connected to the cluster caused `mysqld` to crash. (Bug#42264)

Changes in MySQL Cluster NDB 6.3.21 (5.1.31-ndb-6.3.21)

Functionality added or changed:

- **Important Change:** Formerly, when the management server failed to create a transporter for a data node connection, `net_write_timeout` seconds elapsed before the data node was actually allowed to disconnect. Now in such cases the disconnection occurs immediately. (Bug#41965)

See also [Bug#41713](#).

- It is now possible while in Single User Mode to restart all data nodes using `ALL RESTART` in the management client. Restarting of individual nodes while in Single User Mode remains disallowed. (Bug#31056)
- Formerly, when using MySQL Cluster Replication, records for “empty” epochs — that is, epochs in which no changes to `NDBCLUSTER` data or tables took place — were inserted into the `ndb_apply_status` and `ndb_binlog_index` tables on the slave even when `--log-slave-updates` was disabled. Beginning with MySQL Cluster NDB 6.2.16 and MySQL Cluster NDB 6.3.13 this was changed so that these “empty” epochs were no longer logged. However, it is now possible to re-enable the older behavior (and cause “empty” epochs to be logged) by using the `--ndb-log-empty-epochs` option. For more information, see [Section 16.1.3.3, “Replication Slave Options and Variables”](#).

See also [Bug#37472](#).

Bugs fixed:

- A maximum of 11 `TUP` scans were allowed in parallel. (Bug#42084)

- Trying to execute an `ALTER ONLINE TABLE ... ADD COLUMN` statement while inserting rows into the table caused `mysqld` to crash. ([Bug#41905](#))
- If the master node failed during a global checkpoint, it was possible in some circumstances for the new master to use an incorrect value for the global checkpoint index. This could occur only when the cluster used more than one node group. ([Bug#41469](#))
- API nodes disconnected too aggressively from cluster when data nodes were being restarted. This could sometimes lead to the API node being unable to access the cluster at all during a rolling restart. ([Bug#41462](#))
- It was not possible to perform online upgrades from a MySQL Cluster NDB 6.2 release to MySQL Cluster NDB 6.3.8 or a later MySQL Cluster NDB 6.3 release. ([Bug#41435](#))
- Cluster log files were opened twice by internal log-handling code, resulting in a resource leak. ([Bug#41362](#))
- An abort path in the `DBLQH` kernel block failed to release a commit acknowledgement marker. This meant that, during node failure handling, the local query handler could be added multiple times to the marker record which could lead to additional node failures due an array overflow. ([Bug#41296](#))
- During node failure handling (of a data node other than the master), there was a chance that the master was waiting for a `GCP_NODEFINISHED` signal from the failed node after having received it from all other data nodes. If this occurred while the failed node had a transaction that was still being committed in the current epoch, the master node could crash in the `DBTC` kernel block when discovering that a transaction actually belonged to an epoch which was already completed. ([Bug#41295](#))
- Issuing `EXIT` in the management client sometimes caused the client to hang. ([Bug#40922](#))
- In the event that a MySQL Cluster backup failed due to file permissions issues, conflicting reports were issued in the management client. ([Bug#34526](#))
- If all data nodes were shut down, MySQL clients were unable to access `NDBCLUSTER` tables and data even after the data nodes were restarted, unless the MySQL clients themselves were restarted. ([Bug#33626](#))
- **Disk Data:** Starting a cluster under load such that Disk Data tables used most of the undo buffer could cause data node failures. The fix for this bug also corrected an issue in the `LGMAN` kernel block where the amount of free space left in the undo buffer was miscalculated, causing buffer overruns. This could cause records in the buffer to be overwritten, leading to problems when restarting data nodes. ([Bug#28077](#))
- **Cluster API:** `mgmapi.h` contained constructs which only worked in C++, but not in C. ([Bug#27004](#))

Changes in MySQL Cluster NDB 6.3.20 (5.1.30-ndb-6.3.20)

Bugs fixed:

- If a transaction was aborted during the handling of a data node failure, this could lead to the later handling of an API node failure not being completed. ([Bug#41214](#))
- Issuing `SHOW TABLES` repeatedly could cause `NDBCLUSTER` tables to be dropped. ([Bug#40854](#))
- Statements of the form `UPDATE ... ORDER BY ... LIMIT` run against `NDBCLUSTER` tables failed to update all matching rows, or failed with the error `CAN'T FIND RECORD IN 'TABLE_NAME'`. ([Bug#40081](#))
- Start phase reporting was inconsistent between the management client and the cluster log. ([Bug#39667](#))
- Status messages shown in the management client when restarting a management node were inappropriate and misleading. Now, when restarting a management node, the messages displayed are as follows, where `node_id` is the management node's node ID:

```
ndb_mgm> node_id RESTART
Shutting down MGM node node_id for restart
Node node_id is being restarted
ndb_mgm>
```

([Bug#29275](#))

- **Disk Data:** This improves on a previous fix for this issue that was made in MySQL Cluster 6.3.8. ([Bug#37116](#))

See also [Bug#29186](#).

- **Cluster API:** When creating a scan using an `NdbScanFilter` object, it was possible to specify conditions against a `BIT` column, but the correct rows were not returned when the scan was executed.

As part of this fix, 4 new comparison operators have been implemented for use with scans on `BIT` columns:

- `COL_AND_MASK_EQ_MASK`
- `COL_AND_MASK_NE_MASK`
- `COL_AND_MASK_EQ_ZERO`
- `COL_AND_MASK_NE_ZERO`

For more information about these operators, see [The `NdbScanFilter::BinaryCondition` Type](#).

Equivalent methods are now also defined for `NdbInterpretedCode`; for more information, see [NdbInterpretedCode Bitwise Comparison Operations](#). (Bug#40535)

Changes in MySQL Cluster NDB 6.3.19 (5.1.29-ndb-6.3.19)

Functionality added or changed:

- **Cluster API: Important Change:** MGM API applications exited without raising any errors if the connection to the management server was lost. The fix for this issue includes two changes:
 1. The MGM API now provides its own `SIGPIPE` handler to catch the “broken pipe” error that occurs when writing to a closed or reset socket. This means that MGM API now behaves the same as NDB API in this regard.
 2. A new function `ndb_mgm_set_ignore_sigpipe()` has been added to the MGM API. This function makes it possible to bypass the `SIGPIPE` handler provided by the MGM API. (Bug#40498)
- When performing an initial start of a data node, fragment log files were always created sparsely — that is, not all bytes were written. Now it is possible to override this behavior using the new `InitFragmentLogFiles` configuration parameter. (Bug#40847)

Bugs fixed:

- **Cluster API:** Failed operations on `BLOB` and `TEXT` columns were not always reported correctly to the originating SQL node. Such errors were sometimes reported as being due to timeouts, when the actual problem was a transporter overload due to insufficient buffer space. (Bug#39867, Bug#39879)
- **Cluster API:** Failed operations on `BLOB` and `TEXT` columns were not always reported correctly to the originating SQL node. Such errors were sometimes reported as being due to timeouts, when the actual problem was a transporter overload due to insufficient buffer space. (Bug#39867, Bug#39879)
- Undo logs and data files were created in 32K increments. Now these files are created in 512K increments, resulting in shorter creation times. (Bug#40815)
- Redo log creation was very slow on some platforms, causing MySQL Cluster to start more slowly than necessary with some combinations of hardware and operating system. This was due to all write operations being synchronized to disk while creating a redo log file. Now this synchronization occurs only after the redo log has been created. (Bug#40734)
- Transaction failures took longer to handle than was necessary.

When a data node acting as transaction coordinator (TC) failed, the surviving data nodes did not inform the API node initiating the transaction of this until the failure had been processed by all protocols. However, the API node needed only to know about failure handling by the transaction protocol — that is, it needed to be informed only about the TC takeover process. Now, API nodes (including MySQL servers acting as cluster SQL nodes) are informed as soon as the TC takeover is complete, so that it can carry on operating more quickly. (Bug#40697)

- It was theoretically possible for stale data to be read from `NDBCLUSTER` tables when the transaction isolation level was set to `ReadCommitted`. (Bug#40543)
- The `LockExecuteThreadToCPU` and `LockMaintThreadsToCPU` parameters did not work on Solaris. (Bug#40521)
- `SET SESSION ndb_optimized_node_selection = 1` failed with an invalid warning message. (Bug#40457)

- A restarting data node could fail with an error in the `DBDIH` kernel block when a local or global checkpoint was started or triggered just as the node made a request for data from another data node. (Bug#40370)
- Restoring a MySQL Cluster from a dump made using `mysqldump` failed due to a spurious error: `CAN'T EXECUTE THE GIVEN COMMAND BECAUSE YOU HAVE ACTIVE LOCKED TABLES OR AN ACTIVE TRANSACTION`. (Bug#40346)
- `O_DIRECT` was incorrectly disabled when making MySQL Cluster backups. (Bug#40205)
- Heavy DDL usage caused the `mysqld` processes to hang due to a timeout error (NDB error code 266). (Bug#39885)
- Executing `EXPLAIN SELECT` on an `NDBCLUSTER` table could cause `mysqld` to crash. (Bug#39872)
- Events logged after setting `ALL CLUSTERLOG STATISTICS=15` in the management client did not always include the node ID of the reporting node. (Bug#39839)
- The MySQL Query Cache did not function correctly with `NDBCLUSTER` tables containing `TEXT` columns. (Bug#39295)
- A segfault in `Logger::Log` caused `ndbd` to hang indefinitely. This fix improves on an earlier one for this issue, first made in MySQL Cluster NDB 6.2.16 and MySQL Cluster NDB 6.3.17. (Bug#39180)

See also [Bug#38609](#).

- Memory leaks could occur in handling of strings used for storing cluster metadata and providing output to users. (Bug#38662)
- A duplicate key error raised when inserting into an `NDBCLUSTER` table caused the current transaction to abort, after which any SQL statement other than a `ROLLBACK` failed. With this fix, the `NDBCLUSTER` storage engine now supports rollback of individual statements in such cases, and it is no longer necessary to issue an explicit `ROLLBACK` and then retry the entire transaction. (Bug#32656)
- Error messages for `NDBCLUSTER` error codes 1224 and 1227 were missing. (Bug#28496)
- **Disk Data:** Issuing concurrent `CREATE TABLESPACE`, `ALTER TABLESPACE`, `CREATE LOGFILE GROUP`, or `ALTER LOGFILE GROUP` statements on separate SQL nodes caused a resource leak that led to data node crashes when these statements were used again later. (Bug#40921)
- **Disk Data:** Disk-based variable-length columns were not always handled like their memory-based equivalents, which could potentially lead to a crash of cluster data nodes. (Bug#39645)
- **Disk Data:** `O_SYNC` was incorrectly disabled on platforms that do not support `O_DIRECT`. This issue was noted on Solaris but could have affected other platforms not having `O_DIRECT` capability. (Bug#34638)
- **Cluster API:** The MGM API reset error codes on management server handles before checking them. This meant that calling an MGM API function with a null handle caused applications to crash. (Bug#40455)
- **Cluster API:** It was not always possible to access parent objects directly from `NdbBlob`, `NdbOperation`, and `NdbScanOperation` objects. To alleviate this problem, a new `getNdbOperation()` method has been added to `NdbBlob` and new `getNdbTransaction()` methods have been added to `NdbOperation` and `NdbScanOperation`. In addition, a const variant of `NdbOperation::getErrorLine()` is now also available. (Bug#40242)
- **Cluster API:** `NdbScanOperation::getBlobHandle()` failed when used with incorrect column names or numbers. (Bug#40241)
- **Cluster API:** The MGM API function `ndb_mgm_listen_event()` ignored bind addresses.

As part of this fix, it is now possible to specify bind addresses in connectstrings. See [Section 17.3.4.3, “The MySQL Cluster Connectstring”](#), for more information. (Bug#38473)

- **Cluster API:** The NDB API example programs included in MySQL Cluster source distributions failed to compile. (Bug#37491)

See also [Bug#40238](#).

Changes in MySQL Cluster NDB 6.3.18 (5.1.28-ndb-6.3.18)

Functionality added or changed:

- It is no longer a requirement for database autodiscovery that an SQL node already be connected to the cluster at the time that a database is created on another SQL node. It is no longer necessary to issue `CREATE DATABASE` (or `CREATE SCHEMA`) statements on an SQL node joining the cluster after a database is created in order for the new SQL node to see the database and any

`NDBCLUSTER` tables that it contains. (Bug#39612)

Bugs fixed:

- When a transaction included a multi-row insert to an `NDBCLUSTER` table that caused a constraint violation, the transaction failed to roll back. (Bug#395638)
- Starting the MySQL Server with the `--ndbcluster` option plus an invalid command-line option (for example, using `mysqld --ndbcluster --foobar`) caused it to hang while shutting down the binlog thread. (Bug#39635)
- Dropping and then re-creating a database on one SQL node caused other SQL nodes to hang. (Bug#39613)
- Setting a low value of `MaxNoOfLocalScans` (< 100) and performing a large number of (certain) scans could cause the Transaction Coordinator to run out of scan fragment records, and then crash. Now when this resource is exhausted, the cluster returns Error 291 (`OUT OF SCANFRAG RECORDS IN TC (INCREASE MAXNOOFLOCALSCANS)`) instead. (Bug#39549)
- Creating a unique index on an `NDBCLUSTER` table caused a memory leak in the `NDB` subscription manager (`SUMA`) which could lead to `mysqld` hanging, due to the fact that the resource shortage was not reported back to the `NDB` kernel correctly. (Bug#39518)

See also Bug#39450.

- Embedded `libmysqld` with `NDB` did not drop table events. (Bug#39450)
- Unique identifiers in tables having no primary key were not cached. This fix has been observed to increase the efficiency of `INSERT` operations on such tables by as much as 50%. (Bug#39267)
- When restarting a data node, an excessively long shutdown message could cause the node process to crash. (Bug#38580)
- After a forced shutdown and initial restart of the cluster, it was possible for SQL nodes to retain `.FRM` files corresponding to `NDBCLUSTER` tables that had been dropped, and thus to be unaware that these tables no longer existed. In such cases, attempting to re-create the tables using `CREATE TABLE IF NOT EXISTS` could fail with a spurious `TABLE ... DOESN'T EXIST` error. (Bug#37921)
- A statement of the form `DELETE FROM table WHERE primary_key=value` or `UPDATE table WHERE primary_key=value` where there was no row whose primary key column had the stated `value` appeared to succeed, with the server reporting that 1 row had been changed.

This issue was only known to affect MySQL Cluster NDB 6.3.11 and later NDB 6.3 versions. (Bug#37153)

- **Cluster API:** Passing a value greater than 65535 to `NdbInterpretedCode::add_val()` and `NdbInterpretedCode::sub_val()` caused these methods to have no effect. (Bug#39536)

Changes in MySQL Cluster NDB 6.3.17 (5.1.27-ndb-6.3.17)

Bugs fixed:

- **Packaging:** Support for the `InnoDB` storage engine was missing from the GPL source releases. An updated GPL source tarball `mysql-5.1.27-ndb-6.3.17-innodb.tar.gz` which includes code for building `InnoDB` can be found on [the MySQL FTP site](#).
- `MgmtSrvr::allocNodeId()` left a mutex locked following an `AMBIGUITY FOR NODE IF %D` error. (Bug#39158)
- An invalid path specification caused `mysql-test-run.pl` to fail. (Bug#39026)
- During transactional coordinator takeover (directly after node failure), the LQH finding an operation in the `LOG_COMMIT` state sent an `LQH_TRANS_CONF` signal twice, causing the TC to fail. (Bug#38930)
- An invalid memory access caused the management server to crash on Solaris Sparc platforms. (Bug#38628)
- A segfault in `Logger::Log` caused `ndbd` to hang indefinitely. (Bug#38609)
- `ndb_mgmd` failed to start on older Linux distributions (2.4 kernels) that did not support e-polling. (Bug#38592)
- `ndb_mgmd` sometimes performed unnecessary network I/O with the client. This in combination with other factors led to long-running threads that were attempting to write to clients that no longer existed. (Bug#38563)
- `ndb_restore` failed with a floating point exception due to a division by zero error when trying to restore certain data files.

Bug#38520)

- A failed connection to the management server could cause a resource leak in `ndb_mgmd`. ([Bug#38424](#))
- Failure to parse configuration parameters could cause a memory leak in the NDB log parser. ([Bug#38380](#))
- Renaming an `NDBCLUSTER` table on one SQL node, caused a trigger on this table to be deleted on another SQL node. ([Bug#36658](#))
- Attempting to add a `UNIQUE INDEX` twice to an `NDBCLUSTER` table, then deleting rows from the table could cause the MySQL Server to crash. ([Bug#35599](#))
- `ndb_restore` failed when a single table was specified. ([Bug#33801](#))
- `GCP_COMMIT` did not wait for transaction takeover during node failure. This could cause `GCP_SAVE_REQ` to be executed too early. This could also cause (very rarely) replication to skip rows. ([Bug#30780](#))
- **Cluster API:** Support for Multi-Range Read index scans using the old API (using, for example, `NdbIndexScanOperation::setBound()` or `NdbIndexScanOperation::end_of_bound()`) were dropped in MySQL Cluster NDB 6.2. This functionality is restored in MySQL Cluster NDB 6.3 beginning with 6.3.17, but remains unavailable in MySQL Cluster NDB 6.2. Both MySQL Cluster NDB 6.2 and 6.3 support Multi-Range Read scans via the `NdbRecord` API. ([Bug#38791](#))
- **Cluster API:** The `NdbScanOperation::readTuples()` method could be called multiple times without error. ([Bug#38717](#))
- **Cluster API:** Certain Multi-Range Read scans involving `IS NULL` and `IS NOT NULL` comparisons failed with an error in the NDB local query handler. ([Bug#38204](#))
- **Cluster API:** Problems with the public headers prevented NDB applications from being built with warnings turned on. ([Bug#38177](#))
- **Cluster API:** Creating an `NdbScanFilter` object using an `NdbScanOperation` object that had not yet had its `readTuples()` method called resulted in a crash when later attempting to use the `NdbScanFilter`. ([Bug#37986](#))
- **Cluster API:** Executing an `NdbRecord` interpreted delete created with an `ANYVALUE` option caused the transaction to abort. ([Bug#37672](#))

Changes in MySQL Cluster NDB 6.3.16 (5.1.24-ndb-6.3.16)

Functionality added or changed:

- Event buffer lag reports are now written to the cluster log. ([Bug#37427](#))
- Added the `--no-binlog` option for `ndb_restore`. When used, this option prevents information being written to SQL node binary logs from the restoration of a cluster backup. ([Bug#30452](#))

Bugs fixed:

- **Cluster API:** Changing the system time on data nodes could cause MGM API applications to hang and the data nodes to crash. ([Bug#35607](#))
- **Cluster API:** Changing the system time on data nodes could cause MGM API applications to hang and the data nodes to crash. ([Bug#35607](#))
- Failure of a data node could sometimes cause `mysqld` to crash. ([Bug#37628](#))
- `DELETE ... WHERE unique_index_column=value` deleted the wrong row from the table. ([Bug#37516](#))
- If subscription was terminated while a node was down, the epoch was not properly acknowledged by that node. ([Bug#37442](#))
- `libmysqld` failed to wait for the cluster binlog thread to terminate before exiting. ([Bug#37429](#))
- In rare circumstances, a connection followed by a disconnection could give rise to a “stale” connection where the connection still existed but was not seen by the transporter. ([Bug#37338](#))
- Queries against `NDBCLUSTER` tables were cached only if `autocommit` was in use. ([Bug#36692](#))
- **Cluster API:** When some operations succeeded and some failed following a call to `NdbTransac-`

`tion::execute(Commit, AO_IgnoreOnError)`, a race condition could cause spurious occurrences of NDB API Error 4011 (`INTERNAL ERROR`). ([Bug#37158](#))

- **Cluster API:** Creating a table on an SQL node, then starting an NDB API application that listened for events from this table, then dropping the table from an SQL node, prevented data node restarts. ([Bug#32949](#), [Bug#37279](#))
- **Cluster API:** A buffer overrun in `NdbBlob::setValue()` caused erroneous results on Mac OS X. ([Bug#31284](#))

Changes in MySQL Cluster NDB 6.3.15 (5.1.24-ndb-6.3.15)

Bugs fixed:

- In certain rare situations, `ndb_size.pl` could fail with the error `CAN'T USE STRING ("VALUE") AS A HASH REF WHILE "STRICT REFS" IN USE`. ([Bug#43022](#))
- Under some circumstances, a failed `CREATE TABLE` could mean that subsequent `CREATE TABLE` statements caused node failures. ([Bug#37092](#))
- A fail attempt to create an NDB table could in some cases lead to resource leaks or cluster failures. ([Bug#37072](#))
- Attempting to create a native backup of NDB tables having a large number of `NULL` columns and data could lead to node failures. ([Bug#37039](#))
- Checking of API node connections was not efficiently handled. ([Bug#36843](#))
- Attempting to delete a non-existent row from a table containing a `TEXT` or `BLOB` column within a transaction caused the transaction to fail. ([Bug#36756](#))

See also [Bug#36851](#).

- If the combined total of tables and indexes in the cluster was greater than 4096, issuing `START BACKUP` caused data nodes to fail. ([Bug#36044](#))
- Where column values to be compared in a query were of the `VARCHAR` or `VARBINARY` types, `NDBCLUSTER` passed a value padded to the full size of the column, which caused unnecessary data to be sent to the data nodes. This also had the effect of wasting CPU and network bandwidth, and causing condition pushdown to be disabled where it could (and should) otherwise have been applied. ([Bug#35393](#))
- When dropping a table failed for any reason (such as when in single user mode) then the corresponding `.ndb` file was still removed.
- **Cluster API:** Ordered index scans were not pruned correctly where a partitioning key was specified with an EQ-bound. ([Bug#36950](#))
- **Cluster API:** When an insert operation involving `BLOB` data was attempted on a row which already existed, no duplicate key error was correctly reported and the transaction is incorrectly aborted. In some cases, the existing row could also become corrupted. ([Bug#36851](#))

See also [Bug#26756](#).

- **Cluster API:** `NdbApi.hpp` depended on `ndb_global.h`, which was not actually installed, causing the compilation of programs that used `NdbApi.hpp` to fail. ([Bug#35853](#))

Changes in MySQL Cluster NDB 6.3.14 (5.1.24-ndb-6.3.14)

Bugs fixed:

- `SET GLOBAL ndb_extra_logging` caused `mysqld` to crash. ([Bug#36547](#))
- A race condition caused by a failure in epoll handling could cause data nodes to fail. ([Bug#36537](#))
- Under certain rare circumstances, the failure of the new master node while attempting a node takeover would cause takeover errors to repeat without being resolved. ([Bug#36199](#), [Bug#36246](#), [Bug#36247](#), [Bug#36276](#))
- When more than one SQL node connected to the cluster at the same time, creation of the `mysql.ndb_schema` table failed on one of them with an explicit `TABLE EXISTS` error, which was not necessary. ([Bug#35943](#))
- `mysqld` failed to start after running `mysql_upgrade`. ([Bug#35708](#))

- Notification of a cascading master node failures could sometimes not be transmitted correctly (that is, transmission of the `NF_COMPLETETEREP` signal could fail), leading to transactions hanging and timing out (NDB error 4012), scans hanging, and failure of the management server process. (Bug#32645)
- If an API node disconnected and then reconnected during Start Phase 8, then the connection could be “blocked” — that is, the `QMGR` kernel block failed to detect that the API node was in fact connected to the cluster, causing issues with the NDB Subscription Manager (SUMA).
- NDB error 1427 (`API NODE DIED, WHEN SUB_START_REQ REACHED NODE`) was incorrectly classified as a schema error rather than a temporary error.
- **Cluster API:** Accessing the debug version of `libndbclient` via `dlopen()` resulted in a segmentation fault. (Bug#35927)
- **Cluster API:** Attempting to pass a non-existent column name to the `equal()` and `setValue()` methods of `NdbOperation` caused NDB API applications to crash. Now the column name is checked, and an error is returned in the event that the column is not found. (Bug#33747)
- **Cluster API:** Relocation errors were encountered when trying to compile NDB API applications on a number of platforms, including 64-bit Linux. As a result, `libmysys`, `libmystrings`, and `libdbug` have been changed from normal libraries to “noinst” `libtool` helper libraries. They are no longer installed as separate libraries; instead, all necessary symbols from these are added directly to `libndbclient`. This means that NDB API programs now need to be linked only using `-lndbclient`. (Bug#29791)

Changes in MySQL Cluster NDB 6.3.13 (5.1.24-ndb-6.3.13)

Bugs fixed:

- **Important Change:** `mysqld_safe` now traps Signal 13 (`SIGPIPE`) so that this signal no longer kills the MySQL server process. (Bug#33984)
- Node or system restarts could fail due an uninitialized variable in the `DTUP` kernel block. This issue was found in MySQL Cluster NDB 6.3.11. (Bug#35797)
- If an error occurred while executing a statement involving a `BLOB` or `TEXT` column of an NDB table, a memory leak could result. (Bug#35593)
- It was not possible to determine the value used for the `--ndb-cluster-connection-pool` option in the `mysql` client. Now this value is reported as a system status variable. (Bug#35573)
- The `ndb_waiter` utility wrongly calculated timeouts. (Bug#35435)
- A `SELECT` on a table with a non-indexed, large `VARCHAR` column which resulted in condition pushdown on this column could cause `mysqld` to crash. (Bug#35413)
- `ndb_restore` incorrectly handled some datatypes when applying log files from backups. (Bug#35343)
- In some circumstances, a stopped data node was handled incorrectly, leading to redo log space being exhausted following an initial restart of the node, or an initial or partial restart of the cluster (the wrong CGI might be used in such cases). This could happen, for example, when a node was stopped following the creation of a new table, but before a new LCP could be executed. (Bug#35241)
- `SELECT ... LIKE ...` queries yielded incorrect results when used on NDB tables. As part of this fix, condition pushdown of such queries has been disabled; re-enabling it is expected to be done as part of a later, permanent fix for this issue. (Bug#35185)
- `ndb_mgmd` reported errors to `STDOUT` rather than to `STDERR`. (Bug#35169)
- Nested Multi-Range Read scans failed when the second Multi-Range Read released the first read's unprocessed operations, sometimes leading to an SQL node crash. (Bug#35137)
- In some situations, a problem with synchronizing checkpoints between nodes could cause a system restart or a node restart to fail with `ERROR 630 DURING RESTORE OF TX`. (Bug#34756)
- A node failure during an initial node restart followed by another node start could cause the master data node to fail, because it incorrectly gave the node permission to start even if the invalidated node's LCP was still running. (Bug#34702)
- When a secondary index on a `DECIMAL` column was used to retrieve data from an NDB table, no results were returned even if the target table had a matched value in the column that was defined with the secondary index. (Bug#34515)

- An `UPDATE` on an `NDB` table that set a new value for a unique key column could cause subsequent queries to fail. ([Bug#34208](#))
- If a data node in one node group was placed in the “not started” state (using `node_id RESTART -n`), it was not possible to stop a data node in a different node group. ([Bug#34201](#))
- Numerous `NDBCLUSTER` test failures occurred in builds compiled using `icc` on IA64 platforms. ([Bug#31239](#))
- If a `START BACKUP` command was issued while `ndb_restore` was running, the backup being restored could be overwritten. ([Bug#26498](#))
- `REPLACE` statements did not work correctly with `NDBCLUSTER` tables when all columns were not explicitly listed. ([Bug#22045](#))
- `CREATE TABLE` and `ALTER TABLE` statements using `ENGINE=NDB` or `ENGINE=NDBCLUSTER` caused `mysqld` to fail on Solaris 10 for x86 platforms. ([Bug#19911](#))
- **Cluster API:** Closing a scan before it was executed caused the application to segfault. ([Bug#36375](#))
- **Cluster API:** Using NDB API applications from older MySQL Cluster versions with `libndbclient` from newer ones caused the cluster to fail. ([Bug#36124](#))
- **Cluster API:** Some ordered index scans could return tuples out of order. ([Bug#35908](#))
- **Cluster API:** Scans having no bounds set were handled incorrectly. ([Bug#35876](#))
- **Cluster API:** `NdbScanFilter::getNdbOperation()`, which was inadvertently removed in MySQL Cluster NDB 6.3.11, has been restored. ([Bug#35854](#))

Changes in MySQL Cluster NDB 6.3.10 (5.1.23-ndb-6.3.10)

Bugs fixed:

- Due to the reduction of the number of local checkpoints from 3 to 2 in MySQL Cluster NDB 6.3.8, a data node using `ndbd` from MySQL Cluster NDB 6.3.8 or later started using a file system from an earlier version could incorrectly invalidate local checkpoints too early during the startup process, causing the node to fail. ([Bug#34596](#))

Changes in MySQL Cluster NDB 6.3.9 (5.1.23-ndb-6.3.9)

Bugs fixed:

- Cluster failures could sometimes occur when performing more than three parallel takeovers during node restarts or system restarts. This affected MySQL Cluster NDB 6.3.x releases only. ([Bug#34445](#))
- Upgrades of a cluster using while a `DataMemory` setting in excess of 16 GB caused data nodes to fail. ([Bug#34378](#))
- Performing many SQL statements on `NDB` tables while in `autocommit` mode caused a memory leak in `mysqld`. ([Bug#34275](#))
- In certain rare circumstances, a race condition could occur between an aborted insert and a delete leading a data node crash. ([Bug#34260](#))
- Multi-table updates using ordered indexes during handling of node failures could cause other data nodes to fail. ([Bug#34216](#))
- When configured with `NDB` support, MySQL failed to compile using `gcc` 4.3 on 64bit FreeBSD systems. ([Bug#34169](#))
- The failure of a DDL statement could sometimes lead to node failures when attempting to execute subsequent DDL statements. ([Bug#34160](#))
- Extremely long `SELECT` statements (where the text of the statement was in excess of 50000 characters) against `NDB` tables returned empty results. ([Bug#34107](#))
- When configured with `NDB` support, MySQL failed to compile on 64bit FreeBSD systems. ([Bug#34046](#))
- Statements executing multiple inserts performed poorly on `NDB` tables having `AUTO_INCREMENT` columns. ([Bug#33534](#))
- The `ndb_waiter` utility polled `ndb_mgmd` excessively when obtaining the status of cluster data nodes. ([Bug#32025](#))

See also [Bug#32023](#).

- Transaction atomicity was sometimes not preserved between reads and inserts under high loads. ([Bug#31477](#))
- Having tables with a great many columns could cause Cluster backups to fail. ([Bug#30172](#))
- **Cluster Replication: Disk Data:** Statements violating unique keys on Disk Data tables (such as attempting to insert `NULL` into a `NOT NULL` column) could cause data nodes to fail. When the statement was executed from the binlog, this could also result in failure of the slave cluster. ([Bug#34118](#))
- **Disk Data:** Updating in-memory columns of one or more rows of Disk Data table, followed by deletion of these rows and re-insertion of them, caused data node failures. ([Bug#33619](#))

Changes in MySQL Cluster NDB 6.3.8 (5.1.23-ndb-6.3.8)

Functionality added or changed:

- **Cluster API: Important Change:** Because `NDB_LE_MemoryUsage.page_size_kb` shows memory page sizes in bytes rather than kilobytes, it has been renamed to `page_size_bytes`. The name `page_size_kb` is now deprecated and thus subject to removal in a future release, although it currently remains supported for reasons of backward compatibility. See [The `Ndb_logevent_type` Type](#), for more information about `NDB_LE_MemoryUsage`. ([Bug#30271](#))
- `ndb_restore` now supports basic *attribute promotion*; that is, data from a column of a given type can be restored to a column using a “larger” type. For example, Cluster backup data taken from a `SMALLINT` column can be restored to a `MEDIUMINT`, `INT`, or `BIGINT` column.

For more information, see [Section 17.6.17, “`ndb_restore` — Restore a MySQL Cluster Backup”](#).
- Now only 2 local checkpoints are stored, rather than 3 as in previous MySQL Cluster versions. This lowers disk space requirements and reduces the size and number of redo log files needed.
- The `mysqld` option `--ndb-batch-size` has been added. This allows for controlling the size of batches used for running transactions.
- Node recovery can now be done in parallel, rather than sequentially, which can result in much faster recovery times.
- Persistence of NDB tables can now be controlled using the session variables `ndb_table_temporary` and `ndb_table_no_logging`. `ndb_table_no_logging` causes NDB tables not to be checkpointed to disk; `ndb_table_temporary` does the same, and in addition, no schema files are created.
- `OPTIMIZE TABLE` can now be interrupted. This can be done, for example, by killing the SQL thread performing the `OPTIMIZE` operation.

Bugs fixed:

- **Disk Data: Important Change:** It is no longer possible on 32-bit systems to issue statements appearing to create Disk Data log files or data files greater than 4 GB in size. (Trying to create log files or data files larger than 4 GB on 32-bit systems led to unrecoverable data node failures; such statements now fail with NDB error 1515.) ([Bug#29186](#))
- **Replication:** The code implementing heartbeats did not check for possible errors in some circumstances; this kept the dump thread hanging while waiting for heartbeats loop even though the slave was no longer connected. ([Bug#33332](#))
- High numbers of insert operations, delete operations, or both could cause NDB error 899 (`ROWID ALREADY ALLOCATED`) to occur unnecessarily. ([Bug#34033](#))
- A periodic failure to flush the send buffer by the NDB TCP transporter could cause a unnecessary delay of 10 ms between operations. ([Bug#34005](#))
- `DROP TABLE` did not free all data memory. This bug was observed in MySQL Cluster NDB 6.3.7 only. ([Bug#33802](#))
- A race condition could occur (very rarely) when the release of a GCI was followed by a data node failure. ([Bug#33793](#))
- Some tuple scans caused the wrong memory page to be accessed, leading to invalid results. This issue could affect both in-memory and Disk Data tables. ([Bug#33739](#))
- A failure to initialize an internal variable led to sporadic crashes during cluster testing. ([Bug#33715](#))
- The server failed to reject properly the creation of an NDB table having an unindexed `AUTO_INCREMENT` column. ([Bug#30417](#))

- Issuing an `INSERT ... ON DUPLICATE KEY UPDATE` concurrently with or following a `TRUNCATE` statement on an NDB table failed with NDB error 4350 `TRANSACTION ALREADY ABORTED`. (Bug#29851)
- The Cluster backup process could not detect when there was no more disk space and instead continued to run until killed manually. Now the backup fails with an appropriate error when disk space is exhausted. (Bug#28647)
- It was possible in `config.ini` to define cluster nodes having node IDs greater than the maximum allowed value. (Bug#28298)
- Under some circumstances, a recovering data node did not use its own data, instead copying data from another node even when this was not required. This in effect bypassed the optimized node recovery protocol and caused recovery times to be unnecessarily long. (Bug#26913)
- **Cluster API:** Transactions containing inserts or reads would hang during `NdbTransaction::execute()` calls made from NDB API applications built against a MySQL Cluster version that did not support micro-GCPs accessing a later version that supported micro-GCPs. This issue was observed while upgrading from MySQL Cluster NDB 6.1.23 to MySQL Cluster NDB 6.2.10 when the API application built against the earlier version attempted to access a data node already running the later version, even after disabling micro-GCPs by setting `TimeBetweenEpochs` equal to 0. (Bug#33895)
- **Cluster API:** When reading a `BIT(64)` value using `NdbOperation::getValue()`, 12 bytes were written to the buffer rather than the expected 8 bytes. (Bug#33750)

Changes in MySQL Cluster NDB 6.3.7 (5.1.23-ndb-6.3.7)

Functionality added or changed:

- Compressed local checkpoints and backups are now supported, resulting in a space savings of 50% or more over uncompressed LCPs and backups. Compression of these can be enabled in the `config.ini` file using the two new data node configuration parameters `CompressedLCP` and `CompressedBackup`, respectively.
- `OPTIMIZE TABLE` is now supported for `NDBCLUSTER` tables, subject to the following limitations:
 - Only in-memory tables are supported. `OPTIMIZE` still has no effect on Disk Data tables.
 - Only variable-length columns are supported. However, you can force columns defined using fixed-length data types to be dynamic using the `ROW_FORMAT` or `COLUMN_FORMAT` option with a `CREATE TABLE` or `ALTER TABLE` statement.

Memory reclaimed from an NDB table using `OPTIMIZE` is generally available to the cluster, and not confined to the table from which it was recovered, unlike the case with memory freed using `DELETE`.

The performance of `OPTIMIZE` on NDB tables can be regulated by adjusting the value of the `ndb_optimization_delay` system variable.

- It is now possible to cause statements occurring within the same transaction to be run as a batch by setting the session variable `transaction_allow_batching` to 1 or ON.

Note

To use this feature, autocommit must be disabled.

Bugs fixed:

- **Partitioning:** When partition pruning on an NDB table resulted in an ordered index scan spanning only one partition, any descending flag for the scan was wrongly discarded, causing `ORDER BY DESC` to be treated as `ORDER BY ASC, MAX()` to be handled incorrectly, and similar problems. (Bug#33061)
- When all data and SQL nodes in the cluster were shut down abnormally (that is, other than by using `STOP` in the cluster management client), `ndb_mgm` used excessive amounts of CPU. (Bug#33237)
- When using micro-GCPs, if a node failed while preparing for a global checkpoint, the master node would use the wrong GCI. (Bug#32922)
- Under some conditions, performing an `ALTER TABLE` on an `NDBCLUSTER` table failed with a `TABLE IS FULL` error, even when only 25% of `DataMemory` was in use and the result should have been a table using less memory (for example, changing a `VARCHAR(100)` column to `VARCHAR(80)`). (Bug#32670)

Changes in MySQL Cluster NDB 6.3.6 (5.1.22-ndb-6.3.6)

Functionality added or changed:

- Unnecessary reads when performing a primary key or unique key update have been reduced, and in some cases, eliminated. (It is almost never necessary to read a record prior to an update, the lone exception to this being when a primary key is updated, since this requires a delete followed by an insert, which must be prepared by reading the record.) Depending on the number of primary key and unique key lookups that are performed per transaction, this can yield a considerable improvement in performance.
- Batched operations are now better supported for `DELETE` and `UPDATE`. (`UPDATE WHERE . . .` and multiple `DELETE`.)
- Introduced the `Ndb_execute_count` status variable, which measures the number of round trips made by queries to the NDB kernel.

Bugs fixed:

- An insert or update with combined range and equality constraints failed when run against an NDB table with the error `GOT UNKNOWN ERROR FROM NDB`. An example of such a statement would be `UPDATE t1 SET b = 5 WHERE a IN (7,8) OR a >= 10;`. (Bug#31874)
- An error with an `if` statement in `sql/ha_ndbcluster.cc` could potentially lead to an infinite loop in case of failure when working with `AUTO_INCREMENT` columns in NDB tables. (Bug#31810)
- The NDB storage engine code was not safe for strict-alias optimization in `gcc` 4.2.1. (Bug#31761)
- `ndb_restore` displayed incorrect backup file version information. This meant (for example) that, when attempting to restore a backup made from a MySQL 5.1.22 cluster to a MySQL Cluster NDB 6.3.3 cluster, the restore process failed with the error `RESTORE PROGRAM OLDER THAN BACKUP VERSION. NOT SUPPORTED. USE NEW RESTORE PROGRAM`. (Bug#31723)
- Following an upgrade, `ndb_mgmd` would fail with an `ArbitrationError`. (Bug#31690)
- The NDB management client command `node_id REPORT MEMORY` provided no output when `node_id` was the node ID of a management or API node. Now, when this occurs, the management client responds with `Node node_id: is not a data node`. (Bug#29485)
- Performing `DELETE` operations after a data node had been shut down could lead to inconsistent data following a restart of the node. (Bug#26450)
- `UPDATE IGNORE` could sometimes fail on NDB tables due to the use of uninitialized data when checking for duplicate keys to be ignored. (Bug#25817)

Changes in MySQL Cluster NDB 6.3.5 (5.1.22-ndb-6.3.5)

Bugs fixed:

- A query against a table with `TEXT` or `BLOB` columns that would return more than a certain amount of data failed with `GOT ERROR 4350 'TRANSACTION ALREADY ABORTED' FROM NDBCLUSTER`. (Bug#31482)

This regression was introduced by Bug#29102.

Changes in MySQL Cluster NDB 6.3.4 (5.1.22-ndb-6.3.4)

Functionality added or changed:

- **Incompatible Change:** The `--ndb_optimized_node_selection` startup option for `mysqld` now allows a wider range of values and corresponding behaviors for SQL nodes when selecting a transaction coordinator.

You should be aware that the default value and behavior as well as the value type used for this option have changed, and that you may need to update the setting used for this option in your `my.cnf` file prior to upgrading `mysqld`. See [Section 5.1.3, “Server System Variables”](#), for more information.
- **Incompatible Change:** The `--ndb_optimized_node_selection` startup option for `mysqld` now allows a wider range of values and corresponding behaviors for SQL nodes when selecting a transaction coordinator.

You should be aware that the default value and behavior as well as the value type used for this option have changed, and that you may need to update the setting used for this option in your `my.cnf` file prior to upgrading `mysqld`. See [Section 5.1.3, “Server System Variables”](#), for more information.

Bugs fixed:

- It was possible in some cases for a node group to be “lost” due to missed local checkpoints following a system restart. ([Bug#31525](#))
- `NDB` tables having names containing non-alphanumeric characters (such as “\$”) were not discovered correctly. ([Bug#31470](#))
- A node failure during a local checkpoint could lead to a subsequent failure of the cluster during a system restart. ([Bug#31257](#))
- A cluster restart could sometimes fail due to an issue with table IDs. ([Bug#30975](#))
- Transaction timeouts were not handled well in some circumstances, leading to excessive number of transactions being aborted unnecessarily. ([Bug#30379](#))
- In some cases, the cluster management server logged entries multiple times following a restart of `mgmd`. ([Bug#29565](#))
- `ndb_mgm --help` did not display any information about the `-a` option. ([Bug#29509](#))
- An interpreted program of sufficient size and complexity could cause all cluster data nodes to shut down due to buffer overruns. ([Bug#29390](#))
- The cluster log was formatted inconsistently and contained extraneous newline characters. ([Bug#25064](#))

Changes in MySQL Cluster NDB 6.3.3 (5.1.22-ndb-6.3.3)

Functionality added or changed:

- Mapping of `NDB` error codes to MySQL storage engine error codes has been improved. ([Bug#28423](#))

Bugs fixed:

- **Partitioning:** `EXPLAIN PARTITIONS` reported partition usage by queries on `NDB` tables according to the standard MySQL hash function than the hash function used in the `NDB` storage engine. ([Bug#29550](#))
- Attempting to restore a backup made on a cluster host using one endian to a machine using the other endian could cause the cluster to fail. ([Bug#29674](#))
- The description of the `--print` option provided in the output from `ndb_restore --help` was incorrect. ([Bug#27683](#))
- Restoring a backup made on a cluster host using one endian to a machine using the other endian failed for `BLOB` and `DATE-TIME` columns. ([Bug#27543](#), [Bug#30024](#))

Changes in MySQL Cluster NDB 6.3.2 (5.1.22-ndb-6.3.2)

Functionality added or changed:

- Online `ADD COLUMN`, `ADD INDEX`, and `DROP INDEX` operations can now be performed explicitly for `NDB` tables, as well as online renaming of tables and columns for `NDB` and `MyISAM` tables — that is, without copying or locking of the affected tables — using `ALTER ONLINE TABLE`.

Indexes can also be created and dropped online using `CREATE INDEX` and `DROP INDEX`, respectively, using the `ONLINE` keyword.

You can force operations that would otherwise be performed online to be done offline using the `OFFLINE` keyword.

See [Section 12.1.7, “ALTER TABLE Syntax”](#), [Section 12.1.13, “CREATE INDEX Syntax”](#), and [Section 12.1.24, “DROP INDEX Syntax”](#), for more information.

- It is now possible to control whether fixed-width or variable-width storage is used for a given column of an `NDB` table by means

of the `COLUMN_FORMAT` specifier as part of the column's definition in a `CREATE TABLE` or `ALTER TABLE` statement.

It is also possible to control whether a given column of an NDB table is stored in memory or on disk, using the `STORAGE` specifier as part of the column's definition in a `CREATE TABLE` or `ALTER TABLE` statement.

For permitted values and other information about `COLUMN_FORMAT` and `STORAGE`, see [Section 12.1.17, “CREATE TABLE Syntax”](#).

- A new cluster management server startup option `--bind-address` makes it possible to restrict management client connections to `ndb_mgmd` to a single host and port. For more information, see [Section 17.6.24.3, “Program Options for ndb_mgmd”](#).

Bugs fixed:

- When an NDB event was left behind but the corresponding table was later recreated and received a new table ID, the event could not be dropped. ([Bug#30877](#))
- An insufficiently descriptive and potentially misleading Error 4006 (`CONNECT FAILURE - OUT OF CONNECTION OBJECTS...`) was produced when either of the following two conditions occurred:
 1. There were no more transaction records in the transaction coordinator
 2. An NDB object in the NDB API was initialized with insufficient parallelism
 Separate error messages are now generated for each of these two cases. ([Bug#11313](#))

Changes in MySQL Cluster NDB 6.3.0 (5.1.19-ndb-6.3.0)

Functionality added or changed:

- Reporting functionality has been significantly enhanced in this release:
 - A new configuration parameter `BackupReportFrequency` now makes it possible to cause the management client to provide status reports at regular intervals as well as for such reports to be written to the cluster log (depending on cluster event logging levels). See [Section 17.3.4.6, “Defining MySQL Cluster Data Nodes”](#), for more information about this parameter.
 - A new `REPORT` command has been added in the cluster management client. `REPORT BackupStatus` allows you to obtain a backup status report at any time during a backup. `REPORT MemoryUsage` reports the current data memory and index memory used by each data node. For more about the `REPORT` command, see [Section 17.7.2, “Commands in the MySQL Cluster Management Client”](#).
 - `ndb_restore` now provides running reports of its progress when restoring a backup. In addition, a complete report status report on the backup is written to the cluster log.
- A new configuration parameter `ODirect` causes NDB to attempt using `O_DIRECT` writes for LCP, backups, and redo logs, often lowering CPU usage.

17.16.3. Unified Changelog — MySQL Cluster NDB 6.2.x

This section contains unified change history highlights for all MySQL Cluster releases based on version 6.2 of the `NDBCLUSTER` storage engine through MySQL Cluster NDB 6.2.18. Included are all changelog entries in the categories *MySQL Cluster*, *Disk Data*, and *Cluster API*.

For an overview of features that were added in MySQL Cluster NDB 6.2, see [Section 17.13.3, “Features Added in MySQL Cluster NDB 6.2”](#).

- [Changes in MySQL Cluster NDB 6.2.0 \(5.1.16-ndb-6.2.0\)](#)

Changes in MySQL Cluster NDB 6.2.18 (5.1.34-ndb-6.2.18)

Bugs fixed:

- **Important Change: Partitioning:** User-defined partitioning of an `NDBCLUSTER` table without any primary key sometimes failed, and could cause `mysqld` to crash.

Now, if you wish to create an `NDBCLUSTER` table with user-defined partitioning, the table must have an explicit primary key, and all columns listed in the partitioning expression must be part of the primary key. The hidden primary key used by the `NDBCLUSTER` storage engine is not sufficient for this purpose. However, if the list of columns is empty (that is, the table is defined using `PARTITION BY [LINEAR] KEY()`), then no explicit primary key is required.

This change does not effect the partitioning of tables using any storage engine other than `NDBCLUSTER`. ([Bug#40709](#))
- An internal NDB API buffer was not properly initialized. ([Bug#44977](#))
- When a data node had written its GCI marker to the first page of a megabyte, and that node was later killed during restart after having processed that page (marker) but before completing a LCP, the data node could fail with filesystem errors. ([Bug#44952](#))

See also [Bug#42564](#).
- Inspection of the code revealed that several assignment operators (`=`) were used in place of comparison operators (`==`) in `Db-dihMain.cpp`. ([Bug#44567](#))

See also [Bug#44570](#).
- It was possible for NDB API applications to insert corrupt data into the database, which could subsequently lead to data node crashes. Now, stricter checking is enforced on input data for inserts and updates. ([Bug#44132](#))
- `TransactionDeadlockDetectionTimeout` values less than 100 were treated as 100. This could cause scans to time out unexpectedly. ([Bug#44099](#))
- The file `ndberror.c` contained a C++-style comment, which caused builds to fail with some C compilers. ([Bug#44036](#))
- A race condition could occur when a data node failed to restart just before being included in the next global checkpoint. This could cause other data nodes to fail. ([Bug#43888](#))
- When trying to use a data node with an older version of the management server, the data node crashed on startup. ([Bug#43699](#))
- Using indexes containing variable-sized columns could lead to internal errors when the indexes were being built. ([Bug#43226](#))
- In some cases, data node restarts during a system restart could fail due to insufficient redo log space. ([Bug#43156](#))
- Some queries using combinations of logical and comparison operators on an indexed column in the `WHERE` clause could fail

with the error `GOT ERROR 4541 'INDEXBOUND HAS NO BOUND INFORMATION' FROM NDBCLUSTER`. (Bug#42857)

- `ndb_restore --print_data` did not handle `DECIMAL` columns correctly. (Bug#37171)
- The output of `ndbd --help` did not provide clear information about the program's `--initial` and `--initial-start` options. (Bug#28905)
- It was theoretically possible for the value of a nonexistent column to be read as `NULL`, rather than causing an error. (Bug#27843)
- When aborting an operation involving both an insert and a delete, the insert and delete were aborted separately. This was because the transaction coordinator did not know that the operations affected on same row, and, in the case of a committed-read (tuple or index) scan, the abort of the insert was performed first, then the row was examined after the insert was aborted but before the delete was aborted. In some cases, this would leave the row in a inconsistent state. This could occur when a local checkpoint was performed during a backup. This issue did not affect primary key operations or scans that used locks (these are serialized).

After this fix, for ordered indexes, all operations that follow the operation to be aborted are now also aborted.

