In this case, MySQL Server parses and executes the code within the comment as it would any other SQL statement, but other SQL servers will ignore the extensions. For example, MySQL Server recognizes the `STRAIGHT_JOIN` keyword in the following statement, but other servers will not:

```

SELECT /*! STRAIGHT_JOIN */ col1 FROM table1,table2 WHERE ...

```

If you add a version number after the “!” character, the syntax within the comment is executed only if the MySQL version is greater than or equal to the specified version number. The `TEMPORARY` keyword in the following comment is executed only by servers from MySQL 3.23.02 or higher:

```

CREATE /*!132302 TEMPORARY */ TABLE t (a INT);

```

The comment syntax just described applies to how the `mysqld` server parses SQL statements. The `mysql` client program also performs some parsing of statements before sending them to the server. (It does this to determine statement boundaries within a multiple-statement input line.)

The use of short-form `mysql` commands such as `\C` within multi-line `/* ... */` comments is not supported.

Chapter 9. Internationalization and Localization

This chapter covers issues of internationalization (MySQL's capabilities for adapting to local use) and localization (selecting particular local conventions):

- MySQL support for character sets in SQL statements.
- How to configure the server to support different character sets.
- Selecting the language for error messages.
- How to set the server's time zone and enable per-connection time zone support.
- Selecting the locale for day and month names.

9.1. Character Set Support

MySQL includes character set support that enables you to store data using a variety of character sets and perform comparisons according to a variety of collations. You can specify character sets at the server, database, table, and column level. MySQL supports the use of character sets for the [MyISAM](#), [MEMORY](#), [NDBCLUSTER](#), and [InnoDB](#) storage engines.

This chapter discusses the following topics:

- What are character sets and collations?
- The multiple-level default system for character set assignment
- Syntax for specifying character sets and collations
- Affected functions and operations
- Unicode support
- The character sets and collations that are available, with notes

Character set issues affect not only data storage, but also communication between client programs and the MySQL server. If you want the client program to communicate with the server using a character set different from the default, you'll need to indicate which one. For example, to use the `utf8` Unicode character set, issue this statement after connecting to the server:

```
SET NAMES 'utf8';
```

For more information about configuring character sets for application use and character set-related issues in client/server communication, see [Section 9.1.5, "Configuring the Character Set and Collation for Applications"](#), and [Section 9.1.4, "Connection Character Sets and Collations"](#).

9.1.1. Character Sets and Collations in General

A *character set* is a set of symbols and encodings. A *collation* is a set of rules for comparing characters in a character set. Let's make the distinction clear with an example of an imaginary character set.

Suppose that we have an alphabet with four letters: "A", "B", "a", "b". We give each letter a number: "A" = 0, "B" = 1, "a" = 2, "b" = 3. The letter "A" is a symbol, the number 0 is the **encoding** for "A", and the combination of all four letters and their encodings is a **character set**.

Suppose that we want to compare two string values, "A" and "B". The simplest way to do this is to look at the encodings: 0 for "A" and 1 for "B". Because 0 is less than 1, we say "A" is less than "B". What we've just done is apply a collation to our character set. The collation is a set of rules (only one rule in this case): "compare the encodings." We call this simplest of all possible collations a *binary* collation.

But what if we want to say that the lowercase and uppercase letters are equivalent? Then we would have at least two rules: (1) treat the lowercase letters "a" and "b" as equivalent to "A" and "B"; (2) then compare the encodings. We call this a *case-insensitive* collation. It is a little more complex than a binary collation.

In real life, most character sets have many characters: not just "A" and "B" but whole alphabets, sometimes multiple alphabets or eastern writing systems with thousands of characters, along with many special symbols and punctuation marks. Also in real life,

most collations have many rules, not just for whether to distinguish lettercase, but also for whether to distinguish accents (an “accent” is a mark attached to a character as in German “ö”), and for multiple-character mappings (such as the rule that “ö” = “oe” in one of the two German collations).

MySQL can do these things for you:

- Store strings using a variety of character sets
- Compare strings using a variety of collations
- Mix strings with different character sets or collations in the same server, the same database, or even the same table
- Allow specification of character set and collation at any level

In these respects, MySQL is far ahead of most other database management systems. However, to use these features effectively, you need to know what character sets and collations are available, how to change the defaults, and how they affect the behavior of string operators and functions.

9.1.2. Character Sets and Collations in MySQL

The MySQL server can support multiple character sets. To list the available character sets, use the `SHOW CHARACTER SET` statement. A partial listing follows. For more complete information, see [Section 9.1.12, “Character Sets and Collations That MySQL Supports”](#).

```
mysql> SHOW CHARACTER SET;
```

Charset	Description	Default collation	Maxlen
big5	Big5 Traditional Chinese	big5_chinese_ci	2
dec8	DEC West European	dec8_swedish_ci	1
cp850	DOS West European	cp850_general_ci	1
hp8	HP West European	hp8_english_ci	1
koi8r	KOI8-R Relcom Russian	koi8r_general_ci	1
latin1	cp1252 West European	latin1_swedish_ci	1
latin2	ISO 8859-2 Central European	latin2_general_ci	1
swe7	7bit Swedish	swe7_swedish_ci	1
ascii	US ASCII	ascii_general_ci	1
ujis	EUC-JP Japanese	ujis_japanese_ci	3
sjis	Shift-JIS Japanese	sjis_japanese_ci	2
hebrew	ISO 8859-8 Hebrew	hebrew_general_ci	1
tis620	TIS620 Thai	tis620_thai_ci	1
euckr	EUC-KR Korean	euckr_korean_ci	2
koi8u	KOI8-U Ukrainian	koi8u_general_ci	1
gb2312	GB2312 Simplified Chinese	gb2312_chinese_ci	2
greek	ISO 8859-7 Greek	greek_general_ci	1
cp1250	Windows Central European	cp1250_general_ci	1
gbk	GBK Simplified Chinese	gbk_chinese_ci	2
latin5	ISO 8859-9 Turkish	latin5_turkish_ci	1
...			

Any given character set always has at least one collation. It may have several collations. To list the collations for a character set, use the `SHOW COLLATION` statement. For example, to see the collations for the `latin1` (cp1252 West European) character set, use this statement to find those collation names that begin with `latin1`:

```
mysql> SHOW COLLATION LIKE 'latin1%';
```

Collation	Charset	Id	Default	Compiled	Sortlen
latin1_german1_ci	latin1	5			0
latin1_swedish_ci	latin1	8	Yes	Yes	1
latin1_danish_ci	latin1	15			0
latin1_german2_ci	latin1	31		Yes	2
latin1_bin	latin1	47		Yes	1
latin1_general_ci	latin1	48			0
latin1_general_cs	latin1	49			0
latin1_spanish_ci	latin1	94			0

The `latin1` collations have the following meanings.

Collation	Meaning
<code>latin1_german1_ci</code>	German DIN-1
<code>latin1_swedish_ci</code>	Swedish/Finnish
<code>latin1_danish_ci</code>	Danish/Norwegian
<code>latin1_german2_ci</code>	German DIN-2
<code>latin1_bin</code>	Binary according to <code>latin1</code> encoding

<code>latin1_general_ci</code>	Multilingual (Western European)
<code>latin1_general_cs</code>	Multilingual (ISO Western European), case sensitive
<code>latin1_spanish_ci</code>	Modern Spanish

Collations have these general characteristics:

- Two different character sets cannot have the same collation.
- Each character set has one collation that is the *default collation*. For example, the default collation for `latin1` is `latin1_swedish_ci`. The output for `SHOW CHARACTER SET` indicates which collation is the default for each displayed character set.
- There is a convention for collation names: They start with the name of the character set with which they are associated, they usually include a language name, and they end with `_ci` (case insensitive), `_cs` (case sensitive), or `_bin` (binary).

In cases where a character set has multiple collations, it might not be clear which collation is most suitable for a given application. To avoid choosing the wrong collation, it can be helpful to perform some comparisons with representative data values to make sure that a given collation sorts values the way you expect.

Collation-Charts.Org is a useful site for information that shows how one collation compares to another.

9.1.3. Specifying Character Sets and Collations

There are default settings for character sets and collations at four levels: server, database, table, and column. The description in the following sections may appear complex, but it has been found in practice that multiple-level defaulting leads to natural and obvious results.

`CHARACTER SET` is used in clauses that specify a character set. `CHARSET` can be used as a synonym for `CHARACTER SET`.

Character set issues affect not only data storage, but also communication between client programs and the MySQL server. If you want the client program to communicate with the server using a character set different from the default, you'll need to indicate which one. For example, to use the `utf8` Unicode character set, issue this statement after connecting to the server:

```
SET NAMES 'utf8';
```

For more information about character set-related issues in client/server communication, see [Section 9.1.4, “Connection Character Sets and Collations”](#).

9.1.3.1. Server Character Set and Collation

MySQL Server has a server character set and a server collation. These can be set at server startup on the command line or in an option file and changed at runtime.

Initially, the server character set and collation depend on the options that you use when you start `mysqld`. You can use `--character-set-server` for the character set. Along with it, you can add `--collation-server` for the collation. If you don't specify a character set, that is the same as saying `--character-set-server=latin1`. If you specify only a character set (for example, `latin1`) but not a collation, that is the same as saying `--character-set-server=latin1 --collation-server=latin1_swedish_ci` because `latin1_swedish_ci` is the default collation for `latin1`. Therefore, the following three commands all have the same effect:

```
shell> mysql
shell> mysql --character-set-server=latin1
shell> mysql --character-set-server=latin1 \
    --collation-server=latin1_swedish_ci
```

One way to change the settings is by recompiling. If you want to change the default server character set and collation when building from sources, use: `--with-charset` and `--with-collation` as arguments for `configure`. For example:

```
shell> ./configure --with-charset=latin1
```

Or:

```
shell> ./configure --with-charset=latin1 \
    --with-collation=latin1_german1_ci
```

Both `mysqld` and `configure` verify that the character set/collation combination is valid. If not, each program displays an error message and terminates.

The server character set and collation are used as default values if the database character set and collation are not specified in `CREATE DATABASE` statements. They have no other purpose.

The current server character set and collation can be determined from the values of the `character_set_server` and `collation_server` system variables. These variables can be changed at runtime.

9.1.3.2. Database Character Set and Collation

Every database has a database character set and a database collation. The `CREATE DATABASE` and `ALTER DATABASE` statements have optional clauses for specifying the database character set and collation:

```
CREATE DATABASE db_name
  [[DEFAULT] CHARACTER SET charset_name]
  [[DEFAULT] COLLATE collation_name]

ALTER DATABASE db_name
  [[DEFAULT] CHARACTER SET charset_name]
  [[DEFAULT] COLLATE collation_name]
```

The keyword `SCHEMA` can be used instead of `DATABASE`.

All database options are stored in a text file named `db.opt` that can be found in the database directory.

The `CHARACTER SET` and `COLLATE` clauses make it possible to create databases with different character sets and collations on the same MySQL server.

Example:

```
CREATE DATABASE db_name CHARACTER SET latin1 COLLATE latin1_swedish_ci;
```

MySQL chooses the database character set and database collation in the following manner:

- If both `CHARACTER SET X` and `COLLATE Y` are specified, character set `X` and collation `Y` are used.
- If `CHARACTER SET X` is specified without `COLLATE`, character set `X` and its default collation are used. To see the default collation for each character set, use the `SHOW COLLATION` statement.
- If `COLLATE Y` is specified without `CHARACTER SET`, the character set associated with `Y` and collation `Y` are used.
- Otherwise, the server character set and server collation are used.

The database character set and collation are used as default values for table definitions if the table character set and collation are not specified in `CREATE TABLE` statements. The database character set also is used by `LOAD DATA INFILE`. The character set and collation have no other purposes.

The character set and collation for the default database can be determined from the values of the `character_set_database` and `collation_database` system variables. The server sets these variables whenever the default database changes. If there is no default database, the variables have the same value as the corresponding server-level system variables, `character_set_server` and `collation_server`.

9.1.3.3. Table Character Set and Collation

Every table has a table character set and a table collation. The `CREATE TABLE` and `ALTER TABLE` statements have optional clauses for specifying the table character set and collation:

```
CREATE TABLE tbl_name (column_list)
  [[DEFAULT] CHARACTER SET charset_name]
  [COLLATE collation_name]

ALTER TABLE tbl_name
  [[DEFAULT] CHARACTER SET charset_name]
  [COLLATE collation_name]
```

Example:

```
CREATE TABLE t1 ( ... )
CHARACTER SET latin1 COLLATE latin1_danish_ci;
```

MySQL chooses the table character set and collation in the following manner:

- If both `CHARACTER SET X` and `COLLATE Y` are specified, character set `X` and collation `Y` are used.
- If `CHARACTER SET X` is specified without `COLLATE`, character set `X` and its default collation are used. To see the default collation for each character set, use the `SHOW COLLATION` statement.
- If `COLLATE Y` is specified without `CHARACTER SET`, the character set associated with `Y` and collation `Y` are used.
- Otherwise, the database character set and collation are used.

The table character set and collation are used as default values for column definitions if the column character set and collation are not specified in individual column definitions. The table character set and collation are MySQL extensions; there are no such things in standard SQL.

9.1.3.4. Column Character Set and Collation

Every “character” column (that is, a column of type `CHAR`, `VARCHAR`, or `TEXT`) has a column character set and a column collation. Column definition syntax for `CREATE TABLE` and `ALTER TABLE` has optional clauses for specifying the column character set and collation:

```
col_name {CHAR | VARCHAR | TEXT} (col_length)
[CHARACTER SET charset_name]
[COLLATE collation_name]
```

These clauses can also be used for `ENUM` and `SET` columns:

```
col_name {ENUM | SET} (val_list)
[CHARACTER SET charset_name]
[COLLATE collation_name]
```

Examples:

```
CREATE TABLE t1
(
  coll VARCHAR(5)
  CHARACTER SET latin1
  COLLATE latin1_german1_ci
);
ALTER TABLE t1 MODIFY
  coll VARCHAR(5)
  CHARACTER SET latin1
  COLLATE latin1_swedish_ci;
```

MySQL chooses the column character set and collation in the following manner:

- If both `CHARACTER SET X` and `COLLATE Y` are specified, character set `X` and collation `Y` are used.

```
CREATE TABLE t1
(
  coll CHAR(10) CHARACTER SET utf8 COLLATE utf8_unicode_ci
) CHARACTER SET latin1 COLLATE latin1_bin;
```

The character set and collation are specified for the column, so they are used. The column has character set `utf8` and collation `utf8_unicode_ci`.

- If `CHARACTER SET X` is specified without `COLLATE`, character set `X` and its default collation are used.

```
CREATE TABLE t1
(
  coll CHAR(10) CHARACTER SET utf8
) CHARACTER SET latin1 COLLATE latin1_bin;
```

The character set is specified for the column, but the collation is not. The column has character set `utf8` and the default collation for `utf8`, which is `utf8_general_ci`. To see the default collation for each character set, use the `SHOW COLLATION` statement.

- If `COLLATE Y` is specified without `CHARACTER SET`, the character set associated with `Y` and collation `Y` are used.

```
CREATE TABLE t1
(
```

```
coll CHAR(10) COLLATE utf8_polish_ci
) CHARACTER SET latin1 COLLATE latin1_bin;
```

The collation is specified for the column, but the character set is not. The column has collation `utf8_polish_ci` and the character set is the one associated with the collation, which is `utf8`.

- Otherwise, the table character set and collation are used.

```
CREATE TABLE t1
(
  coll CHAR(10)
) CHARACTER SET latin1 COLLATE latin1_bin;
```

Neither the character set nor collation are specified for the column, so the table defaults are used. The column has character set `latin1` and collation `latin1_bin`.

The `CHARACTER SET` and `COLLATE` clauses are standard SQL.

If you use `ALTER TABLE` to convert a column from one character set to another, MySQL attempts to map the data values, but if the character sets are incompatible, there may be data loss.

9.1.3.5. Character String Literal Character Set and Collation

Every character string literal has a character set and a collation.

A character string literal may have an optional character set introducer and `COLLATE` clause:

```
[_charset_name]'string' [COLLATE collation_name]
```

Examples:

```
SELECT 'string';
SELECT _latin1'string';
SELECT _latin1'string' COLLATE latin1_danish_ci;
```

For the simple statement `SELECT 'string'`, the string has the character set and collation defined by the `character_set_connection` and `collation_connection` system variables.

The `_charset_name` expression is formally called an *introducer*. It tells the parser, “the string that is about to follow uses character set *X*.” Because this has confused people in the past, we emphasize that an introducer does not change the string to the introducer character set like `CONVERT()` would do. It does not change the string's value, although padding may occur. The introducer is just a signal. An introducer is also legal before standard hex literal and numeric hex literal notation (`x'literal'` and `0xn`), or before bit-field literal notation (`b'literal'` and `0bn`).

Examples:

```
SELECT _latin1 x'AABBCC';
SELECT _latin1 0xAABBCC;
SELECT _latin1 b'1100011';
SELECT _latin1 0b1100011;
```

MySQL determines a literal's character set and collation in the following manner:

- If both `_X` and `COLLATE Y` are specified, character set *X* and collation *Y* are used.
- If `_X` is specified but `COLLATE` is not specified, character set *X* and its default collation are used. To see the default collation for each character set, use the `SHOW COLLATION` statement.
- Otherwise, the character set and collation given by the `character_set_connection` and `collation_connection` system variables are used.

Examples:

- A string with `latin1` character set and `latin1_german1_ci` collation:

```
SELECT _latin1'Müller' COLLATE latin1_german1_ci;
```

- A string with `latin1` character set and its default collation (that is, `latin1_swedish_ci`):

```
SELECT _latin1'Müller';
```

- A string with the connection default character set and collation:

```
SELECT 'Müller';
```

Character set introducers and the `COLLATE` clause are implemented according to standard SQL specifications.

An introducer indicates the character set for the following string, but does not change now how the parser performs escape processing within the string. Escapes are always interpreted by the parser according to the character set given by `character_set_connection`.

The following examples show that escape processing occurs using `character_set_connection` even in the presence of an introducer. The examples use `SET NAMES` (which changes `character_set_connection`, as discussed in [Section 9.1.4, “Connection Character Sets and Collations”](#)), and display the resulting strings using the `HEX()` function so that the exact string contents can be seen.

Example 1:

```
mysql> SET NAMES latin1;
Query OK, 0 rows affected (0.01 sec)

mysql> SELECT HEX('\n'), HEX(_sjis'\n');
+-----+-----+
| HEX('\n') | HEX(_sjis'\n') |
+-----+-----+
| E00A      | E00A            |
+-----+-----+
1 row in set (0.00 sec)
```

Here, “`à`” (hex value `E0`) is followed by “`\n`”, the escape sequence for newline. The escape sequence is interpreted using the `character_set_connection` value of `latin1` to produce a literal newline (hex value `0A`). This happens even for the second string. That is, the introducer of `_sjis` does not affect the parser's escape processing.

Example 2:

```
mysql> SET NAMES sjis;
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT HEX('\n'), HEX(_latin1'\n');
+-----+-----+
| HEX('\n') | HEX(_latin1'\n') |
+-----+-----+
| E05C6E    | E05C6E           |
+-----+-----+
1 row in set (0.04 sec)
```

Here, `character_set_connection` is `sjis`, a character set in which the sequence of “`à`” followed by “`\`” (hex values `05` and `5C`) is a valid multi-byte character. Hence, the first two bytes of the string are interpreted as a single `sjis` character, and the “`\`” is not interpreted as an escape character. The following “`n`” (hex value `6E`) is not interpreted as part of an escape sequence. This is true even for the second string; the introducer of `_latin1` does not affect escape processing.

9.1.3.6. National Character Set

Standard SQL defines `NCHAR` or `NATIONAL CHAR` as a way to indicate that a `CHAR` column should use some predefined character set. MySQL 5.4 uses `utf8` as this predefined character set. For example, these data type declarations are equivalent:

```
CHAR(10) CHARACTER SET utf8
NATIONAL CHARACTER(10)
NCHAR(10)
```

As are these:

```
VARCHAR(10) CHARACTER SET utf8
NATIONAL VARCHAR(10)
NCHAR VARCHAR(10)
NATIONAL CHARACTER VARYING(10)
NATIONAL CHAR VARYING(10)
```

You can use `N'literal'` (or `n'literal'`) to create a string in the national character set. These statements are equivalent:

```
SELECT N'some text';
```

```
SELECT n'some text';
SELECT _utf8'some text';
```

For information on upgrading character sets to MySQL 5.4 from versions prior to 4.1, see the *MySQL 3.23, 4.0, 4.1 Reference Manual*.

9.1.3.7. Examples of Character Set and Collation Assignment

The following examples show how MySQL determines default character set and collation values.

Example 1: Table and Column Definition

```
CREATE TABLE t1
(
  c1 CHAR(10) CHARACTER SET latin1 COLLATE latin1_german1_ci
) DEFAULT CHARACTER SET latin2 COLLATE latin2_bin;
```

Here we have a column with a `latin1` character set and a `latin1_german1_ci` collation. The definition is explicit, so that is straightforward. Notice that there is no problem with storing a `latin1` column in a `latin2` table.

Example 2: Table and Column Definition

```
CREATE TABLE t1
(
  c1 CHAR(10) CHARACTER SET latin1
) DEFAULT CHARACTER SET latin1 COLLATE latin1_danish_ci;
```

This time we have a column with a `latin1` character set and a default collation. Although it might seem natural, the default collation is not taken from the table level. Instead, because the default collation for `latin1` is always `latin1_swedish_ci`, column `c1` has a collation of `latin1_swedish_ci` (not `latin1_danish_ci`).

Example 3: Table and Column Definition

```
CREATE TABLE t1
(
  c1 CHAR(10)
) DEFAULT CHARACTER SET latin1 COLLATE latin1_danish_ci;
```

We have a column with a default character set and a default collation. In this circumstance, MySQL checks the table level to determine the column character set and collation. Consequently, the character set for column `c1` is `latin1` and its collation is `latin1_danish_ci`.

Example 4: Database, Table, and Column Definition

```
CREATE DATABASE d1
  DEFAULT CHARACTER SET latin2 COLLATE latin2_czech_ci;
USE d1;
CREATE TABLE t1
(
  c1 CHAR(10)
);
```

We create a column without specifying its character set and collation. We're also not specifying a character set and a collation at the table level. In this circumstance, MySQL checks the database level to determine the table settings, which thereafter become the column settings.) Consequently, the character set for column `c1` is `latin2` and its collation is `latin2_czech_ci`.

9.1.3.8. Compatibility with Other DBMSs

For MaxDB compatibility these two statements are the same:

```
CREATE TABLE t1 (f1 CHAR(N) UNICODE);
CREATE TABLE t1 (f1 CHAR(N) CHARACTER SET ucs2);
```

9.1.4. Connection Character Sets and Collations

Several character set and collation system variables relate to a client's interaction with the server. Some of these have been mentioned in earlier sections:

- The server character set and collation can be determined from the values of the `character_set_server` and `collation_server` system variables.

- The character set and collation of the default database can be determined from the values of the `character_set_database` and `collation_database` system variables.

Additional character set and collation system variables are involved in handling traffic for the connection between a client and the server. Every client has connection-related character set and collation system variables.

Consider what a “connection” is: It is what you make when you connect to the server. The client sends SQL statements, such as queries, over the connection to the server. The server sends responses, such as result sets, over the connection back to the client. This leads to several questions about character set and collation handling for client connections, each of which can be answered in terms of system variables:

- What character set is the statement in when it leaves the client?

The server takes the `character_set_client` system variable to be the character set in which statements are sent by the client.

- What character set should the server translate a statement to after receiving it?

For this, the server uses the `character_set_connection` and `collation_connection` system variables. It converts statements sent by the client from `character_set_client` to `character_set_connection` (except for string literals that have an introducer such as `_latin1` or `_utf8`). `collation_connection` is important for comparisons of literal strings. For comparisons of strings with column values, `collation_connection` does not matter because columns have their own collation, which has a higher collation precedence.

- What character set should the server translate to before shipping result sets or error messages back to the client?

The `character_set_results` system variable indicates the character set in which the server returns query results to the client. This includes result data such as column values, and result metadata such as column names.

You can fine-tune the settings for these variables, or you can depend on the defaults (in which case, you can skip the rest of this section). If you do not use the defaults, you must change the character settings *for each connection to the server*.

There are two statements that affect the connection character sets:

```
SET NAMES 'charset_name'
SET CHARACTER SET charset_name
```

`SET NAMES` indicates what character set the client will use to send SQL statements to the server. Thus, `SET NAMES 'cp1251'` tells the server “future incoming messages from this client are in character set `cp1251`.” It also specifies the character set that the server should use for sending results back to the client. (For example, it indicates what character set to use for column values if you use a `SELECT` statement.)

A `SET NAMES 'x'` statement is equivalent to these three statements:

```
SET character_set_client = x;
SET character_set_results = x;
SET character_set_connection = x;
```

Setting `character_set_connection` to `x` also sets `collation_connection` to the default collation for `x`. It is not necessary to set that collation explicitly. To specify a particular collation for the character sets, use the optional `COLLATE` clause:

```
SET NAMES 'charset_name' COLLATE 'collation_name'
```

`SET CHARACTER SET` is similar to `SET NAMES` but sets `character_set_connection` and `collation_connection` to `character_set_database` and `collation_database`. A `SET CHARACTER SET x` statement is equivalent to these three statements:

```
SET character_set_client = x;
SET character_set_results = x;
SET collation_connection = @@collation_database;
```

Setting `collation_connection` also sets `character_set_connection` to the character set associated with the collation (equivalent to executing `SET character_set_connection = @@character_set_database`). It is not necessary to set `character_set_connection` explicitly.

When a client connects, it sends to the server the name of the character set that it wants to use. The server uses the name to set the `character_set_client`, `character_set_results`, and `character_set_connection` system variables. In effect, the server performs a `SET NAMES` operation using the character set name.

With the `mysql` client, it is not necessary to execute `SET NAMES` every time you start up if you want to use a character set different from the default. You can add the `--default-character-set` option setting to your `mysql` statement line, or in your option file. For example, the following option file setting changes the three character set variables set to `koi8r` each time you invoke `mysql`:

```
[mysql]
default-character-set=koi8r
```

If you are using the `mysql` client with auto-reconnect enabled (which is not recommended), it is preferable to use the `charset` command rather than `SET NAMES`. For example:

```
mysql> charset utf8
Charset changed
```

The `charset` command issues a `SET NAMES` statement, and also changes the default character set that is used if `mysql` reconnects after the connection has dropped.

Example: Suppose that `column1` is defined as `CHAR(5) CHARACTER SET latin2`. If you do not say `SET NAMES` or `SET CHARACTER SET`, then for `SELECT column1 FROM t`, the server sends back all the values for `column1` using the character set that the client specified when it connected. On the other hand, if you say `SET NAMES 'latin1'` or `SET CHARACTER SET latin1` before issuing the `SELECT` statement, the server converts the `latin2` values to `latin1` just before sending results back. Conversion may be lossy if there are characters that are not in both character sets.

If you do not want the server to perform any conversion of result sets, set `character_set_results` to `NULL` or `binary`:

```
SET character_set_results = NULL;
```

Note

`ucs2` cannot be used as a client character set, which means that it does not work for `SET NAMES` or `SET CHARACTER SET`.

To see the values of the character set and collation system variables that apply to your connection, use these statements:

```
SHOW VARIABLES LIKE 'character_set%';
SHOW VARIABLES LIKE 'collation%';
```

You must also consider the environment within which your MySQL applications execute. See [Section 9.1.5, “Configuring the Character Set and Collation for Applications”](#).

9.1.5. Configuring the Character Set and Collation for Applications

For applications that store data using the default MySQL character set and collation (`latin1`, `latin1_swedish_ci`), no special configuration should be needed. If applications require data storage using a different character set or collation, you can configure character set information several ways:

- Specify character settings per database. For example, applications that use one database might require `utf8`, whereas applications that use another database might require `sjis`.
- Specify character settings at server startup. This causes the server to use the given settings for all applications that do not make other arrangements.
- Specify character settings at configuration time, if you build MySQL from source. This causes the server to use the given settings for all applications, without having to specify them at server startup.

When different applications require different character settings, the per-database technique provides a good deal of flexibility. If most or all applications use the same character set, specifying character settings at server startup or configuration time may be most convenient.

For the per-database or server-startup techniques, the settings control the character set for data storage. Applications must also tell the server which character set to use for client/server communications, as described in the following instructions.

The examples shown here assume use of the `utf8` character set and `utf8_general_ci` collation.

Specify character settings per database. To create a database such that its tables will use a given default character set and collation for data storage, use a `CREATE DATABASE` statement like this:

```
CREATE DATABASE mydb
```

```
DEFAULT CHARACTER SET utf8
DEFAULT COLLATE utf8_general_ci;
```

Tables created in the database will use `utf8` and `utf8_general_ci` by default for any character columns.

Applications that use the database should also configure their connection to the server each time they connect. This can be done by executing a `SET NAMES 'utf8'` statement after connecting. The statement can be used regardless of connection method: The `mysql` client, PHP scripts, and so forth.

In some cases, it may be possible to configure the connection to use the desired character set some other way. For example, for connections made using `mysql`, you can specify the `--default-character-set=utf8` command-line option to achieve the same effect as `SET NAMES 'utf8'`.

For more information about configuring client connections, see [Section 9.1.4, “Connection Character Sets and Collations”](#).

Specify character settings at server startup. To select a character set and collation at server startup, use the `--character-set-server` and `--collation-server` options. For example, to specify the options in an option file, include these lines:

```
[mysqld]
character-set-server=utf8
collation-server=utf8_general_ci
```

These settings apply server-wide and apply as the defaults for databases created by any application, and for tables created in those databases.

It is still necessary for applications to configure their connection using `SET NAMES` or equivalent after they connect, as described previously. You might be tempted to start the server with the `--init_connect="SET NAMES 'utf8' "` option to cause `SET NAMES` to be executed automatically for each client that connects. However, this will yield inconsistent results because the `init_connect` value is not executed for users who have the `SUPER` privilege.

Specify character settings at MySQL configuration time. To select a character set and collation when you configure and build MySQL from source, use the `--with-charset` and `--with-collation` options:

```
shell> ./configure --with-charset=utf8 --with-collation=utf8_general_ci
```

The resulting server uses `utf8` and `utf8_general_ci` as the default for databases and tables and for client connections. It is unnecessary to use `--character-set-server` and `--collation-server` at server startup. It is also unnecessary for applications to configure their connection using `SET NAMES` or equivalent after they connect to the server.

Regardless of how you configure the MySQL character set for application use, you must also consider the environment within which those applications execute. If you will send statements using UTF-8 text taken from a file that you create in an editor, you should edit the file with the locale of your environment set to UTF-8 so that the file's encoding is correct and so that the operating system handles it correctly. If you use the `mysql` client from within a terminal window, the window must be configured to use UTF-8 or characters may not display properly. For a script that executes in a Web environment, the script must handle character encoding properly for its interaction with the MySQL server, and it must generate pages that correctly indicate the encoding so that browsers know how to display the content of the pages. For example, you can include this `<meta>` tag within your `<head>` element:

```
<meta http-equiv="Content-Type" content="text/html; charset=utf-8" />
```

9.1.6. Collation Issues

The following sections discuss various aspects of character set collations.

9.1.6.1. Using `COLLATE` in SQL Statements

With the `COLLATE` clause, you can override whatever the default collation is for a comparison. `COLLATE` may be used in various parts of SQL statements. Here are some examples:

- With `ORDER BY`:

```
SELECT k
FROM t1
ORDER BY k COLLATE latin1_german2_ci;
```

- With `AS`:

```
SELECT k COLLATE latin1_german2_ci AS k1
```

```
FROM t1
ORDER BY k1;
```

- With **GROUP BY**:

```
SELECT k
FROM t1
GROUP BY k COLLATE latin1_german2_ci;
```

- With aggregate functions:

```
SELECT MAX(k COLLATE latin1_german2_ci)
FROM t1;
```

- With **DISTINCT**:

```
SELECT DISTINCT k COLLATE latin1_german2_ci
FROM t1;
```

- With **WHERE**:

```
SELECT *
FROM t1
WHERE _latin1 'Müller' COLLATE latin1_german2_ci = k;
```

```
SELECT *
FROM t1
WHERE k LIKE _latin1 'Müller' COLLATE latin1_german2_ci;
```

- With **HAVING**:

```
SELECT k
FROM t1
GROUP BY k
HAVING k = _latin1 'Müller' COLLATE latin1_german2_ci;
```

9.1.6.2. COLLATE Clause Precedence

The **COLLATE** clause has high precedence (higher than `| |`), so the following two expressions are equivalent:

```
x | | y COLLATE z
x | | (y COLLATE z)
```

9.1.6.3. BINARY Operator

The **BINARY** operator casts the string following it to a binary string. This is an easy way to force a comparison to be done byte by byte rather than character by character. **BINARY** also causes trailing spaces to be significant.

```
mysql> SELECT 'a' = 'A';
-> 1
mysql> SELECT BINARY 'a' = 'A';
-> 0
mysql> SELECT 'a' = 'a ';
-> 1
mysql> SELECT BINARY 'a' = 'a ';
-> 0
```

BINARY *str* is shorthand for `CAST(str AS BINARY)`.

The **BINARY** attribute in character column definitions has a different effect. A character column defined with the **BINARY** attribute is assigned the binary collation of the column's character set. Every character set has a binary collation. For example, the binary collation for the `latin1` character set is `latin1_bin`, so if the table default character set is `latin1`, these two column definitions are equivalent:

```
CHAR(10) BINARY
CHAR(10) CHARACTER SET latin1 COLLATE latin1_bin
```

The effect of **BINARY** as a column attribute differs from its effect prior to MySQL 4.1. Formerly, **BINARY** resulted in a column that was treated as a binary string. A binary string is a string of bytes that has no character set or collation, which differs from a nonbinary character string that has a binary collation. For both types of strings, comparisons are based on the numeric values of the

string unit, but for nonbinary strings the unit is the character and some character sets allow multi-byte characters. [Section 10.4.2, “The BINARY and VARBINARY Types”](#).

The use of `CHARACTER SET binary` in the definition of a `CHAR`, `VARCHAR`, or `TEXT` column causes the column to be treated as a binary data type. For example, the following pairs of definitions are equivalent:

```
CHAR(10) CHARACTER SET binary
BINARY(10)

VARCHAR(10) CHARACTER SET binary
VARBINARY(10)

TEXT CHARACTER SET binary
BLOB
```

9.1.6.4. The `_bin` and `binary` Collations

This section describes how `_bin` collations for nonbinary strings differ from the `binary` “collation” for binary strings.

Nonbinary strings (as stored in the `CHAR`, `VARCHAR`, and `TEXT` data types) have a character set and collation. A given character set can have several collations, each of which defines a particular sorting and comparison order for the characters in the set. One of these is the binary collation for the character set, indicated by a `_bin` suffix in the collation name. For example, `latin1` and `utf8` have binary collations named `latin1_bin` and `utf8_bin`.

Binary strings (as stored in the `BINARY`, `VARBINARY`, and `BLOB` data types) have no character set or collation in the sense that nonbinary strings do. (Applied to a binary string, the `CHARSET()` and `COLLATION()` functions both return a value of `binary`.) Binary strings are sequences of bytes and the numeric values of those bytes determine sort order.

The `_bin` collations differ from the `binary` collation in several respects.

The unit for sorting and comparison. Binary strings are sequences of bytes. Sorting and comparison is always based on numeric byte values. Nonbinary strings are sequences of characters, which might be multi-byte. Collations for nonbinary strings define an ordering of the character values for sorting and comparison. For the `_bin` collation, this ordering is based solely on numeric values of the characters (which is similar to ordering for binary strings except that a `_bin` collation must take into account that a character might contain multiple bytes). For other collations, character ordering might take additional factors such as lettercase into account.

Character set conversion. A nonbinary string has a character set and is converted to another character set in many cases, even when the string has a `_bin` collation:

- When assigning column values from another column that has a different character set:

```
UPDATE t1 SET utf8_bin_column=latin1_column;
INSERT INTO t1 (latin1_column) SELECT utf8_bin_column FROM t2;
```

- When assigning column values for `INSERT` or `UPDATE` using a string literal:

```
SET NAMES latin1;
INSERT INTO t1 (utf8_bin_column) VALUES ('string-in-latin1');
```

- When sending results from the server to a client:

```
SET NAMES latin1;
SELECT utf8_bin_column FROM t2;
```

For binary string columns, no conversion occurs. For the preceding cases, the string value is copied byte-wise.

Lettercase conversion. Collations provide information about lettercase of characters, so characters in a nonbinary string can be converted from one lettercase to another, even for `_bin` collations that ignore lettercase for ordering:

```
mysql> SET NAMES latin1 COLLATE latin1_bin;
Query OK, 0 rows affected (0.02 sec)

mysql> SELECT LOWER('aA'), UPPER('zZ');
+-----+-----+
| LOWER('aA') | UPPER('zZ') |
+-----+-----+
| aa          | ZZ          |
+-----+-----+
1 row in set (0.13 sec)
```

The concept of lettercase does not apply to bytes in a binary string. To perform lettercase conversion, the string must be converted to a nonbinary string:

```
mysql> SET NAMES binary;
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT LOWER('aA'), LOWER(CONVERT('aA' USING latin1));
+-----+-----+
| LOWER('aA') | LOWER(CONVERT('aA' USING latin1)) |
+-----+-----+
| aA          | aa          |
+-----+-----+
1 row in set (0.00 sec)
```

Trailing space handling in comparisons. Nonbinary strings have `PADSPACE` behavior for all collations, including `_bin` collations. Trailing spaces are insignificant in comparisons:

```
mysql> SET NAMES utf8 COLLATE utf8_bin;
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT 'a ' = 'a';
+-----+
| 'a ' = 'a' |
+-----+
|           1 |
+-----+
1 row in set (0.00 sec)
```

For binary strings, all characters are significant in comparisons, including trailing spaces:

```
mysql> SET NAMES binary;
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT 'a ' = 'a';
+-----+
| 'a ' = 'a' |
+-----+
|           0 |
+-----+
1 row in set (0.00 sec)
```

Trailing space handling for inserts and retrievals. `CHAR(N)` columns store nonbinary strings. Values shorter than `N` characters are extended with spaces on insertion. For retrieval, trailing spaces are removed.

`BINARY(N)` columns store binary strings. Values shorter than `N` bytes are extended with `0x00` bytes on insertion. For retrieval, nothing is removed; a value of the declared length is always returned.

```
mysql> CREATE TABLE t1 (
->   a CHAR(10) CHARACTER SET utf8 COLLATE utf8_bin,
->   b BINARY(10)
-> );
Query OK, 0 rows affected (0.09 sec)

mysql> INSERT INTO t1 VALUES ('a','a');
Query OK, 1 row affected (0.01 sec)

mysql> SELECT HEX(a), HEX(b) FROM t1;
+-----+-----+
| HEX(a) | HEX(b) |
+-----+-----+
| 61     | 61000000000000000000 |
+-----+-----+
1 row in set (0.04 sec)
```

9.1.6.5. Special Cases Where Collation Determination Is Tricky

In the great majority of statements, it is obvious what collation MySQL uses to resolve a comparison operation. For example, in the following cases, it should be clear that the collation is the collation of column `x`:

```
SELECT x FROM T ORDER BY x;
SELECT x FROM T WHERE x = x;
SELECT DISTINCT x FROM T;
```

However, when multiple operands are involved, there can be ambiguity. For example:

```
SELECT x FROM T WHERE x = 'Y';
```

Should this query use the collation of the column `x`, or of the string literal `'Y'`?

Standard SQL resolves such questions using what used to be called “coercibility” rules. Basically, this means: Both `x` and `'Y'` have collations, so which collation takes precedence? This can be difficult to resolve, but the following rules cover most situations:

- An explicit `COLLATE` clause has a coercibility of 0. (Not coercible at all.)
- The concatenation of two strings with different collations has a coercibility of 1.
- The collation of a column or a stored routine parameter or local variable has a coercibility of 2.
- A “system constant” (the string returned by functions such as `USER()` or `VERSION()`) has a coercibility of 3.
- A literal's collation has a coercibility of 4.
- `NULL` or an expression that is derived from `NULL` has a coercibility of 5.

The preceding coercibility values are current for MySQL 5.4.

Those rules resolve ambiguities in the following manner:

- Use the collation with the lowest coercibility value.
- If both sides have the same coercibility, then:
 - If both sides are Unicode, or both sides are not Unicode, it is an error.
 - If one of the sides has a Unicode character set, and another side has a non-Unicode character set, the side with Unicode character set wins, and automatic character set conversion is applied to the non-Unicode side. For example, the following statement will not return an error:

```
SELECT CONCAT(utf8_column, latin1_column) FROM t1;
```

It will return a result, and the character set of the result will be `utf8`. The collation of the result will be the collation of `utf8_column`. Values of `latin1_column` will be automatically converted to `utf8` before concatenating.

- For an operation with operands from the same character set but that mix a `_bin` collation and a `_ci` or `_cs` collation, the `_bin` collation is used. This is similar to how operations that mix nonbinary and binary strings evaluate the operands as binary strings, except that it is for collations rather than data types.

Although automatic conversion is not in the SQL standard, the SQL standard document does say that every character set is (in terms of supported characters) a “subset” of Unicode. Because it is a well-known principle that “what applies to a superset can apply to a subset,” we believe that a collation for Unicode can apply for comparisons with non-Unicode strings.

Examples:

<code>column1 = 'A'</code>	Use collation of <code>column1</code>
<code>column1 = 'A' COLLATE x</code>	Use collation of <code>'A' COLLATE x</code>
<code>column1 COLLATE x = 'A' COLLATE y</code>	Error

The `COERCIBILITY()` function can be used to determine the coercibility of a string expression:

```
mysql> SELECT COERCIBILITY('A' COLLATE latin1_swedish_ci);
-> 0
mysql> SELECT COERCIBILITY(VERSION());
-> 3
mysql> SELECT COERCIBILITY('A');
-> 4
```

See [Section 11.11.3, “Information Functions”](#).

9.1.6.6. Collations Must Be for the Right Character Set

Each character set has one or more collations, but each collation is associated with one and only one character set. Therefore, the following statement causes an error message because the `latin2_bin` collation is not legal with the `latin1` character set:

```
mysql> SELECT _latin1 'x' COLLATE latin2_bin;
ERROR 1253 (42000): COLLATION 'latin2_bin' is not valid
for CHARACTER SET 'latin1'
```

9.1.6.7. Examples of the Effect of Collation

Example 1: Sorting German Umlauts

Suppose that column `X` in table `T` has these `latin1` column values:

```
Muffler
Müller
MX Systems
MySQL
```

Suppose also that the column values are retrieved using the following statement:

```
SELECT X FROM T ORDER BY X COLLATE collation_name;
```

The following table shows the resulting order of the values if we use `ORDER BY` with different collations.

<code>latin1_swedish_ci</code>	<code>latin1_german1_ci</code>	<code>latin1_german2_ci</code>
Muffler	Muffler	Müller
MX Systems	Müller	Muffler
Müller	MX Systems	MX Systems
MySQL	MySQL	MySQL

The character that causes the different sort orders in this example is the U with two dots over it (ü), which the Germans call “U-umlaut.”

- The first column shows the result of the `SELECT` using the Swedish/Finnish collating rule, which says that U-umlaut sorts with Y.
- The second column shows the result of the `SELECT` using the German DIN-1 rule, which says that U-umlaut sorts with U.
- The third column shows the result of the `SELECT` using the German DIN-2 rule, which says that U-umlaut sorts with UE.

Example 2: Searching for German Umlauts

Suppose that you have three tables that differ only by the character set and collation used:

```
mysql> CREATE TABLE german1 (
->   c CHAR(10)
-> ) CHARACTER SET latin1 COLLATE latin1_german1_ci;
mysql> CREATE TABLE german2 (
->   c CHAR(10)
-> ) CHARACTER SET latin1 COLLATE latin1_german2_ci;
mysql> CREATE TABLE germanutf8 (
->   c CHAR(10)
-> ) CHARACTER SET utf8 COLLATE utf8_unicode_ci;
```

Each table contains two records:

```
mysql> INSERT INTO german1 VALUES ('Bar'), ('Bär');
mysql> INSERT INTO german2 VALUES ('Bar'), ('Bär');
mysql> INSERT INTO germanutf8 VALUES ('Bar'), ('Bär');
```

Two of the above collations have an `A = Ä` equality, and one has no such equality (`latin1_german2_ci`). For that reason, you'll get these results in comparisons:

```
mysql> SELECT * FROM german1 WHERE c = 'Bär';
+-----+
| c      |
+-----+
| Bar    |
| Bär    |
+-----+
mysql> SELECT * FROM german2 WHERE c = 'Bär';
+-----+
| c      |
+-----+
| Bär    |
+-----+
mysql> SELECT * FROM germanutf8 WHERE c = 'Bär';
+-----+
| c      |
+-----+
| Bar    |
| Bär    |
+-----+
```

```
+-----+
```

This is not a bug but rather a consequence of the sorting that `latin1_german1_ci` or `utf8_unicode_ci` do (the sorting shown is done according to the German DIN 5007 standard).

9.1.7. String Repertoire

The *repertoire* of a character set is the collection of characters in the set.

String expressions have a repertoire attribute, which can have two values:

- **ASCII**: The expression can contain only characters in the Unicode range `U+0000` to `U+007F`.
- **UNICODE**: The expression can contain characters in the Unicode range `U+0000` to `U+FFFF`.

The **ASCII** range is a subset of **UNICODE** range, so a string with **ASCII** repertoire can be converted safely without loss of information to the character set of any string with **UNICODE** repertoire or to a character set that is a superset of **ASCII**. (All MySQL character sets are supersets of **ASCII** with the exception of `swe7`, which reuses some punctuation characters for Swedish accented characters.) The use of repertoire enables character set conversion in expressions for many cases where MySQL would otherwise return an “illegal mix of collations” error.

The following discussion provides examples of expressions and their repertoires, and describes how the use of repertoire changes string expression evaluation:

- The repertoire for string constants depends on string content:

```
SET NAMES utf8; SELECT 'abc';
SELECT _utf8'def';
SELECT N'MySQL';
```

Although the character set is `utf8` in each of the preceding cases, the strings do not actually contain any characters outside the ASCII range, so their repertoire is **ASCII** rather than **UNICODE**.

- Columns having the `ascii` character set have **ASCII** repertoire because of their character set. In the following table, `c1` has **ASCII** repertoire:

```
CREATE TABLE t1 (c1 CHAR(1) CHARACTER SET ascii);
```

The following example illustrates how repertoire enables a result to be determined in a case where an error occurs without repertoire:

```
CREATE TABLE t1 (
  c1 CHAR(1) CHARACTER SET latin1,
  c2 CHAR(1) CHARACTER SET ascii
);
INSERT INTO t1 VALUES ('a','b');
SELECT CONCAT(c1,c2) FROM t1;
```

Without repertoire, this error occurs:

```
ERROR 1267 (HY000): Illegal mix of collations (latin1_swedish_ci,IMPLICIT)
and (ascii_general_ci,IMPLICIT) for operation 'concat'
```

Using repertoire, subset to superset (`ascii` to `latin1`) conversion can occur and a result is returned:

```
+-----+
| CONCAT(c1,c2) |
+-----+
| ab             |
+-----+
```

- Functions with one string argument inherit the repertoire of their argument. The result of `UPPER(_utf8'abc')` has **ASCII** repertoire, because its argument has **ASCII** repertoire.
- For functions that return a string but do not have string arguments and use `character_set_connection` as the result character set, the result repertoire is **ASCII** if `character_set_connection` is `ascii`, and **UNICODE** otherwise:

```
FORMAT(numeric_column, 4);
```

Use of repertoire changes how MySQL evaluates the following example:

```
SET NAMES ascii;
CREATE TABLE t1 (a INT, b VARCHAR(10) CHARACTER SET latin1);
INSERT INTO t1 VALUES (1, 'b');
SELECT CONCAT(FORMAT(a, 4), b) FROM t1;
```

Without repertoire, this error occurs:

```
ERROR 1267 (HY000): Illegal mix of collations (ascii_general_ci,COERCIBLE)
and (latin1_swedish_ci,IMPLICIT) for operation 'concat'
```

With repertoire, a result is returned:

```
+-----+
| CONCAT(FORMAT(a, 4), b) |
+-----+
| 1.0000b                 |
+-----+
```

- Functions with two or more string arguments use the “widest” argument repertoire for the result repertoire ([UNICODE](#) is wider than [ASCII](#)). Consider the following `CONCAT()` calls:

```
CONCAT(_ucs2 0x0041, _ucs2 0x0042)
CONCAT(_ucs2 0x0041, _ucs2 0x00C2)
```

For the first call, the repertoire is [ASCII](#) because both arguments are within the range of the `ascii` character set. For the second call, the repertoire is [UNICODE](#) because the second argument is outside the `ascii` character set range.

- The repertoire for function return values is determined based only on the repertoire of the arguments that affect the result's character set and collation.

```
IF(column1 < column2, 'smaller', 'greater')
```

The result repertoire is [ASCII](#) because the two string arguments (the second argument and the third argument) both have [ASCII](#) repertoire. The first argument does not matter for the result repertoire, even if the expression uses string values.

9.1.8. Operations Affected by Character Set Support

This section describes operations that take character set information into account.

9.1.8.1. Result Strings

MySQL has many operators and functions that return a string. This section answers the question: What is the character set and collation of such a string?

For simple functions that take string input and return a string result as output, the output's character set and collation are the same as those of the principal input value. For example, `UPPER(X)` returns a string whose character string and collation are the same as that of `X`. The same applies for `INSTR()`, `LCASE()`, `LOWER()`, `LTRIM()`, `MID()`, `REPEAT()`, `REPLACE()`, `REVERSE()`, `RIGHT()`, `RPAD()`, `RTRIM()`, `SOUNDEX()`, `SUBSTRING()`, `TRIM()`, `UCASE()`, and `UPPER()`.

Note: The `REPLACE()` function, unlike all other functions, always ignores the collation of the string input and performs a case-sensitive comparison.

If a string input or function result is a binary string, the string has no character set or collation. This can be checked by using the `CHARSET()` and `COLLATION()` functions, both of which return `binary` to indicate that their argument is a binary string:

```
mysql> SELECT CHARSET(BINARY 'a'), COLLATION(BINARY 'a');
+-----+-----+
| CHARSET(BINARY 'a') | COLLATION(BINARY 'a') |
+-----+-----+
| binary              | binary                 |
+-----+-----+
```

For operations that combine multiple string inputs and return a single string output, the “aggregation rules” of standard SQL apply for determining the collation of the result:

- If an explicit `COLLATE X` occurs, use `X`.

- If explicit `COLLATE X` and `COLLATE Y` occur, raise an error.
- Otherwise, if all collations are `X`, use `X`.
- Otherwise, the result has no collation.

For example, with `CASE ... WHEN a THEN b WHEN b THEN c COLLATE X END`, the resulting collation is `X`. The same applies for `UNION`, `||`, `CONCAT()`, `ELT()`, `GREATEST()`, `IF()`, and `LEAST()`.

For operations that convert to character data, the character set and collation of the strings that result from the operations are defined by the `character_set_connection` and `collation_connection` system variables. This applies only to `CAST()`, `CONV()`, `FORMAT()`, `HEX()`, and `SPACE()`.

If you are uncertain about the character set or collation of the result returned by a string function, you can use the `CHARSET()` or `COLLATION()` function to find out:

```
mysql> SELECT USER(), CHARSET(USER()), COLLATION(USER());
+-----+-----+-----+
| USER()          | CHARSET(USER()) | COLLATION(USER()) |
+-----+-----+-----+
| test@localhost  | utf8            | utf8_general_ci   |
+-----+-----+-----+
```

9.1.8.2. CONVERT() and CAST()

`CONVERT()` provides a way to convert data between different character sets. The syntax is:

```
CONVERT(expr USING transcoding_name)
```

In MySQL, transcoding names are the same as the corresponding character set names.

Examples:

```
SELECT CONVERT(_latin1'Müller' USING utf8);
INSERT INTO utf8table (utf8column)
  SELECT CONVERT(latin1field USING utf8) FROM latin1table;
```

`CONVERT(... USING ...)` is implemented according to the standard SQL specification.

You may also use `CAST()` to convert a string to a different character set. The syntax is:

```
CAST(character_string AS character_data_type CHARACTER SET charset_name)
```

Example:

```
SELECT CAST(_latin1'test' AS CHAR CHARACTER SET utf8);
```

If you use `CAST()` without specifying `CHARACTER SET`, the resulting character set and collation are defined by the `character_set_connection` and `collation_connection` system variables. If you use `CAST()` with `CHARACTER SET X`, the resulting character set and collation are `X` and the default collation of `X`.

You may not use a `COLLATE` clause inside a `CAST()`, but you may use it outside. That is, `CAST(... COLLATE ...)` is illegal, but `CAST(...) COLLATE ...` is legal.

Example:

```
SELECT CAST(_latin1'test' AS CHAR CHARACTER SET utf8) COLLATE utf8_bin;
```

9.1.8.3. SHOW Statements and INFORMATION_SCHEMA

Several `SHOW` statements provide additional character set information. These include `SHOW CHARACTER SET`, `SHOW COLLATION`, `SHOW CREATE DATABASE`, `SHOW CREATE TABLE` and `SHOW COLUMNS`. These statements are described here briefly. For more information, see [Section 12.5.5, “SHOW Syntax”](#).

`INFORMATION_SCHEMA` has several tables that contain information similar to that displayed by the `SHOW` statements. For example, the `CHARACTER_SETS` and `COLLATIONS` tables contain the information displayed by `SHOW CHARACTER SET` and `SHOW COLLATION`. See [Chapter 19, INFORMATION_SCHEMA Tables](#).

The `SHOW CHARACTER SET` command shows all available character sets. It takes an optional `LIKE` clause that indicates which

character set names to match. For example:

```
mysql> SHOW CHARACTER SET LIKE 'latin%';
```

Charset	Description	Default collation	Maxlen
latin1	cp1252 West European	latin1_swedish_ci	1
latin2	ISO 8859-2 Central European	latin2_general_ci	1
latin5	ISO 8859-9 Turkish	latin5_turkish_ci	1
latin7	ISO 8859-13 Baltic	latin7_general_ci	1

The output from `SHOW COLLATION` includes all available character sets. It takes an optional `LIKE` clause that indicates which collation names to match. For example:

```
mysql> SHOW COLLATION LIKE 'latin1%';
```

Collation	Charset	Id	Default	Compiled	Sortlen
latin1_german1_ci	latin1	5			0
latin1_swedish_ci	latin1	8	Yes	Yes	0
latin1_danish_ci	latin1	15			0
latin1_german2_ci	latin1	31		Yes	2
latin1_bin	latin1	47		Yes	0
latin1_general_ci	latin1	48			0
latin1_general_cs	latin1	49			0
latin1_spanish_ci	latin1	94			0

`SHOW CREATE DATABASE` displays the `CREATE DATABASE` statement that creates a given database:

```
mysql> SHOW CREATE DATABASE test;
```

Database	Create Database
test	CREATE DATABASE `test` /*!40100 DEFAULT CHARACTER SET latin1 */

If no `COLLATE` clause is shown, the default collation for the character set applies.

`SHOW CREATE TABLE` is similar, but displays the `CREATE TABLE` statement to create a given table. The column definitions indicate any character set specifications, and the table options include character set information.

The `SHOW COLUMNS` statement displays the collations of a table's columns when invoked as `SHOW FULL COLUMNS`. Columns with `CHAR`, `VARCHAR`, or `TEXT` data types have collations. Numeric and other non-character types have no collation (indicated by `NULL` as the `Collation` value). For example:

```
mysql> SHOW FULL COLUMNS FROM person\G
***** 1. row *****
Field: id
Type: smallint(5) unsigned
Collation: NULL
Null: NO
Key: PRI
Default: NULL
Extra: auto_increment
Privileges: select,insert,update,references
Comment:
***** 2. row *****
Field: name
Type: char(60)
Collation: latin1_swedish_ci
Null: NO
Key:
Default:
Extra:
Privileges: select,insert,update,references
Comment:
```

The character set is not part of the display but is implied by the collation name.

9.1.9. Unicode Support

MySQL 5.4 supports two character sets for storing Unicode data:

- `ucs2`, the UCS-2 encoding of the Unicode character set using 16 bits per character
- `utf8`, a UTF-8 encoding of the Unicode character set using one to three bytes per character

These two character sets support the characters from the Basic Multilingual Plane (BMP) of Unicode Version 3.0. BMP characters have these characteristics:

- Their code values are between 0 and 65535 (or `U+0000 .. U+FFFF`)
- They can be encoded with a fixed 16-bit word, as in `ucs2`
- They can be encoded with 8, 16, or 24 bits, as in `utf8`
- They are sufficient for almost all characters in major languages

The `ucs2` and `utf8` character sets do not support supplementary characters that lie outside the BMP.

A similar set of collations is available for each Unicode character set. For example, each has a Danish collation, the names of which are `ucs2_danish_ci` and `utf8_danish_ci`. All Unicode collations are listed at [Section 9.1.12.1, “Unicode Character Sets”](#).

In UCS-2, every character is represented by a two-byte Unicode code with the most significant byte first. For example: `LATIN CAPITAL LETTER A` has the code `0x0041` and it is stored as a two-byte sequence: `0x00 0x41`. `CYRILLIC SMALL LETTER YERU` (Unicode `0x044B`) is stored as a two-byte sequence: `0x04 0x4B`. For Unicode characters and their codes, please refer to the [Unicode Home Page](#).

The MySQL implementation of UCS-2 stores characters in big-endian byte order and does not use a byte order mark (BOM) at the beginning of UCS-2 values. Other database systems might use little-endian byte order or a BOM, in which case, conversion of UCS-2 values will need to be performed when transferring data between those systems and MySQL.

UTF-8 (Unicode Transformation Format with 8-bit units) is an alternative way to store Unicode data. It is implemented according to RFC 3629. RFC 3629 describes encoding sequences that take from one to four bytes. Currently, MySQL support for UTF-8 does not include four-byte sequences. (An older standard for UTF-8 encoding is given by RFC 2279, which describes UTF-8 sequences that take from one to six bytes. RFC 3629 renders RFC 2279 obsolete; for this reason, sequences with five and six bytes are no longer used.)

The idea of UTF-8 is that various Unicode characters are encoded using byte sequences of different lengths:

- Basic Latin letters, digits, and punctuation signs use one byte.
- Most European and Middle East script letters fit into a two-byte sequence: extended Latin letters (with tilde, macron, acute, grave and other accents), Cyrillic, Greek, Armenian, Hebrew, Arabic, Syriac, and others.
- Korean, Chinese, and Japanese ideographs use three-byte sequences.

MySQL uses no BOM for UTF-8 values.

Tip: To save space with UTF-8, use `VARCHAR` instead of `CHAR`. Otherwise, MySQL must reserve three bytes for each character in a `CHAR CHARACTER SET utf8` column because that is the maximum possible length. For example, MySQL must reserve 30 bytes for a `CHAR(10) CHARACTER SET utf8` column.

UCS-2 cannot be used as a client character set, which means that `SET NAMES 'ucs2'` does not work. (See [Section 9.1.4, “Connection Character Sets and Collations”](#).)

Client applications that need to communicate with the server using Unicode should set the client character set accordingly; for example, by issuing a `SET NAMES 'utf8'` statement. `ucs2` cannot be used as a client character set, which means that it does not work for `SET NAMES` or `SET CHARACTER SET`. (See [Section 9.1.4, “Connection Character Sets and Collations”](#).)

9.1.10. UTF-8 for Metadata

Metadata is “the data about the data.” Anything that *describes* the database — as opposed to being the *contents* of the database — is metadata. Thus column names, database names, user names, version names, and most of the string results from `SHOW` are metadata. This is also true of the contents of tables in `INFORMATION_SCHEMA`, because those tables by definition contain information about database objects.

Representation of metadata must satisfy these requirements:

- All metadata must be in the same character set. Otherwise, neither the `SHOW` commands nor `SELECT` statements for tables in `INFORMATION_SCHEMA` would work properly because different rows in the same column of the results of these operations would be in different character sets.

- Metadata must include all characters in all languages. Otherwise, users would not be able to name columns and tables using their own languages.

To satisfy both requirements, MySQL stores metadata in a Unicode character set, namely UTF-8. This does not cause any disruption if you never use accented or non-Latin characters. But if you do, you should be aware that metadata is in UTF-8.

The metadata requirements mean that the return values of the `USER()`, `CURRENT_USER()`, `SESSION_USER()`, `SYSTEM_USER()`, `DATABASE()`, and `VERSION()` functions have the UTF-8 character set by default.

The server sets the `character_set_system` system variable to the name of the metadata character set:

```
mysql> SHOW VARIABLES LIKE 'character_set_system';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| character_set_system | utf8 |
+-----+-----+
```

Storage of metadata using Unicode does *not* mean that the server returns headers of columns and the results of `DESCRIBE` functions in the `character_set_system` character set by default. When you use `SELECT column1 FROM t`, the name `column1` itself is returned from the server to the client in the character set determined by the value of the `character_set_results` system variable, which has a default value of `latin1`. If you want the server to pass metadata results back in a different character set, use the `SET NAMES` statement to force the server to perform character set conversion. `SET NAMES` sets the `character_set_results` and other related system variables. (See [Section 9.1.4, “Connection Character Sets and Collations”](#).) Alternatively, a client program can perform the conversion after receiving the result from the server. It is more efficient for the client perform the conversion, but this option is not always available for all clients.

If `character_set_results` is set to `NULL`, no conversion is performed and the server returns metadata using its original character set (the set indicated by `character_set_system`).

Error messages returned from the server to the client are converted to the client character set automatically, as with metadata.

If you are using (for example) the `USER()` function for comparison or assignment within a single statement, don't worry. MySQL performs some automatic conversion for you.

```
SELECT * FROM t1 WHERE USER() = latin1_column;
```

This works because the contents of `latin1_column` are automatically converted to UTF-8 before the comparison.

```
INSERT INTO t1 (latin1_column) SELECT USER();
```

This works because the contents of `USER()` are automatically converted to `latin1` before the assignment.

Although automatic conversion is not in the SQL standard, the SQL standard document does say that every character set is (in terms of supported characters) a “subset” of Unicode. Because it is a well-known principle that “what applies to a superset can apply to a subset,” we believe that a collation for Unicode can apply for comparisons with non-Unicode strings. For more information about coercion of strings, see [Section 9.1.6.5, “Special Cases Where Collation Determination Is Tricky”](#).

9.1.11. Column Character Set Conversion

To convert a binary or nonbinary string column to use a particular character set, use `ALTER TABLE`. For successful conversion to occur, one of the following conditions must apply:

- If the column has a binary data type (`BINARY`, `VARBINARY`, `BLOB`), all the values that it contains must be encoded using a single character set (the character set you're converting the column to). If you use a binary column to store information in multiple character sets, MySQL has no way to know which values use which character set and cannot convert the data properly.
- If the column has a nonbinary data type (`CHAR`, `VARCHAR`, `TEXT`), its contents should be encoded in the column's character set, not some other character set. If the contents are encoded in a different character set, you can convert the column to use a binary data type first, and then to a nonbinary column with the desired character set.

Suppose that a table `t` has a binary column named `col1` defined as `VARBINARY(50)`. Assuming that the information in the column is encoded using a single character set, you can convert it to a nonbinary column that has that character set. For example, if `col1` contains binary data representing characters in the `greek` character set, you can convert it as follows:

```
ALTER TABLE t MODIFY col1 VARCHAR(50) CHARACTER SET greek;
```

If your original column has a type of `BINARY(50)`, you could convert it to `CHAR(50)`, but the resulting values will be padded with `0x00` bytes at the end, which may be undesirable. To remove these bytes, use the `TRIM()` function:

```
UPDATE t SET col1 = TRIM(TRAILING 0x00 FROM col1);
```

Suppose that table `t` has a nonbinary column named `col1` defined as `CHAR(50) CHARACTER SET latin1` but you want to convert it to use `utf8` so that you can store values from many languages. The following statement accomplishes this:

```
ALTER TABLE t MODIFY col1 CHAR(50) CHARACTER SET utf8;
```

Conversion may be lossy if the column contains characters that are not in both character sets.

A special case occurs if you have old tables from MySQL 4.0 or earlier where a nonbinary column contains values that actually are encoded in a character set different from the server's default character set. For example, an application might have stored `sjis` values in a column, even though MySQL's default character set was `latin1`. It is possible to convert the column to use the proper character set but an additional step is required. Suppose that the server's default character set was `latin1` and `col1` is defined as `CHAR(50)` but its contents are `sjis` values. The first step is to convert the column to a binary data type, which removes the existing character set information without performing any character conversion:

```
ALTER TABLE t MODIFY col1 BLOB;
```

The next step is to convert the column to a nonbinary data type with the proper character set:

```
ALTER TABLE t MODIFY col1 CHAR(50) CHARACTER SET sjis;
```

This procedure requires that the table not have been modified already with statements such as `INSERT` or `UPDATE` after an upgrade to MySQL 4.1 or later. In that case, MySQL would store new values in the column using `latin1`, and the column will contain a mix of `sjis` and `latin1` values and cannot be converted properly.

If you specified attributes when creating a column initially, you should also specify them when altering the table with `ALTER TABLE`. For example, if you specified `NOT NULL` and an explicit `DEFAULT` value, you should also provide them in the `ALTER TABLE` statement. Otherwise, the resulting column definition will not include those attributes.

9.1.12. Character Sets and Collations That MySQL Supports

MySQL supports 70+ collations for 30+ character sets. This section indicates which character sets MySQL supports. There is one subsection for each group of related character sets. For each character set, the allowable collations are listed.

You can always list the available character sets and their default collations with the `SHOW CHARACTER SET` statement:

```
mysql> SHOW CHARACTER SET;
```

Charset	Description	Default collation
big5	Big5 Traditional Chinese	big5_chinese_ci
dec8	DEC West European	dec8_swedish_ci
cp850	DOS West European	cp850_general_ci
hp8	HP West European	hp8_english_ci
koi8r	KOI8-R Relcom Russian	koi8r_general_ci
latin1	cp1252 West European	latin1_swedish_ci
latin2	ISO 8859-2 Central European	latin2_general_ci
swe7	7bit Swedish	swe7_swedish_ci
ascii	US ASCII	ascii_general_ci
ujis	EUC-JP Japanese	ujis_japanese_ci
sjis	Shift-JIS Japanese	sjis_japanese_ci
hebrew	ISO 8859-8 Hebrew	hebrew_general_ci
tis620	TIS620 Thai	tis620_thai_ci
euckr	EUC-KR Korean	euckr_korean_ci
koi8u	KOI8-U Ukrainian	koi8u_general_ci
gb2312	GB2312 Simplified Chinese	gb2312_chinese_ci
greek	ISO 8859-7 Greek	greek_general_ci
cp1250	Windows Central European	cp1250_general_ci
gbk	GBK Simplified Chinese	gbk_chinese_ci
latin5	ISO 8859-9 Turkish	latin5_turkish_ci
armscii8	ARMSSCII-8 Armenian	armscii8_general_ci
utf8	UTF-8 Unicode	utf8_general_ci
ucs2	UCS-2 Unicode	ucs2_general_ci
cp866	DOS Russian	cp866_general_ci
keybcs2	DOS Kamenicky Czech-Slovak	keybcs2_general_ci
macce	Mac Central European	macce_general_ci
macroman	Mac West European	macroman_general_ci
cp852	DOS Central European	cp852_general_ci
latin7	ISO 8859-13 Baltic	latin7_general_ci
cp1251	Windows Cyrillic	cp1251_general_ci
cp1256	Windows Arabic	cp1256_general_ci
cp1257	Windows Baltic	cp1257_general_ci
binary	Binary pseudo charset	binary
geostd8	GEOSTD8 Georgian	geostd8_general_ci
cp932	SJIS for Windows Japanese	cp932_japanese_ci

```
| eucjpm | UJIS for Windows Japanese | eucjpm_japanese_ci |  
+-----+-----+-----+
```

In cases where a character set has multiple collations, it might not be clear which collation is most suitable for a given application. To avoid choosing the wrong collation, it can be helpful to perform some comparisons with representative data values to make sure that a given collation sorts values the way you expect.

Collation-Charts.Org is a useful site for information that shows how one collation compares to another.

9.1.12.1. Unicode Character Sets

MySQL 5.4 has two Unicode character sets:

- `ucs2`, the UCS-2 encoding of the Unicode character set using 16 bits per character
- `utf8`, a UTF-8 encoding of the Unicode character set using one to three bytes per character

You can store text in about 650 languages using these character sets. This section lists the collations available for each Unicode character set. For general information about the character sets, see [Section 9.1.9, “Unicode Support”](#).

A similar set of collations is available for each Unicode character set. These are shown in the following list, where `xxx` represents the character set name. For example, `xxx_danish_ci` represents the Danish collations, the specific names of which are `ucs2_danish_ci` and `utf8_danish_ci`.

- `xxx_bin`
- `xxx_czech_ci`
- `xxx_danish_ci`
- `xxx_esperanto_ci`
- `xxx_estonian_ci`
- `xxx_general_ci` (default)
- `xxx_hungarian_ci`
- `xxx_icelandic_ci`
- `xxx_latvian_ci`
- `xxx_lithuanian_ci`
- `xxx_persian_ci`
- `xxx_polish_ci`
- `xxx_roman_ci`
- `xxx_romanian_ci`
- `xxx_slovak_ci`
- `xxx_slovenian_ci`
- `xxx_spanish2_ci`
- `xxx_spanish_ci`
- `xxx_swedish_ci`
- `xxx_turkish_ci`
- `xxx_unicode_ci`

MySQL implements the `xxx_unicode_ci` collations according to the Unicode Collation Algorithm (UCA) described at <http://www.unicode.org/reports/tr10/>. The collation uses the version-4.0.0 UCA weight keys: [ht-](#)

<http://www.unicode.org/Public/UCA/4.0.0/allkeys-4.0.0.txt>. Currently, the `xxx_unicode_ci` collations have only partial support for the Unicode Collation Algorithm. Some characters are not supported yet. Also, combining marks are not fully supported. This affects primarily Vietnamese, Yoruba, and some smaller languages such as Navajo. The following discussion uses `utf8_unicode_ci` for concreteness.

For any Unicode character set, operations performed using the `_general_ci` collation are faster than those for the `_unicode_ci` collation. For example, comparisons for the `utf8_general_ci` collation are faster, but slightly less correct, than comparisons for `utf8_unicode_ci`. The reason for this is that `utf8_unicode_ci` supports mappings such as expansions; that is, when one character compares as equal to combinations of other characters. For example, in German and some other languages “ß” is equal to “ss”. `utf8_unicode_ci` also supports contractions and ignorable characters. `utf8_general_ci` is a legacy collation that does not support expansions, contractions, or ignorable characters. It can make only one-to-one comparisons between characters.

To further illustrate, the following equalities hold in both `utf8_general_ci` and `utf8_unicode_ci` (for the effect this has in comparisons or when doing searches, see [Section 9.1.6.7, “Examples of the Effect of Collation”](#)):

```
Ä = A
Ö = O
Û = U
```

A difference between the collations is that this is true for `utf8_general_ci`:

```
ß = s
```

Whereas this is true for `utf8_unicode_ci`:

```
ß = ss
```

MySQL implements language-specific collations for the `utf8` character set only if the ordering with `utf8_unicode_ci` does not work well for a language. For example, `utf8_unicode_ci` works fine for German and French, so there is no need to create special `utf8` collations for these two languages.

`utf8_general_ci` also is satisfactory for both German and French, except that “ß” is equal to “s”, and not to “ss”. If this is acceptable for your application, then you should use `utf8_general_ci` because it is faster. Otherwise, use `utf8_unicode_ci` because it is more accurate.

`utf8_swedish_ci`, like other `utf8` language-specific collations, is derived from `utf8_unicode_ci` with additional language rules. For example, in Swedish, the following relationship holds, which is not something expected by a German or French speaker:

```
Û = Y < Ö
```

The `xxx_spanish_ci` and `xxx_spanish2_ci` collations correspond to modern Spanish and traditional Spanish, respectively. In both collations, “ñ” (n-tilde) is a separate letter between “n” and “o”. In addition, for traditional Spanish, “ch” is a separate letter between “c” and “d”, and “ll” is a separate letter between “l” and “m”.

In the `xxx_roman_ci` collations, `I` and `J` compare as equal, and `U` and `V` compare as equal.

For additional information about Unicode collations in MySQL, see Collation-Charts.Org ([utf8](#)).

9.1.12.2. West European Character Sets

Western European character sets cover most West European languages, such as French, Spanish, Catalan, Basque, Portuguese, Italian, Albanian, Dutch, German, Danish, Swedish, Norwegian, Finnish, Faroese, Icelandic, Irish, Scottish, and English.

- `ascii` (US ASCII) collations:
 - `ascii_bin`
 - `ascii_general_ci` (default)
- `cp850` (DOS West European) collations:
 - `cp850_bin`
 - `cp850_general_ci` (default)
- `dec8` (DEC Western European) collations:
 - `dec8_bin`

- `dec8_swedish_ci` (default)
- `hp8` (HP Western European) collations:
 - `hp8_bin`
 - `hp8_english_ci` (default)
- `latin1` (cp1252 West European) collations:
 - `latin1_bin`
 - `latin1_danish_ci`
 - `latin1_general_ci`
 - `latin1_general_cs`
 - `latin1_german1_ci`
 - `latin1_german2_ci`
 - `latin1_spanish_ci`
 - `latin1_swedish_ci` (default)

`latin1` is the default character set. MySQL's `latin1` is the same as the Windows `cp1252` character set. This means it is the same as the official [ISO 8859-1](#) or IANA (Internet Assigned Numbers Authority) `latin1`, except that IANA `latin1` treats the code points between `0x80` and `0x9f` as “undefined,” whereas `cp1252`, and therefore MySQL's `latin1`, assign characters for those positions. For example, `0x80` is the Euro sign. For the “undefined” entries in `cp1252`, MySQL translates `0x81` to Unicode `0x0081`, `0x8d` to `0x008d`, `0x8f` to `0x008f`, `0x90` to `0x0090`, and `0x9d` to `0x009d`.

The `latin1_swedish_ci` collation is the default that probably is used by the majority of MySQL customers. Although it is frequently said that it is based on the Swedish/Finnish collation rules, there are Swedes and Finns who disagree with this statement.

The `latin1_german1_ci` and `latin1_german2_ci` collations are based on the DIN-1 and DIN-2 standards, where DIN stands for *Deutsches Institut für Normung* (the German equivalent of ANSI). DIN-1 is called the “dictionary collation” and DIN-2 is called the “phone book collation.” For an example of the effect this has in comparisons or when doing searches, see [Section 9.1.6.7, “Examples of the Effect of Collation”](#).

- `latin1_german1_ci` (dictionary) rules:

```

Ä = A
Ö = O
Û = U
ß = s

```

- `latin1_german2_ci` (phone-book) rules:

```

Ä = AE
Ö = OE
Û = UE
ß = SS

```

For an example of the effect this has in comparisons or when doing searches, see [Section 9.1.6.7, “Examples of the Effect of Collation”](#).

In the `latin1_spanish_ci` collation, “ñ” (n-tilde) is a separate letter between “n” and “o”.

- `macroman` (Mac West European) collations:
 - `macroman_bin`
 - `macroman_general_ci` (default)
- `swe7` (7bit Swedish) collations:
 - `swe7_bin`
 - `swe7_swedish_ci` (default)

For additional information about Western European collations in MySQL, see Collation-Charts.Org ([ascii](#), [cp850](#), [dec8](#), [hp8](#), [latin1](#), [macroman](#), [swe7](#)).

9.1.12.3. Central European Character Sets

MySQL provides some support for character sets used in the Czech Republic, Slovakia, Hungary, Romania, Slovenia, Croatia, Poland, and Serbia (Latin).

- [cp1250](#) (Windows Central European) collations:
 - [cp1250_bin](#)
 - [cp1250_croatian_ci](#)
 - [cp1250_czech_cs](#)
 - [cp1250_general_ci](#) (default)
 - [cp1250_polish_ci](#)
- [cp852](#) (DOS Central European) collations:
 - [cp852_bin](#)
 - [cp852_general_ci](#) (default)
- [keybcs2](#) (DOS Kamenicky Czech-Slovak) collations:
 - [keybcs2_bin](#)
 - [keybcs2_general_ci](#) (default)
- [latin2](#) (ISO 8859-2 Central European) collations:
 - [latin2_bin](#)
 - [latin2_croatian_ci](#)
 - [latin2_czech_cs](#)
 - [latin2_general_ci](#) (default)
 - [latin2_hungarian_ci](#)
- [macce](#) (Mac Central European) collations:
 - [macce_bin](#)
 - [macce_general_ci](#) (default)

For additional information about Central European collations in MySQL, see Collation-Charts.Org ([cp1250](#), [cp852](#), [keybcs2](#), [latin2](#), [macce](#)).

9.1.12.4. South European and Middle East Character Sets

South European and Middle Eastern character sets supported by MySQL include Armenian, Arabic, Georgian, Greek, Hebrew, and Turkish.

- [armscii8](#) (ARMScii-8 Armenian) collations:
 - [armscii8_bin](#)
 - [armscii8_general_ci](#) (default)
- [cp1256](#) (Windows Arabic) collations:
 - [cp1256_bin](#)

- `cp1256_general_ci` (default)
- `geostd8` (GEOSTD8 Georgian) collations:
 - `geostd8_bin`
 - `geostd8_general_ci` (default)
- `greek` (ISO 8859-7 Greek) collations:
 - `greek_bin`
 - `greek_general_ci` (default)
- `hebrew` (ISO 8859-8 Hebrew) collations:
 - `hebrew_bin`
 - `hebrew_general_ci` (default)
- `latin5` (ISO 8859-9 Turkish) collations:
 - `latin5_bin`
 - `latin5_turkish_ci` (default)

For additional information about South European and Middle Eastern collations in MySQL, see Collation-Charts.Org ([armscii8](#), [cp1256](#), [geostd8](#), [greek](#), [hebrew](#), [latin5](#)).

9.1.12.5. Baltic Character Sets

The Baltic character sets cover Estonian, Latvian, and Lithuanian languages.

- `cp1257` (Windows Baltic) collations:
 - `cp1257_bin`
 - `cp1257_general_ci` (default)
 - `cp1257_lithuanian_ci`
- `latin7` (ISO 8859-13 Baltic) collations:
 - `latin7_bin`
 - `latin7_estonian_cs`
 - `latin7_general_ci` (default)
 - `latin7_general_cs`

For additional information about Baltic collations in MySQL, see Collation-Charts.Org ([cp1257](#), [latin7](#)).

9.1.12.6. Cyrillic Character Sets

The Cyrillic character sets and collations are for use with Belarusian, Bulgarian, Russian, Ukrainian, and Serbian (Cyrillic) languages.

- `cp1251` (Windows Cyrillic) collations:
 - `cp1251_bin`
 - `cp1251_bulgarian_ci`
 - `cp1251_general_ci` (default)
 - `cp1251_general_cs`

- `cp1251_ukrainian_ci`
- `cp866` (DOS Russian) collations:
 - `cp866_bin`
 - `cp866_general_ci` (default)
- `koi8r` (KOI8-R Relcom Russian) collations:
 - `koi8r_bin`
 - `koi8r_general_ci` (default)
- `koi8u` (KOI8-U Ukrainian) collations:
 - `koi8u_bin`
 - `koi8u_general_ci` (default)

For additional information about Cyrillic collations in MySQL, see [Collation-Charts.Org](#) ([cp1251](#), [cp866](#), [koi8r](#), [koi8u](#)).).

9.1.12.7. Asian Character Sets

The Asian character sets that we support include Chinese, Japanese, Korean, and Thai. These can be complicated. For example, the Chinese sets must allow for thousands of different characters. See [Section 9.1.12.7.1, “The cp932 Character Set”](#), for additional information about the `cp932` and `sjis` character sets.

For answers to some common questions and problems relating support for Asian character sets in MySQL, see [Section A.11, “MySQL 5.4 FAQ — MySQL Chinese, Japanese, and Korean Character Sets”](#).

- `big5` (Big5 Traditional Chinese) collations:
 - `big5_bin`
 - `big5_chinese_ci` (default)
- `cp932` (SJIS for Windows Japanese) collations:
 - `cp932_bin`
 - `cp932_japanese_ci` (default)
- `ujis` (EUC-JP Japanese) collations:
 - `ujis_bin`
 - `ujis_japanese_ci` (default)
- `euckr` (EUC-KR Korean) collations:
 - `euckr_bin`
 - `euckr_korean_ci` (default)
- `gb2312` (GB2312 Simplified Chinese) collations:
 - `gb2312_bin`
 - `gb2312_chinese_ci` (default)
- `gbk` (GBK Simplified Chinese) collations:
 - `gbk_bin`
 - `gbk_chinese_ci` (default)
- `sjis` (Shift-JIS Japanese) collations:

- `sjis_bin`
- `sjis_japanese_ci` (default)
- `tis620` (TIS620 Thai) collations:
 - `tis620_bin`
 - `tis620_thai_ci` (default)
- `ujis` (EUC-JP Japanese) collations:
 - `ujis_bin`
 - `ujis_japanese_ci` (default)

The `big5_chinese_ci` collation sorts on number of strokes.

For additional information about Asian collations in MySQL, see Collation-Charts.Org ([big5](http://www.collation-charts.org), [cp932](http://www.collation-charts.org), [eucjpms](http://www.collation-charts.org), [euckr](http://www.collation-charts.org), [gb2312](http://www.collation-charts.org), [gbk](http://www.collation-charts.org), [sjis](http://www.collation-charts.org), [tis620](http://www.collation-charts.org), [ujis](http://www.collation-charts.org)).

9.1.12.7.1. The `cp932` Character Set

Why is `cp932` needed?

In MySQL, the `sjis` character set corresponds to the `Shift_JIS` character set defined by IANA, which supports JIS X0201 and JIS X0208 characters. (See <http://www.iana.org/assignments/character-sets>.)

However, the meaning of “SHIFT JIS” as a descriptive term has become very vague and it often includes the extensions to `Shift_JIS` that are defined by various vendors.

For example, “SHIFT JIS” used in Japanese Windows environments is a Microsoft extension of `Shift_JIS` and its exact name is `Microsoft Windows Codepage : 932` or `cp932`. In addition to the characters supported by `Shift_JIS`, `cp932` supports extension characters such as NEC special characters, NEC selected — IBM extended characters, and IBM extended characters.

Many Japanese users have experienced problems using these extension characters. These problems stem from the following factors:

- MySQL automatically converts character sets.
- Character sets are converted via Unicode (`ucs2`).
- The `sjis` character set does not support the conversion of these extension characters.
- There are several conversion rules from so-called “SHIFT JIS” to Unicode, and some characters are converted to Unicode differently depending on the conversion rule. MySQL supports only one of these rules (described later).

The MySQL `cp932` character set is designed to solve these problems.

Because MySQL supports character set conversion, it is important to separate IANA `Shift_JIS` and `cp932` into two different character sets because they provide different conversion rules.

How does `cp932` differ from `sjis`?

The `cp932` character set differs from `sjis` in the following ways:

- `cp932` supports NEC special characters, NEC selected — IBM extended characters, and IBM selected characters.
- Some `cp932` characters have two different code points, both of which convert to the same Unicode code point. When converting from Unicode back to `cp932`, one of the code points must be selected. For this “round trip conversion,” the rule recommended by Microsoft is used. (See <http://support.microsoft.com/kb/170559/EN-US/>.)

The conversion rule works like this:

- If the character is in both JIS X 0208 and NEC special characters, use the code point of JIS X 0208.
- If the character is in both NEC special characters and IBM selected characters, use the code point of NEC special characters.

ters.

- If the character is in both IBM selected characters and NEC selected — IBM extended characters, use the code point of IBM extended characters.

The table shown at <http://www.microsoft.com/globaldev/reference/dbcs/932.htm> provides information about the Unicode values of `cp932` characters. For `cp932` table entries with characters under which a four-digit number appears, the number represents the corresponding Unicode (`ucs2`) encoding. For table entries with an underlined two-digit value appears, there is a range of `cp932` character values that begin with those two digits. Clicking such a table entry takes you to a page that displays the Unicode value for each of the `cp932` characters that begin with those digits.

The following links are of special interest. They correspond to the encodings for the following sets of characters:

- NEC special characters:

http://www.microsoft.com/globaldev/reference/dbcs/932/932_87.htm

- NEC selected — IBM extended characters:

http://www.microsoft.com/globaldev/reference/dbcs/932/932_ED.htm
http://www.microsoft.com/globaldev/reference/dbcs/932/932_EE.htm

- IBM selected characters:

http://www.microsoft.com/globaldev/reference/dbcs/932/932_FA.htm
http://www.microsoft.com/globaldev/reference/dbcs/932/932_FB.htm
http://www.microsoft.com/globaldev/reference/dbcs/932/932_FC.htm

- `cp932` supports conversion of user-defined characters in combination with `ucjpm`s, and solves the problems with `sjis/ujis` conversion. For details, please refer to <http://www.opengroup.or.jp/jvc/cde/sjis-ucjpm.html>.

For some characters, conversion to and from `ucs2` is different for `sjis` and `cp932`. The following tables illustrate these differences.