- **Disk Data: Partitioning:** An `NDBCLUSTER` table created with a very large value for the `MAX_ROWS` option could — if this table was dropped and a new table with fewer partitions, but having the same table ID, was created — cause `ndbd` to crash when performing a system restart. This was because the server attempted to examine each partition whether or not it actually existed. (Bug#45154)
- **Disk Data:** During a checkpoint, restore points are created for both the on-disk and in-memory parts of a Disk Data table. Under certain rare conditions, the in-memory restore point could include or exclude a row that should have been in the snapshot. This would later later lead to a crash during or following recovery. (Bug#41915)

- **Disk Data:** When a log file group had an undo log file whose size was too small, restarting data nodes failed with `READ UNDERFLOW` errors.

As a result of this fix, the minimum allowed `INTIAL_SIZE` for an undo log file is now `1M` (1 megabyte). (Bug#29574)

- **Disk Data:** This fix supercedes and improves on an earlier fix made for this bug in MySQL 5.1.18. (Bug#24521)
- **Cluster API:** If the largest offset of a `RecordSpecification` used for an `NdbRecord` object was for the `NULL` bits (and thus not a column), this offset was not taken into account when calculating the size used for the `RecordSpecification`. This meant that the space for the `NULL` bits could be overwritten by key or other information. (Bug#43891)
- **Cluster API:** The default `NdbRecord` structures created by `NdbDictionary` could have overlapping null bits and data fields. (Bug#43590)
- **Cluster API:** When performing insert or write operations, `NdbRecord` allows key columns to be specified in both the key record and in the attribute record. Only one key column value for each key column should be sent to the NDB kernel, but this was not guaranteed. This is now ensured as follows: For insert and write operations, key column values are taken from the key record; for scan takeover update operations, key column values are taken from the attribute record. (Bug#42238)
- **Cluster API:** Ordered index scans using `NdbRecord` formerly expressed a `BoundEQ` range as separate lower and upper bounds, resulting in 2 copies of the column values being sent to the NDB kernel.

Now, when a range is specified by `NdbScanOperation::setBound()`, the passed pointers, key lengths, and inclusive bits are compared, and only one copy of the equal key columns is sent to the kernel. This makes such operations more efficient, as half the amount of `KeyInfo` is now sent for a `BoundEQ` range as before. (Bug#38793)

Changes in MySQL Cluster NDB 6.2.17 (5.1.32-ndb-6.2.17)

Functionality added or changed:

- **Important Change:** Formerly, when the management server failed to create a transporter for a data node connection, `net_write_timeout` seconds elapsed before the data node was actually allowed to disconnect. Now in such cases the disconnection occurs immediately. (Bug#41965)

See also Bug#41713.

- **Disk Data:** It is now possible to specify default locations for Disk Data data files and undo log files, either together or separately, using the data node configuration parameters `FileSystemPathDD`, `FileSystemPathDataFiles`, and `FileSystemPathUndoFiles`. For information about these configuration parameters, see *Disk Data filesystem parameters*.

It is also now possible to specify a log file group, tablespace, or both, that is created when the cluster is started, using the `Ini-`

`tialLogFileGroup` and `InitialTablespace` data node configuration parameters. For information about these configuration parameters, see *Disk Data object creation parameters*.

Bugs fixed:

- **Packaging:** Packages for MySQL Cluster were missing the `libndbclient.so` and `libndbclient.a` files. (Bug#42278)
- **Partitioning:** Executing `ALTER TABLE ... REORGANIZE PARTITION` on an `NDBCLUSTER` table having only one partition caused `mysqld` to crash. (Bug#41945)

See also Bug#40389.

- **Cluster API:** Failed operations on `BLOB` and `TEXT` columns were not always reported correctly to the originating SQL node. Such errors were sometimes reported as being due to timeouts, when the actual problem was a transporter overload due to insufficient buffer space. (Bug#39867, Bug#39879)
- **Cluster API:** Failed operations on `BLOB` and `TEXT` columns were not always reported correctly to the originating SQL node. Such errors were sometimes reported as being due to timeouts, when the actual problem was a transporter overload due to insufficient buffer space. (Bug#39867, Bug#39879)
- Backup IDs greater than 2^{31} were not handled correctly, causing negative values to be used in backup directory names and printouts. (Bug#43042)
- When using `ndbmttd`, NDB kernel threads could hang while trying to start the data nodes with `LockPagesInMainMemory` set to 1. (Bug#43021)
- When using multiple management servers and starting several API nodes (possibly including one or more SQL nodes) whose connectstrings listed the management servers in different order, it was possible for 2 API nodes to be assigned the same node ID. When this happened it was possible for an API node not to get fully connected, consequently producing a number of errors whose cause was not easily recognizable. (Bug#42973)
- `ndb_error_reporter` worked correctly only with GNU `tar`. (With other versions of `tar`, it produced empty archives.) (Bug#42753)
- Triggers on `NDBCLUSTER` tables caused such tables to become locked. (Bug#42751)

See also Bug#16229, Bug#18135.

- When performing more than 32 index or tuple scans on a single fragment, the scans could be left hanging. This caused unnecessary timeouts, and in addition could possibly lead to a hang of an LCP. (Bug#42559)
- A data node failure that occurred between calls to `NdbIndexScanOperation::readTuples(SF_OrderBy)` and `NdbTransaction::Execute()` was not correctly handled; a subsequent call to `nextResult()` caused a null pointer to be dereferenced, leading to a segfault in `mysqld`. (Bug#42545)
- Issuing `SHOW GLOBAL STATUS LIKE 'NDB%'` before `mysqld` had connected to the cluster caused a segmentation fault. (Bug#42458)
- Data node failures that occurred before all data nodes had connected to the cluster were not handled correctly, leading to additional data node failures. (Bug#42422)
- When a cluster backup failed with Error 1304 (Node `node_id1`: Backup request from `node_id2` failed to start), no clear reason for the failure was provided.

As part of this fix, MySQL Cluster now retries backups in the event of sequence errors. (Bug#42354)

See also Bug#22698.

- Issuing `SHOW ENGINE NDBCLUSTER STATUS` on an SQL node before the management server had connected to the cluster caused `mysqld` to crash. (Bug#42264)
- A maximum of 11 `TUP` scans were allowed in parallel. (Bug#42084)
- Trying to execute an `ALTER ONLINE TABLE ... ADD COLUMN` statement while inserting rows into the table caused `mysqld` to crash. (Bug#41905)
- If the master node failed during a global checkpoint, it was possible in some circumstances for the new master to use an incorrect value for the global checkpoint index. This could occur only when the cluster used more than one node group. (Bug#41469)

- API nodes disconnected too aggressively from cluster when data nodes were being restarted. This could sometimes lead to the API node being unable to access the cluster at all during a rolling restart. (Bug#41462)
- An abort path in the `DBLQH` kernel block failed to release a commit acknowledgement marker. This meant that, during node failure handling, the local query handler could be added multiple times to the marker record which could lead to additional node failures due an array overflow. (Bug#41296)
- During node failure handling (of a data node other than the master), there was a chance that the master was waiting for a `GCP_NODEFINISHED` signal from the failed node after having received it from all other data nodes. If this occurred while the failed node had a transaction that was still being committed in the current epoch, the master node could crash in the `DBTC` kernel block when discovering that a transaction actually belonged to an epoch which was already completed. (Bug#41295)
- If a transaction was aborted during the handling of a data node failure, this could lead to the later handling of an API node failure not being completed. (Bug#41214)
- Given a MySQL Cluster containing no data (that is, whose data nodes had all been started using `--initial`, and into which no data had yet been imported) and having an empty backup directory, executing `START BACKUP` with a user-specified backup ID caused the data nodes to crash. (Bug#41031)
- Issuing `EXIT` in the management client sometimes caused the client to hang. (Bug#40922)
- Redo log creation was very slow on some platforms, causing MySQL Cluster to start more slowly than necessary with some combinations of hardware and operating system. This was due to all write operations being synchronized to disk while creating a redo log file. Now this synchronization occurs only after the redo log has been created. (Bug#40734)
- Transaction failures took longer to handle than was necessary.

When a data node acting as transaction coordinator (TC) failed, the surviving data nodes did not inform the API node initiating the transaction of this until the failure had been processed by all protocols. However, the API node needed only to know about failure handling by the transaction protocol — that is, it needed to be informed only about the TC takeover process. Now, API nodes (including MySQL servers acting as cluster SQL nodes) are informed as soon as the TC takeover is complete, so that it can carry on operating more quickly. (Bug#40697)

- It was theoretically possible for stale data to be read from `NDBCLUSTER` tables when the transaction isolation level was set to `ReadCommitted`. (Bug#40543)
 - In some cases, `NDB` did not check correctly whether tables had changed before trying to use the query cache. This could result in a crash of the debug MySQL server. (Bug#40464)
 - Restoring a MySQL Cluster from a dump made using `mysqldump` failed due to a spurious error: `CAN'T EXECUTE THE GIVEN COMMAND BECAUSE YOU HAVE ACTIVE LOCKED TABLES OR AN ACTIVE TRANSACTION`. (Bug#40346)
 - `O_DIRECT` was incorrectly disabled when making MySQL Cluster backups. (Bug#40205)
 - Events logged after setting `ALL CLUSTERLOG STATISTICS=15` in the management client did not always include the node ID of the reporting node. (Bug#39839)
 - Start phase reporting was inconsistent between the management client and the cluster log. (Bug#39667)
 - The MySQL Query Cache did not function correctly with `NDBCLUSTER` tables containing `TEXT` columns. (Bug#39295)
 - A segfault in `Logger::Log` caused `ndbd` to hang indefinitely. This fix improves on an earlier one for this issue, first made in MySQL Cluster NDB 6.2.16 and MySQL Cluster NDB 6.3.17. (Bug#39180)
- See also Bug#38609.
- Memory leaks could occur in handling of strings used for storing cluster metadata and providing output to users. (Bug#38662)
 - In the event that a MySQL Cluster backup failed due to file permissions issues, conflicting reports were issued in the management client. (Bug#34526)
 - A duplicate key error raised when inserting into an `NDBCLUSTER` table caused the current transaction to abort, after which any SQL statement other than a `ROLLBACK` failed. With this fix, the `NDBCLUSTER` storage engine now supports rollback of individual statements in such cases, and it is no longer necessary to issue an explicit `ROLLBACK` and then retry the entire transaction. (Bug#32656)
 - Error messages for `NDBCLUSTER` error codes 1224 and 1227 were missing. (Bug#28496)
 - **Disk Data:** It was not possible to add an in-memory column online to a table that used a table-level or column-level `STORAGE DISK` option. The same issue prevented `ALTER ONLINE TABLE ... REORGANIZE PARTITION` from working on Disk Data tables. (Bug#42549)

- **Disk Data:** Issuing concurrent `CREATE TABLESPACE`, `ALTER TABLESPACE`, `CREATE LOGFILE GROUP`, or `ALTER LOGFILE GROUP` statements on separate SQL nodes caused a resource leak that led to data node crashes when these statements were used again later. (Bug#40921)
- **Disk Data:** Disk-based variable-length columns were not always handled like their memory-based equivalents, which could potentially lead to a crash of cluster data nodes. (Bug#39645)
- **Disk Data:** Creating a Disk Data tablespace with a very large extent size caused the data nodes to fail. The issue was observed when using extent sizes of 100 MB and larger. (Bug#39096)
- **Disk Data:** Creation of a tablespace data file whose size was greater than 4 GB failed silently on 32-bit platforms. (Bug#37116)

See also Bug#29186.

- **Disk Data:** `O_SYNC` was incorrectly disabled on platforms that do not support `O_DIRECT`. This issue was noted on Solaris but could have affected other platforms not having `O_DIRECT` capability. (Bug#34638)
- **Disk Data:** Trying to execute a `CREATE LOGFILE GROUP` statement using a value greater than 150M for `UNDO_BUFFER_SIZE` caused data nodes to crash.

As a result of this fix, the upper limit for `UNDO_BUFFER_SIZE` is now 600M; attempting to set a higher value now fails gracefully with an error. (Bug#34102)

- **Disk Data:** When attempting to create a tablespace that already existed, the error message returned was `TABLE OR INDEX WITH GIVEN NAME ALREADY EXISTS`. (Bug#32662)
- **Disk Data:** Using a path or filename longer than 128 characters for Disk Data undo log files and tablespace data files caused a number of issues, including failures of `CREATE LOGFILE GROUP`, `ALTER LOGFILE GROUP`, `CREATE TABLESPACE`, and `ALTER TABLESPACE` statements, as well as crashes of management nodes and data nodes.

With this fix, the maximum length for path and file names used for Disk Data undo log files and tablespace data files is now the same as the maximum for the operating system. (Bug#31769, Bug#31770, Bug#31772)

- **Disk Data:** Starting a cluster under load such that Disk Data tables used most of the undo buffer could cause data node failures.

The fix for this bug also corrected an issue in the `LGMAN` kernel block where the amount of free space left in the undo buffer was miscalculated, causing buffer overruns. This could cause records in the buffer to be overwritten, leading to problems when restarting data nodes. (Bug#28077)

- **Disk Data:** Attempting to perform a system restart of the cluster where there existed a logfile group without and undo log files caused the data nodes to crash.

Note

While issuing a `CREATE LOGFILE GROUP` statement without an `ADD UNDOFILE` option fails with an error in the MySQL server, this situation could arise if an SQL node failed during the execution of a valid `CREATE LOGFILE GROUP` statement; it is also possible to create a logfile group without any undo log files using the NDB API.

(Bug#17614)

- **Cluster API:** Some error messages from `ndb_mgmd` contained newline (`\n`) characters. This could break the MGM API protocol, which uses the newline as a line separator. (Bug#43104)
- **Cluster API:** When using an ordered index scan without putting all key columns in the read mask, this invalid use of the NDB API went undetected, which resulted in the use of uninitialized memory. (Bug#42591)
- **Cluster API:** The MGM API reset error codes on management server handles before checking them. This meant that calling an MGM API function with a null handle caused applications to crash. (Bug#40455)
- **Cluster API:** It was not always possible to access parent objects directly from `NdbBlob`, `NdbOperation`, and `NdbScanOperation` objects. To alleviate this problem, a new `getNdbOperation()` method has been added to `NdbBlob` and new `getNdbTransaction()` methods have been added to `NdbOperation` and `NdbScanOperation`. In addition, a const variant of `NdbOperation::getErrorLine()` is now also available. (Bug#40242)
- **Cluster API:** `NdbScanOperation::getBlobHandle()` failed when used with incorrect column names or numbers. (Bug#40241)
- **Cluster API:** The NDB API example programs included in MySQL Cluster source distributions failed to compile. (Bug#37491)

See also Bug#40238.

- **Cluster API:** `mgmapi.h` contained constructs which only worked in C++, but not in C. (Bug#27004)

Changes in MySQL Cluster NDB 6.2.16 (5.1.28-ndb-6.2.16)

Functionality added or changed:

- It is no longer a requirement for database autodiscovery that an SQL node already be connected to the cluster at the time that a database is created on another SQL node. It is no longer necessary to issue `CREATE DATABASE` (or `CREATE SCHEMA`) statements on an SQL node joining the cluster after a database is created in order for the new SQL node to see the database and any `NDBCLUSTER` tables that it contains. (Bug#39612)

Bugs fixed:

- Heavy DDL usage caused the `mysqld` processes to hang due to a timeout error (NDB error code 266). (Bug#39885)
- Executing `EXPLAIN SELECT` on an `NDBCLUSTER` table could cause `mysqld` to crash. (Bug#39872)
- Starting the MySQL Server with the `--ndbcluster` option plus an invalid command-line option (for example, using `mysqld --ndbcluster --foobar`) caused it to hang while shutting down the binlog thread. (Bug#39635)
- Dropping and then re-creating a database on one SQL node caused other SQL nodes to hang. (Bug#39613)
- Setting a low value of `MaxNoOfLocalScans` (< 100) and performing a large number of (certain) scans could cause the Transaction Coordinator to run out of scan fragment records, and then crash. Now when this resource is exhausted, the cluster returns Error 291 (`OUT OF SCANFRAG RECORDS IN TC (INCREASE MAXNOOFLOCALSCANS)`) instead. (Bug#39549)
- Creating a unique index on an `NDBCLUSTER` table caused a memory leak in the NDB subscription manager (`SUMA`) which could lead to `mysqld` hanging, due to the fact that the resource shortage was not reported back to the NDB kernel correctly. (Bug#39518)

See also Bug#39450.

- Unique identifiers in tables having no primary key were not cached. This fix has been observed to increase the efficiency of `INSERT` operations on such tables by as much as 50%. (Bug#39267)
- `MgmtSrvr::allocNodeId()` left a mutex locked following an `AMBIGUITY FOR NODE IF %D` error. (Bug#39158)
- An invalid path specification caused `mysql-test-run.pl` to fail. (Bug#39026)
- During transactional coordinator takeover (directly after node failure), the LQH finding an operation in the `LOG_COMMIT` state sent an `LQH_TRANS_CONF` signal twice, causing the TC to fail. (Bug#38930)
- An invalid memory access caused the management server to crash on Solaris Sparc platforms. (Bug#38628)
- A segfault in `Logger::Log` caused `ndbd` to hang indefinitely. (Bug#38609)
- `ndb_mgmd` failed to start on older Linux distributions (2.4 kernels) that did not support e-polling. (Bug#38592)
- When restarting a data node, an excessively long shutdown message could cause the node process to crash. (Bug#38580)
- `ndb_mgmd` sometimes performed unnecessary network I/O with the client. This in combination with other factors led to long-running threads that were attempting to write to clients that no longer existed. (Bug#38563)
- `ndb_restore` failed with a floating point exception due to a division by zero error when trying to restore certain data files. (Bug#38520)
- A failed connection to the management server could cause a resource leak in `ndb_mgmd`. (Bug#38424)
- Failure to parse configuration parameters could cause a memory leak in the NDB log parser. (Bug#38380)
- After a forced shutdown and initial restart of the cluster, it was possible for SQL nodes to retain `.FRM` files corresponding to `NDBCLUSTER` tables that had been dropped, and thus to be unaware that these tables no longer existed. In such cases, attempting to re-create the tables using `CREATE TABLE IF NOT EXISTS` could fail with a spurious `TABLE ... DOESN'T EXIST` error. (Bug#37921)
- Renaming an `NDBCLUSTER` table on one SQL node, caused a trigger on this table to be deleted on another SQL node. (Bug#36658)

- Attempting to add a `UNIQUE INDEX` twice to an `NDBCLUSTER` table, then deleting rows from the table could cause the MySQL Server to crash. ([Bug#35599](#))
- `ndb_restore` failed when a single table was specified. ([Bug#33801](#))
- `GCP_COMMIT` did not wait for transaction takeover during node failure. This could cause `GCP_SAVE_REQ` to be executed too early. This could also cause (very rarely) replication to skip rows. ([Bug#30780](#))
- **Cluster API:** Passing a value greater than 65535 to `NdbInterpretedCode::add_val()` and `NdbInterpretedCode::sub_val()` caused these methods to have no effect. ([Bug#39536](#))
- **Cluster API:** The `NdbScanOperation::readTuples()` method could be called multiple times without error. ([Bug#38717](#))
- **Cluster API:** Certain Multi-Range Read scans involving `IS NULL` and `IS NOT NULL` comparisons failed with an error in the `NDB` local query handler. ([Bug#38204](#))
- **Cluster API:** Problems with the public headers prevented `NDB` applications from being built with warnings turned on. ([Bug#38177](#))
- **Cluster API:** Creating an `NdbScanFilter` object using an `NdbScanOperation` object that had not yet had its `readTuples()` method called resulted in a crash when later attempting to use the `NdbScanFilter`. ([Bug#37986](#))
- **Cluster API:** Executing an `NdbRecord` interpreted delete created with an `ANYVALUE` option caused the transaction to abort. ([Bug#37672](#))
- **Cluster API:** Accessing the debug version of `libndbclient` via `dlopen()` resulted in a segmentation fault. ([Bug#35927](#))

Changes in MySQL Cluster NDB 6.2.14 (5.1.23-ndb-6.2.14)

Functionality added or changed:

- Added the `MaxBufferedEpochs` data node configuration parameter, which controls the maximum number of unprocessed epochs by which a subscribing node can lag. Subscribers which exceed this number are disconnected and forced to reconnect. See [Section 17.3.4.6, “Defining MySQL Cluster Data Nodes”](#), for more information.

Bugs fixed:

- **Incompatible Change:** The `UPDATE` statement allowed `NULL` to be assigned to `NOT NULL` columns (the implicit default value for the column data type was assigned). This was changed so that an error occurs.

This change was reverted, because the original report was determined not to be a bug: Assigning `NULL` to a `NOT NULL` column in an `UPDATE` statement should produce an error only in strict SQL mode and set the column to the implicit default with a warning otherwise, which was the original behavior. See [Section 10.1.4, “Data Type Default Values”](#), and [Bug#39265](#). ([Bug#33699](#))
- **Cluster API:** Closing a scan before it was executed caused the application to segfault. ([Bug#36375](#))
- **Cluster API:** Using `NDB` API applications from older MySQL Cluster versions with `libndbclient` from newer ones caused the cluster to fail. ([Bug#36124](#))
- **Cluster API:** Scans having no bounds set were handled incorrectly. ([Bug#35876](#))

Changes in MySQL Cluster NDB 6.2.13 (5.1.23-ndb-6.2.13)

Bugs fixed:

- A node failure during an initial node restart followed by another node start could cause the master data node to fail, because it incorrectly gave the node permission to start even if the invalidated node's LCP was still running. ([Bug#34702](#))

Changes in MySQL Cluster NDB 6.2.12 (5.1.23-ndb-6.2.12)

Bugs fixed:

- Upgrades of a cluster using while a `DataMemory` setting in excess of 16 GB caused data nodes to fail. ([Bug#34378](#))
- Performing many SQL statements on NDB tables while in `autocommit` mode caused a memory leak in `mysqld`. ([Bug#34275](#))
- In certain rare circumstances, a race condition could occur between an aborted insert and a delete leading a data node crash. ([Bug#34260](#))
- Multi-table updates using ordered indexes during handling of node failures could cause other data nodes to fail. ([Bug#34216](#))
- When configured with NDB support, MySQL failed to compile using `gcc` 4.3 on 64bit FreeBSD systems. ([Bug#34169](#))
- The failure of a DDL statement could sometimes lead to node failures when attempting to execute subsequent DDL statements. ([Bug#34160](#))
- Extremely long `SELECT` statements (where the text of the statement was in excess of 50000 characters) against NDB tables returned empty results. ([Bug#34107](#))
- Statements executing multiple inserts performed poorly on NDB tables having `AUTO_INCREMENT` columns. ([Bug#33534](#))
- The `ndb_waiter` utility polled `ndb_mgmd` excessively when obtaining the status of cluster data nodes. ([Bug#32025](#))
See also [Bug#32023](#).
- Transaction atomicity was sometimes not preserved between reads and inserts under high loads. ([Bug#31477](#))
- Having tables with a great many columns could cause Cluster backups to fail. ([Bug#30172](#))
- **Cluster Replication: Disk Data:** Statements violating unique keys on Disk Data tables (such as attempting to insert `NULL` into a `NOT NULL` column) could cause data nodes to fail. When the statement was executed from the binlog, this could also result in failure of the slave cluster. ([Bug#34118](#))
- **Disk Data:** Updating in-memory columns of one or more rows of Disk Data table, followed by deletion of these rows and re-insertion of them, caused data node failures. ([Bug#33619](#))

Changes in MySQL Cluster NDB 6.2.11 (5.1.23-ndb-6.2.11)

Functionality added or changed:

- **Cluster API: Important Change:** Because `NDB_LE_MemoryUsage.page_size_kb` shows memory page sizes in bytes rather than kilobytes, it has been renamed to `page_size_bytes`. The name `page_size_kb` is now deprecated and thus subject to removal in a future release, although it currently remains supported for reasons of backward compatibility. See [The `Ndb_logevent_type` Type](#), for more information about `NDB_LE_MemoryUsage`. ([Bug#30271](#))

Bugs fixed:

- High numbers of insert operations, delete operations, or both could cause NDB error 899 (`ROWID ALREADY ALLOCATED`) to occur unnecessarily. ([Bug#34033](#))
- A periodic failure to flush the send buffer by the NDB TCP transporter could cause a unnecessary delay of 10 ms between operations. ([Bug#34005](#))
- A race condition could occur (very rarely) when the release of a GCI was followed by a data node failure. ([Bug#33793](#))
- Some tuple scans caused the wrong memory page to be accessed, leading to invalid results. This issue could affect both in-memory and Disk Data tables. ([Bug#33739](#))
- The server failed to reject properly the creation of an NDB table having an unindexed `AUTO_INCREMENT` column. ([Bug#30417](#))
- Issuing an `INSERT ... ON DUPLICATE KEY UPDATE` concurrently with or following a `TRUNCATE` statement on an NDB table failed with NDB error 4350 `TRANSACTION ALREADY ABORTED`. ([Bug#29851](#))
- The Cluster backup process could not detect when there was no more disk space and instead continued to run until killed manually. Now the backup fails with an appropriate error when disk space is exhausted. ([Bug#28647](#))
- It was possible in `config.ini` to define cluster nodes having node IDs greater than the maximum allowed value. ([Bug#28298](#))

- **Cluster API:** Transactions containing inserts or reads would hang during `NdbTransaction::execute()` calls made from NDB API applications built against a MySQL Cluster version that did not support micro-GCPs accessing a later version that supported micro-GCPs. This issue was observed while upgrading from MySQL Cluster NDB 6.1.23 to MySQL Cluster NDB 6.2.10 when the API application built against the earlier version attempted to access a data node already running the later version, even after disabling micro-GCPs by setting `TimeBetweenEpochs` equal to 0. (Bug#33895)
- **Cluster API:** When reading a `BIT(64)` value using `NdbOperation::getValue()`, 12 bytes were written to the buffer rather than the expected 8 bytes. (Bug#33750)

Changes in MySQL Cluster NDB 6.2.10 (5.1.23-ndb-6.2.10)

Bugs fixed:

- **Partitioning:** When partition pruning on an NDB table resulted in an ordered index scan spanning only one partition, any descending flag for the scan was wrongly discarded, causing `ORDER BY DESC` to be treated as `ORDER BY ASC, MAX()` to be handled incorrectly, and similar problems. (Bug#33061)
- When all data and SQL nodes in the cluster were shut down abnormally (that is, other than by using `STOP` in the cluster management client), `ndb_mgm` used excessive amounts of CPU. (Bug#33237)
- When using micro-GCPs, if a node failed while preparing for a global checkpoint, the master node would use the wrong GCI. (Bug#32922)
- Under some conditions, performing an `ALTER TABLE` on an NDBCLUSTER table failed with a `TABLE IS FULL` error, even when only 25% of `DataMemory` was in use and the result should have been a table using less memory (for example, changing a `VARCHAR(100)` column to `VARCHAR(80)`). (Bug#32670)

Changes in MySQL Cluster NDB 6.2.9 (5.1.22-ndb-6.2.9)

Functionality added or changed:

- Added the `ndb_mgm` client command `DUMP 8011`, which dumps all subscribers to the cluster log. See `DUMP 8011`, for more information.

Bugs fixed:

- A local checkpoint could sometimes be started before the previous LCP was restorable from a global checkpoint. (Bug#32519)
- High numbers of API nodes on a slow or congested network could cause connection negotiation to time out prematurely, leading to the following issues:
 - Excessive retries
 - Excessive CPU usage
 - Partially connected API nodes (Bug#32359)
- The failure of a master node could lead to subsequent failures in local checkpointing. (Bug#32160)
- Adding a new `TINYTEXT` column to an NDB table which used `COLUMN_FORMAT = DYNAMIC`, and when binary logging was enabled, caused all cluster `mysqld` processes to crash. (Bug#30213)
- After adding a new column of one of the `TEXT` or `BLOB` types to an NDB table which used `COLUMN_FORMAT = DYNAMIC`, it was no longer possible to access or drop the table using SQL. (Bug#30205)
- A restart of the cluster failed when more than 1 REDO phase was in use. (Bug#22696)

Changes in MySQL Cluster NDB 6.2.8 (5.1.22-ndb-6.2.8)

Bugs fixed:

- In a cluster running in diskless mode and with arbitration disabled, the failure of a data node during an insert operation caused other data node to fail. (Bug#31980)

- An insert or update with combined range and equality constraints failed when run against an NDB table with the error `GOT UNKNOWN ERROR FROM NDB`. An example of such a statement would be `UPDATE t1 SET b = 5 WHERE a IN (7,8) OR a >= 10;`. (Bug#31874)
- An error with an `if` statement in `sql/ha_ndbcluster.cc` could potentially lead to an infinite loop in case of failure when working with `AUTO_INCREMENT` columns in NDB tables. (Bug#31810)
- The NDB storage engine code was not safe for strict-alias optimization in `gcc` 4.2.1. (Bug#31761)
- Following an upgrade, `ndb_mgmd` would fail with an `ArbitrationError`. (Bug#31690)
- The NDB management client command `node_id REPORT MEMORY` provided no output when `node_id` was the node ID of a management or API node. Now, when this occurs, the management client responds with `Node node_id: is not a data node`. (Bug#29485)
- Performing `DELETE` operations after a data node had been shut down could lead to inconsistent data following a restart of the node. (Bug#26450)
- `UPDATE IGNORE` could sometimes fail on NDB tables due to the use of uninitialized data when checking for duplicate keys to be ignored. (Bug#25817)

Changes in MySQL Cluster NDB 6.2.7 (5.1.22-ndb-6.2.7)

Bugs fixed:

- It was possible in some cases for a node group to be “lost” due to missed local checkpoints following a system restart. (Bug#31525)
- NDB tables having names containing non-alphanumeric characters (such as “\$”) were not discovered correctly. (Bug#31470)
- A node failure during a local checkpoint could lead to a subsequent failure of the cluster during a system restart. (Bug#31257)
- A cluster restart could sometimes fail due to an issue with table IDs. (Bug#30975)
- Transaction timeouts were not handled well in some circumstances, leading to excessive number of transactions being aborted unnecessarily. (Bug#30379)
- In some cases, the cluster management server logged entries multiple times following a restart of `mgmd`. (Bug#29565)
- `ndb_mgm --help` did not display any information about the `-a` option. (Bug#29509)
- The cluster log was formatted inconsistently and contained extraneous newline characters. (Bug#25064)

Changes in MySQL Cluster NDB 6.2.6 (5.1.22-ndb-6.2.6)

Functionality added or changed:

- Mapping of NDB error codes to MySQL storage engine error codes has been improved. (Bug#28423)

Bugs fixed:

- **Partitioning:** `EXPLAIN PARTITIONS` reported partition usage by queries on NDB tables according to the standard MySQL hash function than the hash function used in the NDB storage engine. (Bug#29550)
- When an NDB event was left behind but the corresponding table was later recreated and received a new table ID, the event could not be dropped. (Bug#30877)
- Attempting to restore a backup made on a cluster host using one endian to a machine using the other endian could cause the cluster to fail. (Bug#29674)
- The description of the `--print` option provided in the output from `ndb_restore --help` was incorrect. (Bug#27683)
- Restoring a backup made on a cluster host using one endian to a machine using the other endian failed for `BLOB` and `DATE-TIME` columns. (Bug#27543, Bug#30024)
- An insufficiently descriptive and potentially misleading Error 4006 (`CONNECT FAILURE - OUT OF CONNECTION OBJECTS...`)

was produced when either of the following two conditions occurred:

1. There were no more transaction records in the transaction coordinator
2. An `NDB` object in the NDB API was initialized with insufficient parallelism
Separate error messages are now generated for each of these two cases. (Bug#11313)

Changes in MySQL Cluster NDB 6.2.5 (5.1.22-ndb-6.2.5)

Functionality added or changed:

- The following improvements have been made in the `ndb_size.pl` utility:
 - The script can now be used with multiple databases; lists of databases and tables can also be excluded from analysis.
 - Schema name information has been added to index table calculations.
 - The database name is now an optional parameter, the exclusion of which causes all databases to be examined.
 - If selecting from `INFORMATION_SCHEMA` fails, the script now attempts to fall back to `SHOW TABLES`.
 - A `--real_table_name` option has been added; this designates a table to handle unique index size calculations.
 - The report title has been amended to cover cases where more than one database is being analyzed.

Support for a `--socket` option was also added.

For more information, see [Section 17.6.21, “ndb_size.pl — NDBCLUSTER Size Requirement Estimator”](#). (Bug#28683, Bug#28253)

- Online `ADD COLUMN`, `ADD INDEX`, and `DROP INDEX` operations can now be performed explicitly for `NDB` tables, as well as online renaming of tables and columns for `NDB` and `MyISAM` tables — that is, without copying or locking of the affected tables — using `ALTER ONLINE TABLE`.

Indexes can also be created and dropped online using `CREATE INDEX` and `DROP INDEX`, respectively, using the `ONLINE` keyword.

You can force operations that would otherwise be performed online to be done offline using the `OFFLINE` keyword.

See [Section 12.1.7, “ALTER TABLE Syntax”](#), [Section 12.1.13, “CREATE INDEX Syntax”](#), and [Section 12.1.24, “DROP INDEX Syntax”](#), for more information.

- It is now possible to control whether fixed-width or variable-width storage is used for a given column of an `NDB` table by means of the `COLUMN_FORMAT` specifier as part of the column's definition in a `CREATE TABLE` or `ALTER TABLE` statement.

It is also possible to control whether a given column of an `NDB` table is stored in memory or on disk, using the `STORAGE` specifier as part of the column's definition in a `CREATE TABLE` or `ALTER TABLE` statement.

For permitted values and other information about `COLUMN_FORMAT` and `STORAGE`, see [Section 12.1.17, “CREATE TABLE Syntax”](#).

- A new cluster management server startup option `--bind-address` makes it possible to restrict management client connections to `ndb_mgmd` to a single host and port. For more information, see [Section 17.6.24.3, “Program Options for ndb_mgmd”](#).

Bugs fixed:

- When handling `BLOB` columns, the addition of read locks to the lock queue was not handled correctly. (Bug#30764)
- Discovery of `NDB` tables did not work correctly with `INFORMATION_SCHEMA`. (Bug#30667)
- A file system close operation could fail during a node or system restart. (Bug#30646)
- Using the `--ndb-cluster-connection-pool` option for `mysqld` caused DDL statements to be executed twice. (Bug#30598)
- `ndb_size.pl` failed on tables with `FLOAT` columns whose definitions included commas (for example, `FLOAT(6,2)`). (Bug#29228)

- Reads on `BLOB` columns were not locked when they needed to be to guarantee consistency. (Bug#29102)
See also Bug#31482.
- A query using joins between several large tables and requiring unique index lookups failed to complete, eventually returning `UNKNOWN ERROR` after a very long period of time. This occurred due to inadequate handling of instances where the Transaction Coordinator ran out of `TransactionBufferMemory`, when the cluster should have returned NDB error code 4012 (`REQUEST NDBD TIME-OUT`). (Bug#28804)
- An attempt to perform a `SELECT . . . FROM INFORMATION_SCHEMA.TABLES` whose result included information about NDB tables for which the user had no privileges crashed the MySQL Server on which the query was performed. (Bug#26793)
- **Cluster API:** A call to `CHECK_TIMEDOUT_RET()` in `mgmapi.cpp` should have been a call to `DEBUG_CHECK_TIMEDOUT_RET()`. (Bug#30681)

Changes in MySQL Cluster NDB 6.2.4 (5.1.19-ndb-6.2.4)

Bugs fixed:

- When restarting a data node, queries could hang during that node's start phase 5, and continue only after the node had entered phase 6. (Bug#29364)
- Replica redo logs were inconsistently handled during a system restart. (Bug#29354)
- **Disk Data:** Performing Disk Data schema operations during a node restart could cause forced shutdowns of other data nodes. (Bug#29501)
- **Disk Data:** Disk data meta-information that existed in `ndbd` might not be visible to `mysqld`. (Bug#28720)
- **Disk Data:** The number of free extents was incorrectly reported for some tablespaces. (Bug#28642)

Changes in MySQL Cluster NDB 6.2.3 (5.1.19-ndb-6.2.3)

Functionality added or changed:

- **Important Change:** The `TimeBetweenWatchdogCheckInitial` configuration parameter was added to allow setting of a separate watchdog timeout for memory allocation during startup of the data nodes. See Section 17.3.4.6, “Defining MySQL Cluster Data Nodes”, for more information. (Bug#28899)
- **Cluster API: Important Change:** A new `NdbRecord` object has been added to the NDB API. This object provides mapping to a record stored in NDB. See [The NdbRecord Interface](#), for more information.
- `auto_increment_increment` and `auto_increment_offset` are now supported for NDB tables. (Bug#26342)
- A `REPORT BackupStatus` command has been added in the cluster management client. This command allows you to obtain a backup status report at any time during a backup. For more about this command, see Section 17.7.2, “Commands in the MySQL Cluster Management Client”.
- Reporting functionality has been significantly enhanced in this release:
 - A new configuration parameter `BackupReportFrequency` now makes it possible to cause the management client to provide status reports at regular intervals as well as for such reports to be written to the cluster log (depending on cluster event logging levels). See Section 17.3.4.6, “Defining MySQL Cluster Data Nodes”, for more information about this parameter.
 - A new `REPORT` command has been added in the cluster management client. `REPORT BackupStatus` allows you to obtain a backup status report at any time during a backup. `REPORT MemoryUsage` reports the current data memory and index memory used by each data node. For more about the `REPORT` command, see Section 17.7.2, “Commands in the MySQL Cluster Management Client”.
 - `ndb_restore` now provides running reports of its progress when restoring a backup. In addition, a complete report status report on the backup is written to the cluster log.
- A new configuration parameter `ODirect` causes NDB to attempt using `O_DIRECT` writes for LCP, backups, and redo logs, often lowering CPU usage.
- `ndb_restore` now provides running reports of its progress when restoring a backup. In addition, a complete report status re-

port on the backup is written to the cluster log.

- A new configuration parameter `BackupReportFrequency` now makes it possible to cause the management client to provide status reports at regular intervals as well as for such reports to be written to the cluster log (depending on cluster event logging levels). See [Section 17.3.4.6, “Defining MySQL Cluster Data Nodes”](#), for more information about this parameter.
- A new memory allocator has been implemented for the NDB kernel, which allocates memory to tables 32K page by 32K page rather than allocating it in variable-sized chunks as previously. This removes much of the memory overhead that was associated with the old memory allocator.

Bugs fixed:

- When a node failed to respond to a `COPY_GCI` signal as part of a global checkpoint, the master node was killed instead of the node that actually failed. ([Bug#29331](#))
- Memory corruption could occur due to a problem in the `DBTUP` kernel block. ([Bug#29229](#))
- A query having a large `IN(...)` or `NOT IN(...)` list in the `WHERE` condition on an NDB table could cause `mysqld` to crash. ([Bug#29185](#))
- In the event that two data nodes in the same node group and participating in a GCP crashed before they had written their respective `P0.sysfile` files, `QMGR` could refuse to start, issuing an invalid `INSUFFICIENT NODES FOR RESTART` error instead. ([Bug#29167](#))
- An invalid comparison made during `REDO` validation that could lead to an `ERROR WHILE READING REDO LOG` condition. ([Bug#29118](#))
- Attempting to restore a `NULL` row to a `VARBINARY` column caused `ndb_restore` to fail. ([Bug#29103](#))
- `ndb_error_reporter` now preserves timestamps on files. ([Bug#29074](#))
- The wrong data pages were sometimes invalidated following a global checkpoint. ([Bug#29067](#))
- If at least 2 files were involved in `REDO` invalidation, then file 0 of page 0 was not updated and so pointed to an invalid part of the redo log. ([Bug#29057](#))
- It is now possible to set the maximum size of the allocation unit for table memory using the `MaxAllocate` configuration parameter. ([Bug#29044](#))
- When shutting down `mysqld`, the NDB binlog process was not shut down before log cleanup began. ([Bug#28949](#))
- A corrupt schema file could cause a `FILE ALREADY OPEN` error. ([Bug#28770](#))
- Having large amounts of memory locked caused swapping to disk. ([Bug#28751](#))
- Setting `InitialNoOpenFiles` equal to `MaxNoOfOpenFiles` caused an error. This was due to the fact that the actual value of `MaxNoOfOpenFiles` as used by the cluster was offset by 1 from the value set in `config.ini`. ([Bug#28749](#))
- LCP files were not removed following an initial system restart. ([Bug#28726](#))
- `UPDATE IGNORE` statements involving the primary keys of multiple tables could result in data corruption. ([Bug#28719](#))
- A race condition could result when non-master nodes (in addition to the master node) tried to update active status due to a local checkpoint (that is, between `NODE_FAILREP` and `COPY_GCIREQ` events). Now only the master updates the active status. ([Bug#28717](#))
- A fast global checkpoint under high load with high usage of the redo buffer caused data nodes to fail. ([Bug#28653](#))
- The management client's response to `START BACKUP WAIT COMPLETED` did not include the backup ID. ([Bug#27640](#))
- **Disk Data:** When dropping a page, the stack's bottom entry could sometime be left “cold” rather than “hot”, violating the rules for stack pruning. ([Bug#29176](#))
- **Disk Data:** When loading data into a cluster following a version upgrade, the data nodes could forcibly shut down due to page and buffer management failures (that is, `ndbrequire` failures in `PGMAN`). ([Bug#28525](#))
- **Disk Data:** Repeated `INSERT` and `DELETE` operations on a Disk Data table having one or more large `VARCHAR` columns could cause data nodes to fail. ([Bug#20612](#))
- **Cluster API:** The timeout set using the MGM API `ndb_mgm_set_timeout()` function was incorrectly interpreted as

seconds rather than as milliseconds. ([Bug#29063](#))

- **Cluster API:** An invalid error code could be set on transaction objects by `BLOB` handling code. ([Bug#28724](#))

Changes in MySQL Cluster NDB 6.2.2 (5.1.18-ndb-6.2.2)

Functionality added or changed:

- New cluster management client `DUMP` commands were added to aid in tracking transactions, scan operations, and locks. See `DUMP 2350`, `DUMP 2352`, and `DUMP 2550`, for more information.
- Added the `mysqld` option `--ndb-cluster-connection-pool` that allows a single MySQL server to use multiple connections to the cluster. This allows for scaling out using multiple MySQL clients per SQL node instead of or in addition to using multiple SQL nodes with the cluster.

For more information about this option, see [Section 17.4, “MySQL Cluster Options and Variables”](#).

Changes in MySQL Cluster NDB 6.2.1 (5.1.18-ndb-6.2.1)

Bugs fixed:

- Multiple operations involving deletes followed by reads were not handled correctly.

Note

This issue could also affect MySQL Cluster Replication.

([Bug#28276](#))

- **Cluster API:** Using `NdbBlob::writeData()` to write data in the middle of an existing blob value (that is, updating the value) could overwrite some data past the end of the data to be changed. ([Bug#27018](#))

Changes in MySQL Cluster NDB 6.2.0 (5.1.16-ndb-6.2.0)

Functionality added or changed:

- An `ndb_wait_connected` system variable has been added for `mysqld`. It causes `mysqld` wait a specified amount of time to be connected to the cluster before accepting client connections. For more information, see [Section 17.4.3, “MySQL Cluster System Variables”](#).
- **Cluster API:** The `Ndb::startTransaction()` method now provides an alternative interface for starting a transaction. See `Ndb::startTransaction()`, for more information.
- **Cluster API:** Methods were added to the `Ndb_cluster_connection` class to facilitate iterating over existing `NDB` objects. See `ndb_cluster_connection::get_next_ndb_object()`, for more information.

17.16.4. Unified Changelog — MySQL Cluster NDB 6.1.x

This section contains unified change history highlights for all MySQL Cluster releases based on version 6.1 of the `NDBCLUSTER` storage engine through MySQL Cluster NDB 5.1.15-ndb-6.1.23. Included are all changelog entries in the categories *MySQL Cluster*, *Disk Data*, and *Cluster API*.

For an overview of features that were added in MySQL Cluster NDB 6.1, see [Section 17.13.2, “Features Added in MySQL Cluster NDB 6.1”](#).

Note

MySQL Cluster NDB 6.1 is no longer being developed or maintained, and the information presented in this section should be considered to be of historical interest only. If you are using MySQL Cluster NDB 6.1, you should upgrade as soon as possible to the most recent version of MySQL Cluster NDB 6.2 or later MySQL Cluster release series.

Changes in MySQL Cluster NDB 6.1.23 (5.1.15-ndb-6.1.23)

Bugs fixed:

- The NDB storage engine code was not safe for strict-alias optimization in gcc 4.2.1. ([Bug#31761](#))

Changes in MySQL Cluster NDB 6.1.22 (5.1.15-ndb-6.1.22)

Bugs fixed:

- It was possible in some cases for a node group to be “lost” due to missed local checkpoints following a system restart. ([Bug#31525](#))

Changes in MySQL Cluster NDB 6.1.21 (5.1.15-ndb-6.1.21)

Bugs fixed:

- A node failure during a local checkpoint could lead to a subsequent failure of the cluster during a system restart. ([Bug#31257](#))
- A cluster restart could sometimes fail due to an issue with table IDs. ([Bug#30975](#))

Changes in MySQL Cluster NDB 6.1.19 (5.1.15-ndb-6.1.19)

Functionality added or changed:

- Whenever a TCP send buffer is over 80% full, temporary error 1218 (`SEND BUFFERS OVERLOADED IN NDB KERNEL`) is now returned. See [SendBufferMemory](#) for more information.

Changes in MySQL Cluster NDB 6.1.18 (5.1.15-ndb-6.1.18)

Bugs fixed:

- When restarting a data node, queries could hang during that node's start phase 5, and continue only after the node had entered phase 6. ([Bug#29364](#))
- **Disk Data:** Disk data meta-information that existed in `ndbd` might not be visible to `mysqld`. ([Bug#28720](#))
- **Disk Data:** The number of free extents was incorrectly reported for some tablespaces. ([Bug#28642](#))

Changes in MySQL Cluster NDB 6.1.17 (5.1.15-ndb-6.1.17)

Bugs fixed:

- Replica redo logs were inconsistently handled during a system restart. ([Bug#29354](#))

Changes in MySQL Cluster NDB 6.1.16 (5.1.15-ndb-6.1.16)

Bugs fixed:

- When a node failed to respond to a `COPY_GCI` signal as part of a global checkpoint, the master node was killed instead of the node that actually failed. ([Bug#29331](#))
- An invalid comparison made during `REDO` validation that could lead to an `ERROR WHILE READING REDO LOG` condition. ([Bug#29118](#))
- The wrong data pages were sometimes invalidated following a global checkpoint. ([Bug#29067](#))
- If at least 2 files were involved in `REDO` invalidation, then file 0 of page 0 was not updated and so pointed to an invalid part of the redo log. ([Bug#29057](#))
- **Disk Data:** When dropping a page, the stack's bottom entry could sometime be left “cold” rather than “hot”, violating the rules for stack pruning. ([Bug#29176](#))

Changes in MySQL Cluster NDB 6.1.15 (5.1.15-ndb-6.1.15)

Bugs fixed:

- Memory corruption could occur due to a problem in the `DBTUP` kernel block. ([Bug#29229](#))

Changes in MySQL Cluster NDB 6.1.14 (5.1.15-ndb-6.1.14)

Bugs fixed:

- In the event that two data nodes in the same node group and participating in a GCP crashed before they had written their respective `P0.sysfile` files, `QMGR` could refuse to start, issuing an invalid `INSUFFICIENT NODES FOR RESTART` error instead. ([Bug#29167](#))

Changes in MySQL Cluster NDB 6.1.13 (5.1.15-ndb-6.1.13)

Bugs fixed:

- **Cluster API:** `NdbApi.hpp` depended on `ndb_global.h`, which was not actually installed, causing the compilation of pro-

grams that used `NdbApi.hpp` to fail. (Bug#35853)

Changes in MySQL Cluster NDB 6.1.12 (5.1.15-ndb-6.1.12)

Functionality added or changed:

- New cluster management client `DUMP` commands were added to aid in tracking transactions, scan operations, and locks. See `DUMP 2350`, `DUMP 2352`, and `DUMP 2550`.

Bugs fixed:

- It is now possible to set the maximum size of the allocation unit for table memory using the `MaxAllocate` configuration parameter. (Bug#29044)

Changes in MySQL Cluster NDB 6.1.11 (5.1.15-ndb-6.1.11)

Functionality added or changed:

- **Important Change:** The `TimeBetweenWatchdogCheckInitial` configuration parameter was added to allow setting of a separate watchdog timeout for memory allocation during startup of the data nodes. See [Section 17.3.4.6, “Defining MySQL Cluster Data Nodes”](#), for more information. (Bug#28899)
- A new configuration parameter `ODirect` causes `NDB` to attempt using `O_DIRECT` writes for LCP, backups, and redo logs, often lowering CPU usage.

Bugs fixed:

- Having large amounts of memory locked caused swapping to disk. (Bug#28751)
- LCP files were not removed following an initial system restart. (Bug#28726)
- **Disk Data:** Repeated `INSERT` and `DELETE` operations on a Disk Data table having one or more large `VARCHAR` columns could cause data nodes to fail. (Bug#20612)

Changes in MySQL Cluster NDB 6.1.10 (5.1.15-ndb-6.1.10)

Functionality added or changed:

- A new `times` printout was added in the `ndbd` watchdog thread.
- Some unneeded printouts in the `ndbd` out file were removed.

Bugs fixed:

- A regression in the heartbeat monitoring code could lead to node failure under high load. This issue affected MySQL 5.1.19 and MySQL Cluster NDB 6.1.10 only. (Bug#28783)
- A corrupt schema file could cause a `FILE ALREADY OPEN` error. (Bug#28770)
- Setting `InitialNoOpenFiles` equal to `MaxNoOfOpenFiles` caused an error. This was due to the fact that the actual value of `MaxNoOfOpenFiles` as used by the cluster was offset by 1 from the value set in `config.ini`. (Bug#28749)
- A race condition could result when non-master nodes (in addition to the master node) tried to update active status due to a local checkpoint (that is, between `NODE_FAILREP` and `COPY_GCIREQ` events). Now only the master updates the active status. (Bug#28717)
- A fast global checkpoint under high load with high usage of the redo buffer caused data nodes to fail. (Bug#28653)
- **Disk Data:** When loading data into a cluster following a version upgrade, the data nodes could forcibly shut down due to page and buffer management failures (that is, `ndbrequire` failures in `PGMAN`). (Bug#28525)

Changes in MySQL Cluster NDB 6.1.9 (5.1.15-ndb-6.1.9)

Bugs fixed:

- When an API node sent more than 1024 signals in a single batch, NDB would process only the first 1024 of these, and then hang. (Bug#28443)
- **Disk Data:** The cluster backup process scanned in ACC index order, which had bad effects for disk data. (Bug#28593)

Changes in MySQL Cluster NDB 6.1.8 (5.1.15-ndb-6.1.8)

Bugs fixed:

- Local checkpoint files relating to dropped NDB tables were not removed. (Bug#28348)
- Repeated insertion of data generated by `mysqldump` into NDB tables could eventually lead to failure of the cluster. (Bug#27437)
- **Disk Data:** Extremely large inserts into Disk Data tables could lead to data node failure in some circumstances. (Bug#27942)
- **Cluster API:** In a multi-operation transaction, a delete operation followed by the insertion of an implicit `NULL` failed to overwrite an existing value. (Bug#20535)

Changes in MySQL Cluster NDB 6.1.7 (5.1.15-ndb-6.1.7)

Functionality added or changed:

- **Cluster Replication: Incompatible Change:** The schema for the `ndb_apply_status` table in the `mysql` system database has changed. When upgrading to this release from a previous MySQL Cluster NDB 6.x or mainline MySQL 5.1 release, you must drop the `mysql.ndb_apply_status` table, then restart the server in order for the table to be re-created with the new schema.

See Section 17.9.4, “MySQL Cluster Replication Schema and Tables”, for additional information.

Bugs fixed:

- The cluster waited 30 seconds instead of 30 milliseconds before reading table statistics. (Bug#28093)
- Under certain rare circumstances, `ndbd` could get caught in an infinite loop when one transaction took a read lock and then a second transaction attempted to obtain a write lock on the same tuple in the lock queue. (Bug#28073)
- Under some circumstances, a node restart could fail to update the Global Checkpoint Index (GCI). (Bug#28023)
- An `INSERT` followed by a delete `DELETE` on the same NDB table caused a memory leak. (Bug#27756)
This regression was introduced by Bug#20612.
- Under certain rare circumstances performing a `DROP TABLE` or `TRUNCATE` on an NDB table could cause a node failure or forced cluster shutdown. (Bug#27581)
- Memory usage of a `mysqld` process grew even while idle. (Bug#27560)
- Performing a delete followed by an insert during a local checkpoint could cause a `ROWID ALREADY ALLOCATED` error. (Bug#27205)
- **Cluster Replication: Disk Data:** An issue with replication of Disk Data tables could in some cases lead to node failure. (Bug#28161)
- **Disk Data:** Changes to a Disk Data table made as part of a transaction could not be seen by the client performing the changes until the transaction had been committed. (Bug#27757)
- **Disk Data:** When restarting a data node following the creation of a large number of Disk Data objects (approximately 200 such objects), the cluster could not assign a node ID to the restarting node. (Bug#25741)
- **Disk Data:** Changing a column specification or issuing a `TRUNCATE` statement on a Disk Data table caused the table to be-

come an in-memory table.

This fix supersedes an incomplete fix that was made for this issue in MySQL 5.1.15. ([Bug#24667](#), [Bug#25296](#))

- **Cluster API:** An issue with the way in which the `NdbDictionary::Dictionary::listEvents()` method freed resources could sometimes lead to memory corruption. ([Bug#27663](#))

Changes in MySQL Cluster NDB 6.1.6 (5.1.15-ndb-6.1.6)

Functionality added or changed:

- **Cluster Replication: Incompatible Change:** The schema for the `ndb_apply_status` table in the `mysql` system database has changed. When upgrading to this release from a previous MySQL Cluster NDB 6.x or mainline MySQL 5.1 release, you must drop the `mysql.ndb_apply_status` table, then restart the server in order for the table to be re-created with the new schema.

See [Section 17.9.4, “MySQL Cluster Replication Schema and Tables”](#), for additional information.

Bugs fixed:

- A data node failing while another data node was restarting could leave the cluster in an inconsistent state. In certain rare cases, this could lead to a race condition and the eventual forced shutdown of the cluster. ([Bug#27466](#))
- It was not possible to set `LockPagesInMainMemory` equal to 0. ([Bug#27291](#))
- A race condition could sometimes occur if the node acting as master failed while node IDs were still being allocated during startup. ([Bug#27286](#))
- When a data node was taking over as the master node, a race condition could sometimes occur as the node was assuming responsibility for handling of global checkpoints. ([Bug#27283](#))
- `mysqld` could crash shortly after a data node failure following certain DML operations. ([Bug#27169](#))
- The same failed request from an API node could be handled by the cluster multiple times, resulting in reduced performance. ([Bug#27087](#))
- The failure of a data node while restarting could cause other data nodes to hang or crash. ([Bug#27003](#))
- `mysqld` processes would sometimes crash under high load.

Note

This fix improves on and replaces a fix for this bug that was made in MySQL Cluster NDB 6.1.5.

([Bug#26825](#))

- **Disk Data:** `DROP INDEX` on a Disk Data table did not always move data from memory into the tablespace. ([Bug#25877](#))
- **Cluster API:** An issue with the way in which the `NdbDictionary::Dictionary::listEvents()` method freed resources could sometimes lead to memory corruption. ([Bug#27663](#))
- **Cluster API:** A delete operation using a scan followed by an insert using a scan could cause a data node to fail. ([Bug#27203](#))

Changes in MySQL Cluster NDB 6.1.5 (5.1.15-ndb-6.1.5)

Functionality added or changed:

- **Cluster Replication: Incompatible Change:** The schema for the `ndb_apply_status` table in the `mysql` system database has changed. When upgrading to this release from a previous MySQL Cluster NDB 6.x or mainline MySQL 5.1 release, you must drop the `mysql.ndb_apply_status` table, then restart the server in order for the table to be re-created with the new schema.

See [Section 17.9.4, “MySQL Cluster Replication Schema and Tables”](#), for additional information.

Bugs fixed:

- Creating a table on one SQL node while in single user mode caused other SQL nodes to crash. ([Bug#26997](#))
- `mysqld` processes would sometimes crash under high load.

Note

This fix was reverted in MySQL Cluster NDB 6.1.6.

([Bug#26825](#))

- An infinite loop in an internal logging function could cause trace logs to fill up with `UNKNOWN SIGNAL TYPE` error messages and thus grow to unreasonable sizes. ([Bug#26720](#))
- **Disk Data:** When creating a log file group, setting `INITIAL_SIZE` to less than `UNDO_BUFFER_SIZE` caused data nodes to crash. ([Bug#25743](#))

Changes in MySQL Cluster NDB 6.1.4 (5.1.15-ndb-6.1.4)

Functionality added or changed:

- An `ndb_wait_connected` system variable has been added for `mysqld`. It causes `mysqld` wait a specified amount of time to be connected to the cluster before accepting client connections. For more information, see [Section 17.4.3, “MySQL Cluster System Variables”](#).
- **Cluster API:** It is now possible to specify the transaction coordinator when starting a transaction. See `Ndb::startTransaction()`, for more information.
- **Cluster API:** It is now possible to iterate over all existing NDB objects using three new methods of the `Ndb_cluster_connection` class:
 - `lock_ndb_objects()`
 - `get_next_ndb_object()`
 - `unlock_ndb_objects()`
 For more information about these methods and their use, see `ndb_cluster_connection::get_next_ndb_object()`, in the MySQL Cluster API Guide.

Bugs fixed:

- Using only the `--print_data` option (and no other options) with `ndb_restore` caused `ndb_restore` to fail. ([Bug#26741](#))
This regression was introduced by [Bug#14612](#).
- An inadvertent use of unaligned data caused `ndb_restore` to fail on some 64-bit platforms, including Sparc and Itanium-2. ([Bug#26739](#))

Changes in MySQL Cluster NDB 6.1.3 (5.1.15-ndb-6.1.3)

Functionality added or changed:

- The `ndbd_redo_log_reader` utility is now part of the default build. For more information, see [Section 17.6.16, “ndbd_redo_log_reader — Check and Print Content of Cluster Redo Log”](#).
- The `ndb_show_tables` utility now displays information about table events. See [Section 17.6.20, “ndb_show_tables — Display List of NDB Tables”](#), for more information.
- **Cluster API:** A new `listEvents()` method has been added to the `Dictionary` class. See `Dictionary::listEvents()`, for more information.

Bugs fixed:

- An invalid pointer was returned following a `FSCLOSECONF` signal when accessing the REDO logs during a node restart or

system restart. ([Bug#26515](#))

- The `InvalidUndoBufferSize` error used the same error code (763) as the `IncompatibleVersions` error. `InvalidUndoBufferSize` now uses its own error code (779). ([Bug#26490](#))
- The failure of a data node when restarting it with `--initial` could lead to failures of subsequent data node restarts. ([Bug#26481](#))
- Takeover for local checkpointing due to multiple failures of master nodes was sometimes incorrectly handled. ([Bug#26457](#))
- The `LockPagesInMainMemory` parameter was not read until after distributed communication had already started between cluster nodes. When the value of this parameter was 1, this could sometimes result in data node failure due to missed heartbeats. ([Bug#26454](#))
- Under some circumstances, following the restart of a management node, all data nodes would connect to it normally, but some of them subsequently failed to log any events to the management node. ([Bug#26293](#))
- No appropriate error message was provided when there was insufficient REDO log file space for the cluster to start. ([Bug#25801](#))
- A memory allocation failure in `SUMA` (the cluster Subscription Manager) could cause the cluster to crash. ([Bug#25239](#))
- The message `ERROR 0 IN READAUTOINCREMENTVALUE(): NO ERROR` was written to the error log whenever `SHOW TABLE STATUS` was performed on a Cluster table that did not have an `AUTO_INCREMENT` column.

Note

This improves on and supersedes an earlier fix that was made for this issue in MySQL 5.1.12.

([Bug#21033](#))

- **Disk Data:** A memory overflow could occur with tables having a large amount of data stored on disk, or with queries using a very high degree of parallelism on Disk Data tables. ([Bug#26514](#))
- **Disk Data:** Use of a tablespace whose `INITIAL_SIZE` was greater than 1 GB could cause the cluster to crash. ([Bug#26487](#))

Changes in MySQL Cluster NDB 6.1.2 (5.1.15-ndb-6.1.2)

Bugs fixed:

- Using node IDs greater than 48 could sometimes lead to incorrect memory access and a subsequent forced shutdown of the cluster. ([Bug#26267](#))

Changes in MySQL Cluster NDB 6.1.1 (5.1.15-ndb-6.1.1)

Functionality added or changed:

- A single cluster can now support up to 255 API nodes, including MySQL servers acting as SQL nodes. See [Section 17.12.8, “Issues Exclusive to MySQL Cluster”](#), for more information.

Bugs fixed:

- A memory leak could cause problems during a node or cluster shutdown or failure. ([Bug#25997](#))
- **Cluster API: Disk Data:** A delete and a read performed in the same operation could cause one or more data nodes to crash. This could occur when the operation affected more than 5 columns concurrently, or when one or more of the columns was of the `VARCHAR` type and was stored on disk. ([Bug#25794](#))
- **Cluster API: Disk Data:** A delete and a read performed in the same operation could cause one or more data nodes to crash. This could occur when the operation affected more than 5 columns concurrently, or when one or more of the columns was of the `VARCHAR` type and was stored on disk. ([Bug#25794](#))

Changes in MySQL Cluster NDB 6.1.0 (5.1.14-ndb-6.1.0)

Functionality added or changed:

- A new configuration parameter `MemReportFrequency` allows for additional control of data node memory usage. Previously, only warnings at predetermined percentages of memory allocation were given; setting this parameter allows for that behavior to be overridden. For more information, see [Section 17.3.4.6, “Defining MySQL Cluster Data Nodes”](#).

Bugs fixed:

- When a data node was shut down using the management client `STOP` command, a connection event (`NDB_LE_Connected`) was logged instead of a disconnection event (`NDB_LE_Disconnected`). ([Bug#22773](#))
- `SELECT` statements with a `BLOB` or `TEXT` column in the selected column list and a `WHERE` condition including a primary key lookup on a `VARCHAR` primary key produced empty result sets. ([Bug#19956](#))
- **Disk Data:** `MEDIUMTEXT` columns of Disk Data tables were stored in memory rather than on disk, even if the columns were not indexed. ([Bug#25001](#))
- **Disk Data:** Performing a node restart with a newly dropped Disk Data table could lead to failure of the node during the restart. ([Bug#24917](#))
- **Disk Data:** When restoring from backup a cluster containing any Disk Data tables with hidden primary keys, a node failure resulted which could lead to a crash of the cluster. ([Bug#24166](#))
- **Disk Data:** Repeated `CREATE`, `DROP`, or `TRUNCATE` in various combinations with system restarts between these operations could lead to the eventual failure of a system restart. ([Bug#21948](#))
- **Disk Data:** Extents that should have been available for re-use following a `DROP TABLE` operation were not actually made available again until after the cluster had performed a local checkpoint. ([Bug#17605](#))
- **Cluster API:** Invoking the `NdbTransaction::execute()` method using execution type `Commit` and abort option `AO_IgnoreError` could lead to a crash of the transaction coordinator (DBTC). ([Bug#25090](#))
- **Cluster API:** A unique index lookup on a non-existent tuple could lead to a data node timeout (error 4012). ([Bug#25059](#))
- **Cluster API:** When using the `NdbTransaction::execute()` method, a very long timeout (greater than 5 minutes) could result if the last data node being polled was disconnected from the cluster. ([Bug#24949](#))
- **Cluster API:** Due to an error in the computation of table fragment arrays, some transactions were not executed from the correct starting point. ([Bug#24914](#))

Chapter 18. Partitioning

This chapter discusses MySQL's implementation of *user-defined partitioning*. You can determine whether your MySQL Server supports partitioning by means of a `SHOW VARIABLES` command such as this one:

```
mysql> SHOW VARIABLES LIKE '%partition%';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| have_partitioning | YES |
+-----+-----+
1 row in set (0.00 sec)
```

Note

Prior to MySQL 5.1.6, this variable was named `have_partition_engine`. (Bug#16718)

You can also check the output of the `SHOW PLUGINS` statement, as shown here:

```
mysql> SHOW PLUGINS;
+-----+-----+-----+-----+-----+
| Name      | Status | Type          | Library | License |
+-----+-----+-----+-----+-----+
| binlog    | ACTIVE | STORAGE ENGINE | NULL    | GPL     |
| partition | ACTIVE | STORAGE ENGINE | NULL   | GPL   |
| ARCHIVE   | ACTIVE | STORAGE ENGINE | NULL    | GPL     |
| BLACKHOLE | ACTIVE | STORAGE ENGINE | NULL    | GPL     |
| CSV       | ACTIVE | STORAGE ENGINE | NULL    | GPL     |
| FEDERATED | DISABLED | STORAGE ENGINE | NULL    | GPL     |
| MEMORY    | ACTIVE | STORAGE ENGINE | NULL    | GPL     |
| InnoDB    | ACTIVE | STORAGE ENGINE | NULL    | GPL     |
| MRG_MYISAM | ACTIVE | STORAGE ENGINE | NULL    | GPL     |
| MyISAM    | ACTIVE | STORAGE ENGINE | NULL    | GPL     |
| ndbcluster | DISABLED | STORAGE ENGINE | NULL    | GPL     |
+-----+-----+-----+-----+-----+
11 rows in set (0.00 sec)
```

If you do not see the `have_partitioning` variable with the value `YES` listed in the output of an appropriate `SHOW VARIABLES` statement, or if you do not see the `partition` plugin listed with the value `ACTIVE` for the `Status` column in the output of `SHOW PLUGINS` (show in bold text in the example just given), then your version of MySQL does not support partitioning.

MySQL Community binaries provided by Sun Microsystems include partitioning support. For information about partitioning support offered in commercial MySQL Server binaries, see *MySQL Enterprise Server 5.1*, on the MySQL website.

If you are compiling MySQL 5.1 from source, the build must be configured using `--with-partition` to enable partitioning.

If your MySQL binary is built with partitioning support, nothing further needs to be done in order to enable it (for example, no special entries are required in your `my.cnf` file).

An introduction to partitioning and partitioning concepts may be found in [Section 18.1, "Overview of Partitioning in MySQL"](#).

MySQL supports several types of partitioning, which are discussed in [Section 18.2, "Partition Types"](#), as well as subpartitioning, which is described in [Section 18.2.5, "Subpartitioning"](#).

Methods of adding, removing, and altering partitions in existing partitioned tables are covered in [Section 18.3, "Partition Management"](#).

Table maintenance commands for use with partitioned tables are discussed in [Section 18.3.3, "Maintenance of Partitions"](#).

Beginning with MySQL 5.1.6, the `PARTITIONS` table in the `INFORMATION_SCHEMA` database provides information about partitions and partitioned tables. See [Section 20.19, "The INFORMATION_SCHEMA PARTITIONS Table"](#), for more information; for some examples of queries against this table, see [Section 18.2.6, "How MySQL Partitioning Handles NULL"](#).

Important

Partitioned tables created with MySQL versions prior to 5.1.6 cannot be read by a 5.1.6 or later MySQL Server. In addition, the `INFORMATION_SCHEMA.TABLES` table cannot be used if such tables are present on a 5.1.6 server. Beginning with MySQL 5.1.7, a suitable warning message is generated instead, to alert the user that incompatible partitioned tables have been found by the server.

If you are using partitioned tables which were created in MySQL 5.1.5 or earlier, be sure to see [Section C.1.32, "Changes in MySQL 5.1.6 \(01 February 2006\)"](#) for more information and suggested workarounds *before* upgrading to MySQL 5.1.6 or later.

The partitioning implementation in MySQL 5.1 is still undergoing development. For known issues with MySQL partitioning, see [Section 18.5, “Restrictions and Limitations on Partitioning”](#), where we have noted these.

You may also find the following resources to be useful when working with partitioned tables.

Additional Resources. Other sources of information about user-defined partitioning in MySQL include the following:

- [MySQL Partitioning Forum](#)

This is the official discussion forum for those interested in or experimenting with MySQL Partitioning technology. It features announcements and updates from MySQL developers and others. It is monitored by members of the Partitioning Development and Documentation Teams.

- [Mikael Ronström's Blog](#)

MySQL Partitioning Architect and Lead Developer Mikael Ronström frequently posts articles here concerning his work with MySQL Partitioning and MySQL Cluster.

- [PlanetMySQL](#)

A MySQL news site featuring MySQL-related blogs, which should be of interest to anyone using my MySQL. We encourage you to check here for links to blogs kept by those working with MySQL Partitioning, or to have your own blog added to those covered.

MySQL 5.1 binaries are available from <http://dev.mysql.com/downloads/mysql/5.1.html>. However, for the latest partitioning bug-fixes and feature additions, you can obtain the source from our Bazaar repository. To enable partitioning, you need to compile the server using the `--with-partition` option. For more information about building MySQL, see [Section 2.10, “MySQL Installation Using a Source Distribution”](#). If you have problems compiling a partitioning-enabled MySQL 5.1 build, check the [MySQL Partitioning Forum](#) and ask for assistance there if you do not find a solution to your problem already posted.

18.1. Overview of Partitioning in MySQL

This section provides a conceptual overview of partitioning in MySQL 5.1.

For information on partitioning restrictions and feature limitations, see [Section 18.5, “Restrictions and Limitations on Partitioning”](#).

The SQL standard does not provide much in the way of guidance regarding the physical aspects of data storage. The SQL language itself is intended to work independently of any data structures or media underlying the schemas, tables, rows, or columns with which it works. Nonetheless, most advanced database management systems have evolved some means of determining the physical location to be used for storing specific pieces of data in terms of the file system, hardware or even both. In MySQL, the [InnoDB](#) storage engine has long supported the notion of a tablespace, and the MySQL Server, even prior to the introduction of partitioning, could be configured to employ different physical directories for storing different databases (see [Section 7.6.1, “Using Symbolic Links”](#), for an explanation of how this is done).

Partitioning takes this notion a step further, by allowing you to distribute portions of individual tables across a file system according to rules which you can set largely as needed. In effect, different portions of a table are stored as separate tables in different locations. The user-selected rule by which the division of data is accomplished is known as a *partitioning function*, which in MySQL can be the modulus, simple matching against a set of ranges or value lists, an internal hashing function, or a linear hashing function. The function is selected according to the partitioning type specified by the user, and takes as its parameter the value of a user-supplied expression. This expression can be either an integer column value, or a function acting on one or more column values and returning an integer. The value of this expression is passed to the partitioning function, which returns an integer value representing the number of the partition in which that particular record should be stored. This function must be non-constant and non-random. It may not contain any queries, but may use an SQL expression that is valid in MySQL, as long as that expression returns either `NULL` or an integer *intval* such that

```
-MAXVALUE <= intval <= MAXVALUE
```

(`MAXVALUE` is used to represent the least upper bound for the type of integer in question. `-MAXVALUE` represents the greatest lower bound.) There are some additional restrictions on partitioning functions; see [Section 18.5, “Restrictions and Limitations on Partitioning”](#), for more information about these.

Examples of partitioning functions can be found in the discussions of partitioning types later in this chapter (see [Section 18.2, “Partition Types”](#)), as well as in the partitioning syntax descriptions given in [Section 12.1.17, “CREATE TABLE Syntax”](#).

This is known as *horizontal partitioning* — that is, different rows of a table may be assigned to different physical partitions. MySQL 5.1 does not support *vertical partitioning*, in which different columns of a table are assigned to different physical partitions. There are not at this time any plans to introduce vertical partitioning into MySQL 5.1.

For information about determining whether your MySQL Server binary supports user-defined partitioning, see [Chapter 18, Parti-](#)

tioning.

For creating partitioned tables, you can use most storage engines that are supported by your MySQL server; the MySQL partitioning engine runs in a separate layer and can interact with any of these. In MySQL 5.1, all partitions of the same partitioned table must use the same storage engine; for example, you cannot use `MyISAM` for one partition and `InnoDB` for another. However, there is nothing preventing you from using different storage engines for different partitioned tables on the same MySQL server or even in the same database.

Note

MySQL partitioning cannot be used with the `MERGE` or `CSV` storage engines. Beginning with MySQL 5.1.15, `FEDERATED` tables also cannot be partitioned ([Bug#22451](#)). Prior to MySQL 5.1.6, it was also not feasible to create a partitioned table using the `BLACKHOLE` storage engine ([Bug#14524](#)).

Partitioning by `KEY` or `LINEAR KEY` is possible with `NDBCLUSTER`, but other types of user-defined partitioning are not supported for tables using this storage engine. In addition, an `NDBCLUSTER` table that employs user-defined partitioning must have an explicit primary key, and any columns referenced in the table's partitioning expression must be part of the primary key. However, if no columns are listed in the `PARTITION BY KEY` or `PARTITION BY LINEAR KEY` clause of the `CREATE TABLE` or `ALTER TABLE` statement used to create or modify a user-partitioned `NDBCLUSTER` table, then the table is not required to have an explicit primary key.

For more information, see [Section 18.5.2, “Partitioning Limitations Relating to Storage Engines”](#), and [Section 17.12.1, “Non-Compliance with SQL Syntax in MySQL Cluster”](#).

To employ a particular storage engine for a partitioned table, it is necessary only to use the `[STORAGE] ENGINE` option just as you would for a non-partitioned table. However, you should keep in mind that `[STORAGE] ENGINE` (and other table options) need to be listed *before* any partitioning options are used in a `CREATE TABLE` statement. This example shows how to create a table that is partitioned by hash into 6 partitions and which uses the `InnoDB` storage engine:

```
CREATE TABLE ti (id INT, amount DECIMAL(7,2), tr_date DATE)
ENGINE=INNODB
PARTITION BY HASH( MONTH(tr_date) )
PARTITIONS 6;
```

Note

Each `PARTITION` clause can include a `[STORAGE] ENGINE` option, but in MySQL 5.1 this has no effect.

Important

Partitioning applies to all data and indexes of a table; you cannot partition only the data and not the indexes, or *vice versa*, nor can you partition only a portion of the table.

Data and indexes for each partition can be assigned to a specific directory using the `DATA DIRECTORY` and `INDEX DIRECTORY` options for the `PARTITION` clause of the `CREATE TABLE` statement used to create the partitioned table.

Note

Prior to MySQL 5.1.18, these options were permitted even when the `NO_DIR_IN_CREATE` server SQL mode was in effect. ([Bug#24633](#))

The `DATA DIRECTORY` and `INDEX DIRECTORY` options have no effect when defining partitions for tables using the `InnoDB` storage engine.

`DATA DIRECTORY` and `INDEX DIRECTORY` are not supported for individual partitions or subpartitions on Windows. Beginning with MySQL 5.1.24, these options are ignored on Windows, except that a warning is generated. ([Bug#30459](#))

In addition, `MAX_ROWS` and `MIN_ROWS` can be used to determine the maximum and minimum numbers of rows, respectively, that can be stored in each partition. See [Section 18.3, “Partition Management”](#), for more information on these options.

Some of the advantages of partitioning include:

- Being able to store more data in one table than can be held on a single disk or file system partition.
- Data that loses its usefulness can often be easily removed from the table by dropping the partition containing only that data. Conversely, the process of adding new data can in some cases be greatly facilitated by adding a new partition specifically for that data.
- Some queries can be greatly optimized in virtue of the fact that data satisfying a given `WHERE` clause can be stored only on one or more partitions, thereby excluding any remaining partitions from the search. Because partitions can be altered after a parti-

tioned table has been created, you can reorganize your data to enhance frequent queries that may not have been so when the partitioning scheme was first set up. This capability, sometimes referred to as *partition pruning*, was implemented in MySQL 5.1.6. For more information, see [Section 18.4, “Partition Pruning”](#).

Other benefits usually associated with partitioning include those in the following list. These features are not currently implemented in MySQL Partitioning, but are high on our list of priorities.

- Queries involving aggregate functions such as `SUM()` and `COUNT()` can easily be parallelized. A simple example of such a query might be `SELECT salesperson_id, COUNT(orders) as order_total FROM sales GROUP BY salesperson_id;` By “parallelized,” we mean that the query can be run simultaneously on each partition, and the final result obtained merely by summing the results obtained for all partitions.
- Achieving greater query throughput in virtue of spreading data seeks over multiple disks.

Be sure to check this section and chapter frequently for updates as Partitioning development continues.

18.2. Partition Types

This section discusses the types of partitioning which are available in MySQL 5.1. These include:

- **RANGE partitioning:** Assigns rows to partitions based on column values falling within a given range. See [Section 18.2.1, “RANGE Partitioning”](#).
- **LIST partitioning:** Similar to partitioning by range, except that the partition is selected based on columns matching one of a set of discrete values. See [Section 18.2.2, “LIST Partitioning”](#).
- **HASH partitioning:** A partition is selected based on the value returned by a user-defined expression that operates on column values in rows to be inserted into the table. The function may consist of any expression valid in MySQL that yields a non-negative integer value. See [Section 18.2.3, “HASH Partitioning”](#).
- **KEY partitioning:** Similar to partitioning by hash, except that only one or more columns to be evaluated are supplied, and the MySQL server provides its own hashing function. These columns can contain other than integer values, since the hashing function supplied by MySQL guarantees an integer result regardless of the column data type. See [Section 18.2.4, “KEY Partitioning”](#).

A very common use of database partitioning is to segregate data by date. Some database systems support explicit date partitioning, which MySQL does not implement in 5.1. However, it is not difficult in MySQL to create partitioning schemes based on [DATE](#), [TIME](#), or [DATETIME](#) columns, or based on expressions making use of such columns.

When partitioning by [KEY](#) or [LINEAR KEY](#), you can use a [DATE](#), [TIME](#), or [DATETIME](#) column as the partitioning column without performing any modification of the column value. For example, this table creation statement is perfectly valid in MySQL:

```
CREATE TABLE members (
  firstname VARCHAR(25) NOT NULL,
  lastname VARCHAR(25) NOT NULL,
  username VARCHAR(16) NOT NULL,
  email VARCHAR(35),
  joined DATE NOT NULL
)
PARTITION BY KEY(joined)
PARTITIONS 6;
```

MySQL's other partitioning types, however, require a partitioning expression that yields an integer value or `NULL`. If you wish to use date-based partitioning by [RANGE](#), [LIST](#), [HASH](#), or [LINEAR HASH](#), you can simply employ a function that operates on a [DATE](#), [TIME](#), or [DATETIME](#) column and returns such a value, as shown here:

```
CREATE TABLE members (
  firstname VARCHAR(25) NOT NULL,
  lastname VARCHAR(25) NOT NULL,
  username VARCHAR(16) NOT NULL,
  email VARCHAR(35),
  joined DATE NOT NULL
)
PARTITION BY RANGE( YEAR(joined) ) (
  PARTITION p0 VALUES LESS THAN (1960),
  PARTITION p1 VALUES LESS THAN (1970),
  PARTITION p2 VALUES LESS THAN (1980),
  PARTITION p3 VALUES LESS THAN (1990),
  PARTITION p4 VALUES LESS THAN MAXVALUE
);
```

Additional examples of partitioning using dates may be found here:

- [Section 18.2.1, “RANGE Partitioning”](#)
- [Section 18.2.3, “HASH Partitioning”](#)
- [Section 18.2.3.1, “LINEAR HASH Partitioning”](#)

For more complex examples of date-based partitioning, see:

- [Section 18.4, “Partition Pruning”](#)
- [Section 18.2.5, “Subpartitioning”](#)

MySQL partitioning is optimized for use with the `TO_DAYS()` and `YEAR()` functions. However, you can use other date and time functions that return an integer or `NULL`, such as `WEEKDAY()`, `DAYOFYEAR()`, or `MONTH()`. See [Section 11.6, “Date and Time Functions”](#), for more information about such functions.

It is important to remember — regardless of the type of partitioning that you use — that partitions are always numbered automatically and in sequence when created, starting with 0. When a new row is inserted into a partitioned table, it is these partition numbers that are used in identifying the correct partition. For example, if your table uses 4 partitions, these partitions are numbered 0, 1, 2, and 3. For the `RANGE` and `LIST` partitioning types, it is necessary to ensure that there is a partition defined for each partition number. For `HASH` partitioning, the user function employed must return an integer value greater than 0. For `KEY` partitioning, this issue is taken care of automatically by the hashing function which the MySQL server employs internally.

Names of partitions generally follow the rules governing other MySQL identifiers, such as those for tables and databases. However, you should note that partition names are not case-sensitive. For example, the following `CREATE TABLE` statement fails as shown:

```
mysql> CREATE TABLE t2 (val INT)
-> PARTITION BY LIST(val)(
->     PARTITION mypart VALUES IN (1,3,5),
->     PARTITION MyPart VALUES IN (2,4,6)
-> );
ERROR 1488 (HY000): Duplicate partition name mypart
```

Failure occurs because MySQL sees no difference between the partition names `mypart` and `MyPart`.

When you specify the number of partitions for the table, this must be expressed as a positive, nonzero integer literal with no leading zeroes, and may not be an expression such as `0.8E+01` or `6-2`, even if it evaluates to an integer value. (Beginning with MySQL 5.1.12, decimal fractions are no longer truncated, but instead are disallowed entirely.)

In the sections that follow, we do not necessarily provide all possible forms for the syntax that can be used for creating each partition type; this information may be found in [Section 12.1.17, “CREATE TABLE Syntax”](#).

18.2.1. RANGE Partitioning

A table that is partitioned by range is partitioned in such a way that each partition contains rows for which the partitioning expression value lies within a given range. Ranges should be contiguous but not overlapping, and are defined using the `VALUES LESS THAN` operator. For the next few examples, suppose that you are creating a table such as the following to hold personnel records for a chain of 20 video stores, numbered 1 through 20:

```
CREATE TABLE employees (
  id INT NOT NULL,
  fname VARCHAR(30),
  lname VARCHAR(30),
  hired DATE NOT NULL DEFAULT '1970-01-01',
  separated DATE NOT NULL DEFAULT '9999-12-31',
  job_code INT NOT NULL,
  store_id INT NOT NULL
);
```

This table can be partitioned by range in a number of ways, depending on your needs. One way would be to use the `store_id` column. For instance, you might decide to partition the table 4 ways by adding a `PARTITION BY RANGE` clause as shown here:

```
CREATE TABLE employees (
  id INT NOT NULL,
  fname VARCHAR(30),
  lname VARCHAR(30),
  hired DATE NOT NULL DEFAULT '1970-01-01',
  separated DATE NOT NULL DEFAULT '9999-12-31',
  job_code INT NOT NULL,
  store_id INT NOT NULL
```

```

)
PARTITION BY RANGE (store_id) (
  PARTITION p0 VALUES LESS THAN (6),
  PARTITION p1 VALUES LESS THAN (11),
  PARTITION p2 VALUES LESS THAN (16),
  PARTITION p3 VALUES LESS THAN (21)
);

```

In this partitioning scheme, all rows corresponding to employees working at stores 1 through 5 are stored in partition `p0`, to those employed at stores 6 through 10 are stored in partition `p1`, and so on. Note that each partition is defined in order, from lowest to highest. This is a requirement of the `PARTITION BY RANGE` syntax; you can think of it as being analogous to a series of `if ... elseif ...` statements in C or Java in this regard.

It is easy to determine that a new row containing the data (72, 'Michael', 'Widenius', '1998-06-25', NULL, 13) is inserted into partition `p2`, but what happens when your chain adds a 21st store? Under this scheme, there is no rule that covers a row whose `store_id` is greater than 20, so an error results because the server does not know where to place it. You can keep this from occurring by using a “catchall” `VALUES LESS THAN` clause in the `CREATE TABLE` statement that provides for all values greater than highest value explicitly named:

```

CREATE TABLE employees (
  id INT NOT NULL,
  fname VARCHAR(30),
  lname VARCHAR(30),
  hired DATE NOT NULL DEFAULT '1970-01-01',
  separated DATE NOT NULL DEFAULT '9999-12-31',
  job_code INT NOT NULL,
  store_id INT NOT NULL
)
PARTITION BY RANGE (store_id) (
  PARTITION p0 VALUES LESS THAN (6),
  PARTITION p1 VALUES LESS THAN (11),
  PARTITION p2 VALUES LESS THAN (16),
  PARTITION p3 VALUES LESS THAN MAXVALUE
);

```

Note

Another way to avoid an error when no matching value is found is to use the `IGNORE` keyword as part of the `INSERT` statement. For an example, see [Section 18.2.2, “LIST Partitioning”](#). Also see [Section 12.2.5, “INSERT Syntax”](#), for general information about `IGNORE`.

`MAXVALUE` represents an integer value that is always greater than the largest possible integer value (in mathematical language, it serves as a *least upper bound*). Now, any rows whose `store_id` column value is greater than or equal to 16 (the highest value defined) are stored in partition `p3`. At some point in the future — when the number of stores has increased to 25, 30, or more — you can use an `ALTER TABLE` statement to add new partitions for stores 21-25, 26-30, and so on (see [Section 18.3, “Partition Management”](#), for details of how to do this).

In much the same fashion, you could partition the table based on employee job codes — that is, based on ranges of `job_code` column values. For example — assuming that two-digit job codes are used for regular (in-store) workers, three-digit codes are used for office and support personnel, and four-digit codes are used for management positions — you could create the partitioned table using the following:

```

CREATE TABLE employees (
  id INT NOT NULL,
  fname VARCHAR(30),
  lname VARCHAR(30),
  hired DATE NOT NULL DEFAULT '1970-01-01',
  separated DATE NOT NULL DEFAULT '9999-12-31',
  job_code INT NOT NULL,
  store_id INT NOT NULL
)
PARTITION BY RANGE (job_code) (
  PARTITION p0 VALUES LESS THAN (100),
  PARTITION p1 VALUES LESS THAN (1000),
  PARTITION p2 VALUES LESS THAN (10000)
);

```

In this instance, all rows relating to in-store workers would be stored in partition `p0`, those relating to office and support staff in `p1`, and those relating to managers in partition `p2`.

It is also possible to use an expression in `VALUES LESS THAN` clauses. However, MySQL must be able to evaluate the expression's return value as part of a `LESS THAN (<)` comparison.

Rather than splitting up the table data according to store number, you can use an expression based on one of the two `DATE` columns instead. For example, let us suppose that you wish to partition based on the year that each employee left the company; that is, the value of `YEAR(separated)`. An example of a `CREATE TABLE` statement that implements such a partitioning scheme is shown here:

```
CREATE TABLE employees (
  id INT NOT NULL,
  fname VARCHAR(30),
  lname VARCHAR(30),
  hired DATE NOT NULL DEFAULT '1970-01-01',
  separated DATE NOT NULL DEFAULT '9999-12-31',
  job_code INT,
  store_id INT
)
PARTITION BY RANGE ( YEAR(separated) ) (
  PARTITION p0 VALUES LESS THAN (1991),
  PARTITION p1 VALUES LESS THAN (1996),
  PARTITION p2 VALUES LESS THAN (2001),
  PARTITION p3 VALUES LESS THAN MAXVALUE
);
```

In this scheme, for all employees who left before 1991, the rows are stored in partition `p0`; for those who left in the years 1991 through 1995, in `p1`; for those who left in the years 1996 through 2000, in `p2`; and for any workers who left after the year 2000, in `p3`.

Range partitioning is particularly useful when:

- You want or need to delete “old” data. If you are using the partitioning scheme shown immediately above, you can simply use `ALTER TABLE employees DROP PARTITION p0;` to delete all rows relating to employees who stopped working for the firm prior to 1991. (See [Section 12.1.7, “ALTER TABLE Syntax”](#), and [Section 18.3, “Partition Management”](#), for more information.) For a table with a great many rows, this can be much more efficient than running a `DELETE` query such as `DELETE FROM employees WHERE YEAR(separated) <= 1990;`.
- You want to use a column containing date or time values, or containing values arising from some other series.
- You frequently run queries that depend directly on the column used for partitioning the table. For example, when executing a query such as `EXPLAIN PARTITIONS SELECT COUNT(*) FROM employees WHERE separated BETWEEN '2000-01-01' AND '2000-12-31' GROUP BY store_id;` MySQL can quickly determine that only partition `p2` needs to be scanned because the remaining partitions cannot contain any records satisfying the `WHERE` clause. See [Section 18.4, “Partition Pruning”](#), for more information about how this is accomplished.

18.2.2. LIST Partitioning

List partitioning in MySQL is similar to range partitioning in many ways. As in partitioning by [RANGE](#), each partition must be explicitly defined. The chief difference is that, in list partitioning, each partition is defined and selected based on the membership of a column value in one of a set of value lists, rather than in one of a set of contiguous ranges of values. This is done by using `PARTITION BY LIST(expr)` where `expr` is a column value or an expression based on a column value and returning an integer value, and then defining each partition by means of a `VALUES IN (value_list)`, where `value_list` is a comma-separated list of integers.

Note

In MySQL 5.1, it is possible to match against only a list of integers (and possibly `NULL` — see [Section 18.2.6, “How MySQL Partitioning Handles NULL”](#)) when partitioning by `LIST`.

Unlike the case with partitions defined by range, list partitions do not need to be declared in any particular order. For more detailed syntactical information, see [Section 12.1.17, “CREATE TABLE Syntax”](#).

For the examples that follow, we assume that the basic definition of the table to be partitioned is provided by the `CREATE TABLE` statement shown here:

```
CREATE TABLE employees (
  id INT NOT NULL,
  fname VARCHAR(30),
  lname VARCHAR(30),
  hired DATE NOT NULL DEFAULT '1970-01-01',
  separated DATE NOT NULL DEFAULT '9999-12-31',
  job_code INT,
  store_id INT
);
```

(This is the same table used as a basis for the examples in [Section 18.2.1, “RANGE Partitioning”](#).)

Suppose that there are 20 video stores distributed among 4 franchises as shown in the following table.

Region	Store ID Numbers
North	3, 5, 6, 9, 17

East	1, 2, 10, 11, 19, 20
West	4, 12, 13, 14, 18
Central	7, 8, 15, 16

To partition this table in such a way that rows for stores belonging to the same region are stored in the same partition, you could use the `CREATE TABLE` statement shown here:

```
CREATE TABLE employees (
  id INT NOT NULL,
  fname VARCHAR(30),
  lname VARCHAR(30),
  hired DATE NOT NULL DEFAULT '1970-01-01',
  separated DATE NOT NULL DEFAULT '9999-12-31',
  job_code INT,
  store_id INT
)
PARTITION BY LIST(store_id) (
  PARTITION pNorth VALUES IN (3,5,6,9,17),
  PARTITION pEast VALUES IN (1,2,10,11,19,20),
  PARTITION pWest VALUES IN (4,12,13,14,18),
  PARTITION pCentral VALUES IN (7,8,15,16)
);
```

This makes it easy to add or drop employee records relating to specific regions to or from the table. For instance, suppose that all stores in the West region are sold to another company. All rows relating to employees working at stores in that region can be deleted with the query `ALTER TABLE employees DROP PARTITION pWest;`, which can be executed much more efficiently than the equivalent `DELETE` statement `DELETE FROM employees WHERE store_id IN (4,12,13,14,18);`

As with `RANGE` partitioning, it is possible to combine `LIST` partitioning with partitioning by hash or key to produce a composite partitioning (subpartitioning). See [Section 18.2.5, “Subpartitioning”](#).

Unlike the case with `RANGE` partitioning, there is no “catch-all” such as `MAXVALUE`; all expected values for the partitioning expression should be covered in `PARTITION ... VALUES IN (...)` clauses. An `INSERT` statement containing an unmatched partitioning column value fails with an error, as shown in this example:

```
mysql> CREATE TABLE h2 (
->   c1 INT,
->   c2 INT
-> )
-> PARTITION BY LIST(c1) (
->   PARTITION p0 VALUES IN (1, 4, 7),
->   PARTITION p1 VALUES IN (2, 5, 8)
-> );
Query OK, 0 rows affected (0.11 sec)

mysql> INSERT INTO h2 VALUES (3, 5);
ERROR 1525 (HY000): TABLE HAS NO PARTITION FOR VALUE 3
```

When inserting multiple rows using a single `INSERT` statement, any rows coming before the row containing the unmatched value are inserted, but any coming after it are not:

```
mysql> SELECT * FROM h2;
Empty set (0.00 sec)

mysql> INSERT INTO h2 VALUES (4, 7), (3, 5), (6, 0);
ERROR 1525 (HY000): TABLE HAS NO PARTITION FOR VALUE 3
mysql> SELECT * FROM h2;
+-----+-----+
| c1   | c2   |
+-----+-----+
| 4   | 7   |
+-----+-----+
1 row in set (0.00 sec)
```

You can cause this type of error to be ignored by using the `IGNORE` key word. If you do so, rows containing unmatched partitioning column values are not inserted, but any rows with matching values *are* inserted, and no errors are reported:

```
mysql> TRUNCATE h2;
Query OK, 1 row affected (0.00 sec)

mysql> SELECT * FROM h2;
Empty set (0.00 sec)

mysql> INSERT IGNORE INTO h2 VALUES (2, 5), (6, 10), (7, 5), (3, 1), (1, 9);
Query OK, 3 rows affected (0.00 sec)
Records: 5 Duplicates: 2 Warnings: 0

mysql> SELECT * FROM h2;
+-----+-----+
| c1   | c2   |
+-----+-----+
| 7   | 5   |
| 1   | 9   |
+-----+-----+
```

```
| 2 | 5 |
+---+---+
3 rows in set (0.00 sec)
```

18.2.3. HASH Partitioning

Partitioning by `HASH` is used primarily to ensure an even distribution of data among a predetermined number of partitions. With range or list partitioning, you must specify explicitly into which partition a given column value or set of column values is to be stored; with hash partitioning, MySQL takes care of this for you, and you need only specify a column value or expression based on a column value to be hashed and the number of partitions into which the partitioned table is to be divided.

To partition a table using `HASH` partitioning, it is necessary to append to the `CREATE TABLE` statement a `PARTITION BY HASH (expr)` clause, where `expr` is an expression that returns an integer. This can simply be the name of a column whose type is one of MySQL's integer types. In addition, you will most likely want to follow this with a `PARTITIONS num` clause, where `num` is a positive integer representing the number of partitions into which the table is to be divided.

For example, the following statement creates a table that uses hashing on the `store_id` column and is divided into 4 partitions:

```
CREATE TABLE employees (
  id INT NOT NULL,
  fname VARCHAR(30),
  lname VARCHAR(30),
  hired DATE NOT NULL DEFAULT '1970-01-01',
  separated DATE NOT NULL DEFAULT '9999-12-31',
  job_code INT,
  store_id INT
)
PARTITION BY HASH(store_id)
PARTITIONS 4;
```

If you do not include a `PARTITIONS` clause, the number of partitions defaults to 1.

Using the `PARTITIONS` keyword without a number following it results in a syntax error.

You can also use an SQL expression that returns an integer for `expr`. For instance, you might want to partition based on the year in which an employee was hired. This can be done as shown here:

```
CREATE TABLE employees (
  id INT NOT NULL,
  fname VARCHAR(30),
  lname VARCHAR(30),
  hired DATE NOT NULL DEFAULT '1970-01-01',
  separated DATE NOT NULL DEFAULT '9999-12-31',
  job_code INT,
  store_id INT
)
PARTITION BY HASH( YEAR(hired) )
PARTITIONS 4;
```

`expr` must return a non-constant, non-random integer value (in other words, it should be varying but deterministic), and must not contain any prohibited constructs as described in [Section 18.5, “Restrictions and Limitations on Partitioning”](#). You should also keep in mind that this expression is evaluated each time a row is inserted or updated (or possibly deleted); this means that very complex expressions may give rise to performance issues, particularly when performing operations (such as batch inserts) that affect a great many rows at one time.

The most efficient hashing function is one which operates upon a single table column and whose value increases or decreases consistently with the column value, as this allows for “pruning” on ranges of partitions. That is, the more closely that the expression varies with the value of the column on which it is based, the more efficiently MySQL can use the expression for hash partitioning.

For example, where `date_col` is a column of type `DATE`, then the expression `TO_DAYS(date_col)` is said to vary directly with the value of `date_col`, because for every change in the value of `date_col`, the value of the expression changes in a consistent manner. The variance of the expression `YEAR(date_col)` with respect to `date_col` is not quite as direct as that of `TO_DAYS(date_col)`, because not every possible change in `date_col` produces an equivalent change in `YEAR(date_col)`. Even so, `YEAR(date_col)` is a good candidate for a hashing function, because it varies directly with a portion of `date_col` and there is no possible change in `date_col` that produces a disproportionate change in `YEAR(date_col)`.

By way of contrast, suppose that you have a column named `int_col` whose type is `INT`. Now consider the expression `POW(5-int_col,3) + 6`. This would be a poor choice for a hashing function because a change in the value of `int_col` is not guaranteed to produce a proportional change in the value of the expression. Changing the value of `int_col` by a given amount can produce by widely different changes in the value of the expression. For example, changing `int_col` from 5 to 6 produces a change of `-1` in the value of the expression, but changing the value of `int_col` from 6 to 7 produces a change of `-7` in the expression value.

In other words, the more closely the graph of the column value *versus* the value of the expression follows a straight line as traced

by the equation $y=nx$ where n is some nonzero constant, the better the expression is suited to hashing. This has to do with the fact that the more nonlinear an expression is, the more uneven the distribution of data among the partitions it tends to produce.

In theory, pruning is also possible for expressions involving more than one column value, but determining which of such expressions are suitable can be quite difficult and time-consuming. For this reason, the use of hashing expressions involving multiple columns is not particularly recommended.

When `PARTITION BY HASH` is used, MySQL determines which partition of num partitions to use based on the modulus of the result of the user function. In other words, for an expression $expr$, the partition in which the record is stored is partition number N , where $N = \text{MOD}(expr, num)$. For example, suppose table `t1` is defined as follows, so that it has 4 partitions:

```
CREATE TABLE t1 (col1 INT, col2 CHAR(5), col3 DATE)
PARTITION BY HASH( YEAR(col3) )
PARTITIONS 4;
```

If you insert a record into `t1` whose `col3` value is `'2005-09-15'`, then the partition in which it is stored is determined as follows:

```
MOD(YEAR('2005-09-01'),4)
= MOD(2005,4)
= 1
```

MySQL 5.1 also supports a variant of `HASH` partitioning known as *linear hashing* which employs a more complex algorithm for determining the placement of new rows inserted into the partitioned table. See [Section 18.2.3.1, “LINEAR HASH Partitioning”](#), for a description of this algorithm.

The user function is evaluated each time a record is inserted or updated. It may also — depending on the circumstances — be evaluated when records are deleted.

Note

If a table to be partitioned has a `UNIQUE` key, then any columns supplied as arguments to the `HASH` user function or to the `KEY`'s `column_list` must be part of that key.

18.2.3.1. LINEAR HASH Partitioning

MySQL also supports linear hashing, which differs from regular hashing in that linear hashing utilizes a linear powers-of-two algorithm whereas regular hashing employs the modulus of the hashing function's value.