Conversion to `ucs2`:

<code>sjis/cp932</code> Value	<code>sjis</code> -> <code>ucs2</code> Conversion	<code>cp932</code> -> <code>ucs2</code> Conversion
5C	005C	005C
7E	007E	007E
815C	2015	2015
815F	005C	FF3C
8160	301C	FF5E
8161	2016	2225
817C	2212	FF0D
8191	00A2	FFE0
8192	00A3	FFE1
81CA	00AC	FFE2

Conversion from `ucs2`:

<code>ucs2</code> value	<code>ucs2</code> -> <code>sjis</code> Conversion	<code>ucs2</code> -> <code>cp932</code> Conversion
005C	815F	5C
007E	7E	7E
00A2	8191	3F
00A3	8192	3F
00AC	81CA	3F
2015	815C	815C
2016	8161	3F
2212	817C	3F

2225	3F	8161
301C	8160	3F
FF0D	3F	817C
FF3C	3F	815F
FF5E	3F	8160
FFE0	3F	8191
FFE1	3F	8192
FFE2	3F	81CA

Users of any Japanese character sets should be aware that using `--character-set-client-handshake` (or `--skip-character-set-client-handshake`) has an important effect. See [Section 5.1.2, “Server Command Options”](#).

9.2. The Character Set Used for Data and Sorting

By default, MySQL uses the `latin1` (cp1252 West European) character set and the `latin1_swedish_ci` collation that sorts according to Swedish/Finnish rules. These defaults are suitable for the United States and most of Western Europe.

All MySQL binary distributions are compiled with `--with-extra-charsets=complex`. This adds code to all standard programs that enables them to handle `latin1` and all multi-byte character sets within the binary. Other character sets are loaded from a character-set definition file when needed.

The character set determines what characters are allowed in identifiers. The collation determines how strings are sorted by the `ORDER BY` and `GROUP BY` clauses of the `SELECT` statement.

You can change the default server character set and collation with the `--character-set-server` and `--collation-server` options when you start the server. The collation must be a legal collation for the default character set. (Use the `SHOW COLLATION` statement to determine which collations are available for each character set.) See [Section 5.1.2, “Server Command Options”](#).

The character sets available depend on the `--with-charset=charset_name` and `--with-extra-charsets=list-of-charsets | complex | all | none` options to `configure`, and the character set configuration files listed in `SHAREDIR/charsets/Index`. See [Section 2.10.2, “Typical configure Options”](#).

If you change the character set when running MySQL, that may also change the sort order. Consequently, you must run `mysql-amchk -r -q --set-collation=collation_name` on all `MyISAM` tables, or your indexes may not be ordered correctly.

When a client connects to a MySQL server, the server indicates to the client what the server's default character set is. The client switches to this character set for this connection.

You should use `mysql_real_escape_string()` when escaping strings for an SQL query. `mysql_real_escape_string()` is identical to the old `mysql_escape_string()` function, except that it takes the `MYSQL` connection handle as the first parameter so that the appropriate character set can be taken into account when escaping characters.

If the client is compiled with paths that differ from where the server is installed and the user who configured MySQL didn't include all character sets in the MySQL binary, you must tell the client where it can find the additional character sets it needs if the server runs with a different character set from the client. You can do this by specifying a `--character-sets-dir` option to indicate the path to the directory in which the dynamic MySQL character sets are stored. For example, you can put the following in an option file:

```
[client]
character-sets-dir=/usr/local/mysql/share/mysql/charsets
```

You can force the client to use specific character set as follows:

```
[client]
default-character-set=charset_name
```

This is normally unnecessary, however.

9.2.1. Using the German Character Set

In MySQL 5.4, character set and collation are specified separately. This means that if you want German sort order, you should se-

lect the `latin1` character set and either the `latin1_german1_ci` or `latin1_german2_ci` collation. For example, to start the server with the `latin1_german1_ci` collation, use the `--character-set-server=latin1` and `-collation-server=latin1_german1_ci` options.

For information on the differences between these two collations, see [Section 9.1.12.2, “West European Character Sets”](#).

9.3. Setting the Error Message Language

By default, `mysqld` produces error messages in English, but they can also be displayed in any of these other languages: Czech, Danish, Dutch, Estonian, French, German, Greek, Hungarian, Italian, Japanese, Korean, Norwegian, Norwegian-ny, Polish, Portuguese, Romanian, Russian, Slovak, Spanish, or Swedish.

To start `mysqld` with a particular language for error messages, use the `--language` or `-L` option. The option value can be a language name or the full path to the error message file. For example:

```
shell> mysqld --language=swedish
```

Or:

```
shell> mysqld --language=/usr/local/share/swedish
```

The language name should be specified in lowercase.

By default, the language files are located in the `share/LANGUAGE` directory under the MySQL base directory.

You can also change the content of the error messages produced by the server. Details can be found in the MySQL Internals manual, available at http://forge.mysql.com/wiki/MySQL_Internals_Error_Messages. If you upgrade to a newer version of MySQL after changing the error messages, remember to repeat your changes after the upgrade.

9.4. Adding a New Character Set

This section discusses the procedure for adding a new character set to MySQL. You must have a MySQL source distribution to use these instructions. The proper procedure depends on whether the character set is simple or complex:

- If the character set does not need to use special string collating routines for sorting and does not need multi-byte character support, it is simple.
- If the character set needs either of those features, it is complex.

For example, `greek` and `swe7` are simple character sets, whereas `big5` and `czech` are complex character sets.

In the following instructions, `MYSET` represents the name of the character set that you want to add.

1. Add a `<charset>` element for `MYSET` to the `sql/share/charsets/Index.xml` file. Use the existing contents in the file as a guide to adding new contents.

The `<charset>` element must list all the collations for the character set. These must include at least a binary collation and a default collation. The default collation is usually named using a suffix of `general_ci` (general, case insensitive). It is possible for the binary collation to be the default collation, but usually they are different. The default collation should have a `primary` flag. The binary collation should have a `binary` flag.

You must assign a unique ID number to each collation, chosen from the range 1 to 254. To find the maximum of the currently used collation IDs, use this query:

```
SELECT MAX(ID) FROM INFORMATION_SCHEMA.COLLATIONS;
```

2. This step depends on whether you are adding a simple or complex character set. A simple character set requires only a configuration file, whereas a complex character set requires C source file that defines collation functions, multi-byte functions, or both.

For a simple character set, create a configuration file, `MYSET.xml`, that describes the character set properties. Create this file in the `sql/share/charsets` directory. (You can use a copy of `latin1.xml` as the basis for this file.) The syntax for the file is very simple:

- Comments are written as ordinary XML comments (`<!-- text -->`).

- Words within `<map>` array elements are separated by arbitrary amounts of whitespace.
- Each word within `<map>` array elements must be a number in hexadecimal format.
- The `<map>` array element for the `<ctype>` element has 257 words. The other `<map>` array elements after that have 256 words. See [Section 9.4.1, “The Character Definition Arrays”](#).
- For each collation listed in the `<charset>` element for the character set in `Index.xml`, `MYSET.xml` must contain a `<collation>` element that defines the character ordering.

For a complex character set, create a C source file that describes the character set properties and defines the support routines necessary to properly perform operations on the character set:

- Create the file `ctype-MYSET.c` in the `strings` directory. Look at one of the existing `ctype-*.c` files (such as `ctype-big5.c`) to see what needs to be defined. The arrays in your file must have names like `ctype_MYSET`, `to_lower_MYSET`, and so on. These correspond to the arrays for a simple character set. See [Section 9.4.1, “The Character Definition Arrays”](#).
 - For each collation listed in the `<charset>` element for the character set in `Index.xml`, the `ctype-MYSET.c` file must provide an implementation of the collation.
 - If you need string collating functions, see [Section 9.4.2, “String Collating Support”](#).
 - If you need multi-byte character support, see [Section 9.4.3, “Multi-Byte Character Support”](#).
- Follow these steps to modify the configuration information. Use the existing configuration information as a guide to adding information for `MYSYS`. The example here assumes that the character set has default and binary collations, but more lines will be needed if `MYSET` has additional collations.
 - Edit `mysys/charset-def.c`, and “register” the collations for the new character set.

Add these lines to the “declaration” section:

```
#ifndef HAVE_CHARSET_MYSET
extern CHARSET_INFO my_charset_MYSET_general_ci;
extern CHARSET_INFO my_charset_MYSET_bin;
#endif
```

Add these lines to the “registration” section:

```
#ifndef HAVE_CHARSET_MYSET
    add_compiled_collation(&my_charset_MYSET_general_ci);
    add_compiled_collation(&my_charset_MYSET_bin);
#endif
```

- If the character set uses `ctype-MYSET.c`, edit `strings/Makefile.am` and add `ctype-MYSET.c` to each definition of the `CSRCS` variable, and to the `EXTRA_DIST` variable.
- If the character set uses `ctype-MYSET.c`, edit `libmysql/Makefile.shared` and add `ctype-MYSET.lo` to the `mystringsobjects` definition.
- Edit `config/ac-macros/character_sets.m4`:
 - Add `MYSET` to one of the `define(CHARSETS_AVAILABLE...)` lines in alphabetic order.
 - Add `MYSET` to `CHARSETS_COMPLEX`. This is needed even for simple character sets, or `configure` will not recognize `--with-charset=MYSET`.
 - Add `MYSET` to the first `case` control structure. Omit the `USE_MB` and `USE_MB_IDENT` lines for 8-bit character sets.

```
MYSET)
AC_DEFINE(HAVE_CHARSET_MYSET, 1, [Define to enable charset MYSET])
AC_DEFINE([USE_MB], 1, [Use multi-byte character routines])
AC_DEFINE(USE_MB_IDENT, 1)
;;
```

- Add `MYSET` to the second `case` control structure:

```
MYSET)
default_charset_default_collation="MYSET_general_ci"
default_charset_collations="MYSET_general_ci MYSET_bin"
;;
```

4. Reconfigure, recompile, and test.

9.4.1. The Character Definition Arrays

Each simple character set has a configuration file located in the `sql/shareCharsets` directory. The file is named `MYSET.xml`. It uses `<map>` array elements to list character set properties. `<map>` elements appear within these elements:

- `<ctype>` defines attributes for each character
- `<lower>` and `<upper>` list the lowercase and uppercase characters
- `<unicode>` maps 8-bit character values to Unicode values
- `<collation>` elements indicate character ordering for comparisons and sorts, one element per collation (binary collations need no `<map>` element because the character codes themselves provide the ordering)

For a complex character set as implemented in a `ctype-MYSET.c` file in the `strings` directory, there are corresponding arrays: `ctype_MYSET[]`, `to_lower_MYSET[]`, and so forth. Not every complex character set has all of the arrays. See the existing `ctype-*.c` files for examples. See the `CHARSET_INFO.txt` file in the `strings` directory for additional information.

The `ctype` array is indexed by character value + 1 and has 257 elements. This is an old legacy convention for handling EOF. The other arrays are indexed by character value and have 256 elements.

`ctype` array elements are bit values. Each element describes the attributes of a single character in the character set. Each attribute is associated with a bitmask, as defined in `include/m_ctype.h`:

```
#define _MY_U 01 /* Upper case */
#define _MY_L 02 /* Lower case */
#define _MY_NMR 04 /* Numeral (digit) */
#define _MY_SPC 010 /* Spacing character */
#define _MY_PNT 020 /* Punctuation */
#define _MY_CTR 040 /* Control character */
#define _MY_B 0100 /* Blank */
#define _MY_X 0200 /* hexadecimal digit */
```

The `ctype` value for a given character should be the union of the applicable bitmask values that describe the character. For example, 'A' is an uppercase character (`_MY_U`) as well as a hexadecimal digit (`_MY_X`), so its `ctype` value should be defined like this:

```
ctype['A'+1] = _MY_U | _MY_X = 01 | 0200 = 0201
```

The bitmask values in `m_ctype.h` are octal values, but the elements of the `ctype` array in `MYSET.xml` should be written as hexadecimal values.

The `lower` and `upper` arrays hold the lowercase and uppercase characters corresponding to each member of the character set. For example:

```
lower['A'] should contain 'a'
upper['a'] should contain 'A'
```

Each `collation` array is a map indicating how characters should be ordered for comparison and sorting purposes. MySQL sorts characters based on the values of this information. In some cases, this is the same as the `upper` array, which means that sorting is case-insensitive. For more complicated sorting rules (for complex character sets), see the discussion of string collating in [Section 9.4.2, “String Collating Support”](#).

9.4.2. String Collating Support

For simple character sets, sorting rules are specified in the `MYSET.xml` configuration file using `<map>` array elements within `<collation>` elements. If the sorting rules for your language are too complex to be handled with simple arrays, you need to define string collating functions in the `ctype-MYSET.c` source file in the `strings` directory.

The existing character sets provide the best documentation and examples to show how these functions are implemented. Look at the `ctype-*.c` files in the `strings` directory, such as the files for the `big5`, `czech`, `gbk`, `sjis`, and `tis160` character sets. Take a look at the `MY_COLLATION_HANDLER` structures to see how they are used, and see the `CHARSET_INFO.txt` file in the

`strings` directory for additional information.

9.4.3. Multi-Byte Character Support

If you want to add support for a new character set that includes multi-byte characters, you need to use multi-byte character functions in the `ctype-MYSET.c` source file in the `strings` directory.

The existing character sets provide the best documentation and examples to show how these functions are implemented. Look at the `ctype-*.c` files in the `strings` directory, such as the files for the `euc_kr`, `gb2312`, `gbk`, `sjis`, and `ujis` character sets. Take a look at the `MY_CHARSET_HANDLER` structures to see how they are used, and see the `CHARSET_INFO.txt` file in the `strings` directory for additional information.

9.5. How to Add a New Collation to a Character Set

A collation is a set of rules that defines how to compare and sort character strings. Each collation in MySQL belongs to a single character set. Every character set has at least one collation, and most have two or more collations.

A collation orders characters based on weights. Each character in a character set maps to a weight. Characters with equal weights compare as equal, and characters with unequal weights compare according to the relative magnitude of their weights.

MySQL supports several collation implementations, as discussed in [Section 9.5.1, “Collation Implementation Types”](#). Some of these can be added to MySQL without recompiling:

- Simple collations for 8-bit character sets
- UCA-based collations for Unicode character sets
- Binary (`xxx_bin`) collations

The following discussion describes how to add collations of the first two types to existing character sets. All existing character sets already have a binary collation, so there is no need here to describe how to add one.

Summary of the procedure for adding a new collation:

1. Choose a collation ID
2. Add configuration information that names the collation and describes the character-ordering rules
3. Restart the server
4. Verify that the collation is present

The instructions here cover only collations that can be added without recompiling MySQL. To add a collation that does require recompiling (as implemented by means of functions in a C source file), use the instructions in [Section 9.4, “Adding a New Character Set”](#). However, instead of adding all the information required for a complete character set, just modify the appropriate files for an existing character set. That is, based on what is already present for the character set's current collations, add new data structures, functions, and configuration information for the new collation. For an example, see the MySQL Blog article in the following list of additional resources.

Additional resources

- The Unicode Collation Algorithm (UCA) specification: <http://www.unicode.org/reports/tr10/>
- The Locale Data Markup Language (LDML) specification: <http://www.unicode.org/reports/tr35/>
- MySQL University session “How to Add a Collation”: http://forge.mysql.com/wiki/How_to_Add_a_Collation
- MySQL Blog article “Instructions for adding a new Unicode collation”: <http://blogs.mysql.com/petery/2008/05/19/instructions-for-adding-a-new-unicode-collation/>

9.5.1. Collation Implementation Types

MySQL implements several types of collations:

Simple collations for 8-bit character sets

This kind of collation is implemented using an array of 256 weights that defines a one-to-one mapping from character codes to weights. `latin1_swedish_ci` is an example. It is a case-insensitive collation, so the uppercase and lowercase versions of a character have the same weights and they compare as equal.

```
mysql> SET NAMES 'latin1' COLLATE 'latin1_swedish_ci';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT 'a' = 'A';
+-----+
| 'a' = 'A' |
+-----+
|          1 |
+-----+
1 row in set (0.00 sec)
```

Complex collations for 8-bit character sets

This kind of collation is implemented using functions in a C source file that define how to order characters, as described in [Section 9.4, “Adding a New Character Set”](#).

Collations for non-Unicode multi-byte character sets

For this type of collation, 8-bit (single-byte) and multi-byte characters are handled differently. For 8-bit characters, character codes map to weights in case-insensitive fashion. (For example, the single-byte characters 'a' and 'A' both have a weight of `0x41`.) For multi-byte characters, there are two types of relationship between character codes and weights:

- Weights equal character codes. `sjis_japanese_ci` is an example of this kind of collation. The multi-byte character 'ぢ' has a character code of `0x82C0`, and the weight is also `0x82C0`.
- Character codes map one-to-one to weights, but a code is not necessarily equal to the weight. `gbk_chinese_ci` is an example of this kind of collation. The multi-byte character '腦' has a character code of `0x81B0` but a weight of `0xC286`.

Collations for Unicode multi-byte character sets

Some of these collations are based on the Unicode Collation Algorithm (UCA), others are not.

Non-UCA collations have a one-to-one mapping from character code to weight. In MySQL, such collations are case insensitive and accent insensitive. `utf8_general_ci` is an example: 'a', 'A', 'À', and 'á' each have different character codes but all have a weight of `0x0041` and compare as equal.

```
mysql> SET NAMES 'utf8' COLLATE 'utf8_general_ci';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT 'a' = 'A', 'a' = 'À', 'a' = 'á';
+-----+-----+-----+
| 'a' = 'A' | 'a' = 'À' | 'a' = 'á' |
+-----+-----+-----+
|          1 |          1 |          1 |
+-----+-----+-----+
1 row in set (0.06 sec)
```

UCA-based collations in MySQL have these properties:

- If a character has weights, each weight uses 2 bytes (16 bits)
- A character may have zero weights (or an empty weight). In this case, the character is ignorable. Example: "U+0000 NULL" does not have a weight and is ignorable.
- A character may have one weight. Example: 'a' has a weight of `0x0E33`.
- A character may have many weights. This is an expansion. Example: The German letter 'ß' (SZ LEAGUE, or SHARP S) has a weight of `0x0FEA0FEA`.
- Many characters may have one weight. This is a contraction. Example: 'ch' is a single letter in Czech and has a weight of `0x0EE2`.

A many-characters-to-many-weights mapping is also possible (this is contraction with expansion), but is not supported by MySQL.

Miscellaneous collations

There are also a few collations that do not fall into any of the previous categories.

9.5.2. Choosing a Collation ID

Each collation must have a unique ID. To add a new collation, you must choose an ID value that is not currently used. The value must be in the range from 1 to 254. The collation ID that you choose will show up in these contexts:

- The `Id` column of `SHOW COLLATION` output
- The `ID` column of the `INFORMATION_SCHEMA.COLLATIONS` table
- The `charsetnr` member of the `MYSQL_FIELD` C API data structure
- The `number` member of the `MY_CHARSET_INFO` data structure returned by the `mysql_get_character_set_info()` C API function

To determine the largest currently used ID, issue the following statement:

```
mysql> SELECT MAX(ID) FROM INFORMATION_SCHEMA.COLLATIONS;
+-----+
| MAX(ID) |
+-----+
|      210 |
+-----+
```

For the output just shown, you could choose an ID higher than 210 for the new collation.

To display a list of all currently used IDs, issue this statement:

```
mysql> SELECT ID FROM INFORMATION_SCHEMA.COLLATIONS ORDER BY ID;
+-----+
| ID |
+-----+
| 1 |
| 2 |
| ... |
| 52 |
| 53 |
| 57 |
| 58 |
| ... |
| 98 |
| 99 |
| 128 |
| 129 |
| ... |
| 210 |
+-----+
```

In this case, you can either choose an unused ID from within the current range of IDs, or choose an ID that is higher than the current maximum ID. For example, in the output just shown, there are unused IDs between 53 and 57, and between 99 and 128. Or you could choose an ID higher than 210.

Warning

If you upgrade MySQL, you may find that the collation ID you choose has been assigned to a collation included in the new MySQL distribution. In this case, you will need to choose a new value for your own collation.

In addition, before upgrading, you should save the configuration files that you change. If you upgrade in place, the process will replace the your modified files.

9.5.3. Adding a Simple Collation to an 8-Bit Character Set

To add a simple collation for an 8-bit character set without recompiling MySQL, use the following procedure. The example adds a collation named `latin1_test_ci` to the `latin1` character set.

1. Choose a collation ID, as shown in [Section 9.5.2, “Choosing a Collation ID”](#). The following steps use an ID of 56.
2. You will need to modify the `Index.xml` and `latin1.xml` configuration files. These files will be located in the directory named by the `character_sets_dir` system variable. You can check the variable value as follows, although the path name might be different on your system:

```
mysql> SHOW VARIABLES LIKE 'character_sets_dir';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| character_sets_dir | /user/local/mysql/share/mysql/charsets/ |
+-----+-----+
```

- Choose a name for the collation and list it in the `Index.xml` file. Find the `<charset>` element for the character set to which the collation is being added, and add a `<collation>` element that indicates the collation name and ID. For example:

```
<charset name="latin1">
  ...
  <!-- associate collation name with its ID -->
  <collation name="latin1_test_ci" id="56"/>
  ...
</charset>
```

- In the `latin1.xml` configuration file, add a `<collation>` element that names the collation and that contains a `<map>` element that defines a character code-to-weight mapping table. Each word within the `<map>` element must be a number in hexadecimal format.

```
<collation name="latin1_test_ci">
  <map>
  00 01 02 03 04 05 06 07 08 09 0A 0B 0C 0D 0E 0F
  10 11 12 13 14 15 16 17 18 19 1A 1B 1C 1D 1E 1F
  20 21 22 23 24 25 26 27 28 29 2A 2B 2C 2D 2E 2F
  30 31 32 33 34 35 36 37 38 39 3A 3B 3C 3D 3E 3F
  40 41 42 43 44 45 46 47 48 49 4A 4B 4C 4D 4E 4F
  50 51 52 53 54 55 56 57 58 59 5A 5B 5C 5D 5E 5F
  60 41 42 43 44 45 46 47 48 49 4A 4B 4C 4D 4E 4F
  50 51 52 53 54 55 56 57 58 59 5A 7B 7C 7D 7E 7F
  80 81 82 83 84 85 86 87 88 89 8A 8B 8C 8D 8E 8F
  90 91 92 93 94 95 96 97 98 99 9A 9B 9C 9D 9E 9F
  A0 A1 A2 A3 A4 A5 A6 A7 A8 A9 AA AB AC AD AE AF
  B0 B1 B2 B3 B4 B5 B6 B7 B8 B9 BA BB BC BD BE BF
  41 41 41 41 5B 5D 5B 43 45 45 45 45 49 49 49 49
  44 4E 4F 4F 4F 4F 5C D7 5C 55 55 55 59 59 DE DF
  41 41 41 41 5B 5D 5B 43 45 45 45 45 49 49 49 49
  44 4E 4F 4F 4F 4F 5C F7 5C 55 55 55 59 59 DE FF
  </map>
</collation>
```

- Restart the server and use this statement to verify that the collation is present:

```
mysql> SHOW COLLATION LIKE 'latin1_test_ci';
+-----+-----+-----+-----+-----+-----+
| Collation      | Charset | Id   | Default | Compiled | Sortlen |
+-----+-----+-----+-----+-----+-----+
| latin1_test_ci | latin1  | 56   |         |          | 1       |
+-----+-----+-----+-----+-----+-----+
```

9.5.4. Adding a UCA Collation to a Unicode Character Set

UCA collations for Unicode character sets can be added to MySQL without recompiling by using a subset of the Locale Data Markup Language (LDML), which is available at <http://www.unicode.org/reports/tr35/>. With this method, you begin with an existing “base” collation. Then you describe the new collation in terms of how it differs from the base collation, rather than defining the entire collation. The following table lists the base collations for the Unicode character sets.

Character Set	Base Collation
utf8	utf8_unicode_ci
ucs2	ucs2_unicode_ci

The following brief summary describes the LDML characteristics required for understanding the procedure for adding a collation given later in this section:

- LDML has reset rules and shift rules.
- Characters named in these rules can be written in `\unnnn` format, where `nnnn` is the hexadecimal Unicode code point value. Basic Latin letters `A-Z` and `a-z` can also be written literally (this is a MySQL limitation; the LDML specification allows literal non-Latin1 characters in the rules). Only characters in the Basic Multilingual Plane can be specified. This notation does not apply to characters outside the BMP range of `0000` to `FFFF`.
- A reset rule does not specify any ordering in and of itself. Instead, it “resets” the ordering for subsequent shift rules to cause them to be taken in relation to a given character. Either of the following rules resets subsequent shift rules to be taken in relation to the letter `'A'`:

```
<reset>A</reset>
```

```
<reset>\u0041</reset>
```

- Shift rules define primary, secondary, and tertiary differences of a character from another character. They are specified using `<p>`, `<s>`, and `<t>` elements. Either of the following rules specifies a primary shift rule for the 'G' character:

```
<p>G</p>
<p>\u0047</p>
```

- Use primary differences to distinguish separate letters.
- Use secondary differences to distinguish accent variations.
- Use tertiary differences to distinguish lettercase variations.

To add a UCA collation for a Unicode character set without recompiling MySQL, use the following procedure. The example adds a collation named `utf8_phone_ci` to the `utf8` character set. The collation is designed for a scenario involving a Web application for which users post their names and phone numbers. Phone numbers can be given in very different formats:

```
+7-12345-67
+7-12-345-67
+7 12 345 67
+7 (12) 345 67
+71234567
```

The problem raised by dealing with these kinds of values is that the varying allowable formats make searching for a specific phone number very difficult. The solution is to define a new collation that reorders punctuation characters, making them ignorable.

1. Choose a collation ID, as shown in [Section 9.5.2, “Choosing a Collation ID”](#). The following steps use an ID of 252.
2. You will need to modify the `Index.xml` configuration file. This file will be located in the directory named by the `character_sets_dir` system variable. You can check the variable value as follows, although the path name might be different on your system:

```
mysql> SHOW VARIABLES LIKE 'character_sets_dir';
+-----+-----+
| Variable_name | Value                               |
+-----+-----+
| character_sets_dir | /user/local/mysql/share/mysql/charsets/ |
+-----+-----+
```

3. Choose a name for the collation and list it in the `Index.xml` file. In addition, you'll need to provide the collation ordering rules. Find the `<charset>` element for the character set to which the collation is being added, and add a `<collation>` element that indicates the collation name and ID. Within the `<collation>` element, provide a `<rules>` element containing the ordering rules:

```
<charset name="utf8">
...
<!-- associate collation name with its ID -->
<collation name="utf8_phone_ci" id="252">
  <rules>
    <reset>\u0000</reset>
    <s>\u0020</s> <!-- space -->
    <s>\u0028</s> <!-- left parenthesis -->
    <s>\u0029</s> <!-- right parenthesis -->
    <s>\u002B</s> <!-- plus -->
    <s>\u002D</s> <!-- hyphen -->
  </rules>
</collation>
...
</charset>
```

4. If you want a similar collation for other Unicode character sets, add other `<collation>` elements. For example, to define `ucs2_phone_ci`, add a `<collation>` element to the `<charset name="ucs2">` element. Remember that each collation must have its own unique ID.
5. Restart the server and use this statement to verify that the collation is present:

```
mysql> SHOW COLLATION LIKE 'utf8_phone_ci';
+-----+-----+-----+-----+-----+-----+
| Collation | Charset | Id | Default | Compiled | Sortlen |
+-----+-----+-----+-----+-----+-----+
| utf8_phone_ci | utf8 | 252 | | | 8 |
+-----+-----+-----+-----+-----+-----+

```

Now we can test the collation to make sure that it has the desired properties.

Create a table containing some sample phone numbers using the new collation:

```
mysql> CREATE TABLE phonebook (
->   name VARCHAR(64),
->   phone VARCHAR(64) CHARACTER SET utf8 COLLATE utf8_phone_ci
-> );
Query OK, 0 rows affected (0.09 sec)

mysql> INSERT INTO phonebook VALUES ('Svoj','+7 912 800 80 02');
Query OK, 1 row affected (0.00 sec)

mysql> INSERT INTO phonebook VALUES ('Hf','+7 (912) 800 80 04');
Query OK, 1 row affected (0.00 sec)

mysql> INSERT INTO phonebook VALUES ('Bar','+7-912-800-80-01');
Query OK, 1 row affected (0.00 sec)

mysql> INSERT INTO phonebook VALUES ('Ramil','(7912) 800 80 03');
Query OK, 1 row affected (0.00 sec)

mysql> INSERT INTO phonebook VALUES ('Sanja','+380 (912) 8008005');
Query OK, 1 row affected (0.00 sec)
```

Run some queries to see whether the ignored punctuation characters are in fact ignored for sorting and comparisons:

```
mysql> SELECT * FROM phonebook ORDER BY phone;
+-----+-----+
| name | phone |
+-----+-----+
| Sanja | +380 (912) 8008005 |
| Bar | +7-912-800-80-01 |
| Svoj | +7 912 800 80 02 |
| Ramil | (7912) 800 80 03 |
| Hf | +7 (912) 800 80 04 |
+-----+-----+
5 rows in set (0.00 sec)

mysql> SELECT * FROM phonebook WHERE phone='+7(912)800-80-01';
+-----+-----+
| name | phone |
+-----+-----+
| Bar | +7-912-800-80-01 |
+-----+-----+
1 row in set (0.00 sec)

mysql> SELECT * FROM phonebook WHERE phone='79128008001';
+-----+-----+
| name | phone |
+-----+-----+
| Bar | +7-912-800-80-01 |
+-----+-----+
1 row in set (0.00 sec)

mysql> SELECT * FROM phonebook WHERE phone='7 9 1 2 8 0 0 8 0 0 1';
+-----+-----+
| name | phone |
+-----+-----+
| Bar | +7-912-800-80-01 |
+-----+-----+
1 row in set (0.00 sec)
```

9.6. Problems With Character Sets

If you try to use a character set that is not compiled into your binary, you might run into the following problems:

- Your program uses an incorrect path to determine where the character sets are stored (which is typically the `share/mysql/charsets` or `share/charsets` directory under the MySQL installation directory). This can be fixed by using the `--character-sets-dir` option when you run the program in question. For example, to specify a directory to be used by MySQL client programs, list it in the `[client]` group of your option file. The examples given here show what the setting might look like for Unix or Windows, respectively:

```
[client]
character-sets-dir=/usr/local/mysql/share/mysql/charsets

[client]
character-sets-dir="C:/Program Files/MySQL/MySQL Server 5.4/share/charsets"
```

- The character set is a complex character set that cannot be loaded dynamically. In this case, you must recompile the program

with support for the character set.

For Unicode character sets, you can define collations without recompiling by using LDML notation. See [Section 9.5.4, “Adding a UCA Collation to a Unicode Character Set”](#).

- The character set is a dynamic character set, but you do not have a configuration file for it. In this case, you should install the configuration file for the character set from a new MySQL distribution.
- If your character set index file does not contain the name for the character set, your program displays an error message. The file is named `Index.xml` and the message is:

```
Character set 'charset_name' is not a compiled character set and is not
specified in the '/usr/share/mysql/charsets/Index.xml' file
```

To solve this problem, you should either get a new index file or manually add the name of any missing character sets to the current file.

For [MyISAM](#) tables, you can check the character set name and number for a table with `myisamchk -dvv tbl_name`.

9.7. MySQL Server Time Zone Support

The MySQL server maintains several time zone settings:

- The system time zone. When the server starts, it attempts to determine the time zone of the host machine and uses it to set the `system_time_zone` system variable. The value does not change thereafter.

You can set the system time zone for MySQL Server at startup with the `--timezone=timezone_name` option to `mysqld_safe`. You can also set it by setting the `TZ` environment variable before you start `mysqld`. The allowable values for `--timezone` or `TZ` are system-dependent. Consult your operating system documentation to see what values are acceptable.

- The server's current time zone. The global `time_zone` system variable indicates the time zone the server currently is operating in. The initial value for `time_zone` is `'SYSTEM'`, which indicates that the server time zone is the same as the system time zone.

The initial global server time zone value can be specified explicitly at startup with the `--default-time-zone=timezone` option on the command line, or you can use the following line in an option file:

```
default-time-zone='timezone'
```

If you have the `SUPER` privilege, you can set the global server time zone value at runtime with this statement:

```
mysql> SET GLOBAL time_zone = timezone;
```

- Per-connection time zones. Each client that connects has its own time zone setting, given by the session `time_zone` variable. Initially, the session variable takes its value from the global `time_zone` variable, but the client can change its own time zone with this statement:

```
mysql> SET time_zone = timezone;
```

The current session time zone setting affects display and storage of time values that are zone-sensitive. This includes the values displayed by functions such as `NOW()` or `CURTIME()`, and values stored in and retrieved from `TIMESTAMP` columns. Values for `TIMESTAMP` columns are converted from the current time zone to UTC for storage, and from UTC to the current time zone for retrieval.

The current time zone setting does not affect values displayed by functions such as `UTC_TIMESTAMP()` or values in `DATE`, `TIME`, or `DATETIME` columns. Nor are values in those data types stored in UTC; the time zone applies for them only when converting from `TIMESTAMP` values. If you want locale-specific arithmetic for `DATE`, `TIME`, or `DATETIME` values, convert them to UTC, perform the arithmetic, and then convert back.

The current values of the global and client-specific time zones can be retrieved like this:

```
mysql> SELECT @@global.time_zone, @@session.time_zone;
```

`timezone` values can be given in several formats, none of which are case sensitive:

- The value `'SYSTEM'` indicates that the time zone should be the same as the system time zone.
- The value can be given as a string indicating an offset from UTC, such as `'+10:00'` or `'-6:00'`.
- The value can be given as a named time zone, such as `'Europe/Helsinki'`, `'US/Eastern'`, or `'MET'`. Named time zones can be used only if the time zone information tables in the `mysql` database have been created and populated.

The MySQL installation procedure creates the time zone tables in the `mysql` database, but does not load them. You must do so manually using the following instructions. (If you are upgrading to MySQL 4.1.3 or later from an earlier version, you can create the tables by upgrading your `mysql` database. Use the instructions in [Section 4.4.8, “mysql_upgrade — Check Tables for MySQL Upgrade”](#). After creating the tables, you can load them.)

Note

Loading the time zone information is not necessarily a one-time operation because the information changes occasionally. For example, the rules for Daylight Saving Time in the United States, Mexico, and parts of Canada changed in 2007. When such changes occur, applications that use the old rules become out of date and you may find it necessary to reload the time zone tables to keep the information used by your MySQL server current. See the notes at the end of this section.

If your system has its own `zoneinfo` database (the set of files describing time zones), you should use the `mysql_tzinfo_to_sql` program for filling the time zone tables. Examples of such systems are Linux, FreeBSD, Sun Solaris, and Mac OS X. One likely location for these files is the `/usr/share/zoneinfo` directory. If your system does not have a `zoneinfo` database, you can use the downloadable package described later in this section.

The `mysql_tzinfo_to_sql` program is used to load the time zone tables. On the command line, pass the `zoneinfo` directory path name to `mysql_tzinfo_to_sql` and send the output into the `mysql` program. For example:

```
shell> mysql_tzinfo_to_sql /usr/share/zoneinfo | mysql -u root mysql
```

`mysql_tzinfo_to_sql` reads your system's time zone files and generates SQL statements from them. `mysql` processes those statements to load the time zone tables.

`mysql_tzinfo_to_sql` also can be used to load a single time zone file or to generate leap second information:

- To load a single time zone file `tz_file` that corresponds to a time zone name `tz_name`, invoke `mysql_tzinfo_to_sql` like this:

```
shell> mysql_tzinfo_to_sql tz_file tz_name | mysql -u root mysql
```

With this approach, you must execute a separate command to load the time zone file for each named zone that the server needs to know about.

- If your time zone needs to account for leap seconds, initialize the leap second information like this, where `tz_file` is the name of your time zone file:

```
shell> mysql_tzinfo_to_sql --leap tz_file | mysql -u root mysql
```

- After running `mysql_tzinfo_to_sql`, it is best to restart the server so that it does not continue to use any previously cached time zone data.

If your system is one that has no `zoneinfo` database (for example, Windows or HP-UX), you can use the package of pre-built time zone tables that is available for download at the MySQL Developer Zone:

```
http://dev.mysql.com/downloads/timezones.html
```

This time zone package contains `.frm`, `.MYD`, and `.MYI` files for the `MyISAM` time zone tables. These tables should be part of the `mysql` database, so you should place the files in the `mysql` subdirectory of your MySQL server's data directory. The server should be stopped while you do this and restarted afterward.

Warning

Do not use the downloadable package if your system has a `zoneinfo` database. Use the `mysql_tzinfo_to_sql` utility instead. Otherwise, you may cause a difference in datetime handling between MySQL and other applications on your system.

For information about time zone settings in replication setup, please see [Section 16.3.1, “Replication Features and Issues”](#).

9.7.1. Staying Current with Time Zone Changes

As mentioned earlier, when the time zone rules change, applications that use the old rules become out of date. To stay current, it is necessary to make sure that your system uses current time zone information is used. For MySQL, there are two factors to consider in staying current:

- The operating system time affects the value that the MySQL server uses for times if its time zone is set to `SYSTEM`. Make sure that your operating system is using the latest time zone information. For most operating systems, the latest update or service pack prepares your system for the time changes. Check the Web site for your operating system vendor for an update that addresses the time changes.
- If you replace the system's `/etc/localtime` timezone file with a version that uses rules differing from those in effect at `mysqld` startup, you should restart `mysqld` so that it uses the updated rules. Otherwise, `mysqld` might not notice when the system changes its time.
- If you use named time zones with MySQL, make sure that the time zone tables in the `mysql` database are up to date. If your system has its own zoneinfo database, you should reload the MySQL time zone tables whenever the zoneinfo database is updated, using the instructions given earlier in this section. For systems that do not have their own zoneinfo database, check the MySQL Developer Zone for updates. When a new update is available, download it and use it to replace your current time zone tables. `mysqld` caches time zone information that it looks up, so after replacing the time zone tables, you should restart `mysqld` to make sure that it does not continue to serve outdated time zone data.

If you are uncertain whether named time zones are available, for use either as the server's time zone setting or by clients that set their own time zone, check whether your time zone tables are empty. The following query determines whether the table that contains time zone names has any rows:

```
mysql> SELECT COUNT(*) FROM mysql.time_zone_name;
+-----+
| COUNT(*) |
+-----+
|          0 |
+-----+
```

A count of zero indicates that the table is empty. In this case, no one can be using named time zones, and you don't need to update the tables. A count greater than zero indicates that the table is not empty and that its contents are available to be used for named time zone support. In this case, you should be sure to reload your time zone tables so that anyone who uses named time zones will get correct query results.

To check whether your MySQL installation is updated properly for a change in Daylight Saving Time rules, use a test like the one following. The example uses values that are appropriate for the 2007 DST 1-hour change that occurs in the United States on March 11 at 2 a.m.

The test uses these two queries:

```
SELECT CONVERT_TZ('2007-03-11 2:00:00','US/Eastern','US/Central');
SELECT CONVERT_TZ('2007-03-11 3:00:00','US/Eastern','US/Central');
```

The two time values indicate the times at which the DST change occurs, and the use of named time zones requires that the time zone tables be used. The desired result is that both queries return the same result (the input time, converted to the equivalent value in the 'US/Central' time zone).

Before updating the time zone tables, you would see an incorrect result like this:

```
mysql> SELECT CONVERT_TZ('2007-03-11 2:00:00','US/Eastern','US/Central');
+-----+
| CONVERT_TZ('2007-03-11 2:00:00','US/Eastern','US/Central') |
+-----+
| 2007-03-11 01:00:00 |
+-----+

mysql> SELECT CONVERT_TZ('2007-03-11 3:00:00','US/Eastern','US/Central');
+-----+
| CONVERT_TZ('2007-03-11 3:00:00','US/Eastern','US/Central') |
+-----+
| 2007-03-11 02:00:00 |
+-----+
```

After updating the tables, you should see the correct result:

```
mysql> SELECT CONVERT_TZ('2007-03-11 2:00:00','US/Eastern','US/Central');
```

```

+-----+
| CONVERT_TZ('2007-03-11 2:00:00','US/Eastern','US/Central') |
+-----+
| 2007-03-11 01:00:00 |
+-----+

mysql> SELECT CONVERT_TZ('2007-03-11 3:00:00','US/Eastern','US/Central');
+-----+
| CONVERT_TZ('2007-03-11 3:00:00','US/Eastern','US/Central') |
+-----+
| 2007-03-11 01:00:00 |
+-----+

```

9.7.2. Time Zone Leap Second Support

Leap second values are returned with a time part that ends with `:59:59`. This means that a function such as `NOW()` can return the same value for two or three consecutive seconds during the leap second. It remains true that literal temporal values having a time part that ends with `:59:60` or `:59:61` are considered invalid.

If it is necessary to search for `TIMESTAMP` values one second before the leap second, anomalous results may be obtained if you use a comparison with `'YYYY-MM-DD hh:mm:ss'` values:

```

mysql> CREATE TABLE t1 (a INT, ts TIMESTAMP DEFAULT NOW(), PRIMARY KEY (ts));
Query OK, 0 rows affected (0.11 sec)

mysql> # Simulate NOW() = '2009-01-01 02:59:59'
mysql> SET timestamp = 1230768022;
Query OK, 0 rows affected (0.00 sec)

mysql> INSERT INTO t1 (a) VALUES (1);
Query OK, 1 row affected (0.07 sec)

mysql> # Simulate NOW() = '2009-01-01 02:59:60'
mysql> SET timestamp = 1230768023;
Query OK, 0 rows affected (0.00 sec)

mysql> INSERT INTO t1 (a) VALUES (2);
Query OK, 1 row affected (0.02 sec)

mysql> SELECT * FROM t1;
+-----+
| a | ts |
+-----+
| 1 | 2008-12-31 18:00:22 |
| 2 | 2008-12-31 18:00:23 |
+-----+
2 rows in set (0.02 sec)

mysql> SELECT * FROM t1 WHERE ts = '2009-01-01 02:59:59';
Empty set (0.03 sec)

```

To work around this, you can use a comparison based on the UTC value actually stored in column, which has the leap second correction applied:

```

mysql> SELECT * FROM t1 WHERE UNIX_TIMESTAMP(ts) = 1230768023;
+-----+
| a | ts |
+-----+
| 2 | 2008-12-31 18:00:23 |
+-----+
1 row in set (0.02 sec)

```

9.8. MySQL Server Locale Support

The locale indicated by the `lc_time_names` system variable controls the language used to display day and month names and abbreviations. This variable affects the output from the `DATE_FORMAT()`, `DAYNAME()` and `MONTHNAME()` functions.

Locale names are POSIX-style values such as `'ja_JP'` or `'pt_BR'`. The default value is `'en_US'` regardless of your system's locale setting, but you can set the value at server startup or set the `GLOBAL` value if you have the `SUPER` privilege. Any client can examine the value of `lc_time_names` or set its `SESSION` value to affect the locale for its own connection.

```

mysql> SET NAMES 'utf8';
Query OK, 0 rows affected (0.09 sec)

mysql> SELECT @@lc_time_names;
+-----+
| @@lc_time_names |
+-----+
| en_US |
+-----+
1 row in set (0.00 sec)

mysql> SELECT DAYNAME('2010-01-01'), MONTHNAME('2010-01-01');
+-----+

```

```

| DAYNAME('2010-01-01') | MONTHNAME('2010-01-01') |
+-----+-----+
| Friday | January |
+-----+-----+
1 row in set (0.00 sec)

mysql> SELECT DATE_FORMAT('2010-01-01','%W %a %M %b');
+-----+
| DATE_FORMAT('2010-01-01','%W %a %M %b') |
+-----+
| Friday Fri January Jan |
+-----+
1 row in set (0.00 sec)

mysql> SET lc_time_names = 'es_MX';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT @@lc_time_names;
+-----+
| @@lc_time_names |
+-----+
| es_MX |
+-----+
1 row in set (0.00 sec)

mysql> SELECT DAYNAME('2010-01-01'), MONTHNAME('2010-01-01');
+-----+-----+
| DAYNAME('2010-01-01') | MONTHNAME('2010-01-01') |
+-----+-----+
| viernes | enero |
+-----+-----+
1 row in set (0.00 sec)

mysql> SELECT DATE_FORMAT('2010-01-01','%W %a %M %b');
+-----+
| DATE_FORMAT('2010-01-01','%W %a %M %b') |
+-----+
| viernes vie enero ene |
+-----+
1 row in set (0.00 sec)

```

The day or month name for each of the affected functions is converted from `utf8` to the character set indicated by the `character_set_connection` system variable.

`lc_time_names` may be set to any of the following locale values.

<code>ar_AE</code> : Arabic - United Arab Emirates	<code>ar_BH</code> : Arabic - Bahrain

lc_time_names currently does not affect the STR_TO_DATE() or GET_FORMAT() function.

Chapter 10. Data Types

MySQL supports a number of data types in several categories: numeric types, date and time types, and string (character) types. This chapter first gives an overview of these data types, and then provides a more detailed description of the properties of the types in each category, and a summary of the data type storage requirements. The initial overview is intentionally brief. The more detailed descriptions later in the chapter should be consulted for additional information about particular data types, such as the allowable formats in which you can specify values.

MySQL also supports extensions for handling spatial data. [Section 11.13, “Spatial Extensions”](#), provides information about these data types.

Data type descriptions use these conventions:

- *M* indicates the maximum display width for integer types. For floating-point and fixed-point types, *M* is the total number of digits that can be stored. For string types, *M* is the maximum length. The maximum allowable value of *M* depends on the data type.
- *D* applies to floating-point and fixed-point types and indicates the number of digits following the decimal point. The maximum possible value is 30, but should be no greater than *M*–2.
- Square brackets (“[” and “]”) indicate optional parts of type definitions.

10.1. Data Type Overview

10.1.1. Overview of Numeric Types

A summary of the numeric data types follows. For additional information about properties of the numeric types, see [Section 10.2, “Numeric Types”](#). Storage requirements are given in [Section 10.5, “Data Type Storage Requirements”](#).

M indicates the maximum display width for integer types. The maximum legal display width is 255. Display width is unrelated to the range of values a type can contain, as described in [Section 10.2, “Numeric Types”](#). For floating-point and fixed-point types, *M* is the total number of digits that can be stored.

If you specify `ZEROFILL` for a numeric column, MySQL automatically adds the `UNSIGNED` attribute to the column.

Numeric data types that allow the `UNSIGNED` attribute also allow `SIGNED`. However, these data types are signed by default, so the `SIGNED` attribute has no effect.

`SERIAL` is an alias for `BIGINT UNSIGNED NOT NULL AUTO_INCREMENT UNIQUE`.

`SERIAL DEFAULT VALUE` in the definition of an integer column is an alias for `NOT NULL AUTO_INCREMENT UNIQUE`.

Warning

When you use subtraction between integer values where one is of type `UNSIGNED`, the result is unsigned unless the `NO_UNSIGNED_SUBTRACTION` SQL mode is enabled. See [Section 11.9, “Cast Functions and Operators”](#).

- `BIT(M)`

A bit-field type. *M* indicates the number of bits per value, from 1 to 64. The default is 1 if *M* is omitted.

- `TINYINT(M) [UNSIGNED] [ZEROFILL]`

A very small integer. The signed range is –128 to 127. The unsigned range is 0 to 255.

- `BOOL`, `BOOLEAN`

These types are synonyms for `TINYINT(1)`. A value of zero is considered false. Nonzero values are considered true:

```
mysql> SELECT IF(0, 'true', 'false');
+-----+
| IF(0, 'true', 'false') |
+-----+
| false                  |
+-----+

mysql> SELECT IF(1, 'true', 'false');
+-----+
| IF(1, 'true', 'false') |
+-----+
```

```

| true |
+-----+
mysql> SELECT IF(2, 'true', 'false');
+-----+
| IF(2, 'true', 'false') |
+-----+
| true |
+-----+

```

However, the values `TRUE` and `FALSE` are merely aliases for `1` and `0`, respectively, as shown here:

```

mysql> SELECT IF(0 = FALSE, 'true', 'false');
+-----+
| IF(0 = FALSE, 'true', 'false') |
+-----+
| true |
+-----+

mysql> SELECT IF(1 = TRUE, 'true', 'false');
+-----+
| IF(1 = TRUE, 'true', 'false') |
+-----+
| true |
+-----+

mysql> SELECT IF(2 = TRUE, 'true', 'false');
+-----+
| IF(2 = TRUE, 'true', 'false') |
+-----+
| false |
+-----+

mysql> SELECT IF(2 = FALSE, 'true', 'false');
+-----+
| IF(2 = FALSE, 'true', 'false') |
+-----+
| false |
+-----+

```

The last two statements display the results shown because `2` is equal to neither `1` nor `0`.

We intend to implement full boolean type handling, in accordance with standard SQL, in a future MySQL release.

- `SMALLINT[(M)] [UNSIGNED] [ZEROFILL]`

A small integer. The signed range is `-32768` to `32767`. The unsigned range is `0` to `65535`.

- `MEDIUMINT[(M)] [UNSIGNED] [ZEROFILL]`

A medium-sized integer. The signed range is `-8388608` to `8388607`. The unsigned range is `0` to `16777215`.

- `INT[(M)] [UNSIGNED] [ZEROFILL]`

A normal-size integer. The signed range is `-2147483648` to `2147483647`. The unsigned range is `0` to `4294967295`.

- `INTEGER[(M)] [UNSIGNED] [ZEROFILL]`

This type is a synonym for `INT`.

- `BIGINT[(M)] [UNSIGNED] [ZEROFILL]`

A large integer. The signed range is `-9223372036854775808` to `9223372036854775807`. The unsigned range is `0` to `18446744073709551615`.

`SERIAL` is an alias for `BIGINT UNSIGNED NOT NULL AUTO_INCREMENT UNIQUE`.

Some things you should be aware of with respect to `BIGINT` columns:

- All arithmetic is done using signed `BIGINT` or `DOUBLE` values, so you should not use unsigned big integers larger than `9223372036854775807` (63 bits) except with bit functions! If you do that, some of the last digits in the result may be wrong because of rounding errors when converting a `BIGINT` value to a `DOUBLE`.

MySQL can handle `BIGINT` in the following cases:

- When using integers to store large unsigned values in a `BIGINT` column.
- In `MIN(col_name)` or `MAX(col_name)`, where `col_name` refers to a `BIGINT` column.

- When using operators (+, -, *, and so on) where both operands are integers.
 - You can always store an exact integer value in a `BIGINT` column by storing it using a string. In this case, MySQL performs a string-to-number conversion that involves no intermediate double-precision representation.
 - The -, +, and * operators use `BIGINT` arithmetic when both operands are integer values. This means that if you multiply two big integers (or results from functions that return integers), you may get unexpected results when the result is larger than `9223372036854775807`.
- `FLOAT[(M,D)] [UNSIGNED] [ZEROFILL]`
 A small (single-precision) floating-point number. Allowable values are `-3.402823466E+38` to `-1.175494351E-38`, `0`, and `1.175494351E-38` to `3.402823466E+38`. These are the theoretical limits, based on the IEEE standard. The actual range might be slightly smaller depending on your hardware or operating system.
M is the total number of digits and *D* is the number of digits following the decimal point. If *M* and *D* are omitted, values are stored to the limits allowed by the hardware. A single-precision floating-point number is accurate to approximately 7 decimal places.
`UNSIGNED`, if specified, disallows negative values.
 Using `FLOAT` might give you some unexpected problems because all calculations in MySQL are done with double precision. See [Section B.1.5.7, “Solving Problems with No Matching Rows”](#).
 - `DOUBLE[(M,D)] [UNSIGNED] [ZEROFILL]`
 A normal-size (double-precision) floating-point number. Allowable values are `-1.7976931348623157E+308` to `-2.2250738585072014E-308`, `0`, and `2.2250738585072014E-308` to `1.7976931348623157E+308`. These are the theoretical limits, based on the IEEE standard. The actual range might be slightly smaller depending on your hardware or operating system.
M is the total number of digits and *D* is the number of digits following the decimal point. If *M* and *D* are omitted, values are stored to the limits allowed by the hardware. A double-precision floating-point number is accurate to approximately 15 decimal places.
`UNSIGNED`, if specified, disallows negative values.
 - `DOUBLE PRECISION[(M,D)] [UNSIGNED] [ZEROFILL]`, `REAL[(M,D)] [UNSIGNED] [ZEROFILL]`
 These types are synonyms for `DOUBLE`. Exception: If the `REAL_AS_FLOAT` SQL mode is enabled, `REAL` is a synonym for `FLOAT` rather than `DOUBLE`.
 - `FLOAT(p) [UNSIGNED] [ZEROFILL]`
 A floating-point number. *p* represents the precision in bits, but MySQL uses this value only to determine whether to use `FLOAT` or `DOUBLE` for the resulting data type. If *p* is from 0 to 24, the data type becomes `FLOAT` with no *M* or *D* values. If *p* is from 25 to 53, the data type becomes `DOUBLE` with no *M* or *D* values. The range of the resulting column is the same as for the single-precision `FLOAT` or double-precision `DOUBLE` data types described earlier in this section.
`FLOAT(p)` syntax is provided for ODBC compatibility.
 - `DECIMAL[(M[,D])] [UNSIGNED] [ZEROFILL]`
 A packed “exact” fixed-point number. *M* is the total number of digits (the precision) and *D* is the number of digits after the decimal point (the scale). The decimal point and (for negative numbers) the “-” sign are not counted in *M*. If *D* is 0, values have no decimal point or fractional part. The maximum number of digits (*M*) for `DECIMAL` is 65. The maximum number of supported decimals (*D*) is 30. If *D* is omitted, the default is 0. If *M* is omitted, the default is 10.
`UNSIGNED`, if specified, disallows negative values.
 All basic calculations (+, -, *, /) with `DECIMAL` columns are done with a precision of 65 digits.
 - `DEC[(M[,D])] [UNSIGNED] [ZEROFILL]`, `NUMERIC[(M[,D])] [UNSIGNED] [ZEROFILL]`, `FIXED[(M[,D])] [UNSIGNED] [ZEROFILL]`
 These types are synonyms for `DECIMAL`. The `FIXED` synonym is available for compatibility with other database systems.

10.1.2. Overview of Date and Time Types

A summary of the temporal data types follows. For additional information about properties of the temporal types, see [Section 10.3, “Date and Time Types”](#). Storage requirements are given in [Section 10.5, “Data Type Storage Requirements”](#). Functions that operate on temporal values are described at [Section 11.6, “Date and Time Functions”](#).

For the `DATETIME` and `DATE` range descriptions, “supported” means that although earlier values might work, there is no guarantee.

- `DATE`

A date. The supported range is '1000-01-01' to '9999-12-31'. MySQL displays `DATE` values in 'YYYY-MM-DD' format, but allows assignment of values to `DATE` columns using either strings or numbers.

- `DATETIME`

A date and time combination. The supported range is '1000-01-01 00:00:00' to '9999-12-31 23:59:59'. MySQL displays `DATETIME` values in 'YYYY-MM-DD HH:MM:SS' format, but allows assignment of values to `DATETIME` columns using either strings or numbers.

- `TIMESTAMP`

A timestamp. The range is '1970-01-01 00:00:01' UTC to '2038-01-09 03:14:07' UTC. `TIMESTAMP` values are stored as the number of seconds since the epoch ('1970-01-01 00:00:00' UTC). A `TIMESTAMP` cannot represent the value '1970-01-01 00:00:00' because that is equivalent to 0 seconds from the epoch and the value 0 is reserved for representing '0000-00-00 00:00:00', the “zero” `TIMESTAMP` value.

A `TIMESTAMP` column is useful for recording the date and time of an `INSERT` or `UPDATE` operation. By default, the first `TIMESTAMP` column in a table is automatically set to the date and time of the most recent operation if you do not assign it a value yourself. You can also set any `TIMESTAMP` column to the current date and time by assigning it a `NULL` value. Variations on automatic initialization and update properties are described in [Section 10.3.1.1, “TIMESTAMP Properties”](#).

A `TIMESTAMP` value is returned as a string in the format 'YYYY-MM-DD HH:MM:SS' with a display width fixed at 19 characters. To obtain the value as a number, you should add `+0` to the timestamp column.

Note

The `TIMESTAMP` format that was used prior to MySQL 4.1 is not supported in MySQL 5.4; see *MySQL 3.23, 4.0, 4.1 Reference Manual* for information regarding the old format.

- `TIME`

A time. The range is '-838:59:59' to '838:59:59'. MySQL displays `TIME` values in 'HH:MM:SS' format, but allows assignment of values to `TIME` columns using either strings or numbers.

- `YEAR[(2|4)]`

A year in two-digit or four-digit format. The default is four-digit format. In four-digit format, the allowable values are 1901 to 2155, and 0000. In two-digit format, the allowable values are 70 to 69, representing years from 1970 to 2069. MySQL displays `YEAR` values in `YYYY` format, but allows you to assign values to `YEAR` columns using either strings or numbers.

The `SUM()` and `AVG()` aggregate functions do not work with temporal values. (They convert the values to numbers, which loses the part after the first non-numeric character.) To work around this problem, you can convert to numeric units, perform the aggregate operation, and convert back to a temporal value. Examples:

```
SELECT SEC_TO_TIME(SUM(TIME_TO_SEC(time_col))) FROM tbl_name;  
SELECT FROM_DAYS(SUM(TO_DAYS(date_col))) FROM tbl_name;
```

10.1.3. Overview of String Types

A summary of the string data types follows. For additional information about properties of the string types, see [Section 10.4, “String Types”](#). Storage requirements are given in [Section 10.5, “Data Type Storage Requirements”](#).

In some cases, MySQL may change a string column to a type different from that given in a `CREATE TABLE` or `ALTER TABLE` statement. See [Section 12.1.14.1, “Silent Column Specification Changes”](#).

MySQL interprets length specifications in character column definitions in character units. This applies to `CHAR`, `VARCHAR`, and the `TEXT` types.

Column definitions for many string data types can include attributes that specify the character set or collation of the column. These

attributes apply to the `CHAR`, `VARCHAR`, the `TEXT` types, `ENUM`, and `SET` data types:

- The `CHARACTER SET` attribute specifies the character set, and the `COLLATE` attribute specifies a collation for the character set. For example:

```
CREATE TABLE t
(
  c1 VARCHAR(20) CHARACTER SET utf8,
  c2 TEXT CHARACTER SET latin1 COLLATE latin1_general_cs
);
```

This table definition creates a column named `c1` that has a character set of `utf8` with the default collation for that character set, and a column named `c2` that has a character set of `latin1` and a case-sensitive collation.

The rules for assigning the character set and collation when either or both of the `CHARACTER SET` and `COLLATE` attributes are missing are described in [Section 9.1.3.4, “Column Character Set and Collation”](#).

`CHARSET` is a synonym for `CHARACTER SET`.

- Specifying the `CHARACTER SET binary` attribute for a character data type causes the column to be created as the corresponding binary data type: `CHAR` becomes `BINARY`, `VARCHAR` becomes `VARBINARY`, and `TEXT` becomes `BLOB`. For the `ENUM` and `SET` data types, this does not occur; they are created as declared. Suppose that you specify a table using this definition:

```
CREATE TABLE t
(
  c1 VARCHAR(10) CHARACTER SET binary,
  c2 TEXT CHARACTER SET binary,
  c3 ENUM('a','b','c') CHARACTER SET binary
);
```

The resulting table has this definition:

```
CREATE TABLE t
(
  c1 VARBINARY(10),
  c2 BLOB,
  c3 ENUM('a','b','c') CHARACTER SET binary
);
```

- The `ASCII` attribute is shorthand for `CHARACTER SET latin1`.
- The `UNICODE` attribute is shorthand for `CHARACTER SET ucs2`.
- The `BINARY` attribute is shorthand for specifying the binary collation of the column character set. In this case, sorting and comparison are based on numeric character values.

Character column sorting and comparison are based on the character set assigned to the column. For the `CHAR`, `VARCHAR`, `TEXT`, `ENUM`, and `SET` data types, you can declare a column with a binary collation or the `BINARY` attribute to cause sorting and comparison to use the underlying character code values rather than a lexical ordering.

[Section 9.1, “Character Set Support”](#), provides additional information about use of character sets in MySQL.

- `[NATIONAL] CHAR(M) [CHARACTER SET charset_name] [COLLATE collation_name]`

A fixed-length string that is always right-padded with spaces to the specified length when stored. *M* represents the column length in characters. The range of *M* is 0 to 255. If *M* is omitted, the length is 1.

Note

Trailing spaces are removed when `CHAR` values are retrieved unless the `PAD_CHAR_TO_FULL_LENGTH` SQL mode is enabled.

`CHAR` is shorthand for `CHARACTER`. `NATIONAL CHAR` (or its equivalent short form, `NCHAR`) is the standard SQL way to define that a `CHAR` column should use some predefined character set. MySQL 4.1 and up uses `utf8` as this predefined character set. [Section 9.1.3.6, “National Character Set”](#).

The `CHAR BYTE` data type is an alias for the `BINARY` data type. This is a compatibility feature.

MySQL allows you to create a column of type `CHAR(0)`. This is useful primarily when you have to be compliant with old applications that depend on the existence of a column but that do not actually use its value. `CHAR(0)` is also quite nice when you

need a column that can take only two values: A column that is defined as `CHAR(0) NULL` occupies only one bit and can take only the values `NULL` and `' '` (the empty string).

- `[NATIONAL] VARCHAR(M) [CHARACTER SET charset_name] [COLLATE collation_name]`

A variable-length string. *M* represents the maximum column length in characters. The range of *M* is 0 to 65,535. The effective maximum length of a `VARCHAR` is subject to the maximum row size (65,535 bytes, which is shared among all columns) and the character set used. For example, `utf8` characters can require up to three bytes per character, so a `VARCHAR` column that uses the `utf8` character set can be declared to be a maximum of 21,844 characters.

MySQL stores `VARCHAR` values as a one-byte or two-byte length prefix plus data. The length prefix indicates the number of bytes in the value. A `VARCHAR` column uses one length byte if values require no more than 255 bytes, two length bytes if values may require more than 255 bytes.

Note

MySQL 5.4 follows the standard SQL specification, and does *not* remove trailing spaces from `VARCHAR` values.

`VARCHAR` is shorthand for `CHARACTER VARYING`. `NATIONAL VARCHAR` is the standard SQL way to define that a `VARCHAR` column should use some predefined character set. MySQL 4.1 and up uses `utf8` as this predefined character set. Section 9.1.3.6, “National Character Set”. `NVARCHAR` is shorthand for `NATIONAL VARCHAR`.

- `BINARY(M)`

The `BINARY` type is similar to the `CHAR` type, but stores binary byte strings rather than nonbinary character strings. *M* represents the column length in bytes.

- `VARBINARY(M)`

The `VARBINARY` type is similar to the `VARCHAR` type, but stores binary byte strings rather than nonbinary character strings. *M* represents the maximum column length in bytes.

- `TINYBLOB`

A `BLOB` column with a maximum length of 255 ($2^8 - 1$) bytes. Each `TINYBLOB` value is stored using a one-byte length prefix that indicates the number of bytes in the value.

- `TINYTEXT [CHARACTER SET charset_name] [COLLATE collation_name]`

A `TEXT` column with a maximum length of 255 ($2^8 - 1$) characters. The effective maximum length is less if the value contains multi-byte characters. Each `TINYTEXT` value is stored using a one-byte length prefix that indicates the number of bytes in the value.

- `BLOB(M)`

A `BLOB` column with a maximum length of 65,535 ($2^{16} - 1$) bytes. Each `BLOB` value is stored using a two-byte length prefix that indicates the number of bytes in the value.

An optional length *M* can be given for this type. If this is done, MySQL creates the column as the smallest `BLOB` type large enough to hold values *M* bytes long.

- `TEXT(M) [CHARACTER SET charset_name] [COLLATE collation_name]`

A `TEXT` column with a maximum length of 65,535 ($2^{16} - 1$) characters. The effective maximum length is less if the value contains multi-byte characters. Each `TEXT` value is stored using a two-byte length prefix that indicates the number of bytes in the value.

An optional length *M* can be given for this type. If this is done, MySQL creates the column as the smallest `TEXT` type large enough to hold values *M* characters long.

- `MEDIUMBLOB`

A `BLOB` column with a maximum length of 16,777,215 ($2^{24} - 1$) bytes. Each `MEDIUMBLOB` value is stored using a three-byte length prefix that indicates the number of bytes in the value.

- `MEDIUMTEXT [CHARACTER SET charset_name] [COLLATE collation_name]`

A `TEXT` column with a maximum length of 16,777,215 ($2^{24} - 1$) characters. The effective maximum length is less if the value contains multi-byte characters. Each `MEDIUMTEXT` value is stored using a three-byte length prefix that indicates the number of bytes in the value.

- `LONGBLOB`

A `BLOB` column with a maximum length of 4,294,967,295 or 4GB ($2^{32} - 1$) bytes. The effective maximum length of `LONGBLOB` columns depends on the configured maximum packet size in the client/server protocol and available memory. Each `LONGBLOB` value is stored using a four-byte length prefix that indicates the number of bytes in the value.

- `LONGTEXT [CHARACTER SET charset_name] [COLLATE collation_name]`

A `TEXT` column with a maximum length of 4,294,967,295 or 4GB ($2^{32} - 1$) characters. The effective maximum length is less if the value contains multi-byte characters. The effective maximum length of `LONGTEXT` columns also depends on the configured maximum packet size in the client/server protocol and available memory. Each `LONGTEXT` value is stored using a four-byte length prefix that indicates the number of bytes in the value.

- `ENUM('value1','value2',...) [CHARACTER SET charset_name] [COLLATE collation_name]`

An enumeration. A string object that can have only one value, chosen from the list of values `'value1'`, `'value2'`, ..., `NULL` or the special `'` error value. An `ENUM` column can have a maximum of 65,535 distinct values. `ENUM` values are represented internally as integers.

- `SET('value1','value2',...) [CHARACTER SET charset_name] [COLLATE collation_name]`

A set. A string object that can have zero or more values, each of which must be chosen from the list of values `'value1'`, `'value2'`, ... A `SET` column can have a maximum of 64 members. `SET` values are represented internally as integers.

10.1.4. Data Type Default Values

The `DEFAULT value` clause in a data type specification indicates a default value for a column. With one exception, the default value must be a constant; it cannot be a function or an expression. This means, for example, that you cannot set the default for a date column to be the value of a function such as `NOW()` or `CURRENT_DATE`. The exception is that you can specify `CURRENT_TIMESTAMP` as the default for a `TIMESTAMP` column. See [Section 10.3.1.1, “TIMESTAMP Properties”](#).

`BLOB` and `TEXT` columns cannot be assigned a default value.

If a column definition includes no explicit `DEFAULT` value, MySQL determines the default value as follows:

If the column can take `NULL` as a value, the column is defined with an explicit `DEFAULT NULL` clause.

If the column cannot take `NULL` as the value, MySQL defines the column with no explicit `DEFAULT` clause. For data entry, if an `INSERT` or `REPLACE` statement includes no value for the column, or an `UPDATE` statement sets the column to `NULL`, MySQL handles the column according to the SQL mode in effect at the time:

- If strict SQL mode is not enabled, MySQL sets the column to the implicit default value for the column data type.
- If strict mode is enabled, an error occurs for transactional tables and the statement is rolled back. For non-transactional tables, an error occurs, but if this happens for the second or subsequent row of a multiple-row statement, the preceding rows will have been inserted.

Suppose that a table `t` is defined as follows:

```
CREATE TABLE t (i INT NOT NULL);
```

In this case, `i` has no explicit default, so in strict mode each of the following statements produce an error and no row is inserted. When not using strict mode, only the third statement produces an error; the implicit default is inserted for the first two statements, but the third fails because `DEFAULT(i)` cannot produce a value:

```
INSERT INTO t VALUES ();
INSERT INTO t VALUES (DEFAULT);
INSERT INTO t VALUES (DEFAULT(i));
```

See [Section 5.1.7, “Server SQL Modes”](#).

For a given table, you can use the `SHOW CREATE TABLE` statement to see which columns have an explicit `DEFAULT` clause.

Implicit defaults are defined as follows:

- For numeric types, the default is `0`, with the exception that for integer or floating-point types declared with the

`AUTO_INCREMENT` attribute, the default is the next value in the sequence.

- For date and time types other than `TIMESTAMP`, the default is the appropriate “zero” value for the type. For the first `TIMESTAMP` column in a table, the default value is the current date and time. See [Section 10.3, “Date and Time Types”](#).
- For string types other than `ENUM`, the default value is the empty string. For `ENUM`, the default is the first enumeration value.

`SERIAL DEFAULT VALUE` in the definition of an integer column is an alias for `NOT NULL AUTO_INCREMENT UNIQUE`.

10.2. Numeric Types

MySQL supports all of the standard SQL numeric data types. These types include the exact numeric data types (`INTEGER`, `SMALLINT`, `DECIMAL`, and `NUMERIC`), as well as the approximate numeric data types (`FLOAT`, `REAL`, and `DOUBLE PRECISION`). The keyword `INT` is a synonym for `INTEGER`, and the keyword `DEC` is a synonym for `DECIMAL`. For numeric type storage requirements, see [Section 10.5, “Data Type Storage Requirements”](#).

The numeric types used for the results of calculations depends on the operations being performed and the numeric types of the operands; for more information, see [Section 11.5.1, “Arithmetic Operators”](#).

The `BIT` data type stores bit-field values and is supported for `MyISAM`, `MEMORY`, `InnoDB`, and `NDBCLUSTER` tables.

As an extension to the SQL standard, MySQL also supports the integer types `TINYINT`, `MEDIUMINT`, and `BIGINT`. The following table shows the required storage and range for each of the integer types.

Type	Bytes	Minimum Value (Signed/Unsigned)	Maximum Value (Signed/Unsigned)
<code>TINYINT</code>	1	-128 0	127 255
<code>SMALLINT</code>	2	-32768 0	32767 65535
<code>MEDIUMINT</code>	3	-8388608 0	8388607 16777215
<code>INT</code>	4	-2147483648 0	2147483647 4294967295
<code>BIGINT</code>	8	-9223372036854775808 0	9223372036854775807 18446744073709551615

Another extension is supported by MySQL for optionally specifying the display width of integer data types in parentheses following the base keyword for the type (for example, `INT(4)`). This optional display width may be used by applications to display integer values having a width less than the width specified for the column by left-padding them with spaces. (That is, this width is present in the metadata returned with result sets. Whether it is used or not is up to the application.)

The display width does *not* constrain the range of values that can be stored in the column, nor the number of digits that are displayed for values having a width exceeding that specified for the column. For example, a column specified as `SMALLINT(3)` has the usual `SMALLINT` range of `-32768` to `32767`, and values outside the range allowed by three characters are displayed using more than three characters.

When used in conjunction with the optional extension attribute `ZEROFILL`, the default padding of spaces is replaced with zeros. For example, for a column declared as `INT(5) ZEROFILL`, a value of `4` is retrieved as `00004`. Note that if you store larger values than the display width in an integer column, you may experience problems when MySQL generates temporary tables for some complicated joins, because in these cases MySQL assumes that the data fits into the original column width.

Note

The `ZEROFILL` attribute is ignored when a column is involved in expressions or `UNION` queries.

All integer types can have an optional (non-standard) attribute `UNSIGNED`. Unsigned values can be used when you want to allow only non-negative numbers in a column and you need a larger upper numeric range for the column. For example, if an `INT` column is `UNSIGNED`, the size of the column's range is the same but its endpoints shift from `-2147483648` and `2147483647` up to `0` and `4294967295`.

Floating-point and fixed-point types also can be `UNSIGNED`. As with integer types, this attribute prevents negative values from be-

ing stored in the column. However, unlike the integer types, the upper range of column values remains the same.

If you specify `ZEROFILL` for a numeric column, MySQL automatically adds the `UNSIGNED` attribute to the column.

Integer or floating-point data types can have the additional attribute `AUTO_INCREMENT`. When you insert a value of `NULL` (recommended) or `0` into an indexed `AUTO_INCREMENT` column, the column is set to the next sequence value. Typically this is `value+1`, where `value` is the largest value for the column currently in the table. `AUTO_INCREMENT` sequences begin with `1`.

For floating-point data types, MySQL uses four bytes for single-precision values and eight bytes for double-precision values.

The `FLOAT` and `DOUBLE` data types are used to represent approximate numeric data values. For `FLOAT`, the SQL standard allows an optional specification of the precision (but not the range of the exponent) in bits following the keyword `FLOAT` in parentheses. MySQL also supports this optional precision specification, but the precision value is used only to determine storage size. A precision from 0 to 23 results in a four-byte single-precision `FLOAT` column. A precision from 24 to 53 results in an eight-byte double-precision `DOUBLE` column.

MySQL allows a non-standard syntax: `FLOAT(M,D)` or `REAL(M,D)` or `DOUBLE PRECISION(M,D)`. Here, “`(M,D)`” means that values can be stored with up to `M` digits in total, of which `D` digits may be after the decimal point. For example, a column defined as `FLOAT(7,4)` will look like `-999.9999` when displayed. MySQL performs rounding when storing values, so if you insert `999.00009` into a `FLOAT(7,4)` column, the approximate result is `999.0001`.

MySQL treats `DOUBLE` as a synonym for `DOUBLE PRECISION` (a non-standard extension). MySQL also treats `REAL` as a synonym for `DOUBLE PRECISION` (a non-standard variation), unless the `REAL_AS_FLOAT` SQL mode is enabled.

For maximum portability, code requiring storage of approximate numeric data values should use `FLOAT` or `DOUBLE PRECISION` with no specification of precision or number of digits.

The `DECIMAL` and `NUMERIC` data types are used to store exact numeric data values. In MySQL, `NUMERIC` is implemented as `DECIMAL`. These types are used to store values for which it is important to preserve exact precision, for example with monetary data.

MySQL 5.4 stores `DECIMAL` and `NUMERIC` values in binary format. Before MySQL 5.0.3, they were stored as strings. See [Section 11.14, “Precision Math”](#).

When declaring a `DECIMAL` or `NUMERIC` column, the precision and scale can be (and usually is) specified; for example:

```
salary DECIMAL(5,2)
```

In this example, `5` is the precision and `2` is the scale. The precision represents the number of significant digits that are stored for values, and the scale represents the number of digits that can be stored following the decimal point. If the scale is `0`, `DECIMAL` and `NUMERIC` values contain no decimal point or fractional part.

Standard SQL requires that the `salary` column be able to store any value with five digits and two decimals. In this case, therefore, the range of values that can be stored in the `salary` column is from `-999.99` to `999.99`.

In standard SQL, the syntax `DECIMAL(M)` is equivalent to `DECIMAL(M,0)`. Similarly, the syntax `DECIMAL` is equivalent to `DECIMAL(M,0)`, where the implementation is allowed to decide the value of `M`. MySQL supports both of these variant forms of the `DECIMAL` and `NUMERIC` syntax. The default value of `M` is `10`.

The maximum number of digits for `DECIMAL` or `NUMERIC` is `65`, but the actual range for a given `DECIMAL` or `NUMERIC` column can be constrained by the precision or scale for a given column. When such a column is assigned a value with more digits following the decimal point than are allowed by the specified scale, the value is converted to that scale. (The precise behavior is operating system-specific, but generally the effect is truncation to the allowable number of digits.)

The `BIT` data type is used to store bit-field values. A type of `BIT(M)` allows for storage of `M`-bit values. `M` can range from `1` to `64`.

To specify bit values, `b'value'` notation can be used. `value` is a binary value written using zeros and ones. For example, `b'111'` and `b'1000000'` represent `7` and `128`, respectively. See [Section 8.1.5, “Bit-Field Values”](#).

If you assign a value to a `BIT(M)` column that is less than `M` bits long, the value is padded on the left with zeros. For example, assigning a value of `b'101'` to a `BIT(6)` column is, in effect, the same as assigning `b'000101'`.

When asked to store a value in a numeric column that is outside the data type's allowable range, MySQL's behavior depends on the SQL mode in effect at the time. For example, if no restrictive modes are enabled, MySQL clips the value to the appropriate endpoint of the range and stores the resulting value instead. However, if strict SQL mode is enabled, MySQL rejects a value that is out of range with an error, and the insert fails, in accordance with the SQL standard.

In non-strict mode, when an out-of-range value is assigned to an integer column, MySQL stores the value representing the corresponding endpoint of the column data type range. If you store `256` into a `TINYINT` or `TINYINT UNSIGNED` column, MySQL stores `127` or `255`, respectively. When a floating-point or fixed-point column is assigned a value that exceeds the range implied by the specified (or default) precision and scale, MySQL stores the value representing the corresponding endpoint of that range.

Subtraction between integer values, where one is of type `UNSIGNED`, produces an unsigned result by default. If the result would otherwise have been negative, it becomes the maximum integer value. If the `NO_UNSIGNED_SUBTRACTION` SQL mode is enabled, the result is negative.

```
mysql> SET SQL_MODE = '';
mysql> SELECT CAST(0 AS UNSIGNED) - 1;
+-----+
| CAST(0 AS UNSIGNED) - 1 |
+-----+
| 18446744073709551615 |
+-----+

mysql> SET SQL_MODE = 'NO_UNSIGNED_SUBTRACTION';
mysql> SELECT CAST(0 AS UNSIGNED) - 1;
+-----+
| CAST(0 AS UNSIGNED) - 1 |
+-----+
| -1 |
+-----+
```

If the result of such an operation is used to update an `UNSIGNED` integer column, the result is clipped to the maximum value for the column type, or clipped to 0 if `NO_UNSIGNED_SUBTRACTION` is enabled. If strict SQL mode is enabled, an error occurs and the column remains unchanged.

Conversions that occur due to clipping when MySQL is not operating in strict mode are reported as warnings for `ALTER TABLE`, `LOAD DATA INFILE`, `UPDATE`, and multiple-row `INSERT` statements. When MySQL is operating in strict mode, these statements fail, and some or all of the values will not be inserted or changed, depending on whether the table is a transactional table and other factors. For details, see [Section 5.1.7, “Server SQL Modes”](#).

10.3. Date and Time Types

The date and time types for representing temporal values are `DATETIME`, `DATE`, `TIMESTAMP`, `TIME`, and `YEAR`. Each temporal type has a range of legal values, as well as a “zero” value that may be used when you specify an illegal value that MySQL cannot represent. The `TIMESTAMP` type has special automatic updating behavior, described later on. For temporal type storage requirements, see [Section 10.5, “Data Type Storage Requirements”](#).

MySQL gives warnings or errors if you try to insert an illegal date. By setting the SQL mode to the appropriate value, you can specify more exactly what kind of dates you want MySQL to support. (See [Section 5.1.7, “Server SQL Modes”](#).) You can get MySQL to accept certain dates, such as `'2009-11-31'`, by using the `ALLOW_INVALID_DATES` SQL mode. This is useful when you want to store a “possibly wrong” value which the user has specified (for example, in a web form) in the database for future processing. Under this mode, MySQL verifies only that the month is in the range from 0 to 12 and that the day is in the range from 0 to 31. These ranges are defined to include zero because MySQL allows you to store dates where the day or month and day are zero in a `DATE` or `DATETIME` column. This is extremely useful for applications that need to store a birthdate for which you do not know the exact date. In this case, you simply store the date as `'2009-00-00'` or `'2009-01-00'`. If you store dates such as these, you should not expect to get correct results for functions such as `DATE_SUB()` or `DATE_ADD()` that require complete dates. (If you do *not* want to allow zero in dates, you can use the `NO_ZERO_IN_DATE` SQL mode).

A `DATE` value is coerced to the `DATETIME` type by adding the time portion as `'00:00:00'`. To perform the comparison by ignoring the time part of the `DATETIME` value instead, use the `CAST()` function to perform the comparison in the following way:

```
date_col = CAST(NOW() AS DATE)
```

MySQL also allows you to store `'0000-00-00'` as a “dummy date” (if you are not using the `NO_ZERO_DATE` SQL mode). This is in some cases more convenient (and uses less data and index space) than using `NULL` values.

Here are some general considerations to keep in mind when working with date and time types:

- MySQL retrieves values for a given date or time type in a standard output format, but it attempts to interpret a variety of formats for input values that you supply (for example, when you specify a value to be assigned to or compared to a date or time type). Only the formats described in the following sections are supported. It is expected that you supply legal values. Unpredictable results may occur if you use values in other formats.
- Dates containing two-digit year values are ambiguous because the century is unknown. MySQL interprets two-digit year values using the following rules:
 - Year values in the range `70-99` are converted to `1970-1999`.
 - Year values in the range `00-69` are converted to `2000-2069`.
- Although MySQL tries to interpret values in several formats, dates always must be given in year-month-day order (for example, `'98-09-04'`), rather than in the month-day-year or day-month-year orders commonly used elsewhere (for example, `'09-04-98'`, `'04-09-98'`).

- MySQL automatically converts a date or time type value to a number if the value is used in a numeric context and vice versa.
- By default, when MySQL encounters a value for a date or time type that is out of range or otherwise illegal for the type (as described at the beginning of this section), it converts the value to the “zero” value for that type. The exception is that out-of-range `TIME` values are clipped to the appropriate endpoint of the `TIME` range.

The following table shows the format of the “zero” value for each type. Note that the use of these values produces warnings if the `NO_ZERO_DATE` SQL mode is enabled.

Data Type	“Zero” Value
<code>DATETIME</code>	'0000-00-00 00:00:00'
<code>DATE</code>	'0000-00-00'
<code>TIMESTAMP</code>	'0000-00-00 00:00:00'
<code>TIME</code>	'00:00:00'
<code>YEAR</code>	0000

- The “zero” values are special, but you can store or refer to them explicitly using the values shown in the table. You can also do this using the values '0' or 0, which are easier to write.
- “Zero” date or time values used through MyODBC are converted automatically to `NULL` in MyODBC 2.50.12 and above, because ODBC cannot handle such values.

10.3.1. The `DATETIME`, `DATE`, and `TIMESTAMP` Types

The `DATETIME`, `DATE`, and `TIMESTAMP` types are related. This section describes their characteristics, how they are similar, and how they differ.

The `DATETIME` type is used when you need values that contain both date and time information. MySQL retrieves and displays `DATETIME` values in 'YYYY-MM-DD HH:MM:SS' format. The supported range is '1000-01-01 00:00:00' to '9999-12-31 23:59:59'.

The `DATE` type is used when you need only a date value, without a time part. MySQL retrieves and displays `DATE` values in 'YYYY-MM-DD' format. The supported range is '1000-01-01' to '9999-12-31'.

For the `DATETIME` and `DATE` range descriptions, “supported” means that although earlier values might work, there is no guarantee.

The `TIMESTAMP` data type has a range of '1970-01-01 00:00:01' UTC to '2038-01-09 03:14:07' UTC. It has varying properties, depending on the MySQL version and the SQL mode the server is running in. These properties are described later in this section.

You can specify `DATETIME`, `DATE`, and `TIMESTAMP` values using any of a common set of formats:

- As a string in either 'YYYY-MM-DD HH:MM:SS' or 'YY-MM-DD HH:MM:SS' format. A “relaxed” syntax is allowed: Any punctuation character may be used as the delimiter between date parts or time parts. For example, '98-12-31 11:30:45', '98.12.31 11+30+45', '98/12/31 11*30*45', and '98@12@31 11^30^45' are equivalent.
- As a string in either 'YYYY-MM-DD' or 'YY-MM-DD' format. A “relaxed” syntax is allowed here, too. For example, '98-12-31', '98.12.31', '98/12/31', and '98@12@31' are equivalent.
- As a string with no delimiters in either 'YYYYMMDDHHMMSS' or 'YYMMDDHHMMSS' format, provided that the string makes sense as a date. For example, '20070523091528' and '070523091528' are interpreted as '2007-05-23 09:15:28', but '071122129015' is illegal (it has a nonsensical minute part) and becomes '0000-00-00 00:00:00'.
- As a string with no delimiters in either 'YYYYMMDD' or 'YYMMDD' format, provided that the string makes sense as a date. For example, '20070523' and '070523' are interpreted as '2007-05-23', but '071332' is illegal (it has nonsensical month and day parts) and becomes '0000-00-00'.
- As a number in either `YYYYMMDDHHMMSS` or `YYMMDDHHMMSS` format, provided that the number makes sense as a date. For example, 19830905132800 and 830905132800 are interpreted as '1983-09-05 13:28:00'.
- As a number in either `YYYYMMDD` or `YYMMDD` format, provided that the number makes sense as a date. For example, 19830905 and 830905 are interpreted as '1983-09-05'.

- As the result of a function that returns a value that is acceptable in a `DATETIME`, `DATE`, or `TIMESTAMP` context, such as `NOW()` or `CURRENT_DATE`.

A microseconds part is allowable in temporal values in some contexts, such as in literal values, and in the arguments to or return values from some temporal functions. Microseconds are specified as a trailing `.uuuuuu` part in the value. Example:

```
mysql> SELECT MICROSECOND('2010-12-10 14:12:09.019473');
+-----+
| MICROSECOND('2010-12-10 14:12:09.019473') |
+-----+
| 19473 |
+-----+
```

However, microseconds cannot be stored into a column of any temporal data type. Any microseconds part is discarded.

Conversion of `TIME` or `DATETIME` values to numeric form (for example, by adding `+0`) results in a double value with a micro-seconds part of `.000000`:

```
mysql> SELECT CURTIME(), CURTIME()+0;
+-----+-----+
| CURTIME() | CURTIME()+0 |
+-----+-----+
| 10:41:36 | 104136.000000 |
+-----+-----+
mysql> SELECT NOW(), NOW()+0;
+-----+-----+
| NOW() | NOW()+0 |
+-----+-----+
| 2007-11-30 10:41:47 | 20071130104147.000000 |
+-----+-----+
```

Illegal `DATETIME`, `DATE`, or `TIMESTAMP` values are converted to the “zero” value of the appropriate type (`'0000-00-00 00:00:00'` or `'0000-00-00'`).

For values specified as strings that include date part delimiters, it is not necessary to specify two digits for month or day values that are less than 10. `'1979-6-9'` is the same as `'1979-06-09'`. Similarly, for values specified as strings that include time part delimiters, it is not necessary to specify two digits for hour, minute, or second values that are less than 10. `'1979-10-30 1:2:3'` is the same as `'1979-10-30 01:02:03'`.