Syntactically, the only difference between linear-hash partitioning and regular hashing is the addition of the `LINEAR` keyword in the `PARTITION BY` clause, as shown here:

```
CREATE TABLE employees (
  id INT NOT NULL,
  fname VARCHAR(30),
  lname VARCHAR(30),
  hired DATE NOT NULL DEFAULT '1970-01-01',
  separated DATE NOT NULL DEFAULT '9999-12-31',
  job_code INT,
  store_id INT
)
PARTITION BY LINEAR HASH( YEAR(hired) )
PARTITIONS 4;
```

Given an expression $expr$, the partition in which the record is stored when linear hashing is used is partition number N from among num partitions, where N is derived according to the following algorithm:

1. Find the next power of 2 greater than num . We call this value V ; it can be calculated as:

```
V = POWER(2, CEILING(LOG(2, num)))
```

(For example, suppose that num is 13. Then $\text{LOG}(2, 13)$ is 3.7004397181411. $\text{CEILING}(3.7004397181411)$ is 4, and $V = \text{POWER}(2, 4)$, which is 16.)

2. Set $N = F(\text{column_list}) \& (V - 1)$.
3. While $N \geq num$:
 - Set $V = \text{CEIL}(V / 2)$
 - Set $N = N \& (V - 1)$

For example, suppose that the table `t1`, using linear hash partitioning and having 6 partitions, is created using this statement:

```
CREATE TABLE t1 (col1 INT, col2 CHAR(5), col3 DATE)
PARTITION BY LINEAR HASH( YEAR(col3) )
PARTITIONS 6;
```

Now assume that you want to insert two records into `t1` having the `col3` column values `'2003-04-14'` and `'1998-10-19'`. The partition number for the first of these is determined as follows:

```
V = POWER(2, CEILING( LOG(2,6) )) = 8
N = YEAR('2003-04-14') & (8 - 1)
  = 2003 & 7
  = 3
(3 >= 6 is FALSE: record stored in partition #3)
```

The number of the partition where the second record is stored is calculated as shown here:

```
V = 8
N = YEAR('1998-10-19') & (8-1)
  = 1998 & 7
  = 6
(6 >= 6 is TRUE: additional step required)
N = 6 & CEILING(8 / 2)
  = 6 & 3
  = 2
(2 >= 6 is FALSE: record stored in partition #2)
```

The advantage in partitioning by linear hash is that the adding, dropping, merging, and splitting of partitions is made much faster, which can be beneficial when dealing with tables containing extremely large amounts (terabytes) of data. The disadvantage is that data is less likely to be evenly distributed between partitions as compared with the distribution obtained using regular hash partitioning.

18.2.4. KEY Partitioning

Partitioning by key is similar to partitioning by hash, except that where hash partitioning employs a user-defined expression, the hashing function for key partitioning is supplied by the MySQL server. MySQL Cluster uses `MD5()` for this purpose; for tables using other storage engines, the server employs its own internal hashing function which is based on the same algorithm as `PASS-WORD()`.

The syntax rules for `CREATE TABLE ... PARTITION BY KEY` are similar to those for creating a table that is partitioned by hash. The major differences are that:

- `KEY` is used rather than `HASH`.
- `KEY` takes only a list of one or more column names. Beginning with MySQL 5.1.5, the column or columns used as the partitioning key must comprise part or all of the table's primary key, if the table has one.

Beginning with MySQL 5.1.6, `KEY` takes a list of zero or more column names. Where no column name is specified as the partitioning key, the table's primary key is used, if there is one. For example, the following `CREATE TABLE` statement is valid in MySQL 5.1.6 or later:

```
CREATE TABLE k1 (
  id INT NOT NULL PRIMARY KEY,
  name VARCHAR(20)
)
PARTITION BY KEY()
PARTITIONS 2;
```

If there is no primary key but there is a unique key, then the unique key is used for the partitioning key:

```
CREATE TABLE k1 (
  id INT NOT NULL,
  name VARCHAR(20),
  UNIQUE KEY (id)
)
PARTITION BY KEY()
PARTITIONS 2;
```

However, if the unique key column were not defined as `NOT NULL`, then the previous statement would fail.

In both of these cases, the partitioning key is the `id` column, even though it is not shown in the output of `SHOW CREATE TABLE` or in the `PARTITION_EXPRESSION` column of the `INFORMATION_SCHEMA.PARTITIONS` table.

Unlike the case with other partitioning types, columns used for partitioning by **KEY** are not restricted to integer or **NULL** values. For example, the following **CREATE TABLE** statement is valid:

```
CREATE TABLE tml (
  s1 CHAR(32) PRIMARY KEY
)
PARTITION BY KEY(s1)
PARTITIONS 10;
```

The preceding statement would *not* be valid, were a different partitioning type to be specified.

Note

In this case, simply using **PARTITION BY KEY()** would also be valid and have the same effect as **PARTITION BY KEY(s1)**, since **s1** is the table's primary key.

For additional information about this issue, see [Section 18.5, “Restrictions and Limitations on Partitioning”](#).

Note

Also beginning with MySQL 5.1.6, tables using the **NDBCLUSTER** storage engine are implicitly partitioned by **KEY**, again using the table's primary key as the partitioning key. In the event that the MySQL Cluster table has no explicit primary key, the “hidden” primary key generated by the **NDBCLUSTER** storage engine for each MySQL Cluster table is used as the partitioning key.

Beginning with MySQL Cluster NDB 6.2.18, MySQL Cluster NDB 6.3.25, and MySQL Cluster NDB 7.0.6, if you define an explicit partitioning scheme for an **NDBCLUSTER** table, the table must have an explicit primary key, and any columns used in the partitioning expression must be part of this key. However, if the table uses an “empty” partitioning expression — that is, **PARTITION BY KEY()** with no column references — then no explicit primary key is required.

Important

For a key-partitioned table using any MySQL storage engine other than **NDBCLUSTER**, you cannot execute an **ALTER TABLE DROP PRIMARY KEY**, as doing so generates the error **ERROR 1466 (HY000): FIELD IN LIST OF FIELDS FOR PARTITION FUNCTION NOT FOUND IN TABLE**. This is not an issue for MySQL Cluster tables which are partitioned by **KEY**; in such cases, the table is reorganized using the “hidden” primary key as the table's new partitioning key. See [Chapter 17, *MySQL Cluster NDB 6.X/7.X*](#).

It is also possible to partition a table by linear key. Here is a simple example:

```
CREATE TABLE tk (
  col1 INT NOT NULL,
  col2 CHAR(5),
  col3 DATE
)
PARTITION BY LINEAR KEY (col1)
PARTITIONS 3;
```

Using **LINEAR** has the same effect on **KEY** partitioning as it does on **HASH** partitioning, with the partition number being derived using a powers-of-two algorithm rather than modulo arithmetic. See [Section 18.2.3.1, “LINEAR HASH Partitioning”](#), for a description of this algorithm and its implications.

18.2.5. Subpartitioning

Subpartitioning — also known as *composite partitioning* — is the further division of each partition in a partitioned table. For example, consider the following **CREATE TABLE** statement:

```
CREATE TABLE ts (id INT, purchased DATE)
PARTITION BY RANGE( YEAR(purchased) )
SUBPARTITION BY HASH( TO_DAYS(purchased) )
SUBPARTITIONS 2 (
  PARTITION p0 VALUES LESS THAN (1990),
  PARTITION p1 VALUES LESS THAN (2000),
  PARTITION p2 VALUES LESS THAN MAXVALUE
);
```

Table **ts** has 3 **RANGE** partitions. Each of these partitions — **p0**, **p1**, and **p2** — is further divided into 2 subpartitions. In effect, the entire table is divided into $3 * 2 = 6$ partitions. However, due to the action of the **PARTITION BY RANGE** clause, the first 2 of these store only those records with a value less than 1990 in the **purchased** column.

In MySQL 5.1, it is possible to subpartition tables that are partitioned by [RANGE](#) or [LIST](#). Subpartitions may use either [HASH](#) or [KEY](#) partitioning. This is also known as *composite partitioning*.

It is also possible to define subpartitions explicitly using [SUBPARTITION](#) clauses to specify options for individual subpartitions. For example, a more verbose fashion of creating the same table `ts` as shown in the previous example would be:

```
CREATE TABLE ts (id INT, purchased DATE)
PARTITION BY RANGE( YEAR(purchased) )
SUBPARTITION BY HASH( TO_DAYS(purchased) ) (
  PARTITION p0 VALUES LESS THAN (1990) (
    SUBPARTITION s0,
    SUBPARTITION s1
  ),
  PARTITION p1 VALUES LESS THAN (2000) (
    SUBPARTITION s2,
    SUBPARTITION s3
  ),
  PARTITION p2 VALUES LESS THAN MAXVALUE (
    SUBPARTITION s4,
    SUBPARTITION s5
  )
);
```

Some syntactical items of note:

- Each partition must have the same number of subpartitions.
- If you explicitly define any subpartitions using [SUBPARTITION](#) on any partition of a partitioned table, you must define them all. In other words, the following statement will fail:

```
CREATE TABLE ts (id INT, purchased DATE)
PARTITION BY RANGE( YEAR(purchased) )
SUBPARTITION BY HASH( TO_DAYS(purchased) ) (
  PARTITION p0 VALUES LESS THAN (1990) (
    SUBPARTITION s0,
    SUBPARTITION s1
  ),
  PARTITION p1 VALUES LESS THAN (2000),
  PARTITION p2 VALUES LESS THAN MAXVALUE (
    SUBPARTITION s2,
    SUBPARTITION s3
  )
);
```

This statement would still fail even if it included a [SUBPARTITIONS 2](#) clause.

- Each [SUBPARTITION](#) clause must include (at a minimum) a name for the subpartition. Otherwise, you may set any desired option for the subpartition or allow it to assume its default setting for that option.
- In MySQL 5.1.7 and earlier, names of subpartitions were required to be unique within each partition, but did not have to be unique within the table as a whole. Beginning with MySQL 5.1.8, subpartition names must be unique across the entire table. For example, the following [CREATE TABLE](#) statement is valid in MySQL 5.1.8 and later:

```
CREATE TABLE ts (id INT, purchased DATE)
PARTITION BY RANGE( YEAR(purchased) )
SUBPARTITION BY HASH( TO_DAYS(purchased) ) (
  PARTITION p0 VALUES LESS THAN (1990) (
    SUBPARTITION s0,
    SUBPARTITION s1
  ),
  PARTITION p1 VALUES LESS THAN (2000) (
    SUBPARTITION s2,
    SUBPARTITION s3
  ),
  PARTITION p2 VALUES LESS THAN MAXVALUE (
    SUBPARTITION s4,
    SUBPARTITION s5
  )
);
```

(The previous statement is also valid for versions of MySQL prior to 5.1.8.)

Subpartitions can be used with especially large tables to distribute data and indexes across many disks. Suppose that you have 6 disks mounted as `/disk0`, `/disk1`, `/disk2`, and so on. Now consider the following example:

```
CREATE TABLE ts (id INT, purchased DATE)
PARTITION BY RANGE( YEAR(purchased) )
SUBPARTITION BY HASH( TO_DAYS(purchased) ) (
  PARTITION p0 VALUES LESS THAN (1990) (
    SUBPARTITION s0
    DATA DIRECTORY = '/disk0/data'
    INDEX DIRECTORY = '/disk0/idx',
```

```

        SUBPARTITION s1
          DATA DIRECTORY = '/disk1/data'
          INDEX DIRECTORY = '/disk1/idx'
      ),
      PARTITION p1 VALUES LESS THAN (2000) (
        SUBPARTITION s2
          DATA DIRECTORY = '/disk2/data'
          INDEX DIRECTORY = '/disk2/idx',
        SUBPARTITION s3
          DATA DIRECTORY = '/disk3/data'
          INDEX DIRECTORY = '/disk3/idx'
      ),
      PARTITION p2 VALUES LESS THAN MAXVALUE (
        SUBPARTITION s4
          DATA DIRECTORY = '/disk4/data'
          INDEX DIRECTORY = '/disk4/idx',
        SUBPARTITION s5
          DATA DIRECTORY = '/disk5/data'
          INDEX DIRECTORY = '/disk5/idx'
      )
  );

```

In this case, a separate disk is used for the data and for the indexes of each [RANGE](#). Many other variations are possible; another example might be:

```

CREATE TABLE ts (id INT, purchased DATE)
PARTITION BY RANGE(YEAR(purchased))
SUBPARTITION BY HASH( TO_DAYS(purchased) ) (
  PARTITION p0 VALUES LESS THAN (1990) (
    SUBPARTITION s0a
      DATA DIRECTORY = '/disk0'
      INDEX DIRECTORY = '/disk1',
    SUBPARTITION s0b
      DATA DIRECTORY = '/disk2'
      INDEX DIRECTORY = '/disk3'
  ),
  PARTITION p1 VALUES LESS THAN (2000) (
    SUBPARTITION s1a
      DATA DIRECTORY = '/disk4/data'
      INDEX DIRECTORY = '/disk4/idx',
    SUBPARTITION s1b
      DATA DIRECTORY = '/disk5/data'
      INDEX DIRECTORY = '/disk5/idx'
  ),
  PARTITION p2 VALUES LESS THAN MAXVALUE (
    SUBPARTITION s2a,
    SUBPARTITION s2b
  )
);

```

Here, the storage is as follows:

- Rows with [purchased](#) dates from before 1990 take up a vast amount of space, so are split up 4 ways, with a separate disk dedicated to the data and to the indexes for each of the two subpartitions ([s0a](#) and [s0b](#)) making up partition [p0](#). In other words:
 - The data for subpartition [s0a](#) is stored on [/disk0](#).
 - The indexes for subpartition [s0a](#) are stored on [/disk1](#).
 - The data for subpartition [s0b](#) is stored on [/disk2](#).
 - The indexes for subpartition [s0b](#) are stored on [/disk3](#).
- Rows containing dates ranging from 1990 to 1999 (partition [p1](#)) do not require as much room as those from before 1990. These are split between 2 disks ([/disk4](#) and [/disk5](#)) rather than 4 disks as with the legacy records stored in [p0](#):
 - Data and indexes belonging to [p1](#)'s first subpartition ([s1a](#)) are stored on [/disk4](#) — the data in [/disk4/data](#), and the indexes in [/disk4/idx](#).
 - Data and indexes belonging to [p1](#)'s second subpartition ([s1b](#)) are stored on [/disk5](#) — the data in [/disk5/data](#), and the indexes in [/disk5/idx](#).
- Rows reflecting dates from the year 2000 to the present (partition [p2](#)) do not take up as much space as required by either of the two previous ranges. Currently, it is sufficient to store all of these in the default location.

In future, when the number of purchases for the decade beginning with the year 2000 grows to a point where the default location no longer provides sufficient space, the corresponding rows can be moved using an `ALTER TABLE ... REORGANIZE PARTITION` statement. See [Section 18.3, “Partition Management”](#), for an explanation of how this can be done.

Beginning with MySQL 5.1.18, the `DATA DIRECTORY` and `INDEX DIRECTORY` options are disallowed when the `NO_DIR_IN_CREATE` server SQL mode is in effect. This is true for partitions and subpartitions.

18.2.6. How MySQL Partitioning Handles `NULL`

Partitioning in MySQL does nothing to disallow `NULL` as the value of a partitioning expression, whether it is a column value or the value of a user-supplied expression. Even though it is permitted to use `NULL` as the value of an expression that must otherwise yield an integer, it is important to keep in mind that `NULL` is not a number. Beginning with MySQL 5.1.8, the partitioning implementation treats `NULL` as being less than any non-`NULL` value, just as `ORDER BY` does.

This means that treatment of `NULL` varies between partitioning of different types, and may produce behavior which you do not expect if you are not prepared for it. This being the case, we discuss in this section how each MySQL partitioning type handles `NULL` values when determining the partition in which a row should be stored, and provide examples for each.

Handling of `NULL` with `RANGE` partitioning. If you insert a row into a table partitioned by `RANGE` such that the column value used to determine the partition is `NULL`, the row is inserted into the lowest partition. For example, consider these two tables in a database named `p`, created as follows:

```
mysql> CREATE TABLE t1 (
->   c1 INT,
->   c2 VARCHAR(20)
-> )
-> PARTITION BY RANGE(c1) (
->   PARTITION p0 VALUES LESS THAN (0),
->   PARTITION p1 VALUES LESS THAN (10),
->   PARTITION p2 VALUES LESS THAN MAXVALUE
-> );
Query OK, 0 rows affected (0.09 sec)

mysql> CREATE TABLE t2 (
->   c1 INT,
->   c2 VARCHAR(20)
-> )
-> PARTITION BY RANGE(c1) (
->   PARTITION p0 VALUES LESS THAN (-5),
->   PARTITION p1 VALUES LESS THAN (0),
->   PARTITION p2 VALUES LESS THAN (10),
->   PARTITION p3 VALUES LESS THAN MAXVALUE
-> );
Query OK, 0 rows affected (0.09 sec)
```

You can see the partitions created by these two `CREATE TABLE` statements using the following query against the `PARTITIONS` table in the `INFORMATION_SCHEMA` database:

```
mysql> SELECT TABLE_NAME, PARTITION_NAME, TABLE_ROWS, AVG_ROW_LENGTH, DATA_LENGTH
> FROM INFORMATION_SCHEMA.PARTITIONS
> WHERE TABLE_SCHEMA = 'p' AND TABLE_NAME LIKE 't_';
```

TABLE_NAME	PARTITION_NAME	TABLE_ROWS	AVG_ROW_LENGTH	DATA_LENGTH
t1	p0	0	0	0
t1	p1	0	0	0
t1	p2	0	0	0
t2	p0	0	0	0
t2	p1	0	0	0
t2	p2	0	0	0
t2	p3	0	0	0

7 rows in set (0.00 sec)

(For more information about this table, see [Section 20.19, “The `INFORMATION_SCHEMA PARTITIONS` Table”](#).) Now let us populate each of these tables with a single row containing a `NULL` in the column used as the partitioning key, and verify that the rows were inserted using a pair of `SELECT` statements:

```
mysql> INSERT INTO t1 VALUES (NULL, 'mothra');
Query OK, 1 row affected (0.00 sec)

mysql> INSERT INTO t2 VALUES (NULL, 'mothra');
Query OK, 1 row affected (0.00 sec)

mysql> SELECT * FROM t1;
+----+-----+
| id | name |
+----+-----+
| NULL | mothra |
+----+-----+
1 row in set (0.00 sec)

mysql> SELECT * FROM t2;
+----+-----+
| id | name |
+----+-----+
| NULL | mothra |
+----+-----+
1 row in set (0.00 sec)
```

You can see which partitions are used to store the inserted rows by rerunning the previous query against `INFORMATION_SCHEMA.PARTITIONS` and inspecting the output:

```
mysql> SELECT TABLE_NAME, PARTITION_NAME, TABLE_ROWS, AVG_ROW_LENGTH, DATA_LENGTH
> FROM INFORMATION_SCHEMA.PARTITIONS
> WHERE TABLE_SCHEMA = 'p' AND TABLE_NAME LIKE 't_';
```

TABLE_NAME	PARTITION_NAME	TABLE_ROWS	AVG_ROW_LENGTH	DATA_LENGTH
t1	p0	1	20	20
t1	p1	0	0	0
t1	p2	0	0	0
t2	p0	1	20	20
t2	p1	0	0	0
t2	p2	0	0	0
t2	p3	0	0	0

7 rows in set (0.01 sec)

You can also demonstrate that these rows were stored in the lowest partition of each table by dropping these partitions, and then rerunning the `SELECT` statements:

```
mysql> ALTER TABLE t1 DROP PARTITION p0;
Query OK, 0 rows affected (0.16 sec)

mysql> ALTER TABLE t2 DROP PARTITION p0;
Query OK, 0 rows affected (0.16 sec)

mysql> SELECT * FROM t1;
Empty set (0.00 sec)

mysql> SELECT * FROM t2;
Empty set (0.00 sec)
```

(For more information on `ALTER TABLE ... DROP PARTITION`, see [Section 12.1.7, “ALTER TABLE Syntax”](#).)

Important

Prior to MySQL 5.1.8, `RANGE` partitioning treated a partitioning expression value of `NULL` as 0 with respect to determining placement. (The only way to circumvent this behavior was to design tables so as not to allow nulls, usually by declaring columns `NOT NULL`.) If you have a `RANGE` partitioning scheme that depends on this earlier behavior, you must re-implement it when upgrading to MySQL 5.1.8 or later. ([Bug#15447](#))

`NULL` is also treated in this way for partitioning expressions that use SQL functions. Suppose that we define a table using a `CREATE TABLE` statement such as this one:

```
CREATE TABLE tndate (
  id INT,
  dt DATE
)
PARTITION BY RANGE( YEAR(dt) ) (
  PARTITION p0 VALUES LESS THAN (1990),
  PARTITION p1 VALUES LESS THAN (2000),
  PARTITION p2 VALUES LESS THAN MAXVALUE
);
```

As with other MySQL functions, `YEAR(NULL)` returns `NULL`. A row with a `dt` column value of `NULL` is treated as though the partitioning expression evaluated to a value less than any other value, and so is inserted into partition `p0`.

Handling of `NULL` with `LIST` partitioning. A table that is partitioned by `LIST` admits `NULL` values if and only if one of its partitions is defined using that value-list that contains `NULL`. The converse of this is that a table partitioned by `LIST` which does not explicitly use `NULL` in a value list rejects rows resulting in a `NULL` value for the partitioning expression, as shown in this example:

```
mysql> CREATE TABLE ts1 (
->   c1 INT,
->   c2 VARCHAR(20)
-> )
-> PARTITION BY LIST(c1) (
->   PARTITION p0 VALUES IN (0, 3, 6),
->   PARTITION p1 VALUES IN (1, 4, 7),
->   PARTITION p2 VALUES IN (2, 5, 8)
-> );
Query OK, 0 rows affected (0.01 sec)

mysql> INSERT INTO ts1 VALUES (9, 'mothra');
ERROR 1504 (HY000): TABLE HAS NO PARTITION FOR VALUE 9

mysql> INSERT INTO ts1 VALUES (NULL, 'mothra');
ERROR 1504 (HY000): TABLE HAS NO PARTITION FOR VALUE NULL
```

Only rows having a `c1` value between 0 and 8 inclusive can be inserted into `ts1`. `NULL` falls outside this range, just like the number 9. We can create tables `ts2` and `ts3` having value lists containing `NULL`, as shown here:

```
mysql> CREATE TABLE ts2 (
->   c1 INT,
->   c2 VARCHAR(20)
-> )
-> PARTITION BY LIST(c1) (
```

```

-> PARTITION p0 VALUES IN (0, 3, 6),
-> PARTITION p1 VALUES IN (1, 4, 7),
-> PARTITION p2 VALUES IN (2, 5, 8),
-> PARTITION p3 VALUES IN (NULL)
-> );
Query OK, 0 rows affected (0.01 sec)

mysql> CREATE TABLE ts3 (
->   c1 INT,
->   c2 VARCHAR(20)
-> )
-> PARTITION BY LIST(c1) (
->   PARTITION p0 VALUES IN (0, 3, 6),
->   PARTITION p1 VALUES IN (1, 4, 7, NULL),
->   PARTITION p2 VALUES IN (2, 5, 8)
-> );
Query OK, 0 rows affected (0.01 sec)

```

When defining value lists for partitioning, you can (and should) treat `NULL` just as you would any other value. For example, both `VALUES IN (NULL)` and `VALUES IN (1, 4, 7, NULL)` are valid, as are `VALUES IN (1, NULL, 4, 7)`, `VALUES IN (NULL, 1, 4, 7)`, and so on. You can insert a row having `NULL` for column `c1` into each of the tables `ts2` and `ts3`:

```

mysql> INSERT INTO ts2 VALUES (NULL, 'mothra');
Query OK, 1 row affected (0.00 sec)

mysql> INSERT INTO ts3 VALUES (NULL, 'mothra');
Query OK, 1 row affected (0.00 sec)

```

By issuing the appropriate query against `INFORMATION_SCHEMA.PARTITIONS`, you can determine which partitions were used to store the rows just inserted (we assume, as in the previous examples, that the partitioned tables were created in the `p` database):

```

mysql> SELECT TABLE_NAME, PARTITION_NAME, TABLE_ROWS, AVG_ROW_LENGTH, DATA_LENGTH
> FROM INFORMATION_SCHEMA.PARTITIONS
> WHERE TABLE_SCHEMA = 'p' AND TABLE_NAME LIKE 'ts_';

```

TABLE_NAME	PARTITION_NAME	TABLE_ROWS	AVG_ROW_LENGTH	DATA_LENGTH
ts2	p0	0	0	0
ts2	p1	0	0	0
ts2	p2	0	0	0
ts2	p3	1	20	20
ts3	p0	0	0	0
ts3	p1	1	20	20
ts3	p2	0	0	0

7 rows in set (0.01 sec)

As shown earlier in this section, you can also verify which partitions were used for storing the rows by deleting these partitions and then performing a `SELECT`.

Handling of `NULL` with `HASH` and `KEY` partitioning. `NULL` is handled somewhat differently for tables partitioned by `HASH` or `KEY`. In these cases, any partition expression that yields a `NULL` value is treated as though its return value were zero. We can verify this behavior by examining the effects on the file system of creating a table partitioned by `HASH` and populating it with a record containing appropriate values. Suppose that you have a table `th` (also in the `p` database) created using the following statement:

```

mysql> CREATE TABLE th (
->   c1 INT,
->   c2 VARCHAR(20)
-> )
-> PARTITION BY HASH(c1)
-> PARTITIONS 2;
Query OK, 0 rows affected (0.00 sec)

```

The partitions belonging to this table can be viewed like this:

```

mysql> SELECT TABLE_NAME, PARTITION_NAME, TABLE_ROWS, AVG_ROW_LENGTH, DATA_LENGTH
> FROM INFORMATION_SCHEMA.PARTITIONS
> WHERE TABLE_SCHEMA = 'p' AND TABLE_NAME = 'th';

```

TABLE_NAME	PARTITION_NAME	TABLE_ROWS	AVG_ROW_LENGTH	DATA_LENGTH
th	p0	0	0	0
th	p1	0	0	0

2 rows in set (0.00 sec)

Note that `TABLE_ROWS` for each partition is 0. Now insert two rows into `th` whose `c1` column values are `NULL` and 0, and verify that these rows were inserted:

```

mysql> INSERT INTO th VALUES (NULL, 'mothra'), (0, 'gigan');
Query OK, 1 row affected (0.00 sec)

mysql> SELECT * FROM th;

```

c1	c2
NULL	mothra
0	gigan

```
+-----+-----+
2 rows in set (0.01 sec)
```

Recall that for any integer N , the value of `NULL MOD N` is always `NULL`. For tables that are partitioned by `HASH` or `KEY`, this result is treated for determining the correct partition as `0`. Checking the `INFORMATION_SCHEMA.PARTITIONS` table once again, we can see that both rows were inserted into partition `p0`:

```
mysql> SELECT TABLE_NAME, PARTITION_NAME, TABLE_ROWS, AVG_ROW_LENGTH, DATA_LENGTH
> FROM INFORMATION_SCHEMA.PARTITIONS
> WHERE TABLE_SCHEMA = 'p' AND TABLE_NAME = 'th';
```

TABLE_NAME	PARTITION_NAME	TABLE_ROWS	AVG_ROW_LENGTH	DATA_LENGTH
th	p0	2	20	20
th	p1	0	0	0

```
2 rows in set (0.00 sec)
```

If you repeat this example using `PARTITION BY KEY` in place of `PARTITION BY HASH` in the definition of the table, you can verify easily that `NULL` is also treated like `0` for this type of partitioning as well.

18.3. Partition Management

MySQL 5.1 provides a number of ways to modify partitioned tables. It is possible to add, drop, redefine, merge, or split existing partitions. All of these actions can be carried out using the partitioning extensions to the `ALTER TABLE` command (see [Section 12.1.7, “ALTER TABLE Syntax”](#), for syntax definitions). There are also ways to obtain information about partitioned tables and partitions. We discuss these topics in the sections that follow.

- For information about partition management in tables partitioned by `RANGE` or `LIST`, see [Section 18.3.1, “Management of RANGE and LIST Partitions”](#).
- For a discussion of managing `HASH` and `KEY` partitions, see [Section 18.3.2, “Management of HASH and KEY Partitions”](#).
- See [Section 18.3.4, “Obtaining Information About Partitions”](#), for a discussion of mechanisms provided in MySQL 5.1 for obtaining information about partitioned tables and partitions.
- For a discussion of performing maintenance operations on partitions, see [Section 18.3.3, “Maintenance of Partitions”](#).

Note

In MySQL 5.1, all partitions of a partitioned table must have the same number of subpartitions, and it is not possible to change the subpartitioning once the table has been created.

The statement `ALTER TABLE ... PARTITION BY ...` is available and is functional beginning with MySQL 5.1.6; previously in MySQL 5.1, this was accepted as valid syntax, but the statement did nothing.

To change a table's partitioning scheme, it is necessary only to use the `ALTER TABLE` command with a `partition_options` clause. This clause has the same syntax as that as used with `CREATE TABLE` for creating a partitioned table, and always begins with the keywords `PARTITION BY`. For example, suppose that you have a table partitioned by range using the following `CREATE TABLE` statement:

```
CREATE TABLE trb3 (id INT, name VARCHAR(50), purchased DATE)
PARTITION BY RANGE( YEAR(purchased) ) (
PARTITION p0 VALUES LESS THAN (1990),
PARTITION p1 VALUES LESS THAN (1995),
PARTITION p2 VALUES LESS THAN (2000),
PARTITION p3 VALUES LESS THAN (2005)
);
```

To repartition this table so that it is partitioned by key into two partitions using the `id` column value as the basis for the key, you can use this statement:

```
ALTER TABLE trb3 PARTITION BY KEY(id) PARTITIONS 2;
```

This has the same effect on the structure of the table as dropping the table and re-creating it using `CREATE TABLE trb3 PARTITION BY KEY(id) PARTITIONS 2;`.

In MySQL 5.1.7 and earlier MySQL 5.1 releases, `ALTER TABLE ... ENGINE = ...` removed all partitioning from the affected table. Beginning with MySQL 5.1.8, this statement changes only the storage engine used by the table, and leaves the table's partitioning scheme intact. As of MySQL 5.1.8, use `ALTER TABLE ... REMOVE PARTITIONING` to remove a table's partitioning. See [Section 12.1.7, “ALTER TABLE Syntax”](#).

Important

Only a single `PARTITION BY`, `ADD PARTITION`, `DROP PARTITION`, `REORGANIZE PARTITION`, or `COALESCE PARTITION` clause can be used in a given `ALTER TABLE` statement. If you (for example) wish to drop a partition and reorganize a table's remaining partitions, you must do so in two separate `ALTER TABLE` statements (one using `DROP PARTITION` and then a second one using `REORGANIZE PARTITIONS`).

18.3.1. Management of `RANGE` and `LIST` Partitions

Range and list partitions are very similar with regard to how the adding and dropping of partitions are handled. For this reason we discuss the management of both sorts of partitioning in this section. For information about working with tables that are partitioned by hash or key, see [Section 18.3.2, “Management of `HASH` and `KEY` Partitions”](#). Dropping a `RANGE` or `LIST` partition is more straightforward than adding one, so we discuss this first.

Dropping a partition from a table that is partitioned by either `RANGE` or by `LIST` can be accomplished using the `ALTER TABLE` statement with a `DROP PARTITION` clause. Here is a very basic example, which supposes that you have already created a table which is partitioned by range and then populated with 10 records using the following `CREATE TABLE` and `INSERT` statements:

```
mysql> CREATE TABLE tr (id INT, name VARCHAR(50), purchased DATE)
-> PARTITION BY RANGE( YEAR(purchased) ) (
-> PARTITION p0 VALUES LESS THAN (1990),
-> PARTITION p1 VALUES LESS THAN (1995),
-> PARTITION p2 VALUES LESS THAN (2000),
-> PARTITION p3 VALUES LESS THAN (2005)
-> );
Query OK, 0 rows affected (0.01 sec)

mysql> INSERT INTO tr VALUES
-> (1, 'desk organiser', '2003-10-15'),
-> (2, 'CD player', '1993-11-05'),
-> (3, 'TV set', '1996-03-10'),
-> (4, 'bookcase', '1982-01-10'),
-> (5, 'exercise bike', '2004-05-09'),
-> (6, 'sofa', '1987-06-05'),
-> (7, 'popcorn maker', '2001-11-22'),
-> (8, 'aquarium', '1992-08-04'),
-> (9, 'study desk', '1984-09-16'),
-> (10, 'lava lamp', '1998-12-25');
Query OK, 10 rows affected (0.01 sec)
```

You can see which items should have been inserted into partition `p2` as shown here:

```
mysql> SELECT * FROM tr
-> WHERE purchased BETWEEN '1995-01-01' AND '1999-12-31';
+-----+-----+-----+
| id | name | purchased |
+-----+-----+-----+
| 3 | TV set | 1996-03-10 |
| 10 | lava lamp | 1998-12-25 |
+-----+-----+-----+
2 rows in set (0.00 sec)
```

To drop the partition named `p2`, execute the following command:

```
mysql> ALTER TABLE tr DROP PARTITION p2;
Query OK, 0 rows affected (0.03 sec)
```

Note

The `NDBCLUSTER` storage engine does not support `ALTER TABLE ... DROP PARTITION`. It does, however, support the other partitioning-related extensions to `ALTER TABLE` that are described in this chapter.

It is very important to remember that, *when you drop a partition, you also delete all the data that was stored in that partition*. You can see that this is the case by re-running the previous `SELECT` query:

```
mysql> SELECT * FROM tr WHERE purchased
-> BETWEEN '1995-01-01' AND '1999-12-31';
Empty set (0.00 sec)
```

Because of this, the requirement was added in MySQL 5.1.10 that you have the `DROP` privilege for a table before you can execute `ALTER TABLE ... DROP PARTITION` on that table.

If you wish to drop all data from all partitions while preserving the table definition and its partitioning scheme, use the `TRUNCATE TABLE` command. (See [Section 12.2.10, “`TRUNCATE` Syntax”](#).)

If you intend to change the partitioning of a table *without* losing data, use `ALTER TABLE ... REORGANIZE PARTITION` instead. See below or in [Section 12.1.7, “`ALTER TABLE` Syntax”](#), for information about `REORGANIZE PARTITION`.

If you now execute a `SHOW CREATE TABLE` command, you can see how the partitioning makeup of the table has been changed:

```
mysql> SHOW CREATE TABLE tr\G
***** 1. row *****
Table: tr
Create Table: CREATE TABLE `tr` (
  `id` int(11) default NULL,
  `name` varchar(50) default NULL,
  `purchased` date default NULL
) ENGINE=MyISAM DEFAULT CHARSET=latin1
PARTITION BY RANGE ( YEAR(purchased) ) (
  PARTITION p0 VALUES LESS THAN (1990) ENGINE = MyISAM,
  PARTITION p1 VALUES LESS THAN (1995) ENGINE = MyISAM,
  PARTITION p3 VALUES LESS THAN (2005) ENGINE = MyISAM
)
1 row in set (0.01 sec)
```

When you insert new rows into the changed table with `purchased` column values between `'1995-01-01'` and `'2004-12-31'` inclusive, those rows will be stored in partition `p3`. You can verify this as follows:

```
mysql> INSERT INTO tr VALUES (11, 'pencil holder', '1995-07-12');
Query OK, 1 row affected (0.00 sec)

mysql> SELECT * FROM tr WHERE purchased
-> BETWEEN '1995-01-01' AND '2004-12-31';
+----+-----+-----+
| id | name       | purchased |
+----+-----+-----+
| 11 | pencil holder | 1995-07-12 |
| 1  | desk organiser | 2003-10-15 |
| 5  | exercise bike | 2004-05-09 |
| 7  | popcorn maker | 2001-11-22 |
+----+-----+-----+
4 rows in set (0.00 sec)

mysql> ALTER TABLE tr DROP PARTITION p3;
Query OK, 0 rows affected (0.03 sec)

mysql> SELECT * FROM tr WHERE purchased
-> BETWEEN '1995-01-01' AND '2004-12-31';
Empty set (0.00 sec)
```

Note that the number of rows dropped from the table as a result of `ALTER TABLE ... DROP PARTITION` is not reported by the server as it would be by the equivalent `DELETE` query.

Dropping `LIST` partitions uses exactly the same `ALTER TABLE ... DROP PARTITION` syntax as used for dropping `RANGE` partitions. However, there is one important difference in the effect this has on your use of the table afterward: You can no longer insert into the table any rows having any of the values that were included in the value list defining the deleted partition. (See [Section 18.2.2, "LIST Partitioning"](#), for an example.)

To add a new range or list partition to a previously partitioned table, use the `ALTER TABLE ... ADD PARTITION` statement. For tables which are partitioned by `RANGE`, this can be used to add a new range to the end of the list of existing partitions. For example, suppose that you have a partitioned table containing membership data for your organisation, which is defined as follows:

```
CREATE TABLE members (
  id INT,
  fname VARCHAR(25),
  lname VARCHAR(25),
  dob DATE
)
PARTITION BY RANGE( YEAR(dob) ) (
  PARTITION p0 VALUES LESS THAN (1970),
  PARTITION p1 VALUES LESS THAN (1980),
  PARTITION p2 VALUES LESS THAN (1990)
);
```

Suppose further that the minimum age for members is 16. As the calendar approaches the end of 2005, you realize that you will soon be admitting members who were born in 1990 (and later in years to come). You can modify the `members` table to accommodate new members born in the years 1990-1999 as shown here:

```
ALTER TABLE ADD PARTITION (PARTITION p3 VALUES LESS THAN (2000));
```

Important

With tables that are partitioned by range, you can use `ADD PARTITION` to add new partitions to the high end of the partitions list only. Trying to add a new partition in this manner between or before existing partitions will result in an error as shown here:

```
mysql> ALTER TABLE members
> ADD PARTITION (
> PARTITION p3 VALUES LESS THAN (1960));
ERROR 1463 (HY000): VALUES LESS THAN value must be strictly »
increasing for each partition
```

In a similar fashion, you can add new partitions to a table that is partitioned by `LIST`. For example, given a table defined like so:

```
CREATE TABLE tt (
  id INT,
  data INT
)
PARTITION BY LIST(data) (
  PARTITION p0 VALUES IN (5, 10, 15),
  PARTITION p1 VALUES IN (6, 12, 18)
);
```

You can add a new partition in which to store rows having the `data` column values `7`, `14`, and `21` as shown:

```
ALTER TABLE tt ADD PARTITION (PARTITION p2 VALUES IN (7, 14, 21));
```

Note that you *cannot* add a new `LIST` partition encompassing any values that are already included in the value list of an existing partition. If you attempt to do so, an error will result:

```
mysql> ALTER TABLE tt ADD PARTITION
> (PARTITION np VALUES IN (4, 8, 12));
ERROR 1465 (HY000): Multiple definition of same constant »
in list partitioning
```

Because any rows with the `data` column value `12` have already been assigned to partition `p1`, you cannot create a new partition on table `tt` that includes `12` in its value list. To accomplish this, you could drop `p1`, and add `np` and then a new `p1` with a modified definition. However, as discussed earlier, this would result in the loss of all data stored in `p1` — and it is often the case that this is not what you really want to do. Another solution might appear to be to make a copy of the table with the new partitioning and to copy the data into it using `CREATE TABLE ... SELECT ...`, then drop the old table and rename the new one, but this could be very time-consuming when dealing with a large amounts of data. This also might not be feasible in situations where high availability is a requirement.

Beginning with MySQL 5.1.6, you can add multiple partitions in a single `ALTER TABLE ... ADD PARTITION` statement as shown here:

```
CREATE TABLE employees (
  id INT NOT NULL,
  fname VARCHAR(50) NOT NULL,
  lname VARCHAR(50) NOT NULL,
  hired DATE NOT NULL
)
PARTITION BY RANGE( YEAR(hired) ) (
  PARTITION p1 VALUES LESS THAN (1991),
  PARTITION p2 VALUES LESS THAN (1996),
  PARTITION p3 VALUES LESS THAN (2001),
  PARTITION p4 VALUES LESS THAN (2005)
);

ALTER TABLE employees ADD PARTITION (
  PARTITION p5 VALUES LESS THAN (2010),
  PARTITION p6 VALUES LESS THAN MAXVALUE
);
```

Fortunately, MySQL's partitioning implementation provides ways to redefine partitions without losing data. Let us look first at a couple of simple examples involving `RANGE` partitioning. Recall the `members` table which is now defined as shown here:

```
mysql> SHOW CREATE TABLE members\G
***** 1. row *****
Table: members
Create Table: CREATE TABLE `members` (
  `id` int(11) default NULL,
  `fname` varchar(25) default NULL,
  `lname` varchar(25) default NULL,
  `dob` date default NULL
) ENGINE=MyISAM DEFAULT CHARSET=latin1
PARTITION BY RANGE ( YEAR(dob) ) (
  PARTITION p0 VALUES LESS THAN (1970) ENGINE = MyISAM,
  PARTITION p1 VALUES LESS THAN (1980) ENGINE = MyISAM,
  PARTITION p2 VALUES LESS THAN (1990) ENGINE = MyISAM,
  PARTITION p3 VALUES LESS THAN (2000) ENGINE = MyISAM
)
```

Suppose that you would like to move all rows representing members born before 1960 into a separate partition. As we have already seen, this cannot be done using `ALTER TABLE ... ADD PARTITION`. However, you can use another partition-related extension to `ALTER TABLE` in order to accomplish this:

```
ALTER TABLE members REORGANIZE PARTITION p0 INTO (
  PARTITION s0 VALUES LESS THAN (1960),
  PARTITION s1 VALUES LESS THAN (1970)
);
```

In effect, this command splits partition `p0` into two new partitions `s0` and `s1`. It also moves the data that was stored in `p0` into the new partitions according to the rules embodied in the two `PARTITION ... VALUES ...` clauses, so that `s0` contains only those records for which `YEAR(dob)` is less than 1960 and `s1` contains those rows in which `YEAR(dob)` is greater than or equal to 1960 but less than 1970.

A `REORGANIZE PARTITION` clause may also be used for merging adjacent partitions. You can return the `members` table to its previous partitioning as shown here:

```
ALTER TABLE members REORGANIZE PARTITION s0,s1 INTO (
    PARTITION p0 VALUES LESS THAN (1970)
);
```

No data is lost in splitting or merging partitions using `REORGANIZE PARTITION`. In executing the above statement, MySQL moves all of the records that were stored in partitions `s0` and `s1` into partition `p0`.

The general syntax for `REORGANIZE PARTITION` is:

```
ALTER TABLE tbl_name
    REORGANIZE PARTITION partition_list
    INTO (partition_definitions);
```

Here, `tbl_name` is the name of the partitioned table, and `partition_list` is a comma-separated list of names of one or more existing partitions to be changed. `partition_definitions` is a comma-separated list of new partition definitions, which follow the same rules as for the `partition_definitions` list used in `CREATE TABLE` (see Section 12.1.17, “CREATE TABLE Syntax”). It should be noted that you are not limited to merging several partitions into one, or to splitting one partition into many, when using `REORGANIZE PARTITION`. For example, you can reorganize all four partitions of the `members` table into two, as follows:

```
ALTER TABLE members REORGANIZE PARTITION p0,p1,p2,p3 INTO (
    PARTITION m0 VALUES LESS THAN (1980),
    PARTITION m1 VALUES LESS THAN (2000)
);
```

You can also use `REORGANIZE PARTITION` with tables that are partitioned by `LIST`. Let us return to the problem of adding a new partition to the list-partitioned `tt` table and failing because the new partition had a value that was already present in the value-list of one of the existing partitions. We can handle this by adding a partition that contains only non-conflicting values, and then reorganizing the new partition and the existing one so that the value which was stored in the existing one is now moved to the new one:

```
ALTER TABLE tt ADD PARTITION (PARTITION np VALUES IN (4, 8));
ALTER TABLE tt REORGANIZE PARTITION p1,np INTO (
    PARTITION p1 VALUES IN (6, 18),
    PARTITION np VALUES in (4, 8, 12)
);
```

Here are some key points to keep in mind when using `ALTER TABLE ... REORGANIZE PARTITION` to repartition tables that are partitioned by `RANGE` or `LIST`:

- The `PARTITION` clauses used to determine the new partitioning scheme are subject to the same rules as those used with a `CREATE TABLE` statement.

Most importantly, you should remember that the new partitioning scheme cannot have any overlapping ranges (applies to tables partitioned by `RANGE`) or sets of values (when reorganizing tables partitioned by `LIST`).

Note

Prior to MySQL 5.1.4, you could not reuse the names of existing partitions in the `INTO` clause, even when those partitions were being dropped or redefined. See Section C.1.34, “Changes in MySQL 5.1.4 (21 December 2005)”, for more information.

- The combination of partitions in the `partition_definitions` list should account for the same range or set of values overall as the combined partitions named in the `partition_list`.

For instance, in the `members` table used as an example in this section, partitions `p1` and `p2` together cover the years 1980 through 1999. Therefore, any reorganization of these two partitions should cover the same range of years overall.

- For tables partitioned by `RANGE`, you can reorganize only adjacent partitions; you cannot skip over range partitions.

For instance, you could not reorganize the `members` table used as an example in this section using a statement beginning with `ALTER TABLE members REORGANIZE PARTITION p0,p2 INTO ...` because `p0` covers the years prior to 1970 and `p2` the years from 1990 through 1999 inclusive, and thus the two are not adjacent partitions.

- You cannot use `REORGANIZE PARTITION` to change the table's partitioning type; that is, you cannot (for example) change `RANGE` partitions to `HASH` partitions or *vice versa*. You also cannot use this command to change the partitioning expression or column. To accomplish either of these tasks without dropping and re-creating the table, you can use `ALTER TABLE ... PARTITION BY ...`. For example:

```
ALTER TABLE members
PARTITION BY HASH( YEAR(dob) )
PARTITIONS 8;
```

18.3.2. Management of `HASH` and `KEY` Partitions

Tables which are partitioned by hash or by key are very similar to one another with regard to making changes in a partitioning setup, and both differ in a number of ways from tables which have been partitioned by range or list. For that reason, this section addresses the modification of tables partitioned by hash or by key only. For a discussion of adding and dropping of partitions of tables that are partitioned by range or list, see [Section 18.3.1, “Management of `RANGE` and `LIST` Partitions”](#).

You cannot drop partitions from tables that are partitioned by `HASH` or `KEY` in the same way that you can from tables that are partitioned by `RANGE` or `LIST`. However, you can merge `HASH` or `KEY` partitions using the `ALTER TABLE ... COALESCE PARTITION` command. For example, suppose that you have a table containing data about clients, which is divided into twelve partitions. The `clients` table is defined as shown here:

```
CREATE TABLE clients (
  id INT,
  fname VARCHAR(30),
  lname VARCHAR(30),
  signed DATE
)
PARTITION BY HASH( MONTH(signed) )
PARTITIONS 12;
```

To reduce the number of partitions from twelve to eight, execute the following `ALTER TABLE` command:

```
mysql> ALTER TABLE clients COALESCE PARTITION 4;
Query OK, 0 rows affected (0.02 sec)
```

`COALESCE` works equally well with tables that are partitioned by `HASH`, `KEY`, `LINEAR HASH`, or `LINEAR KEY`. Here is an example similar to the previous one, differing only in that the table is partitioned by `LINEAR KEY`:

```
mysql> CREATE TABLE clients_lk (
->   id INT,
->   fname VARCHAR(30),
->   lname VARCHAR(30),
->   signed DATE
-> )
-> PARTITION BY LINEAR KEY(signed)
-> PARTITIONS 12;
Query OK, 0 rows affected (0.03 sec)

mysql> ALTER TABLE clients_lk COALESCE PARTITION 4;
Query OK, 0 rows affected (0.06 sec)
Records: 0 Duplicates: 0 Warnings: 0
```

Note that the number following `COALESCE PARTITION` is the number of partitions to merge into the remainder — in other words, it is the number of partitions to remove from the table.

If you attempt to remove more partitions than the table has, the result is an error like the one shown:

```
mysql> ALTER TABLE clients COALESCE PARTITION 18;
ERROR 1478 (HY000): Cannot remove all partitions, use DROP TABLE instead
```

To increase the number of partitions for the `clients` table from 12 to 18, use `ALTER TABLE ... ADD PARTITION` as shown here:

```
ALTER TABLE clients ADD PARTITION PARTITIONS 6;
```

18.3.3. Maintenance of Partitions

A number of table and partition maintenance tasks can be carried out using SQL statements intended for such purposes on partitioned tables in MySQL 5.1.

Table maintenance of partitioned tables can be accomplished using the statements `CHECK TABLE`, `OPTIMIZE TABLE`, `ANALYZE TABLE`, and `REPAIR TABLE`, which are supported for partitioned tables as of MySQL 5.1.27.

Also beginning with MySQL 5.1.27, you can use a number of extensions to `ALTER TABLE` for performing operations of this type on one or more partitions directly, as described in the following list:

- **Rebuilding partitions.** Rebuilds the partition; this has the same effect as dropping all records stored in the partition, then reinserting them. This can be useful for purposes of defragmentation.

Example:

```
ALTER TABLE t1 REBUILD PARTITION p0, p1;
```

- **Optimizing partitions.** If you have deleted a large number of rows from a partition or if you have made many changes to a partitioned table with variable-length rows (that is, having `VARCHAR`, `BLOB`, or `TEXT` columns), you can use `ALTER TABLE ... OPTIMIZE PARTITION` to reclaim any unused space and to defragment the partition data file.

Example:

```
ALTER TABLE t1 OPTIMIZE PARTITION p0, p1;
```

Using `OPTIMIZE PARTITION` on a given partition is equivalent to running `CHECK PARTITION`, `ANALYZE PARTITION`, and `REPAIR PARTITION` on that partition.

- **Analyzing partitions.** This reads and stores the key distributions for partitions.

Example:

```
ALTER TABLE t1 ANALYZE PARTITION p3;
```

- **Repairing partitions.** This repairs corrupted partitions.

Example:

```
ALTER TABLE t1 REPAIR PARTITION p0,p1;
```

- **Checking partitions.** You can check partitions for errors in much the same way that you can use `CHECK TABLE` with non-partitioned tables.

Example:

```
ALTER TABLE trb3 CHECK PARTITION p1;
```

This command will tell you if the data or indexes in partition `p1` of table `t1` are corrupted. If this is the case, use `ALTER TABLE ... REPAIR PARTITION` to repair the partition.

Note

The statements `ALTER TABLE ... ANALYZE PARTITION`, `ALTER TABLE ... CHECK PARTITION`, `ALTER TABLE ... OPTIMIZE PARTITION`, and `ALTER TABLE ... REPAIR PARTITION` were originally introduced in MySQL 5.1.5, but did not work properly and were disabled in MySQL 5.1.24. They were re-introduced in MySQL 5.1.27. ([Bug#20129](#)) The use of these partitioning-specific `ALTER TABLE` statements with tables which are not partitioned is not supported; beginning with MySQL 5.1.31, it is expressly disallowed. ([Bug#39434](#))

`ALTER TABLE ... REBUILD PARTITION` was also introduced in MySQL 5.1.5.

18.3.4. Obtaining Information About Partitions

This section discusses obtaining information about existing partitions, which can be done in a number of ways. These include:

- Using the `SHOW CREATE TABLE` statement to view the partitioning clauses used in creating a partitioned table.
- Using the `SHOW TABLE STATUS` statement to determine whether a table is partitioned.
- Querying the `INFORMATION_SCHEMA.PARTITIONS` table.
- Using the statement `EXPLAIN PARTITIONS SELECT` to see which partitions are used by a given `SELECT`.

As discussed elsewhere in this chapter, `SHOW CREATE TABLE` includes in its output the `PARTITION BY` clause used to create a partitioned table. For example:

```
mysql> SHOW CREATE TABLE trb3\G
***** 1. row *****
      Table: trb3
Create Table: CREATE TABLE `trb3` (
  `id` int(11) default NULL,
  `name` varchar(50) default NULL,
  `purchased` date default NULL
) ENGINE=MyISAM DEFAULT CHARSET=latin1
PARTITION BY RANGE (YEAR(purchased)) (
  PARTITION p0 VALUES LESS THAN (1990) ENGINE = MyISAM,
  PARTITION p1 VALUES LESS THAN (1995) ENGINE = MyISAM,
  PARTITION p2 VALUES LESS THAN (2000) ENGINE = MyISAM,
  PARTITION p3 VALUES LESS THAN (2005) ENGINE = MyISAM
)
1 row in set (0.00 sec)
```

Note

In early MySQL 5.1 releases, the `PARTITIONS` clause was not shown for tables partitioned by `HASH` or `KEY`. This issue was fixed in MySQL 5.1.6.

`SHOW TABLE STATUS` works with partitioned tables. Beginning with MySQL 5.1.9, its output is the same as that for non-partitioned tables, except that the `Create_options` column contains the string `partitioned`. In MySQL 5.1.8 and earlier, the `Engine` column always contained the value `PARTITION`; beginning with MySQL 5.1.9, this column contains the name of the storage engine used by all partitions of the table. (See [Section 12.5.5.38, “SHOW TABLE STATUS Syntax”](#), for more information about this statement.)

You can also obtain information about partitions from `INFORMATION_SCHEMA`, which contains a `PARTITIONS` table. See [Section 20.19, “The INFORMATION_SCHEMA PARTITIONS Table”](#).

Beginning with MySQL 5.1.5, it is possible to determine which partitions of a partitioned table are involved in a given `SELECT` query using `EXPLAIN PARTITIONS`. The `PARTITIONS` keyword adds a `partitions` column to the output of `EXPLAIN` listing the partitions from which records would be matched by the query.

Suppose that you have a table `trb1` defined and populated as follows:

```
CREATE TABLE trb1 (id INT, name VARCHAR(50), purchased DATE)
PARTITION BY RANGE(id)
(
  PARTITION p0 VALUES LESS THAN (3),
  PARTITION p1 VALUES LESS THAN (7),
  PARTITION p2 VALUES LESS THAN (9),
  PARTITION p3 VALUES LESS THAN (11)
);

INSERT INTO trb1 VALUES
(1, 'desk organiser', '2003-10-15'),
(2, 'CD player', '1993-11-05'),
(3, 'TV set', '1996-03-10'),
(4, 'bookcase', '1982-01-10'),
(5, 'exercise bike', '2004-05-09'),
(6, 'sofa', '1987-06-05'),
(7, 'popcorn maker', '2001-11-22'),
(8, 'aquarium', '1992-08-04'),
(9, 'study desk', '1984-09-16'),
(10, 'lava lamp', '1998-12-25');
```

You can see which partitions are used in a query such as `SELECT * FROM trb1;`, as shown here:

```
mysql> EXPLAIN PARTITIONS SELECT * FROM trb1\G
***** 1. row *****
      id: 1
select_type: SIMPLE
      table: trb1
  partitions: p0,p1,p2,p3
         type: ALL
possible_keys: NULL
          key: NULL
       key_len: NULL
          ref: NULL
         rows: 10
       Extra: Using filesort
```

In this case, all four partitions are searched. However, when a limiting condition making use of the partitioning key is added to the query, you can see that only those partitions containing matching values are scanned, as shown here:

```
mysql> EXPLAIN PARTITIONS SELECT * FROM trb1 WHERE id < 5\G
***** 1. row *****
      id: 1
select_type: SIMPLE
```

```

table: trb1
partitions: p0,p1
type: ALL
possible_keys: NULL
key: NULL
key_len: NULL
ref: NULL
rows: 10
Extra: Using where

```

`EXPLAIN PARTITIONS` provides information about keys used and possible keys, just as with the standard `EXPLAIN SELECT` statement:

```

mysql> ALTER TABLE trb1 ADD PRIMARY KEY (id);
Query OK, 10 rows affected (0.03 sec)
Records: 10 Duplicates: 0 Warnings: 0

mysql> EXPLAIN PARTITIONS SELECT * FROM trb1 WHERE id < 5\G
***** 1. row *****
id: 1
select_type: SIMPLE
table: trb1
partitions: p0,p1
type: range
possible_keys: PRIMARY
key: PRIMARY
key_len: 4
ref: NULL
rows: 7
Extra: Using where

```

You should take note of the following restrictions and limitations on `EXPLAIN PARTITIONS`:

- You cannot use the `PARTITIONS` and `EXTENDED` keywords together in the same `EXPLAIN . . . SELECT` statement. Attempting to do so produces a syntax error.
- If `EXPLAIN PARTITIONS` is used to examine a query against a non-partitioned table, no error is produced, but the value of the `partitions` column is always `NULL`.

As of MySQL 5.1.28, the `rows` column of `EXPLAIN PARTITIONS` output always displays the total number of records in the table. Previously, this was the number of matching rows. ([Bug#35745](#))

See also [Section 12.3.2, “EXPLAIN Syntax”](#).

18.4. Partition Pruning

This section discusses an optimization known as *partition pruning*, which was implemented for partitioned tables in MySQL 5.1.6. The core concept behind partition pruning is relatively simple, and can be described as “Do not scan partitions where there can be no matching values”. For example, suppose you have a partitioned table `t1` defined by this statement:

```

CREATE TABLE t1 (
  fname VARCHAR(50) NOT NULL,
  lname VARCHAR(50) NOT NULL,
  region_code TINYINT UNSIGNED NOT NULL,
  dob DATE NOT NULL
)
PARTITION BY RANGE( region_code ) (
  PARTITION p0 VALUES LESS THAN (64),
  PARTITION p1 VALUES LESS THAN (128),
  PARTITION p2 VALUES LESS THAN (192),
  PARTITION p3 VALUES LESS THAN MAXVALUE
);

```

Consider the case where you wish to obtain results from a query such as this one:

```

SELECT fname, lname, region_code, dob
FROM t1
WHERE region_code > 125 AND region_code < 130;

```

It is easy to see that none of the rows which ought to be returned will be in either of the partitions `p0` or `p3`; that is, we need to search only in partitions `p1` and `p2` to find matching rows. By doing so, it is possible to expend much more time and effort in finding matching rows than it is to scan all partitions in the table. This “cutting away” of unneeded partitions is known as *pruning*. When the optimizer can make use of partition pruning in performing a query, execution of the query can be an order of magnitude faster than the same query against a non-partitioned table containing the same column definitions and data.

The query optimizer can perform pruning whenever a `WHERE` condition can be reduced to either one of the following:

- `partition_column = constant`
- `partition_column IN (constant1, constant2, ..., constantN)`

In the first case, the optimizer simply evaluates the partitioning expression for the value given, determines which partition contains that value, and scans only this partition. In many cases, the equals sign can be replaced with another arithmetic comparison, including `<`, `>`, `<=`, `>=`, and `<>`. Some queries using `BETWEEN` in the `WHERE` clause can also take advantage of partition pruning. See the examples later in this section.

In the second case, the optimizer evaluates the partitioning expression for each value in the list, creates a list of matching partitions, and then scans only the partitions in this partition list.

Pruning can also be applied to short ranges, which the optimizer can convert into equivalent lists of values. For instance, in the previous example, the `WHERE` clause can be converted to `WHERE region_code IN (125, 126, 127, 128, 129, 130)`. Then the optimizer can determine that the first three values in the list are found in partition `p1`, the remaining three values in partition `p2`, and that the other partitions contain no relevant values and so do not need to be searched for matching rows.

This type of optimization can be applied whenever the partitioning expression consists of an equality or a range which can be reduced to a set of equalities, or when the partitioning expression represents an increasing or decreasing relationship. Pruning can also be applied for tables partitioned on a `DATE` or `DATETIME` column when the partitioning expression uses the `YEAR()` or `TO_DAYS()` function.

Note

We plan to add pruning support in a future MySQL release for additional functions that act on a `DATE` or `DATETIME` value, return an integer, and are increasing or decreasing.

For example, suppose that table `t2`, defined as shown here, is partitioned on a `DATE` column:

```
CREATE TABLE t2 (
  fname VARCHAR(50) NOT NULL,
  lname VARCHAR(50) NOT NULL,
  region_code TINYINT UNSIGNED NOT NULL,
  dob DATE NOT NULL
)
PARTITION BY RANGE( YEAR(dob) ) (
  PARTITION d0 VALUES LESS THAN (1970),
  PARTITION d1 VALUES LESS THAN (1975),
  PARTITION d2 VALUES LESS THAN (1980),
  PARTITION d3 VALUES LESS THAN (1985),
  PARTITION d4 VALUES LESS THAN (1990),
  PARTITION d5 VALUES LESS THAN (2000),
  PARTITION d6 VALUES LESS THAN (2005),
  PARTITION d7 VALUES LESS THAN MAXVALUE
);
```

The following queries on `t2` can make use of partition pruning:

```
SELECT * FROM t2 WHERE dob = '1982-06-23';
SELECT * FROM t2 WHERE dob BETWEEN '1991-02-15' AND '1997-04-25';
SELECT * FROM t2 WHERE dob >= '1984-06-21' AND dob <= '1999-06-21'
```

In the case of the last query, the optimizer can also act as follows:

1. Find the partition containing the low end of the range.
`YEAR('1984-06-21')` yields the value `1984`, which is found in partition `d3`.
2. Find the partition containing the high end of the range.
`YEAR('1999-06-21')` evaluates to `1999`, which is found in partition `d5`.
3. Scan only these two partitions and any partitions that may lie between them.

In this case, this means that only partitions `d3`, `d4`, and `d5` are scanned. The remaining partitions may be safely ignored (and are ignored).

Important

Invalid `DATE` and `DATETIME` values referenced in the `WHERE` clause of a query on a partitioned table are treated as `NULL`. This means that a query such as `SELECT * FROM partitioned_table WHERE date_column <`

■ '2008-12-00' does not return any values (see [Bug#40972](#)).

So far, we have looked only at examples using [RANGE](#) partitioning, but pruning can be applied with other partitioning types as well.

Consider a table that is partitioned by [LIST](#), where the partitioning expression is increasing or decreasing, such as the table `t3` shown here. (In this example, we assume for the sake of brevity that the `region_code` column is limited to values between 1 and 10 inclusive.)

```
CREATE TABLE t3 (
  fname VARCHAR(50) NOT NULL,
  lname VARCHAR(50) NOT NULL,
  region_code TINYINT UNSIGNED NOT NULL,
  dob DATE NOT NULL
)
PARTITION BY LIST(region_code) (
  PARTITION r0 VALUES IN (1, 3),
  PARTITION r1 VALUES IN (2, 5, 8),
  PARTITION r2 VALUES IN (4, 9),
  PARTITION r3 VALUES IN (6, 7, 10)
);
```

For a query such as `SELECT * FROM t3 WHERE region_code BETWEEN 1 AND 3`, the optimizer determines in which partitions the values 1, 2, and 3 are found (`r0` and `r1`) and skips the remaining ones (`r2` and `r3`).

For tables that are partitioned by [HASH](#) or [KEY](#), partition pruning is also possible in cases in which the `WHERE` clause uses a simple `=` relation against a column used in the partitioning expression. Consider a table created like this:

```
CREATE TABLE t4 (
  fname VARCHAR(50) NOT NULL,
  lname VARCHAR(50) NOT NULL,
  region_code TINYINT UNSIGNED NOT NULL,
  dob DATE NOT NULL
)
PARTITION BY KEY(region_code)
PARTITIONS 8;
```

Any query such as this one can be pruned:

```
SELECT * FROM t4 WHERE region_code = 7;
```

Pruning can also be employed for short ranges, because the optimizer can turn such conditions into `IN` relations. For example, using the same table `t4` as defined previously, queries such as these can be pruned:

```
SELECT * FROM t4 WHERE region_code > 2 AND region_code < 6;
SELECT * FROM t4 WHERE region_code BETWEEN 3 AND 5;
```

In both these cases, the `WHERE` clause is transformed by the optimizer into `WHERE region_code IN (3, 4, 5)`.

Important

This optimization is used only if the range size is smaller than the number of partitions. Consider this query:

```
SELECT * FROM t4 WHERE region_code BETWEEN 4 AND 8;
```

The range in the `WHERE` clause covers 5 values (4, 5, 6, 7, 8), but `t4` has only 4 partitions. This means that the previous query cannot be pruned.

Pruning can be used only on integer columns of tables partitioned by [HASH](#) or [KEY](#). For example, this query on table `t4` cannot use pruning because `dob` is a `DATE` column:

```
SELECT * FROM t4 WHERE dob >= '2001-04-14' AND dob <= '2005-10-15';
```

However, if the table stores year values in an `INT` column, then a query having `WHERE year_col >= 2001 AND year_col <= 2005` can be pruned.

18.5. Restrictions and Limitations on Partitioning

This section discusses current restrictions and limitations on MySQL partitioning support, as listed here:

- **Prohibited constructs.** Beginning with MySQL 5.1.12, the following constructs are not permitted in partitioning expressions:
 - Stored functions, stored procedures, UDFs, or plugins.

- Declared variables or user variables.

For a list of SQL functions which are permitted in partitioning expressions, see [Section 18.5.3, “Partitioning Limitations Relating to Functions”](#).

- **Arithmetic and logical operators.** Use of the arithmetic operators `+`, `-`, and `*` is permitted in partitioning expressions. However, the result must be an integer value or `NULL` (except in the case of `[LINEAR] KEY` partitioning, as discussed elsewhere in this chapter — see [Section 18.2, “Partition Types”](#), for more information).

Beginning with MySQL 5.1.23, the `DIV` operator is also supported, and the `/` operator is disallowed. ([Bug#30188](#), [Bug#33182](#))

Beginning with MySQL 5.1.12, the bit operators `|`, `&`, `^`, `<<`, `>>`, and `~` are not permitted in partitioning expressions.

- **Server SQL mode.** Tables employing user-defined partitioning do not preserve the SQL mode in effect at the time that they were created. As discussed in [Section 5.1.7, “Server SQL Modes”](#), the results of many MySQL functions and operators may change according to the server SQL mode. Therefore, a change in the SQL mode at any time after the creation of partitioned tables may lead to major changes in the behavior of such tables, and could easily lead to corruption or loss of data. For these reasons, *it is strongly recommended that you never change the server SQL mode after creating partitioned tables.*

Examples. The following examples illustrate some changes in behavior of partitioned tables due to a change in the server SQL mode:

1. **Error handling.** Suppose you create a partitioned table whose partitioning expression is one such as `column DIV 0` or `column MOD 0`, as shown here:

```
mysql> CREATE TABLE tn (c1 INT)
->     PARTITION BY LIST(1 DIV c1) (
->     PARTITION p0 VALUES IN (NULL),
->     PARTITION p1 VALUES IN (1)
-> );
Query OK, 0 rows affected (0.05 sec)
```

The default behavior for MySQL is to return `NULL` for the result of a division by zero, without producing any errors:

```
mysql> SELECT @@SQL_MODE;
+-----+
| @@SQL_MODE |
+-----+
|             |
+-----+
1 row in set (0.00 sec)

mysql> INSERT INTO tn VALUES (NULL), (0), (1);
Query OK, 3 rows affected (0.00 sec)
Records: 3 Duplicates: 0 Warnings: 0
```

However, changing the server SQL mode to treat division by zero as an error and to enforce strict error handling causes the same `INSERT` statement to fail, as shown here:

```
mysql> SET SQL_MODE='STRICT_ALL_TABLES,ERROR_FOR_DIVISION_BY_ZERO';
Query OK, 0 rows affected (0.00 sec)

mysql> INSERT INTO tn VALUES (NULL), (0), (1);
ERROR 1365 (22012): DIVISION BY 0
```

2. **Table accessibility.** Sometimes a change in the server SQL mode can make partitioned tables unusable. The following `CREATE TABLE` statement can be executed successfully only if the `NO_UNSIGNED_SUBTRACTION` mode is in effect:

```
mysql> SELECT @@SQL_MODE;
+-----+
| @@SQL_MODE |
+-----+
|             |
+-----+
1 row in set (0.00 sec)

mysql> CREATE TABLE tu (c1 BIGINT UNSIGNED)
->     PARTITION BY RANGE(c1 - 10) (
->     PARTITION p0 VALUES LESS THAN (-5),
->     PARTITION p1 VALUES LESS THAN (0),
->     PARTITION p2 VALUES LESS THAN (5),
->     PARTITION p3 VALUES LESS THAN (10),
->     PARTITION p4 VALUES LESS THAN (MAXVALUE)
-> );
ERROR 1563 (HY000): PARTITION CONSTANT IS OUT OF PARTITION FUNCTION DOMAIN

mysql> SET SQL_MODE='NO_UNSIGNED_SUBTRACTION';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT @@SQL_MODE;
+-----+
| @@SQL_MODE |
+-----+
```

```

| NO_UNSIGNED_SUBTRACTION |
+-----+
1 row in set (0.00 sec)

mysql> CREATE TABLE tu (c1 BIGINT UNSIGNED)
-> PARTITION BY RANGE(c1 - 10) (
-> PARTITION p0 VALUES LESS THAN (-5),
-> PARTITION p1 VALUES LESS THAN (0),
-> PARTITION p2 VALUES LESS THAN (5),
-> PARTITION p3 VALUES LESS THAN (10),
-> PARTITION p4 VALUES LESS THAN (MAXVALUE)
-> );
Query OK, 0 rows affected (0.05 sec)

```

If you remove the `NO_UNSIGNED_SUBTRACTION` server SQL mode after creating `tu`, you may no longer be able to access this table:

```

mysql> SET SQL_MODE='';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT * FROM tu;
ERROR 1563 (HY000): PARTITION CONSTANT IS OUT OF PARTITION FUNCTION DOMAIN
mysql> INSERT INTO tu VALUES (20);
ERROR 1563 (HY000): PARTITION CONSTANT IS OUT OF PARTITION FUNCTION DOMAIN

```

- **Performance considerations.**

- **File system operations.** Partitioning and repartitioning operations (such as `ALTER TABLE` with `PARTITION BY ...`, `REORGANIZE PARTITIONS`, or `REMOVE PARTITIONING`) depend on file system operations for their implementation. This means that the speed of these operations is affected by such factors as file system type and characteristics, disk speed, swap space, file handling efficiency of the operating system, and MySQL server options and variables that relate to file handling. In particular, you should make sure that `large_files_support` is enabled and that `open_files_limit` is set properly. For partitioned tables using the `MyISAM` storage engine, increasing `myisam_max_sort_file_size` may improve performance; partitioning and repartitioning operations involving `InnoDB` tables may be made more efficient by enabling `innodb_file_per_table`.
- **Table locks.** The process executing a partitioning operation on a table takes a write lock on the table. Reads from such tables are relatively unaffected; pending `INSERT` and `UPDATE` operations are performed as soon as the partitioning operation has completed.
- **Storage engine.** Partitioning operations, queries, and update operations generally tend to be faster with `MyISAM` tables than with `InnoDB` or `NDB` tables.
- **Use of indexes and partition pruning.** As with non-partitioned tables, proper use of indexes can speed up queries on partitioned tables significantly. In addition, designing partitioned tables and queries on these tables to take advantage of *partition pruning* can improve performance dramatically. See [Section 18.4, “Partition Pruning”](#), for more information.
- **Performance with `LOAD DATA`.** Prior to MySQL 5.1.23, `LOAD DATA` performed very poorly when importing into partitioned tables. The statement now uses buffering to improve performance; however, the buffer uses 130 KB memory per partition to achieve this. ([Bug#26527](#))

- **Maximum number of partitions.** The maximum number of partitions possible for a given table is 1024. This includes subpartitions.

If, when creating tables with a very large number of partitions (but which is less than the maximum stated previously), you encounter an error message such as `GOT ERROR 24 FROM STORAGE ENGINE`, this means that you may need to increase the value of the `open_files_limit` system variable. See [Section B.1.2.18, “‘FILE’ NOT FOUND and Similar Errors”](#).

- **Foreign keys not supported.** Partitioned tables do not support foreign keys. This means that:
 1. Definitions of tables employing user-defined partitioning may not contain foreign key references to other tables.
 2. No table definition may contain a foreign key reference to a partitioned table.
The scope of these restrictions includes tables that use the `InnoDB` storage engine.
- **`ALTER TABLE ... ORDER BY`.** An `ALTER TABLE ... ORDER BY column` statement run against a partitioned table causes ordering of rows only within each partition.
- **FULLTEXT indexes.** Partitioned tables do not support `FULLTEXT` indexes. This includes partitioned tables employing the `MyISAM` storage engine.
- **Spatial columns.** Columns with spatial data types such as `POINT` or `GEOMETRY` cannot be used in partitioned tables.
- **Temporary tables.** As of MySQL 5.1.8, temporary tables cannot be partitioned. ([Bug#17497](#))

- **Log tables.** Beginning with MySQL 5.1.20, it is no longer possible to partition the log tables; beginning with that version, an `ALTER TABLE ... PARTITION BY ...` statement on such a table fails with an error. (Bug#27816)
- **Data type of partitioning key.** A partitioning key must be either an integer column or an expression that resolves to an integer. The column or expression value may also be `NULL`. (See Section 18.2.6, “How MySQL Partitioning Handles `NULL`”.)

The lone exception to this restriction occurs when partitioning by `[LINEAR] KEY`, where it is possible to use columns of other types as partitioning keys, because MySQL's internal key-hashing functions produce the correct data type from these types. For example, the following `CREATE TABLE` statement is valid:

```
CREATE TABLE tkc (c1 CHAR)
PARTITION BY KEY(c1)
PARTITIONS 4;
```

This exception does *not* apply to `BLOB` or `TEXT` column types.

- **Subqueries.** A partitioning key may not be a subquery, even if that subquery resolves to an integer value or `NULL`.
- **Subpartitions.** Subpartitions are limited to `HASH` or `KEY` partitioning. `HASH` and `KEY` partitions cannot be subpartitioned.
- **Key caches not supported.** Key caches are not supported for partitioned tables. The `CACHE INDEX INTO CACHE` statements, when you attempt to use them on tables having user-defined partitioning, fail with the errors `THE STORAGE ENGINE FOR THE TABLE DOESN'T SUPPORT ASSIGN_TO_KEYCACHE` and `THE STORAGE ENGINE FOR THE TABLE DOESN'T SUPPORT PRELOAD_KEYS`, respectively.
- **DELAYED option not supported.** Use of `INSERT DELAYED` to insert rows into a partitioned table is not supported. Beginning with MySQL 5.1.23, attempting to do so fails with an error. (Bug#31210)
- **DATA DIRECTORY and INDEX DIRECTORY options.** `DATA DIRECTORY` and `INDEX DIRECTORY` are subject to the following restrictions when used with partitioned tables:
 - Beginning with MySQL 5.1.23, table-level `DATA DIRECTORY` and `INDEX DIRECTORY` options are ignored. (Bug#32091)
 - On Windows, the `DATA DIRECTORY` and `INDEX DIRECTORY` options are not supported for individual partitions or subpartitions (Bug#30459).
- **Repairing and rebuilding partitioned tables.** The statements `CHECK TABLE`, `OPTIMIZE TABLE`, `ANALYZE TABLE`, and `REPAIR TABLE` are supported for partitioned tables beginning with MySQL 5.1.27. (See Bug#20129.) `mysqlcheck` and `myisamchk` are not supported with partitioned tables.

In addition, you can use `ALTER TABLE ... REBUILD PARTITION` to rebuild one or more partitions of a partitioned table; `ALTER TABLE ... REORGANIZE PARTITION` also causes partitions to be rebuilt. Both of these statements were added in MySQL 5.1.5. See Section 12.1.7, “ALTER TABLE Syntax”, for more information about these two statements.

18.5.1. Partitioning Keys, Primary Keys, and Unique Keys

This section discusses the relationship of partitioning keys with primary keys and unique keys. The rule governing this relationship can be expressed as follows: All columns used in the partitioning expression for a partitioned table must be part of every unique key that the table may have.

In other words, *every unique key on the table must use every column in the table's partitioning expression*. (This also includes the table's primary key, since it is by definition a unique key. This particular case is discussed later in this section.) For example, each of the following table creation statements is invalid:

```
CREATE TABLE t1 (
  col1 INT NOT NULL,
  col2 DATE NOT NULL,
  col3 INT NOT NULL,
  col4 INT NOT NULL,
  UNIQUE KEY (col1, col2)
)
PARTITION BY HASH(col3)
PARTITIONS 4;

CREATE TABLE t2 (
  col1 INT NOT NULL,
  col2 DATE NOT NULL,
  col3 INT NOT NULL,
  col4 INT NOT NULL,
  UNIQUE KEY (col1),
  UNIQUE KEY (col3)
)
PARTITION BY HASH(col1 + col3)
PARTITIONS 4;
```

In each case, the proposed table would have at least one unique key that does not include all columns used in the partitioning expression.

Each of the following statements is valid, and represents one way in which the corresponding invalid table creation statement could be made to work:

```
CREATE TABLE t1 (
  col1 INT NOT NULL,
  col2 DATE NOT NULL,
  col3 INT NOT NULL,
  col4 INT NOT NULL,
  UNIQUE KEY (col1, col2, col3)
)
PARTITION BY HASH(col3)
PARTITIONS 4;

CREATE TABLE t2 (
  col1 INT NOT NULL,
  col2 DATE NOT NULL,
  col3 INT NOT NULL,
  col4 INT NOT NULL,
  UNIQUE KEY (col1, col3)
)
PARTITION BY HASH(col1 + col3)
PARTITIONS 4;
```

This example shows the error produced in such cases:

```
mysql> CREATE TABLE t3 (
->   col1 INT NOT NULL,
->   col2 DATE NOT NULL,
->   col3 INT NOT NULL,
->   col4 INT NOT NULL,
->   UNIQUE KEY (col1, col2),
->   UNIQUE KEY (col3)
-> )
-> PARTITION BY HASH(col1 + col3)
-> PARTITIONS 4;
ERROR 1491 (HY000): A PRIMARY KEY MUST INCLUDE ALL COLUMNS IN THE TABLE'S PARTITIONING FUNCTION
```

The `CREATE` statement fails because both `col1` and `col3` are included in the proposed partitioning key, but neither of these columns is part of both of unique keys on the table. This shows one possible fix for the invalid table definition;

```
mysql> CREATE TABLE t3 (
->   col1 INT NOT NULL,
->   col2 DATE NOT NULL,
->   col3 INT NOT NULL,
->   col4 INT NOT NULL,
->   UNIQUE KEY (col1, col2, col3),
->   UNIQUE KEY (col3)
-> )
-> PARTITION BY HASH(col3)
-> PARTITIONS 4;
Query OK, 0 rows affected (0.05 sec)
```

In this case, the proposed partitioning key `col3` is part of both unique keys, and the table creation statement succeeds.

Since every primary key is by definition a unique key, this restriction also includes the table's primary key, if it has one. For example, the next two statements are invalid:

```
CREATE TABLE t4 (
  col1 INT NOT NULL,
  col2 DATE NOT NULL,
  col3 INT NOT NULL,
  col4 INT NOT NULL,
  PRIMARY KEY(col1, col2)
)
PARTITION BY HASH(col3)
PARTITIONS 4;

CREATE TABLE t5 (
  col1 INT NOT NULL,
  col2 DATE NOT NULL,
  col3 INT NOT NULL,
  col4 INT NOT NULL,
  PRIMARY KEY(col1, col3),
  UNIQUE KEY(col2)
)
PARTITION BY HASH( YEAR(col2) )
PARTITIONS 4;
```

In both cases, the primary key does not include all columns referenced in the partitioning expression. However, both of the next two statements are valid:

```
CREATE TABLE t6 (
```

```

    col1 INT NOT NULL,
    col2 DATE NOT NULL,
    col3 INT NOT NULL,
    col4 INT NOT NULL,
    PRIMARY KEY(col1, col2)
)
PARTITION BY HASH(col1 + YEAR(col2))
PARTITIONS 4;

CREATE TABLE t7 (
    col1 INT NOT NULL,
    col2 DATE NOT NULL,
    col3 INT NOT NULL,
    col4 INT NOT NULL,
    PRIMARY KEY(col1, col2, col4),
    UNIQUE KEY(col2, col1)
)
PARTITION BY HASH(col1 + YEAR(col2))
PARTITIONS 4;

```

If a table has no unique keys — this includes having no primary key — then this restriction does not apply, and you may use any column or columns in the partitioning expression as long as the column type is compatible with the partitioning type.

For the same reason, you cannot later add a unique key to a partitioned table unless the key includes all columns used by the table's partitioning expression. Consider given the partitioned table defined as shown here:

```

mysql> CREATE TABLE t_no_pk (c1 INT, c2 INT)
->     PARTITION BY RANGE(c1) (
->         PARTITION p0 VALUES LESS THAN (10),
->         PARTITION p1 VALUES LESS THAN (20),
->         PARTITION p2 VALUES LESS THAN (30),
->         PARTITION p3 VALUES LESS THAN (40)
->     );
Query OK, 0 rows affected (0.12 sec)

```

It is possible to add a primary key to `t_no_pk` using either of these `ALTER TABLE` statements:

```

# possible PK
mysql> ALTER TABLE t_no_pk ADD PRIMARY KEY(c1);
Query OK, 0 rows affected (0.13 sec)
Records: 0 Duplicates: 0 Warnings: 0

# drop this PK
mysql> ALTER TABLE t_no_pk DROP PRIMARY KEY;
Query OK, 0 rows affected (0.10 sec)
Records: 0 Duplicates: 0 Warnings: 0

# use another possible PK
mysql> ALTER TABLE t_no_pk ADD PRIMARY KEY(c1, c2);
Query OK, 0 rows affected (0.12 sec)
Records: 0 Duplicates: 0 Warnings: 0

# drop this PK
mysql> ALTER TABLE t_no_pk DROP PRIMARY KEY;
Query OK, 0 rows affected (0.09 sec)
Records: 0 Duplicates: 0 Warnings: 0

```

However, the next statement fails, because `c1` is part of the partitioning key, but is not part of the proposed primary key:

```

# fails with error 1503
mysql> ALTER TABLE t_no_pk ADD PRIMARY KEY(c2);
ERROR 1503 (HY000): A PRIMARY KEY MUST INCLUDE ALL COLUMNS IN THE TABLE'S PARTITIONING FUNCTION

```

Since `t_no_pk` has only `c1` in its partitioning expression, attempting to adding a unique key on `c2` alone fails. However, you can add a unique key that uses both `c1` and `c2`.

These rules also apply to existing non-partitioned tables that you wish to partition using `ALTER TABLE ... PARTITION BY`. Consider a table `np_pk` defined as shown here:

```

mysql> CREATE TABLE np_pk (
->     id INT NOT NULL AUTO_INCREMENT,
->     name VARCHAR(50),
->     added DATE,
->     PRIMARY KEY (id)
-> );
Query OK, 0 rows affected (0.08 sec)

```

The following `ALTER TABLE` statements fails with an error, because the `added` column is not part of any unique key in the table:

```

mysql> ALTER TABLE np_pk
->     PARTITION BY HASH( TO_DAYS(added) )
->     PARTITIONS 4;
ERROR 1503 (HY000): A PRIMARY KEY MUST INCLUDE ALL COLUMNS IN THE TABLE'S PARTITIONING FUNCTION

```

However, this statement using the `id` column for the partitioning column is valid, as shown here:

```
mysql> ALTER TABLE np_pk
-> PARTITION BY HASH(id)
-> PARTITIONS 4;
Query OK, 0 rows affected (0.11 sec)
Records: 0 Duplicates: 0 Warnings: 0
```

In the case of `np_pk`, the only column that may be used as part of a partitioning expression is `id`; if you wish to partition this table using any other column or columns in the partitioning expression, you must first modify the table, either by adding the desired column or columns to the primary key, or by dropping the primary key altogether.

We are working to remove this limitation in a future MySQL release series.

18.5.2. Partitioning Limitations Relating to Storage Engines

The following limitations apply to the use of storage engines with user-defined partitioning of tables.

MERGE storage engine. User-defined partitioning and the `MERGE` storage engine are not compatible. Tables using the `MERGE` storage engine cannot be partitioned. Partitioned tables cannot be merged.

FEDERATED storage engine. Partitioning of `FEDERATED` tables is not supported. Beginning with MySQL 5.1.15, it is not possible to create partitioned `FEDERATED` tables at all. We are working to remove this limitation in a future MySQL release.

CSV storage engine. Partitioned tables using the `CSV` storage engine are not supported. Starting with MySQL 5.1.12, it is not possible to create partitioned `CSV` tables at all.

BLACKHOLE storage engine. Prior to MySQL 5.1.6, tables using the `BLACKHOLE` storage engine also could not be partitioned.

NDBCLUSTER storage engine (MySQL Cluster). Partitioning by `KEY` (or `LINEAR KEY`) is the only type of partitioning supported for the `NDBCLUSTER` storage engine. Beginning with MySQL 5.1.12, it is not possible to create a MySQL Cluster table using any partitioning type other than `[LINEAR] KEY`, and attempting to do so fails with an error.

In addition, the maximum number of partitions that can be defined for an `NDBCLUSTER` table is 8 times the number of node groups in the cluster. (See [Section 17.1.2, “MySQL Cluster Nodes, Node Groups, Replicas, and Partitions”](#), for more information about node groups in MySQL Cluster.)

Beginning with MySQL Cluster NDB 6.2.18, MySQL Cluster NDB 6.3.25, and MySQL Cluster NDB 7.0.6, `CREATE TABLE` and `ALTER TABLE` statements that would cause a user-partitioned `NDBCLUSTER` table not to meet either or both of the following two requirements are disallowed, and fail with an error ([Bug#40709](#)):

1. The table must have an explicit primary key.
2. All columns listed in the table's partitioning expression must be part of the primary key.

Exception. If a user-partitioned `NDBCLUSTER` table is created using an empty column-list (that is, using `PARTITION BY KEY()` or `PARTITION BY LINEAR KEY()`), then no explicit primary key is required.

Upgrading partitioned tables. When performing an upgrade, tables which are partitioned by `KEY` and which use any storage engine other than `NDBCLUSTER` must be dumped and reloaded.

Same storage engine for all partitions. All partitions of a partitioned table must use the same storage engine and it must be the same storage engine used by the table as a whole. In addition, if one does not specify an engine on the table level, then one must do either of the following when creating or altering a partitioned table:

- Do *not* specify any engine for *any* partition or subpartition
- Specify the engine for *all* partitions or subpartitions

We are working to remove this limitation in a future MySQL release.

18.5.3. Partitioning Limitations Relating to Functions

This section discusses limitations in MySQL Partitioning relating specifically to functions used in partitioning expressions.

Beginning with MySQL 5.1.12, only the following MySQL functions are supported in partitioning expressions:

- `ABS()`
- `CEILING()` (see *CEILING()* and *FLOOR()*, immediately following this list)
- `DAY()`
- `DAYOFMONTH()`
- `DAYOFWEEK()`
- `DAYOFYEAR()`
- `DATEDIFF()`
- `EXTRACT()`
- `FLOOR()` (see *CEILING()* and *FLOOR()*, immediately following this list)
- `HOUR()`
- `MICROSECOND()`
- `MINUTE()`
- `MOD()`
- `MONTH()`
- `QUARTER()`
- `SECOND()`
- `TIME_TO_SEC()`
- `TO_DAYS()`
- `WEEKDAY()`
- `YEAR()`
- `YEARWEEK()`

Note

CEILING() and **FLOOR()**. Each of these functions returns an integer only if it is passed an integer argument. This means, for example, that the following `CREATE TABLE` statement fails with an error, as shown here:

```
mysql> CREATE TABLE t (c FLOAT) PARTITION BY LIST( FLOOR(c) )(
->     PARTITION p0 VALUES IN (1,3,5),
->     PARTITION p1 VALUES IN (2,4,6)
-> );
ERROR 1490 (HY000): THE PARTITION FUNCTION RETURNS THE WRONG TYPE
```

See [Section 11.5.2, “Mathematical Functions”](#), for more information about the return types of these functions.

Chapter 19. Stored Programs and Views

This chapter discusses stored programs and views, which are database objects defined in terms of SQL code that is stored on the server for later invocation.

Stored programs include these objects:

- Stored routines, that is, stored procedures and functions. A stored function is used much like a built-in function. you invoke it in an expression and it returns a value during expression evaluation. A stored procedure is invoked using the `CALL` statement. A procedure does not have a return value but can modify its parameters for later inspection by the caller. It can also generate result sets to be returned to the client program.
- Triggers. A trigger is a named database object that is associated with a table and that is activated when a particular event occurs for the table, such as an insert or update.
- Events. An event is a task that runs according to schedule.

Views are stored queries that when invoked produce a result set. A view acts as a virtual table.

This chapter describes how to use each type of stored program and views. Additional information about SQL syntax for statements related to these objects is available in the following locations:

- For each object type, there are `CREATE`, `ALTER`, and `DROP` statements that control which objects exist and how they are defined. See [Section 12.1, “Data Definition Statements”](#).
- The `CALL` statement is used to invoke stored procedures. See [Section 12.2.1, “CALL Syntax”](#).
- Stored program definitions contain a body that may use compound statements, loops, conditionals, and declared variables. See [Section 12.8, “MySQL Compound-Statement Syntax”](#).

19.1. Defining Stored Programs

Each stored program contains a body that consists of an SQL statement. This statement may be a compound statement made up of several statements separated by semicolon (`;`) characters. For example, the following stored procedure has a body made up of a `BEGIN . . . END` block that contains a `SET` statement and a `REPEAT` loop that itself contains another `SET` statement:

```
CREATE PROCEDURE dorepeat(p1 INT)
BEGIN
  SET @x = 0;
  REPEAT SET @x = @x + 1; UNTIL @x > p1 END REPEAT;
END
```

If you use the `mysql` client program to define a stored program that contains the semicolon characters within its definition, a problem arises. By default, `mysql` itself recognizes semicolon as a statement delimiter, so you must redefine the delimiter temporarily to cause `mysql` to pass the entire stored program definition to the server.

To redefine the `mysql` delimiter, use the `delimiter` command. The following example shows how to do this for the `dorepeat()` procedure just shown. The delimiter is changed to `//` to enable the entire definition to be passed to the server as a single statement, and then restored to `;` before invoking the procedure. This allows the `;` delimiter used in the procedure body to be passed through to the server rather than being interpreted by `mysql` itself.

```
mysql> delimiter //
mysql> CREATE PROCEDURE dorepeat(p1 INT)
-> BEGIN
->   SET @x = 0;
->   REPEAT SET @x = @x + 1; UNTIL @x > p1 END REPEAT;
-> END
-> //
Query OK, 0 rows affected (0.00 sec)

mysql> delimiter ;
mysql> CALL dorepeat(1000);
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT @x;
+-----+
| @x    |
+-----+
| 1001  |
+-----+
```

```
1 row in set (0.00 sec)
```

You can redefine the delimiter to a string other than `//`, and the delimiter can consist of a single character or multiple characters. You should avoid the use of the backslash (“\”) character because that is the escape character for MySQL.

The following is an example of a function that takes a parameter, performs an operation using an SQL function, and returns the result. In this case, it is unnecessary to use `delimiter` because the function definition contains no internal `;` statement delimiters:

```
mysql> CREATE FUNCTION hello (s CHAR(20))
mysql> RETURNS CHAR(50) DETERMINISTIC
-> RETURN CONCAT('Hello, ',s,'!');
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT hello('world');
+-----+
| hello('world') |
+-----+
| Hello, world!  |
+-----+
1 row in set (0.00 sec)
```

19.2. Using Stored Routines (Procedures and Functions)

Stored routines (procedures and functions) are supported in MySQL 5.1. A stored routine is a set of SQL statements that can be stored in the server. Once this has been done, clients don't need to keep reissuing the individual statements but can refer to the stored routine instead.

Stored routines require the `proc` table in the `mysql` database. This table is created during the MySQL 5.1 installation procedure. If you are upgrading to MySQL 5.1 from an earlier version, be sure to update your grant tables to make sure that the `proc` table exists. See [Section 4.4.8, “mysql_upgrade — Check Tables for MySQL Upgrade”](#).

MySQL Enterprise

For expert advice on using stored procedures and functions subscribe to the MySQL Enterprise Monitor. For more information, see <http://www.mysql.com/products/enterprise/advisors.html>.

Stored routines can be particularly useful in certain situations:

- When multiple client applications are written in different languages or work on different platforms, but need to perform the same database operations.
- When security is paramount. Banks, for example, use stored procedures and functions for all common operations. This provides a consistent and secure environment, and routines can ensure that each operation is properly logged. In such a setup, applications and users would have no access to the database tables directly, but can only execute specific stored routines.

Stored routines can provide improved performance because less information needs to be sent between the server and the client. The tradeoff is that this does increase the load on the database server because more of the work is done on the server side and less is done on the client (application) side. Consider this if many client machines (such as Web servers) are serviced by only one or a few database servers.

Stored routines also allow you to have libraries of functions in the database server. This is a feature shared by modern application languages that allow such design internally (for example, by using classes). Using these client application language features is beneficial for the programmer even outside the scope of database use.

MySQL follows the SQL:2003 syntax for stored routines, which is also used by IBM's DB2.

The MySQL implementation of stored routines is still in progress. All syntax described here is supported and any limitations and extensions are documented where appropriate.

Additional resources

- You may find the [Stored Procedures User Forum](#) of use when working with stored procedures and functions.
- For answers to some commonly asked questions regarding stored routines in MySQL, see [Section A.4, “MySQL 5.1 FAQ — Stored Procedures and Functions”](#).
- There are some restrictions on the use of stored routines. See [Section D.1, “Restrictions on Stored Routines, Triggers, and Events”](#).
- Binary logging for stored routines takes place as described in [Section 19.6, “Binary Logging of Stored Programs”](#).

19.2.1. Stored Routine Syntax

A stored routine is either a procedure or a function. Stored routines are created with the `CREATE PROCEDURE` and `CREATE FUNCTION` statements (see Section 12.1.15, “`CREATE PROCEDURE` and `CREATE FUNCTION` Syntax”). A procedure is invoked using a `CALL` statement (see Section 12.2.1, “`CALL` Syntax”), and can only pass back values using output variables. A function can be called from inside a statement just like any other function (that is, by invoking the function’s name), and can return a scalar value. The body of a stored routine can use compound statements (see Section 12.8, “`MySQL Compound-Statement Syntax`”).

Stored routines can be dropped with the `DROP PROCEDURE` and `DROP FUNCTION` statements (see Section 12.1.26, “`DROP PROCEDURE` and `DROP FUNCTION` Syntax”), and altered with the `ALTER PROCEDURE` and `ALTER FUNCTION` statements (see Section 12.1.5, “`ALTER PROCEDURE` Syntax”).

A stored procedure or function is associated with a particular database. This has several implications:

- When the routine is invoked, an implicit `USE db_name` is performed (and undone when the routine terminates). `USE` statements within stored routines are disallowed.
- You can qualify routine names with the database name. This can be used to refer to a routine that is not in the current database. For example, to invoke a stored procedure `p` or function `f` that is associated with the `test` database, you can say `CALL test.p()` or `test.f()`.
- When a database is dropped, all stored routines associated with it are dropped as well.

Stored functions cannot be recursive.

Recursion in stored procedures is allowed but disabled by default. To enable recursion, set the `max_sp_recursion_depth` server system variable to a value greater than zero. Stored procedure recursion increases the demand on thread stack space. If you increase the value of `max_sp_recursion_depth`, it may be necessary to increase thread stack size by increasing the value of `thread_stack` at server startup. See Section 5.1.3, “`Server System Variables`”, for more information.

MySQL supports the very useful extension that allows the use of regular `SELECT` statements (that is, without using cursors or local variables) inside a stored procedure. The result set of such a query is simply sent directly to the client. Multiple `SELECT` statements generate multiple result sets, so the client must use a MySQL client library that supports multiple result sets. This means the client must use a client library from a version of MySQL at least as recent as 4.1. The client should also specify the `CLIENT_MULTI_RESULTS` option when it connects. For C programs, this can be done with the `mysql_real_connect()` C API function. See Section 21.10.3.52, “`mysql_real_connect()`”, and Section 21.10.12, “`C API Support for Multiple Statement Execution`”.

MySQL Enterprise

MySQL Enterprise subscribers will find numerous articles about stored routines in the MySQL Enterprise Knowledge Base. Access to this collection of articles is one of the advantages of subscribing to MySQL Enterprise. For more information, see <http://www.mysql.com/products/enterprise/advisors.html>.

19.2.2. Stored Routines and MySQL Privileges

The MySQL grant system takes stored routines into account as follows:

- The `CREATE ROUTINE` privilege is needed to create stored routines.
- The `ALTER ROUTINE` privilege is needed to alter or drop stored routines. This privilege is granted automatically to the creator of a routine if necessary, and dropped when the routine creator drops the routine.
- The `EXECUTE` privilege is required to execute stored routines. However, this privilege is granted automatically to the creator of a routine if necessary (and dropped when the creator drops the routine). Also, the default `SQL SECURITY` characteristic for a routine is `DEFINER`, which enables users who have access to the database with which the routine is associated to execute the routine.
- If the `automatic_sp_privileges` system variable is 0, the `EXECUTE` and `ALTER ROUTINE` privileges are not automatically granted and dropped.

The server manipulates the `mysql.proc` table in response to statements that create, alter, or drop stored routines. It is not supported that the server will notice manual manipulation of this table.

19.2.3. Stored Routine Metadata

Metadata about stored routines can be obtained as follows:

- Query the `ROUTINES` table of the `INFORMATION_SCHEMA` database. See [Section 20.14, “The INFORMATION_SCHEMA ROUTINES Table”](#).
- Use the `SHOW CREATE PROCEDURE` and `SHOW CREATE FUNCTION` statements to see routine definitions. See [Section 12.5.5.11, “SHOW CREATE PROCEDURE Syntax”](#).
- Use the `SHOW PROCEDURE STATUS` and `SHOW FUNCTION STATUS` statements to see routine characteristics. See [Section 12.5.5.30, “SHOW PROCEDURE STATUS Syntax”](#).
- `INFORMATION_SCHEMA` does not have a `PARAMETERS` table until MySQL 6.0, so applications that need to acquire routine parameter information at runtime must use workarounds such as parsing the output of `SHOW CREATE` statements or the `param_list` column of the `mysql.proc` table. `param_list` contents can be processed from within a stored routine, unlike the output from `SHOW`.

19.2.4. Stored Procedures, Functions, Triggers, and `LAST_INSERT_ID()`

Within the body of a stored routine (procedure or function) or a trigger, the value of `LAST_INSERT_ID()` changes the same way as for statements executed outside the body of these kinds of objects (see [Section 11.11.3, “Information Functions”](#)). The effect of a stored routine or trigger upon the value of `LAST_INSERT_ID()` that is seen by following statements depends on the kind of routine:

- If a stored procedure executes statements that change the value of `LAST_INSERT_ID()`, the changed value is seen by statements that follow the procedure call.
- For stored functions and triggers that change the value, the value is restored when the function or trigger ends, so following statements do not see a changed value.

19.3. Using Triggers

A trigger is a named database object that is associated with a table, and that activates when a particular event occurs for the table. Some uses for triggers are to perform checks of values to be inserted into a table or to perform calculations on values involved in an update.

A trigger is defined to activate when an `INSERT`, `DELETE`, or `UPDATE` statement executes for the associated table. A trigger can be set to activate either before or after the triggering statement. For example, you can have a trigger activate before each row that is inserted into a table or after each row that is updated.

Important

MySQL triggers are activated by SQL statements *only*. They are not activated by changes in tables made by APIs that do not transmit SQL statements to the MySQL Server; in particular, they are not activated by updates made using the `NDB` API.

To use triggers if you have upgraded to MySQL 5.1 from an older release that did not support triggers, you should upgrade your grant tables so that they contain the trigger-related privileges. See [Section 4.4.8, “mysql_upgrade — Check Tables for MySQL Upgrade”](#).

The following discussion describes the syntax for creating and dropping triggers, and shows some examples of how to use them.

Additional resources

- You may find the [Triggers User Forum](#) of use when working with views.
- For answers to some commonly asked questions regarding triggers in MySQL, see [Section A.5, “MySQL 5.1 FAQ — Triggers”](#).
- There are some restrictions on the use of triggers; see [Section D.1, “Restrictions on Stored Routines, Triggers, and Events”](#).
- Binary logging for triggers takes place as described in [Section 19.6, “Binary Logging of Stored Programs”](#).