Values specified as numbers should be 6, 8, 12, or 14 digits long. If a number is 8 or 14 digits long, it is assumed to be in `YYYYM-MDD` or `YYYYMMDDHHMMSS` format and that the year is given by the first 4 digits. If the number is 6 or 12 digits long, it is assumed to be in `YYMMDD` or `YYMMDDHHMMSS` format and that the year is given by the first 2 digits. Numbers that are not one of these lengths are interpreted as though padded with leading zeros to the closest length.

Values specified as non-delimited strings are interpreted using their length as given. If the string is 8 or 14 characters long, the year is assumed to be given by the first 4 characters. Otherwise, the year is assumed to be given by the first 2 characters. The string is interpreted from left to right to find year, month, day, hour, minute, and second values, for as many parts as are present in the string. This means you should not use strings that have fewer than 6 characters. For example, if you specify `'9903'`, thinking that represents March, 1999, MySQL inserts a “zero” date value into your table. This occurs because the year and month values are 99 and 03, but the day part is completely missing, so the value is not a legal date. However, you can explicitly specify a value of zero to represent missing month or day parts. For example, you can use `'990300'` to insert the value `'1999-03-00'`.

You can to some extent assign values of one date type to an object of a different date type. However, there may be some alteration of the value or loss of information:

- If you assign a `DATE` value to a `DATETIME` or `TIMESTAMP` object, the time part of the resulting value is set to `'00:00:00'` because the `DATE` value contains no time information.
- If you assign a `DATETIME` or `TIMESTAMP` value to a `DATE` object, the time part of the resulting value is deleted because the `DATE` type stores no time information.
- Remember that although `DATETIME`, `DATE`, and `TIMESTAMP` values all can be specified using the same set of formats, the types do not all have the same range of values. For example, `TIMESTAMP` values cannot be earlier than 1970 UTC or later than `'2038-01-09 03:14:07'` UTC. This means that a date such as `'1968-01-01'`, while legal as a `DATETIME` or `DATE` value, is not valid as a `TIMESTAMP` value and is converted to 0.

Be aware of certain problems when specifying date values:

- The relaxed format allowed for values specified as strings can be deceiving. For example, a value such as `'10:11:12'` might look like a time value because of the “:” delimiter, but if used in a date context is interpreted as the year `'2010-11-12'`.

The value `'10:45:15'` is converted to `'0000-00-00'` because `'45'` is not a legal month.

- The server requires that month and day values be legal, and not merely in the range 1 to 12 and 1 to 31, respectively. With strict mode disabled, invalid dates such as `'2004-04-31'` are converted to `'0000-00-00'` and a warning is generated. With strict mode enabled, invalid dates generate an error. To allow such dates, enable `ALLOW_INVALID_DATES`. See [Section 5.1.7, “Server SQL Modes”](#), for more information.
- MySQL does not accept timestamp values that include a zero in the day or month column or values that are not a valid date. The sole exception to this rule is the special value `'0000-00-00 00:00:00'`.
- Dates containing two-digit year values are ambiguous because the century is unknown. MySQL interprets two-digit year values using the following rules:
 - Year values in the range `00-69` are converted to `2000-2069`.
 - Year values in the range `70-99` are converted to `1970-1999`.

10.3.1.1. **TIMESTAMP** Properties

`TIMESTAMP` columns are displayed in the same format as `DATETIME` columns. In other words, the display width is fixed at 19 characters, and the format is `'YYYY-MM-DD HH:MM:SS'`.

`TIMESTAMP` values are converted from the current time zone to UTC for storage, and converted back from UTC to the current time zone for retrieval. (This occurs only for the `TIMESTAMP` data type, not for other types such as `DATETIME`.) By default, the current time zone for each connection is the server's time. The time zone can be set on a per-connection basis, as described in [Section 9.7, “MySQL Server Time Zone Support”](#). As long as the time zone setting remains constant, you get back the same value you store. If you store a `TIMESTAMP` value, and then change the time zone and retrieve the value, the retrieved value is different from the value you stored. This occurs because the same time zone was not used for conversion in both directions. The current time zone is available as the value of the `time_zone` system variable.

The `TIMESTAMP` data type offers automatic initialization and updating. You can choose whether to use these properties and which column should have them:

- For one `TIMESTAMP` column in a table, you can assign the current timestamp as the default value and the auto-update value. It is possible to have the current timestamp be the default value for initializing the column, for the auto-update value, or both. It is not possible to have the current timestamp be the default value for one column and the auto-update value for another column.
- Any single `TIMESTAMP` column in a table can be used as the one that is initialized to the current date and time, or updated automatically. This need not be the first `TIMESTAMP` column.
- If a `DEFAULT` value is specified for the first `TIMESTAMP` column in a table, it is not ignored. The default can be `CURRENT_TIMESTAMP` or a constant date and time value.
- In a `CREATE TABLE` statement, the first `TIMESTAMP` column can be declared in any of the following ways:
 - With both `DEFAULT CURRENT_TIMESTAMP` and `ON UPDATE CURRENT_TIMESTAMP` clauses, the column has the current timestamp for its default value, and is automatically updated.
 - With neither `DEFAULT` nor `ON UPDATE` clauses, it is the same as `DEFAULT CURRENT_TIMESTAMP ON UPDATE CURRENT_TIMESTAMP`.
 - With a `DEFAULT CURRENT_TIMESTAMP` clause and no `ON UPDATE` clause, the column has the current timestamp for its default value but is not automatically updated.
 - With no `DEFAULT` clause and with an `ON UPDATE CURRENT_TIMESTAMP` clause, the column has a default of 0 and is automatically updated.
 - With a constant `DEFAULT` value, the column has the given default and is not automatically initialized to the current timestamp. If the column also has an `ON UPDATE CURRENT_TIMESTAMP` clause, it is automatically updated; otherwise, it has a constant default and is not automatically updated.

In other words, you can use the current timestamp for both the initial value and the auto-update value, or either one, or neither. (For example, you can specify `ON UPDATE` to enable auto-update without also having the column auto-initialized.) The following column definitions demonstrate each of the possibilities:

- Auto-initialization and auto-update:

```
ts TIMESTAMP DEFAULT CURRENT_TIMESTAMP ON UPDATE CURRENT_TIMESTAMP
```

- Auto-initialization only:

```
ts TIMESTAMP DEFAULT CURRENT_TIMESTAMP
```

- Auto-update only:

```
ts TIMESTAMP DEFAULT 0 ON UPDATE CURRENT_TIMESTAMP
```

- Neither:

```
ts TIMESTAMP DEFAULT 0
```

- To specify automatic default or updating for a `TIMESTAMP` column other than the first one, you must suppress the automatic initialization and update behaviors for the first `TIMESTAMP` column by explicitly assigning it a constant `DEFAULT` value (for example, `DEFAULT 0` or `DEFAULT '2003-01-01 00:00:00'`). Then, for the other `TIMESTAMP` column, the rules are the same as for the first `TIMESTAMP` column, except that if you omit both of the `DEFAULT` and `ON UPDATE` clauses, no automatic initialization or updating occurs.

Example:

```
CREATE TABLE t (
  ts1 TIMESTAMP DEFAULT 0,
  ts2 TIMESTAMP DEFAULT CURRENT_TIMESTAMP
  ON UPDATE CURRENT_TIMESTAMP);
```

- `CURRENT_TIMESTAMP` or any of its synonyms (`CURRENT_TIMESTAMP()`, `NOW()`, `LOCALTIME`, `LOCALTIME()`, `LOCALTIMESTAMP`, or `LOCALTIMESTAMP()`) can be used in the `DEFAULT` and `ON UPDATE` clauses. They all mean “the current timestamp.” (`UTC_TIMESTAMP` is not allowed. Its range of values does not align with those of the `TIMESTAMP` column anyway unless the current time zone is `UTC`.)
- The order of the `DEFAULT` and `ON UPDATE` attributes does not matter. If both `DEFAULT` and `ON UPDATE` are specified for a `TIMESTAMP` column, either can precede the other. For example, these statements are equivalent:

```
CREATE TABLE t (ts TIMESTAMP);
CREATE TABLE t (ts TIMESTAMP DEFAULT CURRENT_TIMESTAMP
  ON UPDATE CURRENT_TIMESTAMP);
CREATE TABLE t (ts TIMESTAMP
  ON UPDATE CURRENT_TIMESTAMP
  DEFAULT CURRENT_TIMESTAMP);
```

Note

The examples that use `DEFAULT 0` will not work if the `NO_ZERO_DATE SQL` mode is enabled because that mode causes “zero” date values (specified as `0`, `'0000-00-00`, or `'0000-00-00 00:00:00'`) to be rejected. Be aware that the `TRADITIONAL SQL` mode includes `NO_ZERO_DATE`.

`TIMESTAMP` columns are `NOT NULL` by default, cannot contain `NULL` values, and assigning `NULL` assigns the current timestamp. However, a `TIMESTAMP` column can be allowed to contain `NULL` by declaring it with the `NULL` attribute. In this case, the default value also becomes `NULL` unless overridden with a `DEFAULT` clause that specifies a different default value. `DEFAULT NULL` can be used to explicitly specify `NULL` as the default value. (For a `TIMESTAMP` column not declared with the `NULL` attribute, `DEFAULT NULL` is illegal.) If a `TIMESTAMP` column allows `NULL` values, assigning `NULL` sets it to `NULL`, not to the current timestamp.

The following table contains several `TIMESTAMP` columns that allow `NULL` values:

```
CREATE TABLE t
(
  ts1 TIMESTAMP NULL DEFAULT NULL,
  ts2 TIMESTAMP NULL DEFAULT 0,
  ts3 TIMESTAMP NULL DEFAULT CURRENT_TIMESTAMP
);
```

Note that a `TIMESTAMP` column that allows `NULL` values will *not* take on the current timestamp except under one of the following conditions:

- Its default value is defined as `CURRENT_TIMESTAMP`
- `NOW()` or `CURRENT_TIMESTAMP` is inserted into the column

In other words, a `TIMESTAMP` column defined as `NULL` will auto-initialize only if it is created using a definition such as the following:

```
CREATE TABLE t (ts TIMESTAMP NULL DEFAULT CURRENT_TIMESTAMP);
```

Otherwise — that is, if the `TIMESTAMP` column is defined to allow `NULL` values but not using `DEFAULT CURRENT_TIMESTAMP`, as shown here...

```
CREATE TABLE t1 (ts TIMESTAMP NULL DEFAULT NULL);
CREATE TABLE t2 (ts TIMESTAMP NULL DEFAULT '0000-00-00 00:00:00');
```

...then you must explicitly insert a value corresponding to the current date and time. For example:

```
INSERT INTO t1 VALUES (NOW());
INSERT INTO t2 VALUES (CURRENT_TIMESTAMP);
```

Note

The MySQL server can be run with the `MAXDB` SQL mode enabled. When the server runs with this mode enabled, `TIMESTAMP` is identical with `DATETIME`. That is, if this mode is enabled at the time that a table is created, `TIMESTAMP` columns are created as `DATETIME` columns. As a result, such columns use `DATETIME` display format, have the same range of values, and there is no automatic initialization or updating to the current date and time.

To enable `MAXDB` mode, set the server SQL mode to `MAXDB` at startup using the `--sql-mode=MAXDB` server option or by setting the global `sql_mode` variable at runtime:

```
mysql> SET GLOBAL sql_mode=MAXDB;
```

A client can cause the server to run in `MAXDB` mode for its own connection as follows:

```
mysql> SET SESSION sql_mode=MAXDB;
```

10.3.2. The `TIME` Type

MySQL retrieves and displays `TIME` values in `'HH:MM:SS'` format (or `'HHH:MM:SS'` format for large hours values). `TIME` values may range from `'-838:59:59'` to `'838:59:59'`. The hours part may be so large because the `TIME` type can be used not only to represent a time of day (which must be less than 24 hours), but also elapsed time or a time interval between two events (which may be much greater than 24 hours, or even negative).

You can specify `TIME` values in a variety of formats:

- As a string in `'D HH:MM:SS.fraction'` format. You can also use one of the following “relaxed” syntaxes: `'HH:MM:SS.fraction'`, `'HH:MM:SS'`, `'HH:MM'`, `'D HH:MM:SS'`, `'D HH:MM'`, `'D HH'`, or `'SS'`. Here `D` represents days and can have a value from 0 to 34. Note that MySQL does not store the fraction part.
- As a string with no delimiters in `'HHMMSS'` format, provided that it makes sense as a time. For example, `'101112'` is understood as `'10:11:12'`, but `'109712'` is illegal (it has a nonsensical minute part) and becomes `'00:00:00'`.
- As a number in `HHMMSS` format, provided that it makes sense as a time. For example, `101112` is understood as `'10:11:12'`. The following alternative formats are also understood: `SS`, `MMSS`, `HHMMSS`, `HHMMSS.fraction`. Note that MySQL does not store the fraction part.
- As the result of a function that returns a value that is acceptable in a `TIME` context, such as `CURRENT_TIME`.

A trailing `.uuuuuu` microseconds part of `TIME` values is allowed under the same conditions as for other temporal values, as described in Section 10.3.1, “The `DATETIME`, `DATE`, and `TIMESTAMP` Types”. This includes the property that any microseconds part is discarded from values stored into `TIME` columns.

For `TIME` values specified as strings that include a time part delimiter, it is not necessary to specify two digits for hours, minutes, or seconds values that are less than 10. `'8:3:2'` is the same as `'08:03:02'`.

Be careful about assigning abbreviated values to a `TIME` column. Without colons, MySQL interprets values using the assumption that the two rightmost digits represent seconds. (MySQL interprets `TIME` values as elapsed time rather than as time of day.) For example, you might think of `'1112'` and `1112` as meaning `'11:12:00'` (12 minutes after 11 o'clock), but MySQL interprets them as `'00:11:12'` (11 minutes, 12 seconds). Similarly, `'12'` and `12` are interpreted as `'00:00:12'`. `TIME` values with colons, by contrast, are always treated as time of the day. That is, `'11:12'` mean `'11:12:00'`, not `'00:11:12'`.

By default, values that lie outside the `TIME` range but are otherwise legal are clipped to the closest endpoint of the range. For example, `'-850:00:00'` and `'850:00:00'` are converted to `'-838:59:59'` and `'838:59:59'`. Illegal `TIME` values are converted to `'00:00:00'`. Note that because `'00:00:00'` is itself a legal `TIME` value, there is no way to tell, from a value of `'00:00:00'` stored in a table, whether the original value was specified as `'00:00:00'` or whether it was illegal.

For more restrictive treatment of invalid `TIME` values, enable strict SQL mode to cause errors to occur. See [Section 5.1.7, “Server SQL Modes”](#).

10.3.3. The `YEAR` Type

The `YEAR` type is a one-byte type used for representing years. It can be declared as `YEAR(2)` or `YEAR(4)` to specify a display width of two or four characters. The default is four characters if no width is given.

For four-digit format, MySQL displays `YEAR` values in `YYYY` format, with a range of 1901 to 2155. For two-digit format, MySQL displays values with a range of 70 (1970) to 69 (2069).

You can specify input `YEAR` values in a variety of formats:

- As a four-digit string in the range `'1901'` to `'2155'`.
- As a four-digit number in the range 1901 to 2155.
- As a two-digit string in the range `'00'` to `'99'`. Values in the ranges `'00'` to `'69'` and `'70'` to `'99'` are converted to `YEAR` values in the ranges 2000 to 2069 and 1970 to 1999.
- As a two-digit number in the range 1 to 99. Values in the ranges 1 to 69 and 70 to 99 are converted to `YEAR` values in the ranges 2001 to 2069 and 1970 to 1999. Note that the range for two-digit numbers is slightly different from the range for two-digit strings, because you cannot specify zero directly as a number and have it be interpreted as 2000. You must specify it as a string `'0'` or `'00'` or it is interpreted as 0000.
- As the result of a function that returns a value that is acceptable in a `YEAR` context, such as `NOW()`.

Illegal `YEAR` values are converted to 0000.

10.3.4. Year 2000 Issues and Date Types

MySQL Server itself has no problems with Year 2000 (Y2K) compliance:

- MySQL Server uses Unix time functions that handle dates into the year 2038 for `TIMESTAMP` values. For `DATE` and `DATE-TIME` values, dates through the year 9999 are accepted.
- All MySQL date functions are implemented in one source file, `sql/time.cc`, and are coded very carefully to be year 2000-safe.
- In MySQL, the `YEAR` data type can store the years 0 and 1901 to 2155 in one byte and display them using two or four digits. All two-digit years are considered to be in the range 1970 to 2069, which means that if you store 01 in a `YEAR` column, MySQL Server treats it as 2001.

Although MySQL Server itself is Y2K-safe, you may run into problems if you use it with applications that are not Y2K-safe. For example, many old applications store or manipulate years using two-digit values (which are ambiguous) rather than four-digit values. This problem may be compounded by applications that use values such as 00 or 99 as “missing” value indicators. Unfortunately, these problems may be difficult to fix because different applications may be written by different programmers, each of whom may use a different set of conventions and date-handling functions.

Thus, even though MySQL Server has no Y2K problems, *it is the application's responsibility to provide unambiguous input*. Any value containing a two-digit year is ambiguous, because the century is unknown. Such values must be interpreted into four-digit form because MySQL stores years internally using four digits.

For `DATETIME`, `DATE`, `TIMESTAMP`, and `YEAR` types, MySQL interprets dates with ambiguous year values using the following rules:

- Year values in the range 00–69 are converted to 2000–2069.
- Year values in the range 70–99 are converted to 1970–1999.

Remember that these rules are only heuristics that provide reasonable guesses as to what your data values mean. If the rules used by MySQL do not produce the correct values, you should provide unambiguous input containing four-digit year values.

`ORDER BY` properly sorts `YEAR` values that have two-digit years.

Some functions like `MIN()` and `MAX()` convert a `YEAR` to a number. This means that a value with a two-digit year does not work properly with these functions. The fix in this case is to convert the `TIMESTAMP` or `YEAR` to four-digit year format.

10.4. String Types

The string types are `CHAR`, `VARCHAR`, `BINARY`, `VARBINARY`, `BLOB`, `TEXT`, `ENUM`, and `SET`. This section describes how these types work and how to use them in your queries. For string type storage requirements, see [Section 10.5, “Data Type Storage Requirements”](#).

10.4.1. The `CHAR` and `VARCHAR` Types

The `CHAR` and `VARCHAR` types are similar, but differ in the way they are stored and retrieved. They also differ in maximum length and in whether trailing spaces are retained.

The `CHAR` and `VARCHAR` types are declared with a length that indicates the maximum number of characters you want to store. For example, `CHAR(30)` can hold up to 30 characters.

The length of a `CHAR` column is fixed to the length that you declare when you create the table. The length can be any value from 0 to 255. When `CHAR` values are stored, they are right-padded with spaces to the specified length. When `CHAR` values are retrieved, trailing spaces are removed unless the `PAD_CHAR_TO_FULL_LENGTH` SQL mode is enabled.

Values in `VARCHAR` columns are variable-length strings. The length can be specified as a value from 0 to 65,535. The effective maximum length of a `VARCHAR` is subject to the maximum row size (65,535 bytes, which is shared among all columns) and the character set used.

In contrast to `CHAR`, `VARCHAR` values are stored as a one-byte or two-byte length prefix plus data. The length prefix indicates the number of bytes in the value. A column uses one length byte if values require no more than 255 bytes, two length bytes if values may require more than 255 bytes.

If strict SQL mode is not enabled and you assign a value to a `CHAR` or `VARCHAR` column that exceeds the column's maximum length, the value is truncated to fit and a warning is generated. For truncation of non-space characters, you can cause an error to occur (rather than a warning) and suppress insertion of the value by using strict SQL mode. See [Section 5.1.7, “Server SQL Modes”](#).

For `VARCHAR` columns, trailing spaces in excess of the column length are truncated prior to insertion and a warning is generated, regardless of the SQL mode in use. For `CHAR` columns, truncation of excess trailing spaces from inserted values is performed silently regardless of the SQL mode.

`VARCHAR` values are not padded when they are stored. Trailing spaces are retained when values are stored and retrieved, in conformance with standard SQL.

The following table illustrates the differences between `CHAR` and `VARCHAR` by showing the result of storing various string values into `CHAR(4)` and `VARCHAR(4)` columns (assuming that the column uses a single-byte character set such as `latin1`).

Value	CHAR(4)	Storage Required	VARCHAR(4)	Storage Required
' '	' '	4 bytes	' '	1 byte
'ab'	'ab '	4 bytes	'ab'	3 bytes
'abcd'	'abcd'	4 bytes	'abcd'	5 bytes
'abcdefgh'	'abcd'	4 bytes	'abcd'	5 bytes

The values shown as stored in the last row of the table apply *only when not using strict mode*; if MySQL is running in strict mode, values that exceed the column length are *not stored*, and an error results.

If a given value is stored into the `CHAR(4)` and `VARCHAR(4)` columns, the values retrieved from the columns are not always the same because trailing spaces are removed from `CHAR` columns upon retrieval. The following example illustrates this difference:

```
mysql> CREATE TABLE vc (v VARCHAR(4), c CHAR(4));
Query OK, 0 rows affected (0.01 sec)

mysql> INSERT INTO vc VALUES ('ab ', 'ab ');
Query OK, 1 row affected (0.00 sec)

mysql> SELECT CONCAT('(', v, ')'), CONCAT('(', c, ')') FROM vc;
+-----+-----+
| CONCAT('(', v, ')') | CONCAT('(', c, ')') |
+-----+-----+
```

```

+-----+-----+
| (ab ) | (ab) |
+-----+-----+
1 row in set (0.06 sec)

```

Values in `CHAR` and `VARCHAR` columns are sorted and compared according to the character set collation assigned to the column.

All MySQL collations are of type `PADSPACE`. This means that all `CHAR` and `VARCHAR` values in MySQL are compared without regard to any trailing spaces. For example:

```

mysql> CREATE TABLE names (myname CHAR(10), yourname VARCHAR(10));
Query OK, 0 rows affected (0.09 sec)

mysql> INSERT INTO names VALUES ('Monty ', 'Monty ');
Query OK, 1 row affected (0.00 sec)

mysql> SELECT myname = 'Monty ', yourname = 'Monty ' FROM names;
+-----+-----+
| myname = 'Monty ' | yourname = 'Monty ' |
+-----+-----+
| 1 | 1 |
+-----+-----+
1 row in set (0.00 sec)

```

This is true for all MySQL versions, and that it is not affected by the server SQL mode.

For those cases where trailing pad characters are stripped or comparisons ignore them, if a column has an index that requires unique values, inserting into the column values that differ only in number of trailing pad characters will result in a duplicate-key error. For example, if a table contains 'a', an attempt to store 'a ' causes a duplicate-key error.

10.4.2. The `BINARY` and `VARBINARY` Types

The `BINARY` and `VARBINARY` types are similar to `CHAR` and `VARCHAR`, except that they contain binary strings rather than non-binary strings. That is, they contain byte strings rather than character strings. This means that they have no character set, and sorting and comparison are based on the numeric values of the bytes in the values.

The allowable maximum length is the same for `BINARY` and `VARBINARY` as it is for `CHAR` and `VARCHAR`, except that the length for `BINARY` and `VARBINARY` is a length in bytes rather than in characters.

The `BINARY` and `VARBINARY` data types are distinct from the `CHAR BINARY` and `VARCHAR BINARY` data types. For the latter types, the `BINARY` attribute does not cause the column to be treated as a binary string column. Instead, it causes the binary collation for the column character set to be used, and the column itself contains nonbinary character strings rather than binary byte strings. For example, `CHAR(5) BINARY` is treated as `CHAR(5) CHARACTER SET latin1 COLLATE latin1_bin`, assuming that the default character set is `latin1`. This differs from `BINARY(5)`, which stores 5-bytes binary strings that have no character set or collation. For information about differences between nonbinary string binary collations and binary strings, see [Section 9.1.6.4, “The `_bin` and binary Collations”](#).

If strict SQL mode is not enabled and you assign a value to a `BINARY` or `VARBINARY` column that exceeds the column's maximum length, the value is truncated to fit and a warning is generated. For cases of truncation, you can cause an error to occur (rather than a warning) and suppress insertion of the value by using strict SQL mode. See [Section 5.1.7, “Server SQL Modes”](#).

When `BINARY` values are stored, they are right-padded with the pad value to the specified length. The pad value is `0x00` (the zero byte). Values are right-padded with `0x00` on insert, and no trailing bytes are removed on select. All bytes are significant in comparisons, including `ORDER BY` and `DISTINCT` operations. `0x00` bytes and spaces are different in comparisons, with `0x00 < space`.

Example: For a `BINARY(3)` column, 'a ' becomes 'a \0' when inserted. 'a\0' becomes 'a\0\0' when inserted. Both inserted values remain unchanged when selected.

For `VARBINARY`, there is no padding on insert and no bytes are stripped on select. All bytes are significant in comparisons, including `ORDER BY` and `DISTINCT` operations. `0x00` bytes and spaces are different in comparisons, with `0x00 < space`.

For those cases where trailing pad bytes are stripped or comparisons ignore them, if a column has an index that requires unique values, inserting into the column values that differ only in number of trailing pad bytes will result in a duplicate-key error. For example, if a table contains 'a', an attempt to store 'a\0' causes a duplicate-key error.

You should consider the preceding padding and stripping characteristics carefully if you plan to use the `BINARY` data type for storing binary data and you require that the value retrieved be exactly the same as the value stored. The following example illustrates how `0x00`-padding of `BINARY` values affects column value comparisons:

```

mysql> CREATE TABLE t (c BINARY(3));
Query OK, 0 rows affected (0.01 sec)

mysql> INSERT INTO t SET c = 'a';
Query OK, 1 row affected (0.01 sec)

```

```
mysql> SELECT HEX(c), c = 'a', c = 'a\0\0' from t;
+-----+-----+-----+
| HEX(c) | c = 'a' | c = 'a\0\0' |
+-----+-----+-----+
| 610000 | 0       | 1           |
+-----+-----+-----+
1 row in set (0.09 sec)
```

If the value retrieved must be the same as the value specified for storage with no padding, it might be preferable to use [VARBINARY](#) or one of the [BLOB](#) data types instead.

10.4.3. The [BLOB](#) and [TEXT](#) Types

A [BLOB](#) is a binary large object that can hold a variable amount of data. The four [BLOB](#) types are [TINYBLOB](#), [BLOB](#), [MEDIUMBLOB](#), and [LONGBLOB](#). These differ only in the maximum length of the values they can hold. The four [TEXT](#) types are [TINYTEXT](#), [TEXT](#), [MEDIUMTEXT](#), and [LONGTEXT](#). These correspond to the four [BLOB](#) types and have the same maximum lengths and storage requirements. See [Section 10.5, “Data Type Storage Requirements”](#).

[BLOB](#) columns are treated as binary strings (byte strings). [TEXT](#) columns are treated as nonbinary strings (character strings). [BLOB](#) columns have no character set, and sorting and comparison are based on the numeric values of the bytes in column values. [TEXT](#) columns have a character set, and values are sorted and compared based on the collation of the character set.

If strict SQL mode is not enabled and you assign a value to a [BLOB](#) or [TEXT](#) column that exceeds the column's maximum length, the value is truncated to fit and a warning is generated. For truncation of non-space characters, you can cause an error to occur (rather than a warning) and suppress insertion of the value by using strict SQL mode. See [Section 5.1.7, “Server SQL Modes”](#).

Truncation of excess trailing spaces from values to be inserted into [TEXT](#) columns always generates a warning, regardless of the SQL mode. ([Bug#30059](#))

If a [TEXT](#) column is indexed, index entry comparisons are space-padded at the end. This means that, if the index requires unique values, duplicate-key errors will occur for values that differ only in the number of trailing spaces. For example, if a table contains 'a', an attempt to store 'a ' causes a duplicate-key error. This is not true for [BLOB](#) columns.

In most respects, you can regard a [BLOB](#) column as a [VARBINARY](#) column that can be as large as you like. Similarly, you can regard a [TEXT](#) column as a [VARCHAR](#) column. [BLOB](#) and [TEXT](#) differ from [VARBINARY](#) and [VARCHAR](#) in the following ways:

- For indexes on [BLOB](#) and [TEXT](#) columns, you must specify an index prefix length. For [CHAR](#) and [VARCHAR](#), a prefix length is optional. See [Section 7.4.2, “Column Indexes”](#).
- [BLOB](#) and [TEXT](#) columns cannot have [DEFAULT](#) values.

[LONG](#) and [LONG VARCHAR](#) map to the [MEDIUMTEXT](#) data type. This is a compatibility feature. If you use the [BINARY](#) attribute with a [TEXT](#) data type, the column is assigned the binary collation of the column character set.

MySQL Connector/ODBC defines [BLOB](#) values as [LONGVARBINARY](#) and [TEXT](#) values as [LONGVARCHAR](#).

Because [BLOB](#) and [TEXT](#) values can be extremely long, you might encounter some constraints in using them:

- Only the first `max_sort_length` bytes of the column are used when sorting. The default value of `max_sort_length` is 1024. This value can be changed using the `--max_sort_length=N` option when starting the `mysqld` server. See [Section 5.1.3, “Server System Variables”](#).

You can make more bytes significant in sorting or grouping by increasing the value of `max_sort_length` at runtime. Any client can change the value of its session `max_sort_length` variable:

```
mysql> SET max_sort_length = 2000;
mysql> SELECT id, comment FROM t
-> ORDER BY comment;
```

Another way to use [GROUP BY](#) or [ORDER BY](#) on a [BLOB](#) or [TEXT](#) column containing long values when you want more than `max_sort_length` bytes to be significant is to convert the column value into a fixed-length object. The standard way to do this is with the [SUBSTRING\(\)](#) function. For example, the following statement causes 2000 bytes of the `comment` column to be taken into account for sorting:

```
mysql> SELECT id, SUBSTRING(comment,1,2000) FROM t
-> ORDER BY SUBSTRING(comment,1,2000);
```

- The maximum size of a [BLOB](#) or [TEXT](#) object is determined by its type, but the largest value you actually can transmit between the client and server is determined by the amount of available memory and the size of the communications buffers. You can

change the message buffer size by changing the value of the `max_allowed_packet` variable, but you must do so for both the server and your client program. For example, both `mysql` and `mysqldump` allow you to change the client-side `max_allowed_packet` value. See Section 7.5.3, “Tuning Server Parameters”, Section 4.5.1, “`mysql` — The MySQL Command-Line Tool”, and Section 4.5.4, “`mysqldump` — A Database Backup Program”. You may also want to compare the packet sizes and the size of the data objects you are storing with the storage requirements, see Section 10.5, “Data Type Storage Requirements”

Each `BLOB` or `TEXT` value is represented internally by a separately allocated object. This is in contrast to all other data types, for which storage is allocated once per column when the table is opened.

In some cases, it may be desirable to store binary data such as media files in `BLOB` or `TEXT` columns. You may find MySQL's string handling functions useful for working with such data. See Section 11.4, “String Functions”. For security and other reasons, it is usually preferable to do so using application code rather than allowing application users the `FILE` privilege. You can discuss specifics for various languages and platforms in the MySQL Forums (<http://forums.mysql.com/>).

10.4.4. The `ENUM` Type

An `ENUM` is a string object with a value chosen from a list of allowed values that are enumerated explicitly in the column specification at table creation time.

An enumeration value must be a quoted string literal; it may not be an expression, even one that evaluates to a string value. For example, you can create a table with an `ENUM` column like this:

```
CREATE TABLE sizes (
  name ENUM('small', 'medium', 'large')
);
```

However, this version of the previous `CREATE TABLE` statement does *not* work:

```
CREATE TABLE sizes (
  cl ENUM('small', CONCAT('med','ium')), 'large')
);
```

You also may not employ a user variable as an enumeration value. This pair of statements do *not* work:

```
SET @mysize = 'medium';
CREATE TABLE sizes (
  name ENUM('small', @mysize, 'large')
);
```

If you wish to use a number as an enumeration value, you must enclose it in quotes.

Duplicate values in the definition cause a warning, or an error if strict SQL mode is enabled.

The value may also be the empty string (' ') or `NULL` under certain circumstances:

- If you insert an invalid value into an `ENUM` (that is, a string not present in the list of allowed values), the empty string is inserted instead as a special error value. This string can be distinguished from a “normal” empty string by the fact that this string has the numerical value 0. More about this later.

If strict SQL mode is enabled, attempts to insert invalid `ENUM` values result in an error.

- If an `ENUM` column is declared to allow `NULL`, the `NULL` value is a legal value for the column, and the default value is `NULL`. If an `ENUM` column is declared `NOT NULL`, its default value is the first element of the list of allowed values.

Each enumeration value has an index:

- Values from the list of allowable elements in the column specification are numbered beginning with 1.
- The index value of the empty string error value is 0. This means that you can use the following `SELECT` statement to find rows into which invalid `ENUM` values were assigned:

```
mysql> SELECT * FROM tbl_name WHERE enum_col=0;
```

- The index of the `NULL` value is `NULL`.

- The term “index” here refers only to position within the list of enumeration values. It has nothing to do with table indexes.

For example, a column specified as `ENUM('one', 'two', 'three')` can have any of the values shown here. The index of each value is also shown.

Value	Index
<code>NULL</code>	<code>NULL</code>
<code>' '</code>	0
<code>'one'</code>	1
<code>'two'</code>	2
<code>'three'</code>	3

An enumeration can have a maximum of 65,535 elements.

Trailing spaces are automatically deleted from `ENUM` member values in the table definition when a table is created.

When retrieved, values stored into an `ENUM` column are displayed using the lettercase that was used in the column definition. Note that `ENUM` columns can be assigned a character set and collation. For binary or case-sensitive collations, lettercase is taken into account when assigning values to the column.

If you retrieve an `ENUM` value in a numeric context, the column value's index is returned. For example, you can retrieve numeric values from an `ENUM` column like this:

```
mysql> SELECT enum_col+0 FROM tbl_name;
```

If you store a number into an `ENUM` column, the number is treated as the index into the possible values, and the value stored is the enumeration member with that index. (However, this does *not* work with `LOAD DATA`, which treats all input as strings.) If the numeric value is quoted, it is still interpreted as an index if there is no matching string in the list of enumeration values. For these reasons, it is not advisable to define an `ENUM` column with enumeration values that look like numbers, because this can easily become confusing. For example, the following column has enumeration members with string values of `'0'`, `'1'`, and `'2'`, but numeric index values of 1, 2, and 3:

```
numbers ENUM('0','1','2')
```

If you store 2, it is interpreted as an index value, and becomes `'1'` (the value with index 2). If you store `'2'`, it matches an enumeration value, so it is stored as `'2'`. If you store `'3'`, it does not match any enumeration value, so it is treated as an index and becomes `'2'` (the value with index 3).

```
mysql> INSERT INTO t (numbers) VALUES(2),('2'),('3');
mysql> SELECT * FROM t;
+-----+
| numbers |
+-----+
| 1       |
| 2       |
| 2       |
+-----+
```

`ENUM` values are sorted according to the order in which the enumeration members were listed in the column specification. (In other words, `ENUM` values are sorted according to their index numbers.) For example, `'a'` sorts before `'b'` for `ENUM('a', 'b')`, but `'b'` sorts before `'a'` for `ENUM('b', 'a')`. The empty string sorts before non-empty strings, and `NULL` values sort before all other enumeration values. To prevent unexpected results, specify the `ENUM` list in alphabetical order. You can also use `GROUP BY CAST(col AS CHAR)` or `GROUP BY CONCAT(col)` to make sure that the column is sorted lexically rather than by index number.

Functions such as `SUM()` or `AVG()` that expect a numeric argument cast the argument to a number if necessary. For `ENUM` values, the cast operation causes the index number to be used.

If you want to determine all possible values for an `ENUM` column, use `SHOW COLUMNS FROM tbl_name LIKE enum_col` and parse the `ENUM` definition in the `Type` column of the output.

10.4.5. The `SET` Type

A `SET` is a string object that can have zero or more values, each of which must be chosen from a list of allowed values specified when the table is created. `SET` column values that consist of multiple set members are specified with members separated by commas (`,`). A consequence of this is that `SET` member values should not themselves contain commas.

For example, a column specified as `SET('one', 'two') NOT NULL` can have any of these values:

```
' '
'one'
'two'
'one,two'
```

A `SET` can have a maximum of 64 different members.

Duplicate values in the definition cause a warning, or an error if strict SQL mode is enabled.

Trailing spaces are automatically deleted from `SET` member values in the table definition when a table is created.

When retrieved, values stored in a `SET` column are displayed using the lettercase that was used in the column definition. Note that `SET` columns can be assigned a character set and collation. For binary or case-sensitive collations, lettercase is taken into account when assigning values to the column.

MySQL stores `SET` values numerically, with the low-order bit of the stored value corresponding to the first set member. If you retrieve a `SET` value in a numeric context, the value retrieved has bits set corresponding to the set members that make up the column value. For example, you can retrieve numeric values from a `SET` column like this:

```
mysql> SELECT set_col+0 FROM tbl_name;
```

If a number is stored into a `SET` column, the bits that are set in the binary representation of the number determine the set members in the column value. For a column specified as `SET('a', 'b', 'c', 'd')`, the members have the following decimal and binary values.

SET Member	Decimal Value	Binary Value
'a'	1	0001
'b'	2	0010
'c'	4	0100
'd'	8	1000

If you assign a value of 9 to this column, that is 1001 in binary, so the first and fourth `SET` value members 'a' and 'd' are selected and the resulting value is 'a,d'.

For a value containing more than one `SET` element, it does not matter what order the elements are listed in when you insert the value. It also does not matter how many times a given element is listed in the value. When the value is retrieved later, each element in the value appears once, with elements listed according to the order in which they were specified at table creation time. For example, suppose that a column is specified as `SET('a', 'b', 'c', 'd')`:

```
mysql> CREATE TABLE myset (col SET('a', 'b', 'c', 'd'));
```

If you insert the values 'a,d', 'd,a', 'a,d,d', 'a,d,a', and 'd,a,d':

```
mysql> INSERT INTO myset (col) VALUES
-> ('a,d'), ('d,a'), ('a,d,a'), ('a,d,d'), ('d,a,d');
Query OK, 5 rows affected (0.01 sec)
Records: 5 Duplicates: 0 Warnings: 0
```

Then all of these values appear as 'a,d' when retrieved:

```
mysql> SELECT col FROM myset;
+-----+
| col   |
+-----+
| a,d   |
| a,d   |
| a,d   |
| a,d   |
| a,d   |
+-----+
5 rows in set (0.04 sec)
```

If you set a `SET` column to an unsupported value, the value is ignored and a warning is issued:

```
mysql> INSERT INTO myset (col) VALUES ('a,d,d,s');
Query OK, 1 row affected, 1 warning (0.03 sec)

mysql> SHOW WARNINGS;
+-----+-----+-----+
| Level | Code | Message |
+-----+-----+-----+
```

```

+-----+-----+-----+
| Warning | 1265 | Data truncated for column 'col' at row 1 |
+-----+-----+-----+
1 row in set (0.04 sec)

mysql> SELECT col FROM myset;
+-----+
| col |
+-----+
| a,d |
| a,d |
| a,d |
| a,d |
| a,d |
| a,d |
+-----+
6 rows in set (0.01 sec)

```

If strict SQL mode is enabled, attempts to insert invalid `SET` values result in an error.

`SET` values are sorted numerically. `NULL` values sort before non-`NULL SET` values.

Functions such as `SUM()` or `AVG()` that expect a numeric argument cast the argument to a number if necessary. For `SET` values, the cast operation causes the numeric value to be used.

Normally, you search for `SET` values using the `FIND_IN_SET()` function or the `LIKE` operator:

```

mysql> SELECT * FROM tbl_name WHERE FIND_IN_SET('value',set_col)>0;
mysql> SELECT * FROM tbl_name WHERE set_col LIKE '%value%';

```

The first statement finds rows where `set_col` contains the `value` set member. The second is similar, but not the same: It finds rows where `set_col` contains `value` anywhere, even as a substring of another set member.

The following statements also are legal:

```

mysql> SELECT * FROM tbl_name WHERE set_col & 1;
mysql> SELECT * FROM tbl_name WHERE set_col = 'val1,val2';

```

The first of these statements looks for values containing the first set member. The second looks for an exact match. Be careful with comparisons of the second type. Comparing set values to `'val1,val2'` returns different results than comparing values to `'val2,val1'`. You should specify the values in the same order they are listed in the column definition.

If you want to determine all possible values for a `SET` column, use `SHOW COLUMNS FROM tbl_name LIKE set_col` and parse the `SET` definition in the `Type` column of the output.

10.5. Data Type Storage Requirements

The storage requirements for each of the data types supported by MySQL are listed here by category.

The maximum size of a row in a `MyISAM` table is 65,535 bytes. (However, each `BLOB` or `TEXT` column contributes only 9-12 bytes toward this size.) This limitation may be shared by other storage engines as well. See [Chapter 13, Storage Engines](#), for more information.

Important

For tables using the `NDBCLUSTER` storage engine, there is the factor of *4-byte alignment* to be taken into account when calculating storage requirements. This means that all `NDB` data storage is done in multiples of 4 bytes. Thus, a column value that would take 15 bytes in a table using a storage engine other than `NDB` requires 16 bytes in an `NDB` table. This requirement applies in addition to any other considerations that are discussed in this section. For example, in `NDBCLUSTER` tables, the `TINYINT`, `SMALLINT`, `MEDIUMINT`, and `INTEGER (INT)` column types each require 4 bytes storage per record due to the alignment factor.

An exception to this rule is the `BIT` type, which is *not* 4-byte aligned. In MySQL Cluster tables, a `BIT(M)` column takes M bits of storage space. However, if a table definition contains 1 or more `BIT` columns (up to 32 `BIT` columns), then `NDBCLUSTER` reserves 4 bytes (32 bits) per row for these. If a table definition contains more than 32 `BIT` columns (up to 64 such columns), then `NDBCLUSTER` reserves 8 bytes (that is, 64 bits) per row.

In addition, while a `NULL` itself does not require any storage space, `NDBCLUSTER` reserves 4 bytes per row if the table definition contains any columns defined as `NULL`, up to 32 `NULL` columns. (If a MySQL Cluster table is defined with more than 32 `NULL` columns up to 64 `NULL` columns, then 8 bytes per row is reserved.)

When calculating storage requirements for MySQL Cluster tables, you must also remember that every table using the `NDB-CLUSTER` storage engine requires a primary key; if no primary key is defined by the user, then a “hidden” primary key will be created by `NDB`. This hidden primary key consumes 31-35 bytes per table record.

You may find the `ndb_size.pl` utility to be useful for estimating **NDB** storage requirements. This Perl script connects to a current MySQL (non-Cluster) database and creates a report on how much space that database would require if it used the **NDB-CLUSTER** storage engine. See `ndb_size.pl`, for more information.

Storage Requirements for Numeric Types

Data Type	Storage Required
<code>TINYINT</code>	1 byte
<code>SMALLINT</code>	2 bytes
<code>MEDIUMINT</code>	3 bytes
<code>INT, INTEGER</code>	4 bytes
<code>BIGINT</code>	8 bytes
<code>FLOAT(p)</code>	4 bytes if $0 \leq p \leq 24$, 8 bytes if $25 \leq p \leq 53$
<code>FLOAT</code>	4 bytes
<code>DOUBLE [PRECISION], REAL</code>	8 bytes
<code>DECIMAL(M,D), NUMERIC(M,D)</code>	Varies; see following discussion
<code>BIT(M)</code>	approximately $(M+7)/8$ bytes

Values for **DECIMAL** (and **NUMERIC**) columns are represented using a binary format that packs nine decimal (base 10) digits into four bytes. Storage for the integer and fractional parts of each value are determined separately. Each multiple of nine digits requires four bytes, and the “leftover” digits require some fraction of four bytes. The storage required for excess digits is given by the following table.

Leftover Digits	Number of Bytes
0	0
1	1
2	1
3	2
4	2
5	3
6	3
7	4
8	4

Storage Requirements for Date and Time Types

Data Type	Storage Required
<code>DATE</code>	3 bytes
<code>TIME</code>	3 bytes
<code>DATETIME</code>	8 bytes
<code>TIMESTAMP</code>	4 bytes
<code>YEAR</code>	1 byte

The storage requirements shown in the table arise from the way that MySQL represents temporal values:

- **DATE**: A three-byte integer packed as $DD + MM \times 32 + YYYY \times 16 \times 32$
- **TIME**: A three-byte integer packed as $DD \times 24 \times 3600 + HH \times 3600 + MM \times 60 + SS$
- **DATETIME**: Eight bytes:
 - A four-byte integer packed as $YYYY \times 10000 + MM \times 100 + DD$
 - A four-byte integer packed as $HH \times 10000 + MM \times 100 + SS$

- **TIMESTAMP**: A four-byte integer representing seconds UTC since the epoch ('1970-01-01 00:00:00' UTC)
- **YEAR**: A one-byte integer

Storage Requirements for String Types

In the following table, *M* represents the declared column length in characters for nonbinary string types and bytes for binary string types. *L* represents the actual length in bytes of a given string value.

Data Type	Storage Required
<code>CHAR(M)</code>	$M \times w$ bytes, $0 \leq M \leq 255$, where <i>w</i> is the number of bytes required for the maximum-length character in the character set
<code>BINARY(M)</code>	<i>M</i> bytes, $0 \leq M \leq 255$
<code>VARCHAR(M)</code> , <code>VARBINARY(M)</code>	<i>L</i> + 1 bytes if column values require 0 – 255 bytes, <i>L</i> + 2 bytes if values may require more than 255 bytes
<code>TINYBLOB</code> , <code>TINYTEXT</code>	<i>L</i> + 1 bytes, where $L < 2^8$
<code>BLOB</code> , <code>TEXT</code>	<i>L</i> + 2 bytes, where $L < 2^{16}$
<code>MEDIUMBLOB</code> , <code>MEDIUMTEXT</code>	<i>L</i> + 3 bytes, where $L < 2^{24}$
<code>LONGBLOB</code> , <code>LONGTEXT</code>	<i>L</i> + 4 bytes, where $L < 2^{32}$
<code>ENUM('value1', 'value2', ...)</code>	1 or 2 bytes, depending on the number of enumeration values (65,535 values maximum)
<code>SET('value1', 'value2', ...)</code>	1, 2, 3, 4, or 8 bytes, depending on the number of set members (64 members maximum)

Variable-length string types are stored using a length prefix plus data. The length prefix requires from one to four bytes depending on the data type, and the value of the prefix is *L* (the byte length of the string). For example, storage for a `MEDIUMTEXT` value requires *L* bytes to store the value plus three bytes to store the length of the value.

To calculate the number of bytes used to store a particular `CHAR`, `VARCHAR`, or `TEXT` column value, you must take into account the character set used for that column and whether the value contains multi-byte characters. In particular, when using the `utf8` Unicode character set, you must keep in mind that not all `utf8` characters use the same number of bytes and can require up to three bytes per character. For a breakdown of the storage used for different categories of `utf8` characters, see [Section 9.1.9, “Unicode Support”](#).

`VARCHAR`, `VARBINARY`, and the `BLOB` and `TEXT` types are variable-length types. For each, the storage requirements depend on these factors:

- The actual length of the column value
- The column's maximum possible length
- The character set used for the column, because some character sets contain multi-byte characters

For example, a `VARCHAR(255)` column can hold a string with a maximum length of 255 characters. Assuming that the column uses the `latin1` character set (one byte per character), the actual storage required is the length of the string (*L*), plus one byte to record the length of the string. For the string 'abcd', *L* is 4 and the storage requirement is five bytes. If the same column is instead declared to use the `ucs2` double-byte character set, the storage requirement is 10 bytes: The length of 'abcd' is eight bytes and the column requires two bytes to store lengths because the maximum length is greater than 255 (up to 510 bytes).

Note

The effective maximum number of *bytes* that can be stored in a `VARCHAR` or `VARBINARY` column is subject to the maximum row size of 65,535 bytes, which is shared among all columns. For a `VARCHAR` column that stores multi-byte characters, the effective maximum number of *characters* is less. For example, `utf8` characters can require up to three bytes per character, so a `VARCHAR` column that uses the `utf8` character set can be declared to be a maximum of 21,844 characters.

The size of an `ENUM` object is determined by the number of different enumeration values. One byte is used for enumerations with up to 255 possible values. Two bytes are used for enumerations having between 256 and 65,535 possible values. See [Section 10.4.4, “The ENUM Type”](#).

The size of a `SET` object is determined by the number of different set members. If the set size is *N*, the object occupies $(N+7) / 8$

bytes, rounded up to 1, 2, 3, 4, or 8 bytes. A `SET` can have a maximum of 64 members. See [Section 10.4.5, “The SET Type”](#).

10.6. Choosing the Right Type for a Column

For optimum storage, you should try to use the most precise type in all cases. For example, if an integer column is used for values in the range from 1 to 99999, `MEDIUMINT UNSIGNED` is the best type. Of the types that represent all the required values, this type uses the least amount of storage.

All basic calculations (+, -, *, and /) with `DECIMAL` columns are done with precision of 65 decimal (base 10) digits. See [Section 10.1.1, “Overview of Numeric Types”](#).

If accuracy is not too important or if speed is the highest priority, the `DOUBLE` type may be good enough. For high precision, you can always convert to a fixed-point type stored in a `BIGINT`. This allows you to do all calculations with 64-bit integers and then convert results back to floating-point values as necessary.

`PROCEDURE ANALYSE` can be used to obtain suggestions for optimal column data types. For more information, see [Section 21.4.1, “PROCEDURE ANALYSE”](#).

10.7. Using Data Types from Other Database Engines

To facilitate the use of code written for SQL implementations from other vendors, MySQL maps data types as shown in the following table. These mappings make it easier to import table definitions from other database systems into MySQL.

Other Vendor Type	MySQL Type
<code>BOOL</code>	<code>TINYINT</code>
<code>BOOLEAN</code>	<code>TINYINT</code>
<code>CHARACTER VARYING(M)</code>	<code>VARCHAR(M)</code>
<code>FIXED</code>	<code>DECIMAL</code>
<code>FLOAT4</code>	<code>FLOAT</code>
<code>FLOAT8</code>	<code>DOUBLE</code>
<code>INT1</code>	<code>TINYINT</code>
<code>INT2</code>	<code>SMALLINT</code>
<code>INT3</code>	<code>MEDIUMINT</code>
<code>INT4</code>	<code>INT</code>
<code>INT8</code>	<code>BIGINT</code>
<code>LONG VARBINARY</code>	<code>MEDIUMBLOB</code>
<code>LONG VARCHAR</code>	<code>MEDIUMTEXT</code>
<code>LONG</code>	<code>MEDIUMTEXT</code>
<code>MIDDLEINT</code>	<code>MEDIUMINT</code>
<code>NUMERIC</code>	<code>DECIMAL</code>

Data type mapping occurs at table creation time, after which the original type specifications are discarded. If you create a table with types used by other vendors and then issue a `DESCRIBE tbl_name` statement, MySQL reports the table structure using the equivalent MySQL types. For example:

```
mysql> CREATE TABLE t (a BOOL, b FLOAT8, c LONG VARCHAR, d NUMERIC);
Query OK, 0 rows affected (0.00 sec)

mysql> DESCRIBE t;
+-----+-----+-----+-----+-----+-----+
| Field | Type          | Null | Key | Default | Extra |
+-----+-----+-----+-----+-----+-----+
| a     | tinyint(1)   | YES  |     | NULL    |       |
| b     | double       | YES  |     | NULL    |       |
| c     | mediumtext   | YES  |     | NULL    |       |
| d     | decimal(10,0)| YES  |     | NULL    |       |
+-----+-----+-----+-----+-----+-----+
4 rows in set (0.01 sec)
```

Chapter 11. Functions and Operators

Expressions can be used at several points in SQL statements, such as in the `ORDER BY` or `HAVING` clauses of `SELECT` statements, in the `WHERE` clause of a `SELECT`, `DELETE`, or `UPDATE` statement, or in `SET` statements. Expressions can be written using literal values, column values, `NULL`, built-in functions, stored functions, user-defined functions, and operators. This chapter describes the functions and operators that are allowed for writing expressions in MySQL. Instructions for writing stored functions and user-defined functions are given in [Section 18.2, “Using Stored Routines \(Procedures and Functions\)”](#), and [Section 21.3, “Adding New Functions to MySQL”](#). See [Section 8.2.4, “Function Name Parsing and Resolution”](#), for the rules describing how the server interprets references to different kinds of functions.

An expression that contains `NULL` always produces a `NULL` value unless otherwise indicated in the documentation for a particular function or operator.

Note

By default, there must be no whitespace between a function name and the parenthesis following it. This helps the MySQL parser distinguish between function calls and references to tables or columns that happen to have the same name as a function. However, spaces around function arguments are permitted.

You can tell the MySQL server to accept spaces after function names by starting it with the `--sql-mode=IGNORE_SPACE` option. (See [Section 5.1.7, “Server SQL Modes”](#).) Individual client programs can request this behavior by using the `CLIENT_IGNORE_SPACE` option for `mysql_real_connect()`. In either case, all function names become reserved words.

For the sake of brevity, most examples in this chapter display the output from the `mysql` program in abbreviated form. Rather than showing examples in this format:

```
mysql> SELECT MOD(29,9);
+-----+
| mod(29,9) |
+-----+
|          2 |
+-----+
1 rows in set (0.00 sec)
```

This format is used instead:

```
mysql> SELECT MOD(29,9);
-> 2
```

11.1. Operator and Function Reference

Note

This table is part of an ongoing process to expand and simplify the information provided on these elements. Further improvements to the table, and corresponding descriptions will be applied over the coming months.

Name	Description
<code>ABS()</code>	Return the absolute value
<code>ACOS()</code>	Return the arc cosine
<code>ADDDATE()</code> (v4.1.1)	Add dates
<code>ADDTIME()</code> (v4.1.1)	Add time
<code>AES_DECRYPT()</code>	Decrypt using AES
<code>AES_ENCRYPT()</code>	Encrypt using AES
<code>AND, &&</code>	Logical AND
<code>ASCII()</code>	Return numeric value of left-most character
<code>ASIN()</code>	Return the arc sine
<code>ATAN2(), ATAN()</code>	Return the arc tangent of the two arguments
<code>ATAN()</code>	Return the arc tangent
<code>AVG()</code>	Return the average value of the argument
<code>BENCHMARK()</code>	Repeatedly execute an expression
<code>BETWEEN ... AND ...</code>	Check whether a value is within a range of values
<code>BIN()</code>	Return a string representation of the argument

Name	Description
<code>BINARY</code>	Cast a string to a binary string
<code>BIT_AND()</code>	Return bitwise and
<code>BIT_COUNT()</code>	Return the number of bits that are set
<code>BIT_LENGTH()</code>	Return length of argument in bits
<code>BIT_OR()</code>	Return bitwise or
<code>BIT_XOR()</code> (v4.1.1)	Return bitwise xor
<code>&</code>	Bitwise AND
<code>~</code>	Invert bits
<code> </code>	Bitwise OR
<code>^</code>	Bitwise XOR
<code>CASE</code>	Case operator
<code>CAST()</code>	Cast a value as a certain type
<code>CEIL()</code>	Return the smallest integer value not less than the argument
<code>CEILING()</code>	Return the smallest integer value not less than the argument
<code>CHAR_LENGTH()</code>	Return number of characters in argument
<code>CHAR()</code>	Return the character for each integer passed
<code>CHARACTER_LENGTH()</code>	A synonym for <code>CHAR_LENGTH()</code>
<code>CHARSET()</code> (v4.1.0)	Return the character set of the argument
<code>COALESCE()</code>	Return the first non-NULL argument
<code>COERCIBILITY()</code> (v4.1.1)	Return the collation coercibility value of the string argument
<code>COLLATION()</code> (v4.1.0)	Return the collation of the string argument
<code>COMPRESS()</code> (v4.1.1)	Return result as a binary string
<code>CONCAT_WS()</code>	Return concatenate with separator
<code>CONCAT()</code>	Return concatenated string
<code>CONNECTION_ID()</code>	Return the connection ID (thread ID) for the connection
<code>CONV()</code>	Convert numbers between different number bases
<code>CONVERT_TZ()</code> (v4.1.3)	Convert from one timezone to another
<code>Convert()</code>	Cast a value as a certain type
<code>COS()</code>	Return the cosine
<code>COT()</code>	Return the cotangent
<code>COUNT(DISTINCT)</code>	Return the count of a number of different values
<code>COUNT()</code>	Return a count of the number of rows returned
<code>CRC32()</code> (v4.1.0)	Compute a cyclic redundancy check value
<code>CURDATE()</code>	Return the current date
<code>CURRENT_DATE()</code> , <code>CURRENT_DATE</code>	Synonyms for <code>CURDATE()</code>
<code>CURRENT_TIME()</code> , <code>CURRENT_TIME</code>	Synonyms for <code>CURTIME()</code>
<code>CURRENT_TIMESTAMP()</code> , <code>CURRENT_TIMESTAMP</code>	Synonyms for <code>NOW()</code>
<code>CURRENT_USER()</code> , <code>CURRENT_USER</code>	Return the user name and host name combination
<code>CURTIME()</code>	Return the current time
<code>DATABASE()</code>	Return the default (current) database name
<code>DATE_ADD()</code>	Add two dates
<code>DATE_FORMAT()</code>	Format date as specified
<code>DATE_SUB()</code>	Subtract two dates
<code>DATE()</code> (v4.1.1)	Extract the date part of a date or datetime expression
<code>DATEDIFF()</code> (v4.1.1)	Subtract two dates
<code>DAY()</code> (v4.1.1)	Synonym for <code>DAYOFMONTH()</code>
<code>DAYNAME()</code> (v4.1.21)	Return the name of the weekday

Name	Description
DAYOFMONTH ()	Return the day of the month (0-31)
DAYOFWEEK ()	Return the weekday index of the argument
DAYOFYEAR ()	Return the day of the year (1-366)
DECODE ()	Decodes a string encrypted using ENCODE()
DEFAULT ()	Return the default value for a table column
DEGREES ()	Convert radians to degrees
DES_DECRYPT ()	Decrypt a string
DES_ENCRYPT ()	Encrypt a string
DIV(v4.1.0)	Integer division
/	Division operator
ELT ()	Return string at index number
ENCODE ()	Encode a string
ENCRYPT ()	Encrypt a string
<=>	NULL-safe equal to operator
=	Equal operator
EXP ()	Raise to the power of
EXPORT_SET ()	Return a string such that for every bit set in the value bits, you get an on string and for every unset bit, you get an off string
EXTRACT	Extract part of a date
ExtractValue () (v5.1.5)	Extracts a value from an XML string using XPath notation
FIELD ()	Return the index (position) of the first argument in the subsequent arguments
FIND_IN_SET ()	Return the index position of the first argument within the second argument
FLOOR ()	Return the largest integer value not greater than the argument
FORMAT ()	Return a number formatted to specified number of decimal places
FOUND_ROWS ()	For a SELECT with a LIMIT clause, the number of rows that would be returned were there no LIMIT clause
FROM_DAYS ()	Convert a day number to a date
FROM_UNIXTIME ()	Format UNIX timestamp as a date
GET_FORMAT () (v4.1.1)	Return a date format string
GET_LOCK ()	Get a named lock
>=	Greater than or equal operator
>	Greater than operator
GREATEST ()	Return the largest argument
GROUP_CONCAT () (v4.1)	Return a concatenated string
HEX ()	Return a hexadecimal representation of a decimal or string value
HOUR ()	Extract the hour
IF ()	If/else construct
IFNULL ()	Null if/else construct
IN ()	Check whether a value is within a set of values
INET_ATON ()	Return the numeric value of an IP address
INET_NTOA ()	Return the IP address from a numeric value
INSERT ()	Insert a substring at the specified position up to the specified number of characters
INSTR ()	Return the index of the first occurrence of substring
INTERVAL ()	Return the index of the argument that is less than the first argument
IS_FREE_LOCK ()	Checks whether the named lock is free
IS NOT NULL	NOT NULL value test
IS NOT	Test a value against a boolean

Name	Description
IS NULL	NULL value test
IS_USED_LOCK () (v4.1.0)	Checks whether the named lock is in use. Return connection identifier if true.
IS	Test a value against a boolean
ISNULL ()	Test whether the argument is NULL
LAST_DAY(v4.1.1)	Return the last day of the month for the argument
LAST_INSERT_ID ()	Value of the AUTOINCREMENT column for the last INSERT
LCASE ()	Synonym for LOWER()
LEAST ()	Return the smallest argument
<<	Left shift
LEFT ()	Return the leftmost number of characters as specified
LENGTH ()	Return the length of a string in bytes
<=	Less than or equal operator
<	Less than operator
LIKE	Simple pattern matching
LN ()	Return the natural logarithm of the argument
LOAD_FILE ()	Load the named file
LOCALTIME (), LOCALTIME	Synonym for NOW()
LOCALTIMESTAMP, LOCALTIMESTAMP () (v4.0.6)	Synonym for NOW()
LOCATE ()	Return the position of the first occurrence of substring
LOG10 ()	Return the base-10 logarithm of the argument
LOG2 ()	Return the base-2 logarithm of the argument
LOG ()	Return the natural logarithm of the first argument
LOWER ()	Return the argument in lowercase
LPAD ()	Return the string argument, left-padded with the specified string
LTRIM ()	Remove leading spaces
MAKE_SET ()	Return a set of comma-separated strings that have the corresponding bit in bits set
MAKEDATE () (v4.1.1)	Create a date from the year and day of year
MAKETIME(v4.1.1)	MAKETIME()
MASTER_POS_WAIT ()	Block until the slave has read and applied all updates up to the specified position
MATCH	Perform full-text search
MAX ()	Return the maximum value
MD5 ()	Calculate MD5 checksum
MICROSECOND () (v4.1.1)	Return the microseconds from argument
MID ()	Return a substring starting from the specified position
MIN ()	Return the minimum value
-	Minus operator
MINUTE ()	Return the minute from the argument
MOD ()	Return the remainder
%	Modulo operator
MONTH ()	Return the month from the date passed
MONTHNAME () (v4.1.21)	Return the name of the month
NAME_CONST () (v5.0.12)	Causes the column to have the given name
NOT BETWEEN ... AND ...	Check whether a value is not within a range of values
!=, <>	Not equal operator
NOT IN ()	Check whether a value is not within a set of values

Name	Description
NOT LIKE	Negation of simple pattern matching
NOT REGEXP	Negation of REGEXP
NOT, !	Negates value
NOW()	Return the current date and time
NULLIF()	Return NULL if expr1 = expr2
OCT()	Return an octal representation of a decimal number
OCTET_LENGTH()	A synonym for LENGTH()
OLD_PASSWORD()(v4.1)	Return the value of the old (pre-4.1) implementation of PASSWORD
, OR	Logical OR
ORD()	Return character code for leftmost character of the argument
PASSWORD()	Calculate and return a password string
PERIOD_ADD()	Add a period to a year-month
PERIOD_DIFF()	Return the number of months between periods
PI()	Return the value of pi
+	Addition operator
POSITION()	A synonym for LOCATE()
POW()	Return the argument raised to the specified power
POWER()	Return the argument raised to the specified power
PROCEDURE ANALYSE()	Analyze the results of a query
QUARTER()	Return the quarter from a date argument
QUOTE()	Escape the argument for use in an SQL statement
RADIANS()	Return argument converted to radians
RAND()	Return a random floating-point value
REGEXP	Pattern matching using regular expressions
RELEASE_LOCK()	Releases the named lock
REPEAT()	Repeat a string the specified number of times
REPLACE()	Replace occurrences of a specified string
REVERSE()	Reverse the characters in a string
>>	Right shift
RIGHT()	Return the specified rightmost number of characters
RLIKE	Synonym for REGEXP
ROUND()	Round the argument
ROW_COUNT()(v5.0.1)	The number of rows updated
RPAD()	Append string the specified number of times
RTRIM()	Remove trailing spaces
SCHEMA()(v5.0.2)	A synonym for DATABASE()
SEC_TO_TIME()	Converts seconds to 'HH:MM:SS' format
SECOND()	Return the second (0-59)
SESSION_USER()	Synonym for USER()
SHA1(), SHA()	Calculate an SHA-1 160-bit checksum
SIGN()	Return the sign of the argument
SIN()	Return the sine of the argument
SLEEP()(v5.0.12)	Sleep for a number of seconds
SOUNDEX()	Return a soundex string
SOUNDS LIKE(v4.1.0)	Compare sounds
SPACE()	Return a string of the specified number of spaces
SQRT()	Return the square root of the argument

Name	Description
STD ()	Return the population standard deviation
STDDEV_POP () (v5.0.3)	Return the population standard deviation
STDDEV_SAMP () (v5.0.3)	Return the sample standard deviation
STDDEV ()	Return the population standard deviation
STR_TO_DATE () (v4.1.1)	Convert a string to a date
STRCMP ()	Compare two strings
SUBDATE ()	A synonym for DATE_SUB() when invoked with three arguments
SUBSTR ()	Return the substring as specified
SUBSTRING_INDEX ()	Return a substring from a string before the specified number of occurrences of the delimiter
SUBSTRING ()	Return the substring as specified
SUBTIME () (v4.1.1)	Subtract times
SUM ()	Return the sum
SYSDATE ()	Return the time at which the function executes
SYSTEM_USER ()	Synonym for USER()
TAN ()	Return the tangent of the argument
TIME_FORMAT ()	Format as time
TIME_TO_SEC ()	Return the argument converted to seconds
TIME () (v4.1.1)	Extract the time portion of the expression passed
TIMEDIFF () (v4.1.1)	Subtract time
*	Times operator
TIMESTAMP () (v4.1.1)	With a single argument, this function returns the date or datetime expression; with two arguments, the sum of the arguments
TIMESTAMPADD () (v5.0.0)	Add an interval to a datetime expression
TIMESTAMPDIFF () (v5.0.0)	Subtract an interval from a datetime expression
TO_DAYS ()	Return the date argument converted to days
TRIM ()	Remove leading and trailing spaces
TRUNCATE ()	Truncate to specified number of decimal places
UCASE ()	Synonym for UPPER()
-	Change the sign of the argument
UNCOMPRESS () (v4.1.1)	Uncompress a string compressed
UNCOMPRESSED_LENGTH () (v4.1.1)	Return the length of a string before compression
UNHEX () (v4.1.2)	Convert each pair of hexadecimal digits to a character
UNIX_TIMESTAMP ()	Return a UNIX timestamp
UpdateXML () (v5.1.5)	Return replaced XML fragment
UPPER ()	Convert to uppercase
USER ()	Return the current user name and host name
UTC_DATE () (v4.1.1)	Return the current UTC date
UTC_TIME () (v4.1.1)	Return the current UTC time
UTC_TIMESTAMP () (v4.1.1)	Return the current UTC date and time
UUID_SHORT () (v5.1.20)	Return an integer-valued universal identifier
UUID () (v4.1.2)	Return a Universal Unique Identifier (UUID)
VALUES () (v4.1.1)	Defines the values to be used during an INSERT
VAR_POP () (v5.0.3)	Return the population standard variance
VAR_SAMP () (v5.0.3)	Return the sample variance
VARIANCE () (v4.1)	Return the population standard variance
VERSION ()	Returns a string that indicates the MySQL server version
WEEK ()	Return the week number

Name	Description
WEEKDAY ()	Return the weekday index
WEEKOFYEAR () (v4.1.1)	Return the calendar week of the date (0-53)
XOR	Logical XOR
YEAR ()	Return the year
YEARWEEK ()	Return the year and week

11.2. Operators

Name	Description
AND, &&	Logical AND
BETWEEN ... AND ...	Check whether a value is within a range of values
BINARY	Cast a string to a binary string
&	Bitwise AND
~	Invert bits
	Bitwise OR
^	Bitwise XOR
CASE	Case operator
DIV(v4.1.0)	Integer division
/	Division operator
<=>	NULL-safe equal to operator
=	Equal operator
>=	Greater than or equal operator
>	Greater than operator
IS NOT NULL	NOT NULL value test
IS NOT	Test a value against a boolean
IS NULL	NULL value test
IS	Test a value against a boolean
<<	Left shift
<=	Less than or equal operator
<	Less than operator
LIKE	Simple pattern matching
-	Minus operator
%	Modulo operator
NOT BETWEEN ... AND ...	Check whether a value is not within a range of values
!=, <>	Not equal operator
NOT LIKE	Negation of simple pattern matching
NOT REGEXP	Negation of REGEXP
NOT, !	Negates value
, OR	Logical OR
+	Addition operator
REGEXP	Pattern matching using regular expressions
>>	Right shift
RLIKE	Synonym for REGEXP
SOUNDS LIKE(v4.1.0)	Compare sounds
*	Times operator
-	Change the sign of the argument
XOR	Logical XOR

11.2.1. Operator Precedence

Operator precedences are shown in the following list, from highest precedence to the lowest. Operators that are shown together on a line have the same precedence.

```

INTERVAL
BINARY, COLLATE
!
- (unary minus), ~ (unary bit inversion)
^
*, /, DIV, %, MOD
-, +
<<, >>
&
|
=, <=>, >=, >, <=, <, <>, !=, IS, LIKE, REGEXP, IN
BETWEEN, CASE, WHEN, THEN, ELSE
NOT
&&, AND
XOR
||, OR
:=
    
```

The `||` operator has a precedence between `^` and the unary operators if the `PIPES_AS_CONCAT` SQL mode is enabled.

Note

If the `HIGH_NOT_PRECEDENCE` SQL mode is enabled, the precedence of `NOT` is the same as that of the `!` operator. See [Section 5.1.7, “Server SQL Modes”](#).

The precedence of operators determines the order of evaluation of terms in an expression. To override this order and group terms explicitly, use parentheses. For example:

```

mysql> SELECT 1+2*3;
-> 7
mysql> SELECT (1+2)*3;
-> 9
    
```

11.2.2. Type Conversion in Expression Evaluation

When an operator is used with operands of different types, type conversion occurs to make the operands compatible. Some conversions occur implicitly. For example, MySQL automatically converts numbers to strings as necessary, and vice versa.

```

mysql> SELECT 1+'1';
-> 2
mysql> SELECT CONCAT(2,' test');
-> '2 test'
    
```

It is also possible to perform explicit conversions. If you want to convert a number to a string explicitly, use the `CAST()` or `CONCAT()` function (`CAST()` is preferable):

```

mysql> SELECT 38.8, CAST(38.8 AS CHAR);
-> 38.8, '38.8'
mysql> SELECT 38.8, CONCAT(38.8);
-> 38.8, '38.8'
    
```

The following rules describe how conversion occurs for comparison operations:

- If one or both arguments are `NULL`, the result of the comparison is `NULL`, except for the `NULL`-safe `<=>` equality comparison operator. For `NULL <=> NULL`, the result is true.
- If both arguments in a comparison operation are strings, they are compared as strings.
- If both arguments are integers, they are compared as integers.
- Hexadecimal values are treated as binary strings if not compared to a number.
- If one of the arguments is a `TIMESTAMP` or `DATETIME` column and the other argument is a constant, the constant is converted to a timestamp before the comparison is performed. This is done to be more ODBC-friendly. Note that this is not done for the arguments to `IN()`! To be safe, always use complete datetime, date, or time strings when doing comparisons.
- In all other cases, the arguments are compared as floating-point (real) numbers.

The following examples illustrate conversion of strings to numbers for comparison operations:

```
mysql> SELECT 1 > '6x';
-> 0
mysql> SELECT 7 > '6x';
-> 1
mysql> SELECT 0 > 'x6';
-> 0
mysql> SELECT 0 = 'x6';
-> 1
```

Note that when you are comparing a string column with a number, MySQL cannot use an index on the column to look up the value quickly. If *str_col* is an indexed string column, the index cannot be used when performing the lookup in the following statement:

```
SELECT * FROM tbl_name WHERE str_col=1;
```

The reason for this is that there are many different strings that may convert to the value 1, such as '1', ' 1', or '1a'.

Comparisons that use floating-point numbers (or values that are converted to floating-point numbers) are approximate because such numbers are inexact. This might lead to results that appear inconsistent:

```
mysql> SELECT '18015376320243458' = 18015376320243458;
-> 1
mysql> SELECT '18015376320243459' = 18015376320243459;
-> 0
```

Such results can occur because the values are converted to floating-point numbers, which have only 53 bits of precision and are subject to rounding:

```
mysql> SELECT '18015376320243459'+0.0;
-> 1.8015376320243e+16
```

Furthermore, the conversion from string to floating-point and from integer to floating-point do not necessarily occur the same way. The integer may be converted to floating-point by the CPU, whereas the string is converted digit by digit in an operation that involves floating-point multiplications.

The results shown will vary on different systems, and can be affected by factors such as computer architecture or the compiler version or optimization level. One way to avoid such problems is to use `CAST()` so that a value will not be converted implicitly to a float-point number:

```
mysql> SELECT CAST('18015376320243459' AS UNSIGNED) = 18015376320243459;
-> 1
```

For more information about floating-point comparisons, see [Section B.1.5.8, “Problems with Floating-Point Comparisons”](#).

11.2.3. Comparison Functions and Operators

Name	Description
<code>BETWEEN ... AND ...</code>	Check whether a value is within a range of values
<code>COALESCE()</code>	Return the first non-NULL argument
<code><=></code>	NULL-safe equal to operator
<code>=</code>	Equal operator
<code>>=</code>	Greater than or equal operator
<code>></code>	Greater than operator
<code>GREATEST()</code>	Return the largest argument
<code>IN()</code>	Check whether a value is within a set of values
<code>INTERVAL()</code>	Return the index of the argument that is less than the first argument
<code>IS NOT NULL</code>	NOT NULL value test
<code>IS NOT</code>	Test a value against a boolean
<code>IS NULL</code>	NULL value test
<code>IS</code>	Test a value against a boolean
<code>ISNULL()</code>	Test whether the argument is NULL
<code>LEAST()</code>	Return the smallest argument
<code><=</code>	Less than or equal operator

Name	Description
<	Less than operator
LIKE	Simple pattern matching
NOT BETWEEN ... AND ...	Check whether a value is not within a range of values
!=, <>	Not equal operator
NOT IN()	Check whether a value is not within a set of values
NOT LIKE	Negation of simple pattern matching
STRCMP()	Compare two strings

Comparison operations result in a value of **1** (**TRUE**), **0** (**FALSE**), or **NULL**. These operations work for both numbers and strings. Strings are automatically converted to numbers and numbers to strings as necessary.

The following relational comparison operators can be used to compare not only scalar operands, but row operands:

```
= > < >= <= <> !=
```

For examples of row comparisons, see [Section 12.2.9.5, “Row Subqueries”](#).

Some of the functions in this section return values other than **1** (**TRUE**), **0** (**FALSE**), or **NULL**. For example, [LEAST\(\)](#) and [GREATEST\(\)](#). However, the value they return is based on comparison operations performed according to the rules described in [Section 11.2.2, “Type Conversion in Expression Evaluation”](#).

To convert a value to a specific type for comparison purposes, you can use the [CAST\(\)](#) function. String values can be converted to a different character set using [CONVERT\(\)](#). See [Section 11.9, “Cast Functions and Operators”](#).

By default, string comparisons are not case sensitive and use the current character set. The default is `latin1` (cp1252 West European), which also works well for English.

- =

Equal:

```
mysql> SELECT 1 = 0;
-> 0
mysql> SELECT '0' = 0;
-> 1
mysql> SELECT '0.0' = 0;
-> 1
mysql> SELECT '0.01' = 0;
-> 0
mysql> SELECT '.01' = 0.01;
-> 1
```

- <=>

NULL-safe equal. This operator performs an equality comparison like the = operator, but returns **1** rather than **NULL** if both operands are **NULL**, and **0** rather than **NULL** if one operand is **NULL**.

```
mysql> SELECT 1 <=> 1, NULL <=> NULL, 1 <=> NULL;
-> 1, 1, 0
mysql> SELECT 1 = 1, NULL = NULL, 1 = NULL;
-> 1, NULL, NULL
```

- <>, !=

Not equal:

```
mysql> SELECT '.01' <> '0.01';
-> 1
mysql> SELECT .01 <> '0.01';
-> 0
mysql> SELECT 'zapp' <> 'zappp';
-> 1
```

- <=

Less than or equal:

```
mysql> SELECT 0.1 <= 2;
```

```
-> 1
```

- <

Less than:

```
mysql> SELECT 2 < 2;
-> 0
```

- >=

Greater than or equal:

```
mysql> SELECT 2 >= 2;
-> 1
```

- >

Greater than:

```
mysql> SELECT 2 > 2;
-> 0
```

- IS *boolean_value*

Tests a value against a boolean value, where *boolean_value* can be TRUE, FALSE, or UNKNOWN.

```
mysql> SELECT 1 IS TRUE, 0 IS FALSE, NULL IS UNKNOWN;
-> 1, 1, 1
```

- IS NOT *boolean_value*

Tests a value against a boolean value, where *boolean_value* can be TRUE, FALSE, or UNKNOWN.

```
mysql> SELECT 1 IS NOT UNKNOWN, 0 IS NOT UNKNOWN, NULL IS NOT UNKNOWN;
-> 1, 1, 0
```

- IS NULL

Tests whether a value is NULL.

```
mysql> SELECT 1 IS NULL, 0 IS NULL, NULL IS NULL;
-> 0, 0, 1
```

To work well with ODBC programs, MySQL supports the following extra features when using IS NULL:

- You can find the row that contains the most recent AUTO_INCREMENT value by issuing a statement of the following form immediately after generating the value:

```
SELECT * FROM tbl_name WHERE auto_col IS NULL
```

This behavior can be disabled by setting `sql_auto_is_null = 0`. See [Section 5.1.4, “Session System Variables”](#).

- For DATE and DATETIME columns that are declared as NOT NULL, you can find the special date '0000-00-00' by using a statement like this:

```
SELECT * FROM tbl_name WHERE date_column IS NULL
```

This is needed to get some ODBC applications to work because ODBC does not support a '0000-00-00' date value.

- IS NOT NULL

Tests whether a value is not NULL.

```
mysql> SELECT 1 IS NOT NULL, 0 IS NOT NULL, NULL IS NOT NULL;
-> 1, 1, 0
```

- *expr* BETWEEN *min* AND *max*

If *expr* is greater than or equal to *min* and *expr* is less than or equal to *max*, `BETWEEN` returns 1, otherwise it returns 0. This is equivalent to the expression `(min <= expr AND expr <= max)` if all the arguments are of the same type. Otherwise type conversion takes place according to the rules described in [Section 11.2.2, “Type Conversion in Expression Evaluation”](#), but applied to all the three arguments.

```
mysql> SELECT 2 BETWEEN 1 AND 3, 2 BETWEEN 3 AND 1;
-> 1, 0
mysql> SELECT 1 BETWEEN 2 AND 3;
-> 0
mysql> SELECT 'b' BETWEEN 'a' AND 'c';
-> 1
mysql> SELECT 2 BETWEEN 2 AND '3';
-> 1
mysql> SELECT 2 BETWEEN 2 AND 'x-3';
-> 0
```

For best results when using `BETWEEN` with date or time values, you should use `CAST()` to explicitly convert the values to the desired data type. Examples: If you compare a `DATETIME` to two `DATE` values, convert the `DATE` values to `DATETIME` values. If you use a string constant such as `'2001-1-1'` in a comparison to a `DATE`, cast the string to a `DATE`.

- `expr NOT BETWEEN min AND max`

This is the same as `NOT (expr BETWEEN min AND max)`.

- `COALESCE(value, ...)`

Returns the first non-`NULL` value in the list, or `NULL` if there are no non-`NULL` values.

```
mysql> SELECT COALESCE(NULL,1);
-> 1
mysql> SELECT COALESCE(NULL,NULL,NULL);
-> NULL
```

- `GREATEST(value1,value2,...)`

With two or more arguments, returns the largest (maximum-valued) argument. The arguments are compared using the same rules as for `LEAST()`.

```
mysql> SELECT GREATEST(2,0);
-> 2
mysql> SELECT GREATEST(34.0,3.0,5.0,767.0);
-> 767.0
mysql> SELECT GREATEST('B','A','C');
-> 'C'
```

`GREATEST()` returns `NULL` if any argument is `NULL`.

- `expr IN (value, ...)`

Returns 1 if *expr* is equal to any of the values in the `IN` list, else returns 0. If all values are constants, they are evaluated according to the type of *expr* and sorted. The search for the item then is done using a binary search. This means `IN` is very quick if the `IN` value list consists entirely of constants. Otherwise, type conversion takes place according to the rules described in [Section 11.2.2, “Type Conversion in Expression Evaluation”](#), but applied to all the arguments.

```
mysql> SELECT 2 IN (0,3,5,7);
-> 0
mysql> SELECT 'wefwf' IN ('wee','wefwf','weg');
-> 1
```

You should never mix quoted and unquoted values in an `IN` list because the comparison rules for quoted values (such as strings) and unquoted values (such as numbers) differ. Mixing types may therefore lead to inconsistent results. For example, do not write an `IN` expression like this:

```
SELECT val1 FROM tbl1 WHERE val1 IN (1,2,'a');
```

Instead, write it like this:

```
SELECT val1 FROM tbl1 WHERE val1 IN ('1','2','a');
```

The number of values in the `IN` list is only limited by the `max_allowed_packet` value.

To comply with the SQL standard, `IN` returns `NULL` not only if the expression on the left hand side is `NULL`, but also if no match is found in the list and one of the expressions in the list is `NULL`.

`IN()` syntax can also be used to write certain types of subqueries. See [Section 12.2.9.3, “Subqueries with ANY, IN, and SOME”](#).

- `expr NOT IN (value, ...)`

This is the same as `NOT (expr IN (value, ...))`.

- `ISNULL(expr)`

If `expr` is `NULL`, `ISNULL()` returns `1`, otherwise it returns `0`.

```
mysql> SELECT ISNULL(1+1);
-> 0
mysql> SELECT ISNULL(1/0);
-> 1
```

`ISNULL()` can be used instead of `=` to test whether a value is `NULL`. (Comparing a value to `NULL` using `=` always yields false.)

The `ISNULL()` function shares some special behaviors with the `IS NULL` comparison operator. See the description of `IS NULL`.

- `INTERVAL(N, N1, N2, N3, ...)`

Returns `0` if `N < N1`, `1` if `N < N2` and so on or `-1` if `N` is `NULL`. All arguments are treated as integers. It is required that `N1 < N2 < N3 < ... < Nn` for this function to work correctly. This is because a binary search is used (very fast).

```
mysql> SELECT INTERVAL(23, 1, 15, 17, 30, 44, 200);
-> 3
mysql> SELECT INTERVAL(10, 1, 10, 100, 1000);
-> 2
mysql> SELECT INTERVAL(22, 23, 30, 44, 200);
-> 0
```

- `LEAST(value1, value2, ...)`

With two or more arguments, returns the smallest (minimum-valued) argument. The arguments are compared using the following rules:

- If the return value is used in an `INTEGER` context or all arguments are integer-valued, they are compared as integers.
- If the return value is used in a `REAL` context or all arguments are real-valued, they are compared as reals.
- If any argument is a case-sensitive string, the arguments are compared as case-sensitive strings.
- In all other cases, the arguments are compared as case-insensitive strings.

`LEAST()` returns `NULL` if any argument is `NULL`.

```
mysql> SELECT LEAST(2,0);
-> 0
mysql> SELECT LEAST(34.0,3.0,5.0,767.0);
-> 3.0
mysql> SELECT LEAST('B','A','C');
-> 'A'
```

Note that the preceding conversion rules can produce strange results in some borderline cases:

```
mysql> SELECT CAST(LEAST(3600, 9223372036854775808.0) as SIGNED);
-> -9223372036854775808
```

This happens because MySQL reads `9223372036854775808.0` in an integer context. The integer representation is not good enough to hold the value, so it wraps to a signed integer.

11.2.4. Logical Operators

Name	Description
<code>AND, &&</code>	Logical AND
<code>NOT, !</code>	Negates value
<code> , OR</code>	Logical OR

Name	Description
XOR	Logical XOR

In SQL, all logical operators evaluate to **TRUE**, **FALSE**, or **NULL** (**UNKNOWN**). In MySQL, these are implemented as 1 (**TRUE**), 0 (**FALSE**), and **NULL**. Most of this is common to different SQL database servers, although some servers may return any nonzero value for **TRUE**.

Note that MySQL evaluates any nonzero or non-**NULL** value to **TRUE**. For example, the following statements all assess to **TRUE**:

```
mysql> SELECT 10 IS TRUE;
-> 1
mysql> SELECT -10 IS TRUE;
-> 1
mysql> SELECT 'string' IS NOT NULL;
-> 1
```

- **NOT, !**

Logical NOT. Evaluates to 1 if the operand is 0, to 0 if the operand is nonzero, and **NOT NULL** returns **NULL**.

```
mysql> SELECT NOT 10;
-> 0
mysql> SELECT NOT 0;
-> 1
mysql> SELECT NOT NULL;
-> NULL
mysql> SELECT ! (1+1);
-> 0
mysql> SELECT ! 1+1;
-> 1
```

The last example produces 1 because the expression evaluates the same way as $(!1)+1$.

- **AND, &&**

Logical AND. Evaluates to 1 if all operands are nonzero and not **NULL**, to 0 if one or more operands are 0, otherwise **NULL** is returned.

```
mysql> SELECT 1 && 1;
-> 1
mysql> SELECT 1 && 0;
-> 0
mysql> SELECT 1 && NULL;
-> NULL
mysql> SELECT 0 && NULL;
-> 0
mysql> SELECT NULL && 0;
-> 0
```

- **OR, ||**

Logical OR. When both operands are non-**NULL**, the result is 1 if any operand is nonzero, and 0 otherwise. With a **NULL** operand, the result is 1 if the other operand is nonzero, and **NULL** otherwise. If both operands are **NULL**, the result is **NULL**.

```
mysql> SELECT 1 || 1;
-> 1
mysql> SELECT 1 || 0;
-> 1
mysql> SELECT 0 || 0;
-> 0
mysql> SELECT 0 || NULL;
-> NULL
mysql> SELECT 1 || NULL;
-> 1
```

- **XOR**

Logical XOR. Returns **NULL** if either operand is **NULL**. For non-**NULL** operands, evaluates to 1 if an odd number of operands is nonzero, otherwise 0 is returned.

```
mysql> SELECT 1 XOR 1;
-> 0
mysql> SELECT 1 XOR 0;
-> 1
mysql> SELECT 1 XOR NULL;
-> NULL
mysql> SELECT 1 XOR 1 XOR 1;
-> 1
```

```
-> 1
```

`a XOR b` is mathematically equal to `(a AND (NOT b)) OR ((NOT a) and b)`.

11.3. Control Flow Functions

Name	Description
CASE	Case operator
IF()	If/else construct
IFNULL()	Null if/else construct
NULLIF()	Return NULL if <code>expr1 = expr2</code>

- `CASE value WHEN [compare_value] THEN result [WHEN [compare_value] THEN result ...] [ELSE result] END`

```
CASE WHEN [condition] THEN result [WHEN [condition] THEN result ...] [ELSE result] END
```

The first version returns the `result` where `value=compare_value`. The second version returns the result for the first condition that is true. If there was no matching result value, the result after `ELSE` is returned, or `NULL` if there is no `ELSE` part.

```
mysql> SELECT CASE 1 WHEN 1 THEN 'one'
->      WHEN 2 THEN 'two' ELSE 'more' END;
-> 'one'
mysql> SELECT CASE WHEN 1>0 THEN 'true' ELSE 'false' END;
-> 'true'
mysql> SELECT CASE BINARY 'B'
->      WHEN 'a' THEN 1 WHEN 'b' THEN 2 END;
-> NULL
```

The default return type of a `CASE` expression is the compatible aggregated type of all return values, but also depends on the context in which it is used. If used in a string context, the result is returned as a string. If used in a numeric context, then the result is returned as a decimal, real, or integer value.

Note
The syntax of the `CASE expression` shown here differs slightly from that of the SQL `CASE statement` described in [Section 12.8.6.2, “CASE Statement”](#), for use inside stored programs. The `CASE` statement cannot have an `ELSE NULL` clause, and it is terminated with `END CASE` instead of `END`.

- `IF(expr1, expr2, expr3)`

If `expr1` is `TRUE` (`expr1 <> 0` and `expr1 <> NULL`) then `IF()` returns `expr2`; otherwise it returns `expr3`. `IF()` returns a numeric or string value, depending on the context in which it is used.

```
mysql> SELECT IF(1>2,2,3);
-> 3
mysql> SELECT IF(1<2,'yes','no');
-> 'yes'
mysql> SELECT IF(STRCMP('test','test1'),'no','yes');
-> 'no'
```

If only one of `expr2` or `expr3` is explicitly `NULL`, the result type of the `IF()` function is the type of the non-`NULL` expression.

The default return type of `IF()` (which may matter when it is stored into a temporary table) is calculated as follows.

Expression	Return Value
<code>expr2</code> or <code>expr3</code> returns a string	string
<code>expr2</code> or <code>expr3</code> returns a floating-point value	floating-point
<code>expr2</code> or <code>expr3</code> returns an integer	integer

If `expr2` and `expr3` are both strings, the result is case sensitive if either string is case sensitive.

Note

There is also an *IF statement*, which differs from the *IF() function* described here. See [Section 12.8.6.1, “IF Statement”](#).

- `IFNULL(expr1,expr2)`

If *expr1* is not `NULL`, `IFNULL()` returns *expr1*; otherwise it returns *expr2*. `IFNULL()` returns a numeric or string value, depending on the context in which it is used.

```
mysql> SELECT IFNULL(1,0);
-> 1
mysql> SELECT IFNULL(NULL,10);
-> 10
mysql> SELECT IFNULL(1/0,10);
-> 10
mysql> SELECT IFNULL(1/0,'yes');
-> 'yes'
```

The default result value of `IFNULL(expr1,expr2)` is the more “general” of the two expressions, in the order `STRING`, `REAL`, or `INTEGER`. Consider the case of a table based on expressions or where MySQL must internally store a value returned by `IFNULL()` in a temporary table:

```
mysql> CREATE TABLE tmp SELECT IFNULL(1,'test') AS test;
mysql> DESCRIBE tmp;
+-----+-----+-----+-----+-----+-----+
| Field | Type          | Null | Key | Default | Extra |
+-----+-----+-----+-----+-----+-----+
| test  | varbinary(4) | NO   |     |         |       |
+-----+-----+-----+-----+-----+-----+
```

In this example, the type of the `test` column is `CHAR(4)`.

- `NULLIF(expr1,expr2)`

Returns `NULL` if *expr1* = *expr2* is true, otherwise returns *expr1*. This is the same as `CASE WHEN expr1 = expr2 THEN NULL ELSE expr1 END`.

```
mysql> SELECT NULLIF(1,1);
-> NULL
mysql> SELECT NULLIF(1,2);
-> 1
```

Note that MySQL evaluates *expr1* twice if the arguments are not equal.

11.4. String Functions

Name	Description
<code>ASCII()</code>	Return numeric value of left-most character
<code>BIN()</code>	Return a string representation of the argument
<code>BIT_LENGTH()</code>	Return length of argument in bits
<code>CHAR_LENGTH()</code>	Return number of characters in argument
<code>CHAR()</code>	Return the character for each integer passed
<code>CHARACTER_LENGTH()</code>	A synonym for <code>CHAR_LENGTH()</code>
<code>CONCAT_WS()</code>	Return concatenate with separator
<code>CONCAT()</code>	Return concatenated string
<code>ELT()</code>	Return string at index number
<code>EXPORT_SET()</code>	Return a string such that for every bit set in the value bits, you get an on string and for every unset bit, you get an off string
<code>FIELD()</code>	Return the index (position) of the first argument in the subsequent arguments
<code>FIND_IN_SET()</code>	Return the index position of the first argument within the second argument
<code>FORMAT()</code>	Return a number formatted to specified number of decimal places
<code>HEX()</code>	Return a hexadecimal representation of a decimal or string value
<code>INSERT()</code>	Insert a substring at the specified position up to the specified number of char-

Name	Description
	acters
INSTR ()	Return the index of the first occurrence of substring
LCASE ()	Synonym for LOWER()
LEFT ()	Return the leftmost number of characters as specified
LENGTH ()	Return the length of a string in bytes
LIKE	Simple pattern matching
LOAD_FILE ()	Load the named file
LOCATE ()	Return the position of the first occurrence of substring
LOWER ()	Return the argument in lowercase
LPAD ()	Return the string argument, left-padded with the specified string
LTRIM ()	Remove leading spaces
MAKE_SET ()	Return a set of comma-separated strings that have the corresponding bit in bits set
MATCH	Perform full-text search
MID ()	Return a substring starting from the specified position
NOT LIKE	Negation of simple pattern matching
NOT REGEXP	Negation of REGEXP
OCTET_LENGTH ()	A synonym for LENGTH()
ORD ()	Return character code for leftmost character of the argument
POSITION ()	A synonym for LOCATE()
QUOTE ()	Escape the argument for use in an SQL statement
REGEXP	Pattern matching using regular expressions
REPEAT ()	Repeat a string the specified number of times
REPLACE ()	Replace occurrences of a specified string
REVERSE ()	Reverse the characters in a string
RIGHT ()	Return the specified rightmost number of characters
RLIKE	Synonym for REGEXP
RPAD ()	Append string the specified number of times
RTRIM ()	Remove trailing spaces
SOUNDEX ()	Return a soundex string
SOUNDS LIKE(v4.1.0)	Compare sounds
SPACE ()	Return a string of the specified number of spaces
STRCMP ()	Compare two strings
SUBSTR ()	Return the substring as specified
SUBSTRING_INDEX ()	Return a substring from a string before the specified number of occurrences of the delimiter
SUBSTRING ()	Return the substring as specified
TRIM ()	Remove leading and trailing spaces
UCASE ()	Synonym for UPPER()
UNHEX () (v4.1.2)	Convert each pair of hexadecimal digits to a character
UPPER ()	Convert to uppercase

String-valued functions return `NULL` if the length of the result would be greater than the value of the `max_allowed_packet` system variable. See [Section 7.5.3, “Tuning Server Parameters”](#).

For functions that operate on string positions, the first position is numbered 1.

For functions that take length arguments, non-integer arguments are rounded to the nearest integer.

- `ASCII(str)`

Returns the numeric value of the leftmost character of the string *str*. Returns 0 if *str* is the empty string. Returns `NULL` if *str* is `NULL`. `ASCII()` works for 8-bit characters.

```
mysql> SELECT ASCII('2');
-> 50
mysql> SELECT ASCII(2);
-> 50
mysql> SELECT ASCII('dx');
-> 100
```

See also the `ORD()` function.

- `BIN(N)`

Returns a string representation of the binary value of *N*, where *N* is a longlong (`BIGINT`) number. This is equivalent to `CONV(N, 10, 2)`. Returns `NULL` if *N* is `NULL`.

```
mysql> SELECT BIN(12);
-> '1100'
```

- `BIT_LENGTH(str)`

Returns the length of the string *str* in bits.

```
mysql> SELECT BIT_LENGTH('text');
-> 32
```

- `CHAR(N, ... [USING charset_name])`

`CHAR()` interprets each argument *N* as an integer and returns a string consisting of the characters given by the code values of those integers. `NULL` values are skipped.

```
mysql> SELECT CHAR(77,121,83,81,'76');
-> 'MySQL'
mysql> SELECT CHAR(77,77.3,'77.3');
-> 'MMM'
```

`CHAR()` arguments larger than 255 are converted into multiple result bytes. For example, `CHAR(256)` is equivalent to `CHAR(1,0)`, and `CHAR(256*256)` is equivalent to `CHAR(1,0,0)`:

```
mysql> SELECT HEX(CHAR(1,0)), HEX(CHAR(256));
+-----+-----+
| HEX(CHAR(1,0)) | HEX(CHAR(256)) |
+-----+-----+
| 0100          | 0100          |
+-----+-----+
mysql> SELECT HEX(CHAR(1,0,0)), HEX(CHAR(256*256));
+-----+-----+
| HEX(CHAR(1,0,0)) | HEX(CHAR(256*256)) |
+-----+-----+
| 010000         | 010000         |
+-----+-----+
```

By default, `CHAR()` returns a binary string. To produce a string in a given character set, use the optional `USING` clause:

```
mysql> SELECT CHARSET(CHAR(0x65)), CHARSET(CHAR(0x65 USING utf8));
+-----+-----+
| CHARSET(CHAR(0x65)) | CHARSET(CHAR(0x65 USING utf8)) |
+-----+-----+
| binary              | utf8                            |
+-----+-----+
```

If `USING` is given and the result string is illegal for the given character set, a warning is issued. Also, if strict SQL mode is enabled, the result from `CHAR()` becomes `NULL`.

- `CHAR_LENGTH(str)`

Returns the length of the string *str*, measured in characters. A multi-byte character counts as a single character. This means that for a string containing five two-byte characters, `LENGTH()` returns 10, whereas `CHAR_LENGTH()` returns 5.

- `CHARACTER_LENGTH(str)`

`CHARACTER_LENGTH()` is a synonym for `CHAR_LENGTH()`.

- `CONCAT(str1, str2, ...)`

Returns the string that results from concatenating the arguments. May have one or more arguments. If all arguments are nonbinary strings, the result is a nonbinary string. If the arguments include any binary strings, the result is a binary string. A numeric argument is converted to its equivalent binary string form; if you want to avoid that, you can use an explicit type cast, as in this example:

```
SELECT CONCAT(CAST(int_col AS CHAR), char_col);
```

`CONCAT()` returns `NULL` if any argument is `NULL`.

```
mysql> SELECT CONCAT('My', 'S', 'QL');
-> 'MySQL'
mysql> SELECT CONCAT('My', NULL, 'QL');
-> NULL
mysql> SELECT CONCAT(14.3);
-> '14.3'
```

For quoted strings, concatenation can be performed by placing the strings next to each other:

```
mysql> SELECT 'My' 'S' 'QL';
-> 'MySQL'
```

- `CONCAT_WS(separator, str1, str2, ...)`

`CONCAT_WS()` stands for Concatenate With Separator and is a special form of `CONCAT()`. The first argument is the separator for the rest of the arguments. The separator is added between the strings to be concatenated. The separator can be a string, as can the rest of the arguments. If the separator is `NULL`, the result is `NULL`.

```
mysql> SELECT CONCAT_WS(',', 'First name', 'Second name', 'Last Name');
-> 'First name,Second name,Last Name'
mysql> SELECT CONCAT_WS(',', 'First name', NULL, 'Last Name');
-> 'First name,Last Name'
```

`CONCAT_WS()` does not skip empty strings. However, it does skip any `NULL` values after the separator argument.

- `ELT(N, str1, str2, str3, ...)`

Returns `str1` if `N = 1`, `str2` if `N = 2`, and so on. Returns `NULL` if `N` is less than 1 or greater than the number of arguments. `ELT()` is the complement of `FIELD()`.

```
mysql> SELECT ELT(1, 'ej', 'Heja', 'hej', 'foo');
-> 'ej'
mysql> SELECT ELT(4, 'ej', 'Heja', 'hej', 'foo');
-> 'foo'
```

- `EXPORT_SET(bits, on, off[, separator[, number_of_bits]])`

Returns a string such that for every bit set in the value `bits`, you get an `on` string and for every bit not set in the value, you get an `off` string. Bits in `bits` are examined from right to left (from low-order to high-order bits). Strings are added to the result from left to right, separated by the `separator` string (the default being the comma character “,”). The number of bits examined is given by `number_of_bits` (defaults to 64).

```
mysql> SELECT EXPORT_SET(5, 'Y', 'N', ',', 4);
-> 'Y,N,Y,N'
mysql> SELECT EXPORT_SET(6, '1', '0', ',', 10);
-> '0,1,1,0,0,0,0,0,0,0'
```

- `FIELD(str, str1, str2, str3, ...)`

Returns the index (position) of `str` in the `str1, str2, str3, ...` list. Returns 0 if `str` is not found.

If all arguments to `FIELD()` are strings, all arguments are compared as strings. If all arguments are numbers, they are compared as numbers. Otherwise, the arguments are compared as double.

If `str` is `NULL`, the return value is 0 because `NULL` fails equality comparison with any value. `FIELD()` is the complement of `ELT()`.

```
mysql> SELECT FIELD('ej', 'Hej', 'ej', 'Heja', 'hej', 'foo');
-> 2
mysql> SELECT FIELD('fo', 'Hej', 'ej', 'Heja', 'hej', 'foo');
-> 0
```

- `FIND_IN_SET(str, strlist)`

Returns a value in the range of 1 to *N* if the string *str* is in the string list *strlist* consisting of *N* substrings. A string list is a string composed of substrings separated by “,” characters. If the first argument is a constant string and the second is a column of type `SET`, the `FIND_IN_SET()` function is optimized to use bit arithmetic. Returns 0 if *str* is not in *strlist* or if *strlist* is the empty string. Returns `NULL` if either argument is `NULL`. This function does not work properly if the first argument contains a comma (“,”) character.

```
mysql> SELECT FIND_IN_SET('b', 'a,b,c,d');
-> 2
```

- `FORMAT(X, D)`

Formats the number *X* to a format like '#,###,###.##', rounded to *D* decimal places, and returns the result as a string. If *D* is 0, the result has no decimal point or fractional part.

```
mysql> SELECT FORMAT(12332.123456, 4);
-> '12,332.1235'
mysql> SELECT FORMAT(12332.1, 4);
-> '12,332.1000'
mysql> SELECT FORMAT(12332.2, 0);
-> '12,332'
```

- `HEX(N_or_S)`

If *N_or_S* is a number, returns a string representation of the hexadecimal value of *N*, where *N* is a longlong (`BIGINT`) number. This is equivalent to `CONV(N, 10, 16)`.

If *N_or_S* is a string, returns a hexadecimal string representation of *N_or_S* where each character in *N_or_S* is converted to two hexadecimal digits. The inverse of this operation is performed by the `UNHEX()` function.

```
mysql> SELECT HEX(255);
-> 'FF'
mysql> SELECT HEX(0x616263);
-> 'abc'
mysql> SELECT HEX('abc');
-> 616263
```

- `INSERT(str, pos, len, newstr)`

Returns the string *str*, with the substring beginning at position *pos* and *len* characters long replaced by the string *newstr*. Returns the original string if *pos* is not within the length of the string. Replaces the rest of the string from position *pos* if *len* is not within the length of the rest of the string. Returns `NULL` if any argument is `NULL`.

```
mysql> SELECT INSERT('Quadratic', 3, 4, 'What');
-> 'QuWhattic'
mysql> SELECT INSERT('Quadratic', -1, 4, 'What');
-> 'Quadratic'
mysql> SELECT INSERT('Quadratic', 3, 100, 'What');
-> 'QuWhat'
```

This function is multi-byte safe.

- `INSTR(str, substr)`

Returns the position of the first occurrence of substring *substr* in string *str*. This is the same as the two-argument form of `LOCATE()`, except that the order of the arguments is reversed.

```
mysql> SELECT INSTR('foobarbar', 'bar');
-> 4
mysql> SELECT INSTR('xbar', 'foobar');
-> 0
```

This function is multi-byte safe, and is case sensitive only if at least one argument is a binary string.

- `LCASE(str)`

`LCASE()` is a synonym for `LOWER()`.

- `LEFT(str, len)`

Returns the leftmost *len* characters from the string *str*, or `NULL` if any argument is `NULL`.

```
mysql> SELECT LEFT('foobarbar', 5);
-> 'fooba'
```

- `LENGTH(str)`

Returns the length of the string *str*, measured in bytes. A multi-byte character counts as multiple bytes. This means that for a string containing five two-byte characters, `LENGTH()` returns 10, whereas `CHAR_LENGTH()` returns 5.

```
mysql> SELECT LENGTH('text');
-> 4
```

- `LOAD_FILE(file_name)`

Reads the file and returns the file contents as a string. To use this function, the file must be located on the server host, you must specify the full path name to the file, and you must have the `FILE` privilege. The file must be readable by all and its size less than `max_allowed_packet` bytes. If the `secure_file_priv` system variable is set to a non-empty directory name, the file to be loaded must be located in that directory.

If the file does not exist or cannot be read because one of the preceding conditions is not satisfied, the function returns `NULL`.

The `character_set_filesystem` system variable controls interpretation of file names that are given as literal strings.

```
mysql> UPDATE t
      SET blob_col=LOAD_FILE('/tmp/picture')
      WHERE id=1;
```

- `LOCATE(substr,str)`, `LOCATE(substr,str,pos)`

The first syntax returns the position of the first occurrence of substring *substr* in string *str*. The second syntax returns the position of the first occurrence of substring *substr* in string *str*, starting at position *pos*. Returns 0 if *substr* is not in *str*.

```
mysql> SELECT LOCATE('bar', 'foobarbar');
-> 4
mysql> SELECT LOCATE('xbar', 'foobar');
-> 0
mysql> SELECT LOCATE('bar', 'foobarbar', 5);
-> 7
```

This function is multi-byte safe, and is case-sensitive only if at least one argument is a binary string.

- `LOWER(str)`

Returns the string *str* with all characters changed to lowercase according to the current character set mapping. The default is `latin1` (cp1252 West European).

```
mysql> SELECT LOWER('QUADRATICALLY');
-> 'quadratically'
```

`LOWER()` (and `UPPER()`) are ineffective when applied to binary strings (`BINARY`, `VARBINARY`, `BLOB`). To perform letter-case conversion, convert the string to a nonbinary string:

```
mysql> SET @str = BINARY 'New York';
mysql> SELECT LOWER(@str), LOWER(CONVERT(@str USING latin1));
+-----+-----+
| LOWER(@str) | LOWER(CONVERT(@str USING latin1)) |
+-----+-----+
| New York   | new york                           |
+-----+-----+
```

This function is multi-byte safe.

- `LPAD(str,len,padstr)`

Returns the string *str*, left-padded with the string *padstr* to a length of *len* characters. If *str* is longer than *len*, the return value is shortened to *len* characters.

```
mysql> SELECT LPAD('hi',4,'?');
-> '??hi'
mysql> SELECT LPAD('hi',1,'?');
-> 'h'
```

- `LTRIM(str)`

Returns the string *str* with leading space characters removed.

```
mysql> SELECT LTRIM('  barbar');
-> 'barbar'
```

This function is multi-byte safe.

- `MAKE_SET(bits, str1, str2, ...)`

Returns a set value (a string containing substrings separated by “,” characters) consisting of the strings that have the corresponding bit in *bits* set. *str1* corresponds to bit 0, *str2* to bit 1, and so on. `NULL` values in *str1*, *str2*, ... are not appended to the result.

```
mysql> SELECT MAKE_SET(1, 'a', 'b', 'c');
-> 'a'
mysql> SELECT MAKE_SET(1 | 4, 'hello', 'nice', 'world');
-> 'hello,world'
mysql> SELECT MAKE_SET(1 | 4, 'hello', 'nice', NULL, 'world');
-> 'hello'
mysql> SELECT MAKE_SET(0, 'a', 'b', 'c');
-> ''
```

- `MID(str, pos, len)`

`MID(str, pos, len)` is a synonym for `SUBSTRING(str, pos, len)`.

- `OCTET_LENGTH(str)`

`OCTET_LENGTH()` is a synonym for `LENGTH()`.

- `ORD(str)`

If the leftmost character of the string *str* is a multi-byte character, returns the code for that character, calculated from the numeric values of its constituent bytes using this formula:

```
(1st byte code)
+ (2nd byte code × 256)
+ (3rd byte code × 2562) ...
```

If the leftmost character is not a multi-byte character, `ORD()` returns the same value as the `ASCII()` function.

```
mysql> SELECT ORD('2');
-> 50
```

- `POSITION(substr IN str)`

`POSITION(substr IN str)` is a synonym for `LOCATE(substr, str)`.

- `QUOTE(str)`

Quotes a string to produce a result that can be used as a properly escaped data value in an SQL statement. The string is returned enclosed by single quotes and with each instance of single quote (“'”), backslash (“\”), ASCII `NUL`, and Control-Z preceded by a backslash. If the argument is `NULL`, the return value is the word “NULL” without enclosing single quotes.

```
mysql> SELECT QUOTE('Don\'t!');
-> 'Don\'t!'
mysql> SELECT QUOTE(NULL);
-> NULL
```

- `REPEAT(str, count)`

Returns a string consisting of the string *str* repeated *count* times. If *count* is less than 1, returns an empty string. Returns `NULL` if *str* or *count* are `NULL`.

```
mysql> SELECT REPEAT('MySQL', 3);
-> 'MySQLMySQLMySQL'
```

- `REPLACE(str, from_str, to_str)`

Returns the string *str* with all occurrences of the string *from_str* replaced by the string *to_str*. `REPLACE()` performs a case-sensitive match when searching for *from_str*.

```
mysql> SELECT REPLACE('www.mysql.com', 'w', 'Ww');
-> 'WwWwWw.mysql.com'
```

This function is multi-byte safe.

- `REVERSE(str)`

Returns the string `str` with the order of the characters reversed.

```
mysql> SELECT REVERSE('abc');
-> 'cba'
```

This function is multi-byte safe.

- `RIGHT(str, len)`

Returns the rightmost `len` characters from the string `str`, or `NULL` if any argument is `NULL`.

```
mysql> SELECT RIGHT('foobarbar', 4);
-> 'rbar'
```

This function is multi-byte safe.

- `RPAD(str, len, padstr)`

Returns the string `str`, right-padded with the string `padstr` to a length of `len` characters. If `str` is longer than `len`, the return value is shortened to `len` characters.

```
mysql> SELECT RPAD('hi', 5, '?');
-> 'hi???'
mysql> SELECT RPAD('hi', 1, '?');
-> 'h'
```

This function is multi-byte safe.

- `RTRIM(str)`

Returns the string `str` with trailing space characters removed.

```
mysql> SELECT RTRIM('barbar ');
-> 'barbar'
```

This function is multi-byte safe.

- `SOUNDEX(str)`

Returns a soundex string from `str`. Two strings that sound almost the same should have identical soundex strings. A standard soundex string is four characters long, but the `SOUNDEX()` function returns an arbitrarily long string. You can use `SUBSTRING()` on the result to get a standard soundex string. All non-alphabetic characters in `str` are ignored. All international alphabetic characters outside the A-Z range are treated as vowels.

Important

When using `SOUNDEX()`, you should be aware of the following limitations:

- This function, as currently implemented, is intended to work well with strings that are in the English language only. Strings in other languages may not produce reliable results.
- This function is not guaranteed to provide consistent results with strings that use multi-byte character sets, including `utf-8`.

We hope to remove these limitations in a future release. See [Bug#22638](#) for more information.

```
mysql> SELECT SOUNDEX('Hello');
-> 'H400'
mysql> SELECT SOUNDEX('Quadratically');
-> 'Q36324'
```

Note

This function implements the original Soundex algorithm, not the more popular enhanced version (also described by D. Knuth). The difference is that original version discards vowels first and duplicates second, whereas the enhanced version discards duplicates first and vowels second.

- `expr1 SOUNDS LIKE expr2`

This is the same as `SOUNDEX(expr1) = SOUNDEX(expr2)`.

- `SPACE(N)`

Returns a string consisting of *N* space characters.

```
mysql> SELECT SPACE(6);
-> '      '
```

- `SUBSTR(str, pos)`, `SUBSTR(str FROM pos)`, `SUBSTR(str, pos, len)`, `SUBSTR(str FROM pos FOR len)`

`SUBSTR()` is a synonym for `SUBSTRING()`.

- `SUBSTRING(str, pos)`, `SUBSTRING(str FROM pos)`, `SUBSTRING(str, pos, len)`, `SUBSTRING(str FROM pos FOR len)`

The forms without a *len* argument return a substring from string *str* starting at position *pos*. The forms with a *len* argument return a substring *len* characters long from string *str*, starting at position *pos*. The forms that use `FROM` are standard SQL syntax. It is also possible to use a negative value for *pos*. In this case, the beginning of the substring is *pos* characters from the end of the string, rather than the beginning. A negative value may be used for *pos* in any of the forms of this function.

For all forms of `SUBSTRING()`, the position of the first character in the string from which the substring is to be extracted is reckoned as 1.

```
mysql> SELECT SUBSTRING('Quadratically',5);
-> 'ratically'
mysql> SELECT SUBSTRING('foobarbar' FROM 4);
-> 'barbar'
mysql> SELECT SUBSTRING('Quadratically',5,6);
-> 'ratica'
mysql> SELECT SUBSTRING('Sakila', -3);
-> 'ila'
mysql> SELECT SUBSTRING('Sakila', -5, 3);
-> 'aki'
mysql> SELECT SUBSTRING('Sakila' FROM -4 FOR 2);
-> 'ki'
```

This function is multi-byte safe.

If *len* is less than 1, the result is the empty string.

- `SUBSTRING_INDEX(str, delim, count)`

Returns the substring from string *str* before *count* occurrences of the delimiter *delim*. If *count* is positive, everything to the left of the final delimiter (counting from the left) is returned. If *count* is negative, everything to the right of the final delimiter (counting from the right) is returned. `SUBSTRING_INDEX()` performs a case-sensitive match when searching for *delim*.

```
mysql> SELECT SUBSTRING_INDEX('www.mysql.com', '.', 2);
-> 'www.mysql'
mysql> SELECT SUBSTRING_INDEX('www.mysql.com', '.', -2);
-> 'mysql.com'
```

This function is multi-byte safe.

- `TRIM([{BOTH | LEADING | TRAILING} [remstr] FROM] str)`, `TRIM([remstr FROM] str)`

Returns the string *str* with all *remstr* prefixes or suffixes removed. If none of the specifiers `BOTH`, `LEADING`, or `TRAILING` is given, `BOTH` is assumed. *remstr* is optional and, if not specified, spaces are removed.

```
mysql> SELECT TRIM(' bar ');
-> 'bar'
mysql> SELECT TRIM(LEADING 'x' FROM 'xxxbarxxx');
-> 'barxxx'
mysql> SELECT TRIM(BOTH 'x' FROM 'xxxbarxxx');
-> 'bar'
mysql> SELECT TRIM(TRAILING 'xyz' FROM 'barxyz');
-> 'barx'
```

This function is multi-byte safe.

- `UCASE(str)`

`UCASE()` is a synonym for `UPPER()`.

- `UNHEX(str)`

Performs the inverse operation of `HEX(str)`. That is, it interprets each pair of hexadecimal digits in the argument as a number and converts it to the character represented by the number. The resulting characters are returned as a binary string.

```
mysql> SELECT UNHEX('4D7953514C');
-> 'MySQL'
mysql> SELECT 0x4D7953514C;
-> 'MySQL'
mysql> SELECT UNHEX(HEX('string'));
-> 'string'
mysql> SELECT HEX(UNHEX('1267'));
-> '1267'
```

The characters in the argument string must be legal hexadecimal digits: '0' .. '9', 'A' .. 'F', 'a' .. 'f'. If `UNHEX()` encounters any non-hexadecimal digits in the argument, it returns `NULL`:

```
mysql> SELECT UNHEX('GG');
+-----+
| UNHEX('GG') |
+-----+
| NULL        |
+-----+
```

A `NULL` result can occur if the argument to `UNHEX()` is a `BINARY` column, because values are padded with `0x00` bytes when stored but those bytes are not stripped on retrieval. For example 'aa' is stored into a `CHAR(3)` column as 'aa ' and retrieved as 'aa' (with the trailing pad space stripped), so `UNHEX()` for the column value returns 'A'. By contrast 'aa' is stored into a `BINARY(3)` column as 'aa\0' and retrieved as 'aa\0' (with the trailing pad `0x00` byte not stripped). '\0' is not a legal hexadecimal digit, so `UNHEX()` for the column value returns `NULL`.

- `UPPER(str)`

Returns the string *str* with all characters changed to uppercase according to the current character set mapping. The default is `latin1` (cp1252 West European).

```
mysql> SELECT UPPER('Hej');
-> 'HEJ'
```

`UPPER()` is ineffective when applied to binary strings (`BINARY`, `VARBINARY`, `BLOB`). The description of `LOWER()` shows how to perform lettercase conversion of binary strings.

This function is multi-byte safe.

11.4.1. String Comparison Functions

Name	Description
<code>LIKE</code>	Simple pattern matching
<code>NOT LIKE</code>	Negation of simple pattern matching
<code>STRCMP()</code>	Compare two strings

If a string function is given a binary string as an argument, the resulting string is also a binary string. A number converted to a string is treated as a binary string. This affects only comparisons.

Normally, if any expression in a string comparison is case sensitive, the comparison is performed in case-sensitive fashion.

- `expr LIKE pat [ESCAPE 'escape_char']`

Pattern matching using SQL simple regular expression comparison. Returns 1 (`TRUE`) or 0 (`FALSE`). If either *expr* or *pat* is `NULL`, the result is `NULL`.

The pattern need not be a literal string. For example, it can be specified as a string expression or table column.

Per the SQL standard, `LIKE` performs matching on a per-character basis, thus it can produce results different from the `=` comparison operator:

```
mysql> SELECT 'ä' LIKE 'ae' COLLATE latin1_german2_ci;
+-----+
| 'ä' LIKE 'ae' COLLATE latin1_german2_ci |
+-----+
| 0 |
+-----+
mysql> SELECT 'ä' = 'ae' COLLATE latin1_german2_ci;
+-----+
| 'ä' = 'ae' COLLATE latin1_german2_ci |
+-----+
| 1 |
+-----+
```

In particular, trailing spaces are significant, which is not true for `CHAR` or `VARCHAR` comparisons performed with the `=` operator:

```
mysql> SELECT 'a' = 'a ', 'a' LIKE 'a ';
+-----+-----+
| 'a' = 'a ' | 'a' LIKE 'a ' |
+-----+-----+
| 1 | 0 |
+-----+-----+
1 row in set (0.00 sec)
```

With `LIKE` you can use the following two wildcard characters in the pattern.

Character	Description
<code>%</code>	Matches any number of characters, even zero characters
<code>_</code>	Matches exactly one character

```
mysql> SELECT 'David!' LIKE 'David_';
-> 1
mysql> SELECT 'David!' LIKE '%D%v%';
-> 1
```

To test for literal instances of a wildcard character, precede it by the escape character. If you do not specify the `ESCAPE` character, `"\"` is assumed.

String	Description
<code>\%</code>	Matches one <code>"%"</code> character
<code>_</code>	Matches one <code>"_"</code> character

```
mysql> SELECT 'David!' LIKE 'David\>';
-> 0
mysql> SELECT 'David_' LIKE 'David\_';
-> 1
```

To specify a different escape character, use the `ESCAPE` clause:

```
mysql> SELECT 'David_' LIKE 'David|_' ESCAPE '|';
-> 1
```

The escape sequence should be empty or one character long. If the `NO_BACKSLASH_ESCAPES` SQL mode is enabled, the sequence cannot be empty.

The following two statements illustrate that string comparisons are not case sensitive unless one of the operands is a binary string:

```
mysql> SELECT 'abc' LIKE 'ABC';
-> 1
mysql> SELECT 'abc' LIKE BINARY 'ABC';
-> 0
```

In MySQL, `LIKE` is allowed on numeric expressions. (This is an extension to the standard SQL `LIKE`.)

```
mysql> SELECT 10 LIKE '1%';
-> 1
```

Note

Because MySQL uses C escape syntax in strings (for example, “\n” to represent a newline character), you must double any “\” that you use in `LIKE` strings. For example, to search for “\n”, specify it as “\\n”. To search for “\”, specify it as “\\\\”; this is because the backslashes are stripped once by the parser and again when the pattern match is made, leaving a single backslash to be matched against. (Exception: At the end of the pattern string, backslash can be specified as “\”. At the end of the string, backslash stands for itself because there is nothing following to escape.)

- `expr NOT LIKE pat [ESCAPE 'escape_char']`

This is the same as `NOT (expr LIKE pat [ESCAPE 'escape_char'])`.

Note

Aggregate queries involving `NOT LIKE` comparisons with columns containing `NULL` may yield unexpected results. For example, consider the following table and data:

```
CREATE TABLE foo (bar VARCHAR(10));
INSERT INTO foo VALUES (NULL), (NULL);
```

The query `SELECT COUNT(*) FROM foo WHERE bar LIKE '%baz%'`; returns 0. You might assume that `SELECT COUNT(*) FROM foo WHERE bar NOT LIKE '%baz%'`; would return 2. However, this is not the case: The second query returns 0. This is because `NULL NOT LIKE expr` always returns `NULL`, regardless of the value of `expr`. The same is true for aggregate queries involving `NULL` and comparisons using `NOT RLIKE` or `NOT REGEXP`. In such cases, you must test explicitly for `NOT NULL` using `OR` (and not `AND`), as shown here:

```
SELECT COUNT(*) FROM foo WHERE bar NOT LIKE '%baz%' OR bar IS NULL;
```

- `STRCMP(expr1,expr2)`

`STRCMP()` returns 0 if the strings are the same, -1 if the first argument is smaller than the second according to the current sort order, and 1 otherwise.

```
mysql> SELECT STRCMP('text', 'text2');
-> -1
mysql> SELECT STRCMP('text2', 'text');
-> 1
mysql> SELECT STRCMP('text', 'text');
-> 0
```

`STRCMP()` uses the current character set when performing comparisons. This makes the default comparison behavior case insensitive unless one or both of the operands are binary strings.

11.4.2. Regular Expressions

Name	Description
<code>NOT REGEXP</code>	Negation of <code>REGEXP</code>
<code>REGEXP</code>	Pattern matching using regular expressions
<code>RLIKE</code>	Synonym for <code>REGEXP</code>

A regular expression is a powerful way of specifying a pattern for a complex search.

MySQL uses Henry Spencer's implementation of regular expressions, which is aimed at conformance with POSIX 1003.2. See [Section 1.8, “Credits”](#). MySQL uses the extended version to support pattern-matching operations performed with the `REGEXP` operator in SQL statements.

This section summarizes, with examples, the special characters and constructs that can be used in MySQL for `REGEXP` operations. It does not contain all the details that can be found in Henry Spencer's `regex(7)` manual page. That manual page is included in MySQL source distributions, in the `regex.7` file under the `regex` directory. See also [Section 3.3.4.7, “Pattern Matching”](#).

- `expr NOT REGEXP pat, expr NOT RLIKE pat`

This is the same as `NOT (expr REGEXP pat)`.

- `expr REGEXP pat, expr RLIKE pat`

Performs a pattern match of a string expression `expr` against a pattern `pat`. The pattern can be an extended regular expression. The syntax for regular expressions is discussed in [Section 11.4.2, “Regular Expressions”](#). Returns 1 if `expr` matches `pat`; otherwise it returns 0. If either `expr` or `pat` is NULL, the result is NULL. `RLIKE` is a synonym for `REGEXP`, provided for `MySQL` compatibility.

The pattern need not be a literal string. For example, it can be specified as a string expression or table column.

Note

Because MySQL uses the C escape syntax in strings (for example, “\n” to represent the newline character), you must double any “\” that you use in your `REGEXP` strings.

`REGEXP` is not case sensitive, except when used with binary strings.

```
mysql> SELECT 'Monty!' REGEXP 'm%y%';
-> 0
mysql> SELECT 'Monty!' REGEXP '.*';
-> 1
mysql> SELECT 'new*\n*line' REGEXP 'new\\.*\\*line';
-> 1
mysql> SELECT 'a' REGEXP 'A', 'a' REGEXP BINARY 'A';
-> 1 0
mysql> SELECT 'a' REGEXP '^[a-d]';
-> 1
```

`REGEXP` and `RLIKE` use the current character set when deciding the type of a character. The default is `latin1` (cp1252 West European).

Warning

The `REGEXP` and `RLIKE` operators work in byte-wise fashion, so they are not multi-byte safe and may produce unexpected results with multi-byte character sets. In addition, these operators compare characters by their byte values and accented characters may not compare as equal even if a given collation treats them as equal.

A regular expression describes a set of strings. The simplest regular expression is one that has no special characters in it. For example, the regular expression `hello` matches `hello` and nothing else.

Non-trivial regular expressions use certain special constructs so that they can match more than one string. For example, the regular expression `hello|word` matches either the string `hello` or the string `word`.

As a more complex example, the regular expression `B[an]*s` matches any of the strings `Bananas`, `Baaaaas`, `Bs`, and any other string starting with a `B`, ending with an `s`, and containing any number of `a` or `n` characters in between.

A regular expression for the `REGEXP` operator may use any of the following special characters and constructs:

- `^`

Match the beginning of a string.

```
mysql> SELECT 'fo\nfo' REGEXP '^fo$';
-> 0
mysql> SELECT 'fofo' REGEXP '^fo';
-> 1
```

- `$`

Match the end of a string.

```
mysql> SELECT 'fo\no' REGEXP '^fo\no$';
-> 1
mysql> SELECT 'fo\no' REGEXP '^fo$';
-> 0
```

- `.`

Match any character (including carriage return and newline).

```
mysql> SELECT 'fofo' REGEXP '^f.*$';
-> 1
mysql> SELECT 'fo\r\nfo' REGEXP '^f.*$';
-> 1
```

- `a*`

Match any sequence of zero or more `a` characters.

```
mysql> SELECT 'Ban' REGEXP '^Ba*n';      -> 1
mysql> SELECT 'Baaan' REGEXP '^Ba*n';   -> 1
mysql> SELECT 'Bn' REGEXP '^Ba*n';      -> 1
```

- `a+`

Match any sequence of one or more `a` characters.

```
mysql> SELECT 'Ban' REGEXP '^Ba+n';      -> 1
mysql> SELECT 'Bn' REGEXP '^Ba+n';      -> 0
```

- `a?`

Match either zero or one `a` character.

```
mysql> SELECT 'Bn' REGEXP '^Ba?n';       -> 1
mysql> SELECT 'Ban' REGEXP '^Ba?n';     -> 1
mysql> SELECT 'Baan' REGEXP '^Ba?n';    -> 0
```

- `de|abc`

Match either of the sequences `de` or `abc`.

```
mysql> SELECT 'pi' REGEXP 'pi|apa';      -> 1
mysql> SELECT 'axe' REGEXP 'pi|apa';     -> 0
mysql> SELECT 'apa' REGEXP 'pi|apa';     -> 1
mysql> SELECT 'apa' REGEXP '^ (pi|apa)$'; -> 1
mysql> SELECT 'pi' REGEXP '^ (pi|apa)$'; -> 1
mysql> SELECT 'pix' REGEXP '^ (pi|apa)$'; -> 0
```

- `(abc)*`

Match zero or more instances of the sequence `abc`.

```
mysql> SELECT 'pi' REGEXP '^ (pi)*$';    -> 1
mysql> SELECT 'pip' REGEXP '^ (pi)*$';   -> 0
mysql> SELECT 'pipi' REGEXP '^ (pi)*$';  -> 1
```

- `{1}, {2, 3}`

`{n}` or `{m, n}` notation provides a more general way of writing regular expressions that match many occurrences of the previous atom (or “piece”) of the pattern. `m` and `n` are integers.

- `a*`

Can be written as `a{0, }`.

- `a+`

Can be written as `a{1, }`.

- `a?`

Can be written as `a{0, 1}`.

To be more precise, `a{n}` matches exactly `n` instances of `a`. `a{n, }` matches `n` or more instances of `a`. `a{m, n}` matches `m` through `n` instances of `a`, inclusive.

`m` and `n` must be in the range from 0 to `RE_DUP_MAX` (default 255), inclusive. If both `m` and `n` are given, `m` must be less than or equal to `n`.

```
mysql> SELECT 'abcde' REGEXP 'a[bcd]{2}e'; -> 0
mysql> SELECT 'abcde' REGEXP 'a[bcd]{3}e'; -> 1
mysql> SELECT 'abcde' REGEXP 'a[bcd]{1,10}e'; -> 1
```

- `[a-dX], [^a-dX]`

Matches any character that is (or is not, if `^` is used) either `a`, `b`, `c`, `d` or `X`. A `-` character between two other characters forms a range that matches all characters from the first character to the second. For example, `[0-9]` matches any decimal digit. To include a literal `]` character, it must immediately follow the opening bracket `[`. To include a literal `-` character, it must be written first or last. Any character that does not have a defined special meaning inside a `[]` pair matches only itself.

```
mysql> SELECT 'aXbc' REGEXP '[a-dXYZ]';          -> 1
mysql> SELECT 'aXbc' REGEXP '^[a-dXYZ]$';       -> 0
mysql> SELECT 'aXbc' REGEXP '[a-dXYZ]+$';      -> 1
mysql> SELECT 'aXbc' REGEXP '^^[a-dXYZ]+$';    -> 0
mysql> SELECT 'gheis' REGEXP '^^[a-dXYZ]+$';   -> 1
mysql> SELECT 'gheisa' REGEXP '^^[a-dXYZ]+$';  -> 0
```

- [.characters.]

Within a bracket expression (written using [and]), matches the sequence of characters of that collating element. `characters` is either a single character or a character name like `newline`. The following table lists the allowable character names.

The following table shows the allowable character names and the characters that they match. For characters given as numeric values, the values are represented in octal.

Name	Character	Name	Character
NUL	0	SOH	001
STX	002	ETX	003
EOT	004	ENQ	005
ACK	006	BEL	007
alert	007	BS	010
backspace	'\b'	HT	011
tab	'\t'	LF	012
newline	'\n'	VT	013
vertical-tab	'\v'	FF	014
form-feed	'\f'	CR	015
carriage-return	'\r'	SO	016
SI	017	DLE	020
DC1	021	DC2	022
DC3	023	DC4	024
NAK	025	SYN	026
ETB	027	CAN	030
EM	031	SUB	032
ESC	033	IS4	034
FS	034	IS3	035
GS	035	IS2	036
RS	036	IS1	037
US	037	space	' '
exclamation-mark	'!'	quotation-mark	'\"'
number-sign	'#'	dollar-sign	'\$'
percent-sign	'%'	ampersand	'&'
apostrophe	'\''	left-parenthesis	'('
right-parenthesis	')'	asterisk	'*'
plus-sign	'+'	comma	','
hyphen	'-'	hyphen-minus	'-'
period	'.'	full-stop	'.'
slash	'/'	solidus	'/'
zero	'0'	one	'1'
two	'2'	three	'3'
four	'4'	five	'5'
six	'6'	seven	'7'
eight	'8'	nine	'9'
colon	':'	semicolon	';'

less-than-sign	'<'	equals-sign	'='
greater-than-sign	'>'	question-mark	'?'
commercial-at	'@'	left-square-bracket	'['
backslash	'\'	reverse-solidus	'\/'
right-square-bracket	']'	circumflex	'^'
circumflex-accent	'^'	underscore	'_'
low-line	'_'	grave-accent	'`'
left-brace	'{'	left-curly-bracket	'{'
vertical-line	' '	right-brace	'}'
right-curly-bracket	'}'	tilde	'~'
DEL	177		

```
mysql> SELECT '~' REGEXP '[[.~.]]';           -> 1
mysql> SELECT '~' REGEXP '[[.tilde.]]';      -> 1
```

- [=character_class=]

Within a bracket expression (written using [and]), [=character_class=] represents an equivalence class. It matches all characters with the same collation value, including itself. For example, if o and (+) are the members of an equivalence class, then [[=o=]], [[=(+)=]], and [o(+)] are all synonymous. An equivalence class may not be used as an endpoint of a range.

- [:character_class:]

Within a bracket expression (written using [and]), [:character_class:] represents a character class that matches all characters belonging to that class. The following table lists the standard class names. These names stand for the character classes defined in the ctype(3) manual page. A particular locale may provide other class names. A character class may not be used as an endpoint of a range.

alnum	Alphanumeric characters
alpha	Alphabetic characters
blank	Whitespace characters
cntrl	Control characters
digit	Digit characters
graph	Graphic characters
lower	Lowercase alphabetic characters
print	Graphic or space characters
punct	Punctuation characters
space	Space, tab, newline, and carriage return
upper	Uppercase alphabetic characters
xdigit	Hexadecimal digit characters

```
mysql> SELECT 'justalnums' REGEXP '[:alnum:]+';           -> 1
mysql> SELECT '!!!' REGEXP '[:alnum:]+';                 -> 0
```

- [[:<:]], [[:>:]]

These markers stand for word boundaries. They match the beginning and end of words, respectively. A word is a sequence of word characters that is not preceded by or followed by word characters. A word character is an alphanumeric character in the alnum class or an underscore (_).

```
mysql> SELECT 'a word a' REGEXP '[:<:]word[:>:]';       -> 1
mysql> SELECT 'a xword a' REGEXP '[:<:]word[:>:]';      -> 0
```

To use a literal instance of a special character in a regular expression, precede it by two backslash (\) characters. The MySQL parser interprets one of the backslashes, and the regular expression library interprets the other. For example, to match the string 1+2

that contains the special + character, only the last of the following regular expressions is the correct one:

```
mysql> SELECT '1+2' REGEXP '1+2';          -> 0
mysql> SELECT '1+2' REGEXP '1\\+2';       -> 0
mysql> SELECT '1+2' REGEXP '1\\\\+2';      -> 1
```

11.5. Numeric Functions

Name	Description
ABS ()	Return the absolute value
ACOS ()	Return the arc cosine
ASIN ()	Return the arc sine
ATAN2 (), ATAN ()	Return the arc tangent of the two arguments
ATAN ()	Return the arc tangent
CEIL ()	Return the smallest integer value not less than the argument
CEILING ()	Return the smallest integer value not less than the argument
CONV ()	Convert numbers between different number bases
COS ()	Return the cosine
COT ()	Return the cotangent
CRC32 () (v4.1.0)	Compute a cyclic redundancy check value
DEGREES ()	Convert radians to degrees
DIV (v4.1.0)	Integer division
/	Division operator
EXP ()	Raise to the power of
FLOOR ()	Return the largest integer value not greater than the argument
LN ()	Return the natural logarithm of the argument
LOG10 ()	Return the base-10 logarithm of the argument
LOG2 ()	Return the base-2 logarithm of the argument
LOG ()	Return the natural logarithm of the first argument
-	Minus operator
MOD ()	Return the remainder
%	Modulo operator
OCT ()	Return an octal representation of a decimal number
PI ()	Return the value of pi
+	Addition operator
POW ()	Return the argument raised to the specified power
POWER ()	Return the argument raised to the specified power
RADIANS ()	Return argument converted to radians
RAND ()	Return a random floating-point value
ROUND ()	Round the argument
SIGN ()	Return the sign of the argument
SIN ()	Return the sine of the argument
SQRT ()	Return the square root of the argument
TAN ()	Return the tangent of the argument
*	Times operator
TRUNCATE ()	Truncate to specified number of decimal places
-	Change the sign of the argument

11.5.1. Arithmetic Operators

Name	Description
<code>DIV(v4.1.0)</code>	Integer division
<code>/</code>	Division operator
<code>-</code>	Minus operator
<code>%</code>	Modulo operator
<code>+</code>	Addition operator
<code>*</code>	Times operator
<code>-</code>	Change the sign of the argument

The usual arithmetic operators are available. The result is determined according to the following rules:

- In the case of `-`, `+`, and `*`, the result is calculated with `BIGINT` (64-bit) precision if both arguments are integers.
- If one of the arguments is an unsigned integer, and the other argument is also an integer, the result is an unsigned integer.
- If any of the operands of a `+`, `-`, `/`, `*`, `%` is a real or string value, then the precision of the result is the precision of the argument with the maximum precision.
- In division performed with `/`, the scale of the result when using two exact values is the scale of the first argument plus the value of the `div_precision_increment` system variable (which is 4 by default). For example, the result of the expression `5.05 / 0.014` has a scale of six decimal places (`360.714286`).

These rules are applied for each operation, such that nested calculations imply the precision of each component. Hence, `(14620 / 9432456) / (24250 / 9432456)`, would resolve first to `(0.0014) / (0.0026)`, with the final result having 8 decimal places (`0.60288653`).

Because of these rules and the way they are applied, care should be taken to ensure that components and sub-components of a calculation use the appropriate level of precision. See [Section 11.9, “Cast Functions and Operators”](#).

- `+`

Addition:

```
mysql> SELECT 3+5;
-> 8
```

- `-`

Subtraction:

```
mysql> SELECT 3-5;
-> -2
```

- `-`

Unary minus. This operator changes the sign of the argument.

```
mysql> SELECT - 2;
-> -2
```

Note

If this operator is used with a `BIGINT`, the return value is also a `BIGINT`. This means that you should avoid using `-` on integers that may have the value of -2^{63} .

- `*`

Multiplication:

```
mysql> SELECT 3*5;
-> 15
mysql> SELECT 18014398509481984*18014398509481984.0;
-> 324518553658426726783156020576256.0
mysql> SELECT 18014398509481984*18014398509481984;
-> 0
```

The result of the last expression is incorrect because the result of the integer multiplication exceeds the 64-bit range of `BIGINT` calculations. (See [Section 10.2, “Numeric Types”](#).)

- /

Division:

```
mysql> SELECT 3/5;
-> 0.60
```

Division by zero produces a `NULL` result:

```
mysql> SELECT 102/(1-1);
-> NULL
```

A division is calculated with `BIGINT` arithmetic only if performed in a context where its result is converted to an integer.

- DIV

Integer division. Similar to `FLOOR()`, but is safe with `BIGINT` values. Incorrect results may occur for non-integer operands that exceed `BIGINT` range.

```
mysql> SELECT 5 DIV 2;
-> 2
```

- $N \% M$

Modulo operation. Returns the remainder of N divided by M . For more information, see the description for the `MOD()` function in [Section 11.5.2, “Mathematical Functions”](#).

11.5.2. Mathematical Functions

Name	Description
<code>ABS()</code>	Return the absolute value
<code>ACOS()</code>	Return the arc cosine
<code>ASIN()</code>	Return the arc sine
<code>ATAN2(), ATAN()</code>	Return the arc tangent of the two arguments
<code>ATAN()</code>	Return the arc tangent
<code>CEIL()</code>	Return the smallest integer value not less than the argument
<code>CEILING()</code>	Return the smallest integer value not less than the argument
<code>CONV()</code>	Convert numbers between different number bases
<code>COS()</code>	Return the cosine
<code>COT()</code>	Return the cotangent
<code>CRC32()</code> (v4.1.0)	Compute a cyclic redundancy check value
<code>DEGREES()</code>	Convert radians to degrees
<code>EXP()</code>	Raise to the power of
<code>FLOOR()</code>	Return the largest integer value not greater than the argument
<code>LN()</code>	Return the natural logarithm of the argument
<code>LOG10()</code>	Return the base-10 logarithm of the argument
<code>LOG2()</code>	Return the base-2 logarithm of the argument
<code>LOG()</code>	Return the natural logarithm of the first argument
<code>MOD()</code>	Return the remainder
<code>OCT()</code>	Return an octal representation of a decimal number
<code>PI()</code>	Return the value of pi
<code>POW()</code>	Return the argument raised to the specified power
<code>POWER()</code>	Return the argument raised to the specified power

Name	Description
<code>RADIANS()</code>	Return argument converted to radians
<code>RAND()</code>	Return a random floating-point value
<code>ROUND()</code>	Round the argument
<code>SIGN()</code>	Return the sign of the argument
<code>SIN()</code>	Return the sine of the argument
<code>SQRT()</code>	Return the square root of the argument
<code>TAN()</code>	Return the tangent of the argument
<code>TRUNCATE()</code>	Truncate to specified number of decimal places

All mathematical functions return `NULL` in the event of an error.

- `ABS(X)`

Returns the absolute value of `X`.

```
mysql> SELECT ABS(2);
-> 2
mysql> SELECT ABS(-32);
-> 32
```

This function is safe to use with `BIGINT` values.

- `ACOS(X)`

Returns the arc cosine of `X`, that is, the value whose cosine is `X`. Returns `NULL` if `X` is not in the range `-1` to `1`.

```
mysql> SELECT ACOS(1);
-> 0
mysql> SELECT ACOS(1.0001);
-> NULL
mysql> SELECT ACOS(0);
-> 1.5707963267949
```

- `ASIN(X)`

Returns the arc sine of `X`, that is, the value whose sine is `X`. Returns `NULL` if `X` is not in the range `-1` to `1`.

```
mysql> SELECT ASIN(0.2);
-> 0.20135792079033
mysql> SELECT ASIN('foo');

+-----+
| ASIN('foo') |
+-----+
| 0 |
+-----+
1 row in set, 1 warning (0.00 sec)
```

```
mysql> SHOW WARNINGS;

+-----+-----+-----+
| Level | Code | Message |
+-----+-----+-----+
| Warning | 1292 | Truncated incorrect DOUBLE value: 'foo' |
+-----+-----+-----+
```

- `ATAN(X)`

Returns the arc tangent of `X`, that is, the value whose tangent is `X`.

```
mysql> SELECT ATAN(2);
-> 1.1071487177941
mysql> SELECT ATAN(-2);
-> -1.1071487177941
```

- `ATAN(Y, X)`, `ATAN2(Y, X)`

Returns the arc tangent of the two variables `X` and `Y`. It is similar to calculating the arc tangent of `Y / X`, except that the signs of both arguments are used to determine the quadrant of the result.

```
mysql> SELECT ATAN(-2, 2);
```

```
mysql> SELECT ATAN2(PI(),0);
-> -0.78539816339745
-> 1.5707963267949
```

- `CEIL(X)`

`CEIL()` is a synonym for `CEILING()`.

- `CEILING(X)`

Returns the smallest integer value not less than *X*.

```
mysql> SELECT CEILING(1.23);
-> 2
mysql> SELECT CEILING(-1.23);
-> -1
```

For exact-value numeric arguments, the return value has an exact-value numeric type. For string or floating-point arguments, the return value has a floating-point type.

- `CONV(N,from_base,to_base)`

Converts numbers between different number bases. Returns a string representation of the number *N*, converted from base *from_base* to base *to_base*. Returns `NULL` if any argument is `NULL`. The argument *N* is interpreted as an integer, but may be specified as an integer or a string. The minimum base is 2 and the maximum base is 36. If *to_base* is a negative number, *N* is regarded as a signed number. Otherwise, *N* is treated as unsigned. `CONV()` works with 64-bit precision.

```
mysql> SELECT CONV('a',16,2);
-> '1010'
mysql> SELECT CONV('6E',18,8);
-> '172'
mysql> SELECT CONV(-17,10,-18);
-> '-H'
mysql> SELECT CONV(10+'10'+ '10'+0xa,10,10);
-> '40'
```

- `COS(X)`

Returns the cosine of *X*, where *X* is given in radians.

```
mysql> SELECT COS(PI());
-> -1
```

- `COT(X)`

Returns the cotangent of *X*.

```
mysql> SELECT COT(12);
-> -1.5726734063977
mysql> SELECT COT(0);
-> NULL
```

- `CRC32(expr)`

Computes a cyclic redundancy check value and returns a 32-bit unsigned value. The result is `NULL` if the argument is `NULL`. The argument is expected to be a string and (if possible) is treated as one if it is not.

```
mysql> SELECT CRC32('MySQL');
-> 3259397556
mysql> SELECT CRC32('mysql');
-> 2501908538
```

- `DEGREES(X)`

Returns the argument *X*, converted from radians to degrees.

```
mysql> SELECT DEGREES(PI());
-> 180
mysql> SELECT DEGREES(PI() / 2);
-> 90
```

- `EXP(X)`

Returns the value of *e* (the base of natural logarithms) raised to the power of *X*. The inverse of this function is `LOG()` (using a

single argument only) or `LN()`.

```
mysql> SELECT EXP(2);
-> 7.3890560989307
mysql> SELECT EXP(-2);
-> 0.13533528323661
mysql> SELECT EXP(0);
-> 1
```

- `FLOOR(X)`

Returns the largest integer value not greater than X .

```
mysql> SELECT FLOOR(1.23);
-> 1
mysql> SELECT FLOOR(-1.23);
-> -2
```

For exact-value numeric arguments, the return value has an exact-value numeric type. For string or floating-point arguments, the return value has a floating-point type.

- `FORMAT(X, D)`

Formats the number X to a format like ' $\#, \###, \###. \##$ ', rounded to D decimal places, and returns the result as a string. For details, see [Section 11.4, “String Functions”](#).

- `HEX(N_or_S)`

This function can be used to obtain a hexadecimal representation of a decimal number or a string; the manner in which it does so varies according to the argument's type. See this function's description in [Section 11.4, “String Functions”](#), for details.

- `LN(X)`

Returns the natural logarithm of X ; that is, the base- e logarithm of X . If X is less than or equal to 0, then `NULL` is returned.

```
mysql> SELECT LN(2);
-> 0.69314718055995
mysql> SELECT LN(-2);
-> NULL
```

This function is synonymous with `LOG(X)`. The inverse of this function is the `EXP()` function.

- `LOG(X), LOG(B, X)`

If called with one parameter, this function returns the natural logarithm of X . If X is less than or equal to 0, then `NULL` is returned.

The inverse of this function (when called with a single argument) is the `EXP()` function.

```
mysql> SELECT LOG(2);
-> 0.69314718055995
mysql> SELECT LOG(-2);
-> NULL
```

If called with two parameters, this function returns the logarithm of X to the base B . If X is less than or equal to 0, or if B is less than or equal to 1, then `NULL` is returned.

```
mysql> SELECT LOG(2,65536);
-> 16
mysql> SELECT LOG(10,100);
-> 2
mysql> SELECT LOG(1,100);
-> NULL
```

`LOG(B, X)` is equivalent to `LOG(X) / LOG(B)`.

- `LOG2(X)`

Returns the base-2 logarithm of X .

```
mysql> SELECT LOG2(65536);
-> 16
mysql> SELECT LOG2(-100);
-> NULL
```

`LOG2()` is useful for finding out how many bits a number requires for storage. This function is equivalent to the expression `LOG(X) / LOG(2)`.

- `LOG10(X)`

Returns the base-10 logarithm of *X*.

```
mysql> SELECT LOG10(2);
      -> 0.30102999566398
mysql> SELECT LOG10(100);
      -> 2
mysql> SELECT LOG10(-100);
      -> NULL
```

`LOG10(X)` is equivalent to `LOG(10, X)`.

- `MOD(N,M), N % M, N MOD M`

Modulo operation. Returns the remainder of *N* divided by *M*.

```
mysql> SELECT MOD(234, 10);
      -> 4
mysql> SELECT 253 % 7;
      -> 1
mysql> SELECT MOD(29,9);
      -> 2
mysql> SELECT 29 MOD 9;
      -> 2
```

This function is safe to use with `BIGINT` values.

`MOD()` also works on values that have a fractional part and returns the exact remainder after division:

```
mysql> SELECT MOD(34.5,3);
      -> 1.5
```

`MOD(N, 0)` returns `NULL`.

- `OCT(N)`

Returns a string representation of the octal value of *N*, where *N* is a longlong (`BIGINT`) number. This is equivalent to `CONV(N, 10, 8)`. Returns `NULL` if *N* is `NULL`.

```
mysql> SELECT OCT(12);
      -> '14'
```

- `PI()`

Returns the value of π (pi). The default number of decimal places displayed is seven, but MySQL uses the full double-precision value internally.

```
mysql> SELECT PI();
      -> 3.141593
mysql> SELECT PI()+0.00000000000000000000;
      -> 3.141592653589793116
```

- `POW(X,Y)`

Returns the value of *X* raised to the power of *Y*.

```
mysql> SELECT POW(2,2);
      -> 4
mysql> SELECT POW(2,-2);
      -> 0.25
```

- `POWER(X,Y)`

This is a synonym for `POW()`.

- `RADIANS(X)`

Returns the argument *X*, converted from degrees to radians. (Note that π radians equals 180 degrees.)

```
mysql> SELECT RADIANS(90);
```

```
-> 1.5707963267949
```

- `RAND()`, `RAND(N)`

Returns a random floating-point value v in the range $0 \leq v < 1.0$. If a constant integer argument N is specified, it is used as the seed value, which produces a repeatable sequence of column values. In the following example, note that the sequences of values produced by `RAND(3)` is the same both places where it occurs.

```
mysql> CREATE TABLE t (i INT);
Query OK, 0 rows affected (0.42 sec)

mysql> INSERT INTO t VALUES(1),(2),(3);
Query OK, 3 rows affected (0.00 sec)
Records: 3 Duplicates: 0 Warnings: 0

mysql> SELECT i, RAND() FROM t;
+----+-----+
| i  | RAND() |
+----+-----+
| 1  | 0.61914388706828 |
| 2  | 0.93845168309142 |
| 3  | 0.83482678498591 |
+----+-----+
3 rows in set (0.00 sec)

mysql> SELECT i, RAND(3) FROM t;
+----+-----+
| i  | RAND(3) |
+----+-----+
| 1  | 0.90576975597606 |
| 2  | 0.37307905813035 |
| 3  | 0.14808605345719 |
+----+-----+
3 rows in set (0.00 sec)

mysql> SELECT i, RAND() FROM t;
+----+-----+
| i  | RAND() |
+----+-----+
| 1  | 0.35877890638893 |
| 2  | 0.28941420772058 |
| 3  | 0.37073435016976 |
+----+-----+
3 rows in set (0.00 sec)

mysql> SELECT i, RAND(3) FROM t;
+----+-----+
| i  | RAND(3) |
+----+-----+
| 1  | 0.90576975597606 |
| 2  | 0.37307905813035 |
| 3  | 0.14808605345719 |
+----+-----+
3 rows in set (0.01 sec)
```

With a constant initializer, the seed is initialized once when the statement is compiled, prior to execution. If a non-constant initializer (such as a column name) is used as the argument, the seed is initialized with the value for each invocation of `RAND()`. (One implication of this is that for equal argument values, `RAND()` will return the same value each time.)

To obtain a random integer R in the range $i \leq R < j$, use the expression `FLOOR(i + RAND() * (j - i))`. For example, to obtain a random integer in the range the range $7 \leq R < 12$, you could use the following statement:

```
SELECT FLOOR(7 + (RAND() * 5));
```

`RAND()` in a `WHERE` clause is re-evaluated every time the `WHERE` is executed.

You cannot use a column with `RAND()` values in an `ORDER BY` clause, because `ORDER BY` would evaluate the column multiple times. However, you can retrieve rows in random order like this:

```
mysql> SELECT * FROM tbl_name ORDER BY RAND();
```

`ORDER BY RAND()` combined with `LIMIT` is useful for selecting a random sample from a set of rows:

```
mysql> SELECT * FROM table1, table2 WHERE a=b AND c<d -> ORDER BY RAND() LIMIT 1000;
```

`RAND()` is not meant to be a perfect random generator, but instead is a fast way to generate *ad hoc* random numbers which is portable between platforms for the same MySQL version.

- `ROUND(X)`, `ROUND(X,D)`

Rounds the argument X to D decimal places. The rounding algorithm depends on the data type of X . D defaults to 0 if not specified. D can be negative to cause D digits left of the decimal point of the value X to become zero.

```
mysql> SELECT ROUND(-1.23);
-> -1
mysql> SELECT ROUND(-1.58);
-> -2
mysql> SELECT ROUND(1.58);
-> 2
mysql> SELECT ROUND(1.298, 1);
-> 1.3
mysql> SELECT ROUND(1.298, 0);
-> 1
mysql> SELECT ROUND(23.298, -1);
-> 20
```

The return type is the same type as that of the first argument (assuming that it is integer, double, or decimal). This means that for an integer argument, the result is an integer (no decimal places):

```
mysql> SELECT ROUND(150.000,2), ROUND(150,2);
+-----+-----+
| ROUND(150.000,2) | ROUND(150,2) |
+-----+-----+
| 150.00 | 150 |
+-----+-----+
```

`ROUND()` uses the following rules depending on the type of the first argument:

- For exact-value numbers, `ROUND()` uses the “round half up” or “round toward nearest” rule: A value with a fractional part of .5 or greater is rounded up to the next integer if positive or down to the next integer if negative. (In other words, it is rounded away from zero.) A value with a fractional part less than .5 is rounded down to the next integer if positive or up to the next integer if negative.
- For approximate-value numbers, the result depends on the C library. On many systems, this means that `ROUND()` uses the “round to nearest even” rule: A value with any fractional part is rounded to the nearest even integer.

The following example shows how rounding differs for exact and approximate values:

```
mysql> SELECT ROUND(2.5), ROUND(25E-1);
+-----+-----+
| ROUND(2.5) | ROUND(25E-1) |
+-----+-----+
| 3 | 2 |
+-----+-----+
```

For more information, see [Section 11.14, “Precision Math”](#).

- `SIGN(X)`

Returns the sign of the argument as -1 , 0 , or 1 , depending on whether X is negative, zero, or positive.

```
mysql> SELECT SIGN(-32);
-> -1
mysql> SELECT SIGN(0);
-> 0
mysql> SELECT SIGN(234);
-> 1
```

- `SIN(X)`

Returns the sine of X , where X is given in radians.

```
mysql> SELECT SIN(PI());
-> 1.2246063538224e-16
mysql> SELECT ROUND(SIN(PI()));
-> 0
```

- `SQRT(X)`

Returns the square root of a non-negative number X .

```
mysql> SELECT SQRT(4);
-> 2
mysql> SELECT SQRT(20);
-> 4.4721359549996
mysql> SELECT SQRT(-16);
-> NULL
```

- `TAN(X)`

Returns the tangent of X , where X is given in radians.

```
mysql> SELECT TAN(PI());
-> -1.2246063538224e-16
mysql> SELECT TAN(PI()+1);
-> 1.5574077246549
```

- `TRUNCATE(X,D)`

Returns the number X , truncated to D decimal places. If D is 0, the result has no decimal point or fractional part. D can be negative to cause D digits left of the decimal point of the value X to become zero.

```
mysql> SELECT TRUNCATE(1.223,1);
-> 1.2
mysql> SELECT TRUNCATE(1.999,1);
-> 1.9
mysql> SELECT TRUNCATE(1.999,0);
-> 1
mysql> SELECT TRUNCATE(-1.999,1);
-> -1.9
mysql> SELECT TRUNCATE(122,-2);
-> 100
mysql> SELECT TRUNCATE(10.28*100,0);
-> 1028
```

All numbers are rounded toward zero.

11.6. Date and Time Functions

This section describes the functions that can be used to manipulate temporal values. See [Section 10.3, “Date and Time Types”](#), for a description of the range of values each date and time type has and the valid formats in which values may be specified.

Name	Description
<code>ADDDATE()</code> (v4.1.1)	Add dates
<code>ADDTIME()</code> (v4.1.1)	Add time
<code>CONVERT_TZ()</code> (v4.1.3)	Convert from one timezone to another
<code>CURDATE()</code>	Return the current date
<code>CURRENT_DATE()</code> , <code>CURRENT_DATE</code>	Synonyms for <code>CURDATE()</code>
<code>CURRENT_TIME()</code> , <code>CURRENT_TIME</code>	Synonyms for <code>CURTIME()</code>
<code>CURRENT_TIMESTAMP()</code> , <code>CURRENT_TIMESTAMP</code>	Synonyms for <code>NOW()</code>
<code>CURTIME()</code>	Return the current time
<code>DATE_ADD()</code>	Add two dates
<code>DATE_FORMAT()</code>	Format date as specified
<code>DATE_SUB()</code>	Subtract two dates
<code>DATE()</code> (v4.1.1)	Extract the date part of a date or datetime expression
<code>DATEDIFF()</code> (v4.1.1)	Subtract two dates
<code>DAY()</code> (v4.1.1)	Synonym for <code>DAYOFMONTH()</code>
<code>DAYNAME()</code> (v4.1.21)	Return the name of the weekday
<code>DAYOFMONTH()</code>	Return the day of the month (0-31)
<code>DAYOFWEEK()</code>	Return the weekday index of the argument
<code>DAYOFYEAR()</code>	Return the day of the year (1-366)
<code>EXTRACT</code>	Extract part of a date
<code>FROM_DAYS()</code>	Convert a day number to a date
<code>FROM_UNIXTIME()</code>	Format UNIX timestamp as a date
<code>GET_FORMAT()</code> (v4.1.1)	Return a date format string
<code>HOURLY()</code>	Extract the hour
<code>LAST_DAY()</code> (v4.1.1)	Return the last day of the month for the argument

Name	Description
<code>LOCALTIME () , LOCALTIME</code>	Synonym for <code>NOW()</code>
<code>LOCALTIMESTAMP , LOCALTIMESTAMP () (v4.0.6)</code>	Synonym for <code>NOW()</code>
<code>MAKEDATE () (v4.1.1)</code>	Create a date from the year and day of year
<code>MAKETIME (v4.1.1)</code>	<code>MAKETIME()</code>
<code>MICROSECOND () (v4.1.1)</code>	Return the microseconds from argument
<code>MINUTE ()</code>	Return the minute from the argument
<code>MONTH ()</code>	Return the month from the date passed
<code>MONTHNAME () (v4.1.21)</code>	Return the name of the month
<code>NOW ()</code>	Return the current date and time
<code>PERIOD_ADD ()</code>	Add a period to a year-month
<code>PERIOD_DIFF ()</code>	Return the number of months between periods
<code>QUARTER ()</code>	Return the quarter from a date argument
<code>SEC_TO_TIME ()</code>	Converts seconds to 'HH:MM:SS' format
<code>SECOND ()</code>	Return the second (0-59)
<code>STR_TO_DATE () (v4.1.1)</code>	Convert a string to a date
<code>SUBDATE ()</code>	A synonym for <code>DATE_SUB()</code> when invoked with three arguments
<code>SUBTIME () (v4.1.1)</code>	Subtract times
<code>SYSDATE ()</code>	Return the time at which the function executes
<code>TIME_FORMAT ()</code>	Format as time
<code>TIME_TO_SEC ()</code>	Return the argument converted to seconds
<code>TIME () (v4.1.1)</code>	Extract the time portion of the expression passed
<code>TIMEDIFF () (v4.1.1)</code>	Subtract time
<code>TIMESTAMP () (v4.1.1)</code>	With a single argument, this function returns the date or datetime expression; with two arguments, the sum of the arguments
<code>TIMESTAMPADD () (v5.0.0)</code>	Add an interval to a datetime expression
<code>TIMESTAMPDIFF () (v5.0.0)</code>	Subtract an interval from a datetime expression
<code>TO_DAYS ()</code>	Return the date argument converted to days
<code>UNIX_TIMESTAMP ()</code>	Return a UNIX timestamp
<code>UTC_DATE () (v4.1.1)</code>	Return the current UTC date
<code>UTC_TIME () (v4.1.1)</code>	Return the current UTC time
<code>UTC_TIMESTAMP () (v4.1.1)</code>	Return the current UTC date and time
<code>WEEK ()</code>	Return the week number
<code>WEEKDAY ()</code>	Return the weekday index
<code>WEEKOFYEAR () (v4.1.1)</code>	Return the calendar week of the date (0-53)
<code>YEAR ()</code>	Return the year
<code>YEARWEEK ()</code>	Return the year and week

Here is an example that uses date functions. The following query selects all rows with a `date_col` value from within the last 30 days:

```
mysql> SELECT something FROM tbl_name
-> WHERE DATE_SUB(CURDATE(),INTERVAL 30 DAY) <= date_col;
```

The query also selects rows with dates that lie in the future.

Functions that expect date values usually accept datetime values and ignore the time part. Functions that expect time values usually accept datetime values and ignore the date part.

Functions that return the current date or time each are evaluated only once per query at the start of query execution. This means that multiple references to a function such as `NOW ()` within a single query always produce the same result. (For our purposes, a single query also includes a call to a stored program (stored routine, trigger, or event) and all sub-programs called by that program.) This

principle also applies to `CURDATE()`, `CURTIME()`, `UTC_DATE()`, `UTC_TIME()`, `UTC_TIMESTAMP()`, and to any of their synonyms.

The `CURRENT_TIMESTAMP()`, `CURRENT_TIME()`, `CURRENT_DATE()`, and `FROM_UNIXTIME()` functions return values in the connection's current time zone, which is available as the value of the `time_zone` system variable. In addition, `UNIX_TIMESTAMP()` assumes that its argument is a datetime value in the current time zone. See [Section 9.7, “MySQL Server Time Zone Support”](#).

Some date functions can be used with “zero” dates or incomplete dates such as `'2001-11-00'`, whereas others cannot. Functions that extract parts of dates typically work with incomplete dates and thus can return 0 when you might otherwise expect a nonzero value. For example:

```
mysql> SELECT DAYOFMONTH('2001-11-00'), MONTH('2005-00-00');
-> 0, 0
```

Other functions expect complete dates and return `NULL` for incomplete dates. These include functions that perform date arithmetic or that map parts of dates to names. For example:

```
mysql> SELECT DATE_ADD('2006-05-00',INTERVAL 1 DAY);
-> NULL
mysql> SELECT DAYNAME('2006-05-00');
-> NULL
```

- `ADDDATE(date,INTERVAL expr unit),ADDDATE(expr,days)`

When invoked with the `INTERVAL` form of the second argument, `ADDDATE()` is a synonym for `DATE_ADD()`. The related function `SUBDATE()` is a synonym for `DATE_SUB()`. For information on the `INTERVAL unit` argument, see the discussion for `DATE_ADD()`.

```
mysql> SELECT DATE_ADD('2008-01-02', INTERVAL 31 DAY);
-> '2008-02-02'
mysql> SELECT ADDDATE('2008-01-02', INTERVAL 31 DAY);
-> '2008-02-02'
```

When invoked with the `days` form of the second argument, MySQL treats it as an integer number of days to be added to `expr`.

```
mysql> SELECT ADDDATE('2008-01-02', 31);
-> '2008-02-02'
```

- `ADDTIME(expr1,expr2)`

`ADDTIME()` adds `expr2` to `expr1` and returns the result. `expr1` is a time or datetime expression, and `expr2` is a time expression.

```
mysql> SELECT ADDTIME('2007-12-31 23:59:59.999999', '1 1:1:1.000002');
-> '2008-01-02 01:01:01.000001'
mysql> SELECT ADDTIME('01:00:00.999999', '02:00:00.999998');
-> '03:00:01.999997'
```

- `CONVERT_TZ(dt,from_tz,to_tz)`

`CONVERT_TZ()` converts a datetime value `dt` from the time zone given by `from_tz` to the time zone given by `to_tz` and returns the resulting value. Time zones are specified as described in [Section 9.7, “MySQL Server Time Zone Support”](#). This function returns `NULL` if the arguments are invalid.

If the value falls out of the supported range of the `TIMESTAMP` type when converted from `from_tz` to UTC, no conversion occurs. The `TIMESTAMP` range is described in [Section 10.1.2, “Overview of Date and Time Types”](#).

```
mysql> SELECT CONVERT_TZ('2004-01-01 12:00:00','GMT','MET');
-> '2004-01-01 13:00:00'
mysql> SELECT CONVERT_TZ('2004-01-01 12:00:00','+00:00','+10:00');
-> '2004-01-01 22:00:00'
```

Note

To use named time zones such as `'MET'` or `'Europe/Moscow'`, the time zone tables must be properly set up. See [Section 9.7, “MySQL Server Time Zone Support”](#), for instructions.

- `CURDATE()`

Returns the current date as a value in `'YYYY-MM-DD'` or `YYYYMMDD` format, depending on whether the function is used in a

string or numeric context.

```
mysql> SELECT CURDATE();
-> '2008-06-13'
mysql> SELECT CURDATE() + 0;
-> 20080613
```

- CURRENT_DATE, CURRENT_DATE()

CURRENT_DATE and CURRENT_DATE() are synonyms for CURDATE().

- CURTIME()

Returns the current time as a value in 'HH:MM:SS' or HHMMSS.uuuuuu format, depending on whether the function is used in a string or numeric context. The value is expressed in the current time zone.

```
mysql> SELECT CURTIME();
-> '23:50:26'
mysql> SELECT CURTIME() + 0;
-> 235026.000000
```

- CURRENT_TIME, CURRENT_TIME()

CURRENT_TIME and CURRENT_TIME() are synonyms for CURTIME().

- CURRENT_TIMESTAMP, CURRENT_TIMESTAMP()

CURRENT_TIMESTAMP and CURRENT_TIMESTAMP() are synonyms for NOW().

- DATE(expr)

Extracts the date part of the date or datetime expression *expr*.

```
mysql> SELECT DATE('2003-12-31 01:02:03');
-> '2003-12-31'
```

- DATEDIFF(expr1,expr2)

DATEDIFF() returns *expr1* - *expr2* expressed as a value in days from one date to the other. *expr1* and *expr2* are date or date-and-time expressions. Only the date parts of the values are used in the calculation.

```
mysql> SELECT DATEDIFF('2007-12-31 23:59:59','2007-12-30');
-> 1
mysql> SELECT DATEDIFF('2010-11-30 23:59:59','2010-12-31');
-> -31
```

- DATE_ADD(date,INTERVAL expr unit),DATE_SUB(date,INTERVAL expr unit)

These functions perform date arithmetic. The *date* argument specifies the starting date or datetime value. *expr* is an expression specifying the interval value to be added or subtracted from the starting date. *expr* is a string; it may start with a “-” for negative intervals. *unit* is a keyword indicating the units in which the expression should be interpreted.

The INTERVAL keyword and the unit specifier are not case sensitive.

The following table shows the expected form of the *expr* argument for each *unit* value.

<i>unit</i> Value	Expected <i>expr</i> Format
MICROSECOND	MICROSECONDS
SECOND	SECONDS
MINUTE	MINUTES
HOUR	HOURS
DAY	DAYS
WEEK	WEEKS
MONTH	MONTHS
QUARTER	QUARTERS
YEAR	YEARS
SECOND_MICROSECOND	'SECONDS.MICROSECONDS'

MINUTE_MICROSECOND	'MINUTES:SECONDS.MICROSECONDS'
MINUTE_SECOND	'MINUTES:SECONDS'
HOURL_MICROSECOND	'HOURS:MINUTES:SECONDS.MICROSECONDS'
HOURL_SECOND	'HOURS:MINUTES:SECONDS'
HOURL_MINUTE	'HOURS:MINUTES'
DAY_MICROSECOND	'DAYS HOURS:MINUTES:SECONDS.MICROSECONDS'
DAY_SECOND	'DAYS HOURS:MINUTES:SECONDS'
DAY_MINUTE	'DAYS HOURS:MINUTES'
DAY_HOUR	'DAYS HOURS'
YEAR_MONTH	'YEARS-MONTHS'

The return value depends on the arguments:

- DATETIME if the first argument is a DATETIME (or TIMESTAMP) value, or if the first argument is a DATE and the unit value uses HOURS, MINUTES, or SECONDS.
- String otherwise.

To ensure that the result is DATETIME, you can use CAST() to convert the first argument to DATETIME.

MySQL allows any punctuation delimiter in the expr format. Those shown in the table are the suggested delimiters. If the date argument is a DATE value and your calculations involve only YEAR, MONTH, and DAY parts (that is, no time parts), the result is a DATE value. Otherwise, the result is a DATETIME value.

Date arithmetic also can be performed using INTERVAL together with the + or - operator:

```
date + INTERVAL expr unit
date - INTERVAL expr unit
```

INTERVAL expr unit is allowed on either side of the + operator if the expression on the other side is a date or datetime value. For the - operator, INTERVAL expr unit is allowed only on the right side, because it makes no sense to subtract a date or datetime value from an interval.

```
mysql> SELECT '2008-12-31 23:59:59' + INTERVAL 1 SECOND;
-> '2009-01-01 00:00:00'
mysql> SELECT INTERVAL 1 DAY + '2008-12-31';
-> '2009-01-01'
mysql> SELECT '2005-01-01' - INTERVAL 1 SECOND;
-> '2004-12-31 23:59:59'
mysql> SELECT DATE_ADD('2000-12-31 23:59:59',
-> INTERVAL 1 SECOND);
-> '2001-01-01 00:00:00'
mysql> SELECT DATE_ADD('2010-12-31 23:59:59',
-> INTERVAL 1 DAY);
-> '2011-01-01 23:59:59'
mysql> SELECT DATE_ADD('2100-12-31 23:59:59',
-> INTERVAL '1:1' MINUTE_SECOND);
-> '2101-01-01 00:01:00'
mysql> SELECT DATE_SUB('2005-01-01 00:00:00',
-> INTERVAL '1 1:1:1' DAY_SECOND);
-> '2004-12-30 22:58:59'
mysql> SELECT DATE_ADD('1900-01-01 00:00:00',
-> INTERVAL '-1 10' DAY_HOUR);
-> '1899-12-30 14:00:00'
mysql> SELECT DATE_SUB('1998-01-02', INTERVAL 31 DAY);
-> '1997-12-02'
mysql> SELECT DATE_ADD('1992-12-31 23:59:59.000002',
-> INTERVAL '1.999999' SECOND_MICROSECOND);
-> '1993-01-01 00:00:01.000001'
```

If you specify an interval value that is too short (does not include all the interval parts that would be expected from the unit keyword), MySQL assumes that you have left out the leftmost parts of the interval value. For example, if you specify a unit of DAY_SECOND, the value of expr is expected to have days, hours, minutes, and seconds parts. If you specify a value like '1:10', MySQL assumes that the days and hours parts are missing and the value represents minutes and seconds. In other words, '1:10' DAY_SECOND is interpreted in such a way that it is equivalent to '1:10' MINUTE_SECOND. This is analogous to the way that MySQL interprets TIME values as representing elapsed time rather than as a time of day.

Because expr is treated as a string, be careful if you specify a non-string value with INTERVAL. For example, with an interval specifier of HOUR_MINUTE, 6/4 evaluates to 1.5000 and is treated as 1 hour, 5000 minutes:

```
mysql> SELECT 6/4;
```

```
mysql> SELECT DATE_ADD('2009-01-01', INTERVAL 6/4 HOUR_MINUTE);
-> '2009-01-04 12:20:00'
```

To ensure interpretation of the interval value as you expect, a `CAST()` operation may be used. To treat `6/4` as 1 hour, 5 minutes, cast it to a `DECIMAL` value with a single fractional digit:

```
mysql> SELECT CAST(6/4 AS DECIMAL(3,1));
-> 1.5
mysql> SELECT DATE_ADD('1970-01-01 12:00:00',
-> INTERVAL CAST(6/4 AS DECIMAL(3,1)) HOUR_MINUTE);
-> '1970-01-01 13:05:00'
```

If you add to or subtract from a date value something that contains a time part, the result is automatically converted to a date-time value:

```
mysql> SELECT DATE_ADD('2013-01-01', INTERVAL 1 DAY);
-> '2013-01-02'
mysql> SELECT DATE_ADD('2013-01-01', INTERVAL 1 HOUR);
-> '2013-01-01 01:00:00'
```

If you add `MONTH`, `YEAR_MONTH`, or `YEAR` and the resulting date has a day that is larger than the maximum day for the new month, the day is adjusted to the maximum days in the new month:

```
mysql> SELECT DATE_ADD('2009-01-30', INTERVAL 1 MONTH);
-> '2009-02-28'
```

Date arithmetic operations require complete dates and do not work with incomplete dates such as `'2006-07-00'` or badly malformed dates:

```
mysql> SELECT DATE_ADD('2006-07-00', INTERVAL 1 DAY);
-> NULL
mysql> SELECT '2005-03-32' + INTERVAL 1 MONTH;
-> NULL
```

- `DATE_FORMAT(date, format)`

Formats the *date* value according to the *format* string.

The following specifiers may be used in the *format* string. The “%” character is required before format specifier characters.