19.3.1. Trigger Syntax

To create a trigger or drop a trigger, use the `CREATE TRIGGER` or `DROP TRIGGER` statement. The syntax for these statements is described in [Section 12.1.19, “CREATE TRIGGER Syntax”](#), and [Section 12.1.30, “DROP TRIGGER Syntax”](#).

Here is a simple example that associates a trigger with a table for `INSERT` statements. The trigger acts as an accumulator, summing the values inserted into one of the columns of the table.

```
mysql> CREATE TABLE account (acct_num INT, amount DECIMAL(10,2));
Query OK, 0 rows affected (0.03 sec)

mysql> CREATE TRIGGER ins_sum BEFORE INSERT ON account
-> FOR EACH ROW SET @sum = @sum + NEW.amount;
Query OK, 0 rows affected (0.06 sec)
```

The `CREATE TRIGGER` statement creates a trigger named `ins_sum` that is associated with the `account` table. It also includes clauses that specify the trigger activation time, the triggering event, and what to do with the trigger activates:

- The keyword `BEFORE` indicates the trigger action time. In this case, the trigger should activate before each row inserted into the table. The other allowable keyword here is `AFTER`.
- The keyword `INSERT` indicates the event that activates the trigger. In the example, `INSERT` statements cause trigger activation. You can also create triggers for `DELETE` and `UPDATE` statements.
- The statement following `FOR EACH ROW` defines the statement to execute each time the trigger activates, which occurs once for each row affected by the triggering statement. In the example, the triggered statement is a simple `SET` that accumulates the values inserted into the `amount` column. The statement refers to the column as `NEW.amount` which means “the value of the `amount` column to be inserted into the new row.”

To use the trigger, set the accumulator variable to zero, execute an `INSERT` statement, and then see what value the variable has afterward:

```
mysql> SET @sum = 0;
mysql> INSERT INTO account VALUES(137,14.98),(141,1937.50),(97,-100.00);
mysql> SELECT @sum AS 'Total amount inserted';
+-----+
| Total amount inserted |
+-----+
| 1852.48                |
+-----+
```

In this case, the value of `@sum` after the `INSERT` statement has executed is $14.98 + 1937.50 - 100$, or `1852.48`.

To destroy the trigger, use a `DROP TRIGGER` statement. You must specify the schema name if the trigger is not in the default schema:

```
mysql> DROP TRIGGER test.ins_sum;
```

Triggers for a table are also dropped if you drop the table.

Trigger names exist in the schema namespace, meaning that all triggers must have unique names within a schema. Triggers in different schemas can have the same name.

In addition to the requirement that trigger names be unique for a schema, there are other limitations on the types of triggers you can create. In particular, you cannot have two triggers for a table that have the same activation time and activation event. For example, you cannot define two `BEFORE INSERT` triggers or two `AFTER UPDATE` triggers for a table. This should rarely be a significant limitation, because it is possible to define a trigger that executes multiple statements by using the `BEGIN . . . END` compound statement construct after `FOR EACH ROW`. (An example appears later in this section.)

The `OLD` and `NEW` keywords enable you to access columns in the rows affected by a trigger. (`OLD` and `NEW` are not case sensitive.) In an `INSERT` trigger, only `NEW.col_name` can be used; there is no old row. In a `DELETE` trigger, only `OLD.col_name` can be used; there is no new row. In an `UPDATE` trigger, you can use `OLD.col_name` to refer to the columns of a row before it is updated and `NEW.col_name` to refer to the columns of the row after it is updated.

A column named with `OLD` is read only. You can refer to it (if you have the `SELECT` privilege), but not modify it. A column named with `NEW` can be referred to if you have the `SELECT` privilege for it. In a `BEFORE` trigger, you can also change its value with `SET NEW.col_name = value` if you have the `UPDATE` privilege for it. This means you can use a trigger to modify the values to be inserted into a new row or that are used to update a row.

In a `BEFORE` trigger, the `NEW` value for an `AUTO_INCREMENT` column is 0, not the automatically generated sequence number that will be generated when the new record actually is inserted.

`OLD` and `NEW` are MySQL extensions to triggers.

By using the `BEGIN . . . END` construct, you can define a trigger that executes multiple statements. Within the `BEGIN` block, you also can use other syntax that is allowed within stored routines such as conditionals and loops. However, just as for stored

routines, if you use the `mysql` program to define a trigger that executes multiple statements, it is necessary to redefine the `mysql` statement delimiter so that you can use the `;` statement delimiter within the trigger definition. The following example illustrates these points. It defines an `UPDATE` trigger that checks the new value to be used for updating each row, and modifies the value to be within the range from 0 to 100. This must be a `BEFORE` trigger because the value needs to be checked before it is used to update the row:

```
mysql> delimiter //
mysql> CREATE TRIGGER upd_check BEFORE UPDATE ON account
-> FOR EACH ROW
-> BEGIN
->     IF NEW.amount < 0 THEN
->         SET NEW.amount = 0;
->     ELSEIF NEW.amount > 100 THEN
->         SET NEW.amount = 100;
->     END IF;
-> END; //
mysql> delimiter ;
```

It can be easier to define a stored procedure separately and then invoke it from the trigger using a simple `CALL` statement. This is also advantageous if you want to invoke the same routine from within several triggers.

There are some limitations on what can appear in statements that a trigger executes when activated:

- The trigger cannot use the `CALL` statement to invoke stored procedures that return data to the client or that use dynamic SQL. (Stored procedures are allowed to return data to the trigger through `OUT` or `INOUT` parameters.)
- The trigger cannot use statements that explicitly or implicitly begin or end a transaction such as `START TRANSACTION`, `COMMIT`, or `ROLLBACK`.

MySQL handles errors during trigger execution as follows:

- If a `BEFORE` trigger fails, the operation on the corresponding row is not performed.
- A `BEFORE` trigger is activated by the *attempt* to insert or modify the row, regardless of whether the attempt subsequently succeeds.
- An `AFTER` trigger is executed only if the `BEFORE` trigger (if any) and the row operation both execute successfully.
- An error during either a `BEFORE` or `AFTER` trigger results in failure of the entire statement that caused trigger invocation.
- For transactional tables, failure of a statement should cause rollback of all changes performed by the statement. Failure of a trigger causes the statement to fail, so trigger failure also causes rollback. For non-transactional tables, such rollback cannot be done, so although the statement fails, any changes performed prior to the point of the error remain in effect.

19.3.2. Trigger Metadata

Metadata about triggers can be obtained as follows:

- Query the `TRIGGERS` table of the `INFORMATION_SCHEMA` database. See [Section 20.16, “The INFORMATION_SCHEMA TRIGGERS Table”](#).
- Use the `SHOW TRIGGERS` statement. See [Section 12.5.5.40, “SHOW TRIGGERS Syntax”](#).

19.4. Using the Event Scheduler

The *MySQL Event Scheduler* manages the scheduling and execution of events: Tasks that run according to schedule. Event support was added in MySQL 5.1.6. The following discussion covers the Event Scheduler and is divided into the following sections:

- [Section 19.4.1, “Event Scheduler Overview”](#), provides an introduction to and conceptual overview of MySQL Events.
- [Section 19.4.3, “Event Syntax”](#), discusses the SQL statements for creating, altering, and dropping MySQL Events.
- [Section 19.4.4, “Event Metadata”](#), shows how to obtain information about events and how this information is stored by the MySQL Server.
- [Section 19.4.6, “The Event Scheduler and MySQL Privileges”](#), discusses the privileges required to work with events and the

ramifications that events have with regard to privileges when executing.

Stored routines require the `event` table in the `mysql` database. This table is created during the MySQL 5.1 installation procedure. If you are upgrading to MySQL 5.1 from an earlier version, be sure to update your grant tables to make sure that the `event` table exists. See [Section 4.4.8, “mysql_upgrade — Check Tables for MySQL Upgrade”](#).

Additional resources

- You may find the [MySQL Event Scheduler User Forum](#) of use when working with scheduled events.
- There are some restrictions on the use of events; see [Section D.1, “Restrictions on Stored Routines, Triggers, and Events”](#).
- Binary logging for events takes place as described in [Section 19.6, “Binary Logging of Stored Programs”](#).

19.4.1. Event Scheduler Overview

MySQL Events are tasks that run according to a schedule. Therefore, we sometimes refer to them as *scheduled* events. When you create an event, you are creating a named database object containing one or more SQL statements to be executed at one or more regular intervals, beginning and ending at a specific date and time. Conceptually, this is similar to the idea of the Unix `crontab` (also known as a “cron job”) or the Windows Task Scheduler.

Scheduled tasks of this type are also sometimes known as “temporal triggers”, implying that these are objects that are triggered by the passage of time. While this is essentially correct, we prefer to use the term *events* in order to avoid confusion with triggers of the type discussed in [Section 19.3, “Using Triggers”](#). Events should more specifically not be confused with “temporary triggers”. Whereas a trigger is a database object whose statements are executed in response to a specific type of event that occurs on a given table, a (scheduled) event is an object whose statements are executed in response to the passage of a specified time interval.

While there is no provision in the SQL Standard for event scheduling, there are precedents in other database systems, and you may notice some similarities between these implementations and that found in the MySQL Server.

MySQL Events have the following major features and properties:

- In MySQL 5.1.12 and later, an event is uniquely identified by its name and the schema to which it is assigned. (Previously, an event was also unique to its definer.)
- An event performs a specific action according to a schedule. This action consists of an SQL statement, which can be a compound statement in a `BEGIN . . . END` block if desired (see [Section 12.8, “MySQL Compound-Statement Syntax”](#)). An event's timing can be either *one-time* or *recurrent*. A one-time event executes one time only. A recurrent event repeats its action at a regular interval, and the schedule for a recurring event can be assigned a specific start day and time, end day and time, both, or neither. (By default, a recurring event's schedule begins as soon as it is created, and continues indefinitely, until it is disabled or dropped.)

If a repeating event does not terminate within its scheduling interval, the result may be multiple instances of the event executing simultaneously. If this is undesirable, you should institute a mechanism to prevent simultaneous instances. For example, you could use the `GET_LOCK()` function, or row or table locking.

- Users can create, modify, and drop scheduled events using SQL statements intended for these purposes. Syntactically invalid event creation and modification statements fail with an appropriate error message. *A user may include statements in an event's action which require privileges that the user does not actually have.* The event creation or modification statement succeeds but the event's action fails. See [Section 19.4.6, “The Event Scheduler and MySQL Privileges”](#) for details.
- Many of the properties of an event can be set or modified using SQL statements. These properties include the event's name, timing, persistence (that is, whether it is preserved following the expiration of its schedule), status (enabled or disabled), action to be performed, and the schema to which it is assigned. See [Section 12.1.2, “ALTER EVENT Syntax”](#).

The default definer of an event is the user who created the event, unless the event has been altered, in which case the definer is the user who issued the last `ALTER EVENT` statement affecting that event. An event can be modified by any user having the `EVENT` privilege on the database for which the event is defined. (Prior to MySQL 5.1.12, only an event's definer, or a user having privileges on the `mysql.event` table, could modify a given event.) See [Section 19.4.6, “The Event Scheduler and MySQL Privileges”](#).

- An event's action statement may include most SQL statements permitted within stored routines. For restrictions, see [Section D.1, “Restrictions on Stored Routines, Triggers, and Events”](#).

19.4.2. Event Scheduler Configuration

Events are executed by a special *event scheduler thread*; when we refer to the Event Scheduler, we actually refer to this thread. When running, the event scheduler thread and its current state can be seen by users having the `PROCESS` privilege in the output of `SHOW PROCESSLIST`, as shown in the discussion that follows.

The global `event_scheduler` system variable determines whether the Event Scheduler is enabled and running on the server. Beginning with MySQL 5.1.12, it has one of these 3 values, which affect event scheduling as described here:

- **OFF**: The Event Scheduler is stopped. The event scheduler thread does not run, is not shown in the output of `SHOW PROCESSLIST`, and no scheduled events are executed. **OFF** is the default value for `event_scheduler`.

When the Event Scheduler is stopped (`event_scheduler` is **OFF**), it can be started by setting the value of `event_scheduler` to **ON**. (See next item.)

- **ON**: The Event Scheduler is started; the event scheduler thread runs and executes all scheduled events.

When the Event Scheduler is **ON**, the event scheduler thread is listed in the output of `SHOW PROCESSLIST` as a daemon process, and its state is represented as shown here:

```
mysql> SHOW PROCESSLIST\G
***** 1. row *****
  Id: 1
  User: root
  Host: localhost
  db: NULL
  Command: Query
  Time: 0
  State: NULL
  Info: show processlist
***** 2. row *****
  Id: 2
  User: event_scheduler
  Host: localhost
  db: NULL
  Command: Daemon
  Time: 3
  State: Waiting for next activation
  Info: NULL
2 rows in set (0.00 sec)
```

Event scheduling can be stopped by setting the value of `event_scheduler` to **OFF**.

- **DISABLED**: This value renders the Event Scheduler non-operational. When the Event Scheduler is **DISABLED**, the event scheduler thread does not run (and so does not appear in the output of `SHOW PROCESSLIST`). In addition, the Event Scheduler state cannot be changed at runtime.

If the Event Scheduler status has not been set to **DISABLED**, `event_scheduler` can be toggled between **ON** and **OFF** (using `SET`). It is also possible to use `0` for **OFF**, and `1` for **ON** when setting this variable. Thus, any of the following 4 statements can be used in the `mysql` client to turn on the Event Scheduler:

```
SET GLOBAL event_scheduler = ON;
SET @@global.event_scheduler = ON;
SET GLOBAL event_scheduler = 1;
SET @@global.event_scheduler = 1;
```

Similarly, any of these 4 statements can be used to turn off the Event Scheduler:

```
SET GLOBAL event_scheduler = OFF;
SET @@global.event_scheduler = OFF;
SET GLOBAL event_scheduler = 0;
SET @@global.event_scheduler = 0;
```

Although **ON** and **OFF** have numeric equivalents, the value displayed for `event_scheduler` by `SELECT` or `SHOW VARIABLES` is always one of **OFF**, **ON**, or **DISABLED**. *DISABLED has no numeric equivalent*. For this reason, **ON** and **OFF** are usually preferred over `1` and `0` when setting this variable.

Note that attempting to set `event_scheduler` without specifying it as a global variable causes an error:

```
mysql< SET @@event_scheduler = OFF;
ERROR 1229 (HY000): VARIABLE 'EVENT_SCHEDULER' IS A GLOBAL
VARIABLE AND SHOULD BE SET WITH SET GLOBAL
```

Important

It is possible to set the Event Scheduler to **DISABLED** only at server startup. If `event_scheduler` is **ON** or **OFF**,

you cannot set it to `DISABLED` at runtime. Also, if the Event Scheduler is set to `DISABLED` at startup, you cannot change the value of `event_scheduler` at runtime.

To disable the event scheduler, use one of the following two methods:

- As a command-line option when starting the server:

```
--event-scheduler=DISABLED
```

- In the server configuration file (`my.cnf`, or `my.ini` on Windows systems), include the line where it will be read by the server (for example, in a `[mysqld]` section):

```
event_scheduler=DISABLED
```

To enable the Event Scheduler, restart the server without the `--event-scheduler=DISABLED` command-line option, or after removing or commenting out the line containing `event_scheduler=DISABLED` in the server configuration file, as appropriate. Alternatively, you can use `ON` (or `1`) or `OFF` (or `0`) in place of the `DISABLED` value when starting the server.

Note

You can issue event-manipulation statements when `event_scheduler` is set to `DISABLED`. No warnings or errors are generated in such cases (provided that the statements are themselves valid). However, scheduled events cannot execute until this variable is set to `ON` (or `1`). Once this has been done, the event scheduler thread executes all events whose scheduling conditions are satisfied.

In MySQL 5.1.11, `event_scheduler` behaved as follows: this variable could take one of the values `0` (or `OFF`), `1` (or `ON`), or `2`. Setting it to `0` turned event scheduling off, so that the event scheduler thread did not run; the `event_scheduler` variable could not be set to this value while the server was running. Setting it to `1` so that the event scheduler thread ran and executed scheduled events. In this state, the event scheduler thread appeared to be sleeping when viewed with `SHOW PROCESSLIST`. When `event_scheduler` was set to `2` (which was the default value), the Event Scheduler was considered to be “suspended”; the event scheduler thread ran and could be seen in the output of `SHOW PROCESSLIST` (where `Suspended` was displayed in the `State` column), but did not execute any scheduled events. The value of `event_scheduler` could be changed only between `1` (or `ON`) and `2` while the server was running. Setting it to `0` (or `OFF`) required a server restart, as did changing its value from `0` (or `OFF`) to `1` (or `ON`) or `2`.

Prior to MySQL 5.1.11, `event_scheduler` could take one of only the 2 values `0|OFF` or `1|ON`, and the default value was `0|OFF`. It was also possible to start and stop the event scheduler thread while the MySQL server was running.

For more information concerning the reasons for these changes in behaviour, see [Bug#17619](#).

Beginning with MySQL 5.1.17, starting the MySQL server with the `--skip-grant-tables` option causes `event_scheduler` to be set to `DISABLED`, overriding any other value set either on the command line or in the `my.cnf` or `my.ini` file ([Bug#26807](#)).

For SQL statements used to create, alter, and drop events, see [Section 19.4.3, “Event Syntax”](#).

MySQL 5.1.6 and later provides an `EVENTS` table in the `INFORMATION_SCHEMA` database. This table can be queried to obtain information about scheduled events which have been defined on the server. See [Section 19.4.4, “Event Metadata”](#), and [Section 20.20, “The INFORMATION_SCHEMA EVENTS Table”](#), for more information.

For information regarding event scheduling and the MySQL privilege system, see [Section 19.4.6, “The Event Scheduler and MySQL Privileges”](#).

19.4.3. Event Syntax

MySQL 5.1.6 and later provides several SQL statements for working with scheduled events:

- New events are defined using the `CREATE EVENT` statement. See [Section 12.1.11, “CREATE EVENT Syntax”](#).
- The definition of an existing event can be changed by means of the `ALTER EVENT` statement. See [Section 12.1.2, “ALTER EVENT Syntax”](#).
- When a scheduled event is no longer wanted or needed, it can be deleted from the server by its definer using the `DROP EVENT` statement. See [Section 12.1.22, “DROP EVENT Syntax”](#). Whether an event persists past the end of its schedule also depends on its `ON COMPLETION` clause, if it has one. See [Section 12.1.11, “CREATE EVENT Syntax”](#).

An event can be dropped by any user having the `EVENT` privilege for the database on which the event is defined. Prior to

MySQL 5.1.12, a user other than the definer required privileges on the `mysql.event` table. See [Section 19.4.6, “The Event Scheduler and MySQL Privileges”](#).

19.4.4. Event Metadata

Metadata about events can be obtained as follows:

- Query the `EVENTS` table of the `INFORMATION_SCHEMA` database. See [Section 20.20, “The INFORMATION_SCHEMA EVENTS Table”](#).
- Use the `SHOW CREATE EVENT` statement. See [Section 12.5.5.9, “SHOW CREATE EVENT Syntax”](#).
- Use the `SHOW EVENTS` statement. See [Section 12.5.5.19, “SHOW EVENTS Syntax”](#).

19.4.5. Event Scheduler Status

The Event Scheduler writes information about event execution that terminates with an error or warning to the MySQL Server's error log. See [Section 19.4.6, “The Event Scheduler and MySQL Privileges”](#) for an example. (Before MySQL 5.1.31, the Event Scheduler also logged messages when events started execution and terminated successfully.)

Information about the state of the Event Scheduler for debugging and troubleshooting purposes can be obtained as follows:

- In debugging builds of MySQL 5.1.11, you can use the `SHOW SCHEDULER STATUS` statement; see [Section 12.5.5.34, “SHOW SCHEDULER STATUS Syntax”](#). This statement was removed in MySQL 5.1.12. We intend to implement an SQL statement providing similar functionality in a future MySQL release.
- Beginning with MySQL 5.1.12, event scheduler status information can be obtained by running `mysqladmin debug` (see [Section 4.5.2, “mysqladmin — Client for Administering a MySQL Server”](#)); after running this command, the server's error log contains output relating to the Event Scheduler, similar to what is shown here:

```
Events status:
LLA = Last Locked At   LUA = Last Unlocked At
WOC = Waiting On Condition  DL = Data Locked

Event scheduler status:
State      : INITIALIZED
Thread id  : 0
LLA       : init_scheduler:313
LUA       : init_scheduler:318
WOC       : NO
Workers   : 0
Executed   : 0
Data locked: NO

Event queue status:
Element count : 1
Data locked   : NO
Attempting lock : NO
LLA          : init_queue:148
LUA          : init_queue:168
WOC          : NO
Next activation : 0000-00-00 00:00:00
```

For `SELECT ... INTO var_list` statements, if the query returns no rows, a warning with error code 1329 occurs (`No data`), and the variable values remain unchanged. If the query returns multiple rows, error 1172 occurs (`Result consisted of more than one row`). In the context of such statements that occur as part of events executed by the Event Scheduler, diagnostics messages (not only errors, but also warnings) are written to the error log, and, on Windows, to the application event log. For frequently executed events, it is possible for this to result in many logged messages. For either condition, you can avoid this problem by declaring a condition handler; see [Section 12.8.4.2, “DECLARE for Handlers”](#). For statements that may retrieve multiple rows, another strategy is to use `LIMIT 1` to limit the result set to a single row.

19.4.6. The Event Scheduler and MySQL Privileges

To enable or disable the execution of scheduled events, it is necessary to set the value of the global `event_scheduler` system variable. This requires the `SUPER` privilege.

MySQL 5.1.6 introduces a privilege governing the creation, modification, and deletion of events, the `EVENT` privilege. This privilege can be bestowed using `GRANT`. For example, this `GRANT` statement confers the `EVENT` privilege for the schema named `myschema` on the user `jon@ghidora`:

```
GRANT EVENT ON myschema.* TO jon@ghidora;
```

(We assume that this user account already exists, and that we wish for it to remain unchanged otherwise.)

To grant this same user the `EVENT` privilege on all schemas, use the following statement:

```
GRANT EVENT ON *.* TO jon@ghidora;
```

The `EVENT` privilege has global or schema-level scope. Therefore, trying to grant it on a single table results in an error as shown:

```
mysql> GRANT EVENT ON myschema.mytable TO jon@ghidora;
ERROR 1144 (42000): ILLEGAL GRANT/REVOKE COMMAND; PLEASE
CONSULT THE MANUAL TO SEE WHICH PRIVILEGES CAN BE USED
```

It is important to understand that an event is executed with the privileges of its definer, and that it cannot perform any actions for which its definer does not have the requisite privileges. For example, suppose that `jon@ghidora` has the `EVENT` privilege for `myschema`. Suppose also that this user has the `SELECT` privilege for `myschema`, but no other privileges for this schema. It is possible for `jon@ghidora` to create a new event such as this one:

```
CREATE EVENT e_store_ts
ON SCHEDULE
EVERY 10 SECOND
DO
INSERT INTO myschema.mytable VALUES (UNIX_TIMESTAMP());
```

The user waits for a minute or so, and then performs a `SELECT * FROM mytable;` query, expecting to see several new rows in the table. Instead, the table is empty. Since the user does not have the `INSERT` privilege for the table in question, the event has no effect.

If you inspect the MySQL error log (`hostname.err`), you can see that the event is executing, but the action it is attempting to perform fails, as indicated by `RetCode=0`:

```
060209 22:39:44 [Note] EVEX EXECUTING event newdb.e [EXPR:10]
060209 22:39:44 [Note] EVEX EXECUTED event newdb.e [EXPR:10]. RetCode=0
060209 22:39:54 [Note] EVEX EXECUTING event newdb.e [EXPR:10]
060209 22:39:54 [Note] EVEX EXECUTED event newdb.e [EXPR:10]. RetCode=0
060209 22:40:04 [Note] EVEX EXECUTING event newdb.e [EXPR:10]
060209 22:40:04 [Note] EVEX EXECUTED event newdb.e [EXPR:10]. RetCode=0
```

Since this user very likely does not have access to the error log, it is possible to verify whether the event's action statement is valid by executing it directly:

```
mysql> INSERT INTO myschema.mytable VALUES (UNIX_TIMESTAMP());
ERROR 1142 (42000): INSERT COMMAND DENIED TO USER
'JON'@'GHIDORA' FOR TABLE 'MYTABLE'
```

Inspection of the `INFORMATION_SCHEMA.EVENTS` table shows that `e_store_ts` exists and is enabled, but its `LAST_EXECUTED` column is `NULL`:

```
mysql> SELECT * FROM INFORMATION_SCHEMA.EVENTS
> WHERE EVENT_NAME='e_store_ts'
> AND EVENT_SCHEMA='myschema'\G
***** 1. row *****
EVENT_CATALOG: NULL
EVENT_SCHEMA: myschema
EVENT_NAME: e_store_ts
DEFINER: jon@ghidora
EVENT_BODY: SQL
EVENT_DEFINITION: INSERT INTO myschema.mytable VALUES (UNIX_TIMESTAMP())
EVENT_TYPE: RECURRING
EXECUTE_AT: NULL
INTERVAL_VALUE: 5
INTERVAL_FIELD: SECOND
SQL_MODE: NULL
STARTS: 0000-00-00 00:00:00
ENDS: 0000-00-00 00:00:00
STATUS: ENABLED
ON_COMPLETION: NOT PRESERVE
CREATED: 2006-02-09 22:36:06
LAST ALTERED: 2006-02-09 22:36:06
LAST_EXECUTED: NULL
EVENT_COMMENT:
1 row in set (0.00 sec)
```

Note

Prior to MySQL 5.1.12, there was no `EVENT_DEFINITION` column, and `EVENT_BODY` contained the SQL state-

ment or statements to be executed. See [Section 20.20](#), “The `INFORMATION_SCHEMA` `EVENTS` Table”, for more information.

To rescind the `EVENT` privilege, use the `REVOKE` statement. In this example, the `EVENT` privilege on the schema `myschema` is removed from the `jon@ghidora` user account:

```
REVOKE EVENT ON myschema.* FROM jon@ghidora;
```

Important

Revoking the `EVENT` privilege from a user does not delete or disable any events that may have been created by that user.

An event is not migrated or dropped as a result of renaming or dropping the user who created it.

For example, suppose that the user `jon@ghidora` has been granted the `EVENT` and `INSERT` privileges on the `myschema` schema. This user then creates the following event:

```
CREATE EVENT e_insert
ON SCHEDULE
EVERY 7 SECOND
DO
INSERT INTO myschema.mytable;
```

After this event has been created, `root` revokes the `EVENT` privilege for `jon@ghidora`. However, `e_insert` continues to execute, inserting a new row into `mytable` each seven seconds. The same would be true if `root` had issued either of these statements:

- `DROP USER jon@ghidora;`
- `RENAME USER jon@ghidora TO someotherguy@ghidora;`

You can verify that this is true by examining the `mysql.event` table (discussed later in this section) or the `INFORMATION_SCHEMA.EVENTS` table (see [Section 20.20](#), “The `INFORMATION_SCHEMA` `EVENTS` Table”) before and after issuing a `DROP USER` or `RENAME USER` statement.

Event definitions are stored in the `mysql.event` table, which was added in MySQL 5.1.6. To drop an event created by another user account, the MySQL `root` user (or another user with the necessary privileges) can delete rows from this table. For example, to remove the event `e_insert` shown previously, `root` can use the following statement:

```
DELETE FROM mysql.event
WHERE db = 'myschema'
AND definer = 'jon@ghidora'
AND name = 'e_insert';
```

It is very important to match the event name, database schema name, and user account when deleting rows from the `mysql.event` table. This is because the same user can create different events of the same name in different schemas.

Note

The namespace for scheduled events changed in MySQL 5.1.12. Prior to that MySQL version, different users could create different events having the same name in the same database; in MySQL 5.1.12 and later, that is no longer the case. When upgrading to MySQL 5.1.12 or later from MySQL 5.1.11 or earlier, it is extremely important to make sure that no events in the same database share the same name, *prior to performing the upgrade*.

Users' `EVENT` privileges are stored in the `Event_priv` columns of the `mysql.user` and `mysql.db` tables. In both cases, this column holds one of the values 'Y' or 'N'. 'N' is the default. `mysql.user.Event_priv` is set to 'Y' for a given user only if that user has the global `EVENT` privilege (that is, if the privilege was bestowed using `GRANT EVENT ON *.*`). For a schema-level `EVENT` privilege, `GRANT` creates a row in `mysql.db` and sets that row's `Db` column to the name of the schema, the `User` column to the name of the user, and the `Event_priv` column to 'Y'. There should never be any need to manipulate these tables directly, since the `GRANT EVENT` and `REVOKE EVENT` statements perform the required operations on them.

MySQL 5.1.6 introduces five status variables providing counts of event-related operations (but *not* of statements executed by events; see [Section D.1](#), “Restrictions on Stored Routines, Triggers, and Events”). These are:

- `Com_create_event`: The number of `CREATE EVENT` statements executed since the last server restart.
- `Com_alter_event`: The number of `ALTER EVENT` statements executed since the last server restart.

- `Com_drop_event`: The number of `DROP EVENT` statements executed since the last server restart.
- `Com_show_create_event`: The number of `SHOW CREATE EVENT` statements executed since the last server restart.
- `Com_show_events`: The number of `SHOW EVENTS` statements executed since the last server restart.

You can view current values for all of these at one time by running the statement `SHOW STATUS LIKE '%event%'`;

19.5. Using Views

Views (including updatable views) are available in MySQL Server 5.1. Views are stored queries that when invoked produce a result set. A view acts as a virtual table.

To use views if you have upgraded to MySQL 5.1 from an older release that did not support views, you should upgrade your grant tables so that they contain the view-related privileges. See [Section 4.4.8, “mysql_upgrade — Check Tables for MySQL Upgrade”](#).

The following discussion describes the syntax for creating and dropping views, and shows some examples of how to use them.

Additional resources

- You may find the [Views User Forum](#) of use when working with views.
- For answers to some commonly asked questions regarding views in MySQL, see [Section A.6, “MySQL 5.1 FAQ — Views”](#).
- There are some restrictions on the use of views; see [Section D.4, “Restrictions on Views”](#).

19.5.1. View Syntax

The `CREATE VIEW` statement creates a new view (see [Section 12.1.20, “CREATE VIEW Syntax”](#)). To alter the definition of a view or drop a view, use `ALTER VIEW` (see [Section 12.1.9, “ALTER VIEW Syntax”](#)), or `DROP VIEW` (see [Section 12.1.31, “DROP VIEW Syntax”](#)).

A view can be created from many kinds of `SELECT` statements. It can refer to base tables or other views. It can use joins, `UNION`, and subqueries. The `SELECT` need not even refer to any tables. The following example defines a view that selects two columns from another table, as well as an expression calculated from those columns:

```
mysql> CREATE TABLE t (qty INT, price INT);
mysql> INSERT INTO t VALUES(3, 50), (5, 60);
mysql> CREATE VIEW v AS SELECT qty, price, qty*price AS value FROM t;
mysql> SELECT * FROM v;
+----+-----+-----+
| qty | price | value |
+----+-----+-----+
|  3  |   50  |   150 |
|  5  |   60  |   300 |
+----+-----+-----+
mysql> SELECT * FROM v WHERE qty = 5;
+----+-----+-----+
| qty | price | value |
+----+-----+-----+
|  5  |   60  |   300 |
+----+-----+-----+
```

19.5.2. View Processing Algorithms

The optional `ALGORITHM` clause for `CREATE VIEW` or `ALTER VIEW` is a MySQL extension to standard SQL. It affects how MySQL processes the view. `ALGORITHM` takes three values: `MERGE`, `TEMPTABLE`, or `UNDEFINED`. The default algorithm is `UNDEFINED` if no `ALGORITHM` clause is present.

For `MERGE`, the text of a statement that refers to the view and the view definition are merged such that parts of the view definition replace corresponding parts of the statement.

For `TEMPTABLE`, the results from the view are retrieved into a temporary table, which then is used to execute the statement.

For `UNDEFINED`, MySQL chooses which algorithm to use. It prefers `MERGE` over `TEMPTABLE` if possible, because `MERGE` is usually more efficient and because a view cannot be updatable if a temporary table is used.

A reason to choose `TEMPTABLE` explicitly is that locks can be released on underlying tables after the temporary table has been created and before it is used to finish processing the statement. This might result in quicker lock release than the `MERGE` algorithm so

that other clients that use the view are not blocked as long.

A view algorithm can be `UNDEFINED` for three reasons:

- No `ALGORITHM` clause is present in the `CREATE VIEW` statement.
- The `CREATE VIEW` statement has an explicit `ALGORITHM = UNDEFINED` clause.
- `ALGORITHM = MERGE` is specified for a view that can be processed only with a temporary table. In this case, MySQL generates a warning and sets the algorithm to `UNDEFINED`.

As mentioned earlier, `MERGE` is handled by merging corresponding parts of a view definition into the statement that refers to the view. The following examples briefly illustrate how the `MERGE` algorithm works. The examples assume that there is a view `v_merge` that has this definition:

```
CREATE ALGORITHM = MERGE VIEW v_merge (vc1, vc2) AS
SELECT c1, c2 FROM t WHERE c3 > 100;
```

Example 1: Suppose that we issue this statement:

```
SELECT * FROM v_merge;
```

MySQL handles the statement as follows:

- `v_merge` becomes `t`
- `*` becomes `vc1, vc2`, which corresponds to `c1, c2`
- The view `WHERE` clause is added

The resulting statement to be executed becomes:

```
SELECT c1, c2 FROM t WHERE c3 > 100;
```

Example 2: Suppose that we issue this statement:

```
SELECT * FROM v_merge WHERE vc1 < 100;
```

This statement is handled similarly to the previous one, except that `vc1 < 100` becomes `c1 < 100` and the view `WHERE` clause is added to the statement `WHERE` clause using an `AND` connective (and parentheses are added to make sure the parts of the clause are executed with correct precedence). The resulting statement to be executed becomes:

```
SELECT c1, c2 FROM t WHERE (c3 > 100) AND (c1 < 100);
```

Effectively, the statement to be executed has a `WHERE` clause of this form:

```
WHERE (select WHERE) AND (view WHERE)
```

If the `MERGE` algorithm cannot be used, a temporary table must be used instead. `MERGE` cannot be used if the view contains any of the following constructs:

- Aggregate functions (`SUM()`, `MIN()`, `MAX()`, `COUNT()`, and so forth)
- `DISTINCT`
- `GROUP BY`
- `HAVING`
- `LIMIT`
- `UNION` or `UNION ALL`
- Subquery in the select list

- Refers only to literal values (in this case, there is no underlying table)

19.5.3. Updatable and Insertable Views

Some views are updatable. That is, you can use them in statements such as `UPDATE`, `DELETE`, or `INSERT` to update the contents of the underlying table. For a view to be updatable, there must be a one-to-one relationship between the rows in the view and the rows in the underlying table. There are also certain other constructs that make a view non-updatable. To be more specific, a view is not updatable if it contains any of the following:

- Aggregate functions (`SUM()`, `MIN()`, `MAX()`, `COUNT()`, and so forth)
- `DISTINCT`
- `GROUP BY`
- `HAVING`
- `UNION` or `UNION ALL`
- Subquery in the select list
- Certain joins (see additional join discussion later in this section)
- Non-updatable view in the `FROM` clause
- A subquery in the `WHERE` clause that refers to a table in the `FROM` clause
- Refers only to literal values (in this case, there is no underlying table to update)
- Uses `ALGORITHM = TEMPTABLE` (use of a temporary table always makes a view non-updatable)
- Multiple references to any column of a base table.

With respect to insertability (being updatable with `INSERT` statements), an updatable view is insertable if it also satisfies these additional requirements for the view columns:

- There must be no duplicate view column names.
- The view must contain all columns in the base table that do not have a default value.
- The view columns must be simple column references and not derived columns. A derived column is one that is not a simple column reference but is derived from an expression. These are examples of derived columns:

```
3.14159
col1 + 3
UPPER(col2)
col3 / col4
(subquery)
```

A view that has a mix of simple column references and derived columns is not insertable, but it can be updatable if you update only those columns that are not derived. Consider this view:

```
CREATE VIEW v AS SELECT col1, 1 AS col2 FROM t;
```

This view is not insertable because `col2` is derived from an expression. But it is updatable if the update does not try to update `col2`. This update is allowable:

```
UPDATE v SET col1 = 0;
```

This update is not allowable because it attempts to update a derived column:

```
UPDATE v SET col2 = 0;
```

It is sometimes possible for a multiple-table view to be updatable, assuming that it can be processed with the `MERGE` algorithm. For this to work, the view must use an inner join (not an outer join or a `UNION`). Also, only a single table in the view definition can be

updated, so the `SET` clause must name only columns from one of the tables in the view. Views that use `UNION ALL` are disallowed even though they might be theoretically updatable, because the implementation uses temporary tables to process them.

For a multiple-table updatable view, `INSERT` can work if it inserts into a single table. `DELETE` is not supported.

`INSERT DELAYED` is not supported for views.

If a table contains an `AUTO_INCREMENT` column, inserting into an insertable view on the table that does not include the `AUTO_INCREMENT` column does not change the value of `LAST_INSERT_ID()`, because the side effects of inserting default values into columns not part of the view should not be visible.

The `WITH CHECK OPTION` clause can be given for an updatable view to prevent inserts or updates to rows except those for which the `WHERE` clause in the `select_statement` is true.

In a `WITH CHECK OPTION` clause for an updatable view, the `LOCAL` and `CASCADED` keywords determine the scope of check testing when the view is defined in terms of another view. The `LOCAL` keyword restricts the `CHECK OPTION` only to the view being defined. `CASCADED` causes the checks for underlying views to be evaluated as well. When neither keyword is given, the default is `CASCADED`. Consider the definitions for the following table and set of views:

```
mysql> CREATE TABLE t1 (a INT);
mysql> CREATE VIEW v1 AS SELECT * FROM t1 WHERE a < 2
-> WITH CHECK OPTION;
mysql> CREATE VIEW v2 AS SELECT * FROM v1 WHERE a > 0
-> WITH LOCAL CHECK OPTION;
mysql> CREATE VIEW v3 AS SELECT * FROM v1 WHERE a > 0
-> WITH CASCADED CHECK OPTION;
```

Here the `v2` and `v3` views are defined in terms of another view, `v1`. `v2` has a `LOCAL` check option, so inserts are tested only against the `v2` check. `v3` has a `CASCADED` check option, so inserts are tested not only against its own check, but against those of underlying views. The following statements illustrate these differences:

```
mysql> INSERT INTO v2 VALUES (2);
Query OK, 1 row affected (0.00 sec)
mysql> INSERT INTO v3 VALUES (2);
ERROR 1369 (HY000): CHECK OPTION failed 'test.v3'
```

MySQL sets a flag, called the view updatability flag, at `CREATE VIEW` time. The flag is set to `YES` (true) if `UPDATE` and `DELETE` (and similar operations) are legal for the view. Otherwise, the flag is set to `NO` (false). The `IS_UPDATABLE` column in the `INFORMATION_SCHEMA.VIEWS` table displays the status of this flag. It means that the server always knows whether a view is updatable. If the view is not updatable, statements such `UPDATE`, `DELETE`, and `INSERT` are illegal and will be rejected. (Note that even if a view is updatable, it might not be possible to insert into it, as described elsewhere in this section.)

The updatability of views may be affected by the value of the `updatable_views_with_limit` system variable. See [Section 5.1.3, “Server System Variables”](#).

19.5.4. View Metadata

Metadata about views can be obtained as follows:

- Query the `VIEWS` table of the `INFORMATION_SCHEMA` database. See [Section 20.15, “The INFORMATION_SCHEMA VIEWS Table”](#).
- Use the `SHOW CREATE VIEW` statement. See [Section 12.5.5.14, “SHOW CREATE VIEW Syntax”](#).

19.6. Binary Logging of Stored Programs

The binary log contains information about SQL statements that modify database contents. This information is stored in the form of “events” that describe the modifications. The binary log has two important purposes:

- For replication, the binary log is used on master replication servers as a record of the statements to be sent to slave servers. The master server sends the events contained in its binary log to its slaves, which execute those events to make the same data changes that were made on the master. See [Section 16.4, “Replication Implementation”](#).
- Certain data recovery operations require use of the binary log. After a backup file has been restored, the events in the binary log that were recorded after the backup was made are re-executed. These events bring databases up to date from the point of the backup. See [Section 6.2.2, “Using Backups for Recovery”](#).

However, there are certain binary logging issues that apply with respect to stored programs (stored procedures and functions, trig-

gers, and events), if logging occurs at the statement level:

- In some cases, it is possible that a statement will affect different sets of rows on a master and a slave.
- Replicated statements executed on a slave are processed by the slave SQL thread, which has full privileges. It is possible for a procedure to follow different execution paths on master and slave servers, so a user can write a routine containing a dangerous statement that will execute only on the slave where it is processed by a thread that has full privileges.
- If a stored program that modifies data is non-deterministic, it is not repeatable. This can result in different data on a master and slave, or cause restored data to differ from the original data.

This section describes how MySQL 5.1 handles binary logging for stored programs. It states the current conditions that the implementation places on the use of stored programs, and what you can do to avoid problems. It also provides additional information about the reasons for these conditions.

In general, the issues described here result when binary logging occurs at the SQL statement level. If you use row-based binary logging, the log contains changes made to individual rows as a result of executing SQL statements. When routines or triggers execute, row changes are logged, not the statements that make the changes. For stored procedures, this means that the `CALL` statement is not logged. For stored functions, row changes made within the function are logged, not the function invocation. For triggers, row changes made by the trigger are logged. On the slave side, only the row changes are seen, not the stored program invocation. For general information about row-based logging, see [Section 16.1.2, “Replication Formats”](#).

Unless noted otherwise, the remarks here assume that you have enabled binary logging by starting the server with the `--log-bin` option. (See [Section 5.2.4, “The Binary Log”](#).) If the binary log is not enabled, replication is not possible, nor is the binary log available for data recovery.

The current conditions on the use of stored functions in MySQL 5.1 can be summarized as follows. These conditions do not apply to stored procedures or Event Scheduler events and they do not apply unless binary logging is enabled.

- To create or alter a stored function, you must have the `SUPER` privilege, in addition to the `CREATE ROUTINE` or `ALTER ROUTINE` privilege that is normally required.
- When you create a stored function, you must declare either that it is deterministic or that it does not modify data. Otherwise, it may be unsafe for data recovery or replication.

By default, for a `CREATE FUNCTION` statement to be accepted, at least one of `DETERMINISTIC`, `NO SQL`, or `READS SQL DATA` must be specified explicitly. Otherwise an error occurs:

```
ERROR 1418 (HY000): This function has none of DETERMINISTIC, NO SQL,
or READS SQL DATA in its declaration and binary logging is enabled
(you *might* want to use the less safe log_bin_trust_function_creators
variable)
```

This function is deterministic (and does not modify data), so it is safe:

```
CREATE FUNCTION f1(i INT)
RETURNS INT
DETERMINISTIC
READS SQL DATA
BEGIN
    RETURN i;
END;
```

This function uses `UUID()`, which is not deterministic, so the function also is not deterministic and is not safe:

```
CREATE FUNCTION f2()
RETURNS CHAR(36) CHARACTER SET utf8
BEGIN
    RETURN UUID();
END;
```

This function modifies data, so it may not be safe:

```
CREATE FUNCTION f3(p_id INT)
RETURNS INT
BEGIN
    UPDATE t SET modtime = NOW() WHERE id = p_id;
    RETURN ROW_COUNT();
END;
```

Assessment of the nature of a function is based on the “honesty” of the creator: MySQL does not check that a function declared

`DETERMINISTIC` is free of statements that produce non-deterministic results.

- Although it is possible to create a deterministic stored function without specifying `DETERMINISTIC`, you cannot as of MySQL 5.1.15 execute this function using statement-based binary logging. To execute such a function, you must use row-based or mixed binary logging. Alternatively, if you explicitly specify `DETERMINISTIC` in the function definition, you can use any kind of logging, including statement-based logging.
- To relax the preceding conditions on function creation (that you must have the `SUPER` privilege and that a function must be declared deterministic or to not modify data), set the global `log_bin_trust_function_creators` system variable to 1. By default, this variable has a value of 0, but you can change it like this:

```
mysql> SET GLOBAL log_bin_trust_function_creators = 1;
```

You can also set this variable by using the `--log-bin-trust-function-creators=1` option when starting the server.

If binary logging is not enabled, `log_bin_trust_function_creators` does not apply and `SUPER` is not required for function creation.

- For information about built-in functions that may be unsafe for replication (and thus cause stored functions that use them to be unsafe as well), see [Section 16.3.1, “Replication Features and Issues”](#).

Triggers are similar to stored functions, so the preceding remarks regarding functions also apply to triggers with the following exception: `CREATE TRIGGER` does not have an optional `DETERMINISTIC` characteristic, so triggers are assumed to be always deterministic. However, this assumption might in some cases be invalid. For example, the `UUID()` function is non-deterministic (and does not replicate). You should be careful about using such functions in triggers.

Triggers can update tables, so error messages similar to those for stored functions occur with `CREATE TRIGGER` if you do not have the required privileges. On the slave side, the slave uses the trigger `DEFINER` attribute to determine which user is considered to be the creator of the trigger.

The rest of this section provides additional detail about the logging implementation and its implications. You need not read it unless you are interested in the background on the rationale for the current logging-related conditions on stored routine use. This discussion applies only for statement-based logging, and not for row-based logging, with the exception of the first item: `CREATE` and `DROP` statements are logged as statements regardless of the logging mode.

- The server writes `CREATE EVENT`, `CREATE PROCEDURE`, `CREATE FUNCTION`, `ALTER EVENT`, `ALTER PROCEDURE`, `ALTER FUNCTION`, `DROP EVENT`, `DROP PROCEDURE`, and `DROP FUNCTION` statements to the binary log.
- A stored function invocation is logged as a `SELECT` statement if the function changes data and occurs within a statement that would not otherwise be logged. This prevents non-replication of data changes that result from use of stored functions in non-logged statements. For example, `SELECT` statements are not written to the binary log, but a `SELECT` might invoke a stored function that makes changes. To handle this, a `SELECT func_name()` statement is written to the binary log when the given function makes a change. Suppose that the following statements are executed on the master:

```
CREATE FUNCTION f1(a INT) RETURNS INT
BEGIN
  IF (a < 3) THEN
    INSERT INTO t2 VALUES (a);
  END IF;
  RETURN 0;
END;

CREATE TABLE t1 (a INT);
INSERT INTO t1 VALUES (1),(2),(3);

SELECT f1(a) FROM t1;
```

When the `SELECT` statement executes, the function `f1()` is invoked three times. Two of those invocations insert a row, and MySQL logs a `SELECT` statement for each of them. That is, MySQL writes the following statements to the binary log:

```
SELECT f1(1);
SELECT f1(2);
```

The server also logs a `SELECT` statement for a stored function invocation when the function invokes a stored procedure that causes an error. In this case, the server writes the `SELECT` statement to the log along with the expected error code. On the slave, if the same error occurs, that is the expected result and replication continues. Otherwise, replication stops.

Note: Before MySQL 5.1.7, you will see these `SELECT func_name()` statements logged as `DO func_name()`. The change to `SELECT` was made because use of `DO` was found to yield insufficient control over error code checking.

- Logging stored function invocations rather than the statements executed by a function has a security implication for replication,

which arises from two factors:

- It is possible for a function to follow different execution paths on master and slave servers.
- Statements executed on a slave are processed by the slave SQL thread which has full privileges.

The implication is that although a user must have the `CREATE ROUTINE` privilege to create a function, the user can write a function containing a dangerous statement that will execute only on the slave where it is processed by a thread that has full privileges. For example, if the master and slave servers have server ID values of 1 and 2, respectively, a user on the master server could create and invoke an unsafe function `unsafe_func()` as follows:

```
mysql> delimiter //
mysql> CREATE FUNCTION unsafe_func () RETURNS INT
-> BEGIN
-> IF @@server_id=2 THEN dangerous_statement; END IF;
-> RETURN 1;
-> END;
-> //
mysql> delimiter ;
mysql> INSERT INTO t VALUES(unsafe_func());
```

The `CREATE FUNCTION` and `INSERT` statements are written to the binary log, so the slave will execute them. Because the slave SQL thread has full privileges, it will execute the dangerous statement. Thus, the function invocation has different effects on the master and slave and is not replication-safe.

To guard against this danger for servers that have binary logging enabled, stored function creators must have the `SUPER` privilege, in addition to the usual `CREATE ROUTINE` privilege that is required. Similarly, to use `ALTER FUNCTION`, you must have the `SUPER` privilege in addition to the `ALTER ROUTINE` privilege. Without the `SUPER` privilege, an error will occur:

```
ERROR 1419 (HY000): You do not have the SUPER privilege and
binary logging is enabled (you *might* want to use the less safe
log_bin_trust_function_creators variable)
```

If you do not want to require function creators to have the `SUPER` privilege (for example, if all users with the `CREATE ROUTINE` privilege on your system are experienced application developers), set the global `log_bin_trust_function_creators` system variable to 1. You can also set this variable by using the `--log-bin-trust-function-creators=1` option when starting the server. If binary logging is not enabled, `log_bin_trust_function_creators` does not apply and `SUPER` is not required for function creation.

- If a function that performs updates is non-deterministic, it is not repeatable. This can have two undesirable effects:
 - It will make a slave different from the master.
 - Restored data will be different from the original data.