Specifier	Description
%a	Abbreviated weekday name (Sun..Sat)
%b	Abbreviated month name (Jan..Dec)
%c	Month, numeric (0..12)
%D	Day of the month with English suffix (0th, 1st, 2nd, 3rd, ...)
%d	Day of the month, numeric (00..31)
%e	Day of the month, numeric (0..31)
%f	Microseconds (000000..999999)
%H	Hour (00..23)
%h	Hour (01..12)
%I	Hour (01..12)
%i	Minutes, numeric (00..59)
%j	Day of year (001..366)
%k	Hour (0..23)
%l	Hour (1..12)
%M	Month name (January..December)
%m	Month, numeric (00..12)
%p	AM or PM
%r	Time, 12-hour (hh:mm:ss followed by AM or PM)
%S	Seconds (00..59)
%s	Seconds (00..59)

%T	Time, 24-hour (hh:mm:ss)
%U	Week (00..53), where Sunday is the first day of the week
%u	Week (00..53), where Monday is the first day of the week
%V	Week (01..53), where Sunday is the first day of the week; used with %X
%v	Week (01..53), where Monday is the first day of the week; used with %x
%W	Weekday name (Sunday..Saturday)
%w	Day of the week (0=Sunday..6=Saturday)
%X	Year for the week where Sunday is the first day of the week, numeric, four digits; used with %V
%x	Year for the week, where Monday is the first day of the week, numeric, four digits; used with %v
%Y	Year, numeric, four digits
%y	Year, numeric (two digits)
%%	A literal “%” character
%x	x, for any “x” not listed above

Ranges for the month and day specifiers begin with zero due to the fact that MySQL allows the storing of incomplete dates such as '2014-00-00'.

The language used for day and month names and abbreviations is controlled by the value of the `lc_time_names` system variable (Section 9.8, “MySQL Server Locale Support”).

`DATE_FORMAT()` returns a string with a character set and collation given by `character_set_connection` and `collation_connection` so that it can return month and weekday names containing non-ASCII characters.

```
mysql> SELECT DATE_FORMAT('2009-10-04 22:23:00', '%W %M %Y');
-> 'Sunday October 2009'
mysql> SELECT DATE_FORMAT('2007-10-04 22:23:00', '%H:%i:%s');
-> '22:23:00'
mysql> SELECT DATE_FORMAT('1900-10-04 22:23:00',
-> '%D %y %a %d %m %b %j');
-> '4th 00 Thu 04 10 Oct 277'
mysql> SELECT DATE_FORMAT('1997-10-04 22:23:00',
-> '%H %k %I %r %T %S %w');
-> '22 22 10 10:23:00 PM 22:23:00 00 6'
mysql> SELECT DATE_FORMAT('1999-01-01', '%X %V');
-> '1998 52'
mysql> SELECT DATE_FORMAT('2006-06-00', '%d');
-> '00'
```

- `DATE_SUB(date, INTERVAL expr unit)`

See the description for `DATE_ADD()`.

- `DAY(date)`

`DAY()` is a synonym for `DAYOFMONTH()`.

- `DAYNAME(date)`

Returns the name of the weekday for `date`. The language used for the name is controlled by the value of the `lc_time_names` system variable (Section 9.8, “MySQL Server Locale Support”).

```
mysql> SELECT DAYNAME('2007-02-03');
-> 'Saturday'
```

- `DAYOFMONTH(date)`

Returns the day of the month for `date`, in the range 1 to 31, or 0 for dates such as '0000-00-00' or '2008-00-00' that have a zero day part.

```
mysql> SELECT DAYOFMONTH('2007-02-03');
-> 3
```

- `DAYOFWEEK(date)`

Returns the weekday index for `date` (1 = Sunday, 2 = Monday, ..., 7 = Saturday). These index values correspond to the ODBC standard.

```
mysql> SELECT DAYOFWEEK('2007-02-03');
-> 7
```

- `DAYOFYEAR(date)`

Returns the day of the year for *date*, in the range 1 to 366.

```
mysql> SELECT DAYOFYEAR('2007-02-03');
-> 34
```

- `EXTRACT(unit FROM date)`

The `EXTRACT()` function uses the same kinds of unit specifiers as `DATE_ADD()` or `DATE_SUB()`, but extracts parts from the date rather than performing date arithmetic.

```
mysql> SELECT EXTRACT(YEAR FROM '2009-07-02');
-> 2009
mysql> SELECT EXTRACT(YEAR_MONTH FROM '2009-07-02 01:02:03');
-> 200907
mysql> SELECT EXTRACT(DAY_MINUTE FROM '2009-07-02 01:02:03');
-> 20102
mysql> SELECT EXTRACT(MICROSECOND
-> FROM '2003-01-02 10:30:00.000123');
-> 123
```

- `FROM_DAYS(N)`

Given a day number *N*, returns a `DATE` value.

```
mysql> SELECT FROM_DAYS(730669);
-> '2007-07-03'
```

Use `FROM_DAYS()` with caution on old dates. It is not intended for use with values that precede the advent of the Gregorian calendar (1582). See [Section 11.7, “What Calendar Is Used By MySQL?”](#).

- `FROM_UNIXTIME(unix_timestamp)`, `FROM_UNIXTIME(unix_timestamp, format)`

Returns a representation of the *unix_timestamp* argument as a value in 'YYYY-MM-DD HH:MM:SS' or 'YYYYMMDDH-HMMSS.uuuuuu' format, depending on whether the function is used in a string or numeric context. The value is expressed in the current time zone. *unix_timestamp* is an internal timestamp value such as is produced by the `UNIX_TIMESTAMP()` function.

If *format* is given, the result is formatted according to the *format* string, which is used the same way as listed in the entry for the `DATE_FORMAT()` function.

```
mysql> SELECT FROM_UNIXTIME(1196440219);
-> '2007-11-30 10:30:19'
mysql> SELECT FROM_UNIXTIME(1196440219) + 0;
-> 20071130103019.000000
mysql> SELECT FROM_UNIXTIME(UNIX_TIMESTAMP(),
-> '%Y %D %M %h:%i:%s %x');
-> '2007 30th November 10:30:59 2007'
```

Note: If you use `UNIX_TIMESTAMP()` and `FROM_UNIXTIME()` to convert between `TIMESTAMP` values and Unix timestamp values, the conversion is lossy because the mapping is not one-to-one in both directions. For details, see the description of the `UNIX_TIMESTAMP()` function.

- `GET_FORMAT({DATE|TIME|DATETIME}, {'EUR'|'USA'|'JIS'|'ISO'|'INTERNAL'})`

Returns a format string. This function is useful in combination with the `DATE_FORMAT()` and the `STR_TO_DATE()` functions.

The possible values for the first and second arguments result in several possible format strings (for the specifiers used, see the table in the `DATE_FORMAT()` function description). ISO format refers to ISO 9075, not ISO 8601.

Function Call	Result
<code>GET_FORMAT(DATE, 'USA')</code>	'%m.%d.%Y'
<code>GET_FORMAT(DATE, 'JIS')</code>	'%Y-%m-%d'
<code>GET_FORMAT(DATE, 'ISO')</code>	'%Y-%m-%d'
<code>GET_FORMAT(DATE, 'EUR')</code>	'%d.%m.%Y'

GET_FORMAT(DATE, 'INTERNAL')	'%Y%m%d'
GET_FORMAT(DATETIME, 'USA')	'%Y-%m-%d %H.%i.%s'
GET_FORMAT(DATETIME, 'JIS')	'%Y-%m-%d %H:%i:%s'
GET_FORMAT(DATETIME, 'ISO')	'%Y-%m-%d %H:%i:%s'
GET_FORMAT(DATETIME, 'EUR')	'%Y-%m-%d %H.%i.%s'
GET_FORMAT(DATETIME, 'INTERNAL')	'%Y%m%d%H%i%s'
GET_FORMAT(TIME, 'USA')	'%h:%i:%s %p'
GET_FORMAT(TIME, 'JIS')	'%H:%i:%s'
GET_FORMAT(TIME, 'ISO')	'%H:%i:%s'
GET_FORMAT(TIME, 'EUR')	'%H.%i.%s'
GET_FORMAT(TIME, 'INTERNAL')	'%H%i%s'

TIMESTAMP can also be used as the first argument to GET_FORMAT(), in which case the function returns the same values as for DATETIME.

```
mysql> SELECT DATE_FORMAT('2003-10-03',GET_FORMAT(DATE,'EUR'));
-> '03.10.2003'
mysql> SELECT STR_TO_DATE('10.31.2003',GET_FORMAT(DATE,'USA'));
-> '2003-10-31'
```

- HOUR(*time*)

Returns the hour for *time*. The range of the return value is 0 to 23 for time-of-day values. However, the range of TIME values actually is much larger, so HOUR can return values greater than 23.

```
mysql> SELECT HOUR('10:05:03');
-> 10
mysql> SELECT HOUR('272:59:59');
-> 272
```

- LAST_DAY(*date*)

Takes a date or datetime value and returns the corresponding value for the last day of the month. Returns NULL if the argument is invalid.

```
mysql> SELECT LAST_DAY('2003-02-05');
-> '2003-02-28'
mysql> SELECT LAST_DAY('2004-02-05');
-> '2004-02-29'
mysql> SELECT LAST_DAY('2004-01-01 01:01:01');
-> '2004-01-31'
mysql> SELECT LAST_DAY('2003-03-32');
-> NULL
```

- LOCALTIME, LOCALTIME()

LOCALTIME and LOCALTIME() are synonyms for NOW().

- LOCALTIMESTAMP, LOCALTIMESTAMP()

LOCALTIMESTAMP and LOCALTIMESTAMP() are synonyms for NOW().

- MAKEDATE(*year*, *dayofyear*)

Returns a date, given year and day-of-year values. *dayofyear* must be greater than 0 or the result is NULL.

```
mysql> SELECT MAKEDATE(2011,31), MAKEDATE(2011,32);
-> '2011-01-31', '2011-02-01'
mysql> SELECT MAKEDATE(2011,365), MAKEDATE(2014,365);
-> '2011-12-31', '2014-12-31'
mysql> SELECT MAKEDATE(2011,0);
-> NULL
```

- MAKETIME(*hour*, *minute*, *second*)

Returns a time value calculated from the *hour*, *minute*, and *second* arguments.

```
mysql> SELECT MAKETIME(12,15,30);
```

```
-> '12:15:30'
```

- `MICROSECOND(expr)`

Returns the microseconds from the time or datetime expression *expr* as a number in the range from 0 to 999999.

```
mysql> SELECT MICROSECOND('12:00:00.123456');
-> 123456
mysql> SELECT MICROSECOND('2009-12-31 23:59:59.000010');
-> 10
```

- `MINUTE(time)`

Returns the minute for *time*, in the range 0 to 59.

```
mysql> SELECT MINUTE('2008-02-03 10:05:03');
-> 5
```

- `MONTH(date)`

Returns the month for *date*, in the range 1 to 12 for January to December, or 0 for dates such as '0000-00-00' or '2008-00-00' that have a zero month part.

```
mysql> SELECT MONTH('2008-02-03');
-> 2
```

- `MONTHNAME(date)`

Returns the full name of the month for *date*. The language used for the name is controlled by the value of the `lc_time_names` system variable (Section 9.8, “MySQL Server Locale Support”).

```
mysql> SELECT MONTHNAME('2008-02-03');
-> 'February'
```

- `NOW()`

Returns the current date and time as a value in 'YYYY-MM-DD HH:MM:SS' or YYYYMMDDHHMMSS.uuuuuu format, depending on whether the function is used in a string or numeric context. The value is expressed in the current time zone.

```
mysql> SELECT NOW();
-> '2007-12-15 23:50:26'
mysql> SELECT NOW() + 0;
-> 20071215235026.000000
```

`NOW()` returns a constant time that indicates the time at which the statement began to execute. (Within a stored function or trigger, `NOW()` returns the time at which the function or triggering statement began to execute.) This differs from the behavior for `SYSDATE()`, which returns the exact time at which it executes.

```
mysql> SELECT NOW(), SLEEP(2), NOW();
+-----+-----+-----+
| NOW()          | SLEEP(2) | NOW()          |
+-----+-----+-----+
| 2006-04-12 13:47:36 |          0 | 2006-04-12 13:47:36 |
+-----+-----+-----+

mysql> SELECT SYSDATE(), SLEEP(2), SYSDATE();
+-----+-----+-----+
| SYSDATE()      | SLEEP(2) | SYSDATE()      |
+-----+-----+-----+
| 2006-04-12 13:47:44 |          0 | 2006-04-12 13:47:46 |
+-----+-----+-----+
```

In addition, the `SET TIMESTAMP` statement affects the value returned by `NOW()` but not by `SYSDATE()`. This means that timestamp settings in the binary log have no effect on invocations of `SYSDATE()`.

See the description for `SYSDATE()` for additional information about the differences between the two functions.

- `PERIOD_ADD(P,N)`

Adds *N* months to period *P* (in the format `YYMM` or `YYYYMM`). Returns a value in the format `YYYYMM`. Note that the period argument *P* is *not* a date value.

```
mysql> SELECT PERIOD_ADD(200801,2);
-> 200803
```

- `PERIOD_DIFF(P1, P2)`

Returns the number of months between periods *P1* and *P2*. *P1* and *P2* should be in the format `YYMM` or `YYYYMM`. Note that the period arguments *P1* and *P2* are *not* date values.

```
mysql> SELECT PERIOD_DIFF(200802,200703);
-> 11
```

- `QUARTER(date)`

Returns the quarter of the year for *date*, in the range 1 to 4.

```
mysql> SELECT QUARTER('2008-04-01');
-> 2
```

- `SECOND(time)`

Returns the second for *time*, in the range 0 to 59.

```
mysql> SELECT SECOND('10:05:03');
-> 3
```

- `SEC_TO_TIME(seconds)`

Returns the *seconds* argument, converted to hours, minutes, and seconds, as a `TIME` value. The range of the result is constrained to that of the `TIME` data type. A warning occurs if the argument corresponds to a value outside that range.

```
mysql> SELECT SEC_TO_TIME(2378);
-> '00:39:38'
mysql> SELECT SEC_TO_TIME(2378) + 0;
-> 3938
```

- `STR_TO_DATE(str, format)`

This is the inverse of the `DATE_FORMAT()` function. It takes a string *str* and a format string *format*. `STR_TO_DATE()` returns a `DATETIME` value if the format string contains both date and time parts, or a `DATE` or `TIME` value if the string contains only date or time parts. If the date, time, or datetime value extracted from *str* is illegal, `STR_TO_DATE()` returns `NULL` and produces a warning.

The server scans *str* attempting to match *format* to it. The format string can contain literal characters and format specifiers beginning with `%`. Literal characters in *format* must match literally in *str*. Format specifiers in *format* must match a date or time part in *str*. For the specifiers that can be used in *format*, see the `DATE_FORMAT()` function description.

```
mysql> SELECT STR_TO_DATE('01,5,2013','%d,%m,%Y');
-> '2013-05-01'
mysql> SELECT STR_TO_DATE('May 1, 2013','%M %d,%Y');
-> '2013-05-01'
```

Scanning starts at the beginning of *str* and fails if *format* is found not to match. Extra characters at the end of *str* are ignored.

```
mysql> SELECT STR_TO_DATE('a09:30:17','a%h:%i:%s');
-> '09:30:17'
mysql> SELECT STR_TO_DATE('a09:30:17','%h:%i:%s');
-> NULL
mysql> SELECT STR_TO_DATE('09:30:17a','%h:%i:%s');
-> '09:30:17'
```

Unspecified date or time parts have a value of 0, so incompletely specified values in *str* produce a result with some or all parts set to 0:

```
mysql> SELECT STR_TO_DATE('abc','abc');
-> '0000-00-00'
mysql> SELECT STR_TO_DATE('9','%m');
-> '0000-09-00'
mysql> SELECT STR_TO_DATE('9','%s');
-> '00:00:09'
```

Range checking on the parts of date values is as described in [Section 10.3.1, “The DATETIME, DATE, and TIMESTAMP Types”](#). This means, for example, that “zero” dates or dates with part values of 0 are allowed unless the SQL mode is set to disallow such values.

```
mysql> SELECT STR_TO_DATE('00/00/0000', '%m/%d/%Y');
-> '0000-00-00'
mysql> SELECT STR_TO_DATE('04/31/2004', '%m/%d/%Y');
-> '2004-04-31'
```

Note

You cannot use format "%X%V" to convert a year-week string to a date because the combination of a year and week does not uniquely identify a year and month if the week crosses a month boundary. To convert a year-week to a date, then you should also specify the weekday:

```
mysql> SELECT STR_TO_DATE('200442 Monday', '%X%V %W');
-> '2004-10-18'
```

- `SUBDATE(date, INTERVAL expr unit), SUBDATE(expr, days)`

When invoked with the `INTERVAL` form of the second argument, `SUBDATE()` is a synonym for `DATE_SUB()`. For information on the `INTERVAL unit` argument, see the discussion for `DATE_ADD()`.

```
mysql> SELECT DATE_SUB('2008-01-02', INTERVAL 31 DAY);
-> '2007-12-02'
mysql> SELECT SUBDATE('2008-01-02', INTERVAL 31 DAY);
-> '2007-12-02'
```

The second form allows the use of an integer value for `days`. In such cases, it is interpreted as the number of days to be subtracted from the date or datetime expression `expr`.

```
mysql> SELECT SUBDATE('2008-01-02 12:00:00', 31);
-> '2007-12-02 12:00:00'
```

- `SUBTIME(expr1, expr2)`

`SUBTIME()` returns `expr1 - expr2` expressed as a value in the same format as `expr1`. `expr1` is a time or datetime expression, and `expr2` is a time expression.

```
mysql> SELECT SUBTIME('2007-12-31 23:59:59.999999', '1 1:1:1.000002');
-> '2007-12-30 22:58:58.999997'
mysql> SELECT SUBTIME('01:00:00.999999', '02:00:00.999998');
-> '-00:59:59.999999'
```

- `SYSDATE()`

Returns the current date and time as a value in 'YYYY-MM-DD HH:MM:SS' or YYYYMMDDHHMMSS.uuuuuu format, depending on whether the function is used in a string or numeric context.

`SYSDATE()` returns the time at which it executes. This differs from the behavior for `NOW()`, which returns a constant time that indicates the time at which the statement began to execute. (Within a stored function or trigger, `NOW()` returns the time at which the function or triggering statement began to execute.)

```
mysql> SELECT NOW(), SLEEP(2), NOW();
+-----+-----+-----+
| NOW()          | SLEEP(2) | NOW()          |
+-----+-----+-----+
| 2006-04-12 13:47:36 |          0 | 2006-04-12 13:47:36 |
+-----+-----+-----+

mysql> SELECT SYSDATE(), SLEEP(2), SYSDATE();
+-----+-----+-----+
| SYSDATE()      | SLEEP(2) | SYSDATE()      |
+-----+-----+-----+
| 2006-04-12 13:47:44 |          0 | 2006-04-12 13:47:46 |
+-----+-----+-----+
```

In addition, the `SET TIMESTAMP` statement affects the value returned by `NOW()` but not by `SYSDATE()`. This means that timestamp settings in the binary log have no effect on invocations of `SYSDATE()`.

Because `SYSDATE()` can return different values even within the same statement, and is not affected by `SET TIMESTAMP`, it is non-deterministic and therefore unsafe for replication if statement-based binary logging is used. If that is a problem, you can use row-based logging, or start the server with the `--sysdate-is-now` option to cause `SYSDATE()` to be an alias for `NOW()`. The non-deterministic nature of `SYSDATE()` also means that indexes cannot be used for evaluating expressions that refer to it.

- `TIME(expr)`

Extracts the time part of the time or datetime expression *expr* and returns it as a string.

```
mysql> SELECT TIME('2003-12-31 01:02:03');
-> '01:02:03'
mysql> SELECT TIME('2003-12-31 01:02:03.000123');
-> '01:02:03.000123'
```

- `TIMEDIFF(expr1,expr2)`

`TIMEDIFF()` returns *expr1* – *expr2* expressed as a time value. *expr1* and *expr2* are time or date-and-time expressions, but both must be of the same type.

```
mysql> SELECT TIMEDIFF('2000:01:01 00:00:00',
-> '2000:01:01 00:00:00.000001');
-> '-00:00:00.000001'
mysql> SELECT TIMEDIFF('2008-12-31 23:59:59.000001',
-> '2008-12-30 01:01:01.000002');
-> '46:58:57.999999'
```

- `TIMESTAMP(expr)`, `TIMESTAMP(expr1,expr2)`

With a single argument, this function returns the date or datetime expression *expr* as a datetime value. With two arguments, it adds the time expression *expr2* to the date or datetime expression *expr1* and returns the result as a datetime value.

```
mysql> SELECT TIMESTAMP('2003-12-31');
-> '2003-12-31 00:00:00'
mysql> SELECT TIMESTAMP('2003-12-31 12:00:00','12:00:00');
-> '2004-01-01 00:00:00'
```

- `TIMESTAMPADD(unit,interval,datetime_expr)`

Adds the integer expression *interval* to the date or datetime expression *datetime_expr*. The unit for *interval* is given by the *unit* argument, which should be one of the following values: `MICROSECOND` (microseconds), `SECOND`, `MINUTE`, `HOURL`, `DAY`, `WEEK`, `MONTH`, `QUARTER`, or `YEAR`.

It is possible to use `FRAC_SECOND` in place of `MICROSECOND`, but `FRAC_SECOND` is deprecated.

The *unit* value may be specified using one of keywords as shown, or with a prefix of `SQL_TSI_`. For example, `DAY` and `SQL_TSI_DAY` both are legal.

```
mysql> SELECT TIMESTAMPADD(MINUTE,1,'2003-01-02');
-> '2003-01-02 00:01:00'
mysql> SELECT TIMESTAMPADD(WEEK,1,'2003-01-02');
-> '2003-01-09'
```

- `TIMESTAMPDIFF(unit,datetime_expr1,datetime_expr2)`

Returns *datetime_expr2* – *datetime_expr1*, where *datetime_expr1* and *datetime_expr2* are date or datetime expressions. One expression may be a date and the other a datetime; a date value is treated as a datetime having the time part '00:00:00' where necessary. The unit for the result (an integer) is given by the *unit* argument. The legal values for *unit* are the same as those listed in the description of the `TIMESTAMPADD()` function.

```
mysql> SELECT TIMESTAMPDIFF(MONTH,'2003-02-01','2003-05-01');
-> 3
mysql> SELECT TIMESTAMPDIFF(YEAR,'2002-05-01','2001-01-01');
-> -1
mysql> SELECT TIMESTAMPDIFF(MINUTE,'2003-02-01','2003-05-01 12:05:55');
-> 128885
```

Note

The order of the date or datetime arguments for this function is the opposite of that used with the `TIMESTAMP()` function when invoked with 2 arguments.

- `TIME_FORMAT(time,format)`

This is used like the `DATE_FORMAT()` function, but the *format* string may contain format specifiers only for hours, minutes, seconds, and microseconds. Other specifiers produce a `NULL` value or 0.

If the *time* value contains an hour part that is greater than 23, the `%H` and `%k` hour format specifiers produce a value larger than the usual range of 0..23. The other hour format specifiers produce the hour value modulo 12.

```
mysql> SELECT TIME_FORMAT('100:00:00', '%H %k %h %I %l');
-> '100 100 04 04 4'
```

- `TIME_TO_SEC(time)`

Returns the *time* argument, converted to seconds.

```
mysql> SELECT TIME_TO_SEC('22:23:00');
-> 80580
mysql> SELECT TIME_TO_SEC('00:39:38');
-> 2378
```

- `TO_DAYS(date)`

Given a date *date*, returns a day number (the number of days since year 0).

```
mysql> SELECT TO_DAYS(950501);
-> 728779
mysql> SELECT TO_DAYS('2007-10-07');
-> 733321
```

`TO_DAYS()` is not intended for use with values that precede the advent of the Gregorian calendar (1582), because it does not take into account the days that were lost when the calendar was changed. For dates before 1582 (and possibly a later year in other locales), results from this function are not reliable. See [Section 11.7, “What Calendar Is Used By MySQL?”](#), for details.

Remember that MySQL converts two-digit year values in dates to four-digit form using the rules in [Section 10.3, “Date and Time Types”](#). For example, '2008-10-07' and '08-10-07' are seen as identical dates:

```
mysql> SELECT TO_DAYS('2008-10-07'), TO_DAYS('08-10-07');
-> 733687, 733687
```

- `UNIX_TIMESTAMP()`, `UNIX_TIMESTAMP(date)`

If called with no argument, returns a Unix timestamp (seconds since '1970-01-01 00:00:00' UTC) as an unsigned integer. If `UNIX_TIMESTAMP()` is called with a *date* argument, it returns the value of the argument as seconds since '1970-01-01 00:00:00' UTC. *date* may be a `DATE` string, a `DATETIME` string, a `TIMESTAMP`, or a number in the format `YYMMDD` or `YYYYMMDD`. The server interprets *date* as a value in the current time zone and converts it to an internal value in UTC. Clients can set their time zone as described in [Section 9.7, “MySQL Server Time Zone Support”](#).

```
mysql> SELECT UNIX_TIMESTAMP();
-> 1196440210
mysql> SELECT UNIX_TIMESTAMP('2007-11-30 10:30:19');
-> 1196440219
```

When `UNIX_TIMESTAMP()` is used on a `TIMESTAMP` column, the function returns the internal timestamp value directly, with no implicit “string-to-Unix-timestamp” conversion. If you pass an out-of-range date to `UNIX_TIMESTAMP()`, it returns 0.

Note: If you use `UNIX_TIMESTAMP()` and `FROM_UNIXTIME()` to convert between `TIMESTAMP` values and Unix timestamp values, the conversion is lossy because the mapping is not one-to-one in both directions. For example, due to conventions for local time zone changes, it is possible for two `UNIX_TIMESTAMP()` to map two `TIMESTAMP` values to the same Unix timestamp value. `FROM_UNIXTIME()` will map that value back to only one of the original `TIMESTAMP` values. Here is an example, using `TIMESTAMP` values in the `CET` time zone:

```
mysql> SELECT UNIX_TIMESTAMP('2005-03-27 03:00:00');
+-----+
| UNIX_TIMESTAMP('2005-03-27 03:00:00') |
+-----+
| 1111885200 |
+-----+
mysql> SELECT UNIX_TIMESTAMP('2005-03-27 02:00:00');
+-----+
| UNIX_TIMESTAMP('2005-03-27 02:00:00') |
+-----+
| 1111885200 |
+-----+
mysql> SELECT FROM_UNIXTIME(1111885200);
+-----+
| FROM_UNIXTIME(1111885200) |
+-----+
| 2005-03-27 03:00:00 |
+-----+
```

If you want to subtract `UNIX_TIMESTAMP()` columns, you might want to cast the result to signed integers. See [Section 11.9, “Cast Functions and Operators”](#).

- `UTC_DATE`, `UTC_DATE()`

Returns the current UTC date as a value in 'YYYY-MM-DD' or YYYYMMDD format, depending on whether the function is used in a string or numeric context.

```
mysql> SELECT UTC_DATE(), UTC_DATE() + 0;
-> '2003-08-14', 20030814
```

- `UTC_TIME, UTC_TIME()`

Returns the current UTC time as a value in 'HH:MM:SS' or HHMMSS.uuuuuu format, depending on whether the function is used in a string or numeric context.

```
mysql> SELECT UTC_TIME(), UTC_TIME() + 0;
-> '18:07:53', 180753.000000
```

- `UTC_TIMESTAMP, UTC_TIMESTAMP()`

Returns the current UTC date and time as a value in 'YYYY-MM-DD HH:MM:SS' or YYYYMMDDHHMMSS.uuuuuu format, depending on whether the function is used in a string or numeric context.

```
mysql> SELECT UTC_TIMESTAMP(), UTC_TIMESTAMP() + 0;
-> '2003-08-14 18:08:04', 20030814180804.000000
```

- `WEEK(date[, mode])`

This function returns the week number for *date*. The two-argument form of `WEEK()` allows you to specify whether the week starts on Sunday or Monday and whether the return value should be in the range from 0 to 53 or from 1 to 53. If the *mode* argument is omitted, the value of the `default_week_format` system variable is used. See [Section 5.1.3, “Server System Variables”](#).

The following table describes how the *mode* argument works.

Mode	First day of week	Range	Week 1 is the first week ...
0	Sunday	0-53	with a Sunday in this year
1	Monday	0-53	with more than 3 days this year
2	Sunday	1-53	with a Sunday in this year
3	Monday	1-53	with more than 3 days this year
4	Sunday	0-53	with more than 3 days this year
5	Monday	0-53	with a Monday in this year
6	Sunday	1-53	with more than 3 days this year
7	Monday	1-53	with a Monday in this year

```
mysql> SELECT WEEK('2008-02-20');
-> 7
mysql> SELECT WEEK('2008-02-20',0);
-> 7
mysql> SELECT WEEK('2008-02-20',1);
-> 8
mysql> SELECT WEEK('2008-12-31',1);
-> 53
```

Note that if a date falls in the last week of the previous year, MySQL returns 0 if you do not use 2, 3, 6, or 7 as the optional *mode* argument:

```
mysql> SELECT YEAR('2000-01-01'), WEEK('2000-01-01',0);
-> 2000, 0
```

One might argue that MySQL should return 52 for the `WEEK()` function, because the given date actually occurs in the 52nd week of 1999. We decided to return 0 instead because we want the function to return “the week number in the given year.” This makes use of the `WEEK()` function reliable when combined with other functions that extract a date part from a date.

If you would prefer the result to be evaluated with respect to the year that contains the first day of the week for the given date, use 0, 2, 5, or 7 as the optional *mode* argument.

```
mysql> SELECT WEEK('2000-01-01',2);
-> 52
```

Alternatively, use the `YEARWEEK()` function:

```
mysql> SELECT YEARWEEK('2000-01-01');
-> 199952
mysql> SELECT MID(YEARWEEK('2000-01-01'),5,2);
-> '52'
```

- `WEEKDAY(date)`

Returns the weekday index for `date` (0 = Monday, 1 = Tuesday, ... 6 = Sunday).

```
mysql> SELECT WEEKDAY('2008-02-03 22:23:00');
-> 6
mysql> SELECT WEEKDAY('2007-11-06');
-> 1
```

- `WEEKOFYEAR(date)`

Returns the calendar week of the date as a number in the range from 1 to 53. `WEEKOFYEAR()` is a compatibility function that is equivalent to `WEEK(date, 3)`.

```
mysql> SELECT WEEKOFYEAR('2008-02-20');
-> 8
```

- `YEAR(date)`

Returns the year for `date`, in the range 1000 to 9999, or 0 for the “zero” date.

```
mysql> SELECT YEAR('1987-01-01');
-> 1987
```

- `YEARWEEK(date)`, `YEARWEEK(date, mode)`

Returns year and week for a date. The `mode` argument works exactly like the `mode` argument to `WEEK()`. The year in the result may be different from the year in the date argument for the first and the last week of the year.

```
mysql> SELECT YEARWEEK('1987-01-01');
-> 198653
```

Note that the week number is different from what the `WEEK()` function would return (0) for optional arguments 0 or 1, as `WEEK()` then returns the week in the context of the given year.

11.7. What Calendar Is Used By MySQL?

MySQL uses what is known as a *proleptic Gregorian calendar*.

Every country that has switched from the Julian to the Gregorian calendar has had to discard at least ten days during the switch. To see how this works, consider the month of October 1582, when the first Julian-to-Gregorian switch occurred.

Monday	Tuesday	Wednesday	Thursday	Friday	Saturday	Sunday
1	2	3	4	15	16	17
18	19	20	21	22	23	24
25	26	27	28	29	30	31

There are no dates between October 4 and October 15. This discontinuity is called the *cutover*. Any dates before the cutover are Julian, and any dates following the cutover are Gregorian. Dates during a cutover are non-existent.

A calendar applied to dates when it wasn't actually in use is called *proleptic*. Thus, if we assume there was never a cutover and Gregorian rules always rule, we have a proleptic Gregorian calendar. This is what is used by MySQL, as is required by standard SQL. For this reason, dates prior to the cutover stored as MySQL `DATE` or `DATETIME` values must be adjusted to compensate for the difference. It is important to realize that the cutover did not occur at the same time in all countries, and that the later it happened, the more days were lost. For example, in Great Britain, it took place in 1752, when Wednesday September 2 was followed by Thursday September 14. Russia remained on the Julian calendar until 1918, losing 13 days in the process, and what is popularly referred to as its “October Revolution” occurred in November according to the Gregorian calendar.

11.8. Full-Text Search Functions

```
MATCH (col1,col2,...) AGAINST (expr [search_modifier])
```

```
search_modifier:
{
  IN BOOLEAN MODE
  IN NATURAL LANGUAGE MODE
  IN NATURAL LANGUAGE MODE WITH QUERY EXPANSION
  WITH QUERY EXPANSION
}
```

MySQL has support for full-text indexing and searching:

- A full-text index in MySQL is an index of type `FULLTEXT`.
- Full-text indexes can be used only with `MyISAM` tables, and can be created only for `CHAR`, `VARCHAR`, or `TEXT` columns.
- A `FULLTEXT` index definition can be given in the `CREATE TABLE` statement when a table is created, or added later using `ALTER TABLE` or `CREATE INDEX`.
- For large data sets, it is much faster to load your data into a table that has no `FULLTEXT` index and then create the index after that, than to load data into a table that has an existing `FULLTEXT` index.

Full-text searching is performed using `MATCH() ... AGAINST` syntax. `MATCH()` takes a comma-separated list that names the columns to be searched. `AGAINST` takes a string to search for, and an optional modifier that indicates what type of search to perform. The search string must be a literal string, not a variable or a column name. There are three types of full-text searches:

- A boolean search interprets the search string using the rules of a special query language. The string contains the words to search for. It can also contain operators that specify requirements such that a word must be present or absent in matching rows, or that it should be weighted higher or lower than usual. Common words such as “some” or “then” are stopwords and do not match if present in the search string. The `IN BOOLEAN MODE` modifier specifies a boolean search. For more information, see [Section 11.8.2, “Boolean Full-Text Searches”](#).
- A natural language search interprets the search string as a phrase in natural human language (a phrase in free text). There are no special operators. The stopword list applies. In addition, words that are present in 50% or more of the rows are considered common and do not match. Full-text searches are natural language searches if the `IN NATURAL LANGUAGE MODE` modifier is given or if no modifier is given.
- A query expansion search is a modification of a natural language search. The search string is used to perform a natural language search. Then words from the most relevant rows returned by the search are added to the search string and the search is done again. The query returns the rows from the second search. The `IN NATURAL LANGUAGE MODE WITH QUERY EXPANSION` or `WITH QUERY EXPANSION` modifier specifies a query expansion search. For more information, see [Section 11.8.3, “Full-Text Searches with Query Expansion”](#).

Constraints on full-text searching are listed in [Section 11.8.5, “Full-Text Restrictions”](#).

11.8.1. Natural Language Full-Text Searches

By default or with the `IN NATURAL LANGUAGE MODE` modifier, the `MATCH()` function performs a natural language search for a string against a *text collection*. A collection is a set of one or more columns included in a `FULLTEXT` index. The search string is given as the argument to `AGAINST()`. For each row in the table, `MATCH()` returns a relevance value; that is, a similarity measure between the search string and the text in that row in the columns named in the `MATCH()` list.

```
mysql> CREATE TABLE articles (
->   id INT UNSIGNED AUTO_INCREMENT NOT NULL PRIMARY KEY,
->   title VARCHAR(200),
->   body TEXT,
->   FULLTEXT (title,body)
-> );
Query OK, 0 rows affected (0.00 sec)

mysql> INSERT INTO articles (title,body) VALUES
-> ('MySQL Tutorial','DBMS stands for DataBase ...'),
-> ('How To Use MySQL Well','After you went through a ...'),
-> ('Optimizing MySQL','In this tutorial we will show ...'),
-> ('1001 MySQL Tricks','1. Never run mysqld as root. 2. ...'),
-> ('MySQL vs. YourSQL','In the following database comparison ...'),
-> ('MySQL Security','When configured properly, MySQL ...');
Query OK, 6 rows affected (0.00 sec)
Records: 6  Duplicates: 0  Warnings: 0

mysql> SELECT * FROM articles
```

```
-> WHERE MATCH (title,body)
-> AGAINST ('database' IN NATURAL LANGUAGE MODE);
```

id	title	body
5	MySQL vs. YourSQL	In the following database comparison ...
1	MySQL Tutorial	DBMS stands for DataBase ...

2 rows in set (0.00 sec)

By default, the search is performed in case-insensitive fashion. However, you can perform a case-sensitive full-text search by using a binary collation for the indexed columns. For example, a column that uses the `latin1` character set of can be assigned a collation of `latin1_bin` to make it case sensitive for full-text searches.

When `MATCH()` is used in a `WHERE` clause, as in the example shown earlier, the rows returned are automatically sorted with the highest relevance first. Relevance values are non-negative floating-point numbers. Zero relevance means no similarity. Relevance is computed based on the number of words in the row, the number of unique words in that row, the total number of words in the collection, and the number of documents (rows) that contain a particular word.

To simply count matches, you could use a query like this:

```
mysql> SELECT COUNT(*) FROM articles
-> WHERE MATCH (title,body)
-> AGAINST ('database' IN NATURAL LANGUAGE MODE);
```

COUNT(*)
2

1 row in set (0.00 sec)

However, you might find it quicker to rewrite the query as follows:

```
mysql> SELECT
-> COUNT(IF(MATCH (title,body) AGAINST ('database' IN NATURAL LANGUAGE MODE), 1, NULL))
-> AS count
-> FROM articles;
```

count
2

1 row in set (0.03 sec)

The first query sorts the results by relevance whereas the second does not. However, the second query performs a full table scan and the first does not. The first may be faster if the search matches few rows; otherwise, the second may be faster because it would read many rows anyway.

For natural-language full-text searches, it is a requirement that the columns named in the `MATCH()` function be the same columns included in some `FULLTEXT` index in your table. For the preceding query, note that the columns named in the `MATCH()` function (`title` and `body`) are the same as those named in the definition of the `article` table's `FULLTEXT` index. If you wanted to search the `title` or `body` separately, you would need to create separate `FULLTEXT` indexes for each column.

It is also possible to perform a boolean search or a search with query expansion. These search types are described in [Section 11.8.2, "Boolean Full-Text Searches"](#), and [Section 11.8.3, "Full-Text Searches with Query Expansion"](#).

A full-text search that uses an index can name columns only from a single table in the `MATCH()` clause because an index cannot span multiple tables. A boolean search can be done in the absence of an index (albeit more slowly), in which case it is possible to name columns from multiple tables.

The preceding example is a basic illustration that shows how to use the `MATCH()` function where rows are returned in order of decreasing relevance. The next example shows how to retrieve the relevance values explicitly. Returned rows are not ordered because the `SELECT` statement includes neither `WHERE` nor `ORDER BY` clauses:

```
mysql> SELECT id, MATCH (title,body)
-> AGAINST ('Tutorial' IN NATURAL LANGUAGE MODE) AS score
-> FROM articles;
```

id	score
1	0.65545833110809
2	0
3	0.66266459226608
4	0
5	0
6	0

6 rows in set (0.00 sec)

The following example is more complex. The query returns the relevance values and it also sorts the rows in order of decreasing

relevance. To achieve this result, you should specify `MATCH()` twice: once in the `SELECT` list and once in the `WHERE` clause. This causes no additional overhead, because the MySQL optimizer notices that the two `MATCH()` calls are identical and invokes the full-text search code only once.

```
mysql> SELECT id, body, MATCH (title,body) AGAINST
-> ('Security implications of running MySQL as root'
-> IN NATURAL LANGUAGE MODE) AS score
-> FROM articles WHERE MATCH (title,body) AGAINST
-> ('Security implications of running MySQL as root'
-> IN NATURAL LANGUAGE MODE);
```

id	body	score
4	1. Never run mysqld as root. 2. ...	1.5219271183014
6	When configured properly, MySQL ...	1.3114095926285

```
2 rows in set (0.00 sec)
```

The MySQL `FULLTEXT` implementation regards any sequence of true word characters (letters, digits, and underscores) as a word. That sequence may also contain apostrophes (“’”), but not more than one in a row. This means that `aaa'bbb` is regarded as one word, but `aaa' 'bbb` is regarded as two words. Apostrophes at the beginning or the end of a word are stripped by the `FULLTEXT` parser; `'aaa'bbb'` would be parsed as `aaa'bbb`.

The `FULLTEXT` parser determines where words start and end by looking for certain delimiter characters; for example, “ ” (space), “,” (comma), and “.” (period). If words are not separated by delimiters (as in, for example, Chinese), the `FULLTEXT` parser cannot determine where a word begins or ends. To be able to add words or other indexed terms in such languages to a `FULLTEXT` index, you must preprocess them so that they are separated by some arbitrary delimiter such as “#”.

In MySQL 5.4, it is possible to write a plugin that replaces the built-in full-text parser. For details, see [Section 21.2, “The MySQL Plugin Interface”](#). For example parser plugin source code, see the `plugin/fulltext` directory of a MySQL source distribution.

Some words are ignored in full-text searches:

- Any word that is too short is ignored. The default minimum length of words that are found by full-text searches is four characters.
- Words in the stopword list are ignored. A stopword is a word such as “the” or “some” that is so common that it is considered to have zero semantic value. There is a built-in stopword list, but it can be overwritten by a user-defined list.

The default stopword list is given in [Section 11.8.4, “Full-Text Stopwords”](#). The default minimum word length and stopword list can be changed as described in [Section 11.8.6, “Fine-Tuning MySQL Full-Text Search”](#).

Every correct word in the collection and in the query is weighted according to its significance in the collection or query. Consequently, a word that is present in many documents has a lower weight (and may even have a zero weight), because it has lower semantic value in this particular collection. Conversely, if the word is rare, it receives a higher weight. The weights of the words are combined to compute the relevance of the row.

Such a technique works best with large collections (in fact, it was carefully tuned this way). For very small tables, word distribution does not adequately reflect their semantic value, and this model may sometimes produce bizarre results. For example, although the word “MySQL” is present in every row of the `articles` table shown earlier, a search for the word produces no results:

```
mysql> SELECT * FROM articles
-> WHERE MATCH (title,body)
-> AGAINST ('MySQL' IN NATURAL LANGUAGE MODE);
Empty set (0.00 sec)
```

The search result is empty because the word “MySQL” is present in at least 50% of the rows. As such, it is effectively treated as a stopword. For large data sets, this is the most desirable behavior: A natural language query should not return every second row from a 1GB table. For small data sets, it may be less desirable.

A word that matches half of the rows in a table is less likely to locate relevant documents. In fact, it most likely finds plenty of irrelevant documents. We all know this happens far too often when we are trying to find something on the Internet with a search engine. It is with this reasoning that rows containing the word are assigned a low semantic value for *the particular data set in which they occur*. A given word may reach the 50% threshold in one data set but not another.

The 50% threshold has a significant implication when you first try full-text searching to see how it works: If you create a table and insert only one or two rows of text into it, every word in the text occurs in at least 50% of the rows. As a result, no search returns any results. Be sure to insert at least three rows, and preferably many more. Users who need to bypass the 50% limitation can use the boolean search mode; see [Section 11.8.2, “Boolean Full-Text Searches”](#).

11.8.2. Boolean Full-Text Searches

MySQL can perform boolean full-text searches using the `IN BOOLEAN MODE` modifier:

```
mysql> SELECT * FROM articles WHERE MATCH (title,body)
-> AGAINST ('+MySQL -YourSQL' IN BOOLEAN MODE);
+-----+-----+-----+
| id | title | body |
+-----+-----+-----+
| 1 | MySQL Tutorial | DBMS stands for DataBase ... |
| 2 | How To Use MySQL Well | After you went through a ... |
| 3 | Optimizing MySQL | In this tutorial we will show ... |
| 4 | 1001 MySQL Tricks | 1. Never run mysqld as root. 2. ... |
| 6 | MySQL Security | When configured properly, MySQL ... |
+-----+-----+-----+
```

The `+` and `-` operators indicate that a word is required to be present or absent, respectively, for a match to occur. Thus, this query retrieves all the rows that contain the word “MySQL” but that do *not* contain the word “YourSQL”.

Note

In implementing this feature, MySQL uses what is sometimes referred to as *implied Boolean logic*, in which

- `+` stands for `AND`
- `-` stands for `NOT`
- `[no operator]` implies `OR`

Boolean full-text searches have these characteristics:

- They do not use the 50% threshold.
- They do not automatically sort rows in order of decreasing relevance. You can see this from the preceding query result: The row with the highest relevance is the one that contains “MySQL” twice, but it is listed last, not first.
- They can work even without a `FULLTEXT` index, although a search executed in this fashion would be quite slow.
- The minimum and maximum word length full-text parameters apply.
- The stopword list applies.

The boolean full-text search capability supports the following operators:

- `+`

A leading plus sign indicates that this word *must* be present in each row that is returned.

- `-`

A leading minus sign indicates that this word must *not* be present in any of the rows that are returned.

Note: The `-` operator acts only to exclude rows that are otherwise matched by other search terms. Thus, a boolean-mode search that contains only terms preceded by `-` returns an empty result. It does not return “all rows except those containing any of the excluded terms.”

- (no operator)

By default (when neither `+` nor `-` is specified) the word is optional, but the rows that contain it are rated higher. This mimics the behavior of `MATCH() ... AGAINST()` without the `IN BOOLEAN MODE` modifier.

- `>` `<`

These two operators are used to change a word's contribution to the relevance value that is assigned to a row. The `>` operator increases the contribution and the `<` operator decreases it. See the example following this list.

- `()`

Parentheses group words into subexpressions. Parenthesized groups can be nested.

- `~`

A leading tilde acts as a negation operator, causing the word's contribution to the row's relevance to be negative. This is useful for marking “noise” words. A row containing such a word is rated lower than others, but is not excluded altogether, as it would be with the `-` operator.

- `*`

The asterisk serves as the truncation (or wildcard) operator. Unlike the other operators, it should be *appended* to the word to be affected. Words match if they begin with the word preceding the `*` operator.

If a stopword or too-short word is specified with the truncation operator, it will not be stripped from a boolean query. For example, a search for `'+word +stopword*'` will likely return fewer rows than a search for `'+word +stopword'` because the former query remains as is and requires `stopword*` to be present in a document. The latter query is transformed to `+word`.

- `"`

A phrase that is enclosed within double quote (“”) characters matches only rows that contain the phrase *literally, as it was typed*. The full-text engine splits the phrase into words, performs a search in the `FULLTEXT` index for the words. Non-word characters need not be matched exactly: Phrase searching requires only that matches contain exactly the same words as the phrase and in the same order. For example, `"test phrase"` matches `"test, phrase"`.

If the phrase contains no words that are in the index, the result is empty. For example, if all words are either stopwords or shorter than the minimum length of indexed words, the result is empty.

The following examples demonstrate some search strings that use boolean full-text operators:

- `'apple banana'`

Find rows that contain at least one of the two words.

- `'+apple +juice'`

Find rows that contain both words.

- `'+apple macintosh'`

Find rows that contain the word “apple”, but rank rows higher if they also contain “macintosh”.

- `'+apple -macintosh'`

Find rows that contain the word “apple” but not “macintosh”.

- `'+apple ~macintosh'`

Find rows that contain the word “apple”, but if the row also contains the word “macintosh”, rate it lower than if row does not. This is “softer” than a search for `'+apple -macintosh'`, for which the presence of “macintosh” causes the row not to be returned at all.

- `'+apple +(>turnover <strudel)'`

Find rows that contain the words “apple” and “turnover”, or “apple” and “strudel” (in any order), but rank “apple turnover” higher than “apple strudel”.

- `'apple*'`

Find rows that contain words such as “apple”, “apples”, “applesauce”, or “applet”.

- `'"some words"'`

Find rows that contain the exact phrase “some words” (for example, rows that contain “some words of wisdom” but not “some noise words”). Note that the “” characters that enclose the phrase are operator characters that delimit the phrase. They are not the quotes that enclose the search string itself.

11.8.3. Full-Text Searches with Query Expansion

Full-text search supports query expansion (and in particular, its variant “blind query expansion”). This is generally useful when a search phrase is too short, which often means that the user is relying on implied knowledge that the full-text search engine lacks.

For example, a user searching for “database” may really mean that “MySQL”, “Oracle”, “DB2”, and “RDBMS” all are phrases that should match “databases” and should be returned, too. This is implied knowledge.

Blind query expansion (also known as automatic relevance feedback) is enabled by adding `WITH QUERY EXPANSION` or `IN NATURAL LANGUAGE MODE WITH QUERY EXPANSION` following the search phrase. It works by performing the search twice, where the search phrase for the second search is the original search phrase concatenated with the few most highly relevant documents from the first search. Thus, if one of these documents contains the word “databases” and the word “MySQL”, the second search finds the documents that contain the word “MySQL” even if they do not contain the word “database”. The following example shows this difference:

```
mysql> SELECT * FROM articles
-> WHERE MATCH (title,body)
-> AGAINST ('database' IN NATURAL LANGUAGE MODE);
+-----+-----+-----+
| id | title | body |
+-----+-----+-----+
| 5 | MySQL vs. YourSQL | In the following database comparison ... |
| 1 | MySQL Tutorial | DBMS stands for DataBase ... |
+-----+-----+-----+
2 rows in set (0.00 sec)

mysql> SELECT * FROM articles
-> WHERE MATCH (title,body)
-> AGAINST ('database' WITH QUERY EXPANSION);
+-----+-----+-----+
| id | title | body |
+-----+-----+-----+
| 1 | MySQL Tutorial | DBMS stands for DataBase ... |
| 5 | MySQL vs. YourSQL | In the following database comparison ... |
| 3 | Optimizing MySQL | In this tutorial we will show ... |
+-----+-----+-----+
3 rows in set (0.00 sec)
```

Another example could be searching for books by Georges Simenon about Maigret, when a user is not sure how to spell “Maigret”. A search for “Megre and the reluctant witnesses” finds only “Maigret and the Reluctant Witnesses” without query expansion. A search with query expansion finds all books with the word “Maigret” on the second pass.

Note

Because blind query expansion tends to increase noise significantly by returning non-relevant documents, it is meaningful to use only when a search phrase is rather short.

11.8.4. Full-Text Stopwords

The following table shows the default list of full-text stopwords.

a's	able	about	above	according

11.8.5. Full-Text Restrictions

- Full-text searches are supported for [MyISAM](#) tables only.
- Full-text searches can be used with most multi-byte character sets. The exception is that for Unicode, the `utf8` character set can be used, but not the `ucs2` character set. However, although `FULLTEXT` indexes on `ucs2` columns cannot be used, you can perform `IN BOOLEAN MODE` searches on a `ucs2` column that has no such index.

- Ideographic languages such as Chinese and Japanese do not have word delimiters. Therefore, the `FULLTEXT` parser *cannot determine where words begin and end in these and other such languages*. The implications of this and some workarounds for the problem are described in [Section 11.8, “Full-Text Search Functions”](#).
- Although the use of multiple character sets within a single table is supported, all columns in a `FULLTEXT` index must use the same character set and collation.
- The `MATCH()` column list must match exactly the column list in some `FULLTEXT` index definition for the table, unless this `MATCH()` is `IN BOOLEAN MODE`. Boolean-mode searches can be done on non-indexed columns, although they are likely to be slow.
- The argument to `AGAINST()` must be a constant string.
- Index hints are more limited for `FULLTEXT` searches than for non-`FULLTEXT` searches. See [Section 12.2.8.2, “Index Hint Syntax”](#).

11.8.6. Fine-Tuning MySQL Full-Text Search

MySQL's full-text search capability has few user-tunable parameters. You can exert more control over full-text searching behavior if you have a MySQL source distribution because some changes require source code modifications. See [Section 2.10, “MySQL Installation Using a Source Distribution”](#).

Note that full-text search is carefully tuned for the most effectiveness. Modifying the default behavior in most cases can actually decrease effectiveness. *Do not alter the MySQL sources unless you know what you are doing.*

Most full-text variables described in this section must be set at server startup time. A server restart is required to change them; they cannot be modified while the server is running.

Some variable changes require that you rebuild the `FULLTEXT` indexes in your tables. Instructions for doing this are given at the end of this section.

- The minimum and maximum lengths of words to be indexed are defined by the `ft_min_word_len` and `ft_max_word_len` system variables. (See [Section 5.1.3, “Server System Variables”](#).) The default minimum value is four characters; the default maximum is version dependent. If you change either value, you must rebuild your `FULLTEXT` indexes. For example, if you want three-character words to be searchable, you can set the `ft_min_word_len` variable by putting the following lines in an option file:

```
[mysqld]
ft_min_word_len=3
```

Then you must restart the server and rebuild your `FULLTEXT` indexes. Note particularly the remarks regarding `myisamchk` in the instructions following this list.

- To override the default stopword list, set the `ft_stopword_file` system variable. (See [Section 5.1.3, “Server System Variables”](#).) The variable value should be the path name of the file containing the stopword list, or the empty string to disable stopword filtering. After changing the value of this variable or the contents of the stopword file, restart the server and rebuild your `FULLTEXT` indexes.

The stopword list is free-form. That is, you may use any non-alphanumeric character such as newline, space, or comma to separate stopwords. Exceptions are the underscore character (“_”) and a single apostrophe (“'”) which are treated as part of a word. The character set of the stopword list is the server's default character set; see [Section 9.1.3.1, “Server Character Set and Collation”](#).

- The 50% threshold for natural language searches is determined by the particular weighting scheme chosen. To disable it, look for the following line in `storage/myisam/ftdefs.h`:

```
#define GWS_IN_USE GWS_PROB
```

Change that line to this:

```
#define GWS_IN_USE GWS_FREQ
```

Then recompile MySQL. There is no need to rebuild the indexes in this case.

Note

By making this change, you *severely* decrease MySQL's ability to provide adequate relevance values for the

MATCH() function. If you really need to search for such common words, it would be better to search using **IN BOOLEAN MODE** instead, which does not observe the 50% threshold.

- To change the operators used for boolean full-text searches, set the `ft_boolean_syntax` system variable. This variable can be changed while the server is running, but you must have the **SUPER** privilege to do so. No rebuilding of indexes is necessary in this case. See [Section 5.1.3, “Server System Variables”](#), which describes the rules governing how to set this variable.
- If you want to change the set of characters that are considered word characters, you can do so in two ways. Suppose that you want to treat the hyphen character ('-') as a word character. Use either of these methods:
 - Modify the MySQL source: In `storage/myisam/ftdefs.h`, see the `true_word_char()` and `misc_word_char()` macros. Add '-' to one of those macros and recompile MySQL.
 - Modify a character set file: This requires no recompilation. The `true_word_char()` macro uses a “character type” table to distinguish letters and numbers from other characters. You can edit the `<ctype><map>` contents in one of the character set XML files to specify that '-' is a “letter.” Then use the given character set for your **FULLTEXT** indexes.

After making the modification, you must rebuild the indexes for each table that contains any **FULLTEXT** indexes.

If you modify full-text variables that affect indexing (`ft_min_word_len`, `ft_max_word_len`, or `ft_stopword_file`), or if you change the stopwords file itself, you must rebuild your **FULLTEXT** indexes after making the changes and restarting the server. To rebuild the indexes in this case, it is sufficient to do a **QUICK** repair operation:

```
mysql> REPAIR TABLE tbl_name QUICK;
```

Each table that contains any **FULLTEXT** index must be repaired as just shown. Otherwise, queries for the table may yield incorrect results, and modifications to the table will cause the server to see the table as corrupt and in need of repair.

Note that if you use `myisamchk` to perform an operation that modifies table indexes (such as repair or analyze), the **FULLTEXT** indexes are rebuilt using the *default* full-text parameter values for minimum word length, maximum word length, and stopwords file unless you specify otherwise. This can result in queries failing.

The problem occurs because these parameters are known only by the server. They are not stored in **MyISAM** index files. To avoid the problem if you have modified the minimum or maximum word length or stopwords file values used by the server, specify the same `ft_min_word_len`, `ft_max_word_len`, and `ft_stopword_file` values to `myisamchk` that you use for `mysqld`. For example, if you have set the minimum word length to 3, you can repair a table with `myisamchk` like this:

```
shell> myisamchk --recover --ft_min_word_len=3 tbl_name.MYI
```

To ensure that `myisamchk` and the server use the same values for full-text parameters, place each one in both the `[mysqld]` and `[myisamchk]` sections of an option file:

```
[mysqld]
ft_min_word_len=3

[myisamchk]
ft_min_word_len=3
```

An alternative to using `myisamchk` is to use the **REPAIR TABLE**, **ANALYZE TABLE**, **OPTIMIZE TABLE**, or **ALTER TABLE** statements. These statements are performed by the server, which knows the proper full-text parameter values to use.

11.9. Cast Functions and Operators

Name	Description
BINARY	Cast a string to a binary string
CAST()	Cast a value as a certain type
Convert()	Cast a value as a certain type

- **BINARY**

The **BINARY** operator casts the string following it to a binary string. This is an easy way to force a column comparison to be done byte by byte rather than character by character. This causes the comparison to be case sensitive even if the column isn't defined as **BINARY** or **BLOB**. **BINARY** also causes trailing spaces to be significant.

```
mysql> SELECT 'a' = 'A';
-> 1
```

```
mysql> SELECT BINARY 'a' = 'A';
-> 0
mysql> SELECT 'a' = 'a ';
-> 1
mysql> SELECT BINARY 'a' = 'a ';
-> 0
```

In a comparison, `BINARY` affects the entire operation; it can be given before either operand with the same result.

`BINARY str` is shorthand for `CAST(str AS BINARY)`.

Note that in some contexts, if you cast an indexed column to `BINARY`, MySQL is not able to use the index efficiently.

- `CAST(expr AS type)`

The `CAST()` function takes a value of one type and produce a value of another type, similar to `CONVERT()`. See the description of `CONVERT()` for more information.

- `CONVERT(expr, type), CONVERT(expr USING transcoding_name)`

The `CONVERT()` and `CAST()` functions take a value of one type and produce a value of another type.

The `type` can be one of the following values:

- `BINARY[(N)]`
- `CHAR[(N)]`
- `DATE`
- `DATETIME`
- `DECIMAL[(M[,D])]`
- `SIGNED [INTEGER]`
- `TIME`
- `UNSIGNED [INTEGER]`

`BINARY` produces a string with the `BINARY` data type. See [Section 10.4.2, “The BINARY and VARBINARY Types”](#) for a description of how this affects comparisons. If the optional length `N` is given, `BINARY(N)` causes the cast to use no more than `N` bytes of the argument. Values shorter than `N` bytes are padded with `0x00` bytes to a length of `N`.

`CHAR(N)` causes the cast to use no more than `N` characters of the argument.

`CAST()` and `CONVERT(... USING ...)` are standard SQL syntax. The non-`USING` form of `CONVERT()` is ODBC syntax.

`CONVERT()` with `USING` is used to convert data between different character sets. In MySQL, transcoding names are the same as the corresponding character set names. For example, this statement converts the string `'abc'` in the default character set to the corresponding string in the `utf8` character set:

```
SELECT CONVERT('abc' USING utf8);
```

Normally, you cannot compare a `BLOB` value or other binary string in case-insensitive fashion because binary strings have no character set, and thus no concept of lettercase. To perform a case-insensitive comparison, use the `CONVERT()` function to convert the value to a nonbinary string. If the character set of the result has a case-insensitive collation, the `LIKE` operation is not case sensitive:

```
SELECT 'A' LIKE CONVERT(blob_col USING latin1) FROM tbl_name;
```

To use a different character set, substitute its name for `latin1` in the preceding statement. To ensure that a case-insensitive collation is used, specify a `COLLATE` clause following the `CONVERT()` call.

`CONVERT()` can be used more generally for comparing strings that are represented in different character sets.

The cast functions are useful when you want to create a column with a specific type in a `CREATE ... SELECT` statement:

```
CREATE TABLE new_table SELECT CAST('2000-01-01' AS DATE);
```

The functions also can be useful for sorting [ENUM](#) columns in lexical order. Normally, sorting of [ENUM](#) columns occurs using the internal numeric values. Casting the values to [CHAR](#) results in a lexical sort:

```
SELECT enum_col FROM tbl_name ORDER BY CAST(enum_col AS CHAR);
```

`CAST(str AS BINARY)` is the same thing as `BINARY str`. `CAST(expr AS CHAR)` treats the expression as a string with the default character set.

`CAST()` also changes the result if you use it as part of a more complex expression such as `CONCAT('Date: ',CAST(NOW() AS DATE))`.

You should not use `CAST()` to extract data in different formats but instead use string functions like `LEFT()` or `EXTRACT()`. See [Section 11.6, “Date and Time Functions”](#).

To cast a string to a numeric value in numeric context, you normally do not have to do anything other than to use the string value as though it were a number:

```
mysql> SELECT 1+'1';
-> 2
```

If you use a number in string context, the number automatically is converted to a [BINARY](#) string.

```
mysql> SELECT CONCAT('hello you ',2);
-> 'hello you 2'
```

MySQL supports arithmetic with both signed and unsigned 64-bit values. If you are using numeric operators (such as `+` or `-`) and one of the operands is an unsigned integer, the result is unsigned. You can override this by using the [SIGNED](#) and [UNSIGNED](#) cast operators to cast the operation to a signed or unsigned 64-bit integer, respectively.

```
mysql> SELECT CAST(1-2 AS UNSIGNED)
-> 18446744073709551615
mysql> SELECT CAST(CAST(1-2 AS UNSIGNED) AS SIGNED);
-> -1
```

Note that if either operand is a floating-point value, the result is a floating-point value and is not affected by the preceding rule. (In this context, [DECIMAL](#) column values are regarded as floating-point values.)

```
mysql> SELECT CAST(1 AS UNSIGNED) - 2.0;
-> -1.0
```

If you are using a string in an arithmetic operation, this is converted to a floating-point number.

If you convert a “zero” date string to a date, `CONVERT()` and `CAST()` return `NULL` and produce a warning when the `NO_ZERO_DATE` SQL mode is enabled.

11.10. XML Functions

Name	Description
<code>ExtractValue()</code> (v5.1.5)	Extracts a value from an XML string using XPath notation
<code>UpdateXML()</code> (v5.1.5)	Return replaced XML fragment

This section discusses XML and related functionality in MySQL.

Note

It is possible to obtain XML-formatted output from MySQL in the `mysql` and `mysqldump` clients by invoking them with the `--xml` option. See [Section 4.5.1, “mysql — The MySQL Command-Line Tool”](#), and [Section 4.5.4, “mysqldump — A Database Backup Program”](#).

Two functions providing basic XPath 1.0 (XML Path Language, version 1.0) capabilities are available. Some basic information about XPath syntax and usage is provided later in this section; however, an in-depth discussion of these topics is beyond the scope of this Manual, and you should refer to the [XML Path Language \(XPath\) 1.0 standard](#) for definitive information. A useful resource for those new to XPath or who desire a refresher in the basics is the [Zvon.org XPath Tutorial](#), which is available in several languages.

Note

These functions remain under development. We continue to improve these and other aspects of XML and XPath functionality in MySQL 5.4 and onwards. You may discuss these, ask questions about them, and obtain help from other users with them in the [MySQL XML User Forum](#).

XPath expressions used with these functions support user variables and local stored program variables. User variables are weakly checked; variables local to stored programs are strongly checked (see also [Bug#26518](#)):

- **User variables (weak checking).** Variables using the syntax ``${variable_name}` (that is, user variables) are not checked. No warnings or errors are issued by the server if a variable has the wrong type or has previously not been assigned a value. This also means the user is fully responsible for any typographical errors, since no warnings will be given if (for example) ``${myvairable}` is used where ``${myvariable}` was intended.

Example.

```
mysql> SET @xml = '<a><b>X</b><b>Y</b></a>';
Query OK, 0 rows affected (0.00 sec)

mysql> SET @i = 1, @j = 2;
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT @i, ExtractValue(@xml, '//b[${@i}]');
+-----+-----+
| @i | ExtractValue(@xml, '//b[${@i}]') |
+-----+-----+
| 1 | X |
+-----+-----+
1 row in set (0.00 sec)

mysql> SELECT @j, ExtractValue(@xml, '//b[${@j}]');
+-----+-----+
| @j | ExtractValue(@xml, '//b[${@j}]') |
+-----+-----+
| 2 | Y |
+-----+-----+
1 row in set (0.00 sec)

mysql> SELECT @k, ExtractValue(@xml, '//b[${@k}]');
+-----+-----+
| @k | ExtractValue(@xml, '//b[${@k}]') |
+-----+-----+
| NULL | |
+-----+-----+
1 row in set (0.00 sec)
```

- **Variables in stored programs (strong checking).** Variables using the syntax ``${variable_name}` can be declared and used with these functions when they are called inside stored programs. Such variables are local to the stored program in which they are defined, and are strongly checked for type and value.

Example.

```
mysql> DELIMITER |
mysql> CREATE PROCEDURE myproc ()
-> BEGIN
->   DECLARE i INT DEFAULT 1;
->   DECLARE xml VARCHAR(25) DEFAULT '<a>X</a><a>Y</a><a>Z</a>';

```

Parameters. Variables used in XPath expressions inside stored routines that are passed in as parameters are also subject to strong checking.

Expressions containing user variables or variables local to stored programs must otherwise (except for notation) conform to the rules for XPath expressions containing variables as given in the XPath 1.0 specification.

Note

Currently, a user variable used to store an XPath expression is treated as an empty string. Because of this, it is not possible to store an XPath expression as a user variable. We intend to fix this issue in a future MySQL release. (Bug#32911)

- `ExtractValue(xml_frag, xpath_expr)`

`ExtractValue()` takes two string arguments, a fragment of XML markup *xml_frag* and an XPath expression *xpath_expr* (also known as a *locator*); it returns the text (CDATA) of the first text node which is a child of the element(s) matched by the XPath expression. It is the equivalent of performing a match using the *xpath_expr* after appending `/text()`. In other words, `ExtractValue(' <a>Sakila', '/a/b')` and `ExtractValue(' <a>Sakila', '/a/b/text()')` produce the same result.

If multiple matches are found, then the content of the first child text node of each matching element is returned (in the order matched) as a single, space-delimited string.

If no matching text node is found for the expression (including the implicit `/text()`) — for whatever reason, as long as *xpath_expr* is valid, and *xml_frag* consists of elements which are properly nested and closed — an empty string is returned. No distinction is made between a match on an empty element and no match at all. This is by design.

If you need to determine whether no matching element was found in *xml_frag* or such an element was found but contained no child text nodes, you should test the result of an expression that uses the XPath `count()` function. For example, both of these statements return an empty string, as shown here:

```
mysql> SELECT ExtractValue('<a><b/></a>', '/a/b');
+-----+
| ExtractValue('<a><b/></a>', '/a/b') |
+-----+
|                                     |
+-----+
1 row in set (0.00 sec)

mysql> SELECT ExtractValue('<a><c/></a>', '/a/b');
+-----+
| ExtractValue('<a><c/></a>', '/a/b') |
+-----+
|                                     |
+-----+
1 row in set (0.00 sec)
```

However, you can determine whether there was actually a matching element using the following:

```
mysql> SELECT ExtractValue('<a><b/></a>', 'count(/a/b)');
+-----+
| ExtractValue('<a><b/></a>', 'count(/a/b)') |
+-----+
| 1 |
+-----+
1 row in set (0.00 sec)

mysql> SELECT ExtractValue('<a><c/></a>', 'count(/a/b)');
+-----+
| ExtractValue('<a><c/></a>', 'count(/a/b)') |
+-----+
| 0 |
+-----+
1 row in set (0.01 sec)
```

Important

`ExtractValue()` returns only CDATA, and does not return any tags that might be contained within a matching tag, nor any of their content (see the result returned as *val1* in the following example).

```
mysql> SELECT
-> ExtractValue('<a>ccc<b>ddd</b></a>', '/a') AS val1,
-> ExtractValue('<a>ccc<b>ddd</b></a>', '/a/b') AS val2,
-> ExtractValue('<a>ccc<b>ddd</b></a>', '//b') AS val3,
-> ExtractValue('<a>ccc<b>ddd</b></a>', '/b') AS val4,
```

```
-> ExtractValue('<a>ccc<b>ddd</b><b>eee</b></a>', '//b') AS val5;
```

val1	val2	val3	val4	val5
ccc	ddd	ddd		ddd eee

This function uses the current SQL collation for making comparisons with `contains()`, performing the same collation aggregation as other string functions (such as `CONCAT()`), in taking into account the collation coercibility of their arguments; see [Section 9.1.6.5, “Special Cases Where Collation Determination Is Tricky”](#), for an explanation of the rules governing this behavior.

(Previously, binary — that is, case-sensitive — comparison was always used.)

`NULL` is returned if `xml_frag` contains elements which are not properly nested or closed, and a warning is generated, as shown in this example:

```
mysql> SELECT ExtractValue('<a>c</a><b', '//a');
+-----+
| ExtractValue('<a>c</a><b', '//a') |
+-----+
| NULL                               |
+-----+
1 row in set, 1 warning (0.00 sec)

mysql> SHOW WARNINGS;
+-----+-----+-----+
| Level | Code | Message
+-----+-----+-----+
| Warning | 1523 | Incorrect XML value: 'parse error at line 1 pos 11: END-OF-INPUT unexpected ('>' wanted)'
+-----+-----+-----+
1 row in set (0.00 sec)

mysql> SELECT ExtractValue('<a>c</a><b/>', '//a');
+-----+
| ExtractValue('<a>c</a><b/>', '//a') |
+-----+
| c                                     |
+-----+
1 row in set (0.00 sec)
```

- `UpdateXML(xml_target, xpath_expr, new_xml)`

This function replaces a single portion of a given fragment of XML markup `xml_target` with a new XML fragment `new_xml`, and then returns the changed XML. The portion of `xml_target` that is replaced matches an XPath expression `xpath_expr` supplied by the user. If no expression matching `xpath_expr` is found, or if multiple matches are found, the function returns the original `xml_target` XML fragment. All three arguments should be strings.

```
mysql> SELECT
-> UpdateXML('<a><b>ccc</b><d></d></a>', '/a', '<e>fff</e>') AS val1,
-> UpdateXML('<a><b>ccc</b><d></d></a>', '/b', '<e>fff</e>') AS val2,
-> UpdateXML('<a><b>ccc</b><d></d></a>', '//b', '<e>fff</e>') AS val3,
-> UpdateXML('<a><b>ccc</b><d></d></a>', '/a/d', '<e>fff</e>') AS val4,
-> UpdateXML('<a><d></d><b>ccc</b><d></d></a>', '/a/d', '<e>fff</e>') AS val5
-> \G

***** 1. row *****
val1: <e>fff</e>
val2: <a><b>ccc</b><d></d></a>
val3: <a><e>fff</e><d></d></a>
val4: <a><b>ccc</b><e>fff</e></a>
val5: <a><d></d><b>ccc</b><d></d></a>
```

Note

A discussion in depth of XPath syntax and usage are beyond the scope of this Manual. Please see the [XML Path Language \(XPath\) 1.0 specification](#) for definitive information. A useful resource for those new to XPath or who are wishing a refresher in the basics is the [Zvon.org XPath Tutorial](#), which is available in several languages.

Descriptions and examples of some basic XPath expressions follow:

- `/tag`

Matches `<tag/>` if and only if `<tag/>` is the root element.

Example: `/a` has a match in `<a>` because it matches the outermost (root) tag. It does not match the inner `a` element in `<a>` because in this instance it is the child of another element.

- `/tag1/tag2`

Matches `<tag2/>` if and only if it is a child of `<tag1/>`, and `<tag1/>` is the root element.

Example: `/a/b` matches the `b` element in the XML fragment `<a>` because it is a child of the root element `a`. It does not have a match in `<a/>` because in this case, `b` is the root element (and hence the child of no other element). Nor does the XPath expression have a match in `<a><c></c>`; here, `b` is a descendant of `a`, but not actually a child of `a`.

This construct is extendable to three or more elements. For example, the XPath expression `/a/b/c` matches the `c` element in the fragment `<a><c/>`.

- `//tag`

Matches any instance of `<tag>`.

Example: `//a` matches the `a` element in any of the following: `<a><c/>`; `<c><a>`; `<c><a/></c>`.

`//` can be combined with `/`. For example, `//a/b` matches the `b` element in either of the fragments `<a>` or `<a><c/>`

Note

`//tag` is the equivalent of `/descendant-or-self::*<tag>`. A common error is to confuse this with `/descendant-or-self::<tag>`, although the latter expression can actually lead to very different results, as can be seen here:

```
mysql> SET @xml = '<a><b><c>w</c><b>x</b><d>y</d>z</b></a>';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT @xml;
+-----+
| @xml |
+-----+
| <a><b><c>w</c><b>x</b><d>y</d>z</b></a> |
+-----+
1 row in set (0.00 sec)

mysql> SELECT ExtractValue(@xml, '//b[1]');
+-----+
| ExtractValue(@xml, '//b[1]') |
+-----+
| x z |
+-----+
1 row in set (0.00 sec)

mysql> SELECT ExtractValue(@xml, '//b[2]');
+-----+
| ExtractValue(@xml, '//b[2]') |
+-----+
| |
+-----+
1 row in set (0.01 sec)

mysql> SELECT ExtractValue(@xml, '/descendant-or-self::*b[1]');
+-----+
| ExtractValue(@xml, '/descendant-or-self::*b[1]') |
+-----+
| x z |
+-----+
1 row in set (0.06 sec)

mysql> SELECT ExtractValue(@xml, '/descendant-or-self::*b[2]');
+-----+
| ExtractValue(@xml, '/descendant-or-self::*b[2]') |
+-----+
| |
+-----+
1 row in set (0.00 sec)

mysql> SELECT ExtractValue(@xml, '/descendant-or-self::b[1]');
+-----+
| ExtractValue(@xml, '/descendant-or-self::b[1]') |
+-----+
| z |
+-----+
1 row in set (0.00 sec)

mysql> SELECT ExtractValue(@xml, '/descendant-or-self::b[2]');
+-----+
| ExtractValue(@xml, '/descendant-or-self::b[2]') |
+-----+
| x |
+-----+
1 row in set (0.00 sec)
```

- The `*` operator acts as a “wildcard” that matches any element. For example, the expression `*/b` matches the `b` element in either of the XML fragments `<a>` or `<c></c>`. However, the expression does not produce a match in the fragment `<a/>` because `b` must be a child of some other element. The wildcard may be used in any position: The expression `*/b/*` will match any child of a `b` element that is itself not the root element.
- You can match any of several locators using the `|` (UNION) operator. For example, the expression `//b|//c` matches all `b` and `c` elements in the XML target.
- It is also possible to match an element based on the value of one or more of its attributes. This done using the syntax `tag[@attribute="value"]`. For example, the expression `//b[@id="idB"]` matches the second `b` element in the fragment `<a><b id="idA"/><c/><b id="idB"/>`. To match against *any* element having `attribute="value"`, use the XPath expression `//*[attribute="value"]`.

To filter multiple attribute values, simply use multiple attribute-comparison clauses in succession. For example, the expression `//b[@c="x"][@d="y"]` matches the element `<b c="x" d="y"/>` occurring anywhere in a given XML fragment.

To find elements for which the same attribute matches any of several values, you can use multiple locators joined by the `|` operator. For example, to match all `b` elements whose `c` attributes have either of the values 23 or 17, use the expression `//b[@c="23"]|//b[@c="17"]`. You can also use the logical `or` operator for this purpose: `//b[@c="23" or @c="17"]`.

Note

The difference between `or` and `|` is that `or` joins conditions, while `|` joins result sets.

XPath Limitations. The XPath syntax supported by these functions is currently subject to the following limitations:

- Noderset-to-noderset comparison (such as `'/a/b[@c=@d]'`) is not supported.
- All of the standard XPath comparison operators are supported. (Bug#22823)
- Relative locator expressions are resolved in the context of the root node. For example, consider the following query and result:

```
mysql> SELECT ExtractValue(
->   '<a><b c="1">X</b><b c="2">Y</b></a>',
->   'a/b'
-> ) AS result;
+-----+
| result |
+-----+
| X Y    |
+-----+
1 row in set (0.03 sec)
```

In this case, the locator `a/b` resolves to `/a/b`.

Relative locators are also supported within predicates. In the following example, `d[../@c="1"]` is resolved as `/a/b[d[../@c="1"]]/d`:

```
mysql> SELECT ExtractValue(
->   '<a>
->     <b c="1"><d>X</d></b>
->     <b c="2"><d>X</d></b>
->   </a>',
->   'a/b/d[../@c="1"]'
-> ) AS result;
+-----+
| result |
+-----+
| X      |
+-----+
1 row in set (0.00 sec)
```

- Locators prefixed with expressions that evaluate as scalar values — including variable references, literals, numbers, and scalar function calls — are disallowed, and their use results in an error.
- The `::` operator is not supported in combination with node types such as the following:
 - `axis::comment()`
 - `axis::text()`

- `axis::processing-instructions()`
- `axis::node()`

However, name tests (such as `axis::name` and `axis::*`) are supported, as shown in these examples:

```
mysql> SELECT ExtractValue('<a><b>x</b><c>y</c></a>', '/a/child:b');
+-----+
| ExtractValue('<a><b>x</b><c>y</c></a>', '/a/child:b') |
+-----+
| x |
+-----+
1 row in set (0.02 sec)

mysql> SELECT ExtractValue('<a><b>x</b><c>y</c></a>', '/a/child::*');
+-----+
| ExtractValue('<a><b>x</b><c>y</c></a>', '/a/child::*') |
+-----+
| x y |
+-----+
1 row in set (0.01 sec)
```

- “Up-and-down” navigation is not supported in cases where the path would lead “above” the root element. That is, you cannot use expressions which match on descendants of ancestors of a given element, where one or more of the ancestors of the current element is also an ancestor of the root element (see [Bug#16321](#)).
- The following XPath functions are not supported, or have known issues as indicated:
 - `id()`
 - `lang()`
 - `local-name()`
 - `name()`
 - `namespace-uri()`
 - `normalize-space()`
 - `starts-with()`
 - `string()`
 - `substring-after()`
 - `substring-before()`
 - `translate()`
- The following axes are not supported:
 - `following-sibling`
 - `following`
 - `preceding-sibling`
 - `preceding`

XPath expressions passed as arguments to `ExtractValue()` and `UpdateXML()` may contain the colon character (“:”) in element selectors, which enables their use with markup employing XML namespaces notation. For example:

```
mysql> SET @xml = '<a>111<b:c>222<d>333</d><e:f>444</e:f></b:c></a>';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT ExtractValue(@xml, '//e:f');
+-----+
| ExtractValue(@xml, '//e:f') |
+-----+
| 444 |
+-----+
1 row in set (0.00 sec)

mysql> SELECT UpdateXML(@xml, '//b:c', '<g:h>555</g:h>');
+-----+
| UpdateXML(@xml, '//b:c', '<g:h>555</g:h>') |
+-----+
```

```
+-----+
| <a>l1l<g:h>555</g:h></a> |
+-----+
1 row in set (0.00 sec)
```

This is similar in some respects to what is allowed by [Apache Xalan](#) and some other parsers, and is much simpler than requiring namespace declarations or the use of the `namespace-uri()` and `local-name()` functions.

Error handling. For both `ExtractValue()` and `UpdateXML()`, the XPath locator used must be valid and the XML to be searched must consist of elements which are properly nested and closed. If the locator is invalid, an error is generated:

```
mysql> SELECT ExtractValue('<a>c</a><b/>', '&a');
ERROR 1105 (HY000): XPATH SYNTAX ERROR: '&a'
```

If `xml_frag` does not consist of elements which are properly nested and closed, then `NULL` is returned, and a warning is generated, as shown in this example:

```
mysql> SELECT ExtractValue('<a>c</a><b', '//a');
+-----+
| ExtractValue('<a>c</a><b', '//a') |
+-----+
| NULL |
+-----+
1 row in set, 1 warning (0.00 sec)
```

```
mysql> SHOW WARNINGS;
```

```
+-----+-----+-----+
| Level | Code | Message |
+-----+-----+-----+
| Warning | 1523 | Incorrect XML value: 'parse error at line 1 pos 11: END-OF-INPUT unexpected ('>' wanted)' |
+-----+-----+-----+
1 row in set (0.00 sec)
```

```
mysql> SELECT ExtractValue('<a>c</a><b/>', '//a');
+-----+
| ExtractValue('<a>c</a><b/>', '//a') |
+-----+
| c |
+-----+
1 row in set (0.00 sec)
```

Important

The replacement XML used as the third argument to `UpdateXML()` is *not* checked to determine whether it consists solely of elements which are properly nested and closed.

XPath Injection. *code injection* occurs when malicious code is introduced into the system to gain unauthorized access to privileges and data. It is based on exploiting assumptions made by developers about the type and content of data input from users. XPath is no exception in this regard.

A common scenario in which this can happen is the case of application which handles authorization by matching the combination of a login name and password with those found in an XML file, using an XPath expression like this one:

```
//user[login/text()='neapolitan' and password/text()='1c3cr34m']/attribute::id
```

This is the XPath equivalent of an SQL statement like this one:

```
SELECT id FROM users WHERE login='neapolitan' AND password='1c3cr34m';
```

A PHP application employing XPath might handle the login process like this:

```
<?php
    $file      = "users.xml";
    $login     = $_POST["login"];
    $password  = $_POST["password"];

    $xpath = "//user[login/text()=$login and password/text()=$password]/attribute::id";

    if( file_exists($file) )
    {
        $xml = simplexml_load_file($file);

        if($result = $xml->xpath($xpath))
            echo "You are now logged in as user $result[0].";
        else
            echo "Invalid login name or password.";
    }
    else
        exit("Failed to open $file.");
?>
```

No checks are performed on the input. This means that a malevolent user can “short-circuit” the test by entering ' or 1=1 for both the login name and password, resulting in `$xpath` being evaluated as shown here:

```
//user[login/text()=' or 1=1 and password/text()=' or 1=1]/attribute::id
```

Since the expression inside the square brackets always evaluates as `true`, it is effectively the same as this one, which matches the `id` attribute of every `user` element in the XML document:

```
//user/attribute::id
```

One way in which this particular attack can be circumvented is simply by quoting the variable names to be interpolated in the definition of `$xpath`, forcing the values passed from a Web form to be converted to strings:

```
$xpath = "//user[login/text()=' $login' and password/text()=' $password']/attribute::id";
```

This is the same strategy that is often recommended for preventing SQL injection attacks. In general, the practices you should follow for preventing XPath injection attacks are the same as for preventing SQL injection:

- Never accepted untested data from users in your application.
- Check all user-submitted data for type; reject or convert data that is of the wrong type
- Test numerical data for out of range values; truncate, round, or reject values that are out of range. Test strings for illegal characters and either strip them out or reject input containing them.
- Do not output explicit error messages that might provide an unauthorized user with clues that could be used to compromise the system; log these to a file or database table instead.

Just as SQL injection attacks can be used to obtain information about database schemas, so can XPath injection be used to traverse XML files to uncover their structure, as discussed in Amit Klein's paper [Blind XPath Injection](#) (PDF file, 46KB).

It is also important to check the output being sent back to the client. Consider what can happen when we use the MySQL `ExtractValue()` function:

```
mysql> SELECT ExtractValue(
->     LOAD_FILE('users.xml'),
->     '//user[login/text()=' or 1=1 and password/text()=' or 1=1]/attribute::id'
-> ) AS id;
+-----+
| id     |
+-----+
| 00327 13579 02403 42354 28570 |
+-----+
1 row in set (0.01 sec)
```

Because `ExtractValue()` returns multiple matches as a single space-delimited string, this injection attack provides every valid ID contained within `users.xml` to the user as a single row of output. As an extra safeguard, you should also test output before returning it to the user. Here is a simple example:

```
mysql> SELECT @id = ExtractValue(
->     LOAD_FILE('users.xml'),
->     '//user[login/text()=' or 1=1 and password/text()=' or 1=1]/attribute::id'
-> );
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT IF(
->     INSTR(@id, ' ') = 0,
->     @id,
->     'Unable to retrieve user ID')
-> AS singleID;
+-----+
| singleID |
+-----+
| Unable to retrieve user ID |
+-----+
1 row in set (0.00 sec)
```

In general, the guidelines for returning data to users securely are the same as for accepting user input. These can be summed up as:

- Always test outgoing data for type and allowable values.

- Never allow unauthorized users to view error messages that might provide information about the application that could be used to exploit it.

11.11. Other Functions

Name	Description
AES_DECRYPT()	Decrypt using AES
AES_ENCRYPT()	Encrypt using AES
BENCHMARK()	Repeatedly execute an expression
BIT_COUNT()	Return the number of bits that are set
&	Bitwise AND
~	Invert bits
 	Bitwise OR
^	Bitwise XOR
CHARSET() (v4.1.0)	Return the character set of the argument
COERCIBILITY() (v4.1.1)	Return the collation coercibility value of the string argument
COLLATION() (v4.1.0)	Return the collation of the string argument
COMPRESS() (v4.1.1)	Return result as a binary string
CONNECTION_ID()	Return the connection ID (thread ID) for the connection
CURRENT_USER() , CURRENT_USER	Return the user name and host name combination
DATABASE()	Return the default (current) database name
DECODE()	Decodes a string encrypted using ENCODE()
DEFAULT()	Return the default value for a table column
DES_DECRYPT()	Decrypt a string
DES_ENCRYPT()	Encrypt a string
ENCODE()	Encode a string
ENCRYPT()	Encrypt a string
FOUND_ROWS()	For a SELECT with a LIMIT clause, the number of rows that would be returned were there no LIMIT clause
GET_LOCK()	Get a named lock
INET_ATON()	Return the numeric value of an IP address
INET_NTOA()	Return the IP address from a numeric value
IS_FREE_LOCK()	Checks whether the named lock is free
IS_USED_LOCK() (v4.1.0)	Checks whether the named lock is in use. Return connection identifier if true.
LAST_INSERT_ID()	Value of the AUTOINCREMENT column for the last INSERT
<<	Left shift
MASTER_POS_WAIT()	Block until the slave has read and applied all updates up to the specified position
MD5()	Calculate MD5 checksum
NAME_CONST() (v5.0.12)	Causes the column to have the given name
OLD_PASSWORD() (v4.1)	Return the value of the old (pre-4.1) implementation of PASSWORD
PASSWORD()	Calculate and return a password string
RAND()	Return a random floating-point value
RELEASE_LOCK()	Releases the named lock
>>	Right shift
ROW_COUNT() (v5.0.1)	The number of rows updated
SCHEMA() (v5.0.2)	A synonym for DATABASE()
SESSION_USER()	Synonym for USER()
SHA1() , SHA()	Calculate an SHA-1 160-bit checksum

Name	Description
<code>SLEEP()</code> (v5.0.12)	Sleep for a number of seconds
<code>SYSTEM_USER()</code>	Synonym for <code>USER()</code>
<code>UNCOMPRESS()</code> (v4.1.1)	Uncompress a string compressed
<code>UNCOMPRESSED_LENGTH()</code> (v4.1.1)	Return the length of a string before compression
<code>USER()</code>	Return the current user name and host name
<code>UUID_SHORT()</code> (v5.1.20)	Return an integer-valued universal identifier
<code>UUID()</code> (v4.1.2)	Return a Universal Unique Identifier (UUID)
<code>VALUES()</code> (v4.1.1)	Defines the values to be used during an <code>INSERT</code>
<code>VERSION()</code>	Returns a string that indicates the MySQL server version

11.11.1. Bit Functions

Name	Description
<code>BIT_COUNT()</code>	Return the number of bits that are set
<code>&</code>	Bitwise AND
<code>~</code>	Invert bits
<code> </code>	Bitwise OR
<code>^</code>	Bitwise XOR
<code><<</code>	Left shift
<code>>></code>	Right shift

MySQL uses `BIGINT` (64-bit) arithmetic for bit operations, so these operators have a maximum range of 64 bits.

- `|`

Bitwise OR:

```
mysql> SELECT 29 | 15;
-> 31
```

The result is an unsigned 64-bit integer.

- `&`

Bitwise AND:

```
mysql> SELECT 29 & 15;
-> 13
```

The result is an unsigned 64-bit integer.

- `^`

Bitwise XOR:

```
mysql> SELECT 1 ^ 1;
-> 0
mysql> SELECT 1 ^ 0;
-> 1
mysql> SELECT 11 ^ 3;
-> 8
```

The result is an unsigned 64-bit integer.

- `<<`

Shifts a longlong (`BIGINT`) number to the left.

```
mysql> SELECT 1 << 2;
-> 4
```

The result is an unsigned 64-bit integer. The value is truncated to 64 bits. In particular, if the shift count is greater or equal to the width of an unsigned 64-bit number, the result is zero.

- >>

Shifts a longlong (`BIGINT`) number to the right.

```
mysql> SELECT 4 >> 2;
-> 1
```

The result is an unsigned 64-bit integer. The value is truncated to 64 bits. In particular, if the shift count is greater or equal to the width of an unsigned 64-bit number, the result is zero.

- ~

Invert all bits.

```
mysql> SELECT 5 & ~1;
-> 4
```

The result is an unsigned 64-bit integer.

- `BIT_COUNT(N)`

Returns the number of bits that are set in the argument *N*.

```
mysql> SELECT BIT_COUNT(29), BIT_COUNT(b'101010');
-> 4, 3
```

11.11.2. Encryption and Compression Functions

Name	Description
<code>AES_DECRYPT()</code>	Decrypt using AES
<code>AES_ENCRYPT()</code>	Encrypt using AES
<code>COMPRESS()</code> (v4.1.1)	Return result as a binary string
<code>DECODE()</code>	Decodes a string encrypted using <code>ENCODE()</code>
<code>DES_DECRYPT()</code>	Decrypt a string
<code>DES_ENCRYPT()</code>	Encrypt a string
<code>ENCODE()</code>	Encode a string
<code>ENCRYPT()</code>	Encrypt a string
<code>MD5()</code>	Calculate MD5 checksum
<code>OLD_PASSWORD()</code> (v4.1)	Return the value of the old (pre-4.1) implementation of <code>PASSWORD</code>
<code>PASSWORD()</code>	Calculate and return a password string
<code>SHA1()</code> , <code>SHA()</code>	Calculate an SHA-1 160-bit checksum
<code>UNCOMPRESS()</code> (v4.1.1)	Uncompress a string compressed
<code>UNCOMPRESSED_LENGTH()</code> (v4.1.1)	Return the length of a string before compression

Note

The encryption and compression functions return binary strings. For many of these functions, the result might contain arbitrary byte values. If you want to store these results, use a column with a `VARBINARY` or `BLOB` binary string data type. This will avoid potential problems with trailing space removal or character set conversion that would change data values, such as may occur if you use a nonbinary string data type (`CHAR`, `VARCHAR`, `TEXT`).

Note

Exploits for the MD5 and SHA-1 algorithms have become known. You may wish to consider using one of the other encryption functions described in this section instead.

- `AES_DECRYPT(crypt_str,key_str)`

This function allows decryption of data using the official AES (Advanced Encryption Standard) algorithm. For more information, see the description of `AES_ENCRYPT()`.

- `AES_ENCRYPT(str,key_str)`

`AES_ENCRYPT()` and `AES_DECRYPT()` allow encryption and decryption of data using the official AES (Advanced Encryption Standard) algorithm, previously known as “Rijndael.” Encoding with a 128-bit key length is used, but you can extend it up to 256 bits by modifying the source. We chose 128 bits because it is much faster and it is secure enough for most purposes.

`AES_ENCRYPT()` encrypts a string and returns a binary string. `AES_DECRYPT()` decrypts the encrypted string and returns the original string. The input arguments may be any length. If either argument is `NULL`, the result of this function is also `NULL`.

Because AES is a block-level algorithm, padding is used to encode uneven length strings and so the result string length may be calculated using this formula:

$$16 \times (\text{trunc}(\text{string_length} / 16) + 1)$$

If `AES_DECRYPT()` detects invalid data or incorrect padding, it returns `NULL`. However, it is possible for `AES_DECRYPT()` to return a non-`NULL` value (possibly garbage) if the input data or the key is invalid.

You can use the AES functions to store data in an encrypted form by modifying your queries:

```
INSERT INTO t VALUES (1,AES_ENCRYPT('text','password'));
```

`AES_ENCRYPT()` and `AES_DECRYPT()` can be considered the most cryptographically secure encryption functions currently available in MySQL.

- `COMPRESS(string_to_compress)`

Compresses a string and returns the result as a binary string. This function requires MySQL to have been compiled with a compression library such as `zlib`. Otherwise, the return value is always `NULL`. The compressed string can be uncompressed with `UNCOMPRESS()`.

```
mysql> SELECT LENGTH(COMPRESS(REPEAT('a',1000)));
-> 21
mysql> SELECT LENGTH(COMPRESS(''));
-> 0
mysql> SELECT LENGTH(COMPRESS('a'));
-> 13
mysql> SELECT LENGTH(COMPRESS(REPEAT('a',16)));
-> 15
```

The compressed string contents are stored the following way:

- Empty strings are stored as empty strings.
- Non-empty strings are stored as a four-byte length of the uncompressed string (low byte first), followed by the compressed string. If the string ends with space, an extra “.” character is added to avoid problems with endspace trimming should the result be stored in a `CHAR` or `VARCHAR` column. (However, use of nonbinary string data types such as `CHAR` or `VARCHAR` to store compressed strings is not recommended anyway because character set conversion may occur. Use a `VARBINARY` or `BLOB` binary string column instead.)
- `DECODE(crypt_str,pass_str)`

Decrypts the encrypted string `crypt_str` using `pass_str` as the password. `crypt_str` should be a string returned from `ENCODE()`.

- `ENCODE(str,pass_str)`

Encrypt `str` using `pass_str` as the password. To decrypt the result, use `DECODE()`.

The result is a binary string of the same length as `str`.

The strength of the encryption is based on how good the random generator is. It should suffice for short strings.

- `DES_DECRYPT(crypt_str[,key_str])`

Decrypts a string encrypted with `DES_ENCRYPT()`. If an error occurs, this function returns `NULL`.

This function works only if MySQL has been configured with SSL support. See [Section 5.5.7, “Using SSL for Secure Connec-](#)

tions”.

If no *key_str* argument is given, `DES_DECRYPT()` examines the first byte of the encrypted string to determine the DES key number that was used to encrypt the original string, and then reads the key from the DES key file to decrypt the message. For this to work, the user must have the `SUPER` privilege. The key file can be specified with the `--des-key-file` server option.

If you pass this function a *key_str* argument, that string is used as the key for decrypting the message.

If the *crypt_str* argument does not appear to be an encrypted string, MySQL returns the given *crypt_str*.

- `DES_ENCRYPT(str[, {key_num|key_str}])`

Encrypts the string with the given key using the Triple-DES algorithm.

This function works only if MySQL has been configured with SSL support. See [Section 5.5.7, “Using SSL for Secure Connections”](#).

The encryption key to use is chosen based on the second argument to `DES_ENCRYPT()`, if one was given. With no argument, the first key from the DES key file is used. With a *key_num* argument, the given key number (0-9) from the DES key file is used. With a *key_str* argument, the given key string is used to encrypt *str*.

The key file can be specified with the `--des-key-file` server option.

The return string is a binary string where the first character is `CHAR(128 | key_num)`. If an error occurs, `DES_ENCRYPT()` returns `NULL`.

The 128 is added to make it easier to recognize an encrypted key. If you use a string key, *key_num* is 127.

The string length for the result is given by this formula:

```
new_len = orig_len + (8 - (orig_len % 8)) + 1
```

Each line in the DES key file has the following format:

```
key_num des_key_str
```

Each *key_num* value must be a number in the range from 0 to 9. Lines in the file may be in any order. *des_key_str* is the string that is used to encrypt the message. There should be at least one space between the number and the key. The first key is the default key that is used if you do not specify any key argument to `DES_ENCRYPT()`.

You can tell MySQL to read new key values from the key file with the `FLUSH DES_KEY_FILE` statement. This requires the `RELOAD` privilege.

One benefit of having a set of default keys is that it gives applications a way to check for the existence of encrypted column values, without giving the end user the right to decrypt those values.

```
mysql> SELECT customer_address FROM customer_table
> WHERE crypted_credit_card = DES_ENCRYPT('credit_card_number');
```

- `ENCRYPT(str[, salt])`

Encrypts *str* using the Unix `crypt()` system call and returns a binary string. The *salt* argument should be a string with at least two characters. If no *salt* argument is given, a random value is used.

```
mysql> SELECT ENCRYPT('hello');
-> 'VxuFAJXVARROc'
```

`ENCRYPT()` ignores all but the first eight characters of *str*, at least on some systems. This behavior is determined by the implementation of the underlying `crypt()` system call.

The use of `ENCRYPT()` with multi-byte character sets other than `utf8` is not recommended because the system call expects a string terminated by a zero byte.

If `crypt()` is not available on your system (as is the case with Windows), `ENCRYPT()` always returns `NULL`.

- `MD5(str)`

Calculates an MD5 128-bit checksum for the string. The value is returned as a binary string of 32 hex digits, or `NULL` if the argument was `NULL`. The return value can, for example, be used as a hash key.

```
mysql> SELECT MD5('testing');
```

```
-> 'ae2b1fca515949e5d54fb22b8ed95575'
```

This is the “RSA Data Security, Inc. MD5 Message-Digest Algorithm.”

If you want to convert the value to uppercase, see the description of binary string conversion given in the entry for the `BINARY` operator in [Section 11.9, “Cast Functions and Operators”](#).

See the note regarding the MD5 algorithm at the beginning this section.

- `OLD_PASSWORD(str)`

`OLD_PASSWORD()` was added to MySQL when the implementation of `PASSWORD()` was changed to improve security. `OLD_PASSWORD()` returns the value of the old (pre-4.1) implementation of `PASSWORD()` as a binary string, and is intended to permit you to reset passwords for any pre-4.1 clients that need to connect to your version 5.4 MySQL server without locking them out. See [Section 5.5.6.3, “Password Hashing in MySQL”](#).

- `PASSWORD(str)`

Calculates and returns a password string from the plaintext password `str` and returns a binary string, or `NULL` if the argument was `NULL`. This is the function that is used for encrypting MySQL passwords for storage in the `Password` column of the `user` grant table.

```
mysql> SELECT PASSWORD('badpwd');
-> '*AAB3E285149C0135D51A520E1940DD3263DC008C'
```

`PASSWORD()` encryption is one-way (not reversible).

`PASSWORD()` does not perform password encryption in the same way that Unix passwords are encrypted. See `ENCRYPT()`.

Note

The `PASSWORD()` function is used by the authentication system in MySQL Server; you should *not* use it in your own applications. For that purpose, consider `MD5()` or `SHA1()` instead. Also see [RFC 2195, section 2 \(Challenge-Response Authentication Mechanism \(CRAM\)\)](#), for more information about handling passwords and authentication securely in your applications.

- `SHA1(str), SHA(str)`

Calculates an SHA-1 160-bit checksum for the string, as described in RFC 3174 (Secure Hash Algorithm). The value is returned as a binary string of 40 hex digits, or `NULL` if the argument was `NULL`. One of the possible uses for this function is as a hash key. You can also use it as a cryptographic function for storing passwords. `SHA()` is synonymous with `SHA1()`.

```
mysql> SELECT SHA1('abc');
-> 'a9993e364706816aba3e25717850c26c9cd0d89d'
```

`SHA1()` can be considered a cryptographically more secure equivalent of `MD5()`. However, see the note regarding the MD5 and SHA-1 algorithms at the beginning this section.

- `UNCOMPRESS(string_to_uncompress)`

Uncompresses a string compressed by the `COMPRESS()` function. If the argument is not a compressed value, the result is `NULL`. This function requires MySQL to have been compiled with a compression library such as `zlib`. Otherwise, the return value is always `NULL`.

```
mysql> SELECT UNCOMPRESS(COMPRESS('any string'));
-> 'any string'
mysql> SELECT UNCOMPRESS('any string');
-> NULL
```

- `UNCOMPRESSED_LENGTH(compressed_string)`

Returns the length that the compressed string had before being compressed.

```
mysql> SELECT UNCOMPRESSED_LENGTH(COMPRESS(REPEAT('a', 30)));
-> 30
```

11.11.3. Information Functions

Name	Description
<code>BENCHMARK()</code>	Repeatedly execute an expression
<code>CHARSET()</code> (v4.1.0)	Return the character set of the argument
<code>COERCIBILITY()</code> (v4.1.1)	Return the collation coercibility value of the string argument
<code>COLLATION()</code> (v4.1.0)	Return the collation of the string argument
<code>CONNECTION_ID()</code>	Return the connection ID (thread ID) for the connection
<code>CURRENT_USER()</code> , <code>CURRENT_USER</code>	Return the user name and host name combination
<code>DATABASE()</code>	Return the default (current) database name
<code>FOUND_ROWS()</code>	For a <code>SELECT</code> with a <code>LIMIT</code> clause, the number of rows that would be returned were there no <code>LIMIT</code> clause
<code>LAST_INSERT_ID()</code>	Value of the <code>AUTOINCREMENT</code> column for the last <code>INSERT</code>
<code>ROW_COUNT()</code> (v5.0.1)	The number of rows updated
<code>SCHEMA()</code> (v5.0.2)	A synonym for <code>DATABASE()</code>
<code>SESSION_USER()</code>	Synonym for <code>USER()</code>
<code>SYSTEM_USER()</code>	Synonym for <code>USER()</code>
<code>USER()</code>	Return the current user name and host name
<code>VERSION()</code>	Returns a string that indicates the MySQL server version

- `BENCHMARK(count, expr)`

The `BENCHMARK()` function executes the expression `expr` repeatedly `count` times. It may be used to time how quickly MySQL processes the expression. The result value is always 0. The intended use is from within the `mysql` client, which reports query execution times:

```
mysql> SELECT BENCHMARK(1000000, ENCODE('hello', 'goodbye'));
+-----+
| BENCHMARK(1000000, ENCODE('hello', 'goodbye')) |
+-----+
| 0 |
+-----+
1 row in set (4.74 sec)
```

The time reported is elapsed time on the client end, not CPU time on the server end. It is advisable to execute `BENCHMARK()` several times, and to interpret the result with regard to how heavily loaded the server machine is.

`BENCHMARK()` is intended for measuring the runtime performance of scalar expressions, which has some significant implications for the way that you use it and interpret the results:

- Only scalar expressions can be used. Although the expression can be a subquery, it must return a single column and at most a single row. For example, `BENCHMARK(10, (SELECT * FROM t))` will fail if the table `t` has more than one column or more than one row.
- Executing a `SELECT expr` statement `N` times differs from executing `SELECT BENCHMARK(N, expr)` in terms of the amount of overhead involved. The two have very different execution profiles and you should not expect them to take the same amount of time. The former involves the parser, optimizer, table locking, and runtime evaluation `N` times each. The latter involves only runtime evaluation `N` times, and all the other components just once. Memory structures already allocated are reused, and runtime optimizations such as local caching of results already evaluated for aggregate functions can alter the results. Use of `BENCHMARK()` thus measures performance of the runtime component by giving more weight to that component and removing the “noise” introduced by the network, parser, optimizer, and so forth.

- `CHARSET(str)`

Returns the character set of the string argument.

```
mysql> SELECT CHARSET('abc');
-> 'latin1'
mysql> SELECT CHARSET(CONVERT('abc' USING utf8));
-> 'utf8'
mysql> SELECT CHARSET(USER());
-> 'utf8'
```

- `COERCIBILITY(str)`

Returns the collation coercibility value of the string argument.

```
mysql> SELECT COERCIBILITY('abc' COLLATE latin1_swedish_ci);
-> 0
mysql> SELECT COERCIBILITY(USER());
-> 3
mysql> SELECT COERCIBILITY('abc');
-> 4
```

The return values have the meanings shown in the following table. Lower values have higher precedence.

Coercibility	Meaning	Example
0	Explicit collation	Value with <code>COLLATE</code> clause
1	No collation	Concatenation of strings with different collations
2	Implicit collation	Column value, stored routine parameter or local variable
3	System constant	<code>USER()</code> return value
4	Coercible	Literal string
5	Ignorable	<code>NULL</code> or an expression derived from <code>NULL</code>

- `COLLATION(str)`

Returns the collation of the string argument.

```
mysql> SELECT COLLATION('abc');
-> 'latin1_swedish_ci'
mysql> SELECT COLLATION(_utf8'abc');
-> 'utf8_general_ci'
```

- `CONNECTION_ID()`

Returns the connection ID (thread ID) for the connection. Every connection has an ID that is unique among the set of currently connected clients.

```
mysql> SELECT CONNECTION_ID();
-> 23786
```

- `CURRENT_USER`, `CURRENT_USER()`

Returns the user name and host name combination for the MySQL account that the server used to authenticate the current client. This account determines your access privileges. The return value is a string in the `utf8` character set.

The value of `CURRENT_USER()` can differ from the value of `USER()`.

```
mysql> SELECT USER();
-> 'david@localhost'
mysql> SELECT * FROM mysql.user;
ERROR 1044: Access denied for user ''@'localhost' to
database 'mysql'
mysql> SELECT CURRENT_USER();
-> '@localhost'
```

The example illustrates that although the client specified a user name of `david` (as indicated by the value of the `USER()` function), the server authenticated the client using an anonymous user account (as seen by the empty user name part of the `CURRENT_USER()` value). One way this might occur is that there is no account listed in the grant tables for `david`.

Within a stored program or view, `CURRENT_USER()` returns the account for the user who defined the object (as given by its `DEFINER` value). For stored procedures and functions and views defined with the `SQL SECURITY INVOKER` characteristic, `CURRENT_USER()` returns the object's invoker.

- `DATABASE()`

Returns the default (current) database name as a string in the `utf8` character set. If there is no default database, `DATABASE()` returns `NULL`. Within a stored routine, the default database is the database that the routine is associated with, which is not necessarily the same as the database that is the default in the calling context.

```
mysql> SELECT DATABASE();
-> 'test'
```

If there is no default database, `DATABASE()` returns `NULL`.

- `FOUND_ROWS()`

A `SELECT` statement may include a `LIMIT` clause to restrict the number of rows the server returns to the client. In some cases, it is desirable to know how many rows the statement would have returned without the `LIMIT`, but without running the statement again. To obtain this row count, include a `SQL_CALC_FOUND_ROWS` option in the `SELECT` statement, and then invoke `FOUND_ROWS()` afterward:

```
mysql> SELECT SQL_CALC_FOUND_ROWS * FROM tbl_name
-> WHERE id > 100 LIMIT 10;
mysql> SELECT FOUND_ROWS();
```

The second `SELECT` returns a number indicating how many rows the first `SELECT` would have returned had it been written without the `LIMIT` clause.

In the absence of the `SQL_CALC_FOUND_ROWS` option in the most recent successful `SELECT` statement, `FOUND_ROWS()` returns the number of rows in the result set returned by that statement. If the statement includes a `LIMIT` clause, `FOUND_ROWS()` returns the number of rows up to the limit. For example, `FOUND_ROWS()` returns 10 or 60, respectively, if the statement includes `LIMIT 10` or `LIMIT 50, 10`.

The row count available through `FOUND_ROWS()` is transient and not intended to be available past the statement following the `SELECT SQL_CALC_FOUND_ROWS` statement. If you need to refer to the value later, save it:

```
mysql> SELECT SQL_CALC_FOUND_ROWS * FROM ... ;
mysql> SET @rows = FOUND_ROWS();
```

If you are using `SELECT SQL_CALC_FOUND_ROWS`, MySQL must calculate how many rows are in the full result set. However, this is faster than running the query again without `LIMIT`, because the result set need not be sent to the client.

`SQL_CALC_FOUND_ROWS` and `FOUND_ROWS()` can be useful in situations when you want to restrict the number of rows that a query returns, but also determine the number of rows in the full result set without running the query again. An example is a Web script that presents a paged display containing links to the pages that show other sections of a search result. Using `FOUND_ROWS()` allows you to determine how many other pages are needed for the rest of the result.

The use of `SQL_CALC_FOUND_ROWS` and `FOUND_ROWS()` is more complex for `UNION` statements than for simple `SELECT` statements, because `LIMIT` may occur at multiple places in a `UNION`. It may be applied to individual `SELECT` statements in the `UNION`, or global to the `UNION` result as a whole.

The intent of `SQL_CALC_FOUND_ROWS` for `UNION` is that it should return the row count that would be returned without a global `LIMIT`. The conditions for use of `SQL_CALC_FOUND_ROWS` with `UNION` are:

- The `SQL_CALC_FOUND_ROWS` keyword must appear in the first `SELECT` of the `UNION`.
- The value of `FOUND_ROWS()` is exact only if `UNION ALL` is used. If `UNION` without `ALL` is used, duplicate removal occurs and the value of `FOUND_ROWS()` is only approximate.
- If no `LIMIT` is present in the `UNION`, `SQL_CALC_FOUND_ROWS` is ignored and returns the number of rows in the temporary table that is created to process the `UNION`.

Beyond the cases described here, the behavior of `FOUND_ROWS()` is undefined (for example, its value following a `SELECT` statement that fails with an error).

Important

`FOUND_ROWS()` is not replicated reliably using statement-based replication. This function is automatically replicated using row-based replication.

- `LAST_INSERT_ID()`, `LAST_INSERT_ID(expr)`

`LAST_INSERT_ID()` (no arguments) returns the *first* automatically generated value *successfully* inserted for an `AUTO_INCREMENT` column as a result of the most recently executed `INSERT` statement. The value of `LAST_INSERT_ID()` remains unchanged if no rows are successfully inserted.

For example, after inserting a row that generates an `AUTO_INCREMENT` value, you can get the value like this:

```
mysql> SELECT LAST_INSERT_ID();
-> 195
```

The currently executing statement does not affect the value of `LAST_INSERT_ID()`. Suppose that you generate an `AUTO_INCREMENT` value with one statement, and then refer to `LAST_INSERT_ID()` in a multiple-row `INSERT` statement that inserts rows into a table with its own `AUTO_INCREMENT` column. The value of `LAST_INSERT_ID()` will remain stable in the second statement; its value for the second and later rows is not affected by the earlier row insertions. (However, if you

mix references to `LAST_INSERT_ID()` and `LAST_INSERT_ID(expr)`, the effect is undefined.)

If the previous statement returned an error, the value of `LAST_INSERT_ID()` is undefined. For transactional tables, if the statement is rolled back due to an error, the value of `LAST_INSERT_ID()` is left undefined. For manual `ROLLBACK`, the value of `LAST_INSERT_ID()` is not restored to that before the transaction; it remains as it was at the point of the `ROLLBACK`.

Within the body of a stored routine (procedure or function) or a trigger, the value of `LAST_INSERT_ID()` changes the same way as for statements executed outside the body of these kinds of objects. The effect of a stored routine or trigger upon the value of `LAST_INSERT_ID()` that is seen by following statements depends on the kind of routine:

- If a stored procedure executes statements that change the value of `LAST_INSERT_ID()`, the changed value will be seen by statements that follow the procedure call.
- For stored functions and triggers that change the value, the value is restored when the function or trigger ends, so following statements will not see a changed value.

The ID that was generated is maintained in the server on a *per-connection basis*. This means that the value returned by the function to a given client is the first `AUTO_INCREMENT` value generated for most recent statement affecting an `AUTO_INCREMENT` column *by that client*. This value cannot be affected by other clients, even if they generate `AUTO_INCREMENT` values of their own. This behavior ensures that each client can retrieve its own ID without concern for the activity of other clients, and without the need for locks or transactions.

The value of `LAST_INSERT_ID()` is not changed if you set the `AUTO_INCREMENT` column of a row to a non-“magic” value (that is, a value that is not `NULL` and not `0`).

Important

If you insert multiple rows using a single `INSERT` statement, `LAST_INSERT_ID()` returns the value generated for the *first* inserted row *only*. The reason for this is to make it possible to reproduce easily the same `INSERT` statement against some other server.

For example:

```
mysql> USE test;
Database changed
mysql> CREATE TABLE t (
  ->   id INT AUTO_INCREMENT NOT NULL PRIMARY KEY,
  ->   name VARCHAR(10) NOT NULL
  -> );
Query OK, 0 rows affected (0.09 sec)

mysql> INSERT INTO t VALUES (NULL, 'Bob');
Query OK, 1 row affected (0.01 sec)

mysql> SELECT * FROM t;
+----+-----+
| id | name |
+----+-----+
|  1 | Bob  |
+----+-----+
1 row in set (0.01 sec)

mysql> SELECT LAST_INSERT_ID();
+-----+
| LAST_INSERT_ID() |
+-----+
|                1 |
+-----+
1 row in set (0.00 sec)

mysql> INSERT INTO t VALUES
  -> (NULL, 'Mary'), (NULL, 'Jane'), (NULL, 'Lisa');
Query OK, 3 rows affected (0.00 sec)
Records: 3  Duplicates: 0  Warnings: 0

mysql> SELECT * FROM t;
+----+-----+
| id | name |
+----+-----+
|  1 | Bob  |
|  2 | Mary |
|  3 | Jane |
|  4 | Lisa |
+----+-----+
4 rows in set (0.01 sec)

mysql> SELECT LAST_INSERT_ID();
+-----+
| LAST_INSERT_ID() |
+-----+
|                2 |
+-----+
1 row in set (0.00 sec)
```

Although the second `INSERT` statement inserted three new rows into `t`, the ID generated for the first of these rows was 2, and it is this value that is returned by `LAST_INSERT_ID()` for the following `SELECT` statement.

If you use `INSERT IGNORE` and the row is ignored, the `AUTO_INCREMENT` counter is not incremented and `LAST_INSERT_ID()` returns 0, which reflects that no row was inserted.

If `expr` is given as an argument to `LAST_INSERT_ID()`, the value of the argument is returned by the function and is remembered as the next value to be returned by `LAST_INSERT_ID()`. This can be used to simulate sequences:

1. Create a table to hold the sequence counter and initialize it:

```
mysql> CREATE TABLE sequence (id INT NOT NULL);
mysql> INSERT INTO sequence VALUES (0);
```

2. Use the table to generate sequence numbers like this:

```
mysql> UPDATE sequence SET id=LAST_INSERT_ID(id+1);
mysql> SELECT LAST_INSERT_ID();
```

The `UPDATE` statement increments the sequence counter and causes the next call to `LAST_INSERT_ID()` to return the updated value. The `SELECT` statement retrieves that value. The `mysql_insert_id()` C API function can also be used to get the value. See [Section 20.10.3.37](#), “`mysql_insert_id()`”.

You can generate sequences without calling `LAST_INSERT_ID()`, but the utility of using the function this way is that the ID value is maintained in the server as the last automatically generated value. It is multi-user safe because multiple clients can issue the `UPDATE` statement and get their own sequence value with the `SELECT` statement (or `mysql_insert_id()`), without affecting or being affected by other clients that generate their own sequence values.

Note that `mysql_insert_id()` is only updated after `INSERT` and `UPDATE` statements, so you cannot use the C API function to retrieve the value for `LAST_INSERT_ID(expr)` after executing other SQL statements like `SELECT` or `SET`.

- `ROW_COUNT()`

`ROW_COUNT()` returns the number of rows updated, inserted, or deleted by the preceding statement. This is the same as the row count that the `mysql` client displays and the value from the `mysql_affected_rows()` C API function.

```
mysql> INSERT INTO t VALUES(1),(2),(3);
Query OK, 3 rows affected (0.00 sec)
Records: 3 Duplicates: 0 Warnings: 0

mysql> SELECT ROW_COUNT();
+-----+
| ROW_COUNT() |
+-----+
|           3 |
+-----+
1 row in set (0.00 sec)

mysql> DELETE FROM t WHERE i IN(1,2);
Query OK, 2 rows affected (0.00 sec)

mysql> SELECT ROW_COUNT();
+-----+
| ROW_COUNT() |
+-----+
|           2 |
+-----+
1 row in set (0.00 sec)
```

Important

`ROW_COUNT()` is not replicated reliably using statement-based replication. This function is automatically replicated using row-based replication.

- `SCHEMA()`

This function is a synonym for `DATABASE()`.

- `SESSION_USER()`

`SESSION_USER()` is a synonym for `USER()`.

- `SYSTEM_USER()`

`SYSTEM_USER()` is a synonym for `USER()`.

- `USER()`

Returns the current MySQL user name and host name as a string in the `utf8` character set.

```
mysql> SELECT USER();
-> 'davida@localhost'
```

The value indicates the user name you specified when connecting to the server, and the client host from which you connected. The value can be different from that of `CURRENT_USER()`.

You can extract only the user name part like this:

```
mysql> SELECT SUBSTRING_INDEX(USER(), '@', 1);
-> 'davida'
```

- `VERSION()`

Returns a string that indicates the MySQL server version. The string uses the `utf8` character set.

```
mysql> SELECT VERSION();
-> '5.4.0-standard'
```

Note that if your version string ends with `-log` this means that logging is enabled.

11.11.4. Miscellaneous Functions

Name	Description
<code>DEFAULT()</code>	Return the default value for a table column
<code>GET_LOCK()</code>	Get a named lock
<code>INET_ATON()</code>	Return the numeric value of an IP address
<code>INET_NTOA()</code>	Return the IP address from a numeric value
<code>IS_FREE_LOCK()</code>	Checks whether the named lock is free
<code>IS_USED_LOCK()</code> (v4.1.0)	Checks whether the named lock is in use. Return connection identifier if true.
<code>MASTER_POS_WAIT()</code>	Block until the slave has read and applied all updates up to the specified position
<code>NAME_CONST()</code> (v5.0.12)	Causes the column to have the given name
<code>RAND()</code>	Return a random floating-point value
<code>RELEASE_LOCK()</code>	Releases the named lock
<code>SLEEP()</code> (v5.0.12)	Sleep for a number of seconds
<code>UUID_SHORT()</code> (v5.1.20)	Return an integer-valued universal identifier
<code>UUID()</code> (v4.1.2)	Return a Universal Unique Identifier (UUID)
<code>VALUES()</code> (v4.1.1)	Defines the values to be used during an INSERT

- `DEFAULT(col_name)`

Returns the default value for a table column. An error results if the column has no default value.

```
mysql> UPDATE t SET i = DEFAULT(i)+1 WHERE id < 100;
```

- `FORMAT(X, D)`

Formats the number `X` to a format like `'#,###,###.##'`, rounded to `D` decimal places, and returns the result as a string. For details, see [Section 11.4, “String Functions”](#).

- `GET_LOCK(str, timeout)`

Tries to obtain a lock with a name given by the string `str`, using a timeout of `timeout` seconds. Returns `1` if the lock was ob-

tained successfully, 0 if the attempt timed out (for example, because another client has previously locked the name), or NULL if an error occurred (such as running out of memory or the thread was killed with `mysqladmin kill`). If you have a lock obtained with `GET_LOCK()`, it is released when you execute `RELEASE_LOCK()`, execute a new `GET_LOCK()`, or your connection terminates (either normally or abnormally). Locks obtained with `GET_LOCK()` do not interact with transactions. That is, committing a transaction does not release any such locks obtained during the transaction.

This function can be used to implement application locks or to simulate record locks. Names are locked on a server-wide basis. If a name has been locked by one client, `GET_LOCK()` blocks any request by another client for a lock with the same name. This allows clients that agree on a given lock name to use the name to perform cooperative advisory locking. But be aware that it also allows a client that is not among the set of cooperating clients to lock a name, either inadvertently or deliberately, and thus prevent any of the cooperating clients from locking that name. One way to reduce the likelihood of this is to use lock names that are database-specific or application-specific. For example, use lock names of the form `db_name.str` or `app_name.str`.

```
mysql> SELECT GET_LOCK('lock1',10);
-> 1
mysql> SELECT IS_FREE_LOCK('lock2');
-> 1
mysql> SELECT GET_LOCK('lock2',10);
-> 1
mysql> SELECT RELEASE_LOCK('lock2');
-> 1
mysql> SELECT RELEASE_LOCK('lock1');
-> NULL
```

The second `RELEASE_LOCK()` call returns NULL because the lock 'lock1' was automatically released by the second `GET_LOCK()` call.

If multiple clients are waiting for a lock, the order in which they will acquire it is undefined and depends on factors such as the thread library in use. In particular, applications should not assume that clients will acquire the lock in the same order that they issued the lock requests.

Note

If a client attempts to acquire a lock that is already held by another client, it blocks according to the `timeout` argument. If the blocked client terminates, its thread does not die until the lock request times out. This is a known bug (fixed in MySQL 6.0).

- `INET_ATON(expr)`

Given the dotted-quad representation of a network address as a string, returns an integer that represents the numeric value of the address. Addresses may be 4- or 8-byte addresses.

```
mysql> SELECT INET_ATON('209.207.224.40');
-> 3520061480
```

The generated number is always in network byte order. For the example just shown, the number is calculated as $209 \times 256^3 + 207 \times 256^2 + 224 \times 256 + 40$.

`INET_ATON()` also understands short-form IP addresses:

```
mysql> SELECT INET_ATON('127.0.0.1'), INET_ATON('127.1');
-> 2130706433, 2130706433
```

Note

When storing values generated by `INET_ATON()`, it is recommended that you use an `INT UNSIGNED` column. If you use a (signed) `INT` column, values corresponding to IP addresses for which the first octet is greater than 127 cannot be stored correctly. See [Section 10.2, “Numeric Types”](#).

- `INET_NTOA(expr)`

Given a numeric network address in network byte order (4 or 8 byte), returns the dotted-quad representation of the address as a string.

```
mysql> SELECT INET_NTOA(3520061480);
-> '209.207.224.40'
```

- `IS_FREE_LOCK(str)`

Checks whether the lock named `str` is free to use (that is, not locked). Returns 1 if the lock is free (no one is using the lock), 0 if the lock is in use, and NULL if an error occurs (such as an incorrect argument).

- `IS_USED_LOCK(str)`

Checks whether the lock named *str* is in use (that is, locked). If so, it returns the connection identifier of the client that holds the lock. Otherwise, it returns `NULL`.

- `MASTER_POS_WAIT(log_name, log_pos[, timeout])`

This function is useful for control of master/slave synchronization. It blocks until the slave has read and applied all updates up to the specified position in the master log. The return value is the number of log events the slave had to wait for to advance to the specified position. The function returns `NULL` if the slave SQL thread is not started, the slave's master information is not initialized, the arguments are incorrect, or an error occurs. It returns `-1` if the timeout has been exceeded. If the slave SQL thread stops while `MASTER_POS_WAIT()` is waiting, the function returns `NULL`. If the slave is past the specified position, the function returns immediately.

If a *timeout* value is specified, `MASTER_POS_WAIT()` stops waiting when *timeout* seconds have elapsed. *timeout* must be greater than 0; a zero or negative *timeout* means no timeout.

- `NAME_CONST(name, value)`

Returns the given value. When used to produce a result set column, `NAME_CONST()` causes the column to have the given name. The arguments should be constants.

```
mysql> SELECT NAME_CONST('myname', 14);
+-----+
| myname |
+-----+
|      14 |
+-----+
```

This function was added in MySQL 5.0.12. It is for internal use only. The server uses it when writing statements from stored programs that contain references to local program variables, as described in [Section 18.6, “Binary Logging of Stored Programs”](#). You might see this function in the output from `mysqlbinlog`.

- `RELEASE_LOCK(str)`

Releases the lock named by the string *str* that was obtained with `GET_LOCK()`. Returns `1` if the lock was released, `0` if the lock was not established by this thread (in which case the lock is not released), and `NULL` if the named lock did not exist. The lock does not exist if it was never obtained by a call to `GET_LOCK()` or if it has previously been released.

The `DO` statement is convenient to use with `RELEASE_LOCK()`. See [Section 12.2.3, “DO Syntax”](#).

- `SLEEP(duration)`

Sleeps (pauses) for the number of seconds given by the *duration* argument, then returns 0. If `SLEEP()` is interrupted, it returns 1. The duration may have a fractional part given in microseconds.

- `UUID()`

Returns a Universal Unique Identifier (UUID) generated according to “DCE 1.1: Remote Procedure Call” (Appendix A) CAE (Common Applications Environment) Specifications published by The Open Group in October 1997 (Document Number C706, <http://www.opengroup.org/public/pubs/catalog/c706.htm>).

A UUID is designed as a number that is globally unique in space and time. Two calls to `UUID()` are expected to generate two different values, even if these calls are performed on two separate computers that are not connected to each other.

A UUID is a 128-bit number represented by a `utf8` string of five hexadecimal numbers in `aaaaaaa-bbbb-cccc-dddd-eeeeeeeeeeee` format:

- The first three numbers are generated from a timestamp.
- The fourth number preserves temporal uniqueness in case the timestamp value loses monotonicity (for example, due to daylight saving time).
- The fifth number is an IEEE 802 node number that provides spatial uniqueness. A random number is substituted if the latter is not available (for example, because the host computer has no Ethernet card, or we do not know how to find the hardware address of an interface on your operating system). In this case, spatial uniqueness cannot be guaranteed. Nevertheless, a collision should have *very* low probability.

Currently, the MAC address of an interface is taken into account only on FreeBSD and Linux. On other operating systems, MySQL uses a randomly generated 48-bit number.

```
mysql> SELECT UUID();
-> '6ccd780c-baba-1026-9564-0040f4311e29'
```

Warning

The `UUID()` function returns a string using the character set defined by the `character_set_server` parameter. If you are using UUID values in your tables and these columns are indexed the character set of your column or table should match the character set used when the `UUID()` was called. If you do not use the same character set for the column and the UUID value, then the indexes on those columns will not be used, which may lead to a reduction in performance and locked tables during operations as the table is searched sequentially for the value.

You can convert between different character sets when using UUID-based strings using the `CONVERT()` function.

Note

`UUID()` does not work with statement-based replication.

- `UUID_SHORT()`

Returns a “short” universal identifier as a 64-bit unsigned integer (rather than a string-form 128-bit identifier as returned by the `UUID()` function).

The value of `UUID_SHORT()` is guaranteed to be unique if the following conditions hold:

- The `server_id` of the current host is unique among your set of master and slave servers
- `server_id` is between 0 and 255
- You don't set back your system time for your server between `mysqld` restarts
- You do not invoke `UUID_SHORT()` on average more than 16 million times per second between `mysqld` restarts

The `UUID_SHORT()` return value is constructed this way:

```
(server_id & 255) << 56
+ (server_startup_time_in_seconds << 24)
+ incremented_variable++;
```

```
mysql> SELECT UUID_SHORT();
-> 92395783831158784
```

Note that `UUID_SHORT()` does not work with statement-based replication.

- `VALUES(col_name)`

In an `INSERT ... ON DUPLICATE KEY UPDATE` statement, you can use the `VALUES(col_name)` function in the `UPDATE` clause to refer to column values from the `INSERT` portion of the statement. In other words, `VALUES(col_name)` in the `UPDATE` clause refers to the value of `col_name` that would be inserted, had no duplicate-key conflict occurred. This function is especially useful in multiple-row inserts. The `VALUES()` function is meaningful only in `INSERT ... ON DUPLICATE KEY UPDATE` statements and returns `NULL` otherwise. [Section 12.2.5.3, “INSERT ... ON DUPLICATE KEY UPDATE Syntax”](#).

```
mysql> INSERT INTO table (a,b,c) VALUES (1,2,3),(4,5,6)
-> ON DUPLICATE KEY UPDATE c=VALUES(a)+VALUES(b);
```

11.12. Functions and Modifiers for Use with **GROUP BY** Clauses

11.12.1. **GROUP BY** (Aggregate) Functions

Name	Description
<code>AVG()</code>	Return the average value of the argument
<code>BIT_AND()</code>	Return bitwise and
<code>BIT_OR()</code>	Return bitwise or
<code>BIT_XOR()</code> (v4.1.1)	Return bitwise xor
<code>COUNT(DISTINCT)</code>	Return the count of a number of different values
<code>COUNT()</code>	Return a count of the number of rows returned

Name	Description
<code>GROUP_CONCAT()</code> (v4.1)	Return a concatenated string
<code>MAX()</code>	Return the maximum value
<code>MIN()</code>	Return the minimum value
<code>STD()</code>	Return the population standard deviation
<code>STDDEV_POP()</code> (v5.0.3)	Return the population standard deviation
<code>STDDEV_SAMP()</code> (v5.0.3)	Return the sample standard deviation
<code>STDDEV()</code>	Return the population standard deviation
<code>SUM()</code>	Return the sum
<code>VAR_POP()</code> (v5.0.3)	Return the population standard variance
<code>VAR_SAMP()</code> (v5.0.3)	Return the sample variance
<code>VARIANCE()</code> (v4.1)	Return the population standard variance

This section describes group (aggregate) functions that operate on sets of values. Unless otherwise stated, group functions ignore `NULL` values.

If you use a group function in a statement containing no `GROUP BY` clause, it is equivalent to grouping on all rows.

For numeric arguments, the variance and standard deviation functions return a `DOUBLE` value. The `SUM()` and `AVG()` functions return a `DECIMAL` value for exact-value arguments (integer or `DECIMAL`), and a `DOUBLE` value for approximate-value arguments (`FLOAT` or `DOUBLE`).

The `SUM()` and `AVG()` aggregate functions do not work with temporal values. (They convert the values to numbers, losing everything after the first non-numeric character.) To work around this problem, you can convert to numeric units, perform the aggregate operation, and convert back to a temporal value. Examples:

```
SELECT SEC_TO_TIME(SUM(TIME_TO_SEC(time_col))) FROM tbl_name;  
SELECT FROM_DAYS(SUM(TO_DAYS(date_col))) FROM tbl_name;
```

Functions such as `SUM()` or `AVG()` that expect a numeric argument cast the argument to a number if necessary. For `SET` or `ENUM` values, the cast operation causes the underlying numeric value to be used.

- `AVG([DISTINCT] expr)`

Returns the average value of *expr*. The `DISTINCT` option can be used to return the average of the distinct values of *expr*.

`AVG()` returns `NULL` if there were no matching rows.

```
mysql> SELECT student_name, AVG(test_score)  
-> FROM student  
-> GROUP BY student_name;
```

- `BIT_AND(expr)`

Returns the bitwise `AND` of all bits in *expr*. The calculation is performed with 64-bit (`BIGINT`) precision.

This function returns `18446744073709551615` if there were no matching rows. (This is the value of an unsigned `BIGINT` value with all bits set to 1.)

- `BIT_OR(expr)`

Returns the bitwise `OR` of all bits in *expr*. The calculation is performed with 64-bit (`BIGINT`) precision.

This function returns `0` if there were no matching rows.

- `BIT_XOR(expr)`

Returns the bitwise `XOR` of all bits in *expr*. The calculation is performed with 64-bit (`BIGINT`) precision.

This function returns `0` if there were no matching rows.

- `COUNT(expr)`

Returns a count of the number of non-`NULL` values of *expr* in the rows retrieved by a `SELECT` statement. The result is a `BI-`

GINT value.

COUNT () returns 0 if there were no matching rows.

```
mysql> SELECT student.student_name,COUNT(*)
-> FROM student,course
-> WHERE student.student_id=course.student_id
-> GROUP BY student_name;
```

COUNT (*) is somewhat different in that it returns a count of the number of rows retrieved, whether or not they contain NULL values.

COUNT (*) is optimized to return very quickly if the SELECT retrieves from one table, no other columns are retrieved, and there is no WHERE clause. For example:

```
mysql> SELECT COUNT(*) FROM student;
```

This optimization applies only to MyISAM tables only, because an exact row count is stored for this storage engine and can be accessed very quickly. For transactional storage engines such as InnoDB, storing an exact row count is more problematic because multiple transactions may be occurring, each of which may affect the count.

- COUNT(DISTINCT expr,[expr...])

Returns a count of the number of different non-NULL values.

COUNT(DISTINCT) returns 0 if there were no matching rows.

```
mysql> SELECT COUNT(DISTINCT results) FROM student;
```

In MySQL, you can obtain the number of distinct expression combinations that do not contain NULL by giving a list of expressions. In standard SQL, you would have to do a concatenation of all expressions inside COUNT(DISTINCT ...).

- GROUP_CONCAT(expr)

This function returns a string result with the concatenated non-NULL values from a group. It returns NULL if there are no non-NULL values. The full syntax is as follows:

```
GROUP_CONCAT([DISTINCT] expr [,expr ...]
             [ORDER BY {unsigned_integer | col_name | expr}
              [ASC | DESC] [,col_name ...]]
             [SEPARATOR str_val])
```

```
mysql> SELECT student_name,
-> GROUP_CONCAT(test_score)
-> FROM student
-> GROUP BY student_name;
```

Or:

```
mysql> SELECT student_name,
-> GROUP_CONCAT(DISTINCT test_score
-> ORDER BY test_score DESC SEPARATOR ' ')
-> FROM student
-> GROUP BY student_name;
```

In MySQL, you can get the concatenated values of expression combinations. You can eliminate duplicate values by using DISTINCT. If you want to sort values in the result, you should use ORDER BY clause. To sort in reverse order, add the DESC (descending) keyword to the name of the column you are sorting by in the ORDER BY clause. The default is ascending order; this may be specified explicitly using the ASC keyword. SEPARATOR is followed by the string value that should be inserted between values of result. The default is a comma (“,”). You can eliminate the separator altogether by specifying SEPARATOR ‘’.

The result is truncated to the maximum length that is given by the group_concat_max_len system variable, which has a default value of 1024. The value can be set higher, although the effective maximum length of the return value is constrained by the value of max_allowed_packet. The syntax to change the value of group_concat_max_len at runtime is as follows, where val is an unsigned integer:

```
SET [GLOBAL | SESSION] group_concat_max_len = val;
```

See also CONCAT () and CONCAT_WS (): Section 11.4, “String Functions”.

- `MAX([DISTINCT] expr)`

Returns the maximum value of *expr*. `MAX()` may take a string argument; in such cases, it returns the maximum string value. See [Section 7.4.4, “How MySQL Uses Indexes”](#). The `DISTINCT` keyword can be used to find the maximum of the distinct values of *expr*, however, this produces the same result as omitting `DISTINCT`.

`MAX()` returns `NULL` if there were no matching rows.

```
mysql> SELECT student_name, MIN(test_score), MAX(test_score)
-> FROM student
-> GROUP BY student_name;
```

For `MAX()`, MySQL currently compares `ENUM` and `SET` columns by their string value rather than by the string's relative position in the set. This differs from how `ORDER BY` compares them. This is expected to be rectified in a future MySQL release.

- `MIN([DISTINCT] expr)`

Returns the minimum value of *expr*. `MIN()` may take a string argument; in such cases, it returns the minimum string value. See [Section 7.4.4, “How MySQL Uses Indexes”](#). The `DISTINCT` keyword can be used to find the minimum of the distinct values of *expr*, however, this produces the same result as omitting `DISTINCT`.

`MIN()` returns `NULL` if there were no matching rows.

```
mysql> SELECT student_name, MIN(test_score), MAX(test_score)
-> FROM student
-> GROUP BY student_name;
```

For `MIN()`, MySQL currently compares `ENUM` and `SET` columns by their string value rather than by the string's relative position in the set. This differs from how `ORDER BY` compares them. This is expected to be rectified in a future MySQL release.

- `STD(expr)`

Returns the population standard deviation of *expr*. This is an extension to standard SQL. The standard SQL function `STDDEV_POP()` can be used instead.

This function returns `NULL` if there were no matching rows.

- `STDDEV(expr)`

Returns the population standard deviation of *expr*. This function is provided for compatibility with Oracle. The standard SQL function `STDDEV_POP()` can be used instead.

This function returns `NULL` if there were no matching rows.

- `STDDEV_POP(expr)`

Returns the population standard deviation of *expr* (the square root of `VAR_POP()`). You can also use `STD()` or `STDDEV()`, which are equivalent but not standard SQL.

`STDDEV_POP()` returns `NULL` if there were no matching rows.

- `STDDEV_SAMP(expr)`

Returns the sample standard deviation of *expr* (the square root of `VAR_SAMP()`).

`STDDEV_SAMP()` returns `NULL` if there were no matching rows.

- `SUM([DISTINCT] expr)`

Returns the sum of *expr*. If the return set has no rows, `SUM()` returns `NULL`. The `DISTINCT` keyword can be used in MySQL 5.4 to sum only the distinct values of *expr*.

`SUM()` returns `NULL` if there were no matching rows.

- `VAR_POP(expr)`

Returns the population standard variance of *expr*. It considers rows as the whole population, not as a sample, so it has the number of rows as the denominator. You can also use `VARIANCE()`, which is equivalent but is not standard SQL.

`VAR_POP()` returns `NULL` if there were no matching rows.

- `VAR_SAMP(expr)`

Returns the sample variance of *expr*. That is, the denominator is the number of rows minus one.

`VAR_SAMP ()` returns `NULL` if there were no matching rows.

- `VARIANCE (expr)`

Returns the population standard variance of *expr*. This is an extension to standard SQL. The standard SQL function `VAR_POP ()` can be used instead.

`VARIANCE ()` returns `NULL` if there were no matching rows.

11.12.2. GROUP BY Modifiers

The `GROUP BY` clause allows a `WITH ROLLUP` modifier that causes extra rows to be added to the summary output. These rows represent higher-level (or super-aggregate) summary operations. `ROLLUP` thus allows you to answer questions at multiple levels of analysis with a single query. It can be used, for example, to provide support for OLAP (Online Analytical Processing) operations.

Suppose that a table named `sales` has `year`, `country`, `product`, and `profit` columns for recording sales profitability:

```
CREATE TABLE sales
(
  year      INT NOT NULL,
  country   VARCHAR(20) NOT NULL,
  product   VARCHAR(32) NOT NULL,
  profit    INT
);
```

The table's contents can be summarized per year with a simple `GROUP BY` like this:

```
mysql> SELECT year, SUM(profit) FROM sales GROUP BY year;
+-----+-----+
| year | SUM(profit) |
+-----+-----+
| 2000 |          4525 |
| 2001 |          3010 |
+-----+-----+
```

This output shows the total profit for each year, but if you also want to determine the total profit summed over all years, you must add up the individual values yourself or run an additional query.

Or you can use `ROLLUP`, which provides both levels of analysis with a single query. Adding a `WITH ROLLUP` modifier to the `GROUP BY` clause causes the query to produce another row that shows the grand total over all year values:

```
mysql> SELECT year, SUM(profit) FROM sales GROUP BY year WITH ROLLUP;
+-----+-----+
| year | SUM(profit) |
+-----+-----+
| 2000 |          4525 |
| 2001 |          3010 |
| NULL |          7535 |
+-----+-----+
```

The grand total super-aggregate line is identified by the value `NULL` in the `year` column.

`ROLLUP` has a more complex effect when there are multiple `GROUP BY` columns. In this case, each time there is a “break” (change in value) in any but the last grouping column, the query produces an extra super-aggregate summary row.

For example, without `ROLLUP`, a summary on the `sales` table based on `year`, `country`, and `product` might look like this:

```
mysql> SELECT year, country, product, SUM(profit)
-> FROM sales
-> GROUP BY year, country, product;
+-----+-----+-----+-----+
| year | country | product | SUM(profit) |
+-----+-----+-----+-----+
| 2000 | Finland | Computer |          1500 |
| 2000 | Finland | Phone   |           100 |
| 2000 | India   | Calculator |           150 |
| 2000 | India   | Computer |          1200 |
| 2000 | USA     | Calculator |            75 |
| 2000 | USA     | Computer |          1500 |
| 2001 | Finland | Phone   |            10 |
| 2001 | USA     | Calculator |            50 |
| 2001 | USA     | Computer |          2700 |
| 2001 | USA     | TV       |            250 |
+-----+-----+-----+-----+
```

The output indicates summary values only at the year/country/product level of analysis. When `ROLLUP` is added, the query produces several extra rows:

```
mysql> SELECT year, country, product, SUM(profit)
-> FROM sales
-> GROUP BY year, country, product WITH ROLLUP;
```

year	country	product	SUM(profit)
2000	Finland	Computer	1500
2000	Finland	Phone	100
2000	Finland	NULL	1600
2000	India	Calculator	150
2000	India	Computer	1200
2000	India	NULL	1350
2000	USA	Calculator	75
2000	USA	Computer	1500
2000	USA	NULL	1575
2000	NULL	NULL	4525
2001	Finland	Phone	10
2001	Finland	NULL	10
2001	USA	Calculator	50
2001	USA	Computer	2700
2001	USA	TV	250
2001	USA	NULL	3000
2001	NULL	NULL	3010
NULL	NULL	NULL	7535

For this query, adding `ROLLUP` causes the output to include summary information at four levels of analysis, not just one. Here is how to interpret the `ROLLUP` output:

- Following each set of product rows for a given year and country, an extra summary row is produced showing the total for all products. These rows have the `product` column set to `NULL`.
- Following each set of rows for a given year, an extra summary row is produced showing the total for all countries and products. These rows have the `country` and `products` columns set to `NULL`.
- Finally, following all other rows, an extra summary row is produced showing the grand total for all years, countries, and products. This row has the `year`, `country`, and `products` columns set to `NULL`.

Other Considerations When using `ROLLUP`

The following items list some behaviors specific to the MySQL implementation of `ROLLUP`:

When you use `ROLLUP`, you cannot also use an `ORDER BY` clause to sort the results. In other words, `ROLLUP` and `ORDER BY` are mutually exclusive. However, you still have some control over sort order. `GROUP BY` in MySQL sorts results, and you can use explicit `ASC` and `DESC` keywords with columns named in the `GROUP BY` list to specify sort order for individual columns. (The higher-level summary rows added by `ROLLUP` still appear after the rows from which they are calculated, regardless of the sort order.)

`LIMIT` can be used to restrict the number of rows returned to the client. `LIMIT` is applied after `ROLLUP`, so the limit applies against the extra rows added by `ROLLUP`. For example:

```
mysql> SELECT year, country, product, SUM(profit)
-> FROM sales
-> GROUP BY year, country, product WITH ROLLUP
-> LIMIT 5;
```

year	country	product	SUM(profit)
2000	Finland	Computer	1500
2000	Finland	Phone	100
2000	Finland	NULL	1600
2000	India	Calculator	150
2000	India	Computer	1200

Using `LIMIT` with `ROLLUP` may produce results that are more difficult to interpret, because you have less context for understanding the super-aggregate rows.

The `NULL` indicators in each super-aggregate row are produced when the row is sent to the client. The server looks at the columns named in the `GROUP BY` clause following the leftmost one that has changed value. For any column in the result set with a name that is a lexical match to any of those names, its value is set to `NULL`. (If you specify grouping columns by column number, the server identifies which columns to set to `NULL` by number.)

Because the `NULL` values in the super-aggregate rows are placed into the result set at such a late stage in query processing, you cannot test them as `NULL` values within the query itself. For example, you cannot add `HAVING product IS NULL` to the query to eliminate from the output all but the super-aggregate rows.

On the other hand, the `NULL` values do appear as `NULL` on the client side and can be tested as such using any MySQL client programming interface.

11.12.3. GROUP BY and HAVING with Hidden Columns

MySQL extends the use of `GROUP BY` so that you can use non-aggregated columns or calculations in the `SELECT` list that do not appear in the `GROUP BY` clause. You can use this feature to get better performance by avoiding unnecessary column sorting and grouping. For example, you do not need to group on `customer.name` in the following query:

```
SELECT order.custid, customer.name, MAX(payments)
FROM order, customer
WHERE order.custid = customer.custid
GROUP BY order.custid;
```

In standard SQL, you would have to add `customer.name` to the `GROUP BY` clause. In MySQL, the name is redundant.

Do *not* use this feature if the columns you omit from the `GROUP BY` part are not constant in the group. The server is free to return any value from the group, so the results are indeterminate unless all values are the same.

A similar MySQL extension applies to the `HAVING` clause. The SQL standard does not allow the `HAVING` clause to name any column that is not found in the `GROUP BY` clause if it is not enclosed in an aggregate function. MySQL allows the use of such columns to simplify calculations. This extension assumes that the non-grouped columns will have the same group-wise values. Otherwise, the result is indeterminate.

If the `ONLY_FULL_GROUP_BY` SQL mode is enabled, the MySQL extension to `GROUP BY` does not apply. That is, columns not named in the `GROUP BY` clause cannot be used in the `SELECT` list or `HAVING` clause if not used in an aggregate function.

The select list extension also applies to `ORDER BY`. That is, you can use non-aggregated columns or calculations in the `ORDER BY` clause that do not appear in the `GROUP BY` clause. This extension does not apply if the `ONLY_FULL_GROUP_BY` SQL mode is enabled.

In some cases, you can use `MIN()` and `MAX()` to obtain a specific column value even if it isn't unique. The following gives the value of `column` from the row containing the smallest value in the `sort` column:

```
SUBSTR(MIN(CONCAT(RPAD(sort,6,' '),column)),7)
```

See [Section 3.6.4, “The Rows Holding the Group-wise Maximum of a Certain Field”](#).

Note that if you are trying to follow standard SQL, you can't use expressions in `GROUP BY` clauses. You can work around this limitation by using an alias for the expression:

```
SELECT id, FLOOR(value/100) AS val
FROM tbl_name
GROUP BY id, val;
```

MySQL does allow expressions in `GROUP BY` clauses. For example:

```
SELECT id, FLOOR(value/100)
FROM tbl_name
GROUP BY id, FLOOR(value/100);
```

11.13. Spatial Extensions

MySQL supports spatial extensions to allow the generation, storage, and analysis of geographic features. These features are available for `MyISAM`, `InnoDB`, `NDB`, and `ARCHIVE` tables.

For spatial columns, `MyISAM` supports both `SPATIAL` and non-`SPATIAL` indexes. Other storage engines support non-`SPATIAL` indexes, as described in [Section 12.1.11, “CREATE INDEX Syntax”](#).

This chapter covers the following topics:

- The basis of these spatial extensions in the OpenGIS geometry model
- Data formats for representing spatial data
- How to use spatial data in MySQL
- Use of indexing for spatial data

- MySQL differences from the OpenGIS specification

Additional resources

- The Open Geospatial Consortium publishes the *OpenGIS® Simple Features Specifications For SQL*, a document that proposes several conceptual ways for extending an SQL RDBMS to support spatial data. This specification is available from the OGC Web site at <http://www.opengis.org/docs/99-049.pdf>.
- If you have questions or concerns about the use of the spatial extensions to MySQL, you can discuss them in the GIS forum: <http://forums.mysql.com/list.php?23>.

11.13.1. Introduction to MySQL Spatial Support

MySQL implements spatial extensions following the specification of the Open Geospatial Consortium (OGC). This is an international consortium of more than 250 companies, agencies, and universities participating in the development of publicly available conceptual solutions that can be useful with all kinds of applications that manage spatial data. The OGC maintains a Web site at <http://www.opengis.org/>.

In 1997, the Open Geospatial Consortium published the *OpenGIS® Simple Features Specifications For SQL*, a document that proposes several conceptual ways for extending an SQL RDBMS to support spatial data. This specification is available from the OGC Web site at <http://www.opengis.org/docs/99-049.pdf>. It contains additional information relevant to this chapter.

MySQL implements a subset of the **SQL with Geometry Types** environment proposed by OGC. This term refers to an SQL environment that has been extended with a set of geometry types. A geometry-valued SQL column is implemented as a column that has a geometry type. The specification describe a set of SQL geometry types, as well as functions on those types to create and analyze geometry values.

A **geographic feature** is anything in the world that has a location. A feature can be:

- An entity. For example, a mountain, a pond, a city.
- A space. For example, town district, the tropics.
- A definable location. For example, a crossroad, as a particular place where two streets intersect.

Some documents use the term **geospatial feature** to refer to geographic features.

Geometry is another word that denotes a geographic feature. Originally the word **geometry** meant measurement of the earth. Another meaning comes from cartography, referring to the geometric features that cartographers use to map the world.

This chapter uses all of these terms synonymously: **geographic feature**, **geospatial feature**, **feature**, or **geometry**. Here, the term most commonly used is **geometry**, defined as *a point or an aggregate of points representing anything in the world that has a location*.

11.13.2. The OpenGIS Geometry Model

The set of geometry types proposed by OGC's **SQL with Geometry Types** environment is based on the **OpenGIS Geometry Model**. In this model, each geometric object has the following general properties:

- It is associated with a Spatial Reference System, which describes the coordinate space in which the object is defined.
- It belongs to some geometry class.

11.13.2.1. The Geometry Class Hierarchy

The geometry classes define a hierarchy as follows:

- **Geometry** (non-instantiable)
 - **Point** (instantiable)
 - **Curve** (non-instantiable)

- `LineString` (instantiable)
 - `Line`
 - `LinearRing`
- `Surface` (non-instantiable)
 - `Polygon` (instantiable)
- `GeometryCollection` (instantiable)
 - `MultiPoint` (instantiable)
 - `MultiCurve` (non-instantiable)
 - `MultiLineString` (instantiable)
 - `MultiSurface` (non-instantiable)
 - `MultiPolygon` (instantiable)

It is not possible to create objects in non-instantiable classes. It is possible to create objects in instantiable classes. All classes have properties, and instantiable classes may also have assertions (rules that define valid class instances).

`Geometry` is the base class. It is an abstract class. The instantiable subclasses of `Geometry` are restricted to zero-, one-, and two-dimensional geometric objects that exist in two-dimensional coordinate space. All instantiable geometry classes are defined so that valid instances of a geometry class are topologically closed (that is, all defined geometries include their boundary).

The base `Geometry` class has subclasses for `Point`, `Curve`, `Surface`, and `GeometryCollection`:

- `Point` represents zero-dimensional objects.
- `Curve` represents one-dimensional objects, and has subclass `LineString`, with sub-subclasses `Line` and `LinearRing`.
- `Surface` is designed for two-dimensional objects and has subclass `Polygon`.
- `GeometryCollection` has specialized zero-, one-, and two-dimensional collection classes named `MultiPoint`, `MultiLineString`, and `MultiPolygon` for modeling geometries corresponding to collections of `Points`, `LineStrings`, and `Polygons`, respectively. `MultiCurve` and `MultiSurface` are introduced as abstract superclasses that generalize the collection interfaces to handle `Curves` and `Surfaces`.

`Geometry`, `Curve`, `Surface`, `MultiCurve`, and `MultiSurface` are defined as non-instantiable classes. They define a common set of methods for their subclasses and are included for extensibility.

`Point`, `LineString`, `Polygon`, `GeometryCollection`, `MultiPoint`, `MultiLineString`, and `MultiPolygon` are instantiable classes.

11.13.2.2. Class `Geometry`

`Geometry` is the root class of the hierarchy. It is a non-instantiable class but has a number of properties that are common to all geometry values created from any of the `Geometry` subclasses. These properties are described in the following list. Particular subclasses have their own specific properties, described later.

Geometry Properties

A geometry value has the following properties:

- Its **type**. Each geometry belongs to one of the instantiable classes in the hierarchy.
- Its **SRID**, or Spatial Reference Identifier. This value identifies the geometry's associated Spatial Reference System that describes the coordinate space in which the geometry object is defined.

In MySQL, the SRID value is just an integer associated with the geometry value. All calculations are done assuming Euclidean (planar) geometry.

- Its **coordinates** in its Spatial Reference System, represented as double-precision (eight-byte) numbers. All non-empty geometries include at least one pair of (X,Y) coordinates. Empty geometries contain no coordinates.

Coordinates are related to the SRID. For example, in different coordinate systems, the distance between two objects may differ even when objects have the same coordinates, because the distance on the **planar** coordinate system and the distance on the **geocentric** system (coordinates on the Earth's surface) are different things.

- Its **interior, boundary, and exterior**.

Every geometry occupies some position in space. The exterior of a geometry is all space not occupied by the geometry. The interior is the space occupied by the geometry. The boundary is the interface between the geometry's interior and exterior.

- Its **MBR** (Minimum Bounding Rectangle), or Envelope. This is the bounding geometry, formed by the minimum and maximum (X,Y) coordinates:

```
((MINX MINY, MAXX MINY, MAXX MAXY, MINX MAXY, MINX MINY))
```

- Whether the value is **simple** or **non-simple**. Geometry values of types (`LineString`, `MultiPoint`, `MultiLineString`) are either simple or non-simple. Each type determines its own assertions for being simple or non-simple.
- Whether the value is **closed** or **not closed**. Geometry values of types (`LineString`, `MultiString`) are either closed or not closed. Each type determines its own assertions for being closed or not closed.
- Whether the value is **empty** or **non-empty**. A geometry is empty if it does not have any points. Exterior, interior, and boundary of an empty geometry are not defined (that is, they are represented by a `NULL` value). An empty geometry is defined to be always simple and has an area of 0.
- Its **dimension**. A geometry can have a dimension of -1, 0, 1, or 2:
 - -1 for an empty geometry.
 - 0 for a geometry with no length and no area.
 - 1 for a geometry with nonzero length and zero area.
 - 2 for a geometry with nonzero area.

`Point` objects have a dimension of zero. `LineString` objects have a dimension of 1. `Polygon` objects have a dimension of 2. The dimensions of `MultiPoint`, `MultiLineString`, and `MultiPolygon` objects are the same as the dimensions of the elements they consist of.

11.13.2.3. Class `Point`

A `Point` is a geometry that represents a single location in coordinate space.

`Point` Examples

- Imagine a large-scale map of the world with many cities. A `Point` object could represent each city.
- On a city map, a `Point` object could represent a bus stop.

`Point` Properties

- X-coordinate value.
- Y-coordinate value.
- `Point` is defined as a zero-dimensional geometry.
- The boundary of a `Point` is the empty set.

11.13.2.4. Class `Curve`

A `Curve` is a one-dimensional geometry, usually represented by a sequence of points. Particular subclasses of `Curve` define the type of interpolation between points. `Curve` is a non-instantiable class.

Curve Properties

- A `Curve` has the coordinates of its points.
- A `Curve` is defined as a one-dimensional geometry.
- A `Curve` is simple if it does not pass through the same point twice.
- A `Curve` is closed if its start point is equal to its endpoint.
- The boundary of a closed `Curve` is empty.
- The boundary of a non-closed `Curve` consists of its two endpoints.
- A `Curve` that is simple and closed is a `LinearRing`.

11.13.2.5. Class `LineString`

A `LineString` is a `Curve` with linear interpolation between points.

`LineString` Examples

- On a world map, `LineString` objects could represent rivers.
- In a city map, `LineString` objects could represent streets.

`LineString` Properties

- A `LineString` has coordinates of segments, defined by each consecutive pair of points.
- A `LineString` is a `Line` if it consists of exactly two points.
- A `LineString` is a `LinearRing` if it is both closed and simple.

11.13.2.6. Class `Surface`

A `Surface` is a two-dimensional geometry. It is a non-instantiable class. Its only instantiable subclass is `Polygon`.

`Surface` Properties

- A `Surface` is defined as a two-dimensional geometry.
- The OpenGIS specification defines a simple `Surface` as a geometry that consists of a single “patch” that is associated with a single exterior boundary and zero or more interior boundaries.
- The boundary of a simple `Surface` is the set of closed curves corresponding to its exterior and interior boundaries.

11.13.2.7. Class `Polygon`

A `Polygon` is a planar `Surface` representing a multisided geometry. It is defined by a single exterior boundary and zero or more interior boundaries, where each interior boundary defines a hole in the `Polygon`.

`Polygon` Examples

- On a region map, `Polygon` objects could represent forests, districts, and so on.

`Polygon` Assertions

- The boundary of a `Polygon` consists of a set of `LinearRing` objects (that is, `LineString` objects that are both simple and closed) that make up its exterior and interior boundaries.

- A `Polygon` has no rings that cross. The rings in the boundary of a `Polygon` may intersect at a `Point`, but only as a tangent.
- A `Polygon` has no lines, spikes, or punctures.
- A `Polygon` has an interior that is a connected point set.
- A `Polygon` may have holes. The exterior of a `Polygon` with holes is not connected. Each hole defines a connected component of the exterior.

The preceding assertions make a `Polygon` a simple geometry.

11.13.2.8. Class `GeometryCollection`

A `GeometryCollection` is a geometry that is a collection of one or more geometries of any class.

All the elements in a `GeometryCollection` must be in the same Spatial Reference System (that is, in the same coordinate system). There are no other constraints on the elements of a `GeometryCollection`, although the subclasses of `GeometryCollection` described in the following sections may restrict membership. Restrictions may be based on:

- Element type (for example, a `MultiPoint` may contain only `Point` elements)
- Dimension
- Constraints on the degree of spatial overlap between elements

11.13.2.9. Class `MultiPoint`

A `MultiPoint` is a geometry collection composed of `Point` elements. The points are not connected or ordered in any way.

`MultiPoint` Examples

- On a world map, a `MultiPoint` could represent a chain of small islands.
- On a city map, a `MultiPoint` could represent the outlets for a ticket office.

`MultiPoint` Properties

- A `MultiPoint` is a zero-dimensional geometry.
- A `MultiPoint` is simple if no two of its `Point` values are equal (have identical coordinate values).
- The boundary of a `MultiPoint` is the empty set.

11.13.2.10. Class `MultiCurve`

A `MultiCurve` is a geometry collection composed of `Curve` elements. `MultiCurve` is a non-instantiable class.

`MultiCurve` Properties

- A `MultiCurve` is a one-dimensional geometry.
- A `MultiCurve` is simple if and only if all of its elements are simple; the only intersections between any two elements occur at points that are on the boundaries of both elements.
- A `MultiCurve` boundary is obtained by applying the “mod 2 union rule” (also known as the “odd-even rule”): A point is in the boundary of a `MultiCurve` if it is in the boundaries of an odd number of `MultiCurve` elements.
- A `MultiCurve` is closed if all of its elements are closed.
- The boundary of a closed `MultiCurve` is always empty.

11.13.2.11. Class `MultiLineString`

A `MultiLineString` is a `MultiCurve` geometry collection composed of `LineString` elements.

`MultiLineString` Examples

- On a region map, a `MultiLineString` could represent a river system or a highway system.

11.13.2.12. Class `MultiSurface`

A `MultiSurface` is a geometry collection composed of surface elements. `MultiSurface` is a non-instantiable class. Its only instantiable subclass is `MultiPolygon`.

`MultiSurface` Assertions

- Two `MultiSurface` surfaces have no interiors that intersect.
- Two `MultiSurface` elements have boundaries that intersect at most at a finite number of points.

11.13.2.13. Class `MultiPolygon`

A `MultiPolygon` is a `MultiSurface` object composed of `Polygon` elements.

`MultiPolygon` Examples

- On a region map, a `MultiPolygon` could represent a system of lakes.

`MultiPolygon` Assertions

- A `MultiPolygon` has no two `Polygon` elements with interiors that intersect.
- A `MultiPolygon` has no two `Polygon` elements that cross (crossing is also forbidden by the previous assertion), or that touch at an infinite number of points.
- A `MultiPolygon` may not have cut lines, spikes, or punctures. A `MultiPolygon` is a regular, closed point set.
- A `MultiPolygon` that has more than one `Polygon` has an interior that is not connected. The number of connected components of the interior of a `MultiPolygon` is equal to the number of `Polygon` values in the `MultiPolygon`.

`MultiPolygon` Properties

- A `MultiPolygon` is a two-dimensional geometry.
- A `MultiPolygon` boundary is a set of closed curves (`LineString` values) corresponding to the boundaries of its `Polygon` elements.
- Each `Curve` in the boundary of the `MultiPolygon` is in the boundary of exactly one `Polygon` element.
- Every `Curve` in the boundary of an `Polygon` element is in the boundary of the `MultiPolygon`.

11.13.3. Supported Spatial Data Formats

This section describes the standard spatial data formats that are used to represent geometry objects in queries. They are:

- Well-Known Text (WKT) format
- Well-Known Binary (WKB) format

Internally, MySQL stores geometry values in a format that is not identical to either WKT or WKB format.

11.13.3.1. Well-Known Text (WKT) Format

The Well-Known Text (WKT) representation of Geometry is designed to exchange geometry data in ASCII form.

Examples of WKT representations of geometry objects:

- A `Point`:

```
POINT(15 20)
```

Note that point coordinates are specified with no separating comma.

- A `LineString` with four points:

```
LINSTRING(0 0, 10 10, 20 25, 50 60)
```

Note that point coordinate pairs are separated by commas.

- A `Polygon` with one exterior ring and one interior ring:

```
POLYGON((0 0,10 0,10 10,0 10,0 0),(5 5,7 5,7 7,5 7, 5 5))
```

- A `MultiPoint` with three `Point` values:

```
MULTIPOINT(0 0, 20 20, 60 60)
```

- A `MultiLineString` with two `LineString` values:

```
MULTILINESTRING((10 10, 20 20), (15 15, 30 15))
```

- A `MultiPolygon` with two `Polygon` values:

```
MULTIPOLYGON(((0 0,10 0,10 10,0 10,0 0)),((5 5,7 5,7 7,5 7, 5 5)))
```

- A `GeometryCollection` consisting of two `Point` values and one `LineString`:

```
GEOMETRYCOLLECTION(POINT(10 10), POINT(30 30), LINSTRING(15 15, 20 20))
```

A Backus-Naur grammar that specifies the formal production rules for writing WKT values can be found in the OpenGIS specification document referenced near the beginning of this chapter.

11.13.3.2. Well-Known Binary (WKB) Format

The Well-Known Binary (WKB) representation for geometric values is defined by the OpenGIS specification. It is also defined in the ISO *SQL/MM Part 3: Spatial* standard.

WKB is used to exchange geometry data as binary streams represented by `BLOB` values containing geometric WKB information.

WKB uses one-byte unsigned integers, four-byte unsigned integers, and eight-byte double-precision numbers (IEEE 754 format). A byte is eight bits.

For example, a WKB value that corresponds to `POINT(1 1)` consists of this sequence of 21 bytes (each represented here by two hex digits):

```
010100000000000000000000F03F00000000000000F03F
```

The sequence may be broken down into these components:

```
Byte order : 01
WKB type   : 01000000
X          : 00000000000000F03F
Y          : 00000000000000F03F
```

Component representation is as follows:

- The byte order may be either 1 or 0 to indicate little-endian or big-endian storage. The little-endian and big-endian byte orders are also known as Network Data Representation (NDR) and External Data Representation (XDR), respectively.

- The WKB type is a code that indicates the geometry type. Values from 1 through 7 indicate [Point](#), [LineString](#), [Polygon](#), [MultiPoint](#), [MultiLineString](#), [MultiPolygon](#), and [GeometryCollection](#).
- A [Point](#) value has X and Y coordinates, each represented as a double-precision value.

WKB values for more complex geometry values are represented by more complex data structures, as detailed in the OpenGIS specification.

11.13.4. Creating a Spatially Enabled MySQL Database

This section describes the data types you can use for representing spatial data in MySQL, and the functions available for creating and retrieving spatial values.

11.13.4.1. MySQL Spatial Data Types

MySQL has data types that correspond to OpenGIS classes. Some of these types hold single geometry values:

- [GEOMETRY](#)
- [POINT](#)
- [LINESTRING](#)
- [POLYGON](#)

[GEOMETRY](#) can store geometry values of any type. The other single-value types ([POINT](#), [LINESTRING](#), and [POLYGON](#)) restrict their values to a particular geometry type.

The other data types hold collections of values:

- [MULTIPOINT](#)
- [MULTILINESTRING](#)
- [MULTIPOLYGON](#)
- [GEOMETRYCOLLECTION](#)

[GEOMETRYCOLLECTION](#) can store a collection of objects of any type. The other collection types ([MULTIPOINT](#), [MULTILINESTRING](#), [MULTIPOLYGON](#), and [GEOMETRYCOLLECTION](#)) restrict collection members to those having a particular geometry type.

11.13.4.2. Creating Spatial Values

This section describes how to create spatial values using Well-Known Text and Well-Known Binary functions that are defined in the OpenGIS standard, and using MySQL-specific functions.

11.13.4.2.1. Creating Geometry Values Using WKT Functions

MySQL provides a number of functions that take as input parameters a Well-Known Text representation and, optionally, a spatial reference system identifier (SRID). They return the corresponding geometry.

[GeomFromText\(\)](#) accepts a WKT of any geometry type as its first argument. An implementation also provides type-specific construction functions for construction of geometry values of each geometry type.

- [GeomCollFromText\(wkt\[,srid\]\), GeometryCollectionFromText\(wkt\[,srid\]\)](#)

Constructs a [GEOMETRYCOLLECTION](#) value using its WKT representation and SRID.

- [GeomFromText\(wkt\[,srid\]\), GeometryFromText\(wkt\[,srid\]\)](#)

Constructs a geometry value of any type using its WKT representation and SRID.

- [LineFromText\(wkt\[,srid\]\), LineStringFromText\(wkt\[,srid\]\)](#)

Constructs a `LINestring` value using its WKT representation and SRID.

- `MLineFromText(wkt[,srid]), MultiLineStringFromText(wkt[,srid])`

Constructs a `MULTILINESTRING` value using its WKT representation and SRID.

- `MPointFromText(wkt[,srid]), MultiPointFromText(wkt[,srid])`

Constructs a `MULTIPOINT` value using its WKT representation and SRID.

- `MPolyFromText(wkt[,srid]), MultiPolygonFromText(wkt[,srid])`

Constructs a `MULTIPOLYGON` value using its WKT representation and SRID.

- `PointFromText(wkt[,srid])`

Constructs a `POINT` value using its WKT representation and SRID.

- `PolyFromText(wkt[,srid]), PolygonFromText(wkt[,srid])`

Constructs a `POLYGON` value using its WKT representation and SRID.

The OpenGIS specification also defines the following optional functions, which MySQL does not implement. These functions construct `Polygon` or `MultiPolygon` values based on the WKT representation of a collection of rings or closed `LineString` values. These values may intersect.

- `BdMPolyFromText(wkt,srid)`

Constructs a `MultiPolygon` value from a `MultiLineString` value in WKT format containing an arbitrary collection of closed `LineString` values.

- `BdPolyFromText(wkt,srid)`

Constructs a `Polygon` value from a `MultiLineString` value in WKT format containing an arbitrary collection of closed `LineString` values.

11.13.4.2.2. Creating Geometry Values Using WKB Functions

MySQL provides a number of functions that take as input parameters a `BLOB` containing a Well-Known Binary representation and, optionally, a spatial reference system identifier (SRID). They return the corresponding geometry.

`GeomFromWKB()` accepts a WKB of any geometry type as its first argument. An implementation also provides type-specific construction functions for construction of geometry values of each geometry type.

- `GeomCollFromWKB(wkb[,srid]), GeometryCollectionFromWKB(wkb[,srid])`

Constructs a `GEOMETRYCOLLECTION` value using its WKB representation and SRID.

- `GeomFromWKB(wkb[,srid]), GeometryFromWKB(wkb[,srid])`

Constructs a geometry value of any type using its WKB representation and SRID.

- `LineFromWKB(wkb[,srid]), LineStringFromWKB(wkb[,srid])`

Constructs a `LINestring` value using its WKB representation and SRID.

- `MLineFromWKB(wkb[,srid]), MultiLineStringFromWKB(wkb[,srid])`

Constructs a `MULTILINESTRING` value using its WKB representation and SRID.

- `MPointFromWKB(wkb[,srid]), MultiPointFromWKB(wkb[,srid])`

Constructs a `MULTIPOINT` value using its WKB representation and SRID.

- `MPolyFromWKB(wkb[,srid]), MultiPolygonFromWKB(wkb[,srid])`

Constructs a `MULTIPOLYGON` value using its WKB representation and SRID.

- `PointFromWKB(wkb[,srid])`
Constructs a `POINT` value using its WKB representation and SRID.
- `PolyFromWKB(wkb[,srid]), PolygonFromWKB(wkb[,srid])`
Constructs a `POLYGON` value using its WKB representation and SRID.

The OpenGIS specification also describes optional functions for constructing `Polygon` or `MultiPolygon` values based on the WKB representation of a collection of rings or closed `LineString` values. These values may intersect. MySQL does not implement these functions:

- `BdMPolyFromWKB(wkb,srid)`
Constructs a `MultiPolygon` value from a `MultiLineString` value in WKB format containing an arbitrary collection of closed `LineString` values.
- `BdPolyFromWKB(wkb,srid)`
Constructs a `Polygon` value from a `MultiLineString` value in WKB format containing an arbitrary collection of closed `LineString` values.

11.13.4.2.3. Creating Geometry Values Using MySQL-Specific Functions

MySQL provides a set of useful non-standard functions for creating geometry WKB representations. The functions described in this section are MySQL extensions to the OpenGIS specification. The results of these functions are `BLOB` values containing WKB representations of geometry values with no SRID. The results of these functions can be substituted as the first argument for any function in the `GeomFromWKB()` function family.

- `GeometryCollection(g1,g2,...)`
Constructs a WKB `GeometryCollection`. If any argument is not a well-formed WKB representation of a geometry, the return value is `NULL`.
- `LineString(pt1,pt2,...)`
Constructs a WKB `LineString` value from a number of WKB `Point` arguments. If any argument is not a WKB `Point`, the return value is `NULL`. If the number of `Point` arguments is less than two, the return value is `NULL`.
- `MultiLineString(ls1,ls2,...)`
Constructs a WKB `MultiLineString` value using WKB `LineString` arguments. If any argument is not a WKB `LineString`, the return value is `NULL`.
- `MultiPoint(pt1,pt2,...)`
Constructs a WKB `MultiPoint` value using WKB `Point` arguments. If any argument is not a WKB `Point`, the return value is `NULL`.
- `MultiPolygon(poly1,poly2,...)`
Constructs a WKB `MultiPolygon` value from a set of WKB `Polygon` arguments. If any argument is not a WKB `Polygon`, the return value is `NULL`.
- `Point(x,y)`
Constructs a WKB `Point` using its coordinates.
- `Polygon(ls1,ls2,...)`
Constructs a WKB `Polygon` value from a number of WKB `LineString` arguments. If any argument does not represent the WKB of a `LinearRing` (that is, not a closed and simple `LineString`) the return value is `NULL`.

11.13.4.3. Creating Spatial Columns

MySQL provides a standard way of creating spatial columns for geometry types, for example, with `CREATE TABLE` or `ALTER`

TABLE. Currently, spatial columns are supported for [MyISAM](#), [InnoDB](#), [NDB](#), and [ARCHIVE](#) tables. See also the annotations about spatial indexes under [Section 11.13.6.1, “Creating Spatial Indexes”](#).

- Use the [CREATE TABLE](#) statement to create a table with a spatial column:

```
CREATE TABLE geom (g GEOMETRY);
```

- Use the [ALTER TABLE](#) statement to add or drop a spatial column to or from an existing table:

```
ALTER TABLE geom ADD pt POINT;
ALTER TABLE geom DROP pt;
```

11.13.4.4. Populating Spatial Columns

After you have created spatial columns, you can populate them with spatial data.

Values should be stored in internal geometry format, but you can convert them to that format from either Well-Known Text (WKT) or Well-Known Binary (WKB) format. The following examples demonstrate how to insert geometry values into a table by converting WKT values into internal geometry format:

- Perform the conversion directly in the [INSERT](#) statement:

```
INSERT INTO geom VALUES (GeomFromText('POINT(1 1)'));
SET @g = 'POINT(1 1)';
INSERT INTO geom VALUES (GeomFromText(@g));
```

- Perform the conversion prior to the [INSERT](#):

```
SET @g = GeomFromText('POINT(1 1)');
INSERT INTO geom VALUES (@g);
```

The following examples insert more complex geometries into the table:

```
SET @g = 'LINESTRING(0 0,1 1,2 2)';
INSERT INTO geom VALUES (GeomFromText(@g));

SET @g = 'POLYGON((0 0,10 0,10 10,0 10,0 0),(5 5,7 5,7 7, 5 5))';
INSERT INTO geom VALUES (GeomFromText(@g));

SET @g =
'GEOMETRYCOLLECTION(POINT(1 1),LINESTRING(0 0,1 1,2 2,3 3,4 4))';
INSERT INTO geom VALUES (GeomFromText(@g));
```

The preceding examples all use [GeomFromText\(\)](#) to create geometry values. You can also use type-specific functions:

```
SET @g = 'POINT(1 1)';
INSERT INTO geom VALUES (PointFromText(@g));

SET @g = 'LINESTRING(0 0,1 1,2 2)';
INSERT INTO geom VALUES (LineStringFromText(@g));

SET @g = 'POLYGON((0 0,10 0,10 10,0 10,0 0),(5 5,7 5,7 7, 5 5))';
INSERT INTO geom VALUES (PolygonFromText(@g));

SET @g =
'GEOMETRYCOLLECTION(POINT(1 1),LINESTRING(0 0,1 1,2 2,3 3,4 4))';
INSERT INTO geom VALUES (GeomCollFromText(@g));
```

Note that if a client application program wants to use WKB representations of geometry values, it is responsible for sending correctly formed WKB in queries to the server. However, there are several ways of satisfying this requirement. For example:

- Inserting a [POINT\(1 1\)](#) value with hex literal syntax:

```
mysql> INSERT INTO geom VALUES
-> (GeomFromWKB(0x01010000000000000000000000F03F000000000000F03F));
```

- An ODBC application can send a WKB representation, binding it to a placeholder using an argument of [BLOB](#) type:

```
INSERT INTO geom VALUES (GeomFromWKB(?))
```

Other programming interfaces may support a similar placeholder mechanism.