To deal with these problems, MySQL enforces the following requirement: On a master server, creation and alteration of a function is refused unless you declare the function to be deterministic or to not modify data. Two sets of function characteristics apply here:

- The `DETERMINISTIC` and `NOT DETERMINISTIC` characteristics indicate whether a function always produces the same result for given inputs. The default is `NOT DETERMINISTIC` if neither characteristic is given. To declare that a function is deterministic, you must specify `DETERMINISTIC` explicitly.
- The `CONTAINS SQL`, `NO SQL`, `READS SQL DATA`, and `MODIFIES SQL DATA` characteristics provide information about whether the function reads or writes data. Either `NO SQL` or `READS SQL DATA` indicates that a function does not change data, but you must specify one of these explicitly because the default is `CONTAINS SQL` if no characteristic is given.

By default, for a `CREATE FUNCTION` statement to be accepted, at least one of `DETERMINISTIC`, `NO SQL`, or `READS SQL DATA` must be specified explicitly. Otherwise an error occurs:

```
ERROR 1418 (HY000): This function has none of DETERMINISTIC, NO SQL,
or READS SQL DATA in its declaration and binary logging is enabled
(you *might* want to use the less safe log_bin_trust_function_creators
variable)
```

If you set `log_bin_trust_function_creators` to 1, the requirement that functions be deterministic or not modify data is dropped.

- Stored procedure calls are logged at the statement level rather than at the `CALL` level. That is, the server does not log the `CALL` statement, it logs those statements within the procedure that actually execute. As a result, the same changes that occur on the master will be observed on slave servers. This prevents problems that could result from a procedure having different execution paths on different machines.

In general, statements executed within a stored procedure are written to the binary log using the same rules that would apply were the statements to be executed in standalone fashion. Some special care is taken when logging procedure statements because statement execution within procedures is not quite the same as in non-procedure context:

- A statement to be logged might contain references to local procedure variables. These variables do not exist outside of stored procedure context, so a statement that refers to such a variable cannot be logged literally. Instead, each reference to a local variable is replaced by this construct for logging purposes:

```
NAME_CONST(var_name, var_value)
```

var_name is the local variable name, and *var_value* is a constant indicating the value that the variable has at the time the statement is logged. `NAME_CONST()` has a value of *var_value*, and a “name” of *var_name*. Thus, if you invoke this function directly, you get a result like this:

```
mysql> SELECT NAME_CONST('myname', 14);
+-----+
| myname |
+-----+
|      14 |
+-----+
```

`NAME_CONST()` allows a logged standalone statement to be executed on a slave with the same effect as the original statement that was executed on the master within a stored procedure.

The use of `NAME_CONST()` can result in a problem for `CREATE TABLE ... SELECT` statements when the source column expressions refer to local variables. Converting these references to `NAME_CONST()` expressions can result in column names that are different on the master and slave servers, or names that are too long to be legal column identifiers. A workaround is to supply aliases for columns that refer to local variables. Consider this statement when `myvar` has a value of 1:

```
CREATE TABLE t1 SELECT myvar;
```

That will be rewritten as follows:

```
CREATE TABLE t1 SELECT NAME_CONST(myvar, 1);
```

To ensure that the master and slave tables have the same column names, write the statement like this:

```
CREATE TABLE t1 SELECT myvar AS myvar;
```

The rewritten statement becomes:

```
CREATE TABLE t1 SELECT NAME_CONST(myvar, 1) AS myvar;
```

- A statement to be logged might contain references to user-defined variables. To handle this, MySQL writes a `SET` statement to the binary log to make sure that the variable exists on the slave with the same value as on the master. For example, if a statement refers to a variable `@my_var`, that statement will be preceded in the binary log by the following statement, where *value* is the value of `@my_var` on the master:

```
SET @my_var = value;
```

- Procedure calls can occur within a committed or rolled-back transaction. Transactional context is accounted for so that the transactional aspects of procedure execution are replicated correctly. That is, the server logs those statements within the procedure that actually execute and modify data, and also logs `BEGIN`, `COMMIT`, and `ROLLBACK` statements as necessary. For example, if a procedure updates only transactional tables and is executed within a transaction that is rolled back, those updates are not logged. If the procedure occurs within a committed transaction, `BEGIN` and `COMMIT` statements are logged with the updates. For a procedure that executes within a rolled-back transaction, its statements are logged using the same rules that would apply if the statements were executed in standalone fashion:
 - Updates to transactional tables are not logged.
 - Updates to non-transactional tables are logged because rollback does not cancel them.
 - Updates to a mix of transactional and non-transactional tables are logged surrounded by `BEGIN` and `ROLLBACK` so that slaves will make the same changes and rollbacks as on the master.
- A stored procedure call is *not* written to the binary log at the statement level if the procedure is invoked from within a stored function. In that case, the only thing logged is the statement that invokes the function (if it occurs within a statement that is

logged) or a `DO` statement (if it occurs within a statement that is not logged). For this reason, care should be exercised in the use of stored functions that invoke a procedure, even if the procedure is otherwise safe in itself.

Chapter 20. INFORMATION_SCHEMA Tables

`INFORMATION_SCHEMA` provides access to database metadata.

Metadata is data about the data, such as the name of a database or table, the data type of a column, or access privileges. Other terms that sometimes are used for this information are *data dictionary* and *system catalog*.

`INFORMATION_SCHEMA` is the information database, the place that stores information about all the other databases that the MySQL server maintains. Inside `INFORMATION_SCHEMA` there are several read-only tables. They are actually views, not base tables, so there are no files associated with them.

In effect, we have a database named `INFORMATION_SCHEMA`, although the server does not create a database directory with that name. It is possible to select `INFORMATION_SCHEMA` as the default database with a `USE` statement, but it is possible only to read the contents of tables. You cannot insert into them, update them, or delete from them.

Here is an example of a statement that retrieves information from `INFORMATION_SCHEMA`:

```
mysql> SELECT table_name, table_type, engine
-> FROM information_schema.tables
-> WHERE table_schema = 'db5'
-> ORDER BY table_name DESC;
```

table_name	table_type	engine
v56	VIEW	NULL
v3	VIEW	NULL
v2	VIEW	NULL
v	VIEW	NULL
tables	BASE TABLE	MyISAM
t7	BASE TABLE	MyISAM
t3	BASE TABLE	MyISAM
t2	BASE TABLE	MyISAM
t	BASE TABLE	MyISAM
pk	BASE TABLE	InnoDB
loop	BASE TABLE	MyISAM
kurs	BASE TABLE	MyISAM
k	BASE TABLE	MyISAM
into	BASE TABLE	MyISAM
goto	BASE TABLE	MyISAM
fk2	BASE TABLE	InnoDB
fk	BASE TABLE	InnoDB

```
17 rows in set (0.01 sec)
```

Explanation: The statement requests a list of all the tables in database `db5`, in reverse alphabetical order, showing just three pieces of information: the name of the table, its type, and its storage engine.

Each MySQL user has the right to access these tables, but can see only the rows in the tables that correspond to objects for which the user has the proper access privileges. In some cases (for example, the `ROUTINE_DEFINITION` column in the `INFORMATION_SCHEMA.ROUTINES` table), users who have insufficient privileges will see `NULL`.

The `SELECT . . . FROM INFORMATION_SCHEMA` statement is intended as a more consistent way to provide access to the information provided by the various `SHOW` statements that MySQL supports (`SHOW DATABASES`, `SHOW TABLES`, and so forth). Using `SELECT` has these advantages, compared to `SHOW`:

- It conforms to Codd's rules. That is, all access is done on tables.
- Nobody needs to learn a new statement syntax. Because they already know how `SELECT` works, they only need to learn the object names.
- The implementor need not worry about adding keywords.
- There are millions of possible output variations, instead of just one. This provides more flexibility for applications that have varying requirements about what metadata they need.
- Migration is easier because every other DBMS does it this way.

However, because `SHOW` is popular with MySQL employees and users, and because it might be confusing were it to disappear, the advantages of conventional syntax are not a sufficient reason to eliminate `SHOW`. In fact, along with the implementation of `INFORMATION_SCHEMA`, there are enhancements to `SHOW` as well. These are described in [Section 20.28, "Extensions to SHOW Statements"](#).

There is no difference between the privileges required for `SHOW` statements and those required to select information from `INFORMATION_SCHEMA`. In either case, you have to have some privilege on an object in order to see information about it.

The implementation for the `INFORMATION_SCHEMA` table structures in MySQL follows the ANSI/ISO SQL:2003 standard Part 11 *Schemata*. Our intent is approximate compliance with SQL:2003 core feature F021 *Basic information schema*.

Users of SQL Server 2000 (which also follows the standard) may notice a strong similarity. However, MySQL has omitted many columns that are not relevant for our implementation, and added columns that are MySQL-specific. One such column is the `ENGINE` column in the `INFORMATION_SCHEMA.TABLES` table.

Although other DBMSs use a variety of names, like `syscat` or `system`, the standard name is `INFORMATION_SCHEMA`.

The following sections describe each of the tables and columns that are in `INFORMATION_SCHEMA`. For each column, there are three pieces of information:

- “`INFORMATION_SCHEMA Name`” indicates the name for the column in the `INFORMATION_SCHEMA` table. This corresponds to the standard SQL name unless the “Remarks” field says “MySQL extension.”
- “`SHOW Name`” indicates the equivalent field name in the closest `SHOW` statement, if there is one.
- “Remarks” provides additional information where applicable. If this field is `NULL`, it means that the value of the column is always `NULL`. If this field says “MySQL extension,” the column is a MySQL extension to standard SQL.

To avoid using any name that is reserved in the standard or in DB2, SQL Server, or Oracle, we changed the names of some columns marked “MySQL extension”. (For example, we changed `COLLATION` to `TABLE_COLLATION` in the `TABLES` table.) See the list of reserved words near the end of this article: http://web.archive.org/web/20070409075643rn_1/www.dbazine.com/db2/db2-disarticles/gulutzan5.

The definition for character columns (for example, `TABLES.TABLE_NAME`) is generally `VARCHAR(N) CHARACTER SET utf8` where `N` is at least 64. MySQL uses the default collation for this character set (`utf8_general_ci`) for all searches, sorts, comparisons, and other string operations on such columns. If the default collation is not correct for your needs, you can force a suitable collation with a `COLLATE` clause (Section 9.1.6.1, “Using `COLLATE` in SQL Statements”).

Each section indicates what `SHOW` statement is equivalent to a `SELECT` that retrieves information from `INFORMATION_SCHEMA`, if there is such a statement. For `SHOW` statements that display information for the current database if you omit a `FROM db_name` clause, you can often select information for the current database by adding an `AND TABLE_SCHEMA = CURRENT_SCHEMA()` condition to the `WHERE` clause of a query that retrieves information from an `INFORMATION_SCHEMA` table.

Note

At present, there are some missing columns and some columns out of order. We are working on this and updating the documentation as changes are made.

For answers to questions that are often asked concerning the `INFORMATION_SCHEMA` database, see Section A.7, “MySQL 5.0 FAQ — `INFORMATION_SCHEMA`”.

20.1. The `INFORMATION_SCHEMA SCHEMATA` Table

A schema is a database, so the `SCHEMATA` table provides information about databases.

<code>INFORMATION_SCHEMA Name</code>	<code>SHOW Name</code>	Remarks
<code>CATALOG_NAME</code>		<code>NULL</code>
<code>SCHEMA_NAME</code>		Database
<code>DEFAULT_CHARACTER_SET_NAME</code>		
<code>DEFAULT_COLLATION_NAME</code>		
<code>SQL_PATH</code>		<code>NULL</code>

The following statements are equivalent:

```
SELECT SCHEMA_NAME AS `Database`
FROM INFORMATION_SCHEMA.SCHEMATA
[WHERE SCHEMA_NAME LIKE 'wild']

SHOW DATABASES
[LIKE 'wild']
```

20.2. The `INFORMATION_SCHEMA TABLES` Table

The `TABLES` table provides information about tables in databases.

INFORMATION_SCHEMA Name	SHOW Name	Remarks
<code>TABLE_CATALOG</code>		<code>NULL</code>
<code>TABLE_SCHEMA</code>	<code>Table_...</code>	
<code>TABLE_NAME</code>	<code>Table_...</code>	
<code>TABLE_TYPE</code>		
<code>ENGINE</code>	<code>Engine</code>	MySQL extension
<code>VERSION</code>	<code>Version</code>	The version number of the table's <code>.frm</code> file, MySQL extension
<code>ROW_FORMAT</code>	<code>Row_format</code>	MySQL extension
<code>TABLE_ROWS</code>	<code>Rows</code>	MySQL extension
<code>AVG_ROW_LENGTH</code>	<code>Avg_row_length</code>	MySQL extension
<code>DATA_LENGTH</code>	<code>Data_length</code>	MySQL extension
<code>MAX_DATA_LENGTH</code>	<code>Max_data_length</code>	MySQL extension
<code>INDEX_LENGTH</code>	<code>Index_length</code>	MySQL extension
<code>DATA_FREE</code>	<code>Data_free</code>	MySQL extension
<code>AUTO_INCREMENT</code>	<code>Auto_increment</code>	MySQL extension
<code>CREATE_TIME</code>	<code>Create_time</code>	MySQL extension
<code>UPDATE_TIME</code>	<code>Update_time</code>	MySQL extension
<code>CHECK_TIME</code>	<code>Check_time</code>	MySQL extension
<code>TABLE_COLLATION</code>	<code>Collation</code>	MySQL extension
<code>CHECKSUM</code>	<code>Checksum</code>	MySQL extension
<code>CREATE_OPTIONS</code>	<code>Create_options</code>	MySQL extension
<code>TABLE_COMMENT</code>	<code>Comment</code>	MySQL extension

Notes:

- `TABLE_SCHEMA` and `TABLE_NAME` are a single field in a `SHOW` display, for example `Table_in_db1`.
- `TABLE_TYPE` should be `BASE TABLE` or `VIEW`. Currently, the `TABLES` table does not list `TEMPORARY` tables.
- For partitioned tables, beginning with MySQL 5.1.9, the `ENGINE` column shows the name of the storage engine used by all partitions. (Previously, this column showed `PARTITION` for such tables.)
- The `TABLE_ROWS` column is `NULL` if the table is in the `INFORMATION_SCHEMA` database.

For `InnoDB` tables, the row count is only a rough estimate used in SQL optimization. (This is also true if the `InnoDB` table is partitioned.)

- For tables using the `NDBCLUSTER` storage engine, beginning with MySQL 5.1.12, the `DATA_LENGTH` column reflects the true amount of storage for variable-width columns. (See [Bug#18413](#).)

Note

Because MySQL Cluster allocates storage for variable-width columns in 10-page extents of 32 kilobytes each, space usage for such columns is reported in increments of 320 KB.

- Beginning with MySQL 5.1.28, the `DATA_FREE` column shows the free space in bytes for `InnoDB` tables.
- We have nothing for the table's default character set. `TABLE_COLLATION` is close, because collation names begin with a character set name.
- Beginning with MySQL 5.1.9, the `CREATE_OPTIONS` column shows `partitioned` if the table is partitioned.

The following statements are equivalent:

```
SELECT table_name FROM INFORMATION_SCHEMA.TABLES
WHERE table_schema = 'db_name'
```

```
[AND table_name LIKE 'wild']
SHOW TABLES
FROM db_name
[LIKE 'wild']
```

20.3. The INFORMATION_SCHEMA COLUMNS Table

The `COLUMNS` table provides information about columns in tables.

INFORMATION_SCHEMA Name	SHOW Name	Remarks
TABLE_CATALOG		NULL
TABLE_SCHEMA		
TABLE_NAME		
COLUMN_NAME	Field	
ORDINAL_POSITION		see notes
COLUMN_DEFAULT	Default	
IS_NULLABLE	Null	
DATA_TYPE	Type	
CHARACTER_MAXIMUM_LENGTH	Type	
CHARACTER_OCTET_LENGTH		
NUMERIC_PRECISION	Type	
NUMERIC_SCALE	Type	
CHARACTER_SET_NAME		
COLLATION_NAME	Collation	
COLUMN_TYPE	Type	MySQL extension
COLUMN_KEY	Key	MySQL extension
EXTRA	Extra	MySQL extension
PRIVILEGES	Privileges	MySQL extension
COLUMN_COMMENT	Comment	MySQL extension

Notes:

- In `SHOW`, the `Type` display includes values from several different `COLUMNS` columns.
- `ORDINAL_POSITION` is necessary because you might want to say `ORDER BY ORDINAL_POSITION`. Unlike `SHOW, SELECT` does not have automatic ordering.
- `CHARACTER_OCTET_LENGTH` should be the same as `CHARACTER_MAXIMUM_LENGTH`, except for multi-byte character sets.
- `CHARACTER_SET_NAME` can be derived from `Collation`. For example, if you say `SHOW FULL COLUMNS FROM t`, and you see in the `Collation` column a value of `latin1_swedish_ci`, the character set is what is before the first underscore: `latin1`.

The following statements are nearly equivalent:

```
SELECT COLUMN_NAME, DATA_TYPE, IS_NULLABLE, COLUMN_DEFAULT
FROM INFORMATION_SCHEMA.COLUMNS
WHERE table_name = 'tbl_name'
[AND table_schema = 'db_name']
[AND column_name LIKE 'wild']

SHOW COLUMNS
FROM tbl_name
[FROM db_name]
[LIKE 'wild']
```

20.4. The INFORMATION_SCHEMA STATISTICS Table

The `STATISTICS` table provides information about table indexes.

INFORMATION_SCHEMA Name	SHOW Name	Remarks
TABLE_CATALOG		NULL
TABLE_SCHEMA		= Database
TABLE_NAME	Table	
NON_UNIQUE	Non_unique	
INDEX_SCHEMA		= Database
INDEX_NAME	Key_name	
SEQ_IN_INDEX	Seq_in_index	
COLUMN_NAME	Column_name	
COLLATION	Collation	
CARDINALITY	Cardinality	
SUB_PART	Sub_part	MySQL extension
PACKED	Packed	MySQL extension
NULLABLE	Null	MySQL extension
INDEX_TYPE	Index_type	MySQL extension
COMMENT	Comment	MySQL extension

Notes:

- There is no standard table for indexes. The preceding list is similar to what SQL Server 2000 returns for `sp_statistics`, except that we replaced the name `QUALIFIER` with `CATALOG` and we replaced the name `OWNER` with `SCHEMA`.

Clearly, the preceding table and the output from `SHOW INDEX` are derived from the same parent. So the correlation is already close.

The following statements are equivalent:

```
SELECT * FROM INFORMATION_SCHEMA.STATISTICS
  WHERE table_name = 'tbl_name'
  AND table_schema = 'db_name'

SHOW INDEX
  FROM tbl_name
  FROM db_name
```

20.5. The INFORMATION_SCHEMA USER_PRIVILEGES Table

The `USER_PRIVILEGES` table provides information about global privileges. This information comes from the `mysql.user` grant table.

INFORMATION_SCHEMA Name	SHOW Name	Remarks
GRANTEE		'user_name'@'host_name' value, MySQL extension
TABLE_CATALOG		NULL, MySQL extension
PRIVILEGE_TYPE		MySQL extension
IS_GRANTABLE		MySQL extension

Notes:

- This is a non-standard table. It takes its values from the `mysql.user` table.

20.6. The INFORMATION_SCHEMA SCHEMA_PRIVILEGES Table

The `SCHEMA_PRIVILEGES` table provides information about schema (database) privileges. This information comes from the `mysql.db` grant table.

INFORMATION_SCHEMA Name	SHOW Name	Remarks
GRANTEE		'user_name'@'host_name' value, MySQL extension
TABLE_CATALOG		NULL, MySQL extension
TABLE_SCHEMA		MySQL extension
PRIVILEGE_TYPE		MySQL extension
IS_GRANTABLE		MySQL extension

Notes:

- This is a non-standard table. It takes its values from the `mysql.db` table.

20.7. The INFORMATION_SCHEMA TABLE_PRIVILEGES Table

The `TABLE_PRIVILEGES` table provides information about table privileges. This information comes from the `mysql.tables_priv` grant table.

INFORMATION_SCHEMA Name	SHOW Name	Remarks
GRANTEE		'user_name'@'host_name' value
TABLE_CATALOG		NULL
TABLE_SCHEMA		
TABLE_NAME		
PRIVILEGE_TYPE		
IS_GRANTABLE		

Notes:

- `PRIVILEGE_TYPE` can contain one (and only one) of these values: `SELECT`, `INSERT`, `UPDATE`, `REFERENCES`, `ALTER`, `INDEX`, `DROP`, `CREATE VIEW`.

The following statements are *not* equivalent:

```
SELECT ... FROM INFORMATION_SCHEMA.TABLE_PRIVILEGES
SHOW GRANTS ...
```

20.8. The INFORMATION_SCHEMA COLUMN_PRIVILEGES Table

The `COLUMN_PRIVILEGES` table provides information about column privileges. This information comes from the `mysql.columns_priv` grant table.

INFORMATION_SCHEMA Name	SHOW Name	Remarks
GRANTEE		'user_name'@'host_name' value
TABLE_CATALOG		NULL
TABLE_SCHEMA		
TABLE_NAME		
COLUMN_NAME		
PRIVILEGE_TYPE		
IS_GRANTABLE		

Notes:

- In the output from `SHOW FULL COLUMNS`, the privileges are all in one field and in lowercase, for example, `select, insert, update, references`. In `COLUMN_PRIVILEGES`, there is one privilege per row, in uppercase.
- `PRIVILEGE_TYPE` can contain one (and only one) of these values: `SELECT, INSERT, UPDATE, REFERENCES`.
- If the user has `GRANT OPTION` privilege, `IS_GRANTABLE` should be `YES`. Otherwise, `IS_GRANTABLE` should be `NO`. The output does not list `GRANT OPTION` as a separate privilege.

The following statements are *not* equivalent:

```
SELECT ... FROM INFORMATION_SCHEMA.COLUMN_PRIVILEGES
SHOW GRANTS ...
```

20.9. The INFORMATION_SCHEMA CHARACTER_SETS Table

The `CHARACTER_SETS` table provides information about available character sets.

INFORMATION_SCHEMA Name	SHOW Name	Remarks
<code>CHARACTER_SET_NAME</code>	<code>Charset</code>	
<code>DEFAULT_COLLATE_NAME</code>	<code>Default collation</code>	
<code>DESCRIPTION</code>	<code>Description</code>	MySQL extension
<code>MAXLEN</code>	<code>Maxlen</code>	MySQL extension

The following statements are equivalent:

```
SELECT * FROM INFORMATION_SCHEMA.CHARACTER_SETS
  [WHERE name LIKE 'wild']
SHOW CHARACTER SET
  [LIKE 'wild']
```

20.10. The INFORMATION_SCHEMA COLLATIONS Table

The `COLLATIONS` table provides information about collations for each character set.

INFORMATION_SCHEMA Name	SHOW Name	Remarks
<code>COLLATION_NAME</code>	<code>Collation</code>	
<code>CHARACTER_SET_NAME</code>	<code>Charset</code>	MySQL extension
<code>ID</code>	<code>Id</code>	MySQL extension
<code>IS_DEFAULT</code>	<code>Default</code>	MySQL extension
<code>IS_COMPILED</code>	<code>Compiled</code>	MySQL extension
<code>SORTLEN</code>	<code>Sortlen</code>	MySQL extension

The following statements are equivalent:

```
SELECT COLLATION_NAME FROM INFORMATION_SCHEMA.COLLATIONS
  [WHERE collation_name LIKE 'wild']
SHOW COLLATION
  [LIKE 'wild']
```

20.11. The INFORMATION_SCHEMA COLLATION_CHARACTER_SET_APPLICABILITY Table

The `COLLATION_CHARACTER_SET_APPLICABILITY` table indicates what character set is applicable for what collation. The columns are equivalent to the first two display fields that we get from `SHOW COLLATION`.

INFORMATION_SCHEMA Name	SHOW Name	Remarks
<code>COLLATION_NAME</code>	<code>Collation</code>	

CHARACTER_SET_NAME	Charset	
--------------------	---------	--

20.12. The INFORMATION_SCHEMA TABLE_CONSTRAINTS Table

The `TABLE_CONSTRAINTS` table describes which tables have constraints.

INFORMATION_SCHEMA Name	SHOW Name	Remarks
CONSTRAINT_CATALOG		NULL
CONSTRAINT_SCHEMA		
CONSTRAINT_NAME		
TABLE_SCHEMA		
TABLE_NAME		
CONSTRAINT_TYPE		

Notes:

- The `CONSTRAINT_TYPE` value can be `UNIQUE`, `PRIMARY KEY`, or `FOREIGN KEY`.
- The `UNIQUE` and `PRIMARY KEY` information is about the same as what you get from the `Key_name` field in the output from `SHOW INDEX` when the `Non_unique` field is 0.
- The `CONSTRAINT_TYPE` column can contain one of these values: `UNIQUE`, `PRIMARY KEY`, `FOREIGN KEY`, `CHECK`. This is a `CHAR` (not `ENUM`) column. The `CHECK` value is not available until we support `CHECK`.

20.13. The INFORMATION_SCHEMA KEY_COLUMN_USAGE Table

The `KEY_COLUMN_USAGE` table describes which key columns have constraints.

INFORMATION_SCHEMA Name	SHOW Name	Remarks
CONSTRAINT_CATALOG		NULL
CONSTRAINT_SCHEMA		
CONSTRAINT_NAME		
TABLE_CATALOG		
TABLE_SCHEMA		
TABLE_NAME		
COLUMN_NAME		
ORDINAL_POSITION		
POSITION_IN_UNIQUE_CONSTRAINT		
REFERENCED_TABLE_SCHEMA		
REFERENCED_TABLE_NAME		
REFERENCED_COLUMN_NAME		

Notes:

- If the constraint is a foreign key, then this is the column of the foreign key, not the column that the foreign key references.
- The value of `ORDINAL_POSITION` is the column's position within the constraint, not the column's position within the table. Column positions are numbered beginning with 1.
- The value of `POSITION_IN_UNIQUE_CONSTRAINT` is `NULL` for unique and primary-key constraints. For foreign-key constraints, it is the ordinal position in key of the table that is being referenced.

For example, suppose that there are two tables name `t1` and `t3` that have the following definitions:

```
CREATE TABLE t1
```

```
(
  s1 INT,
  s2 INT,
  s3 INT,
  PRIMARY KEY(s3)
) ENGINE=InnoDB;

CREATE TABLE t3
(
  s1 INT,
  s2 INT,
  s3 INT,
  KEY(s1),
  CONSTRAINT CO FOREIGN KEY (s2) REFERENCES t1(s3)
) ENGINE=InnoDB;
```

For those two tables, the `KEY_COLUMN_USAGE` table has two rows:

- One row with `CONSTRAINT_NAME = 'PRIMARY'`, `TABLE_NAME = 't1'`, `COLUMN_NAME = 's3'`, `ORDINAL_POSITION = 1`, `POSITION_IN_UNIQUE_CONSTRAINT = NULL`.
- One row with `CONSTRAINT_NAME = 'CO'`, `TABLE_NAME = 't3'`, `COLUMN_NAME = 's2'`, `ORDINAL_POSITION = 1`, `POSITION_IN_UNIQUE_CONSTRAINT = 1`.

20.14. The INFORMATION_SCHEMA ROUTINES Table

The `ROUTINES` table provides information about stored routines (both procedures and functions). The `ROUTINES` table does not include user-defined functions (UDFs) at this time.

The column named “`mysql.proc name`” indicates the `mysql.proc` table column that corresponds to the `INFORMATION_SCHEMA.ROUTINES` table column, if any.

INFORMATION_SCHEMA Name	mysql.proc Name	Remarks
SPECIFIC_NAME	specific_name	
ROUTINE_CATALOG		NULL
ROUTINE_SCHEMA	db	
ROUTINE_NAME	name	
ROUTINE_TYPE	type	{PROCEDURE FUNCTION}
DTD_IDENTIFIER		data type descriptor
ROUTINE_BODY		SQL
ROUTINE_DEFINITION	body	
EXTERNAL_NAME		NULL
EXTERNAL_LANGUAGE	language	NULL
PARAMETER_STYLE		SQL
IS_DETERMINISTIC	is_deterministic	
SQL_DATA_ACCESS	sql_data_access	
SQL_PATH		NULL
SECURITY_TYPE	security_type	
CREATED	created	
LAST_ALTERED	modified	
SQL_MODE	sql_mode	MySQL extension
ROUTINE_COMMENT	comment	MySQL extension
DEFINER	definer	MySQL extension
CHARACTER_SET_CLIENT		MySQL extension
COLLATION_CONNECTION		MySQL extension
DATABASE_COLLATION		MySQL extension

Notes:

- MySQL calculates `EXTERNAL_LANGUAGE` thus:
 - If `mysql.proc.language='SQL'`, `EXTERNAL_LANGUAGE` is `NULL`
 - Otherwise, `EXTERNAL_LANGUAGE` is what is in `mysql.proc.language`. However, we do not have external languages yet, so it is always `NULL`.
- `CHARACTER_SET_CLIENT` is the session value of the `character_set_client` system variable when the routine was created. `COLLATION_CONNECTION` is the session value of the `collation_connection` system variable when the routine was created. `DATABASE_COLLATION` is the collation of the database with which the routine is associated. These columns were added in MySQL 5.1.21.

20.15. The INFORMATION_SCHEMA VIEWS Table

The `VIEWS` table provides information about views in databases. You must have the `SHOW VIEW` privilege to access this table.

INFORMATION_SCHEMA Name	SHOW Name	Remarks
<code>TABLE_CATALOG</code>		<code>NULL</code>
<code>TABLE_SCHEMA</code>		
<code>TABLE_NAME</code>		
<code>VIEW_DEFINITION</code>		
<code>CHECK_OPTION</code>		
<code>IS_UPDATABLE</code>		
<code>DEFINER</code>		
<code>SECURITY_TYPE</code>		
<code>CHARACTER_SET_CLIENT</code>		MySQL extension
<code>COLLATION_CONNECTION</code>		MySQL extension

Notes:

- The `VIEW_DEFINITION` column has most of what you see in the `Create Table` field that `SHOW CREATE VIEW` produces. Skip the words before `SELECT` and skip the words `WITH CHECK OPTION`. Suppose that the original statement was:

```
CREATE VIEW v AS
SELECT s2,s1 FROM t
WHERE s1 > 5
ORDER BY s1
WITH CHECK OPTION;
```

Then the view definition looks like this:

```
SELECT s2,s1 FROM t WHERE s1 > 5 ORDER BY s1
```

- The `CHECK_OPTION` column has a value of `NONE`, `CASCADE`, or `LOCAL`.
- MySQL sets a flag, called the view updatability flag, at `CREATE VIEW` time. The flag is set to `YES` (true) if `UPDATE` and `DELETE` (and similar operations) are legal for the view. Otherwise, the flag is set to `NO` (false). The `IS_UPDATABLE` column in the `VIEWS` table displays the status of this flag. It means that the server always knows whether a view is updatable. If the view is not updatable, statements such `UPDATE`, `DELETE`, and `INSERT` are illegal and will be rejected. (Note that even if a view is updatable, it might not be possible to insert into it; for details, refer to [Section 12.1.20, “CREATE VIEW Syntax”](#).)
- The `DEFINER` column indicates who defined the view. `SECURITY_TYPE` has a value of `DEFINER` or `INVOKER`.
- `CHARACTER_SET_CLIENT` is the session value of the `character_set_client` system variable when the view was created. `COLLATION_CONNECTION` is the session value of the `collation_connection` system variable when the view was created. These columns were added in MySQL 5.1.21.

MySQL lets you use different `sql_mode` settings to tell the server the type of SQL syntax to support. For example, you might use the `ANSI SQL` mode to ensure MySQL correctly interprets the standard SQL concatenation operator, the double bar (`||`), in your queries. If you then create a view that concatenates items, you might worry that changing the `sql_mode` setting to a value different from `ANSI` could cause the view to become invalid. But this is not the case. No matter how you write out a view definition,

MySQL always stores it the same way, in a canonical form. Here is an example that shows how the server changes a double bar concatenation operator to a `CONCAT()` function:

```
mysql> SET sql_mode = 'ANSI';
Query OK, 0 rows affected (0.00 sec)

mysql> CREATE VIEW test.v AS SELECT 'a' || 'b' as coll;
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT VIEW_DEFINITION FROM INFORMATION_SCHEMA.VIEWS
-> WHERE TABLE_SCHEMA = 'test' AND TABLE_NAME = 'v';
+-----+
| VIEW_DEFINITION |
+-----+
| select concat('a','b') AS `coll` |
+-----+
1 row in set (0.00 sec)
```

The advantage of storing a view definition in canonical form is that changes made later to the value of `sql_mode` will not affect the results from the view. However an additional consequence is that comments prior to `SELECT` are stripped from the definition by the server.

20.16. The INFORMATION_SCHEMA TRIGGERS Table

The `TRIGGERS` table provides information about triggers. You must have the `TRIGGER` privilege to access this table (prior to MySQL 5.1.22, you must have the `SUPER` privilege).

INFORMATION_SCHEMA Name	SHOW Name	Remarks
TRIGGER_CATALOG		NULL
TRIGGER_SCHEMA		
TRIGGER_NAME	Trigger	
EVENT_MANIPULATION	Event	
EVENT_OBJECT_CATALOG		NULL
EVENT_OBJECT_SCHEMA		
EVENT_OBJECT_TABLE	Table	
ACTION_ORDER		0
ACTION_CONDITION		NULL
ACTION_STATEMENT	Statement	
ACTION_ORIENTATION		ROW
ACTION_TIMING	Timing	
ACTION_REFERENCE_OLD_TABLE		NULL
ACTION_REFERENCE_NEW_TABLE		NULL
ACTION_REFERENCE_OLD_ROW		OLD
ACTION_REFERENCE_NEW_ROW		NEW
CREATED		NULL (0)
SQL_MODE		MySQL extension
DEFINER		MySQL extension
CHARACTER_SET_CLIENT		MySQL extension
COLLATION_CONNECTION		MySQL extension
DATABASE_COLLATION		MySQL extension

Notes:

- The `TRIGGER_SCHEMA` and `TRIGGER_NAME` columns contain the name of the database in which the trigger occurs and the trigger name, respectively.
- The `EVENT_MANIPULATION` column contains one of the values `'INSERT'`, `'DELETE'`, or `'UPDATE'`.
- As noted in Section 19.3, “Using Triggers”, every trigger is associated with exactly one table. The `EVENT_OBJECT_SCHEMA` and `EVENT_OBJECT_TABLE` columns contain the database in which this table occurs, and the table's name.

- The `ACTION_ORDER` statement contains the ordinal position of the trigger's action within the list of all similar triggers on the same table. Currently, this value is always 0, because it is not possible to have more than one trigger with the same `EVENT_MANIPULATION` and `ACTION_TIMING` on the same table.
- The `ACTION_STATEMENT` column contains the statement to be executed when the trigger is invoked. This is the same as the text displayed in the `Statement` column of the output from `SHOW TRIGGERS`. Note that this text uses UTF-8 encoding.
- The `ACTION_ORIENTATION` column always contains the value 'ROW'.
- The `ACTION_TIMING` column contains one of the two values 'BEFORE' or 'AFTER'.
- The columns `ACTION_REFERENCE_OLD_ROW` and `ACTION_REFERENCE_NEW_ROW` contain the old and new column identifiers, respectively. This means that `ACTION_REFERENCE_OLD_ROW` always contains the value 'OLD' and `ACTION_REFERENCE_NEW_ROW` always contains the value 'NEW'.
- The `SQL_MODE` column shows the server SQL mode that was in effect at the time when the trigger was created (and thus which remains in effect for this trigger whenever it is invoked, *regardless of the current server SQL mode*). The possible range of values for this column is the same as that of the `sql_mode` system variable. See [Section 5.1.7, “Server SQL Modes”](#).
- The `DEFINER` column was added in MySQL 5.1.2. `DEFINER` indicates who defined the trigger.
- `CHARACTER_SET_CLIENT` is the session value of the `character_set_client` system variable when the trigger was created. `COLLATION_CONNECTION` is the session value of the `collation_connection` system variable when the trigger was created. `DATABASE_COLLATION` is the collation of the database with which the trigger is associated. These columns were added in MySQL 5.1.21.
- The following columns currently always contain NULL: `TRIGGER_CATALOG`, `EVENT_OBJECT_CATALOG`, `ACTION_CONDITION`, `ACTION_REFERENCE_OLD_TABLE`, `ACTION_REFERENCE_NEW_TABLE`, and `CREATED`.

Example, using the `ins_sum` trigger defined in [Section 19.3, “Using Triggers”](#):

```
mysql> SELECT * FROM INFORMATION_SCHEMA.TRIGGERS\G
***** 1. row *****
      TRIGGER_CATALOG: NULL
      TRIGGER_SCHEMA: test
      TRIGGER_NAME: ins_sum
      EVENT_MANIPULATION: INSERT
      EVENT_OBJECT_CATALOG: NULL
      EVENT_OBJECT_SCHEMA: test
      EVENT_OBJECT_TABLE: account
      ACTION_ORDER: 0
      ACTION_CONDITION: NULL
      ACTION_STATEMENT: SET @sum = @sum + NEW.amount
      ACTION_ORIENTATION: ROW
      ACTION_TIMING: BEFORE
      ACTION_REFERENCE_OLD_TABLE: NULL
      ACTION_REFERENCE_NEW_TABLE: NULL
      ACTION_REFERENCE_OLD_ROW: OLD
      ACTION_REFERENCE_NEW_ROW: NEW
      CREATED: NULL
      SQL_MODE:
      DEFINER: me@localhost
```

See also [Section 12.5.5.40, “SHOW TRIGGERS Syntax”](#).

20.17. The INFORMATION_SCHEMA PLUGINS Table

The `PLUGINS` table provides information about server plugins.

INFORMATION_SCHEMA Name	SHOW Name	Remarks
<code>PLUGIN_NAME</code>	Name	MySQL extension
<code>PLUGIN_VERSION</code>		MySQL extension
<code>PLUGIN_STATUS</code>	Status	MySQL extension
<code>PLUGIN_TYPE</code>	Type	MySQL extension
<code>PLUGIN_TYPE_VERSION</code>		MySQL extension
<code>PLUGIN_LIBRARY</code>	Library	MySQL extension
<code>PLUGIN_LIBRARY_VERSION</code>		MySQL extension
<code>PLUGIN_AUTHOR</code>		MySQL extension
<code>PLUGIN_DESCRIPTION</code>		MySQL extension

PLUGIN_LICENSE		MySQL extension
----------------	--	-----------------

Notes:

- The `PLUGINS` table is a non-standard table. It was added in MySQL 5.1.5.
- The `PLUGIN_LICENSE` column was added in MySQL 5.1.12.

See also [Section 12.5.5.27](#), “`SHOW PLUGINS Syntax`”.

20.18. The INFORMATION_SCHEMA ENGINES Table

The `PLUGINS` table provides information about storage engines.

INFORMATION_SCHEMA Name	SHOW Name	Remarks
ENGINE	Engine	MySQL extension
SUPPORT	Support	MySQL extension
COMMENT	Comment	MySQL extension
TRANSACTIONS	Transactions	MySQL extension
XA	XA	MySQL extension
SAVEPOINTS	Savepoints	MySQL extension

Notes:

- The `ENGINES` table is a non-standard table. It was added in MySQL 5.1.5.

See also [Section 12.5.5.17](#), “`SHOW ENGINES Syntax`”.

20.19. The INFORMATION_SCHEMA PARTITIONS Table

The `PARTITIONS` table provides information about table partitions. See [Chapter 18, Partitioning](#), for more information about partitioning tables.

INFORMATION_SCHEMA Name	SHOW Name	Remarks
TABLE_CATALOG		MySQL extension
TABLE_SCHEMA		MySQL extension
TABLE_NAME		MySQL extension
PARTITION_NAME		MySQL extension
SUBPARTITION_NAME		MySQL extension
PARTITION_ORDINAL_POSITION		MySQL extension
SUBPARTITION_ORDINAL_POSITION		MySQL extension
PARTITION_METHOD		MySQL extension
SUBPARTITION_METHOD		MySQL extension
PARTITION_EXPRESSION		MySQL extension
SUBPARTITION_EXPRESSION		MySQL extension
PARTITION_DESCRIPTION		MySQL extension
TABLE_ROWS		MySQL extension
AVG_ROW_LENGTH		MySQL extension
DATA_LENGTH		MySQL extension
MAX_DATA_LENGTH		MySQL extension
INDEX_LENGTH		MySQL extension
DATA_FREE		MySQL extension

CREATE_TIME		MySQL extension
UPDATE_TIME		MySQL extension
CHECK_TIME		MySQL extension
CHECKSUM		MySQL extension
PARTITION_COMMENT		MySQL extension
NODEGROUP		MySQL extension
TABLESPACE_NAME		MySQL extension

Notes:

- The `PARTITIONS` table is a non-standard table. It was added in MySQL 5.1.6.
Each record in this table corresponds to an individual partition or subpartition of a partitioned table.
- `TABLE_CATALOG`: This column is always `NULL`.
- `TABLE_SCHEMA`: This column contains the name of the database to which the table belongs.
- `TABLE_NAME`: This column contains the name of the table containing the partition.
- `PARTITION_NAME`: The name of the partition.
- `SUBPARTITION_NAME`: If the `PARTITIONS` table record represents a subpartition, then this column contains the name of subpartition; otherwise it is `NULL`.
- `PARTITION_ORDINAL_POSITION`: All partitions are indexed in the same order as they are defined, with `1` being the number assigned to the first partition. The indexing can change as partitions are added, dropped, and reorganized; the number shown in this column reflects the current order, taking into account any indexing changes.
- `SUBPARTITION_ORDINAL_POSITION`: Subpartitions within a given partition are also indexed and reindexed in the same manner as partitions are indexed within a table.
- `PARTITION_METHOD`: One of the values `RANGE`, `LIST`, `HASH`, `LINEAR HASH`, `KEY`, or `LINEAR KEY`; that is, one of the available partitioning types as discussed in [Section 18.2, “Partition Types”](#).
- `SUBPARTITION_METHOD`: One of the values `HASH`, `LINEAR HASH`, `KEY`, or `LINEAR KEY`; that is, one of the available subpartitioning types as discussed in [Section 18.2.5, “Subpartitioning”](#).
- `PARTITION_EXPRESSION`: This is the expression for the partitioning function used in the `CREATE TABLE` or `ALTER TABLE` statement that created the table's current partitioning scheme.

For example, consider a partitioned table created in the `test` database using this statement:

```
CREATE TABLE tp (
  c1 INT,
  c2 INT,
  c3 VARCHAR(25)
)
PARTITION BY HASH(c1 + c2)
PARTITIONS 4;
```

The `PARTITION_EXPRESSION` column in a `PARTITIONS` table record for a partition from this table displays `c1 + c2`, as shown here:

```
mysql> SELECT DISTINCT PARTITION_EXPRESSION
> FROM INFORMATION_SCHEMA.PARTITIONS
> WHERE TABLE_NAME='tp' AND TABLE_SCHEMA='test';
+-----+
| PARTITION_EXPRESSION |
+-----+
| c1 + c2              |
+-----+
1 row in set (0.09 sec)
```

- `SUBPARTITION_EXPRESSION`: This works in the same fashion for the subpartitioning expression that defines the subpartitioning for a table as `PARTITION_EXPRESSION` does for the partitioning expression used to define a table's partitioning.

If the table has no subpartitions, then this column is `NULL`.

- **PARTITION_DESCRIPTION**: This column is used for RANGE and LIST partitions. For a RANGE partition, it contains the value set in the partition's VALUES LESS THAN clause, which can be either an integer or MAXVALUE. For a LIST partition, this column contains the values defined in the partition's VALUES IN clause, which is a comma-separated list of integer values.

For partitions whose PARTITION_METHOD is other than RANGE or LIST, this column is always NULL.

- **TABLE_ROWS**: The number of table rows in the partition.

For partitioned InnoDB tables, the row count given in the TABLE_ROWS column is only an estimated value used in SQL optimization, and may not always be exact.

- **AVG_ROW_LENGTH**: The average length of the rows stored in this partition or subpartition, in bytes.

This is the same as DATA_LENGTH divided by TABLE_ROWS.

- **DATA_LENGTH**: The total length of all rows stored in this partition or subpartition, in bytes — that is, the total number of bytes stored in the partition or subpartition.
- **MAX_DATA_LENGTH**: The maximum number of bytes that can be stored in this partition or subpartition.
- **INDEX_LENGTH**: The length of the index file for this partition or subpartition, in bytes.
- **DATA_FREE**: The number of bytes allocated to the partition or subpartition but not used.
- **CREATE_TIME**: The time of the partition's or subpartition's creation.
- **UPDATE_TIME**: The time that the partition or subpartition was last modified.
- **CHECK_TIME**: The last time that the table to which this partition or subpartition belongs was checked.

Note

Some storage engines do not update this time; for tables using these storage engines, this value is always NULL.

- **CHECKSUM**: The checksum value, if any; otherwise, this column is NULL.
- **PARTITION_COMMENT**: This column contains the text of any comment made for the partition.

The default value for this column is an empty string.

- **NODEGROUP**: This is the nodegroup to which the partition belongs. This is relevant only to MySQL Cluster tables; otherwise the value of this column is always 0.
- **TABLESPACE_NAME**: This column contains the name of tablespace to which the partition belongs. In MySQL 5.1, the value of this column is always DEFAULT.

Important

If any partitioned tables created in a MySQL version prior to MySQL 5.1.6 are present following an upgrade to MySQL 5.1.6 or later, it is not possible to SELECT from, SHOW, or DESCRIBE the PARTITIONS table. See Section C.1.32, “Changes in MySQL 5.1.6 (01 February 2006)” before upgrading from MySQL 5.1.5 or earlier to MySQL 5.1.6 or later.

- A non-partitioned table has one record in INFORMATION_SCHEMA.PARTITIONS; however, the values of the PARTITION_NAME, SUBPARTITION_NAME, PARTITION_ORDINAL_POSITION, SUBPARTITION_ORDINAL_POSITION, PARTITION_METHOD, SUBPARTITION_METHOD, PARTITION_EXPRESSION, SUBPARTITION_EXPRESSION, and PARTITION_DESCRIPTION columns are all NULL. (The PARTITION_COMMENT column in this case is blank.)

In MySQL 5.1, there is also only one record in the PARTITIONS table for a table using the NDBCLUSTER storage engine. The same columns are also NULL (or empty) as for a non-partitioned table.

20.20. The INFORMATION_SCHEMA EVENTS Table

The EVENTS table provides information about scheduled events, which are discussed in Section 19.4, “Using the Event Scheduler”.

INFORMATION_SCHEMA Name	SHOW Name	Remarks
-------------------------	-----------	---------

EVENT_CATALOG		NULL, MySQL extension
EVENT_SCHEMA	Db	MySQL extension
EVENT_NAME	Name	MySQL extension
DEFINER	Definer	MySQL extension
TIME_ZONE	Time zone	MySQL extension
EVENT_BODY		MySQL extension
EVENT_DEFINITION		MySQL extension
EVENT_TYPE	Type	MySQL extension
EXECUTE_AT	Execute at	MySQL extension
INTERVAL_VALUE	Interval value	MySQL extension
INTERVAL_FIELD	Interval field	MySQL extension
SQL_MODE		MySQL extension
STARTS	Starts	MySQL extension
ENDS	Ends	MySQL extension
STATUS	Status	MySQL extension
ON_COMPLETION		MySQL extension
CREATED		MySQL extension
LAST_ALTERED		MySQL extension
LAST_EXECUTED		MySQL extension
EVENT_COMMENT		MySQL extension
ORIGINATOR	Originator	MySQL extension
CHARACTER_SET_CLIENT		MySQL extension
COLLATION_CONNECTION		MySQL extension
DATABASE_COLLATION		MySQL extension

Notes:

- The `EVENTS` table is a non-standard table. It was added in MySQL 5.1.6.
- `EVENT_CATALOG`: The value of this column is always `NULL`.
- `EVENT_SCHEMA`: The name of the schema (database) to which this event belongs.
- `EVENT_NAME`: The name of the event.
- `DEFINER`: The user who created the event. Always displayed in '`user_name`'@'`host_name`' format.
- `TIME_ZONE`: The time zone in effect when schedule for the event was last modified. If the event's schedule has not been modified since the event was created, then this is the time zone that was in effect at the event's creation. The default value is `SYS-TEM`.

This column was added in MySQL 5.1.17. See [Section C.1.21, "Changes in MySQL 5.1.17 \(04 April 2007\)"](#), for important information if you are using the Event Scheduler and are upgrading from MySQL 5.1.16 (or earlier) to MySQL 5.1.17 (or later).

- `EVENT_BODY`: The language used for the statements in the event's `DO` clause; in MySQL 5.1, this is always `SQL`.

This column was added in MySQL 5.1.12. It is not to be confused with the column of the same name (now named `EVENT_DEFINITION`) that existed in earlier MySQL versions.

- `EVENT_DEFINITION`: The text of the SQL statement making up the event's `DO` clause; in other words, the statement executed by this event.

Note

Prior to MySQL 5.1.12, this column was named `EVENT_BODY`.

- `EVENT_TYPE`: One of the two values `ONE TIME` or `RECURRING`.

- **EXECUTE_AT:** For a one-time event, this is the `DATETIME` value specified in the `AT` clause of the `CREATE EVENT` statement used to create the event, or of the last `ALTER EVENT` statement that modified the event. The value shown in this column reflects the addition or subtraction of any `INTERVAL` value included in the event's `AT` clause. For example, if an event is created using `ON SCHEDULE AT CURRENT_TIMESTAMP + '1:6' DAY_HOUR`, and the event was created at 2006-02-09 14:05:30, the value shown in this column would be `'2006-02-10 20:05:30'`.

If the event's timing is determined by an `EVERY` clause instead of an `AT` clause (that is, if the event is recurring), the value of this column is `NULL`.

- **INTERVAL_VALUE:** For recurring events, this column contains the numeric portion of the event's `EVERY` clause.

For a one-time event (that is, an event whose timing is determined by an `AT` clause), this column's value is `NULL`.

- **INTERVAL_FIELD:** For recurring events, this column contains the units portion of the `EVERY` clause governing the timing of the event. Thus, this column contains a value such as `'YEAR'`, `'QUARTER'`, `'DAY'`, and so on.

Note

In early MySQL 5.1 releases, this value was prefixed with `'INTERVAL_'`, and was displayed as `'INTERVAL_YEAR'`, `'INTERVAL_QUARTER'`, `'INTERVAL_DAY'`, and so on.

For a one-time event (that is, an event whose timing is determined by an `AT` clause), this column's value is `NULL`.

- **SQL_MODE:** The SQL mode in effect at the time the event was created or altered.
- **STARTS:** For a recurring event whose definition includes a `STARTS` clause, this column contains the corresponding `DATE-TIME` value. As with the `EXECUTE_AT` column, this value resolves any expressions used.

If there is no `STARTS` clause affecting the timing of the event, this column is empty. (Prior to MySQL 5.1.8, it contained `NULL` in such cases.)

- **ENDS:** For a recurring event whose definition includes a `ENDS` clause, this column contains the corresponding `DATETIME` value. As with the `EXECUTE_AT` column (see previous example), this value resolves any expressions used.

If there is no `ENDS` clause affecting the timing of the event, this column contains `NULL`.

- **STATUS:** One of the three values `ENABLED`, `DISABLED`, or `SLAVESIDE_DISABLED`.

`SLAVESIDE_DISABLED` was added to the list of possible values for this column in MySQL 5.1.18. This value indicates that the creation of the event occurred on another MySQL server acting as a replication master and was replicated to the current MySQL server which is acting as a slave, but the event is not presently being executed on the slave. See [Section 16.3.1.7, “Replication of Invoked Features”](#), for more information.

- **ON_COMPLETION:** One of the two values `PRESERVE` or `NOT PRESERVE`.
- **CREATED:** The date and time when the event was created. This is a `DATETIME` value.
- **LAST_ALTERED:** The date and time when the event was last modified. This is a `DATETIME` value. If the event has not been modified since its creation, this column holds the same value as the `CREATED` column.
- **LAST_EXECUTED:** The date and time when the event last executed. A `DATETIME` value. If the event has never executed, this column's value is `NULL`.

Before MySQL 5.1.23, `LAST_EXECUTED` indicates when event finished executing. As of 5.1.23, `LAST_EXECUTED` instead indicates when the event started. As a result, the `ENDS` column is never less than `LAST_EXECUTED`.

- **EVENT_COMMENT:** The text of a comment, if the event has one. If there is no comment, the value of this column is an empty string.
- **ORIGINATOR:** The server ID of the MySQL server on which the event was created; used in replication. The default value is 0. This column was added in MySQL 5.1.18.
- **CHARACTER_SET_CLIENT** is the session value of the `character_set_client` system variable when the event was created. **COLLATION_CONNECTION** is the session value of the `collation_connection` system variable when the event was created. **DATABASE_COLLATION** is the collation of the database with which the event is associated. These columns were added in MySQL 5.1.21.

Example: Suppose the user `jon@ghidora` creates an event named `e_daily`, and then modifies it a few minutes later using an `ALTER EVENT` statement, as shown here:

```
DELIMITER |
```

```

CREATE EVENT e_daily
ON SCHEDULE
EVERY 1 DAY
COMMENT 'Saves total number of sessions then clears the table each day'
DO
BEGIN
INSERT INTO site_activity.totals (time, total)
SELECT CURRENT_TIMESTAMP, COUNT(*)
FROM site_activity.sessions;
DELETE FROM site_activity.sessions;
END |
DELIMITER ;
ALTER EVENT e_daily
ENABLED;

```

(Note that comments can span multiple lines.)

This user can then run the following `SELECT` statement, and obtain the output shown:

```

mysql> SELECT * FROM INFORMATION_SCHEMA.EVENTS
> WHERE EVENT_NAME = 'e_daily'
> AND EVENT_SCHEMA = 'myschema'\G
***** 1. row *****
EVENT_CATALOG: NULL
EVENT_SCHEMA: test
EVENT_NAME: e_daily
DEFINER: paul@localhost
TIME_ZONE: SYSTEM
EVENT_BODY: SQL
EVENT_DEFINITION: BEGIN
INSERT INTO site_activity.totals (time, total)
SELECT CURRENT_TIMESTAMP, COUNT(*)
FROM site_activity.sessions;
DELETE FROM site_activity.sessions;
END
EVENT_TYPE: RECURRING
EXECUTE_AT: NULL
INTERVAL_VALUE: 1
INTERVAL_FIELD: DAY
SQL_MODE:
STARTS: 2008-09-03 12:13:39
ENDS: NULL
STATUS: ENABLED
ON_COMPLETION: NOT PRESERVE
CREATED: 2008-09-03 12:13:39
LAST_ALTERED: 2008-09-03 12:13:39
LAST_EXECUTED: NULL
EVENT_COMMENT: Saves total number of sessions then clears the
table each day
ORIGINATOR: 1
CHARACTER_SET_CLIENT: latin1
COLLATION_CONNECTION: latin1_swedish_ci
DATABASE_COLLATION: latin1_swedish_ci

```

Prior to MySQL 5.1.17, the times displayed in the `STARTS`, `ENDS`, and `LAST_EXECUTED` columns were given in terms of Universal Time (GMT or UTC), regardless of the server's time zone setting ([Bug#16420](#)). Beginning with MySQL 5.1.17, these times are all given in terms of local time as determined by the MySQL server's `time_zone` setting. (The same was true of the `starts`, `ends`, and `last_executed` columns of the `mysql.event` table as well as the `Starts` and `Ends` columns in the output of `SHOW [FULL] EVENTS`.)

The `CREATED` and `LAST_ALTERED` columns use the server time zone (as do the `created` and `last_altered` columns of the `mysql.event` table).

See also [Section 12.5.5.19, "SHOW EVENTS Syntax"](#).

20.21. The INFORMATION_SCHEMA FILES Table

The `FILES` table provides information about the files in which MySQL NDB Disk Data tables are stored.

INFORMATION_SCHEMA Name	SHOW Name	Remarks
<code>FILE_ID</code>		MySQL extension
<code>FILE_NAME</code>		MySQL extension
<code>FILE_TYPE</code>		MySQL extension
<code>TABLESPACE_NAME</code>		MySQL extension
<code>TABLE_CATALOG</code>		MySQL extension
<code>TABLE_SCHEMA</code>		MySQL extension

TABLE_NAME		MySQL extension
LOGFILE_GROUP_NAME		MySQL extension
LOGFILE_GROUP_NUMBER		MySQL extension
ENGINE		MySQL extension
FULLTEXT_KEYS		MySQL extension
DELETED_ROWS		MySQL extension
UPDATE_COUNT		MySQL extension
FREE_EXTENTS		MySQL extension
TOTAL_EXTENTS		MySQL extension
EXTENT_SIZE		MySQL extension
INITIAL_SIZE		MySQL extension
MAXIMUM_SIZE		MySQL extension
AUTOEXTEND_SIZE		MySQL extension
CREATION_TIME		MySQL extension
LAST_UPDATE_TIME		MySQL extension
LAST_ACCESS_TIME		MySQL extension
RECOVER_TIME		MySQL extension
TRANSACTION_COUNTER		MySQL extension
VERSION		MySQL extension
ROW_FORMAT		MySQL extension
TABLE_ROWS		MySQL extension
AVG_ROW_LENGTH		MySQL extension
DATA_LENGTH		MySQL extension
MAX_DATA_LENGTH		MySQL extension
INDEX_LENGTH		MySQL extension
DATA_FREE		MySQL extension
CREATE_TIME		MySQL extension
UPDATE_TIME		MySQL extension
CHECK_TIME		MySQL extension
CHECKSUM		MySQL extension
STATUS		MySQL extension
EXTRA		MySQL extension

Notes:

- `FILE_ID` column values are auto-generated.
- `FILE_NAME` is the name of an `UNDO` log file created by `CREATE LOGFILE GROUP` or `ALTER LOGFILE GROUP`, or of a data file created by `CREATE TABLESPACE` or `ALTER TABLESPACE`.
- `FILE_TYPE` is one of the values `UNDOFILE` or `DATAFILE`.
- `TABLESPACE_NAME` is the name of the tablespace with which the file is associated.
- Currently, the value of the `TABLESPACE_CATALOG` column is always `NULL`.
- `TABLE_NAME` is the name of the Disk Data table with which the file is associated, if any.
- The `LOGFILE_GROUP_NAME` column gives the name of the log file group to which the log file or data file belongs.
- For an `UNDO` log file, the `LOGFILE_GROUP_NUMBER` contains the auto-generated ID number of the log file group to which the log file belongs.
- For a MySQL Cluster Disk Data log file or data file, the value of the `ENGINE` column is always `NDB` or `NDBCLUSTER`.

- For a MySQL Cluster Disk Data log file or data file, the value of the `FULLTEXT_KEYS` column is always empty.
- The `FREE_EXTENTS` column displays the number of extents which have not yet been used by the file. The `TOTAL_EXTENTS` column show the total number of extents allocated to the file.

The difference between these two columns is the number of extents currently in use by the file:

```
SELECT TOTAL_EXTENTS - FREE_EXTENTS AS extents_used
FROM INFORMATION_SCHEMA.FILES
WHERE FILE_NAME = 'myfile.dat';
```

You can approximate the amount of disk space in use by the file by multiplying this difference by the value of the `EXTENT_SIZE` column, which gives the size of an extent for the file in bytes:

```
SELECT (TOTAL_EXTENTS - FREE_EXTENTS) * EXTENT_SIZE AS bytes_used
FROM INFORMATION_SCHEMA.FILES
WHERE FILE_NAME = 'myfile.dat';
```

Similarly, you can estimate the amount of space that remains available in a given file by multiplying `FREE_EXTENTS` by `EXTENT_SIZE`:

```
SELECT FREE_EXTENTS * EXTENT_SIZE AS bytes_free
FROM INFORMATION_SCHEMA.FILES
WHERE FILE_NAME = 'myfile.dat';
```

Important

The byte values produced by the preceding queries are approximations only, and their precision is inversely proportional to the value of `EXTENT_SIZE`. That is, the larger `EXTENT_SIZE` becomes, the less accurate the approximations are.

It is also important to remember that once an extent is used, it cannot be freed again without dropping the data file of which it is a part. This means that deletes from a Disk Data table do *not* release disk space.

The extent size can be set in a `CREATE TABLESPACE` statement. See [Section 12.1.18, “CREATE TABLESPACE Syntax”](#), for more information.

- The `INITIAL_SIZE` column shows the size in bytes of the file. This is the same value that was used in the `INITIAL_SIZE` clause of the `CREATE LOGFILE GROUP`, `ALTER LOGFILE GROUP`, `CREATE TABLESPACE`, or `ALTER TABLESPACE` statement used to create the file.

For MySQL Cluster Disk Data files, the value of the `MAXIMUM_SIZE` column is always the same as `INITIAL_SIZE`, and the `AUTOEXTEND_SIZE` column is always empty.

- The `CREATION_TIME` column shows the date and time when the file was created. The `LAST_UPDATE_TIME` column displays the date and time when the file was last modified. The `LAST_ACCESSED` column provides the date and time when the file was last accessed by the server.

Currently, the values of these columns are as reported by the operating system, and are not supplied by the NDB storage engine. Where no value is provided by the operating system, these columns display `0000-00-00 00:00:00`.

- For MySQL Cluster Disk Data files, the value of the `RECOVER_TIME` and `TRANSACTION_COUNTER` columns is always 0.
- For MySQL Cluster Disk Data files, the following columns are always `NULL`:
 - `VERSION`
 - `ROW_FORMAT`
 - `TABLE_ROWS`
 - `AVG_ROW_LENGTH`
 - `DATA_LENGTH`
 - `MAX_DATA_LENGTH`
 - `INDEX_LENGTH`
 - `DATA_FREE`
 - `CREATE_TIME`

- `UPDATE_TIME`
- `CHECK_TIME`
- `CHECKSUM`
- For MySQL Cluster Disk Data files, the value of the `STATUS` column is always `NORMAL`.
- For MySQL Cluster Disk Data files, the `EXTRA` column shows which data node the file belongs to, as each data node has its own copy of the file. For example, suppose you use this statement on a MySQL Cluster with four data nodes:

```
CREATE LOGFILE GROUP mygroup
  ADD UNDOFILE 'new_undo.dat'
  INITIAL_SIZE 2G
  ENGINE NDB;
```

After running the `CREATE LOGFILE GROUP` statement successfully, you should see a result similar to the one shown here for this query against the `FILES` table:

```
mysql> SELECT LOGFILE_GROUP_NAME, FILE_TYPE, EXTRA
-> FROM INFORMATION_SCHEMA.FILES
-> WHERE FILE_NAME = 'new_undo.dat';
```

LOGFILE_GROUP_NAME	FILE_TYPE	EXTRA
mygroup	UNDO FILE	CLUSTER_NODE=3
mygroup	UNDO FILE	CLUSTER_NODE=4
mygroup	UNDO FILE	CLUSTER_NODE=5
mygroup	UNDO FILE	CLUSTER_NODE=6

4 rows in set (0.01 sec)

- The `FILES` table is a non-standard table. It was added in MySQL 5.1.6.
- Beginning with MySQL 5.1.14, an additional row is present in the `FILES` table following the creation of a logfile group. This row has `NULL` for the value of the `FILE_NAME` column. For this row, the value of the `FILE_ID` column is always `0`, that of the `FILE_TYPE` column is always `UNDO FILE`, and that of the `STATUS` column is always `NORMAL`. Currently, the value of the `ENGINE` column is always `NDBCLUSTER`.

The `FREE_EXTENTS` column in this row shows the total number of free extents available to all undo files belonging to a given log file group whose name and number are shown in the `LOGFILE_GROUP_NAME` and `LOGFILE_GROUP_NUMBER` columns, respectively.

Suppose there are no existing log file groups on your MySQL Cluster, and you create one using the following statement:

```
mysql> CREATE LOGFILE GROUP lg1
-> ADD UNDOFILE 'undofile.dat'
-> INITIAL_SIZE = 16M
-> UNDO_BUFFER_SIZE = 1M
-> ENGINE = NDB;
Query OK, 0 rows affected (3.81 sec)
```

You can now see this `NULL` row when you query the `FILES` table:

```
mysql> SELECT DISTINCT
-> FILE_NAME AS File,
-> FREE_EXTENTS AS Free,
-> TOTAL_EXTENTS AS Total,
-> EXTENT_SIZE AS Size,
-> INITIAL_SIZE AS Initial
-> FROM INFORMATION_SCHEMA.FILES;
```

File	Free	Total	Size	Initial
undofile.dat	NULL	4194304	4	16777216
NULL	4184068	NULL	4	NULL

2 rows in set (0.01 sec)

The total number of free extents available for undo logging is always somewhat less than the sum of the `TOTAL_EXTENTS` column values for all undo files in the log file group due to overhead required for maintaining the undo files. This can be seen by adding a second undo file to the log file group, then repeating the previous query against the `FILES` table:

```
mysql> ALTER LOGFILE GROUP lg1
-> ADD UNDOFILE 'undofile02.dat'
-> INITIAL_SIZE = 4M
-> ENGINE = NDB;
Query OK, 0 rows affected (1.02 sec)
```

```
mysql> SELECT DISTINCT
-> FILE_NAME AS File,
-> FREE_EXTENTS AS Free,
-> TOTAL_EXTENTS AS Total,
-> EXTENT_SIZE AS Size,
-> INITIAL_SIZE AS Initial
-> FROM INFORMATION_SCHEMA.FILES;
+-----+-----+-----+-----+-----+
| File          | Free  | Total | Size | Initial |
+-----+-----+-----+-----+-----+
| undofile.dat  | NULL  | 4194304 | 4    | 16777216 |
| undofile02.dat | NULL  | 1048576 | 4    | 4194304  |
| NULL         | 5223944 | NULL  | 4    | NULL     |
+-----+-----+-----+-----+-----+
3 rows in set (0.01 sec)
```

The amount of free space in bytes which is available for undo logging by Disk Data tables using this log file group can be approximated by multiplying the number of free extents by the initial size:

```
mysql> SELECT
-> FREE_EXTENTS AS 'Free Extents',
-> FREE_EXTENTS * EXTENT_SIZE AS 'Free Bytes'
-> FROM INFORMATION_SCHEMA.FILES
-> WHERE LOGFILE_GROUP_NAME = 'lg1'
-> AND FILE_NAME IS NULL;
+-----+-----+
| Free Extents | Free Bytes |
+-----+-----+
| 5223944     | 20895776  |
+-----+-----+
1 row in set (0.02 sec)
```

If you create a MySQL Cluster Disk Data table and then insert some rows into it, you can see approximately how much space remains for undo logging afterwards, for example:

```
mysql> CREATE TABLESPACE ts1
-> ADD DATAFILE 'data1.dat'
-> USE LOGFILE GROUP lg1
-> INITIAL_SIZE 512M
-> ENGINE = NDB;
Query OK, 0 rows affected (8.71 sec)

mysql> CREATE TABLE dd (
-> c1 INT NOT NULL PRIMARY KEY,
-> c2 INT,
-> c3 DATE
-> )
-> TABLESPACE ts1 STORAGE DISK
-> ENGINE = NDB;
Query OK, 0 rows affected (2.11 sec)

mysql> INSERT INTO dd VALUES
-> (NULL, 1234567890, '2007-02-02'),
-> (NULL, 1126789005, '2007-02-03'),
-> (NULL, 1357924680, '2007-02-04'),
-> (NULL, 1642097531, '2007-02-05');
Query OK, 4 rows affected (0.01 sec)

mysql> SELECT
-> FREE_EXTENTS AS 'Free Extents',
-> FREE_EXTENTS * EXTENT_SIZE AS 'Free Bytes'
-> FROM INFORMATION_SCHEMA.FILES
-> WHERE LOGFILE_GROUP_NAME = 'lg1'
-> AND FILE_NAME IS NULL;
+-----+-----+
| Free Extents | Free Bytes |
+-----+-----+
| 5207565     | 20830260  |
+-----+-----+
1 row in set (0.01 sec)
```

- There are no `SHOW` commands associated with the `FILES` table.
- For additional information, and examples of creating and dropping MySQL Cluster Disk Data objects, see [Section 17.10, “MySQL Cluster Disk Data Tables”](#).

20.22. The INFORMATION_SCHEMA PROCESSLIST Table

The `PROCESSLIST` table provides information about which threads are running.

INFORMATION_SCHEMA Name	SHOW Name	Remarks
ID	Id	MySQL extension

USER	User	MySQL extension
HOST	Host	MySQL extension
DB	db	MySQL extension
COMMAND	Command	MySQL extension
TIME	Time	MySQL extension
STATE	State	MySQL extension
INFO	Info	MySQL extension

For an extensive description of the table columns, see [Section 12.5.5.31, “SHOW PROCESSLIST Syntax”](#).

Notes:

- The `PROCESSLIST` table is a non-standard table. It was added in MySQL 5.1.7.
- Like the output from the corresponding `SHOW` statement, the `PROCESSLIST` table will only show information about your own threads, unless you have the `PROCESS` privilege, in which case you will see information about other threads, too. As an anonymous user, you cannot see any rows at all.
- If an SQL statement refers to `INFORMATION_SCHEMA.PROCESSLIST`, then MySQL will populate the entire table once, when statement execution begins, so there is read consistency during the statement. There is no read consistency for a multi-statement transaction, though.

The following statements are equivalent:

```
SELECT * FROM INFORMATION_SCHEMA.PROCESSLIST
SHOW FULL PROCESSLIST
```

20.23. The INFORMATION_SCHEMA REFERENTIAL_CONSTRAINTS Table

The `REFERENTIAL_CONSTRAINTS` table provides information about foreign keys.

INFORMATION_SCHEMA Name	SHOW Name	Remarks
CONSTRAINT_CATALOG		NULL
CONSTRAINT_SCHEMA		
CONSTRAINT_NAME		
UNIQUE_CONSTRAINT_CATALOG		NULL
UNIQUE_CONSTRAINT_SCHEMA		
UNIQUE_CONSTRAINT_NAME		
MATCH_OPTION		
UPDATE_RULE		
DELETE_RULE		
TABLE_NAME		
REFERENCED_TABLE_NAME		

Notes:

- The `REFERENTIAL_CONSTRAINTS` table was added in MySQL 5.1.10. The `REFERENCED_TABLE_NAME` column was added in MySQL 5.1.16.
- `TABLE_NAME` has the same value as `TABLE_NAME` in `INFORMATION_SCHEMA.TABLE_CONSTRAINTS`.
- `CONSTRAINT_SCHEMA` and `CONSTRAINT_NAME` identify the foreign key.
- `UNIQUE_CONSTRAINT_SCHEMA`, `UNIQUE_CONSTRAINT_NAME`, and `REFERENCED_TABLE_NAME` identify the refer-

enced key. (Note: Before MySQL 5.1.16, `UNIQUE_CONSTRAINT_NAME` incorrectly named the referenced table, not the constraint.)

- The only valid value at this time for `MATCH_OPTION` is `NONE`.
- The possible values for `UPDATE_RULE` or `DELETE_RULE` are `CASCADE`, `SET NULL`, `SET DEFAULT`, `RESTRICT`, `NO ACTION`.

20.24. The INFORMATION_SCHEMA GLOBAL_STATUS and SESSION_STATUS Tables

The `GLOBAL_STATUS` and `SESSION_STATUS` tables provide information about server status variables. Their contents correspond to the information produced by the `SHOW GLOBAL STATUS` and `SHOW SESSION STATUS` statements (see [Section 12.5.5.37](#), “`SHOW STATUS Syntax`”).

INFORMATION_SCHEMA Name	SHOW Name	Remarks
VARIABLE_NAME	Variable_name	
VARIABLE_VALUE	Value	

Notes:

- The `GLOBAL_STATUS` and `SESSION_STATUS` tables were added in MySQL 5.1.12.
- Beginning with MySQL 5.1.19, the `VARIABLE_VALUE` column for each of these tables is defined as `VARCHAR(20480)`. Previously, this column had the data type `DECIMAL(22,7)`, but was changed to avoid loss of data when working with status variables whose values were strings ([Bug#26994](#)).

20.25. The INFORMATION_SCHEMA GLOBAL_VARIABLES and SESSION_VARIABLES Tables

The `GLOBAL_VARIABLES` and `SESSION_VARIABLES` tables provide information about server status variables. Their contents correspond to the information produced by the `SHOW GLOBAL VARIABLES` and `SHOW SESSION VARIABLES` statements (see [Section 12.5.5.41](#), “`SHOW VARIABLES Syntax`”).

INFORMATION_SCHEMA Name	SHOW Name	Remarks
VARIABLE_NAME	Variable_name	
VARIABLE_VALUE	Value	

Notes:

- The `GLOBAL_VARIABLES` and `SESSION_VARIABLES` tables were added in MySQL 5.1.12.
- Beginning with MySQL 5.1.19, the `VARIABLE_VALUE` column for each of these tables is defined as `VARCHAR(20480)`. Previously, this column had the data type `LONGTEXT`; this was changed in order to make these tables consistent with the `GLOBAL_STATUS` and `SESSION_STATUS` tables, whose definitions had been changed in that version (see [Section 20.24](#), “[The INFORMATION_SCHEMA GLOBAL_STATUS and SESSION_STATUS Tables](#)”).

20.26. The INFORMATION_SCHEMA PROFILING Table

The `PROFILING` table provides statement profiling information. Its contents correspond to the information produced by the `SHOW PROFILES` and `SHOW PROFILE` statements (see [Section 12.5.5.33](#), “`SHOW PROFILES Syntax`”). The table is empty unless the `profiling` session variable is set to 1.

INFORMATION_SCHEMA Name	SHOW Name	Remarks
QUERY_ID	Query_ID	
SEQ		

STATE	Status	
DURATION	Duration	
CPU_USER	CPU_user	
CPU_SYSTEM	CPU_system	
CONTEXT_VOLUNTARY	Context_voluntary	
CONTEXT_INVOLUNTARY	Context_involuntary	
BLOCK_OPS_IN	Block_ops_in	
BLOCK_OPS_OUT	Block_ops_out	
MESSAGES_SENT	Messages_sent	
MESSAGES_RECEIVED	Messages_received	
PAGE_FAULTS_MAJOR	Page_faults_major	
PAGE_FAULTS_MINOR	Page_faults_minor	
SWAPS	Swaps	
SOURCE_FUNCTION	Source_function	
SOURCE_FILE	Source_file	
SOURCE_LINE	Source_line	

Notes:

- The `PROFILING` table was added in MySQL 5.1.24.
- `QUERY_ID` is a numeric statement identifier.
- `SEQ` is a sequence number indicating the display order for rows with the same `QUERY_ID` value.
- `STATE` is the profiling state to which the row measurements apply.
- `DURATION` indicates how long statement execution remained in the given state, in seconds.
- `CPU_USER` and `CPU_SYSTEM` indicate user and system CPU use, in seconds.
- `CONTEXT_VOLUNTARY` and `CONTEXT_INVOLUNTARY` indicate how many voluntary and involuntary context switches occurred.
- `BLOCK_OPS_IN` and `BLOCK_OPS_OUT` indicate the number of block input and output operations.
- `MESSAGES_SENT` and `MESSAGES_RECEIVED` indicate the number of communication messages sent and received.
- `PAGE_FAULTS_MAJOR` and `PAGE_FAULTS_MINOR` indicate the number of major and minor page faults.
- `SWAPS` indicates how many swaps occurred.
- `SOURCE_FUNCTION`, `SOURCE_FILE`, and `SOURCE_LINE` provide information indicating where in the source code the profiled state executes.

20.27. Other INFORMATION_SCHEMA Tables

We intend to implement additional `INFORMATION_SCHEMA` tables. In particular, we acknowledge the need for the `PARAMETERS` table. (`PARAMETERS` is implemented in MySQL 6.0.)

20.28. Extensions to SHOW Statements

Some extensions to `SHOW` statements accompany the implementation of `INFORMATION_SCHEMA`:

- `SHOW` can be used to get information about the structure of `INFORMATION_SCHEMA` itself.
- Several `SHOW` statements accept a `WHERE` clause that provides more flexibility in specifying which rows to display.

`INFORMATION_SCHEMA` is an information database, so its name is included in the output from `SHOW DATABASES`. Similarly, `SHOW TABLES` can be used with `INFORMATION_SCHEMA` to obtain a list of its tables:

```
mysql> SHOW TABLES FROM INFORMATION_SCHEMA;
+-----+
| Tables_in_INFORMATION_SCHEMA |
+-----+
| CHARACTER_SETS                |
| COLLATIONS                    |
| COLLATION_CHARACTER_SET_APPLICABILITY |
| COLUMNS                      |
| COLUMN_PRIVILEGES             |
| ENGINES                      |
| EVENTS                       |
| FILES                         |
| GLOBAL_STATUS                 |
| GLOBAL_VARIABLES             |
| KEY_COLUMN_USAGE              |
| PARTITIONS                    |
| PLUGINS                      |
| PROCESSLIST                   |
| REFERENTIAL_CONSTRAINTS      |
| ROUTINES                     |
| SCHEMATA                     |
| SCHEMA_PRIVILEGES            |
| SESSION_STATUS               |
| SESSION_VARIABLES            |
| STATISTICS                    |
| TABLES                      |
| TABLE_CONSTRAINTS           |
| TABLE_PRIVILEGES            |
| TRIGGERS                     |
| USER_PRIVILEGES              |
| VIEWS                        |
+-----+
27 rows in set (0.00 sec)
```

`SHOW COLUMNS` and `DESCRIBE` can display information about the columns in individual `INFORMATION_SCHEMA` tables.

`SHOW` statements that accept a `LIKE` clause to limit the rows displayed also allow a `WHERE` clause that enables specification of more general conditions that selected rows must satisfy:

```
SHOW CHARACTER SET
SHOW COLLATION
SHOW COLUMNS
SHOW DATABASES
SHOW FUNCTION STATUS
SHOW INDEX
SHOW OPEN TABLES
SHOW PROCEDURE STATUS
SHOW STATUS
SHOW TABLE STATUS
SHOW TABLES
SHOW TRIGGERS
SHOW VARIABLES
```

The `WHERE` clause, if present, is evaluated against the column names displayed by the `SHOW` statement. For example, the `SHOW CHARACTER SET` statement produces these output columns:

```
mysql> SHOW CHARACTER SET;
+-----+-----+-----+-----+
| Charset | Description | Default collation | Maxlen |
+-----+-----+-----+-----+
| big5    | Big5 Traditional Chinese | big5_chinese_ci | 2 |
| dec8    | DEC West European | dec8_swedish_ci | 1 |
| cp850   | DOS West European | cp850_general_ci | 1 |
| hp8     | HP West European | hp8_english_ci | 1 |
| koi8r   | KOI8-R Relcom Russian | koi8r_general_ci | 1 |
| latin1  | cp1252 West European | latin1_swedish_ci | 1 |
| latin2  | ISO 8859-2 Central European | latin2_general_ci | 1 |
| ...     | ... | ... | ... |
```

To use a `WHERE` clause with `SHOW CHARACTER SET`, you would refer to those column names. As an example, the following statement displays information about character sets for which the default collation contains the string `'japanese'`:

```
mysql> SHOW CHARACTER SET WHERE `Default collation` LIKE '%japanese%';
+-----+-----+-----+-----+
| Charset | Description | Default collation | Maxlen |
+-----+-----+-----+-----+
| ujis    | EUC-JP Japanese | ujis_japanese_ci | 3 |
| sjis    | Shift-JIS Japanese | sjis_japanese_ci | 2 |
| cp932   | SJIS for Windows Japanese | cp932_japanese_ci | 2 |
| eucjpms | UJIS for Windows Japanese | eucjpms_japanese_ci | 3 |
+-----+-----+-----+-----+
```

This statement displays the multi-byte character sets:

```
mysql> SHOW CHARACTER SET WHERE Maxlen > 1;
```

Charset	Description	Default collation	Maxlen
big5	Big5 Traditional Chinese	big5_chinese_ci	2
ujis	EUC-JP Japanese	ujis_japanese_ci	3
sjis	Shift-JIS Japanese	sjis_japanese_ci	2
euckr	EUC-KR Korean	euckr_korean_ci	2
gb2312	GB2312 Simplified Chinese	gb2312_chinese_ci	2
gbk	GBK Simplified Chinese	gbk_chinese_ci	2
utf8	UTF-8 Unicode	utf8_general_ci	3
ucs2	UCS-2 Unicode	ucs2_general_ci	2
cp932	SJIS for Windows Japanese	cp932_japanese_ci	2
eucjpms	UJIS for Windows Japanese	eucjpms_japanese_ci	3

Chapter 21. Connectors and APIs

MySQL Connectors provide connectivity to the MySQL server for client programs. APIs provide low-level access to the MySQL protocol and MySQL resources. Both Connectors and the APIs enable you to connect and execute MySQL statements from another language or environment, including Java (JDBC), ODBC, Perl, Python, PHP, Ruby, and native C and embedded MySQL instances.

Note

Connector version numbers do not correlate with MySQL Server version numbers. See also [Table 21.2, “MySQL Connector versions and MySQL Server versions”](#).

A number of connectors are developed by MySQL:

- Connector/ODBC provides driver support for connecting to a MySQL server using the Open Database Connectivity (ODBC) API. Support is available for ODBC connectivity from Windows, Unix and Mac OS X platforms.
- Connector/NET enables developers to create .NET applications that use data stored in a MySQL database. Connector/NET implements a fully-functional ADO.NET interface and provides support for use with ADO.NET aware tools. Applications that want to use Connector/NET can be written in any of the supported .NET languages.

The MySQL Visual Studio Plugin works with Connector/NET and Visual Studio 2005. The plugin is a MySQL DDEX Provider, which means that you can use the schema and data manipulation tools within Visual Studio to create and edit objects within a MySQL database.

- Connector/J provides driver support for connecting to MySQL from a Java application using the standard Java Database Connectivity (JDBC) API.
- Connector/MXJ is a tool that enables easy deployment and management of MySQL server and database through your Java application.
- Connector/C++ is a tool that enables easy deployment and management of MySQL server and database through your C++ application.
- Connector/C is a stand-alone replacement for the MySQL Client Library ([libmysql](#)).
- Connector/OpenOffice.org is a tool that enables OpenOffice.org applications to connect to MySQL server.

There are two direct access methods for using MySQL natively within a C application:

- The C API provides low-level access to the MySQL protocol through the [libmysql](#) client library; this is the primary method used to connect to an instance of the MySQL server, and is used both by MySQL command line clients and many of the APIs also detailed in this section. MySQL Connector/C can now also be used for this purpose.
- [libmysqld](#) is an embedded MySQL server library that enables you to embed an instance of the MySQL server into your C applications.

If you need to access MySQL from a C application, or build an interface to MySQL for a language not supported by the Connectors or APIs in this chapter, the C API is where you would start. A number of programmers utilities are available to help with the process, and also covered in this section.

The remaining APIs provide an interface to MySQL from specific application languages. These solutions are not developed or supported by MySQL. Basic information on their usage and abilities is provided here for reference purposes only.

All the language APIs are developed using one of two methods, using [libmysql](#) or by building a *native driver*. The two solutions offer different benefits:

- Using [libmysql](#) offers complete compatibility with MySQL as it uses the same libraries as the MySQL client applications. However, the feature set is limited to the implementation and interfaces exposed through [libmysql](#) and the performance may be lower as data is copied between the native language, and the MySQL API components. MySQL Connector/C is a possible alternative to using [libmysql](#).
- *Native drivers* are an implementation of the MySQL network protocol entirely within the host language or environment. Native drivers are fast, as there is less copying of data between components, and they can offer advanced functionality not available through the standard MySQL API. Native drivers are also easier to build and deploy, as you do not need a copy of the MySQL client libraries to build the native driver components.

A list of many of the libraries and interfaces available for MySQL are shown in the table. See Table 21.1, “MySQL APIs and Interfaces”.

Table 21.1. MySQL APIs and Interfaces

Environment	API	Type	Notes
Ada	MySQL Bindings for GNU Ada	<code>libmysql</code>	See MySQL Bindings for GNU Ada
C	Connector/C	Replacement for <code>libmysql</code>	See Section 21.7, “MySQL Connector/C” .
C++	Connector/C++	<code>libmysql</code>	See Section 21.6, “MySQL Connector/C++” .
	MySQL++	<code>libmysql</code>	See Section 21.13, “MySQL C++ API” .
	MySQL wrapped	<code>libmysql</code>	See MySQL wrapped .
Cocoa	MySQL-Cocoa	<code>libmysql</code>	Compatible with the Objective-C Cocoa environment. See http://mysql-cocoa.sourceforge.net/
D	MySQL for D	<code>libmysql</code>	See MySQL for D .
Eiffel	Eiffel MySQL	<code>libmysql</code>	See Section 21.17, “MySQL Eiffel Wrapper” .
Erlang	<code>erlang-mysql-driver</code>	<code>libmysql</code>	See erlang-mysql-driver .
Haskell	Haskell MySQL Bindings	Native Driver	See Brian O’Sullivan’s pure Haskell MySQL bindings .
	<code>hsqldb-mysql</code>	<code>libmysql</code>	See MySQL driver for Haskell .

Octave	Database bindings for GNU Octave	<code>libmysql</code>	See Database bindings for GNU Octave .
ODBC	Connector/ODBC	<code>libmysql</code>	See Section 21.1, “MySQL Connector/ODBC” .
OpenOffice	MySQL Connector/OpenOffice.org	<code>libmysql</code>	Direct connectivity, without using JDBC/ODBC. See Section 21.8, “MySQL Connector/OpenOffice.org” .
Perl	<code>DBI/DBD::mysql</code>	<code>libmysql</code>	See Section 21.12, “MySQL Perl API” .
	<code>Net::MySQL</code>	Native Driver	See Net::MySQL at CPAN
PHP	<code>mysql</code> , <code>ext/mysql</code> interface (deprecated)	<code>libmysql</code>	See Section 21.11.1, “MySQL” .
	<code>mysqli</code> , <code>ext/mysqli</code> interface	<code>libmysql</code>	See Section 21.11.2, “MySQL Improved Extension (mysqli)” .
	<code>PDO_MYSQL</code>	<code>libmysql</code>	See Section 21.11.3, “MySQL Functions (PDO_MYSQL)” .
	<code>PDO mysqlnd</code>	Native Driver	See PHP PDO mysqlnd .
Python	MySQLdb	<code>libmysql</code>	See Section 21.14, “MySQL Python API” .
Ruby	MySQL/Ruby	<code>libmysql</code>	Uses <code>libmysql</code> . See Section 21.15.1, “The MySQL/Ruby API” .
	Ruby/MySQL	Native Driver	See Section 21.15.2, “The Ruby/MySQL API” .
Scheme	<code>Myscsh</code>	<code>libmysql</code>	See Myscsh .
SPL	<code>sql_mysql</code>	<code>libmysql</code>	See sql_mysql for SPL.
Tcl	MySQLtcl	<code>libmysql</code>	See Section 21.16, “MySQL Tcl API” .

Table 21.2. MySQL Connector versions and MySQL Server versions

Connector	Connector version	MySQL Server version
Connector/C++	1.0.5 (Beta)	5.1, 5.4, 6.0

Connector	Connector version	MySQL Server version
Connector/OpenOffice.org	1.0 (Alpha)	5.0, 5.1, 5.4, 6.0
Connector/J	5.1	4.1, 5.0, 5.1, 5.4, 6.0
Connector/NET	1.0	4.0, 5.0
Connector/NET	5.2	4.0, 4.1, 5.0, 5.1, 5.4, 6.0
Connector/NET	5.3	4.1, 5.0, 5.1, 5.4, 6.0
Connector/ODBC	3.51 (Unicode not supported)	4.1, 5.0, 5.1, 5.4, 6.0
Connector/ODBC	5.1	4.1, 5.0, 5.1, 5.4, 6.0

21.1. MySQL Connector/ODBC

The MySQL Connector/ODBC is the name for the family of MySQL ODBC drivers (previously called MyODBC drivers) that provide access to a MySQL database using the industry standard Open Database Connectivity (ODBC) API. This reference covers Connector/ODBC 3.51 and Connector/ODBC 5.1. Both releases provide an ODBC compliant interface to MySQL Server.

MySQL Connector/ODBC provides both driver-manager based and native interfaces to the MySQL database, which full support for MySQL functionality, including stored procedures, transactions and, with Connector/ODBC 5.1, full Unicode compliance.

For more information on the ODBC API standard and how to use it, refer to <http://support.microsoft.com/kb/110093>.

The application development part of this reference assumes a good working knowledge of C, general DBMS knowledge, and finally, but not least, familiarity with MySQL. For more information about MySQL functionality and its syntax, refer to <http://dev.mysql.com/doc/>.

Typically, you need to install Connector/ODBC only on Windows machines. For Unix and Mac OS X you can use the native MySQL network or named pipe to communicate with your MySQL database. You may need Connector/ODBC for Unix or Mac OS X if you have an application that requires an ODBC interface to communicate with the database. Applications that require ODBC to communicate with MySQL include ColdFusion, Microsoft Office, and Filemaker Pro.

Key topics:

- For help installing Connector/ODBC see [Section 21.1.3, “Connector/ODBC Installation”](#).
- For information on the configuration options, see [Section 21.1.4.2, “Connector/ODBC Connection Parameters”](#).
- For more information on connecting to a MySQL database from a Windows host using Connector/ODBC see [Section 21.1.5.2, “Step-by-step Guide to Connecting to a MySQL Database through Connector/ODBC”](#).
- If you want to use Microsoft Access as an interface to a MySQL database using Connector/ODBC see [Section 21.1.5.4, “Using Connector/ODBC with Microsoft Access”](#).
- General tips on using Connector/ODBC, including obtaining the last auto-increment ID see [Section 21.1.7.1, “Connector/ODBC General Functionality”](#).
- For tips and common questions on using Connector/ODBC with specific application see [Section 21.1.7.2, “Connector/ODBC Application Specific Tips”](#).
- For a general list of Frequently Asked Questions see [Section 21.1.7.3, “Connector/ODBC Errors and Resolutions \(FAQ\)”](#).
- Additional support when using Connector/ODBC is available, see [Section 21.1.8, “Connector/ODBC Support”](#).

MySQL Enterprise

MySQL Enterprise subscribers will find more information about MySQL and ODBC in the Knowledge Base articles about [ODBC](#). Access to the MySQL Knowledge Base collection of articles is one of the advantages of subscribing to MySQL Enterprise. For more information, see <http://www.mysql.com/products/enterprise/advisors.html>.

21.1.1. Connector/ODBC Versions

There are currently two version of Connector/ODBC available:

- Connector/ODBC 5.1, currently in GA status, is a partial rewrite of the of the 3.51 code base and is designed to work with all versions of MySQL from 4.1. Connector/ODBC 5.1 will be a complete implementation of the ODBC Core interface, plus more

Level 1 and Level 2 functionality of the ODBC specification than that currently supported by Connector/ODBC 3.51. See [Section 21.1.2.1, “Connector/ODBC Roadmap”](#).

Connector/ODBC 5.1 also includes the following changes and improvements over the 3.51 release:

- Improved support on Windows 64-bit platforms.
- Full Unicode support at the driver level. This includes support for the `SQL_WCHAR` datatype, and support for Unicode login, password and DSN configurations. For more information, see [Microsoft Knowledgebase Article #716246](#).
- Support for the `SQL_NUMERIC_STRUCT` datatype, which provides easier access to the precise definition of numeric values. For more information, see [Microsoft Knowledgebase Article #714556](#)
- Native Windows setup library. This replaces the Qt library based interface for configuring DSN information within the ODBC Data Sources application.
- Support for the ODBC descriptor, which improves the handling and metadata of columns and parameter data. For more information, see [Microsoft Knowledgebase Article #716339](#).
- Connector/ODBC 3.51 is the current release of the 32-bit ODBC driver, also known as the MySQL ODBC 3.51 driver. Connector/ODBC 3.51 has support for ODBC 3.5x specification level 1 (complete core API + level 2 features) in order to continue to provide all functionality of ODBC for accessing MySQL.

The manual for versions of Connector/ODBC older than 3.51 can be located in the corresponding binary or source distribution. Please note that versions of Connector/ODBC earlier than the 3.51 revision were not fully compliant with the ODBC specification.

Note

Development on Connector/ODBC 5.0 was stopped due to development issues. Connector/ODBC 5.1 is now the current development release.

Note

From this section onward, the primary focus of this guide is the Connector/ODBC 3.51 and Connector/ODBC 5.1 drivers.

Note

Version numbers for MySQL products are formatted as X.X.X. However, Windows tools (Control Panel, properties display) may show the version numbers as XX.XX.XX. For example, the official MySQL formatted version number 5.0.9 may be displayed by Windows tools as 5.00.09. The two versions are the same; only the number display format is different.

21.1.2. Connector/ODBC Introduction

ODBC (Open Database Connectivity) provides a way for client programs to access a wide range of databases or data sources. ODBC is a standardized API that allows connections to SQL database servers. It was developed according to the specifications of the SQL Access Group and defines a set of function calls, error codes, and data types that can be used to develop database-independent applications. ODBC usually is used when database independence or simultaneous access to different data sources is required.

For more information about ODBC, refer to <http://support.microsoft.com/kb/110093>.

21.1.2.1. Connector/ODBC Roadmap

Connector/ODBC 5.1 is currently in development and will be a complete implementation of the ODBC Core interface, plus more Level 1 and Level 2 functionality of the ODBC specification than that currently supported by Connector/ODBC 3.51.

The following functionality was added or changed as part of 5.1:

- Add support for `SQL_NUMERIC_STRUCT`: [MSDN Article 714556](#).
- Replace installer library with new implementation (from v5 tree).
- Implement native Windows setup library.
- Implement `SQLCancel()` ([Bug#15601](#)): [MSDN Article 714112](#).

The following functionality will be added in a version after 5.1:

- Implement native Mac OS X setup library.
- Replace OPTIONS flags with individual DSN settings (but support OPTIONS for backwards-compatibility).
- Fix support for SQLBIGINT ([Bug#28887](#)): [MSDN Article 714121](#).
- Make diagnostics support standards-compliant: [MSDN Article 711021](#).
- Add support for SQL_ATTR_METADATA_ID: [MSDN Article 716447](#).
- Implement SQLBrowseConnect(): [MSDN Article 714565](#), [MSDN Article 712446](#).
- Implement arrays of parameters: [MSDN Article 711818](#).

21.1.2.2. General Information About ODBC and Connector/ODBC

Open Database Connectivity (ODBC) is a widely accepted application-programming interface (API) for database access. It is based on the Call-Level Interface (CLI) specifications from X/Open and ISO/IEC for database APIs and uses Structured Query Language (SQL) as its database access language.

A survey of ODBC functions supported by Connector/ODBC is given at [Section 21.1.6.1, "Connector/ODBC API Reference"](#). For general information about ODBC, see <http://support.microsoft.com/kb/110093>.

21.1.2.2.1. Connector/ODBC Architecture

The Connector/ODBC architecture is based on five components, as shown in the following diagram:

- **Application:**

The Application uses the ODBC API to access the data from the MySQL server. The ODBC API in turn uses the communicates with the Driver Manager. The Application communicates with the Driver Manager using the standard ODBC calls. The Application does not care where the data is stored, how it is stored, or even how the system is configured to access the data. It needs to know only the Data Source Name (DSN).

A number of tasks are common to all applications, no matter how they use ODBC. These tasks are:

- Selecting the MySQL server and connecting to it
- Submitting SQL statements for execution
- Retrieving results (if any)
- Processing errors
- Committing or rolling back the transaction enclosing the SQL statement
- Disconnecting from the MySQL server

Because most data access work is done with SQL, the primary tasks for applications that use ODBC are submitting SQL statements and retrieving any results generated by those statements.

- **Driver manager:**

The Driver Manager is a library that manages communication between application and driver or drivers. It performs the following tasks:

- Resolves Data Source Names (DSN). The DSN is a configuration string that identifies a given database driver, database, database host and optionally authentication information that enables an ODBC application to connect to a database using a standardized reference.

Because the database connectivity information is identified by the DSN, any ODBC compliant application can connect to the data source using the same DSN reference. This eliminates the need to separately configure each application that needs access to a given database; instead you instruct the application to use a pre-configured DSN.

- Loading and unloading of the driver required to access a specific database as defined within the DSN. For example, if you have configured a DSN that connects to a MySQL database then the driver manager will load the Connector/ODBC driver to enable the ODBC API to communicate with the MySQL host.
- Processes ODBC function calls or passes them to the driver for processing.

- **Connector/ODBC Driver:**

The Connector/ODBC driver is a library that implements the functions supported by the ODBC API. It processes ODBC function calls, submits SQL requests to MySQL server, and returns results back to the application. If necessary, the driver modifies an application's request so that the request conforms to syntax supported by MySQL.

- **DSN Configuration:**

The ODBC configuration file stores the driver and database information required to connect to the server. It is used by the Driver Manager to determine which driver to be loaded according to the definition in the DSN. The driver uses this to read connection parameters based on the DSN specified. For more information, [Section 21.1.4, “Connector/ODBC Configuration”](#).

- **MySQL Server:**

The MySQL database where the information is stored. The database is used as the source of the data (during queries) and the destination for data (during inserts and updates).

21.1.2.2.2. ODBC Driver Managers

An ODBC Driver Manager is a library that manages communication between the ODBC-aware application and any drivers. Its main functionality includes:

- Resolving Data Source Names (DSN).
- Driver loading and unloading.
- Processing ODBC function calls or passing them to the driver.

Both Windows and Mac OS X include ODBC driver managers with the operating system. Most ODBC Driver Manager implementations also include an administration application that makes the configuration of DSN and drivers easier. Examples and information on these managers, including Unix ODBC driver managers are listed below:

- Microsoft Windows ODBC Driver Manager (`odbc32.dll`), <http://support.microsoft.com/kb/110093>.
- Mac OS X includes [ODBC Administrator](#), a GUI application that provides a simpler configuration mechanism for the Unix iODBC Driver Manager. You can configure DSN and driver information either through ODBC Administrator or through the iODBC configuration files. This also means that you can test ODBC Administrator configurations using the `iodbctest` command. <http://www.apple.com>.
- [unixODBC Driver Manager for Unix](#) (`libodbc.so`). See <http://www.unixodbc.org>, for more information. The [unixODBC Driver Manager](#) includes the Connector/ODBC driver 3.51 in the installation package, starting with version [unixODBC 2.1.2](#).
- [iODBC ODBC Driver Manager for Unix](#) (`libiodbc.so`), see <http://www.iodbc.org>, for more information.

21.1.3. Connector/ODBC Installation

You can install the Connector/ODBC drivers using two different methods, a binary installation and a source installation. The binary

installation is the easiest and most straightforward method of installation. Using the source installation methods should only be necessary on platforms where a binary installation package is not available, or in situations where you want to customize or modify the installation process or Connector/ODBC drivers before installation.

Where to Get Connector/ODBC

Sun Microsystems, Inc distributes its MySQL products under the General Public License (GPL). You can get a copy of the latest version of Connector/ODBC binaries and sources from our Web site at <http://dev.mysql.com/downloads/>.

For more information about Connector/ODBC, visit <http://www.mysql.com/products/myodbc/>.

For more information about licensing, visit <http://www.mysql.com/company/legal/licensing/>.

Supported Platforms

Connector/ODBC can be used on all major platforms supported by MySQL. You can install it on:

- Windows 95, 98, Me, NT, 2000, XP, and 2003
- All Unix-like Operating Systems, including: AIX, Amiga, BSDI, DEC, FreeBSD, HP-UX 10/11, Linux, NetBSD, OpenBSD, OS/2, SGI Irix, Solaris, SunOS, SCO OpenServer, SCO UnixWare, Tru64 Unix
- Mac OS X and Mac OS X Server

Using a binary distribution offers the most straightforward method for installing Connector/ODBC. If you want more control over the driver, the installation location and or to customize elements of the driver you will need to build and install from the source.