- In a C program, you can escape a binary value using `mysql_real_escape_string()` and include the result in a query string that is sent to the server. See [Section 20.10.3.53](#), “`mysql_real_escape_string()`”.

11.13.4.5. Fetching Spatial Data

Geometry values stored in a table can be fetched in internal format. You can also convert them into WKT or WKB format.

- Fetching spatial data in internal format:

Fetching geometry values using internal format can be useful in table-to-table transfers:

```
CREATE TABLE geom2 (g GEOMETRY) SELECT g FROM geom;
```

- Fetching spatial data in WKT format:

The `AsText()` function converts a geometry from internal format into a WKT string.

```
SELECT AsText(g) FROM geom;
```

- Fetching spatial data in WKB format:

The `AsBinary()` function converts a geometry from internal format into a `BLOB` containing the WKB value.

```
SELECT AsBinary(g) FROM geom;
```

11.13.5. Analyzing Spatial Information

After populating spatial columns with values, you are ready to query and analyze them. MySQL provides a set of functions to perform various operations on spatial data. These functions can be grouped into four major categories according to the type of operation they perform:

- Functions that convert geometries between various formats
- Functions that provide access to qualitative or quantitative properties of a geometry
- Functions that describe relations between two geometries
- Functions that create new geometries from existing ones

Spatial analysis functions can be used in many contexts, such as:

- Any interactive SQL program, such as `mysql` or MySQL Query Browser
- Application programs written in any language that supports a MySQL client API

11.13.5.1. Geometry Format Conversion Functions

MySQL supports the following functions for converting geometry values between internal format and either WKT or WKB format:

- `AsBinary(g)`, `AsWKB(g)`

Converts a value in internal geometry format to its WKB representation and returns the binary result.

```
SELECT AsBinary(g) FROM geom;
```

- `AsText(g)`, `AsWKT(g)`

Converts a value in internal geometry format to its WKT representation and returns the string result.

```
mysql> SET @g = 'LineString(1 1,2 2,3 3)';
mysql> SELECT AsText(GeomFromText(@g));
+-----+
| AsText(GeomFromText(@g)) |
+-----+
| LINESTRING(1 1,2 2,3 3) |
+-----+
```

- `GeomFromText(wkt[,srid])`

Converts a string value from its WKT representation into internal geometry format and returns the result. A number of type-specific functions are also supported, such as `PointFromText()` and `LineFromText()`. See [Section 11.13.4.2.1, “Creating Geometry Values Using WKT Functions”](#).

- `GeomFromWKB(wkb[,srid])`

Converts a binary value from its WKB representation into internal geometry format and returns the result. A number of type-specific functions are also supported, such as `PointFromWKB()` and `LineFromWKB()`. See [Section 11.13.4.2.2, “Creating Geometry Values Using WKB Functions”](#).

11.13.5.2. Geometry Functions

Each function that belongs to this group takes a geometry value as its argument and returns some quantitative or qualitative property of the geometry. Some functions restrict their argument type. Such functions return `NULL` if the argument is of an incorrect geometry type. For example, `Area()` returns `NULL` if the object type is neither `Polygon` nor `MultiPolygon`.

11.13.5.2.1. General Geometry Functions

The functions listed in this section do not restrict their argument and accept a geometry value of any type.

- `Dimension(g)`

Returns the inherent dimension of the geometry value `g`. The result can be `-1`, `0`, `1`, or `2`. The meaning of these values is given in [Section 11.13.2.2, “Class Geometry”](#).

```
mysql> SELECT Dimension(GeomFromText('LineString(1 1,2 2)'));
+-----+
| Dimension(GeomFromText('LineString(1 1,2 2)')) |
+-----+
| 1 |
+-----+
```

- `Envelope(g)`

Returns the Minimum Bounding Rectangle (MBR) for the geometry value `g`. The result is returned as a `Polygon` value.

The polygon is defined by the corner points of the bounding box:

```
POLYGON((MINX MINY, MAXX MINY, MAXX MAXY, MINX MAXY, MINX MINY))
```

```
mysql> SELECT AsText(Envelope(GeomFromText('LineString(1 1,2 2)')));
+-----+
| AsText(Envelope(GeomFromText('LineString(1 1,2 2)'))) |
+-----+
| POLYGON((1 1,2 1,2 2,1 2,1 1)) |
+-----+
```

- `GeometryType(g)`

Returns as a string the name of the geometry type of which the geometry instance `g` is a member. The name corresponds to one of the instantiable `Geometry` subclasses.

```
mysql> SELECT GeometryType(GeomFromText('POINT(1 1)'));
+-----+
| GeometryType(GeomFromText('POINT(1 1)')) |
+-----+
| POINT |
+-----+
```

- `SRID(g)`

Returns an integer indicating the Spatial Reference System ID for the geometry value g .

In MySQL, the SRID value is just an integer associated with the geometry value. All calculations are done assuming Euclidean (planar) geometry.

```
mysql> SELECT SRID(GeomFromText('LineString(1 1,2 2)',101));
+-----+
| SRID(GeomFromText('LineString(1 1,2 2)',101)) |
+-----+
| 101 |
+-----+
```

The OpenGIS specification also defines the following functions, which MySQL does not implement:

- `Boundary(g)`

Returns a geometry that is the closure of the combinatorial boundary of the geometry value g .

- `IsEmpty(g)`

Returns 1 if the geometry value g is the empty geometry, 0 if it is not empty, and -1 if the argument is `NULL`. If the geometry is empty, it represents the empty point set.

- `IsSimple(g)`

Currently, this function is a placeholder and should not be used. If implemented, its behavior will be as described in the next paragraph.

Returns 1 if the geometry value g has no anomalous geometric points, such as self-intersection or self-tangency. `IsSimple()` returns 0 if the argument is not simple, and -1 if it is `NULL`.

The description of each instantiable geometric class given earlier in the chapter includes the specific conditions that cause an instance of that class to be classified as not simple. (See [Section 11.13.2.1](#), “The Geometry Class Hierarchy”.)

11.13.5.2.2. Point Functions

A `Point` consists of X and Y coordinates, which may be obtained using the following functions:

- `X(p)`

Returns the X-coordinate value for the point p as a double-precision number.

```
mysql> SET @pt = 'Point(56.7 53.34)';
mysql> SELECT X(GeomFromText(@pt));
+-----+
| X(GeomFromText(@pt)) |
+-----+
| 56.7 |
+-----+
```

- `Y(p)`

Returns the Y-coordinate value for the point p as a double-precision number.

```
mysql> SET @pt = 'Point(56.7 53.34)';
mysql> SELECT Y(GeomFromText(@pt));
+-----+
| Y(GeomFromText(@pt)) |
+-----+
| 53.34 |
+-----+
```

11.13.5.2.3. LineString Functions

A `LineString` consists of `Point` values. You can extract particular points of a `LineString`, count the number of points that it contains, or obtain its length.

- `EndPoint(ls)`

Returns the `Point` that is the endpoint of the `LineString` value `ls`.

```
mysql> SET @ls = 'LineString(1 1,2 2,3 3)';
mysql> SELECT AsText(EndPoint(GeomFromText(@ls)));
+-----+
| AsText(EndPoint(GeomFromText(@ls))) |
+-----+
| POINT(3 3) |
+-----+
```

- `GLength(ls)`

Returns as a double-precision number the length of the `LineString` value `ls` in its associated spatial reference.

```
mysql> SET @ls = 'LineString(1 1,2 2,3 3)';
mysql> SELECT GLength(GeomFromText(@ls));
+-----+
| GLength(GeomFromText(@ls)) |
+-----+
| 2.8284271247462 |
+-----+
```

`GLength()` is a non-standard name. It corresponds to the OpenGIS `Length()` function.

- `NumPoints(ls)`

Returns the number of `Point` objects in the `LineString` value `ls`.

```
mysql> SET @ls = 'LineString(1 1,2 2,3 3)';
mysql> SELECT NumPoints(GeomFromText(@ls));
+-----+
| NumPoints(GeomFromText(@ls)) |
+-----+
| 3 |
+-----+
```

- `PointN(ls,N)`

Returns the `N`-th `Point` in the `LineString` value `ls`. Points are numbered beginning with 1.

```
mysql> SET @ls = 'LineString(1 1,2 2,3 3)';
mysql> SELECT AsText(PointN(GeomFromText(@ls),2));
+-----+
| AsText(PointN(GeomFromText(@ls),2)) |
+-----+
| POINT(2 2) |
+-----+
```

- `StartPoint(ls)`

Returns the `Point` that is the start point of the `LineString` value `ls`.

```
mysql> SET @ls = 'LineString(1 1,2 2,3 3)';
mysql> SELECT AsText(StartPoint(GeomFromText(@ls)));
+-----+
| AsText(StartPoint(GeomFromText(@ls))) |
+-----+
| POINT(1 1) |
+-----+
```

The OpenGIS specification also defines the following function, which MySQL does not implement:

- `IsRing(ls)`

Returns 1 if the `LineString` value `ls` is closed (that is, its `StartPoint()` and `EndPoint()` values are the same) and is simple (does not pass through the same point more than once). Returns 0 if `ls` is not a ring, and -1 if it is `NULL`.

11.13.5.2.4. MultiLineString Functions

These functions return properties of `MultiLineString` values.

- `GLength(mls)`

Returns as a double-precision number the length of the `MultiLineString` value `mls`. The length of `mls` is equal to the sum of the lengths of its elements.

```
mysql> SET @mls = 'MultiLineString((1 1,2 2,3 3),(4 4,5 5))';
mysql> SELECT GLength(GeomFromText(@mls));
+-----+
| GLength(GeomFromText(@mls)) |
+-----+
|                4.2426406871193 |
+-----+
```

`GLength()` is a non-standard name. It corresponds to the OpenGIS `Length()` function.

- `IsClosed(mls)`

Returns 1 if the `MultiLineString` value `mls` is closed (that is, the `StartPoint()` and `EndPoint()` values are the same for each `LineString` in `mls`). Returns 0 if `mls` is not closed, and -1 if it is NULL.

```
mysql> SET @mls = 'MultiLineString((1 1,2 2,3 3),(4 4,5 5))';
mysql> SELECT IsClosed(GeomFromText(@mls));
+-----+
| IsClosed(GeomFromText(@mls)) |
+-----+
|                0 |
+-----+
```

11.13.5.2.5. Polygon Functions

These functions return properties of `Polygon` values.

- `Area(poly)`

Returns as a double-precision number the area of the `Polygon` value `poly`, as measured in its spatial reference system.

```
mysql> SET @poly = 'Polygon((0 0,0 3,3 0,0 0),(1 1,1 2,2 1,1 1))';
mysql> SELECT Area(GeomFromText(@poly));
+-----+
| Area(GeomFromText(@poly)) |
+-----+
|                4 |
+-----+
```

- `ExteriorRing(poly)`

Returns the exterior ring of the `Polygon` value `poly` as a `LineString`.

```
mysql> SET @poly =
-> 'Polygon((0 0,0 3,3 3,3 0,0 0),(1 1,1 2,2 2,2 1,1 1))';
mysql> SELECT AsText(ExteriorRing(GeomFromText(@poly)));
+-----+
| AsText(ExteriorRing(GeomFromText(@poly))) |
+-----+
| LINESTRING(0 0,0 3,3 3,3 0,0 0) |
+-----+
```

- `InteriorRingN(poly,N)`

Returns the `N`-th interior ring for the `Polygon` value `poly` as a `LineString`. Rings are numbered beginning with 1.

```
mysql> SET @poly =
-> 'Polygon((0 0,0 3,3 3,3 0,0 0),(1 1,1 2,2 2,2 1,1 1))';
mysql> SELECT AsText(InteriorRingN(GeomFromText(@poly),1));
+-----+
| AsText(InteriorRingN(GeomFromText(@poly),1)) |
+-----+
| LINESTRING(1 1,1 2,2 2,2 1,1 1) |
+-----+
```

- `NumInteriorRings(poly)`

Returns the number of interior rings in the `Polygon` value `poly`.

```
mysql> SET @poly =
-> 'Polygon((0 0,0 3,3 3,3 0,0 0),(1 1,1 2,2 2,2 1,1 1))';
mysql> SELECT NumInteriorRings(GeomFromText(@poly));
+-----+
```

```

| NumInteriorRings(GeomFromText(@poly)) |
+-----+-----+
|                                     1 |
+-----+-----+

```

11.13.5.2.6. MultiPolygon Functions

These functions return properties of `MultiPolygon` values.

- `Area(mpoly)`

Returns as a double-precision number the area of the `MultiPolygon` value *mpoly*, as measured in its spatial reference system.

```

mysql> SET @mpoly =
-> 'MultiPolygon(((0 0,0 3,3 3,3 0,0 0),(1 1,1 2,2 2,2 1,1 1)))';
mysql> SELECT Area(GeomFromText(@mpoly));
+-----+-----+
| Area(GeomFromText(@mpoly)) |
+-----+-----+
|                             8 |
+-----+-----+

```

The OpenGIS specification also defines the following functions, which MySQL does not implement:

- `Centroid(mpoly)`
Returns the mathematical centroid for the `MultiPolygon` value *mpoly* as a `Point`. The result is not guaranteed to be on the `MultiPolygon`.
- `PointOnSurface(mpoly)`
Returns a `Point` value that is guaranteed to be on the `MultiPolygon` value *mpoly*.

11.13.5.2.7. GeometryCollection Functions

These functions return properties of `GeometryCollection` values.

- `GeometryN(gc,N)`

Returns the *N*-th geometry in the `GeometryCollection` value *gc*. Geometries are numbered beginning with 1.

```

mysql> SET @gc = 'GeometryCollection(Point(1 1),LineString(2 2, 3 3))';
mysql> SELECT AsText(GeometryN(GeomFromText(@gc),1));
+-----+-----+
| AsText(GeometryN(GeomFromText(@gc),1)) |
+-----+-----+
| POINT(1 1)                             |
+-----+-----+

```

- `NumGeometries(gc)`

Returns the number of geometries in the `GeometryCollection` value *gc*.

```

mysql> SET @gc = 'GeometryCollection(Point(1 1),LineString(2 2, 3 3))';
mysql> SELECT NumGeometries(GeomFromText(@gc));
+-----+-----+
| NumGeometries(GeomFromText(@gc)) |
+-----+-----+
|                                     2 |
+-----+-----+

```

11.13.5.3. Functions That Create New Geometries from Existing Ones

The following sections describe functions that take geometry values as arguments and return new geometry values.

11.13.5.3.1. Geometry Functions That Produce New Geometries

Section 11.13.5.2, “Geometry Functions”, discusses several functions that construct new geometries from existing ones. See that section for descriptions of these functions:

- `Envelope(g)`
- `StartPoint(ls)`
- `EndPoint(ls)`
- `PointN(ls,N)`
- `ExteriorRing(poly)`
- `InteriorRingN(poly,N)`
- `GeometryN(gc,N)`

11.13.5.3.2. Spatial Operators

OpenGIS proposes a number of other functions that can produce geometries. They are designed to implement spatial operators.

These functions are not implemented in MySQL. They may appear in future releases.

- `Buffer(g,d)`
Returns a geometry that represents all points whose distance from the geometry value *g* is less than or equal to a distance of *d*.
- `ConvexHull(g)`
Returns a geometry that represents the convex hull of the geometry value *g*.
- `Difference(g1,g2)`
Returns a geometry that represents the point set difference of the geometry value *g1* with *g2*.
- `Intersection(g1,g2)`
Returns a geometry that represents the point set intersection of the geometry values *g1* with *g2*.
- `SymDifference(g1,g2)`
Returns a geometry that represents the point set symmetric difference of the geometry value *g1* with *g2*.
- `Union(g1,g2)`
Returns a geometry that represents the point set union of the geometry values *g1* and *g2*.

11.13.5.4. Functions for Testing Spatial Relations Between Geometric Objects

The functions described in these sections take two geometries as input parameters and return a qualitative or quantitative relation between them.

11.13.5.5. Relations on Geometry Minimal Bounding Rectangles (MBRs)

MySQL provides several functions that test relations between minimal bounding rectangles of two geometries *g1* and *g2*. The return values 1 and 0 indicate true and false, respectively.

- `MBRContains(g1,g2)`
Returns 1 or 0 to indicate whether the Minimum Bounding Rectangle of *g1* contains the Minimum Bounding Rectangle of *g2*. This tests the opposite relationship as `MBRWithin()`.

```
mysql> SET @g1 = GeomFromText('Polygon((0 0,0 3,3 3,3 0,0 0))');
mysql> SET @g2 = GeomFromText('Point(1 1)');
mysql> SELECT MBRContains(@g1,@g2), MBRContains(@g2,@g1);
+-----+-----+
| MBRContains(@g1,@g2) | MBRContains(@g2,@g1) |
+-----+-----+
```

1	0
---	---

- `MBRDisjoint(g1,g2)`

Returns 1 or 0 to indicate whether the Minimum Bounding Rectangles of the two geometries *g1* and *g2* are disjoint (do not intersect).
- `MBREqual(g1,g2)`

Returns 1 or 0 to indicate whether the Minimum Bounding Rectangles of the two geometries *g1* and *g2* are the same.
- `MBRIntersects(g1,g2)`

Returns 1 or 0 to indicate whether the Minimum Bounding Rectangles of the two geometries *g1* and *g2* intersect.
- `MBROverlaps(g1,g2)`

Returns 1 or 0 to indicate whether the Minimum Bounding Rectangles of the two geometries *g1* and *g2* overlap. The term *spatially overlaps* is used if two geometries intersect and their intersection results in a geometry of the same dimension but not equal to either of the given geometries.
- `MBRTouches(g1,g2)`

Returns 1 or 0 to indicate whether the Minimum Bounding Rectangles of the two geometries *g1* and *g2* touch. Two geometries *spatially touch* if the interiors of the geometries do not intersect, but the boundary of one of the geometries intersects either the boundary or the interior of the other.
- `MBRWithin(g1,g2)`

Returns 1 or 0 to indicate whether the Minimum Bounding Rectangle of *g1* is within the Minimum Bounding Rectangle of *g2*. This tests the opposite relationship as `MBRContains()`.

```
mysql> SET @g1 = GeomFromText('Polygon((0 0,0 3,3 3,3 0,0 0))');
mysql> SET @g2 = GeomFromText('Polygon((0 0,0 5,5 5,5 0,0 0))');
mysql> SELECT MBRWithin(@g1,@g2), MBRWithin(@g2,@g1);
```

1	0
---	---

11.13.5.6. Functions That Test Spatial Relationships Between Geometries

The OpenGIS specification defines the following functions. They test the relationship between two geometry values *g1* and *g2*. The return values 1 and 0 indicate true and false, respectively.

Note

Currently, MySQL does not implement these functions according to the specification. Those that are implemented return the same result as the corresponding MBR-based functions. This includes functions in the following list other than `Distance()` and `Related()`.

These functions may be implemented in future releases with full support for spatial analysis, not just MBR-based support.

- `Contains(g1,g2)`

Returns 1 or 0 to indicate whether *g1* completely contains *g2*. This tests the opposite relationship as `Within()`.
- `Crosses(g1,g2)`

Returns 1 if *g1* spatially crosses *g2*. Returns NULL if *g1* is a `Polygon` or a `MultiPolygon`, or if *g2* is a `Point` or a `MultiPoint`. Otherwise, returns 0.

The term *spatially crosses* denotes a spatial relation between two given geometries that has the following properties:

 - The two geometries intersect

- Their intersection results in a geometry that has a dimension that is one less than the maximum dimension of the two given geometries
- Their intersection is not equal to either of the two given geometries
- `Disjoint(g1,g2)`
Returns 1 or 0 to indicate whether `g1` is spatially disjoint from (does not intersect) `g2`.
- `Distance(g1,g2)`
Returns as a double-precision number the shortest distance between any two points in the two geometries.
- `Equals(g1,g2)`
Returns 1 or 0 to indicate whether `g1` is spatially equal to `g2`.
- `Intersects(g1,g2)`
Returns 1 or 0 to indicate whether `g1` spatially intersects `g2`.
- `Overlaps(g1,g2)`
Returns 1 or 0 to indicate whether `g1` spatially overlaps `g2`. The term *spatially overlaps* is used if two geometries intersect and their intersection results in a geometry of the same dimension but not equal to either of the given geometries.
- `Related(g1,g2,pattern_matrix)`
Returns 1 or 0 to indicate whether the spatial relationship specified by `pattern_matrix` exists between `g1` and `g2`. Returns -1 if the arguments are `NULL`. The pattern matrix is a string. Its specification will be noted here if this function is implemented.
- `Touches(g1,g2)`
Returns 1 or 0 to indicate whether `g1` spatially touches `g2`. Two geometries *spatially touch* if the interiors of the geometries do not intersect, but the boundary of one of the geometries intersects either the boundary or the interior of the other.
- `Within(g1,g2)`
Returns 1 or 0 to indicate whether `g1` is spatially within `g2`. This tests the opposite relationship as `Contains()`.

11.13.6. Optimizing Spatial Analysis

Search operations in non-spatial databases can be optimized using `SPATIAL` indexes. This is true for spatial databases as well. With the help of a great variety of multi-dimensional indexing methods that have previously been designed, it is possible to optimize spatial searches. The most typical of these are:

- Point queries that search for all objects that contain a given point
- Region queries that search for all objects that overlap a given region

MySQL uses **R-Trees with quadratic splitting** for `SPATIAL` indexes on spatial columns. A `SPATIAL` index is built using the MBR of a geometry. For most geometries, the MBR is a minimum rectangle that surrounds the geometries. For a horizontal or a vertical linestring, the MBR is a rectangle degenerated into the linestring. For a point, the MBR is a rectangle degenerated into the point.

It is also possible to create normal indexes on spatial columns. In a non-`SPATIAL` index, you must declare a prefix for any spatial column except for `POINT` columns.

MyISAM supports both `SPATIAL` and non-`SPATIAL` indexes. Other storage engines support non-`SPATIAL` indexes, as described in [Section 12.1.11, “CREATE INDEX Syntax”](#).

11.13.6.1. Creating Spatial Indexes

MySQL can create spatial indexes using syntax similar to that for creating regular indexes, but extended with the `SPATIAL` keyword. Currently, columns in spatial indexes must be declared `NOT NULL`. The following examples demonstrate how to create spatial indexes:

- With `CREATE TABLE`:

```
CREATE TABLE geom (g GEOMETRY NOT NULL, SPATIAL INDEX(g));
```

- With `ALTER TABLE`:

```
ALTER TABLE geom ADD SPATIAL INDEX(g);
```

- With `CREATE INDEX`:

```
CREATE SPATIAL INDEX sp_index ON geom (g);
```

For `MyISAM` tables, `SPATIAL INDEX` creates an R-tree index. For storage engines that support non-spatial indexing of spatial columns, the engine creates a B-tree index. A B-tree index on spatial values will be useful for exact-value lookups, but not for range scans.

For more information on indexing spatial columns, see [Section 12.1.11, “CREATE INDEX Syntax”](#).

To drop spatial indexes, use `ALTER TABLE` or `DROP INDEX`:

- With `ALTER TABLE`:

```
ALTER TABLE geom DROP INDEX g;
```

- With `DROP INDEX`:

```
DROP INDEX sp_index ON geom;
```

Example: Suppose that a table `geom` contains more than 32,000 geometries, which are stored in the column `g` of type `GEOMETRY`. The table also has an `AUTO_INCREMENT` column `fid` for storing object ID values.

```
mysql> DESCRIBE geom;
+-----+-----+-----+-----+-----+-----+
| Field | Type      | Null | Key | Default | Extra          |
+-----+-----+-----+-----+-----+-----+
| fid   | int(11)   |      | PRI | NULL    | auto_increment |
| g     | geometry  |      |     |         |                |
+-----+-----+-----+-----+-----+-----+
2 rows in set (0.00 sec)

mysql> SELECT COUNT(*) FROM geom;
+-----+
| count(*) |
+-----+
|      32376 |
+-----+
1 row in set (0.00 sec)
```

To add a spatial index on the column `g`, use this statement:

```
mysql> ALTER TABLE geom ADD SPATIAL INDEX(g);
Query OK, 32376 rows affected (4.05 sec)
Records: 32376 Duplicates: 0 Warnings: 0
```

11.13.6.2. Using a Spatial Index

The optimizer investigates whether available spatial indexes can be involved in the search for queries that use a function such as `MBRContains()` or `MBRWithin()` in the `WHERE` clause. The following query finds all objects that are in the given rectangle:

```
mysql> SET @poly =
-> 'Polygon((30000 15000,
              31000 15000,
              31000 16000,
              30000 16000,
              30000 15000))';
mysql> SELECT fid, AsText(g) FROM geom WHERE
-> MBRContains(GeomFromText(@poly), g);
+-----+-----+
| fid | AsText(g) |
+-----+-----+
| 21 | LINESTRING(30350.4 15828.8,30350.6 15845,30333.8 15845,30... |
| 22 | LINESTRING(30350.6 15871.4,30350.6 15887.8,30334 15887.8, ... |
| 23 | LINESTRING(30350.6 15914.2,30350.6 15930.4,30334 15930.4, ... |
| 24 | LINESTRING(30290.2 15823,30290.2 15839.4,30273.4 15839.4, ... |
+-----+-----+
```

```

25 | LINESTRING(30291.4 15866.2,30291.6 15882.4,30274.8 15882. ...
26 | LINESTRING(30291.6 15918.2,30291.6 15934.4,30275 15934.4, ...

2 | LINESTRING(30220.2 15122.8,30217.2 15137.8,30207.6 15136. ...
3 | LINESTRING(30179 15114.4,30176.6 15129.4,30167 15128,3016 ...
4 | LINESTRING(30155.2 15121.4,30140.4 15118.6,30142 15109,30 ...
5 | LINESTRING(30192.4 15085,30177.6 15082.2,30179.2 15072.4, ...
6 | LINESTRING(30244 15087,30229 15086.2,30229.4 15076.4,3024 ...
7 | LINESTRING(30200.6 15059.4,30185.6 15058.6,30186 15048.8, ...
10 | LINESTRING(30179.6 15017.8,30181 15002.8,30190.8 15003.6, ...
11 | LINESTRING(30154.2 15000.4,30168.6 15004.8,30166 15014.2, ...
13 | LINESTRING(30105 15065.8,30108.4 15050.8,30118 15053,3011 ...
154 | LINESTRING(30276.2 15143.8,30261.4 15141,30263 15131.4,30 ...
155 | LINESTRING(30269.8 15084,30269.4 15093.4,30258.6 15093,30 ...
157 | LINESTRING(30128.2 15011,30113.2 15010.2,30113.6 15000.4, ...
+-----+-----+
20 rows in set (0.00 sec)

```

Use `EXPLAIN` to check the way this query is executed:

```

mysql> SET @poly =
-> 'Polygon((30000 15000,
           31000 15000,
           31000 16000,
           30000 16000,
           30000 15000))';
mysql> EXPLAIN SELECT fid,AsText(g) FROM geom WHERE
-> MBRContains(GeomFromText(@poly),g)\G
***** 1. row *****
      id: 1
  select_type: SIMPLE
        table: geom
         type: range
possible_keys: g
         key: g
        key_len: 32
         ref: NULL
         rows: 50
      Extra: Using where
1 row in set (0.00 sec)

```

Check what would happen without a spatial index:

```

mysql> SET @poly =
-> 'Polygon((30000 15000,
           31000 15000,
           31000 16000,
           30000 16000,
           30000 15000))';
mysql> EXPLAIN SELECT fid,AsText(g) FROM geom IGNORE INDEX (g) WHERE
-> MBRContains(GeomFromText(@poly),g)\G
***** 1. row *****
      id: 1
  select_type: SIMPLE
        table: geom
         type: ALL
possible_keys: NULL
         key: NULL
        key_len: NULL
         ref: NULL
         rows: 32376
      Extra: Using where
1 row in set (0.00 sec)

```

Executing the `SELECT` statement without the spatial index yields the same result but causes the execution time to rise from 0.00 seconds to 0.46 seconds:

```

mysql> SET @poly =
-> 'Polygon((30000 15000,
           31000 15000,
           31000 16000,
           30000 16000,
           30000 15000))';
mysql> SELECT fid,AsText(g) FROM geom IGNORE INDEX (g) WHERE
-> MBRContains(GeomFromText(@poly),g);
+-----+-----+
| fid | AsText(g)
+-----+-----+
1 | LINESTRING(30250.4 15129.2,30248.8 15138.4,30238.2 15136. ...
2 | LINESTRING(30220.2 15122.8,30217.2 15137.8,30207.6 15136. ...
3 | LINESTRING(30179 15114.4,30176.6 15129.4,30167 15128,3016 ...

+-----+-----+
20 rows in set (0.46 sec)

```

In future releases, spatial indexes may also be used for optimizing other functions. See [Section 11.13.5.4, “Functions for Testing Spatial Relations Between Geometric Objects”](#).

11.13.7. MySQL Conformance and Compatibility

MySQL does not yet implement the following GIS features:

- **Additional Metadata Views**
OpenGIS specifications propose several additional metadata views. For example, a system view named `GEOMETRY_COLUMNS` contains a description of geometry columns, one row for each geometry column in the database.
- **The OpenGIS function `Length()` on `LineString` and `MultiLineString` currently should be called in MySQL as `GLength()`**
The problem is that there is an existing SQL function `Length()` that calculates the length of string values, and sometimes it is not possible to distinguish whether the function is called in a textual or spatial context. We need either to solve this somehow, or decide on another function name.

11.14. Precision Math

MySQL 5.4 provides support for precision math: numeric value handling that results in extremely accurate results and a high degree of control over invalid values. Precision math is based on these two features:

- SQL modes that control how strict the server is about accepting or rejecting invalid data.
- The MySQL library for fixed-point arithmetic.

These features have several implications for numeric operations:

- **Precise calculations:** For exact-value numbers, calculations do not introduce floating-point errors. Instead, exact precision is used. For example, a number such as `.0001` is treated as an exact value rather than as an approximation, and summing it 10,000 times produces a result of exactly `1`, not a value that merely “close” to 1.
- **Well-defined rounding behavior:** For exact-value numbers, the result of `ROUND()` depends on its argument, not on environmental factors such as how the underlying C library works.
- **Platform independence:** Operations on exact numeric values are the same across different platforms such as Windows and Unix.
- **Control over handling of invalid values:** Overflow and division by zero are detectable and can be treated as errors. For example, you can treat a value that is too large for a column as an error rather than having the value truncated to lie within the range of the column's data type. Similarly, you can treat division by zero as an error rather than as an operation that produces a result of `NULL`. The choice of which approach to take is determined by the setting of the `sql_mode` system variable.

An important result of these features is that MySQL 5.4 provides a high degree of compliance with standard SQL.

The following discussion covers several aspects of how precision math works (including possible incompatibilities with older applications). At the end, some examples are given that demonstrate how MySQL 5.4 handles numeric operations precisely. For information about using the `sql_mode` system variable to control the SQL mode, see [Section 5.1.7, “Server SQL Modes”](#).

11.14.1. Types of Numeric Values

The scope of precision math for exact-value operations includes the exact-value data types (`DECIMAL` and integer types) and exact-value numeric literals. Approximate-value data types and numeric literals still are handled as floating-point numbers.

Exact-value numeric literals have an integer part or fractional part, or both. They may be signed. Examples: `1`, `.2`, `3.4`, `-5`, `-6.78`, `+9.10`.

Approximate-value numeric literals are represented in scientific notation with a mantissa and exponent. Either or both parts may be signed. Examples: `1.2E3`, `1.2E-3`, `-1.2E3`, `-1.2E-3`.

Two numbers that look similar need not be both exact-value or both approximate-value. For example, `2.34` is an exact-value (fixed-point) number, whereas `2.34E0` is an approximate-value (floating-point) number.

The `DECIMAL` data type is a fixed-point type and calculations are exact. In MySQL, the `DECIMAL` type has several synonyms: `NUMERIC`, `DEC`, `FIXED`. The integer types also are exact-value types.

The `FLOAT` and `DOUBLE` data types are floating-point types and calculations are approximate. In MySQL, types that are synonymous with `FLOAT` or `DOUBLE` are `DOUBLE PRECISION` and `REAL`.

11.14.2. `DECIMAL` Data Type Changes

This section discusses the characteristics of the `DECIMAL` data type (and its synonyms) in MySQL 5.4, with particular regard to the following topics:

- Maximum number of digits
- Storage format
- Storage requirements
- The non-standard MySQL extension to the upper range of `DECIMAL` columns

Possible incompatibilities with applications that are written for older versions of MySQL are noted throughout this section.

The declaration syntax for a `DECIMAL` column is `DECIMAL(M,D)`. The ranges of values for the arguments in MySQL 5.4 are as follows:

- `M` is the maximum number of digits (the precision). It has a range of 1 to 65. (Older versions of MySQL allowed a range of 1 to 254.)
- `D` is the number of digits to the right of the decimal point (the scale). It has a range of 0 to 30 and must be no larger than `M`.

The maximum value of 65 for `M` means that calculations on `DECIMAL` values are accurate up to 65 digits. This limit of 65 digits of precision also applies to exact-value numeric literals, so the maximum range of such literals is different from before. (In older versions of MySQL, decimal values could have up to 254 digits. However, calculations were done using floating-point and thus were approximate, not exact.)

Values for `DECIMAL` columns in MySQL 5.4 are stored using a binary format that packs nine decimal digits into four bytes. The storage requirements for the integer and fractional parts of each value are determined separately. Each multiple of nine digits requires four bytes, and any digits left over require some fraction of four bytes. For example, a `DECIMAL(18,9)` column has nine digits on either side of the decimal point, so the integer part and the fractional part each require four bytes. A `DECIMAL(20,10)` column has ten digits on either side of the decimal point. Each part requires four bytes for nine of the digits, and one byte for the remaining digit.

The storage required for leftover digits is given by the following table.

Leftover Digits	Number of Bytes
0	0
1	1
2	1
3	2
4	2
5	3
6	3
7	4
8	4

9	4
---	---

Unlike some older versions of MySQL (prior to 5.0.3), `DECIMAL` columns in MySQL 5.4 do not store a leading `+` character or `-` character or leading `0` digits. If you insert `+0003.1` into a `DECIMAL(5,1)` column, it is stored as `3.1`. For negative numbers, a literal `-` character is not stored. Applications that rely on the older behavior must be modified to account for this change.

`DECIMAL` columns in MySQL 5.4 do not allow values larger than the range implied by the column definition. For example, a `DECIMAL(3,0)` column supports a range of `-999` to `999`. A `DECIMAL(M,D)` column allows at most `M - D` digits to the left of the decimal point. This is not compatible with applications relying on older versions of MySQL that allowed storing an extra digit in lieu of a `+` sign.

The SQL standard requires that the precision of `NUMERIC(M,D)` be *exactly* `M` digits. For `DECIMAL(M,D)`, the standard requires a precision of at least `M` digits but allows more. In MySQL, `DECIMAL(M,D)` and `NUMERIC(M,D)` are the same, and both have a precision of exactly `M` digits.

For more detailed information about porting applications that rely on the old treatment of the `DECIMAL` data type, see the *MySQL 5.0 Reference Manual*.

11.14.3. Expression Handling

With precision math, exact-value numbers are used as given whenever possible. For example, numbers in comparisons are used exactly as given without a change in value. In strict SQL mode, for `INSERT` into a column with an exact data type (`DECIMAL` or integer), a number is inserted with its exact value if it is within the column range. When retrieved, the value should be the same as what was inserted. (Without strict mode, truncation for `INSERT` is allowable.)

Handling of a numeric expression depends on what kind of values the expression contains:

- If any approximate values are present, the expression is approximate and is evaluated using floating-point arithmetic.
- If no approximate values are present, the expression contains only exact values. If any exact value contains a fractional part (a value following the decimal point), the expression is evaluated using `DECIMAL` exact arithmetic and has a precision of 65 digits. (The term “exact” is subject to the limits of what can be represented in binary. For example, `1.0/3.0` can be approximated in decimal notation as `.333...`, but not written as an exact number, so `(1.0/3.0)*3.0` does not evaluate to exactly `1.0`.)
- Otherwise, the expression contains only integer values. The expression is exact and is evaluated using integer arithmetic and has a precision the same as `BIGINT` (64 bits).

If a numeric expression contains any strings, they are converted to double-precision floating-point values and the expression is approximate.

Inserts into numeric columns are affected by the SQL mode, which is controlled by the `sql_mode` system variable. (See [Section 5.1.7, “Server SQL Modes”](#).) The following discussion mentions strict mode (selected by the `STRICT_ALL_TABLES` or `STRICT_TRANS_TABLES` mode values) and `ERROR_FOR_DIVISION_BY_ZERO`. To turn on all restrictions, you can simply use `TRADITIONAL` mode, which includes both strict mode values and `ERROR_FOR_DIVISION_BY_ZERO`:

```
mysql> SET sql_mode='TRADITIONAL';
```

If a number is inserted into an exact type column (`DECIMAL` or integer), it is inserted with its exact value if it is within the column range.

If the value has too many digits in the fractional part, rounding occurs and a warning is generated. Rounding is done as described in [Section 11.14.4, “Rounding Behavior”](#).

If the value has too many digits in the integer part, it is too large and is handled as follows:

- If strict mode is not enabled, the value is truncated to the nearest legal value and a warning is generated.
- If strict mode is enabled, an overflow error occurs.

Underflow is not detected, so underflow handling is undefined.

By default, division by zero produces a result of `NULL` and no warning. With the `ERROR_FOR_DIVISION_BY_ZERO` SQL mode enabled, MySQL handles division by zero differently:

- If strict mode is not enabled, a warning occurs.
- If strict mode is enabled, inserts and updates involving division by zero are prohibited, and an error occurs.

In other words, inserts and updates involving expressions that perform division by zero can be treated as errors, but this requires `ERROR_FOR_DIVISION_BY_ZERO` in addition to strict mode.

Suppose that we have this statement:

```
INSERT INTO t SET i = 1/0;
```

This is what happens for combinations of strict and `ERROR_FOR_DIVISION_BY_ZERO` modes.

sql_mode Value	Result
' ' (Default)	No warning, no error; <code>i</code> is set to <code>NULL</code> .
strict	No warning, no error; <code>i</code> is set to <code>NULL</code> .
<code>ERROR_FOR_DIVISION_BY_ZERO</code>	Warning, no error; <code>i</code> is set to <code>NULL</code> .
strict, <code>ERROR_FOR_DIVISION_BY_ZERO</code>	Error condition; no row is inserted.

For inserts of strings into numeric columns, conversion from string to number is handled as follows if the string has non-numeric contents:

- A string that does not begin with a number cannot be used as a number and produces an error in strict mode, or a warning otherwise. *This includes the empty string.*
- A string that begins with a number can be converted, but the trailing non-numeric portion is truncated. If the truncated portion contains anything other than spaces, this produces an error in strict mode, or a warning otherwise.

11.14.4. Rounding Behavior

This section discusses precision math rounding for the `ROUND()` function and for inserts into columns with exact-value types (`DECIMAL` and integer).

The `ROUND()` function rounds differently depending on whether its argument is exact or approximate:

- For exact-value numbers, `ROUND()` uses the “round half up” rule: A value with a fractional part of .5 or greater is rounded up to the next integer if positive or down to the next integer if negative. (In other words, it is rounded away from zero.) A value with a fractional part less than .5 is rounded down to the next integer if positive or up to the next integer if negative.
- For approximate-value numbers, the result depends on the C library. On many systems, this means that `ROUND()` uses the “round to nearest even” rule: A value with any fractional part is rounded to the nearest even integer.

The following example shows how rounding differs for exact and approximate values:

```
mysql> SELECT ROUND(2.5), ROUND(25E-1);
+-----+-----+
| ROUND(2.5) | ROUND(25E-1) |
+-----+-----+
| 3          | 2            |
+-----+-----+
```

For inserts into a `DECIMAL` or integer column, the target is an exact data type, so rounding uses “round half up,” regardless of whether the value to be inserted is exact or approximate:

```
mysql> CREATE TABLE t (d DECIMAL(10,0));
Query OK, 0 rows affected (0.00 sec)

mysql> INSERT INTO t VALUES(2.5),(2.5E0);
Query OK, 2 rows affected, 2 warnings (0.00 sec)
Records: 2 Duplicates: 0 Warnings: 2

mysql> SELECT d FROM t;
+-----+
| d     |
+-----+
| 3     |
| 3     |
+-----+
```

+-----+

11.14.5. Precision Math Examples

This section provides some examples that show precision math query results in MySQL 5.4.

Example 1. Numbers are used with their exact value as given when possible:

```
mysql> SELECT .1 + .2 = .3;
+-----+
| .1 + .2 = .3 |
+-----+
|              1 |
+-----+
```

For floating-point values, results are inexact:

```
mysql> SELECT .1E0 + .2E0 = .3E0;
+-----+
| .1E0 + .2E0 = .3E0 |
+-----+
|                    0 |
+-----+
```

Another way to see the difference in exact and approximate value handling is to add a small number to a sum many times. Consider the following stored procedure, which adds `.0001` to a variable 1,000 times.

```
CREATE PROCEDURE p ()
BEGIN
  DECLARE i INT DEFAULT 0;
  DECLARE d DECIMAL(10,4) DEFAULT 0;
  DECLARE f FLOAT DEFAULT 0;
  WHILE i < 10000 DO
    SET d = d + .0001;
    SET f = f + .0001E0;
    SET i = i + 1;
  END WHILE;
  SELECT d, f;
END;
```

The sum for both `d` and `f` logically should be 1, but that is true only for the decimal calculation. The floating-point calculation introduces small errors:

```
+-----+
| d      | f      |
+-----+
| 1.0000 | 0.999999999999991 |
+-----+
```

Example 2. Multiplication is performed with the scale required by standard SQL. That is, for two numbers `X1` and `X2` that have scale `S1` and `S2`, the scale of the result is `S1 + S2`:

```
mysql> SELECT .01 * .01;
+-----+
| .01 * .01 |
+-----+
| 0.0001    |
+-----+
```

Example 3. Rounding behavior is well-defined:

Rounding behavior (for example, with the `ROUND()` function) is independent of the implementation of the underlying C library, which means that results are consistent from platform to platform.

Rounding for exact-value columns (`DECIMAL` and integer) and exact-valued numbers uses the “round half up” rule. Values with a fractional part of `.5` or greater are rounded away from zero to the nearest integer, as shown here:

```
mysql> SELECT ROUND(2.5), ROUND(-2.5);
+-----+
| ROUND(2.5) | ROUND(-2.5) |
+-----+
| 3          | -3          |
+-----+
```

However, rounding for floating-point values uses the C library, which on many systems uses the “round to nearest even” rule. Values with any fractional part on such systems are rounded to the nearest even integer:

```
mysql> SELECT ROUND(2.5E0), ROUND(-2.5E0);
```

```

+-----+
| ROUND(2.5E0) | ROUND(-2.5E0) |
+-----+
|          2 |          -2 |
+-----+

```

Example 4. In strict mode, inserting a value that is too large results in overflow and causes an error, rather than truncation to a legal value.

When MySQL is not running in strict mode, truncation to a legal value occurs:

```

mysql> SET sql_mode='';
Query OK, 0 rows affected (0.00 sec)

mysql> CREATE TABLE t (i TINYINT);
Query OK, 0 rows affected (0.01 sec)

mysql> INSERT INTO t SET i = 128;
Query OK, 1 row affected, 1 warning (0.00 sec)

mysql> SELECT i FROM t;
+-----+
| i     |
+-----+
| 127  |
+-----+
1 row in set (0.00 sec)

```

However, an overflow condition occurs if strict mode is in effect:

```

mysql> SET sql_mode='STRICT_ALL_TABLES';
Query OK, 0 rows affected (0.00 sec)

mysql> CREATE TABLE t (i TINYINT);
Query OK, 0 rows affected (0.00 sec)

mysql> INSERT INTO t SET i = 128;
ERROR 1264 (22003): Out of range value adjusted for column 'i' at row 1

mysql> SELECT i FROM t;
Empty set (0.00 sec)

```

Example 5: In strict mode and with `ERROR_FOR_DIVISION_BY_ZERO` set, division by zero causes an error, and not a result of `NULL`.

In non-strict mode, division by zero has a result of `NULL`:

```

mysql> SET sql_mode='';
Query OK, 0 rows affected (0.01 sec)

mysql> CREATE TABLE t (i TINYINT);
Query OK, 0 rows affected (0.00 sec)

mysql> INSERT INTO t SET i = 1 / 0;
Query OK, 1 row affected (0.00 sec)

mysql> SELECT i FROM t;
+-----+
| i     |
+-----+
| NULL  |
+-----+
1 row in set (0.03 sec)

```

However, division by zero is an error if the proper SQL modes are in effect:

```

mysql> SET sql_mode='STRICT_ALL_TABLES,ERROR_FOR_DIVISION_BY_ZERO';
Query OK, 0 rows affected (0.00 sec)

mysql> CREATE TABLE t (i TINYINT);
Query OK, 0 rows affected (0.00 sec)

mysql> INSERT INTO t SET i = 1 / 0;
ERROR 1365 (22012): Division by 0

mysql> SELECT i FROM t;
Empty set (0.01 sec)

```

Example 6. Prior to MySQL 5.0.3 (before precision math was introduced), exact-value and approximate-value literals both are converted to double-precision floating-point values:

```

mysql> SELECT VERSION();
+-----+
| VERSION() |
+-----+

```

```
| 4.1.18-log |
+-----+
1 row in set (0.01 sec)

mysql> CREATE TABLE t SELECT 2.5 AS a, 25E-1 AS b;
Query OK, 1 row affected (0.07 sec)
Records: 1 Duplicates: 0 Warnings: 0

mysql> DESCRIBE t;
+-----+-----+-----+-----+-----+-----+
| Field | Type          | Null | Key | Default | Extra |
+-----+-----+-----+-----+-----+-----+
| a     | double(3,1)   |      |     | 0.0     |       |
| b     | double        |      |     | 0       |       |
+-----+-----+-----+-----+-----+-----+
2 rows in set (0.04 sec)
```

As of MySQL 5.0.3, the approximate-value literal still is converted to floating-point, but the exact-value literal is handled as **DECIMAL**:

```
mysql> SELECT VERSION();
+-----+
| VERSION() |
+-----+
| 5.1.6-alpha-log |
+-----+
1 row in set (0.11 sec)

mysql> CREATE TABLE t SELECT 2.5 AS a, 25E-1 AS b;
Query OK, 1 row affected (0.01 sec)
Records: 1 Duplicates: 0 Warnings: 0

mysql> DESCRIBE t;
+-----+-----+-----+-----+-----+-----+
| Field | Type          | Null | Key | Default | Extra |
+-----+-----+-----+-----+-----+-----+
| a     | decimal(2,1) unsigned | NO   |     | 0.0     |       |
| b     | double        | NO   |     | 0       |       |
+-----+-----+-----+-----+-----+-----+
2 rows in set (0.01 sec)
```

Example 7. If the argument to an aggregate function is an exact numeric type, the result is also an exact numeric type, with a scale at least that of the argument.

Consider these statements:

```
mysql> CREATE TABLE t (i INT, d DECIMAL, f FLOAT);
mysql> INSERT INTO t VALUES(1,1,1);
mysql> CREATE TABLE y SELECT AVG(i), AVG(d), AVG(f) FROM t;
```

Result before MySQL 5.0.3 (prior to the introduction of precision math in MySQL):

```
mysql> DESCRIBE y;
+-----+-----+-----+-----+-----+-----+
| Field | Type          | Null | Key | Default | Extra |
+-----+-----+-----+-----+-----+-----+
| AVG(i) | double(17,4)  | YES  |     | NULL    |       |
| AVG(d) | double(17,4)  | YES  |     | NULL    |       |
| AVG(f) | double        | YES  |     | NULL    |       |
+-----+-----+-----+-----+-----+-----+
```

The result is a double no matter the argument type.

Result as of MySQL 5.0.3:

```
mysql> DESCRIBE y;
+-----+-----+-----+-----+-----+-----+
| Field | Type          | Null | Key | Default | Extra |
+-----+-----+-----+-----+-----+-----+
| AVG(i) | decimal(14,4) | YES  |     | NULL    |       |
| AVG(d) | decimal(14,4) | YES  |     | NULL    |       |
| AVG(f) | double        | YES  |     | NULL    |       |
+-----+-----+-----+-----+-----+-----+
```

The result is a double only for the floating-point argument. For exact type arguments, the result is also an exact type.

Chapter 12. SQL Statement Syntax

This chapter describes the syntax for the SQL statements supported by MySQL.

12.1. Data Definition Statements

12.1.1. ALTER DATABASE Syntax

```
ALTER {DATABASE | SCHEMA} [db_name]
    alter_specification ...
ALTER {DATABASE | SCHEMA} db_name
    UPGRADE DATA DIRECTORY NAME

alter_specification:
    [DEFAULT] CHARACTER SET [=] charset_name
    | [DEFAULT] COLLATE [=] collation_name
```

`ALTER DATABASE` enables you to change the overall characteristics of a database. These characteristics are stored in the `db.opt` file in the database directory. To use `ALTER DATABASE`, you need the `ALTER` privilege on the database. `ALTER SCHEMA` is a synonym for `ALTER DATABASE`.

The `CHARACTER SET` clause changes the default database character set. The `COLLATE` clause changes the default database collation. Section 9.1, “Character Set Support”, discusses character set and collation names.

You can see what character sets and collations are available using, respectively, the `SHOW CHARACTER SET` and `SHOW COLLATION` statements. See Section 12.5.5.4, “`SHOW CHARACTER SET Syntax`”, and Section 12.5.5.5, “`SHOW COLLATION Syntax`”, for more information.

The database name can be omitted from the first syntax, in which case the statement applies to the default database.

The syntax that includes the `UPGRADE DATA DIRECTORY NAME` clause updates the name of the directory associated with the database to use the encoding implemented in MySQL 5.1 for mapping database names to database directory names (see Section 8.2.3, “Mapping of Identifiers to File Names”). This clause is for use under these conditions:

- It is intended when upgrading MySQL to 5.1 or later from older versions.
- It is intended to update a database directory name to the current encoding format if the name contains special characters that need encoding.
- The statement is used by `mysqlcheck` (as invoked by `mysql_upgrade`).

For example, if a database in MySQL 5.0 has a name of `a-b-c`, the name contains instance of the ‘-’ character. In 5.0, the database directory is also named `a-b-c`, which is not necessarily safe for all file systems. In MySQL 5.1 and up, the same database name is encoded as `a@002db@002dc` to produce a file system-neutral directory name.

When a MySQL installation is upgraded to MySQL 5.1 or later from an older version, the server displays a name such as `a-b-c` (which is in the old format) as `#mysql150#a-b-c`, and you must refer to the name using the `#mysql150#` prefix. Use `UPGRADE DATA DIRECTORY NAME` in this case to explicitly tell the server to re-encode the database directory name to the current encoding format:

```
ALTER DATABASE `#mysql150#a-b-c` UPGRADE DATA DIRECTORY NAME;
```

After executing this statement, you can refer to the database as `a-b-c` without the special `#mysql150#` prefix.

MySQL Enterprise

In a production environment, alteration of a database is not a common occurrence and may indicate a security breach. Advisors provided as part of the MySQL Enterprise Monitor automatically alert you when data definition statements are issued. For more information, see <http://www.mysql.com/products/enterprise/advisors.html>.

12.1.2. ALTER EVENT Syntax

```
ALTER
    [DEFINER = { user | CURRENT_USER }]
    EVENT event_name
    [ON SCHEDULE schedule]
    [ON COMPLETION [NOT] PRESERVE]
    [RENAME TO new_event_name]
    [ENABLE | DISABLE | DISABLE ON SLAVE]
```

```
[COMMENT 'comment']
[DO sql_statement]
```

The `ALTER EVENT` statement is used to change one or more of the characteristics of an existing event without the need to drop and recreate it. The syntax for each of the `DEFINER`, `ON SCHEDULE`, `ON COMPLETION`, `COMMENT`, `ENABLE / DISABLE`, and `DO` clauses is exactly the same as when used with `CREATE EVENT`. (See [Section 12.1.9, “CREATE EVENT Syntax”](#).)

Any user can alter an event defined on a database for which that user has the `EVENT` privilege. When a user executes a successful `ALTER EVENT` statement, that user becomes the definer for the affected event.

`ALTER EVENT` works only with an existing event:

```
mysql> ALTER EVENT no_such_event
> ON SCHEDULE
> EVERY '2:3' DAY_HOUR;
ERROR 1517 (HY000): UNKNOWN EVENT 'NO_SUCH_EVENT'
```

In each of the following examples, assume that the event named `myevent` is defined as shown here:

```
CREATE EVENT myevent
ON SCHEDULE
EVERY 6 HOUR
COMMENT 'A sample comment.'
DO
UPDATE myschema.mytable SET mycol = mycol + 1;
```

The following statement changes the schedule for `myevent` from once every six hours starting immediately to once every twelve hours, starting four hours from the time the statement is run:

```
ALTER EVENT myevent
ON SCHEDULE
EVERY 12 HOUR
STARTS CURRENT_TIMESTAMP + INTERVAL 4 HOUR;
```

It is possible to change multiple characteristics of an event in a single statement. This example changes the SQL statement executed by `myevent` to one that deletes all records from `mytable`; it also changes the schedule for the event such that it executes once, one day after this `ALTER EVENT` statement is run.

```
ALTER TABLE myevent
ON SCHEDULE
AT CURRENT_TIMESTAMP + INTERVAL 1 DAY
DO
TRUNCATE TABLE myschema.mytable;
```

It is necessary to include only those options in an `ALTER EVENT` statement which correspond to characteristics that you actually wish to change; options which are omitted retain their existing values. This includes any default values for `CREATE EVENT` such as `ENABLE`.

To disable `myevent`, use this `ALTER EVENT` statement:

```
ALTER EVENT myevent
DISABLE;
```

The `ON SCHEDULE` clause may use expressions involving built-in MySQL functions and user variables to obtain any of the *timestamp* or *interval* values which it contains. You may not use stored routines or user-defined functions in such expressions, nor may you use any table references; however, you may use `SELECT FROM DUAL`. This is true for both `ALTER EVENT` and `CREATE EVENT` statements. References to stored routines, user-defined functions, and tables in such cases are specifically disallowed, and fail with an error (see [Bug#22830](#)).

An `ALTER EVENT` statement that contains another `ALTER EVENT` statement in its `DO` clause appears to succeed; however, when the server attempts to execute the resulting scheduled event, the execution fails with an error.

To rename an event, use the `ALTER EVENT` statement's `RENAME TO` clause. This statement renames the event `myevent` to `yourevent`:

```
ALTER EVENT myevent
RENAME TO yourevent;
```

You can also move an event to a different database using `ALTER EVENT ... RENAME TO ...` and `db_name.event_name` notation, as shown here:

```
ALTER EVENT olddb.myevent
RENAME TO newdb.myevent;
```

To execute the previous statement, the user executing it must have the `EVENT` privilege on both the `olddb` and `newdb` databases.

Note

There is no `RENAME EVENT` statement.

A third value may also appear in place of `ENABLED` or `DISABLED`; `DISABLE ON SLAVE` is used on a replication slave to indicate an event which was created on the master and replicated to the slave, but which is not executed on the slave. Normally, `DISABLE ON SLAVE` is set automatically as required; however, there are some circumstances under which you may want or need to change it manually. See [Section 16.3.1.7, “Replication of Invoked Features”](#), for more information.

12.1.3. ALTER FUNCTION Syntax

```
ALTER FUNCTION func_name [characteristic ...]

characteristic:
{ CONTAINS SQL | NO SQL | READS SQL DATA | MODIFIES SQL DATA }
SQL SECURITY { DEFINER | INVOKER }
COMMENT 'string'
```

This statement can be used to change the characteristics of a stored function. More than one change may be specified in an `ALTER FUNCTION` statement. However, you cannot change the parameters or body of a stored function using this statement; to make such changes, you must drop and re-create the function using `DROP FUNCTION` and `CREATE FUNCTION`.

You must have the `ALTER ROUTINE` privilege for the function. (That privilege is granted automatically to the function creator.) If binary logging is enabled, the `ALTER FUNCTION` statement might also require the `SUPER` privilege, as described in [Section 18.6, “Binary Logging of Stored Programs”](#).

12.1.4. ALTER PROCEDURE Syntax

```
ALTER PROCEDURE proc_name [characteristic ...]

characteristic:
{ CONTAINS SQL | NO SQL | READS SQL DATA | MODIFIES SQL DATA }
SQL SECURITY { DEFINER | INVOKER }
COMMENT 'string'
```

This statement can be used to change the characteristics of a stored procedure. More than one change may be specified in an `ALTER PROCEDURE` statement. However, you cannot change the parameters or body of a stored procedure using this statement; to make such changes, you must drop and re-create the procedure using `DROP PROCEDURE` and `CREATE PROCEDURE`.

You must have the `ALTER ROUTINE` privilege for the procedure. (That privilege is granted automatically to the procedure creator.)

12.1.5. ALTER SERVER Syntax

```
ALTER SERVER server_name
OPTIONS (option [, option] ...)
```

Alters the server information for *server_name*, adjusting the specified options as per the `CREATE SERVER` command. See [Section 12.1.13, “CREATE SERVER Syntax”](#). The corresponding fields in the `mysql.servers` table are updated accordingly. This statement requires the `SUPER` privilege.

For example, to update the `USER` option:

```
ALTER SERVER s OPTIONS (USER 'sally');
```

`ALTER SERVER` does not cause an automatic commit.

12.1.6. ALTER TABLE Syntax

```
ALTER [ONLINE | OFFLINE] [IGNORE] TABLE tbl_name
alter_specification [, alter_specification] ...

alter_specification:
col_name column_definition
  [FIRST | AFTER col_name]
| ADD [COLUMN] (col_name column_definition,...)
| ADD {INDEX|KEY} [index_name]
  [index_type] (index_col_name,...) [index_option] ...
| ADD [CONSTRAINT [symbol]] PRIMARY KEY
  [index_type] (index_col_name,...) [index_option] ...
```

```

| ADD [CONSTRAINT [symbol]]
  UNIQUE [INDEX|KEY] [index_name]
  [index_type] (index_col_name,...) [index_option] ...
| ADD FULLTEXT [INDEX|KEY] [index_name]
  (index_col_name,...) [index_option] ...
| ADD SPATIAL [INDEX|KEY] [index_name]
  (index_col_name,...) [index_option] ...
| ADD [CONSTRAINT [symbol]]
  FOREIGN KEY [index_name] (index_col_name,...)
  reference_definition
| ALTER [COLUMN] col_name {SET DEFAULT literal | DROP DEFAULT}
| CHANGE [COLUMN] old_col_name new_col_name column_definition
  [FIRST|AFTER col_name]
| MODIFY [COLUMN] col_name column_definition
  [FIRST | AFTER col_name]
| DROP [COLUMN] col_name
| DROP PRIMARY KEY
| DROP {INDEX|KEY} index_name
| DROP FOREIGN KEY fk_symbol
| DISABLE KEYS
| ENABLE KEYS
| RENAME [TO] new_tbl_name
| ORDER BY col_name [, col_name] ...
| CONVERT TO CHARACTER SET charset_name [COLLATE collation_name]
| [DEFAULT] CHARACTER SET [=] charset_name [COLLATE [=] collation_name]
| DISCARD TABLESPACE
| IMPORT TABLESPACE
| partition_options
| ADD PARTITION (partition_definition)
| DROP PARTITION partition_names
| COALESCE PARTITION number
| REORGANIZE PARTITION [partition_names INTO (partition_definitions)]
| ANALYZE PARTITION partition_names
| CHECK PARTITION partition_names
| OPTIMIZE PARTITION partition_names
| REBUILD PARTITION partition_names
| REPAIR PARTITION partition_names
| REMOVE PARTITIONING

index_col_name:
  col_name [(length)] [ASC | DESC]

index_type:
  USING {BTREE | HASH | RTREE}

index_option:
  KEY_BLOCK_SIZE [=] value
  | index_type
  | WITH PARSER parser_name
  | COMMENT 'string'

table_option [[,] table_option] ...

```

ALTER TABLE enables you to change the structure of an existing table. For example, you can add or delete columns, create or destroy indexes, change the type of existing columns, or rename columns or the table itself. You can also change the comment for the table and type of the table.

The syntax for many of the allowable alterations is similar to clauses of the **CREATE TABLE** statement. See [Section 12.1.14, “CREATE TABLE Syntax”](#), for more information.

Some operations may result in warnings if attempted on a table for which the storage engine does not support the operation. These warnings can be displayed with **SHOW WARNINGS**. See [Section 12.5.5.41, “SHOW WARNINGS Syntax”](#).

In most cases, **ALTER TABLE** works by making a temporary copy of the original table. The alteration is performed on the copy, and then the original table is deleted and the new one is renamed. While **ALTER TABLE** is executing, the original table is readable by other sessions. Updates and writes to the table are stalled until the new table is ready, and then are automatically redirected to the new table without any failed updates. The temporary table is created in the database directory of the new table. This can be different from the database directory of the original table if **ALTER TABLE** is renaming the table to a different database.

In some cases, no temporary table is necessary:

- Alterations that modify only table metadata and not table data can be made immediately by altering the table's `.frm` file and not touching table contents. The following changes are fast alterations that can be made this way:
 - Renaming a column or index.
 - Changing the default value of a column.
 - Changing the definition of an **ENUM** or **SET** column by adding new enumeration or set members to the *end* of the list of valid member values.

In some cases, an operation such as changing a **VARCHAR(10)** column to **VARCHAR(15)** may be immediate, but this depends on the storage engine for the table. A change such as **VARCHAR(10)** to a length greater than 255 is not immediate be-

cause data values must be modified from using one byte to store the length to using two bytes.

- If you use `ALTER TABLE tbl_name RENAME TO new_tbl_name` without any other options, MySQL simply renames any files that correspond to the table `tbl_name`. (You can also use the `RENAME TABLE` statement to rename tables. See [Section 12.1.26, “RENAME TABLE Syntax”](#).) Any privileges granted specifically for the renamed table are not migrated to the new name. They must be changed manually.
- `ALTER TABLE ... ADD PARTITION` creates no temporary table except for MySQL Cluster. `ADD` or `DROP` operations for `RANGE` or `LIST` partitions are immediate operations or nearly so. `ADD` or `COALESCE` operations for `HASH` or `KEY` partitions copy data between changed partitions; unless `LINEAR HASH` or `LINEAR KEY` was used, this is much the same as creating a new table (although the operation is done partition by partition). `REORGANIZE` operations copy only changed partitions and do not touch unchanged ones.

If other cases, MySQL creates a temporary table, even if the data wouldn't strictly need to be copied. For `MyISAM` tables, you can speed up the index re-creation operation (which is the slowest part of the alteration process) by setting the `myisam_sort_buffer_size` system variable to a high value.

For information on troubleshooting `ALTER TABLE`, see [Section B.1.7.1, “Problems with ALTER TABLE”](#).

- To use `ALTER TABLE`, you need `ALTER`, `INSERT`, and `CREATE` privileges for the table.
- `ADD INDEX` and `DROP INDEX` operations are performed online when the indexes are on variable-width columns only.

The `ONLINE` keyword can be used to perform online `ADD COLUMN`, `ADD INDEX` (including `CREATE INDEX` statements), and `DROP INDEX` operations on `NDBCLUSTER` tables beginning with MySQL Cluster NDB 6.2.5 and MySQL Cluster NDB 6.3.3. Online renaming of `NDBCLUSTER` tables is also supported.

Currently you cannot add disk-based columns to `NDBCLUSTER` tables online. This means that, if you wish to add an in-memory column to an `NDBCLUSTER` table that uses a table-level `STORAGE DISK` option, you must declare the new column as using memory-based storage explicitly. For example — assuming that you have already created tablespace `ts1` — suppose that you create table `t1` as follows:

```
mysql> CREATE TABLE t1 (
>   c1 INT NOT NULL PRIMARY KEY,
>   c2 VARCHAR(30)
> )
> TABLESPACE ts1 STORAGE DISK
> ENGINE NDBCLUSTER;
Query OK, 0 rows affected (1.73 sec)
Records: 0 Duplicates: 0 Warnings: 0
```

You can add a new in-memory column to this table online as shown here:

```
mysql> ALTER ONLINE TABLE t1 ADD COLUMN c3 INT COLUMN_FORMAT DYNAMIC STORAGE MEMORY;
Query OK, 0 rows affected (1.25 sec)
Records: 0 Duplicates: 0 Warnings: 0
```

This statement fails if the `STORAGE MEMORY` option is omitted:

```
mysql> ALTER ONLINE TABLE t1 ADD COLUMN c3 INT COLUMN_FORMAT DYNAMIC;
ERROR 1235 (42000): THIS VERSION OF MYSQL DOESN'T YET SUPPORT
'ALTER ONLINE TABLE t1 ADD COLUMN c3 INT COLUMN_FORMAT DYNAMIC'
```

If you omit the `COLUMN_FORMAT DYNAMIC` option, the dynamic column format is employed automatically, but a warning is issued, as shown here:

```
mysql> ALTER ONLINE TABLE t1 ADD COLUMN c3 INT STORAGE MEMORY;
Query OK, 0 rows affected, 1 warning (1.17 sec)
Records: 0 Duplicates: 0 Warnings: 0

mysql> SHOW WARNINGS;
+-----+-----+-----+
| Level | Code | Message |
+-----+-----+-----+
| Warning | 1478 | Converted FIXED field to DYNAMIC to enable on-line ADD COLUMN |
+-----+-----+-----+
1 row in set (0.00 sec)

mysql> SHOW CREATE TABLE t1\G
***** 1. row *****
Table: t1
Create Table: CREATE TABLE `t1` (
  `c1` int(11) NOT NULL,
  `c2` varchar(30) DEFAULT NULL,
  `c3` int(11) /*!50120 STORAGE MEMORY */ /*!50120 COLUMN_FORMAT DYNAMIC */ DEFAULT NULL,
  `t4` int(11) /*!50120 STORAGE MEMORY */ DEFAULT NULL,
```

```
PRIMARY KEY (`c1`)
) /*!50100 TABLESPACE ts_1 STORAGE DISK */ ENGINE=ndbcluster DEFAULT CHARSET=latin1
1 row in set (0.03 sec)
```

Prior to MySQL Cluster NDB 6.2.17, 6.3.23, and 6.4.3, adding in-memory columns to tables that were created using a table-level or column-level `STORAGE DISK` option did not work correctly. ([Bug#42549](#))

It is also possible to rename `MyISAM` tables and columns online. However, you cannot use `ONLINE` with operations that add or drop columns or indexes of `MyISAM` tables.

Online operations are non-copying; that is, they do not require that indexes be re-created. They do not lock the table being altered from access by other API nodes in a MySQL Cluster (but see *Limitations* later in this section). Such operations do not require single user mode for `NDBCLUSTER` table alterations made in a cluster with multiple API nodes; transactions can continue uninterrupted during online DDL operations.

In MySQL Cluster NDB 7.0, it is also possible to use the statement `ALTER ONLINE TABLE ... REORGANIZE PARTITION` with no `partition_names INTO (partition_definitions)` option on `NDBCLUSTER` tables. This can be used to redistribute MySQL Cluster data among new data nodes that have been added to the cluster online. More information about this statement is given later in this section. For more information about adding data nodes online to a MySQL Cluster, see [Adding MySQL Cluster Data Nodes Online](#).

Prior to MySQL Cluster NDB 6.4.3, `ALTER ONLINE TABLE ... REORGANIZE PARTITION` with no `partition_names INTO (partition_definitions)` option did not work correctly with Disk Data tables or with in-memory `NDBCLUSTER` tables having one or more disk-based columns. ([Bug#42549](#))

The `ONLINE` and `OFFLINE` keywords are supported only in MySQL Cluster NDB 6.2, 6.3, 7.0 (beginning with versions 6.2.5, 6.3.3, and 6.4.0), and later MySQL Cluster release series. In other versions of MySQL:

1. The server determines automatically whether an `ADD INDEX` or `DROP INDEX` operation can be (and is) performed online or offline; if the column is of a variable-width data type, then the operation is performed online. It is not possible to override the server behavior in this regard.
2. Attempting to use the `ONLINE` or `OFFLINE` keyword in an `ALTER TABLE` statement results in an error.

Limitations. Online `ALTER TABLE` operations that add columns are subject to the following limitations:

- The table being altered is not locked with respect to API nodes other than the one on which an online `ALTER TABLE`, `ADD COLUMN`, `CREATE INDEX` or `DROP INDEX` statement is run. However, the table is locked against any other operations originating on the *same* API node while the online operation is being executed.
- The table to be altered must have an explicit primary key; the hidden primary key created by the `NDBCLUSTER` storage engine is not sufficient for this purpose. Columns to be added online must meet the following criteria:
 - Such columns must be dynamic; that is, it must be possible to create them using `COLUMN_FORMAT DYNAMIC`.
 - Such columns must be nullable, and not have any explicit default value other than `NULL`. Columns added online are automatically created as `DEFAULT NULL`, as can be seen here:

```
mysql> CREATE TABLE t1 (
>   c1 INT NOT NULL AUTO_INCREMENT PRIMARY KEY
> ) ENGINE=NDBCLUSTER;
Query OK, 0 rows affected (1.44 sec)

mysql> ALTER ONLINE TABLE t1
>   ADD COLUMN c2 INT,
>   ADD COLUMN c3 INT;
Query OK, 0 rows affected, 2 warnings (0.93 sec)

mysql> SHOW CREATE TABLE t2\G
***** 1. row *****
Table: t2
Create Table: CREATE TABLE `t2` (
  `c1` int(11) NOT NULL AUTO_INCREMENT,
  `c2` int(11) DEFAULT NULL,
  `c3` int(11) DEFAULT NULL,
  PRIMARY KEY (`c1`)
) ENGINE=ndbcluster DEFAULT CHARSET=latin1
1 row in set (0.00 sec)
```

- Columns must be added following any existing columns. If you attempt to add a column online before any existing columns, the statement fails with an error. Trying to add a column online using the `FIRST` keyword also fails.

In addition, existing table columns cannot be reordered online.

- The storage engine used by the table cannot be changed online.

The preceding limitations do not apply to operations that merely rename tables or columns.

If the storage engine supports online `ALTER TABLE`, then fixed-format columns will be converted to dynamic when columns are added online, or when indexes are created or dropped online, as shown here:

```
mysql> CREATE TABLE t1 (
>   c1 INT NOT NULL AUTO_INCREMENT PRIMARY KEY
> ) ENGINE=NDBCLUSTER;
Query OK, 0 rows affected (1.44 sec)

Columns are not converted from `FIXED` to `DYNAMIC` column format by renaming operations. For more information about `COLUMN_FORMAT`, see [Section 12.1.14, “CREATE TABLE Syntax”](#).

- Online `DROP COLUMN` operations are not supported.
- A given online `ALTER TABLE` can use only one of `ADD COLUMN`, `ADD INDEX`, or `DROP INDEX`. One or more columns can be added online in a single statement; only one index may be created or dropped online in a single statement.

The `KEY`, `CONSTRAINT`, and `IGNORE` keywords are supported in `ALTER TABLE` statements using the `ONLINE` keyword.

The `ONLINE` and `OFFLINE` keywords are also supported in `ALTER TABLE ... CHANGE ...` statements that rename columns of `MyISAM` tables.

- `IGNORE` is a MySQL extension to standard SQL. It controls how `ALTER TABLE` works if there are duplicates on unique keys in the new table or if warnings occur when strict mode is enabled. If `IGNORE` is not specified, the copy is aborted and rolled back if duplicate-key errors occur. If `IGNORE` is specified, only the first row is used of rows with duplicates on a unique key. The other conflicting rows are deleted. Incorrect values are truncated to the closest matching acceptable value.
- `table_option` signifies a table option of the kind that can be used in the `CREATE TABLE` statement, such as `ENGINE`, `AUTO_INCREMENT`, or `AVG_ROW_LENGTH`. ([Section 12.1.14, “CREATE TABLE Syntax”](#), lists all table options.) However, `ALTER TABLE` ignores the `DATA DIRECTORY` and `INDEX DIRECTORY` table options.

For example, to convert a table to be an `InnoDB` table, use this statement:

```
ALTER TABLE t1 ENGINE = InnoDB;
```

The outcome of attempting to change a table's storage engine is affected by whether the desired storage engine is available and the setting of the `NO_ENGINE_SUBSTITUTION` SQL mode, as described in [Section 5.1.7, “Server SQL Modes”](#).

To prevent inadvertent loss of data, `ALTER TABLE` cannot be used to change the storage engine of a table to `MERGE` or `BLACKHOLE`.

To change the value of the `AUTO_INCREMENT` counter to be used for new rows, do this:

```
ALTER TABLE t2 AUTO_INCREMENT = value;
```

You cannot reset the counter to a value less than or equal to any that have already been used. For `MyISAM`, if the value is less than or equal to the maximum value currently in the `AUTO_INCREMENT` column, the value is reset to the current maximum plus one. For `InnoDB`, if the value is less than the current maximum value in the column, no error occurs and the current sequence value is not changed.

- You can issue multiple `ADD`, `ALTER`, `DROP`, and `CHANGE` clauses in a single `ALTER TABLE` statement, separated by commas. This is a MySQL extension to standard SQL, which allows only one of each clause per `ALTER TABLE` statement. For example, to drop multiple columns in a single statement, do this:

```
ALTER TABLE t2 DROP COLUMN c, DROP COLUMN d;
```

- `CHANGE col_name`, `DROP col_name`, and `DROP INDEX` are MySQL extensions to standard SQL.
- `MODIFY` is an Oracle extension to `ALTER TABLE`.
- The word `COLUMN` is optional and can be omitted.
- `column_definition` clauses use the same syntax for `ADD` and `CHANGE` as for `CREATE TABLE`. See [Section 12.1.14, “CREATE TABLE Syntax”](#).
- You can rename a column using a `CHANGE old_col_name new_col_name column_definition` clause. To do so, specify the old and new column names and the definition that the column currently has. For example, to rename an `INTEGER` column from `a` to `b`, you can do this:

```
ALTER TABLE t1 CHANGE a b INTEGER;
```

If you want to change a column's type but not the name, `CHANGE` syntax still requires an old and new column name, even if they are the same. For example:

```
ALTER TABLE t1 CHANGE b b BIGINT NOT NULL;
```

You can also use `MODIFY` to change a column's type without renaming it:

```
ALTER TABLE t1 MODIFY b BIGINT NOT NULL;
```

When you use `CHANGE` or `MODIFY`, `column_definition` must include the data type and all attributes that should apply to the new column, other than index attributes such as `PRIMARY KEY` or `UNIQUE`. Attributes present in the original definition but not specified for the new definition are not carried forward. Suppose a column `col1` is defined as `INT UNSIGNED DEFAULT 1 COMMENT 'my column'` and you modify the column as follows:

```
ALTER TABLE t1 MODIFY col1 BIGINT;
```

The resulting column will be defined as `BIGINT`, but will not include the attributes `UNSIGNED DEFAULT 1 COMMENT 'my column'`. To retain them, the statement should be:

```
ALTER TABLE t1 MODIFY col1 BIGINT UNSIGNED DEFAULT 1 COMMENT 'my column';
```

- When you change a data type using `CHANGE` or `MODIFY`, MySQL tries to convert existing column values to the new type as well as possible.

Warning

This conversion may result in alteration of data. For example, if you shorten a string column, values may be truncated. To prevent the operation from succeeding if conversions to the new data type would result in loss of data, enable strict SQL mode before using `ALTER TABLE` (see [Section 5.1.7, “Server SQL Modes”](#)).

- To add a column at a specific position within a table row, use `FIRST` or `AFTER col_name`. The default is to add the column last. You can also use `FIRST` and `AFTER` in `CHANGE` or `MODIFY` operations to reorder columns within a table.
- `ALTER ... SET DEFAULT` or `ALTER ... DROP DEFAULT` specify a new default value for a column or remove the old default value, respectively. If the old default is removed and the column can be `NULL`, the new default is `NULL`. If the column cannot be `NULL`, MySQL assigns a default value as described in [Section 10.1.4, “Data Type Default Values”](#).

- `DROP INDEX` removes an index. This is a MySQL extension to standard SQL. See [Section 12.1.20, “DROP INDEX Syntax”](#). If you are unsure of the index name, use `SHOW INDEX FROM tbl_name`.
- If columns are dropped from a table, the columns are also removed from any index of which they are a part. If all columns that make up an index are dropped, the index is dropped as well. If you use `CHANGE` or `MODIFY` to shorten a column for which an index exists on the column, and the resulting column length is less than the index length, MySQL shortens the index automatically.
- If a table contains only one column, the column cannot be dropped. If what you intend is to remove the table, use `DROP TABLE` instead.
- `DROP PRIMARY KEY` drops the primary key. If there is no primary key, an error occurs.

If you add a `UNIQUE INDEX` or `PRIMARY KEY` to a table, it is stored before any non-unique index so that MySQL can detect duplicate keys as early as possible.

- Some storage engines allow you to specify an index type when creating an index. The syntax for the *index_type* specifier is `USING type_name`. For details about `USING`, see [Section 12.1.11, “CREATE INDEX Syntax”](#). The preferred position is after the column list. Use of the option before the column list will no longer be recognized in a future MySQL release.

index_option values specify additional options for an index. `USING` is one such option. For details about allowable *index_option* values, see [Section 12.1.11, “CREATE INDEX Syntax”](#).

- After an `ALTER TABLE` statement, it may be necessary to run `ANALYZE TABLE` to update index cardinality information. See [Section 12.5.5.23, “SHOW INDEX Syntax”](#).
- `ORDER BY` enables you to create the new table with the rows in a specific order. Note that the table does not remain in this order after inserts and deletes. This option is useful primarily when you know that you are mostly to query the rows in a certain order most of the time. By using this option after major changes to the table, you might be able to get higher performance. In some cases, it might make sorting easier for MySQL if the table is in order by the column that you want to order it by later.

`ORDER BY` syntax allows for one or more column names to be specified for sorting, each of which optionally can be followed by `ASC` or `DESC` to indicate ascending or descending sort order, respectively. The default is ascending order. Only column names are allowed as sort criteria; arbitrary expressions are not allowed.

`ORDER BY` does not make sense for `InnoDB` tables that contain a user-defined clustered index (`PRIMARY KEY` or `NOT NULL UNIQUE` index). `InnoDB` always orders table rows according to such an index if one is present.

Note

When used on a partitioned table, `ALTER TABLE ... ORDER BY` orders rows within each partition only.

- If you use `ALTER TABLE` on a `MyISAM` table, all non-unique indexes are created in a separate batch (as for `REPAIR TABLE`). This should make `ALTER TABLE` much faster when you have many indexes.

This feature can be activated explicitly for a `MyISAM` table. `ALTER TABLE ... DISABLE KEYS` tells MySQL to stop updating non-unique indexes. `ALTER TABLE ... ENABLE KEYS` then should be used to re-create missing indexes. MySQL does this with a special algorithm that is much faster than inserting keys one by one, so disabling keys before performing bulk insert operations should give a considerable speedup. Using `ALTER TABLE ... DISABLE KEYS` requires the `INDEX` privilege in addition to the privileges mentioned earlier.

While the non-unique indexes are disabled, they are ignored for statements such as `SELECT` and `EXPLAIN` that otherwise would use them.

- If `ALTER TABLE` for an `InnoDB` table results in changes to column values (for example, because a column is truncated), `InnoDB`'s `FOREIGN KEY` constraint checks do not notice possible violations caused by changing the values.
- The `FOREIGN KEY` and `REFERENCES` clauses are supported by the `InnoDB` storage engine, which implements `ADD [CONSTRAINT [symbol]] FOREIGN KEY (...) REFERENCES ... (...)`. See [Section 13.6.4.4, “FOREIGN KEY Constraints”](#). For other storage engines, the clauses are parsed but ignored. The `CHECK` clause is parsed but ignored by all storage engines. See [Section 12.1.14, “CREATE TABLE Syntax”](#). The reason for accepting but ignoring syntax clauses is for compatibility, to make it easier to port code from other SQL servers, and to run applications that create tables with references. See [Section 1.7.5, “MySQL Differences from Standard SQL”](#).

Important

The inline `REFERENCES` specifications where the references are defined as part of the column specification are silently ignored by `InnoDB`. `InnoDB` only accepts `REFERENCES` clauses defined as part of a separate `FOREIGN KEY` specification.

Note

Partitioned tables do not support foreign keys. See [Section 17.5, “Restrictions and Limitations on Partitioning”](#), for more information.

- [InnoDB](#) supports the use of `ALTER TABLE` to drop foreign keys:

```
ALTER TABLE tbl_name DROP FOREIGN KEY fk_symbol;
```

For more information, see [Section 13.6.4.4, “FOREIGN KEY Constraints”](#).

- You cannot add a foreign key and drop a foreign key in separate clauses of a single `ALTER TABLE` statement. You must use separate statements.
- For an [InnoDB](#) table that is created with its own tablespace in an `.ibd` file, that file can be discarded and imported. To discard the `.ibd` file, use this statement:

```
ALTER TABLE tbl_name DISCARD TABLESPACE;
```

This deletes the current `.ibd` file, so be sure that you have a backup first. Attempting to access the table while the tablespace file is discarded results in an error.

To import the backup `.ibd` file back into the table, copy it into the database directory, and then issue this statement:

```
ALTER TABLE tbl_name IMPORT TABLESPACE;
```

See [Section 13.6.2.1, “Using Per-Table Tablespaces”](#).

- Pending `INSERT DELAYED` statements are lost if a table is write locked and `ALTER TABLE` is used to modify the table structure.
- If you want to change the table default character set and all character columns (`CHAR`, `VARCHAR`, `TEXT`) to a new character set, use a statement like this:

```
ALTER TABLE tbl_name CONVERT TO CHARACTER SET charset_name;
```

For a column that has a data type of `VARCHAR` or one of the `TEXT` types, `CONVERT TO CHARACTER SET` will change the data type as necessary to ensure that the new column is long enough to store as many characters as the original column. For example, a `TEXT` column has two length bytes, which store the byte-length of values in the column, up to a maximum of 65,535. For a `latin1 TEXT` column, each character requires a single byte, so the column can store up to 65,535 characters. If the column is converted to `utf8`, each character might require up to three bytes, for a maximum possible length of $3 \times 65,535 = 196,605$ bytes. That length will not fit in a `TEXT` column's length bytes, so MySQL will convert the data type to `MEDIUMTEXT`, which is the smallest string type for which the length bytes can record a value of 196,605. Similarly, a `VARCHAR` column might be converted to `MEDIUMTEXT`.

To avoid data type changes of the type just described, do not use `CONVERT TO CHARACTER SET`. Instead, use `MODIFY` to change individual columns. For example:

```
ALTER TABLE t MODIFY latin1_text_col TEXT CHARACTER SET utf8;
ALTER TABLE t MODIFY latin1_varchar_col VARCHAR(M) CHARACTER SET utf8;
```

If you specify `CONVERT TO CHARACTER SET binary`, the `CHAR`, `VARCHAR`, and `TEXT` columns are converted to their corresponding binary string types (`BINARY`, `VARBINARY`, `BLOB`). This means that the columns no longer will have a character set and a subsequent `CONVERT TO` operation will not apply to them.

If `charset_name` is `DEFAULT`, the database character set is used.

Warning

The `CONVERT TO` operation converts column values between the character sets. This is *not* what you want if you have a column in one character set (like `latin1`) but the stored values actually use some other, incompatible character set (like `utf8`). In this case, you have to do the following for each such column:

```
ALTER TABLE t1 CHANGE c1 c1 BLOB;
ALTER TABLE t1 CHANGE c1 c1 TEXT CHARACTER SET utf8;
```

The reason this works is that there is no conversion when you convert to or from `BLOB` columns.

To change only the *default* character set for a table, use this statement:

```
ALTER TABLE tbl_name DEFAULT CHARACTER SET charset_name;
```

The word `DEFAULT` is optional. The default character set is the character set that is used if you do not specify the character set for columns that you add to a table later (for example, with `ALTER TABLE ... ADD column`).

- Partitioning-related clauses for `ALTER TABLE` can be used with partitioned tables for repartitioning, for adding, dropping, merging, and splitting partitions, and for performing partitioning maintenance.

Simply using a *partition_options* clause with `ALTER TABLE` on a partitioned table repartitions the table according to the partitioning scheme defined by the *partition_options*. This clause always begins with `PARTITION BY`, and follows the same syntax and other rules as apply to the *partition_options* clause for `CREATE TABLE` (see [Section 12.1.14, “CREATE TABLE Syntax”](#), for more detailed information), and can also be used to partition an existing table that is not already partitioned. For example, consider a (non-partitioned) table defined as shown here:

```
CREATE TABLE t1 (
  id INT,
  year_col INT
);
```

This table can be partitioned by `HASH`, using the `id` column as the partitioning key, into 8 partitions by means of this statement:

```
ALTER TABLE t1
  PARTITION BY HASH(id)
  PARTITIONS 8;
```

The table that results from using an `ALTER TABLE ... PARTITION BY` statement must follow the same rules as one created using `CREATE TABLE ... PARTITION BY`. This includes the rules governing the relationship between any unique keys (including any primary key) that the table might have, and the column or columns used in the partitioning expression, as discussed in [Section 17.5.1, “Partitioning Keys, Primary Keys, and Unique Keys”](#). The `CREATE TABLE ... PARTITION BY` rules for specifying the number of partitions also apply to `ALTER TABLE ... PARTITION BY`.

The *partition_definition* clause for `ALTER TABLE ADD PARTITION` supports the same options as the clause of the same name for the `CREATE TABLE` statement. (See [Section 12.1.14, “CREATE TABLE Syntax”](#), for the syntax and description.) Suppose that you have the partitioned table created as shown here:

```
CREATE TABLE t1 (
  id INT,
  year_col INT
)
PARTITION BY RANGE (year_col) (
  PARTITION p0 VALUES LESS THAN (1991),
  PARTITION p1 VALUES LESS THAN (1995),
  PARTITION p2 VALUES LESS THAN (1999)
);
```

You can add a new partition `p3` to this table for storing values less than 2002 as follows:

```
ALTER TABLE t1 ADD PARTITION (PARTITION p3 VALUES LESS THAN (2002));
```

`DROP PARTITION` can be used to drop one or more `RANGE` or `LIST` partitions. This statement cannot be used with `HASH` or `KEY` partitions; instead, use `COALESCE PARTITION` (see below). Any data that was stored in the dropped partitions named in the *partition_names* list is discarded. For example, given the table `t1` defined previously, you can drop the partitions named `p0` and `p1` as shown here:

```
ALTER TABLE t1 DROP PARTITION p0, p1;
```

Note

`DROP PARTITION` does not work with tables that use the `NDBCLUSTER` storage engine. See [Section 17.3.1, “Management of RANGE and LIST Partitions”](#), and [Known Limitations of MySQL Cluster](#).

`ADD PARTITION` and `DROP PARTITION` do not currently support `IF [NOT] EXISTS`. It is also not possible to rename a partition or a partitioned table. Instead, if you wish to rename a partition, you must drop and re-create the partition; if you wish to rename a partitioned table, you must instead drop all partitions, rename the table, and then add back the partitions that were dropped.

`COALESCE PARTITION` can be used with a table that is partitioned by `HASH` or `KEY` to reduce the number of partitions by

number. Suppose that you have created table *t2* using the following definition:

```
CREATE TABLE t2 (
  name VARCHAR (30),
  started DATE
)
PARTITION BY HASH( YEAR(started) )
PARTITIONS 6;
```

You can reduce the number of partitions used by *t2* from 6 to 4 using the following statement:

```
ALTER TABLE t2 COALESCE PARTITION 2;
```

The data contained in the last *number* partitions will be merged into the remaining partitions. In this case, partitions 4 and 5 will be merged into the first 4 partitions (the partitions numbered 0, 1, 2, and 3).

To change some but not all the partitions used by a partitioned table, you can use `REORGANIZE PARTITION`. This statement can be used in several ways:

- To merge a set of partitions into a single partition. This can be done by naming several partitions in the *partition_names* list and supplying a single definition for *partition_definition*.
- To split an existing partition into several partitions. You can accomplish this by naming a single partition for *partition_names* and providing multiple *partition_definitions*.
- To change the ranges for a subset of partitions defined using `VALUES LESS THAN` or the value lists for a subset of partitions defined using `VALUES IN`.
- This statement may also be used without the *partition_names INTO (partition_definitions)* option on tables that are automatically partitioned using `HASH` partitioning in order to force redistribution of data. (Currently, only `NDBCLUSTER` tables are automatically partitioned in this way.) This is useful in MySQL Cluster NDB 6.4.0 and later where, after you have added new MySQL Cluster data nodes online to an existing MySQL Cluster, you wish to redistribute existing MySQL Cluster table data to the new data nodes. In such cases, you should invoke the statement with the `ONLINE` option; in words words, as shown here:

```
ALTER ONLINE TABLE table REORGANIZE PARTITION;
```

You cannot perform other DDL concurrently with online table reorganization — that is, no other DDL statements can be issued while an `ALTER ONLINE TABLE ... REORGANIZE PARTITION` statement is executing. For more information about adding MySQL Cluster data nodes online, see [Adding MySQL Cluster Data Nodes Online](#).

Attempting to use `REORGANIZE PARTITION` without the *partition_names INTO (partition_definitions)* option on explicitly partitioned tables results in the error `REORGANIZE PARTITION WITHOUT PARAMETERS CAN ONLY BE USED ON AUTO-PARTITIONED TABLES USING HASH PARTITIONING`.

Note

For partitions that have not been explicitly named, MySQL automatically provides the default names `p0`, `p1`, `p2`, and so on. The same is true with regard to subpartitions.

For more detailed information about and examples of `ALTER TABLE ... REORGANIZE PARTITION` statements, see [Section 17.3, “Partition Management”](#).

Important

Only a single `PARTITION BY`, `ADD PARTITION`, `DROP PARTITION`, `REORGANIZE PARTITION`, or `COALESCE PARTITION` clause can be used in a given `ALTER TABLE` statement.

- Several additional options provide partition maintenance and repair functionality analogous to that implemented for non-partitioned tables by statements such as `CHECK TABLE` and `REPAIR TABLE` (which are also supported for partitioned tables; see [Section 12.5.2, “Table Maintenance Statements”](#) for more information). These include `ANALYZE PARTITION`, `CHECK PARTITION`, `OPTIMIZE PARTITION`, `REBUILD PARTITION`, and `REPAIR PARTITION`. Each of these options takes a *partition_names* clause consisting of one or more names of partitions, separated by commas. The partitions must already exist in the table to be altered. For more information and examples, see [Section 17.3.3, “Maintenance of Partitions”](#).

The `ANALYZE PARTITION`, `CHECK PARTITION`, `OPTIMIZE PARTITION`, and `REPAIR PARTITION` options are disallowed for tables which are not partitioned.

- `REMOVE PARTITIONING` enables you to remove a table's partitioning without otherwise affecting the table or its data. This option can be combined with other `ALTER TABLE` options such as those used to add, drop, or rename drop columns or indexes.

- Using the `ENGINE` option with `ALTER TABLE` changes the storage engine used by the table without affecting the partitioning.

With the `mysql_info()` C API function, you can find out how many rows were copied, and (when `IGNORE` is used) how many rows were deleted due to duplication of unique key values. See [Section 20.10.3.35](#), “`mysql_info()`”.

Here are some examples that show uses of `ALTER TABLE`. Begin with a table `t1` that is created as shown here:

```
CREATE TABLE t1 (a INTEGER,b CHAR(10));
```

To rename the table from `t1` to `t2`:

```
ALTER TABLE t1 RENAME t2;
```

To change column `a` from `INTEGER` to `TINYINT NOT NULL` (leaving the name the same), and to change column `b` from `CHAR(10)` to `CHAR(20)` as well as renaming it from `b` to `c`:

```
ALTER TABLE t2 MODIFY a TINYINT NOT NULL, CHANGE b c CHAR(20);
```

To add a new `TIMESTAMP` column named `d`:

```
ALTER TABLE t2 ADD d TIMESTAMP;
```

To add an index on column `d` and a `UNIQUE` index on column `a`:

```
ALTER TABLE t2 ADD INDEX (d), ADD UNIQUE (a);
```

To remove column `c`:

```
ALTER TABLE t2 DROP COLUMN c;
```

To add a new `AUTO_INCREMENT` integer column named `c`:

```
ALTER TABLE t2 ADD c INT UNSIGNED NOT NULL AUTO_INCREMENT,
ADD PRIMARY KEY (c);
```

We indexed `c` (as a `PRIMARY KEY`) because `AUTO_INCREMENT` columns must be indexed, and we declare `c` as `NOT NULL` because primary key columns cannot be `NULL`.

For `NDB` tables, it is also possible to change the storage type used for a table or column. For example, consider an `NDB` table created as shown here:

```
mysql> CREATE TABLE t1 (c1 INT) TABLESPACE ts_1 ENGINE NDB;
Query OK, 0 rows affected (1.27 sec)
```

To convert this table to disk-based storage, you can use the following `ALTER TABLE` statement:

```
mysql> ALTER TABLE t1 TABLESPACE ts_1 STORAGE DISK;
Query OK, 0 rows affected (2.99 sec)
Records: 0 Duplicates: 0 Warnings: 0

mysql> SHOW CREATE TABLE t1\G
***** 1. row *****
      Table: t1
Create Table: CREATE TABLE `t1` (
  `c1` int(11) DEFAULT NULL
) /*!50100 TABLESPACE ts_1 STORAGE DISK */
ENGINE=ndbcluster DEFAULT CHARSET=latin1
1 row in set (0.01 sec)
```

It is not necessary that the tablespace was referenced when the table was originally created; however, the tablespace must be referenced by the `ALTER TABLE`:

```
mysql> CREATE TABLE t2 (c1 INT) ts_1 ENGINE NDB;
Query OK, 0 rows affected (1.00 sec)

mysql> ALTER TABLE t2 STORAGE DISK;
ERROR 1005 (HY000): CAN'T CREATE TABLE 'c.#SQL-1750_3' (ERRNO: 140)
mysql> ALTER TABLE t2 TABLESPACE ts_1 STORAGE DISK;
Query OK, 0 rows affected (3.42 sec)
Records: 0 Duplicates: 0 Warnings: 0
mysql> SHOW CREATE TABLE t2\G
***** 1. row *****
      Table: t1
```

```
Create Table: CREATE TABLE `t2` (
  `c1` int(11) DEFAULT NULL
) /*!50100 TABLESPACE ts_1 STORAGE DISK */
ENGINE=ndbcluster DEFAULT CHARSET=latin1
1 row in set (0.01 sec)
```

To change the storage type of an individual column, you can use `ALTER TABLE ... MODIFY [COLUMN]`. For example, suppose you create a MySQL Cluster Disk Data table with two columns, using this `CREATE TABLE` statement:

```
mysql> CREATE TABLE t3 (c1 INT, c2 INT)
->     TABLESPACE ts_1 STORAGE DISK ENGINE NDB;
Query OK, 0 rows affected (1.34 sec)
```

To change column `c2` from disk-based to in-memory storage, include a `STORAGE MEMORY` clause in the column definition used by the `ALTER TABLE` statement, as shown here:

```
mysql> ALTER TABLE t3 MODIFY c2 INT STORAGE MEMORY;
Query OK, 0 rows affected (3.14 sec)
Records: 0 Duplicates: 0 Warnings: 0
```

You can make an in-memory column into a disk-based column by using `STORAGE DISK` in a similar fashion.

Column `c1` uses disk-based storage, since this is the default for the table (determined by the table-level `STORAGE DISK` clause in the `CREATE TABLE` statement). However, column `c2` uses in-memory storage, as can be seen here in the output of `SHOW CREATE TABLE`:

```
mysql> SHOW CREATE TABLE t3\G
***** 1. row *****
      Table: t3
Create Table: CREATE TABLE `t3` (
  `c1` int(11) DEFAULT NULL,
  `c2` int(11) /*!50120 STORAGE MEMORY */ DEFAULT NULL
) /*!50100 TABLESPACE ts_1 STORAGE DISK */ ENGINE=ndbcluster DEFAULT CHARSET=latin1
1 row in set (0.02 sec)
```

When you add an `AUTO_INCREMENT` column, column values are filled in with sequence numbers automatically. For `MyISAM` tables, you can set the first sequence number by executing `SET INSERT_ID=value` before `ALTER TABLE` or by using the `AUTO_INCREMENT=value` table option. See Section 5.1.4, “Session System Variables”.

With `MyISAM` tables, if you do not change the `AUTO_INCREMENT` column, the sequence number is not affected. If you drop an `AUTO_INCREMENT` column and then add another `AUTO_INCREMENT` column, the numbers are resequenced beginning with 1.

When replication is used, adding an `AUTO_INCREMENT` column to a table might not produce the same ordering of the rows on the slave and the master. This occurs because the order in which the rows are numbered depends on the specific storage engine used for the table and the order in which the rows were inserted. If it is important to have the same order on the master and slave, the rows must be ordered before assigning an `AUTO_INCREMENT` number. Assuming that you want to add an `AUTO_INCREMENT` column to the table `t1`, the following statements produce a new table `t2` identical to `t1` but with an `AUTO_INCREMENT` column:

```
CREATE TABLE t2 (id INT AUTO_INCREMENT PRIMARY KEY)
SELECT * FROM t1 ORDER BY col1, col2;
```

This assumes that the table `t1` has columns `col1` and `col2`.

This set of statements will also produce a new table `t2` identical to `t1`, with the addition of an `AUTO_INCREMENT` column:

```
CREATE TABLE t2 LIKE t1;
ALTER TABLE T2 ADD id INT AUTO_INCREMENT PRIMARY KEY;
INSERT INTO t2 SELECT * FROM t1 ORDER BY col1, col2;
```

Important

To guarantee the same ordering on both master and slave, *all* columns of `t1` must be referenced in the `ORDER BY` clause.

Regardless of the method used to create and populate the copy having the `AUTO_INCREMENT` column, the final step is to drop the original table and then rename the copy:

```
DROP t1;
ALTER TABLE t2 RENAME t1;
```

12.1.7. ALTER VIEW Syntax

```
ALTER
[ALGORITHM = {UNDEFINED | MERGE | TEMPTABLE}]
```

```
[DEFINER = { user | CURRENT_USER }]
[SQL SECURITY { DEFINER | INVOKER }]
VIEW view_name [(column_list)]
AS select_statement
[WITH [CASCADED | LOCAL] CHECK OPTION]
```

This statement changes the definition of a view, which must exist. The syntax is similar to that for `CREATE VIEW` and the effect is the same as for `CREATE OR REPLACE VIEW`. See [Section 12.1.16, “CREATE VIEW Syntax”](#). This statement requires the `CREATE VIEW` and `DROP` privileges for the view, and some privilege for each column referred to in the `SELECT` statement. `ALTER VIEW` is allowed only to the definer or users with the `SUPER` privilege.

12.1.8. CREATE DATABASE Syntax

```
CREATE {DATABASE | SCHEMA} [IF NOT EXISTS] db_name
[create_specification] ...

create_specification:
[DEFAULT] CHARACTER SET [=] charset_name
| [DEFAULT] COLLATE [=] collation_name
```

`CREATE DATABASE` creates a database with the given name. To use this statement, you need the `CREATE` privilege for the database. `CREATE SCHEMA` is a synonym for `CREATE DATABASE`.

An error occurs if the database exists and you did not specify `IF NOT EXISTS`.

`create_specification` options specify database characteristics. Database characteristics are stored in the `db.opt` file in the database directory. The `CHARACTER SET` clause specifies the default database character set. The `COLLATE` clause specifies the default database collation. [Section 9.1, “Character Set Support”](#), discusses character set and collation names.

A database in MySQL is implemented as a directory containing files that correspond to tables in the database. Because there are no tables in a database when it is initially created, the `CREATE DATABASE` statement creates only a directory under the MySQL data directory and the `db.opt` file. Rules for allowable database names are given in [Section 8.2, “Schema Object Names”](#). If a database name contains special characters, the name for the database directory contains encoded versions of those characters as described in [Section 8.2.3, “Mapping of Identifiers to File Names”](#).

If you manually create a directory under the data directory (for example, with `mkdir`), the server considers it a database directory and it shows up in the output of `SHOW DATABASES`.

You can also use the `mysqladmin` program to create databases. See [Section 4.5.2, “mysqladmin — Client for Administering a MySQL Server”](#).

12.1.9. CREATE EVENT Syntax

```
CREATE
[DEFINER = { user | CURRENT_USER }]
EVENT
[IF NOT EXISTS]
event_name
ON SCHEDULE schedule
[ON COMPLETION [NOT] PRESERVE]
[ENABLE | DISABLE | DISABLE ON SLAVE]
[COMMENT 'comment']
DO sql_statement;

schedule:
AT timestamp [+ INTERVAL interval] ...
| EVERY interval
[STARTS timestamp [+ INTERVAL interval] ...]
[ENDS timestamp [+ INTERVAL interval] ...]

interval:
quantity {YEAR | QUARTER | MONTH | DAY | HOUR | MINUTE |
WEEK | SECOND | YEAR_MONTH | DAY_HOUR | DAY_MINUTE |
DAY_SECOND | HOUR_MINUTE | HOUR_SECOND | MINUTE_SECOND}
```

This statement creates and schedules a new event. It requires the `EVENT` privilege for the schema in which the event is to be created.

The minimum requirements for a valid `CREATE EVENT` statement are as follows:

- The keywords `CREATE EVENT` plus an event name, which uniquely identifies the event in the current schema.
- An `ON SCHEDULE` clause, which determines when and how often the event executes.
- A `DO` clause, which contains the SQL statement to be executed by an event.

This is an example of a minimal `CREATE EVENT` statement:

```
CREATE EVENT myevent
ON SCHEDULE AT CURRENT_TIMESTAMP + INTERVAL 1 HOUR
DO
UPDATE myschema.mytable SET mycol = mycol + 1;
```

The previous statement creates an event named `myevent`. This event executes once — one hour following its creation — by running an SQL statement that increments the value of the `myschema.mytable` table's `mycol` column by 1.

The `event_name` must be a valid MySQL identifier with a maximum length of 64 characters. It may be delimited using back ticks, and may be qualified with the name of a database schema. An event is associated with both a MySQL user (the definer) and a schema, and its name must be unique among names of events within that schema. In general, the rules governing event names are the same as those for names of stored routines. See [Section 8.2, “Schema Object Names”](#).

If no schema is indicated as part of `event_name`, the default (current) schema is assumed.

Note

MySQL uses case-insensitive comparisons when checking for the uniqueness of event names. This means that, for example, you cannot have two events named `myevent` and `MyEvent` in the same database schema.

The `DEFINER` clause specifies the MySQL account to be used when checking access privileges at event execution time. If a `user` value is given, it should be a MySQL account in `'user_name'@'host_name'` format (the same format used in the `GRANT` statement). The `user_name` and `host_name` values both are required. The definer can also be given as `CURRENT_USER` or `CURRENT_USER()`. The default `DEFINER` value is the user who executes the `CREATE EVENT` statement. (This is the same as `DEFINER = CURRENT_USER`.)

If you specify the `DEFINER` clause, these rules determine the legal `DEFINER` user values:

- If you do not have the `SUPER` privilege, the only legal `user` value is your own account, either specified literally or by using `CURRENT_USER`. You cannot set the definer to some other account.
- If you have the `SUPER` privilege, you can specify any syntactically legal account name. If the account does not actually exist, a warning is generated.
- Although it is possible to create events with a non-existent `DEFINER` value, an error occurs if the event executes with definer privileges but the definer does not exist at execution time.

Within an event, the `CURRENT_USER()` function returns the account used to check privileges at event execution time, which is the `DEFINER` user. For information about user auditing within events, see [Section 5.5.9, “Auditing MySQL Account Activity”](#).

`IF NOT EXISTS` has the same meaning for `CREATE EVENT` as for `CREATE TABLE`: If an event named `event_name` already exists in the same schema, no action is taken, and no error results. (However, a warning is generated in such cases.)

The `ON SCHEDULE` clause determines when, how often, and for how long the `sql_statement` defined for the event repeats. This clause takes one of two forms:

- `AT timestamp` is used for a one-time event. It specifies that the event executes one time only at the date and time given by `timestamp`, which must include both the date and time, or must be an expression that resolves to a datetime value. You may use a value of either the `DATETIME` or `TIMESTAMP` type for this purpose. If the date is in the past, a warning occurs, as shown here:

```
mysql> SELECT NOW();
+-----+
| NOW() |
+-----+
| 2006-02-10 23:59:01 |
+-----+
1 row in set (0.04 sec)

mysql> CREATE EVENT e_totals
-> ON SCHEDULE AT '2006-02-10 23:59:00'
-> DO INSERT INTO test.totals VALUES (NOW());
Query OK, 0 rows affected, 1 warning (0.00 sec)

mysql> SHOW WARNINGS\G
***** 1. row *****
Level: Note
Code: 1588
Message: Event execution time is in the past and ON COMPLETION NOT
PRESERVE is set. The event was dropped immediately after
creation.
```

`CREATE EVENT` statements which are themselves invalid — for whatever reason — fail with an error.

You may use `CURRENT_TIMESTAMP` to specify the current date and time. In such a case, the event acts as soon as it is created.

To create an event which occurs at some point in the future relative to the current date and time — such as that expressed by the phrase “three weeks from now” — you can use the optional clause `+ INTERVAL interval`. The *interval* portion consists of two parts, a quantity and a unit of time, and follows the same syntax rules that govern intervals used in the `DATE_ADD()` function (see Section 11.6, “Date and Time Functions”). The units keywords are also the same, except that you cannot use any units involving microseconds when defining an event. With some interval types, complex time units may be used. For example, “two minutes and ten seconds” can be expressed as `+ INTERVAL '2:10' MINUTE_SECOND`.

You can also combine intervals. For example, `AT CURRENT_TIMESTAMP + INTERVAL 3 WEEK + INTERVAL 2 DAY` is equivalent to “three weeks and two days from now”. Each portion of such a clause must begin with `+ INTERVAL`.

- To repeat actions at a regular interval, use an `EVERY` clause. The `EVERY` keyword is followed by an *interval* as described in the previous discussion of the `AT` keyword. (`+ INTERVAL` is *not* used with `EVERY`.) For example, `EVERY 6 WEEK` means “every six weeks”.

Although `+ INTERVAL` clauses are not allowed in an `EVERY` clause, you can use the same complex time units allowed in a `+ INTERVAL`.

An `EVERY` clause may also contain an optional `STARTS` clause. `STARTS` is followed by a *timestamp* value which indicates when the action should begin repeating, and may also use `+ INTERVAL interval` in order to specify an amount of time “from now”. For example, `EVERY 3 MONTH STARTS CURRENT_TIMESTAMP + INTERVAL 1 WEEK` means “every three months, beginning one week from now”. Similarly, you can express “every two weeks, beginning six hours and fifteen minutes from now” as `EVERY 2 WEEK STARTS CURRENT_TIMESTAMP + INTERVAL '6:15' HOUR_MINUTE`. Not specifying `STARTS` is the same as using `STARTS CURRENT_TIMESTAMP` — that is, the action specified for the event begins repeating immediately upon creation of the event.

An `EVERY` clause may also contain an optional `ENDS` clause. The `ENDS` keyword is followed by a *timestamp* value which tells MySQL when the event should stop repeating. You may also use `+ INTERVAL interval` with `ENDS`; for instance, `EVERY 12 HOUR STARTS CURRENT_TIMESTAMP + INTERVAL 30 MINUTE ENDS CURRENT_TIMESTAMP + INTERVAL 4 WEEK` is equivalent to “every twelve hours, beginning thirty minutes from now, and ending four weeks from now”. Not using `ENDS` means that the event continues executing indefinitely.

`ENDS` supports the same syntax for complex time units as `STARTS` does.

You may use `STARTS`, `ENDS`, both, or neither in an `EVERY` clause.

Note

In MySQL 5.4, `STARTS` or `ENDS` uses the MySQL server's local time zone, as shown in the `INFORMATION_SCHEMA.EVENTS` and `mysql.event` tables, as well as in the output of `SHOW EVENTS`.

See Section 19.20, “The `INFORMATION_SCHEMA.EVENTS` Table”, and Section 12.5.5.19, “`SHOW EVENTS Syntax`” for more information.

If a repeating event does not terminate within its scheduling interval, the result may be multiple instances of the event executing simultaneously. If this is undesirable, you should institute a mechanism to prevent simultaneous instances. For example, you could use the `GET_LOCK()` function, or row or table locking.

The `ON SCHEDULE` clause may use expressions involving built-in MySQL functions and user variables to obtain any of the *timestamp* or *interval* values which it contains. You may not use stored functions or user-defined functions in such expressions, nor may you use any table references; however, you may use `SELECT FROM DUAL`. This is true for both `CREATE EVENT` and `ALTER EVENT` statements. References to stored functions, user-defined functions, and tables in such cases are specifically disallowed, and fail with an error (see Bug#22830).

Normally, once an event has expired, it is immediately dropped. You can override this behavior by specifying `ON COMPLETION PRESERVE`. Using `ON COMPLETION NOT PRESERVE` merely makes the default non-persistent behavior explicit.

You can create an event but keep it from being active using the `DISABLE` keyword. Alternatively, you may use `ENABLE` to make explicit the default status, which is active. This is most useful in conjunction with `ALTER EVENT` (see Section 12.1.2, “`ALTER EVENT Syntax`”).

A third value may also appear in place of `ENABLED` or `DISABLED`; `DISABLE ON SLAVE` is set for the status of an event on a replication slave to indicate that the event was created on the master and replicated to the slave, but is not executed on the slave. See Section 16.3.1.7, “Replication of Invoked Features”.

You may supply a comment for an event using a `COMMENT` clause. *comment* may be any string of up to 64 characters that you wish to use for describing the event. The comment text, being a string literal, must be surrounded by quotation marks.

The `DO` clause specifies an action carried by the event, and consists of an SQL statement. Nearly any valid MySQL statement which can be used in a stored routine can also be used as the action statement for a scheduled event. (See [Section D.1, “Restrictions on Stored Routines, Triggers, and Events”](#).) For example, the following event `e_hourly` deletes all rows from the `sessions` table once per hour, where this table is part of the `site_activity` schema:

```
CREATE EVENT e_hourly
ON SCHEDULE
EVERY 1 HOUR
COMMENT 'Clears out sessions table each hour.'
DO
DELETE FROM site_activity.sessions;
```

MySQL stores the `sql_mode` system variable setting that is in effect at the time an event is created, and always executes the event with this setting in force, *regardless of the current server SQL mode*.

A `CREATE EVENT` statement that contains an `ALTER EVENT` statement in its `DO` clause appears to succeed; however, when the server attempts to execute the resulting scheduled event, the execution fails with an error.

Note

Statements such as `SELECT` or `SHOW` that merely return a result set have no effect when used in an event; the output from these is not sent to the MySQL Monitor, nor is it stored anywhere. However, you can use statements such as `SELECT ... INTO` and `INSERT INTO ... SELECT` that store a result. (See the next example in this section for an instance of the latter.)

The schema to which an event belongs is the default schema for table references in the `DO` clause. Any references to tables in other schemas must be qualified with the proper schema name.

As with stored routines, you can use compound-statement syntax in the `DO` clause by using the `BEGIN` and `END` keywords, as shown here:

```
delimiter |
CREATE EVENT e_daily
ON SCHEDULE
EVERY 1 DAY
COMMENT 'Saves total number of sessions then clears the table each day'
DO
BEGIN
INSERT INTO site_activity.totals (time, total)
SELECT CURRENT_TIMESTAMP, COUNT(*)
FROM site_activity.sessions;
DELETE FROM site_activity.sessions;
END |
delimiter ;
```

Note the use of the `delimiter` command to change the statement delimiter. See [Section 18.1, “Defining Stored Programs”](#).

More complex compound statements, such as those used in stored routines, are possible in an event. This example uses local variables, an error handler, and a flow control construct:

```
delimiter |
CREATE EVENT e
ON SCHEDULE
EVERY 5 SECOND
DO
BEGIN
DECLARE v INTEGER;
DECLARE CONTINUE HANDLER FOR SQLEXCEPTION BEGIN END;

SET v = 0;

WHILE v < 5 DO
INSERT INTO t1 VALUES (0);
UPDATE t2 SET s1 = s1 + 1;
SET v = v + 1;
END WHILE;
END |
delimiter ;
```

There is no way to pass parameters directly to or from events; however, it is possible to invoke a stored routine with parameters:

```
CREATE EVENT e_call_myproc
ON SCHEDULE
```

```
AT CURRENT_TIMESTAMP + INTERVAL 1 DAY
DO CALL myproc(5, 27);
```

In addition, if the event's definer has the `SUPER` privilege, that event may read and write global variables. As granting this privilege entails a potential for abuse, extreme care must be taken in doing so.

Generally, any statements which are valid in stored routines may be used for action statements executed by events. For more information about statements allowable within stored routines, see [Section 18.2.1, “Stored Routine Syntax”](#). You can create an event as part of a stored routine, but an event cannot be created by another event.

12.1.10. CREATE FUNCTION Syntax

The `CREATE FUNCTION` statement is used to create stored functions and user-defined functions (UDFs):

- For information about creating stored functions, see [Section 12.1.12, “CREATE PROCEDURE and CREATE FUNCTION Syntax”](#).
- For information about creating user-defined functions, see [Section 12.5.3.1, “CREATE FUNCTION Syntax”](#).

12.1.11. CREATE INDEX Syntax

```
CREATE [ONLINE|OFFLINE] [UNIQUE|FULLTEXT|SPATIAL] INDEX index_name
  [index_type]
  ON tbl_name (index_col_name,...)
  [index_option] ...

index_col_name:
  col_name [(length)] [ASC | DESC]

index_type:
  USING {BTREE | HASH | RTREE}

index_option:
  KEY_BLOCK_SIZE [=] value
  | index_type
  | WITH PARSER parser_name
```

`CREATE INDEX` is mapped to an `ALTER TABLE` statement to create indexes. See [Section 12.1.6, “ALTER TABLE Syntax”](#). `CREATE INDEX` cannot be used to create a `PRIMARY KEY`; use `ALTER TABLE` instead. For more information about indexes, see [Section 7.4.4, “How MySQL Uses Indexes”](#).

Normally, you create all indexes on a table at the time the table itself is created with `CREATE TABLE`. See [Section 12.1.14, “CREATE TABLE Syntax”](#). `CREATE INDEX` enables you to add indexes to existing tables.

A column list of the form `(col1,col2,...)` creates a multiple-column index. Index values are formed by concatenating the values of the given columns.

Indexes can be created that use only the leading part of column values, using `col_name(length)` syntax to specify an index prefix length:

- Prefixes can be specified for `CHAR`, `VARCHAR`, `BINARY`, and `VARBINARY` columns.
- `BLOB` and `TEXT` columns also can be indexed, but a prefix length *must* be given.
- Prefix lengths are given in characters for nonbinary string types and in bytes for binary string types. That is, index entries consist of the first *length* characters of each column value for `CHAR`, `VARCHAR`, and `TEXT` columns, and the first *length* bytes of each column value for `BINARY`, `VARBINARY`, and `BLOB` columns.
- For spatial columns, prefix values cannot be given, as described later in this section.

The statement shown here creates an index using the first 10 characters of the `name` column:

```
CREATE INDEX part_of_name ON customer (name(10));
```

If names in the column usually differ in the first 10 characters, this index should not be much slower than an index created from the entire `name` column. Also, using column prefixes for indexes can make the index file much smaller, which could save a lot of disk space and might also speed up `INSERT` operations.

Prefix lengths are storage engine-dependent (for example, a prefix can be up to 1000 bytes long for `MyISAM` tables, 767 bytes for

InnoDB tables). Note that prefix limits are measured in bytes, whereas the prefix length in `CREATE INDEX` statements is interpreted as number of characters for nonbinary data types (`CHAR`, `VARCHAR`, `TEXT`). Take this into account when specifying a prefix length for a column that uses a multi-byte character set. For example, `utf8` columns require up to three index bytes per character.

Indexes on variable-width columns are created online; that is, creating the indexes does not require any copying of the table. For `NDBCLUSTER` tables, the table is not locked against access from other MySQL Cluster API nodes, although it is locked against other operations on the *same* API node for the duration of the online operation. This is done automatically by the server whenever it determines that it is possible to do so; you do not have to use any special SQL syntax or server options to cause it to happen.

In standard MySQL 5.4 releases, it is not possible to override the server when it determines that an index is to be created online. In MySQL Cluster, beginning with MySQL Cluster NDB 6.2.5 and MySQL Cluster NDB 6.3.3, you can create indexes offline (which causes the table to be locked to all API nodes in the cluster) using the `OFFLINE` keyword. The rules and limitations governing online `CREATE OFFLINE INDEX` and `CREATE ONLINE INDEX` are the same as for `ALTER OFFLINE TABLE ... ADD INDEX` and `ALTER ONLINE TABLE ... ADD INDEX`. You cannot cause the online creation of an index that would normally be created offline by using the `ONLINE` keyword (if it is not possible to perform the `CREATE INDEX` operation online, then the `ONLINE` keyword is ignored). For more information, see [Section 12.1.6, “ALTER TABLE Syntax”](#).

Note

The `ONLINE` and `OFFLINE` keywords are available only in MySQL Cluster NDB 6.2 and MySQL Cluster NDB 6.3 releases beginning with versions 6.2.5 and 6.3.3, respectively; attempting to use them in earlier MySQL Cluster NDB 6.2 or 6.3 releases, standard MySQL 5.1 releases, or MySQL Cluster NDB 6.1 releases results in a syntax error.

A `UNIQUE` index creates a constraint such that all values in the index must be distinct. An error occurs if you try to add a new row with a key value that matches an existing row. For all engines, a `UNIQUE` index allows multiple `NULL` values for columns that can contain `NULL`. If you specify a prefix value for a column in a `UNIQUE` index, the column values must be unique within the prefix.

MySQL Enterprise

Lack of proper indexes can greatly reduce performance. Subscribe to the MySQL Enterprise Monitor for notification of inefficient use of indexes. For more information, see <http://www.mysql.com/products/enterprise/advisors.html>.

`FULLTEXT` indexes are supported only for `MyISAM` tables and can include only `CHAR`, `VARCHAR`, and `TEXT` columns. Indexing always happens over the entire column; column prefix indexing is not supported and any prefix length is ignored if specified. See [Section 11.8, “Full-Text Search Functions”](#), for details of operation.

The `MyISAM`, `InnoDB`, `NDB`, `BDB`, and `ARCHIVE` storage engines support spatial columns such as (`POINT` and `GEOMETRY`. ([Section 11.13, “Spatial Extensions”](#), describes the spatial data types.) However, support for spatial column indexing varies among engines. Spatial and non-spatial indexes are available according to the following rules.

Spatial indexes (created using `SPATIAL INDEX`):

- Available only for `MyISAM` tables. Specifying a `SPATIAL INDEX` for other storage engines results in an error.
- Indexed columns must be `NOT NULL`.
- In MySQL 5.4, column prefix lengths are prohibited. The full width of each column is indexed.

Non-spatial indexes (created with `INDEX`, `UNIQUE`, or `PRIMARY KEY`):

- Allowed for any storage engine that supports spatial columns except `ARCHIVE`.
- Columns can be `NULL` unless the index is a primary key.
- For each spatial column in a non-`SPATIAL` index except `POINT` columns, a column prefix length must be specified. (This is the same requirement as for indexed `BLOB` columns.) The prefix length is given in bytes.
- The index type for a non-`SPATIAL` index depends on the storage engine. Currently, B-tree is used.

In MySQL 5.4:

- You can add an index on a column that can have `NULL` values only if you are using the `MyISAM`, `InnoDB`, or `MEMORY` storage engine.
- You can add an index on a `BLOB` or `TEXT` column only if you are using the `MyISAM`, or `InnoDB` storage engine.

An *index_col_name* specification can end with `ASC` or `DESC`. These keywords are allowed for future extensions for specifying ascending or descending index value storage. Currently, they are parsed but ignored; index values are always stored in ascending order.

Following the index column list, index options can be given. An *index_option* value can be any of the following:

- `KEY_BLOCK_SIZE [=] value`

This option provides a hint to the storage engine about the size in bytes to use for index key blocks. The engine is allowed to change the value if necessary. A value of 0 indicates that the default value should be used.

- *index_type*

Some storage engines allow you to specify an index type when creating an index. The allowable index type values supported by different storage engines are shown in the following table. Where multiple index types are listed, the first one is the default when no index type specifier is given.

Storage Engine	Allowable Index Types
MyISAM	BTREE, RTREE
InnoDB	BTREE
MEMORY/HEAP	HASH, BTREE
NDB	HASH, BTREE (see note in text)

Note

BTREE indexes are implemented by the NDBCLUSTER storage engine as T-tree indexes.

For indexes on NDBCLUSTER table columns, the `USING` clause can be specified only for a unique index or primary key. In such cases, the `USING HASH` clause prevents the creation of an implicit ordered index. Without `USING HASH`, a statement defining a unique index or primary key automatically results in the creation of a `HASH` index in addition to the ordered index, both of which index the same set of columns.

The `RTREE` index type is allowable only for `SPATIAL` indexes.

If you specify an index type that is not legal for a given storage engine, but there is another index type available that the engine can use without affecting query results, the engine uses the available type.

Examples:

```
CREATE TABLE lookup (id INT) ENGINE = MEMORY;
CREATE INDEX id_index USING BTREE ON lookup (id);
```

`TYPE type_name` is recognized as a synonym for `USING type_name`. However, `USING` is the preferred form.

Use of this option before the `ON tbl_name` clause is deprecated; support for use of the option in this position is to be dropped in a future MySQL release. If an *index_type* option is given in both the earlier and later positions, the final option applies.

- `WITH PARSEER parser_name`

This option can be used only with `FULLTEXT` indexes. It associates a parser plugin with the index if full-text indexing and searching operations need special handling. See [Section 21.2, “The MySQL Plugin Interface”](#), for details on creating plugins.

12.1.12. CREATE PROCEDURE and CREATE FUNCTION Syntax

```
CREATE
[DEFINER = { user | CURRENT_USER }]
PROCEDURE sp_name ([proc_parameter[,...]])
[characteristic ...] routine_body

CREATE
[DEFINER = { user | CURRENT_USER }]
FUNCTION sp_name ([func_parameter[,...]])
RETURNS type
[characteristic ...] routine_body

proc_parameter:
[ IN | OUT | INOUT ] param_name type

func_parameter:
param_name type
```

```

type:
    Any valid MySQL data type

characteristic:
    LANGUAGE SQL
    [NOT] DETERMINISTIC
    { CONTAINS SQL | NO SQL | READS SQL DATA | MODIFIES SQL DATA }
    SQL SECURITY { DEFINER | INVOKER }
    COMMENT 'string'

routine_body:
    Valid SQL procedure statement

```

These statements create stored routines. By default, a routine is associated with the default database. To associate the routine explicitly with a given database, specify the name as *db_name.sp_name* when you create it.

The `CREATE FUNCTION` statement is also used in MySQL to support UDFs (user-defined functions). See [Section 21.3, “Adding New Functions to MySQL”](#). A UDF can be regarded as an external stored function. However, do note that stored functions share their namespace with UDFs. See [Section 8.2.4, “Function Name Parsing and Resolution”](#), for the rules describing how the server interprets references to different kinds of functions.

To invoke a stored procedure, use the `CALL` statement (see [Section 12.2.1, “CALL Syntax”](#)). To invoke a stored function, refer to it in an expression. The function returns a value during expression evaluation.

To execute the `CREATE PROCEDURE` or `CREATE FUNCTION` statement, it is necessary to have the `CREATE ROUTINE` privilege. By default, MySQL automatically grants the `ALTER ROUTINE` and `EXECUTE` privileges to the routine creator. This behavior can be changed by disabling the `automatic_sp_privileges` system variable. See [Section 18.2.2, “Stored Routines and MySQL Privileges”](#). If binary logging is enabled, the `CREATE FUNCTION` statement might also require the `SUPER` privilege, as described in [Section 18.6, “Binary Logging of Stored Programs”](#).

The `DEFINER` and `SQL SECURITY` clauses specify the security context to be used when checking access privileges at routine execution time, as described later.

If the routine name is the same as the name of a built-in SQL function, a syntax error occurs unless you use a space between the name and the following parenthesis when defining the routine or invoking it later. For this reason, avoid using the names of existing SQL functions for your own stored routines.

The `IGNORE_SPACE` SQL mode applies to built-in functions, not to stored routines. It is always allowable to have spaces after a stored routine name, regardless of whether `IGNORE_SPACE` is enabled.

The parameter list enclosed within parentheses must always be present. If there are no parameters, an empty parameter list of `()` should be used. Parameter names are not case sensitive.

Each parameter is an `IN` parameter by default. To specify otherwise for a parameter, use the keyword `OUT` or `INOUT` before the parameter name.

Note

Specifying a parameter as `IN`, `OUT`, or `INOUT` is valid only for a `PROCEDURE`. (`FUNCTION` parameters are always regarded as `IN` parameters.)

An `IN` parameter passes a value into a procedure. The procedure might modify the value, but the modification is not visible to the caller when the procedure returns. An `OUT` parameter passes a value from the procedure back to the caller. Its initial value is `NULL` within the procedure, and its value is visible to the caller when the procedure returns. An `INOUT` parameter is initialized by the caller, can be modified by the procedure, and any change made by the procedure is visible to the caller when the procedure returns.

For each `OUT` or `INOUT` parameter, pass a user-defined variable in the `CALL` statement that invokes the procedure so that you can obtain its value when the procedure returns. If you are calling the procedure from within another stored procedure or function, you can also pass a routine parameter or local routine variable as an `IN` or `INOUT` parameter.

The following example shows a simple stored procedure that uses an `OUT` parameter:

```

mysql> delimiter //
mysql> CREATE PROCEDURE simpleproc (OUT param1 INT)
-> BEGIN
->   SELECT COUNT(*) INTO param1 FROM t;
-> END//
Query OK, 0 rows affected (0.00 sec)

mysql> delimiter ;
mysql> CALL simpleproc(@a);
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT @a;
+-----+
| @a    |

```

```
+-----+
| 3 |
+-----+
1 row in set (0.00 sec)
```

The example uses the `mysql` client `delimiter` command to change the statement delimiter from `;` to `//` while the procedure is being defined. This allows the `;` delimiter used in the procedure body to be passed through to the server rather than being interpreted by `mysql` itself. See [Section 18.1, “Defining Stored Programs”](#).

The `RETURNS` clause may be specified only for a `FUNCTION`, for which it is mandatory. It indicates the return type of the function, and the function body must contain a `RETURN value` statement. If the `RETURN` statement returns a value of a different type, the value is coerced to the proper type. For example, if a function specifies an `ENUM` or `SET` value in the `RETURNS` clause, but the `RETURN` statement returns an integer, the value returned from the function is the string for the corresponding `ENUM` member of set of `SET` members.

The following example function takes a parameter, performs an operation using an SQL function, and returns the result. In this case, it is unnecessary to use `delimiter` because the function definition contains no internal `;` statement delimiters:

```
mysql> CREATE FUNCTION hello (s CHAR(20))
mysql> RETURNS CHAR(50) DETERMINISTIC
-> RETURN CONCAT('Hello, ',s,'!');
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT hello('world');
+-----+
| hello('world') |
+-----+
| Hello, world! |
+-----+
1 row in set (0.00 sec)
```

Parameter types and function return types can be declared to use any valid data type, except that the `COLLATE` attribute cannot be used.

The `routine_body` consists of a valid SQL procedure statement. This can be a simple statement such as `SELECT` or `INSERT`, or it can be a compound statement written using `BEGIN` and `END`. Compound statements can contain declarations, loops, and other control structure statements. The syntax for these statements is described in [Section 12.8, “MySQL Compound-Statement Syntax”](#).

MySQL allows routines to contain DDL statements, such as `CREATE` and `DROP`. MySQL also allows stored procedures (but not stored functions) to contain SQL transaction statements such as `COMMIT`. Stored functions may not contain statements that perform explicit or implicit commit or rollback. Support for these statements is not required by the SQL standard, which states that each DBMS vendor may decide whether to allow them.

Statements that return a result set can be used within a stored procedure but not within a stored function. This prohibition includes `SELECT` statements that do not have an `INTO var_list` clause and other statements such as `SHOW`, `EXPLAIN`, and `CHECK TABLE`. For statements that can be determined at function definition time to return a result set, a `Not allowed to return a result set from a function` error occurs (`ER_SP_NO_RETSET`). For statements that can be determined only at runtime to return a result set, a `PROCEDURE %s can't return a result set in the given context` error occurs (`ER_SP_BADSELECT`).

`USE` statements within stored routines are disallowed. When a routine is invoked, an implicit `USE db_name` is performed (and undone when the routine terminates). This causes the routine to have the given default database while it executes. References to objects in databases other than the routine default database should be qualified with the appropriate database name.

For additional information about statements that are not allowed in stored routines, see [Section D.1, “Restrictions on Stored Routines, Triggers, and Events”](#).

For information about invoking stored procedures from within programs written in a language that has a MySQL interface, see [Section 12.2.1, “CALL Syntax”](#).

MySQL stores the `sql_mode` system variable setting that is in effect at the time a routine is created, and always executes the routine with this setting in force, *regardless of the server SQL mode in effect when the routine is invoked*.

The switch from the SQL mode of the invoker to that of the routine occurs after evaluation of arguments and assignment of the resulting values to routine parameters. If you define a routine in strict SQL mode but invoke it in non-strict mode, assignment of arguments to routine parameters does not take place in strict mode. If you require that expressions passed to a routine be assigned in strict SQL mode, you should invoke the routine with strict mode in effect.

A procedure or function is considered “deterministic” if it always produces the same result for the same input parameters, and “not deterministic” otherwise. If neither `DETERMINISTIC` nor `NOT DETERMINISTIC` is given in the routine definition, the default is `NOT DETERMINISTIC`.

A routine that contains the `NOW()` function (or its synonyms) or `RAND()` is non-deterministic, but it might still be replication-safe. For `NOW()`, the binary log includes the timestamp and replicates correctly. `RAND()` also replicates correctly as long as it is called

only a single time during the execution of a routine. (You can consider the routine execution timestamp and random number seed as implicit inputs that are identical on the master and slave.)

If binary logging is enabled, the `DETERMINISTIC` characteristic affects which routine definitions MySQL accepts. See [Section 18.6, “Binary Logging of Stored Programs”](#).

Several characteristics provide information about the nature of data use by the routine. In MySQL, these characteristics are advisory only. The server does not use them to constrain what kinds of statements a routine will be allowed to execute.

- `CONTAINS SQL` indicates that the routine does not contain statements that read or write data. This is the default if none of these characteristics is given explicitly. Examples of such statements are `SET @x = 1` or `DO RELEASE_LOCK('abc')`, which execute but neither read nor write data.
- `NO SQL` indicates that the routine contains no SQL statements.
- `READS SQL DATA` indicates that the routine contains statements that read data (for example, `SELECT`), but not statements that write data.
- `MODIFIES SQL DATA` indicates that the routine contains statements that may write data (for example, `INSERT` or `DELETE`).

The `SQL SECURITY` characteristic can be used to specify whether the routine should be executed using the permissions of the user who creates the routine or the user who invokes it. The default value is `DEFINER`. This feature is new in SQL:2003. The creator or invoker must have permission to access the database with which the routine is associated. It is necessary to have the `EXECUTE` privilege to be able to execute the routine. The user that must have this privilege is either the definer or invoker, depending on how the `SQL SECURITY` characteristic is set.

The `COMMENT` characteristic is a MySQL extension, and may be used to describe the stored routine. This information is displayed by the `SHOW CREATE PROCEDURE` and `SHOW CREATE FUNCTION` statements.

The optional `DEFINER` clause specifies the MySQL account to be used when checking access privileges at routine execution time for routines that have the `SQL SECURITY DEFINER` characteristic.

If a `user` value is given for the `DEFINER` clause, it should be a MySQL account in `'user_name'@'host_name'` format (the same format used in the `GRANT` statement). The `user_name` and `host_name` values both are required. The definer can also be given as `CURRENT_USER` or `CURRENT_USER()`. The default `DEFINER` value is the user who executes the `CREATE PROCEDURE` or `CREATE FUNCTION` or statement. (This is the same as `DEFINER = CURRENT_USER`.)

If you specify the `DEFINER` clause, these rules determine the legal `DEFINER` user values:

- If you do not have the `SUPER` privilege, the only legal `user` value is your own account, either specified literally or by using `CURRENT_USER`. You cannot set the definer to some other account.
- If you have the `SUPER` privilege, you can specify any syntactically legal account name. If the account does not actually exist, a warning is generated.
- Although it is possible to create routines with a non-existent `DEFINER` value, an error occurs if the routine executes with definer privileges but the definer does not exist at execution time.

Within a stored routine that is defined with the `SQL SECURITY DEFINER` characteristic, `CURRENT_USER` returns the routine's `DEFINER` value. For information about user auditing within stored routines, see [Section 5.5.9, “Auditing MySQL Account Activity”](#).

Consider the following procedure, which displays a count of the number of MySQL accounts listed in the `mysql.user` table:

```
CREATE DEFINER = 'admin'@'localhost' PROCEDURE account_count()
BEGIN
  SELECT 'Number of accounts:', COUNT(*) FROM mysql.user;
END;
```

The procedure is assigned a `DEFINER` account of `'admin'@'localhost'` no matter which user defines it. It executes with the privileges of that account no matter which user invokes it (because the default security characteristic is `DEFINER`). The procedure succeeds or fails depending on whether `'admin'@'localhost'` has the `EXECUTE` privilege for it and the `SELECT` privilege for the `mysql.user` table.

Now suppose that the procedure is defined with the `SQL SECURITY INVOKER` characteristic:

```
CREATE DEFINER = 'admin'@'localhost' PROCEDURE account_count()
SQL SECURITY INVOKER
```

```
BEGIN
  SELECT 'Number of accounts:', COUNT(*) FROM mysql.user;
END;
```

The procedure still has a `DEFINER` of `'admin'@'localhost'`, but in this case, it executes with the privileges of the invoking user. Thus, the procedure succeeds or fails depending on whether the invoker has the required privileges.

The server handles the data type of a routine parameter, local routine variable created with `DECLARE`, or function return value as follows:

- Assignments are checked for data type mismatches and overflow. Conversion and overflow problems result in warnings, or errors in strict SQL mode.
- Only scalar values can be assigned. For example, a statement such as `SET x = (SELECT 1, 2)` is invalid.
- For character data types, if there is a `CHARACTER SET` attribute in the declaration, the specified character set and its default collation are used. If there is no such attribute, the database character set in effect at routine creation time and its default collation are used. (The database character set is given by the value of the `character_set_database` system variable.) The `COLLATE` attribute is not supported. (This includes use of `BINARY`, because in this context `BINARY` specifies the binary collation of the character set.)

12.1.13. CREATE SERVER Syntax

```
CREATE SERVER server_name
  FOREIGN DATA WRAPPER wrapper_name
  OPTIONS (option [, option] ...)

option:
{
  HOST character-literal
  DATABASE character-literal
  USER character-literal
  PASSWORD character-literal
  SOCKET character-literal
  OWNER character-literal
  PORT numeric-literal }
```

This statement creates the definition of a server for use with the `FEDERATED` storage engine. The `CREATE SERVER` statement creates a new row within the `servers` table within the `mysql` database. This statement requires the `SUPER` privilege.

The `server_name` should be a unique reference to the server. Server definitions are global within the scope of the server, it is not possible to qualify the server definition to a specific database. `server_name` has a maximum length of 64 characters (names longer than 64 characters are silently truncated), and is case insensitive. You may specify the name as a quoted string.

The `wrapper_name` should be `mysql`, and may be quoted with single quotes. Other values for `wrapper_name` are not currently supported.

For each `option` you must specify either a character literal or numeric literal. Character literals are UTF-8, support a maximum length of 64 characters and default to a blank (empty) string. String literals are silently truncated to 64 characters. Numeric literals must be a number between 0 and 9999, default value is 0.

Note

Note that the `OWNER` option is currently not applied, and has no effect on the ownership or operation of the server connection that is created.

The `CREATE SERVER` statement creates an entry in the `mysql.server` table that can later be used with the `CREATE TABLE` statement when creating a `FEDERATED` table. The options that you specify will be used to populate the columns in the `mysql.server` table. The table columns are `Server_name`, `Host`, `Db`, `Username`, `Password`, `Port` and `Socket`.

For example:

```
CREATE SERVER s
  FOREIGN DATA WRAPPER mysql
  OPTIONS (USER 'Remote', HOST '192.168.1.106', DATABASE 'test');
```

The data stored in the table can be used when creating a connection to a `FEDERATED` table:

```
CREATE TABLE t (s1 INT) ENGINE=FEDERATED CONNECTION='s';
```

For more information, see [Section 13.11, “The FEDERATED Storage Engine”](#).

`CREATE SERVER` does not cause an automatic commit.

12.1.14. CREATE TABLE Syntax

```
CREATE [TEMPORARY] TABLE [IF NOT EXISTS] tbl_name
(create_definition,...)
[table_options]
[partition_options]
```

Or:

```
CREATE [TEMPORARY] TABLE [IF NOT EXISTS] tbl_name
[(create_definition,...)]
[table_options]
[partition_options]
select_statement
```

Or:

```
CREATE [TEMPORARY] TABLE [IF NOT EXISTS] tbl_name
{ LIKE old_tbl_name | (LIKE old_tbl_name) }
```

```

```

CREATE TABLE creates a table with the given name. You must have the **CREATE** privilege for the table.

Rules for allowable table names are given in [Section 8.2, “Schema Object Names”](#). By default, the table is created in the default database. An error occurs if the table exists, if there is no default database, or if the database does not exist.

The table name can be specified as *db_name.tbl_name* to create the table in a specific database. This works regardless of whether there is a default database, assuming that the database exists. If you use quoted identifiers, quote the database and table names separately. For example, write ``mydb`.`mytbl``, not ``mydb.mytbl``.

You can use the `TEMPORARY` keyword when creating a table. A `TEMPORARY` table is visible only to the current connection, and is dropped automatically when the connection is closed. This means that two different connections can use the same temporary table name without conflicting with each other or with an existing non-`TEMPORARY` table of the same name. (The existing table is hidden until the temporary table is dropped.) To create temporary tables, you must have the `CREATE TEMPORARY TABLES` privilege.

Note

`CREATE TABLE` does not automatically commit the current active transaction if you use the `TEMPORARY` keyword.

The keywords `IF NOT EXISTS` prevent an error from occurring if the table exists. However, there is no verification that the existing table has a structure identical to that indicated by the `CREATE TABLE` statement.

MySQL represents each table by an `.frm` table format (definition) file in the database directory. The storage engine for the table might create other files as well. In the case of `MyISAM` tables, the storage engine creates data and index files. Thus, for each `MyISAM` table `tbl_name`, there are three disk files.

File	Purpose
<code>tbl_name.frm</code>	Table format (definition) file
<code>tbl_name.MYD</code>	Data file
<code>tbl_name.MYI</code>	Index file

Chapter 13, *Storage Engines*, describes what files each storage engine creates to represent tables. If a table name contains special characters, the names for the table files contain encoded versions of those characters as described in Section 8.2.3, “Mapping of Identifiers to File Names”.

`data_type` represents the data type in a column definition. `spatial_type` represents a spatial data type. The data type syntax shown is representative only. For a full description of the syntax available for specifying column data types, as well as information about the properties of each type, see Chapter 10, *Data Types*, and Section 11.13, “Spatial Extensions”.

Some attributes do not apply to all data types. `AUTO_INCREMENT` applies only to integer and floating-point types. `DEFAULT` does not apply to the `BLOB` or `TEXT` types.

- If neither `NULL` nor `NOT NULL` is specified, the column is treated as though `NULL` had been specified.
- An integer or floating-point column can have the additional attribute `AUTO_INCREMENT`. When you insert a value of `NULL` (recommended) or `0` into an indexed `AUTO_INCREMENT` column, the column is set to the next sequence value. Typically this is `value+1`, where `value` is the largest value for the column currently in the table. `AUTO_INCREMENT` sequences begin with `1`.

To retrieve an `AUTO_INCREMENT` value after inserting a row, use the `LAST_INSERT_ID()` SQL function or the `mysql_insert_id()` C API function. See Section 11.11.3, “Information Functions”, and Section 20.10.3.37, “`mysql_insert_id()`”.

If the `NO_AUTO_VALUE_ON_ZERO` SQL mode is enabled, you can store `0` in `AUTO_INCREMENT` columns as `0` without generating a new sequence value. See Section 5.1.7, “Server SQL Modes”.

Note

There can be only one `AUTO_INCREMENT` column per table, it must be indexed, and it cannot have a `DEFAULT` value. An `AUTO_INCREMENT` column works properly only if it contains only positive values. Inserting a negative number is regarded as inserting a very large positive number. This is done to avoid precision problems when numbers “wrap” over from positive to negative and also to ensure that you do not accidentally get an `AUTO_INCREMENT` column that contains `0`.

For `MyISAM` tables, you can specify an `AUTO_INCREMENT` secondary column in a multiple-column key. See Section 3.6.9, “Using `AUTO_INCREMENT`”.

To make MySQL compatible with some ODBC applications, you can find the `AUTO_INCREMENT` value for the last inserted row with the following query:

```
SELECT * FROM tbl_name WHERE auto_col IS NULL
```

For information about `InnoDB` and `AUTO_INCREMENT`, see Section 13.6.4.3, “`AUTO_INCREMENT` Handling in `InnoDB`”.

- Character data types (`CHAR`, `VARCHAR`, `TEXT`) can include `CHARACTER SET` and `COLLATE` attributes to specify the charac-

ter set and collation for the column. For details, see [Section 9.1, “Character Set Support”](#). `CHARSET` is a synonym for `CHARACTER SET`. Example:

```
CREATE TABLE t (c CHAR(20) CHARACTER SET utf8 COLLATE utf8_bin);
```

MySQL 5.4 interprets length specifications in character column definitions in characters. (Versions before MySQL 4.1 interpreted them in bytes.) Lengths for `BINARY` and `VARBINARY` are in bytes.

- The `DEFAULT` clause specifies a default value for a column. With one exception, the default value must be a constant; it cannot be a function or an expression. This means, for example, that you cannot set the default for a date column to be the value of a function such as `NOW()` or `CURRENT_DATE`. The exception is that you can specify `CURRENT_TIMESTAMP` as the default for a `TIMESTAMP` column. See [Section 10.3.1.1, “TIMESTAMP Properties”](#).

If a column definition includes no explicit `DEFAULT` value, MySQL determines the default value as described in [Section 10.1.4, “Data Type Default Values”](#).

`BLOB` and `TEXT` columns cannot be assigned a default value.

`CREATE TABLE` fails if a date-valued default is not correct according to the `NO_ZERO_IN_DATE` SQL mode, even if strict SQL mode is not enabled. For example, `c1 DATE DEFAULT '2010-00-00'` causes `CREATE TABLE` to fail with `In-valid default value for 'c1'`.

- A comment for a column can be specified with the `COMMENT` option, up to 255 characters long. The comment is displayed by the `SHOW CREATE TABLE` and `SHOW FULL COLUMNS` statements.
- Beginning with MySQL Cluster NDB 6.2.5 and MySQL Cluster NDB 6.3.2, it is also possible to specify a data storage format for individual columns of `NDB` tables using `COLUMN_FORMAT`. Allowable column formats are `FIXED`, `DYNAMIC`, and `DEFAULT`. `FIXED` is used to specify fixed-width storage, `DYNAMIC` allows the column to be variable-width, and `DEFAULT` causes the column to use fixed-width or variable-width storage as determined by the column's data type (possibly overridden by a `ROW_FORMAT` specifier).

For `NDB` tables, the default value for `COLUMN_FORMAT` is `DEFAULT`.

`COLUMN_FORMAT` currently has no effect on columns of tables using storage engines other than `NDB`.

- For `NDB` tables, beginning with MySQL Cluster NDB 6.2.5 and MySQL Cluster NDB 6.3.2, it is also possible to specify whether the column is stored on disk or in memory by using a `STORAGE` clause. `STORAGE DISK` causes the column to be stored on disk, and `STORAGE MEMORY` causes in-memory storage to be used. The `CREATE TABLE` statement used must still include a `TABLESPACE` clause:

```
mysql> CREATE TABLE t1 (
->   c1 INT STORAGE DISK,
->   c2 INT STORAGE MEMORY
-> ) ENGINE NDB;
ERROR 1005 (HY000): CAN'T CREATE TABLE 'c.t1' (ERRNO: 140)

mysql> CREATE TABLE t1 (
->   c1 INT STORAGE DISK,
->   c2 INT STORAGE MEMORY
-> ) TABLESPACE ts_1 ENGINE NDB;
Query OK, 0 rows affected (1.06 sec)
```

For `NDB` tables, `STORAGE DEFAULT` is equivalent to `STORAGE MEMORY`.

The `STORAGE` clause has no effect on tables using storage engines other than `NDB`.

- `KEY` is normally a synonym for `INDEX`. The key attribute `PRIMARY KEY` can also be specified as just `KEY` when given in a column definition. This was implemented for compatibility with other database systems.
- A `UNIQUE` index creates a constraint such that all values in the index must be distinct. An error occurs if you try to add a new row with a key value that matches an existing row. For all engines, a `UNIQUE` index allows multiple `NULL` values for columns that can contain `NULL`.
- A `PRIMARY KEY` is a unique index where all key columns must be defined as `NOT NULL`. If they are not explicitly declared as `NOT NULL`, MySQL declares them so implicitly (and silently). A table can have only one `PRIMARY KEY`. If you do not have a `PRIMARY KEY` and an application asks for the `PRIMARY KEY` in your tables, MySQL returns the first `UNIQUE` index that has no `NULL` columns as the `PRIMARY KEY`.

In `InnoDB` tables, having a long `PRIMARY KEY` wastes a lot of space. (See [Section 13.6.10, “InnoDB Table and Index Structures”](#).)

- In the created table, a `PRIMARY KEY` is placed first, followed by all `UNIQUE` indexes, and then the non-unique indexes. This helps the MySQL optimizer to prioritize which index to use and also more quickly to detect duplicated `UNIQUE` keys.

- A `PRIMARY KEY` can be a multiple-column index. However, you cannot create a multiple-column index using the `PRIMARY KEY` key attribute in a column specification. Doing so only marks that single column as primary. You must use a separate `PRIMARY KEY(index_col_name, ...)` clause.
- If a `PRIMARY KEY` or `UNIQUE` index consists of only one column that has an integer type, you can also refer to the column as `_rowid` in `SELECT` statements.
- In MySQL, the name of a `PRIMARY KEY` is `PRIMARY`. For other indexes, if you do not assign a name, the index is assigned the same name as the first indexed column, with an optional suffix (`_2`, `_3`, ...) to make it unique. You can see index names for a table using `SHOW INDEX FROM tbl_name`. See [Section 12.5.5.23, “SHOW INDEX Syntax”](#).
- Some storage engines allow you to specify an index type when creating an index. The syntax for the `index_type` specifier is `USING type_name`.

Example:

```
CREATE TABLE lookup
(id INT, INDEX USING BTREE (id))
ENGINE = MEMORY;
```

The preferred position is after the column list. Use of the option before the column list will no longer be recognized in a future MySQL release.

`index_option` values specify additional options for an index. `USING` is one such option. For details about allowable `index_option` values, see [Section 12.1.11, “CREATE INDEX Syntax”](#).

For more information about indexes, see [Section 7.4.4, “How MySQL Uses Indexes”](#).

- In MySQL 5.4, only the `MyISAM`, `InnoDB`, and `MEMORY` storage engines support indexes on columns that can have `NULL` values. In other cases, you must declare indexed columns as `NOT NULL` or an error results.
- For `CHAR`, `VARCHAR`, `BINARY`, and `VARBINARY` columns, indexes can be created that use only the leading part of column values, using `col_name(length)` syntax to specify an index prefix length. `BLOB` and `TEXT` columns also can be indexed, but a prefix length *must* be given. Prefix lengths are given in characters for nonbinary string types and in bytes for binary string types. That is, index entries consist of the first `length` characters of each column value for `CHAR`, `VARCHAR`, and `TEXT` columns, and the first `length` bytes of each column value for `BINARY`, `VARBINARY`, and `BLOB` columns. Indexing only a prefix of column values like this can make the index file much smaller. See [Section 7.4.2, “Column Indexes”](#).

Only the `MyISAM` and `InnoDB` storage engines support indexing on `BLOB` and `TEXT` columns. For example:

```
CREATE TABLE test (blob_col BLOB, INDEX(blob_col(10)));
```

Prefixes can be up to 1000 bytes long (767 bytes for `InnoDB` tables). Note that prefix limits are measured in bytes, whereas the prefix length in `CREATE TABLE` statements is interpreted as number of characters for nonbinary data types (`CHAR`, `VARCHAR`, `TEXT`). Take this into account when specifying a prefix length for a column that uses a multi-byte character set.

- An `index_col_name` specification can end with `ASC` or `DESC`. These keywords are allowed for future extensions for specifying ascending or descending index value storage. Currently, they are parsed but ignored; index values are always stored in ascending order.
- When you use `ORDER BY` or `GROUP BY` on a `TEXT` or `BLOB` column in a `SELECT`, the server sorts values using only the initial number of bytes indicated by the `max_sort_length` system variable. See [Section 10.4.3, “The BLOB and TEXT Types”](#).
- You can create special `FULLTEXT` indexes, which are used for full-text searches. Only the `MyISAM` storage engine supports `FULLTEXT` indexes. They can be created only from `CHAR`, `VARCHAR`, and `TEXT` columns. Indexing always happens over the entire column; column prefix indexing is not supported and any prefix length is ignored if specified. See [Section 11.8, “Full-Text Search Functions”](#), for details of operation. A `WITH PARSER` clause can be specified as an `index_option` value to associate a parser plugin with the index if full-text indexing and searching operations need special handling. This clause is legal only for `FULLTEXT` indexes. See [Section 21.2, “The MySQL Plugin Interface”](#), for details on creating plugins.
- You can create `SPATIAL` indexes on spatial data types. Spatial types are supported only for `MyISAM` tables and indexed columns must be declared as `NOT NULL`. See [Section 11.13, “Spatial Extensions”](#).
- `InnoDB` tables support checking of foreign key constraints. See [Section 13.6, “The InnoDB Storage Engine”](#). Note that the `FOREIGN KEY` syntax in `InnoDB` is more restrictive than the syntax presented for the `CREATE TABLE` statement at the beginning of this section: The columns of the referenced table must always be explicitly named. `InnoDB` supports both `ON DELETE` and `ON UPDATE` actions on foreign keys. For the precise syntax, see [Section 13.6.4.4, “FOREIGN KEY Constraints”](#).

For other storage engines, MySQL Server parses and ignores the `FOREIGN KEY` and `REFERENCES` syntax in `CREATE TABLE` statements. The `CHECK` clause is parsed but ignored by all storage engines. See [Section 1.7.5.4, “Foreign Keys”](#).

Important

For users familiar with the ANSI/ISO SQL Standard, please note that no storage engine, including `InnoDB`, recognizes or enforces the `MATCH` clause used in referential integrity constraint definitions. Use of an explicit `MATCH` clause will not have the specified effect, and also causes `ON DELETE` and `ON UPDATE` clauses to be ignored. For these reasons, specifying `MATCH` should be avoided.

The `MATCH` clause in the SQL standard controls how `NULL` values in a composite (multiple-column) foreign key are handled when comparing to a primary key. `InnoDB` essentially implements the semantics defined by `MATCH SIMPLE`, which allow a foreign key to be all or partially `NULL`. In that case, the (child table) row containing such a foreign key is allowed to be inserted, and does not match any row in the referenced (parent) table. It is possible to implement other semantics using triggers.

Additionally, MySQL and `InnoDB` require that the referenced columns be indexed for performance. However, the system does not enforce a requirement that the referenced columns be `UNIQUE` or be declared `NOT NULL`. The handling of foreign key references to non-unique keys or keys that contain `NULL` values is not well defined for operations such as `UPDATE` or `DELETE CASCADE`. You are advised to use foreign keys that reference only `UNIQUE` and `NOT NULL` keys.

Furthermore, `InnoDB` does not recognize or support “inline `REFERENCES` specifications” (as defined in the SQL standard) where the references are defined as part of the column specification. `InnoDB` accepts `REFERENCES` clauses only when specified as part of a separate `FOREIGN KEY` specification. For other storage engines, MySQL Server parses and ignores foreign key specifications.

Note

Partitioned tables do not support foreign keys. See [Section 17.5, “Restrictions and Limitations on Partitioning”](#), for more information.

- There is a hard limit of 4096 columns per table, but the effective maximum may be less for a given table and depends on the factors discussed in [Section D.7.2, “The Maximum Number of Columns Per Table”](#).

The `TABLESPACE` and `STORAGE` table options are employed only with `NDBCLUSTER` tables. The tablespace named `tablespace_name` must already have been created using `CREATE TABLESPACE`. `STORAGE` determines the type of storage used (disk or memory), and can be one of `DISK`, `MEMORY`, or `DEFAULT`.

`TABLESPACE ... STORAGE DISK` assigns a table to a MySQL Cluster Disk Data tablespace. See [MySQL Cluster Disk Data Tables](#), for more information.

Important

A `STORAGE` clause cannot be used in a `CREATE TABLE` statement without a `TABLESPACE` clause.

The `ENGINE` table option specifies the storage engine for the table.

The `ENGINE` table option takes the storage engine names shown in the following table.

Storage Engine	Description
<code>ARCHIVE</code>	The archiving storage engine. See Section 13.12, “The ARCHIVE Storage Engine” .
<code>CSV</code>	Tables that store rows in comma-separated values format. See Section 13.13, “The CSV Storage Engine” .
<code>EXAMPLE</code>	An example engine. See Section 13.10, “The EXAMPLE Storage Engine” .
<code>FEDERATED</code>	Storage engine that accesses remote tables. See Section 13.11, “The FEDERATED Storage Engine” .
<code>HEAP</code>	This is a synonym for <code>MEMORY</code> .
<code>ISAM (OBSOLETE)</code>	Not available in MySQL 5.4. If you are upgrading to MySQL 5.4 from a previous version, you should convert any existing <code>ISAM</code> tables to <code>MyISAM</code> before performing the upgrade.
<code>InnoDB</code>	Transaction-safe tables with row locking and foreign keys. See Section 13.6, “The InnoDB Storage Engine” .
<code>MEMORY</code>	The data for this storage engine is stored only in memory. See Section 13.9, “The MEMORY (HEAP) Storage Engine” .
<code>MERGE</code>	A collection of <code>MyISAM</code> tables used as one table. Also known as <code>MRG_MyISAM</code> . See Section 13.8, “The MERGE Storage Engine” .
<code>MyISAM</code>	The binary portable storage engine that is the default storage engine used by MySQL. See Section 13.7, “The MyISAM Storage Engine” .

	tion 13.5, “The MyISAM Storage Engine”.
NDBCLUSTER	Clustered, fault-tolerant, memory-based tables. Also known as NDB. See MySQL Cluster NDB 6.X/7.X .

If a storage engine is specified that is not available, MySQL uses the default engine instead. Normally, this is [MyISAM](#). For example, if a table definition includes the `ENGINE=INNODB` option but the MySQL server does not support `INNODB` tables, the table is created as a [MyISAM](#) table. This makes it possible to have a replication setup where you have transactional tables on the master but tables created on the slave are non-transactional (to get more speed). In MySQL 5.4, a warning occurs if the storage engine specification is not honored.

Engine substitution can be controlled by the setting of the `NO_ENGINE_SUBSTITUTION` SQL mode, as described in [Section 5.1.7, “Server SQL Modes”](#).

Note

The older `TYPE` option was synonymous with `ENGINE`. `TYPE` has been deprecated since MySQL 4.0 but is still supported for backward compatibility (with a warning) in MySQL 5.4. It is removed as of MySQL 6.0. *You should not use `TYPE` in any new applications, and you should immediately begin conversion of existing applications to use `ENGINE` instead.*

The other table options are used to optimize the behavior of the table. In most cases, you do not have to specify any of them. These options apply to all storage engines unless otherwise indicated. Options that do not apply to a given storage engine may be accepted and remembered as part of the table definition. Such options then apply if you later use `ALTER TABLE` to convert the table to use a different storage engine.

- `AUTO_INCREMENT`

The initial `AUTO_INCREMENT` value for the table. In MySQL 5.4, this works for [MyISAM](#), [MEMORY](#), [InnoDB](#), and [ARCHIVE](#) tables. To set the first auto-increment value for engines that do not support the `AUTO_INCREMENT` table option, insert a “dummy” row with a value one less than the desired value after creating the table, and then delete the dummy row.

For engines that support the `AUTO_INCREMENT` table option in `CREATE TABLE` statements, you can also use `ALTER TABLE tbl_name AUTO_INCREMENT = N` to reset the `AUTO_INCREMENT` value. The value cannot be set lower than the maximum value currently in the column.

- `AVG_ROW_LENGTH`

An approximation of the average row length for your table. You need to set this only for large tables with variable-size rows.

When you create a [MyISAM](#) table, MySQL uses the product of the `MAX_ROWS` and `AVG_ROW_LENGTH` options to decide how big the resulting table is. If you don't specify either option, the maximum size for [MyISAM](#) data and index files is 256TB by default. (If your operating system does not support files that large, table sizes are constrained by the file size limit.) If you want to keep down the pointer sizes to make the index smaller and faster and you don't really need big files, you can decrease the default pointer size by setting the `myisam_data_pointer_size` system variable. (See [Section 5.1.3, “Server System Variables”](#).) If you want all your tables to be able to grow above the default limit and are willing to have your tables slightly slower and larger than necessary, you can increase the default pointer size by setting this variable. Setting the value to 7 allows table sizes up to 65,536TB.

- `[DEFAULT] CHARACTER SET`

Specify a default character set for the table. `CHARSET` is a synonym for `CHARACTER SET`. If the character set name is `DEFAULT`, the database character set is used.

- `CHECKSUM`

Set this to 1 if you want MySQL to maintain a live checksum for all rows (that is, a checksum that MySQL updates automatically as the table changes). This makes the table a little slower to update, but also makes it easier to find corrupted tables. The `CHECKSUM TABLE` statement reports the checksum. ([MyISAM](#) only.)

- `[DEFAULT] COLLATE`

Specify a default collation for the table.

- `COMMENT`

A comment for the table, up to 60 characters long.

- `CONNECTION`

The connection string for a `FEDERATED` table.

Note

Older versions of MySQL used a `COMMENT` option for the connection string.

- `DATA DIRECTORY`, `INDEX DIRECTORY`

By using `DATA DIRECTORY='directory'` or `INDEX DIRECTORY='directory'` you can specify where the `MyISAM` storage engine should put a table's data file and index file. The directory must be the full path name to the directory, not a relative path.

Important

Table-level `DATA DIRECTORY` and `INDEX DIRECTORY` options are ignored for partitioned tables. ([Bug#32091](#))

These options work only when you are not using the `--skip-symbolic-links` option. Your operating system must also have a working, thread-safe `realpath()` call. See [Section 7.6.1.2, “Using Symbolic Links for Tables on Unix”](#), for more complete information.

If a `MyISAM` table is created with no `DATA DIRECTORY` option, the `.MYD` file is created in the database directory. By default, if `MyISAM` finds an existing `.MYD` file in this case, it overwrites it. The same applies to `.MYI` files for tables created with no `INDEX DIRECTORY` option. To suppress this behavior, start the server with the `--keep_files_on_create` option, in which case `MyISAM` will not overwrite existing files and returns an error instead.

If a `MyISAM` table is created with a `DATA DIRECTORY` or `INDEX DIRECTORY` option and an existing `.MYD` or `.MYI` file is found, `MyISAM` always returns an error. It will not overwrite a file in the specified directory.

Important

You cannot use path names that contain the MySQL data directory with `DATA DIRECTORY` or `INDEX DIRECTORY`. This includes partitioned tables and individual table partitions. (See [Bug#32167](#).)

- `DELAY_KEY_WRITE`

Set this to 1 if you want to delay key updates for the table until the table is closed. See the description of the `delay_key_write` system variable in [Section 5.1.3, “Server System Variables”](#). (`MyISAM` only.)

- `INSERT_METHOD`

If you want to insert data into a `MERGE` table, you must specify with `INSERT_METHOD` the table into which the row should be inserted. `INSERT_METHOD` is an option useful for `MERGE` tables only. Use a value of `FIRST` or `LAST` to have inserts go to the first or last table, or a value of `NO` to prevent inserts. See [Section 13.8, “The MERGE Storage Engine”](#).

- `KEY_BLOCK_SIZE`

This option provides a hint to the storage engine about the size in bytes to use for index key blocks. The engine is allowed to change the value if necessary. A value of 0 indicates that the default value should be used. Individual index definitions can specify a `KEY_BLOCK_SIZE` value of their own to override the table value.

- `MAX_ROWS`

The maximum number of rows you plan to store in the table. This is not a hard limit, but rather a hint to the storage engine that the table must be able to store at least this many rows.

- `MIN_ROWS`

The minimum number of rows you plan to store in the table. The `MEMORY` storage engine uses this option as a hint about memory use.

- `PACK_KEYS`

`PACK_KEYS` takes effect only with `MyISAM` tables. Set this option to 1 if you want to have smaller indexes. This usually makes updates slower and reads faster. Setting the option to 0 disables all packing of keys. Setting it to `DEFAULT` tells the storage engine to pack only long `CHAR`, `VARCHAR`, `BINARY`, or `VARBINARY` columns.

If you do not use `PACK_KEYS`, the default is to pack strings, but not numbers. If you use `PACK_KEYS=1`, numbers are packed as well.

When packing binary number keys, MySQL uses prefix compression:

- Every key needs one extra byte to indicate how many bytes of the previous key are the same for the next key.
- The pointer to the row is stored in high-byte-first order directly after the key, to improve compression.

This means that if you have many equal keys on two consecutive rows, all following “same” keys usually only take two bytes (including the pointer to the row). Compare this to the ordinary case where the following keys takes `storage_size_for_key + pointer_size` (where the pointer size is usually 4). Conversely, you get a significant benefit from prefix compression only if you have many numbers that are the same. If all keys are totally different, you use one byte more per key, if the key is not a key that can have `NULL` values. (In this case, the packed key length is stored in the same byte that is used to mark if a key is `NULL`.)

- `PASSWORD`

This option is unused. If you have a need to scramble your `.frm` files and make them unusable to any other MySQL server, please contact our sales department.

- `RAID_TYPE`

`RAID` support has been removed as of MySQL 5.0. For information on `RAID`, see [CREATE TABLE Syntax](#).

- `ROW_FORMAT`

Defines how the rows should be stored. For `MyISAM` tables, the option value can be `FIXED` or `DYNAMIC` for static or variable-length row format. `myisampack` sets the type to `COMPRESSED`. See [Section 13.5.3, “MyISAM Table Storage Formats”](#).

For `InnoDB` tables, rows are stored in compact format (`ROW_FORMAT=COMPACT`) by default. The non-compact format used in older versions of MySQL can still be requested by specifying `ROW_FORMAT=REDUNDANT`.

Note

When executing a `CREATE TABLE` statement, if you specify a row format which is not supported by the storage engine that is used for the table, the table is created using that storage engine's default row format. The information reported in this column in response to `SHOW TABLE STATUS` is the actual row format used. This may differ from the value in the `Create_options` column because the original `CREATE TABLE` definition is retained during creation.

- `UNION`

`UNION` is used when you want to access a collection of identical `MyISAM` tables as one. This works only with `MERGE` tables. See [Section 13.8, “The MERGE Storage Engine”](#).

You must have `SELECT`, `UPDATE`, and `DELETE` privileges for the tables you map to a `MERGE` table.

Note

Formerly, all tables used had to be in the same database as the `MERGE` table itself. This restriction no longer applies.

`partition_options` can be used to control partitioning of the table created with `CREATE TABLE`.

Important

Not all options shown in the syntax for `partition_options` at the beginning of this section are available for all partitioning types. Please see the listings for the following individual types for information specific to each type, and see [Chapter 17, Partitioning](#), for more complete information about the workings of and uses for partitioning in MySQL, as well as additional examples of table creation and other statements relating to MySQL partitioning.

If used, a `partition_options` clause begins with `PARTITION BY`. This clause contains the function that is used to determine the partition; the function returns an integer value ranging from 1 to `num`, where `num` is the number of partitions. (The maximum number of user-defined partitions which a table may contain is 1024; the number of subpartitions — discussed later in this section — is included in this maximum.) The choices that are available for this function in MySQL 5.4 are shown in the following list:

- `HASH(expr)`: Hashes one or more columns to create a key for placing and locating rows. `expr` is an expression using one or more table columns. This can be any legal MySQL expression (including MySQL functions) that yields a single integer value. For example, these are all valid `CREATE TABLE` statements using `PARTITION BY HASH`:

```
CREATE TABLE t1 (col1 INT, col2 CHAR(5))
PARTITION BY HASH(col1);

CREATE TABLE t1 (col1 INT, col2 CHAR(5))
PARTITION BY HASH( ORD(col2) );
```

```
CREATE TABLE t1 (col1 INT, col2 CHAR(5), col3 DATETIME)
PARTITION BY HASH ( YEAR(col3) );
```

You may not use either `VALUES LESS THAN` or `VALUES IN` clauses with `PARTITION BY HASH`.

`PARTITION BY HASH` uses the remainder of *expr* divided by the number of partitions (that is, the modulus). For examples and additional information, see [Section 17.2.3, “HASH Partitioning”](#).

The `LINEAR` keyword entails a somewhat different algorithm. In this case, the number of the partition in which a row is stored is calculated as the result of one or more logical `AND` operations. For discussion and examples of linear hashing, see [Section 17.2.3.1, “LINEAR HASH Partitioning”](#).

- `KEY(column_list)`: This is similar to `HASH`, except that MySQL supplies the hashing function so as to guarantee an even data distribution. The *column_list* argument is simply a list of table columns. This example shows a simple table partitioned by key, with 4 partitions:

```
CREATE TABLE tk (col1 INT, col2 CHAR(5), col3 DATE)
PARTITION BY KEY(col3)
PARTITIONS 4;
```

For tables that are partitioned by key, you can employ linear partitioning by using the `LINEAR` keyword. This has the same effect as with tables that are partitioned by `HASH`. That is, the partition number is found using the `&` operator rather than the modulus (see [Section 17.2.3.1, “LINEAR HASH Partitioning”](#), and [Section 17.2.4, “KEY Partitioning”](#), for details). This example uses linear partitioning by key to distribute data between 5 partitions:

```
CREATE TABLE tk (col1 INT, col2 CHAR(5), col3 DATE)
PARTITION BY LINEAR KEY(col3)
PARTITIONS 5;
```

You may not use either `VALUES LESS THAN` or `VALUES IN` clauses with `PARTITION BY KEY`.

- `RANGE`: In this case, *expr* shows a range of values using a set of `VALUES LESS THAN` operators. When using range partitioning, you must define at least one partition using `VALUES LESS THAN`. You cannot use `VALUES IN` with range partitioning.

`VALUES LESS THAN` can be used with either a literal value or an expression that evaluates to a single value.

Suppose that you have a table that you wish to partition on a column containing year values, according to the following scheme.

Partition Number:	Years Range:
0	1990 and earlier
1	1991 – 1994
2	1995 – 1998
3	1999 – 2002
4	2003 – 2005
5	2006 and later

A table implementing such a partitioning scheme can be realized by the `CREATE TABLE` statement shown here:

```
CREATE TABLE t1 (
  year_col INT,
  some_data INT
)
PARTITION BY RANGE (year_col) (
  PARTITION p0 VALUES LESS THAN (1991),
  PARTITION p1 VALUES LESS THAN (1995),
  PARTITION p2 VALUES LESS THAN (1999),
  PARTITION p3 VALUES LESS THAN (2002),
  PARTITION p4 VALUES LESS THAN (2006),
  PARTITION p5 VALUES LESS THAN MAXVALUE
);
```

`PARTITION ... VALUES LESS THAN ...` statements work in a consecutive fashion. `VALUES LESS THAN MAXVALUE` works to specify “leftover” values that are greater than the maximum value otherwise specified.

Note that `VALUES LESS THAN` clauses work sequentially in a manner similar to that of the `case` portions of a `switch ... case` block (as found in many programming languages such as C, Java, and PHP). That is, the clauses must be arranged in such a way that the upper limit specified in each successive `VALUES LESS THAN` is greater than that of the previous one,

with the one referencing `MAXVALUE` coming last of all in the list.

- `LIST (expr)`: This is useful when assigning partitions based on a table column with a restricted set of possible values, such as a state or country code. In such a case, all rows pertaining to a certain state or country can be assigned to a single partition, or a partition can be reserved for a certain set of states or countries. It is similar to `RANGE`, except that only `VALUES IN` may be used to specify allowable values for each partition.

`VALUES IN` is used with a list of values to be matched. For instance, you could create a partitioning scheme such as the following:

```
CREATE TABLE client_firms (
  id INT,
  name VARCHAR(35)
)
PARTITION BY LIST (id) (
  PARTITION r0 VALUES IN (1, 5, 9, 13, 17, 21),
  PARTITION r1 VALUES IN (2, 6, 10, 14, 18, 22),
  PARTITION r2 VALUES IN (3, 7, 11, 15, 19, 23),
  PARTITION r3 VALUES IN (4, 8, 12, 16, 20, 24)
);
```

When using list partitioning, you must define at least one partition using `VALUES IN`. You cannot use `VALUES LESS THAN` with `PARTITION BY LIST`.

Note

Currently, the value list used with `VALUES IN` must consist of integer values only.

- The number of partitions may optionally be specified with a `PARTITIONS num` clause, where `num` is the number of partitions. If both this clause *and* any `PARTITION` clauses are used, `num` must be equal to the total number of any partitions that are declared using `PARTITION` clauses.

Note

Whether or not you use a `PARTITIONS` clause in creating a table that is partitioned by `RANGE` or `LIST`, you must still include at least one `PARTITION VALUES` clause in the table definition (see below).

- A partition may optionally be divided into a number of subpartitions. This can be indicated by using the optional `SUBPARTITION BY` clause. Subpartitioning may be done by `HASH` or `KEY`. Either of these may be `LINEAR`. These work in the same way as previously described for the equivalent partitioning types. (It is not possible to subpartition by `LIST` or `RANGE`.)

The number of subpartitions can be indicated using the `SUBPARTITIONS` keyword followed by an integer value.

- Rigorous checking of the value used in `PARTITIONS` or `SUBPARTITIONS` clauses is applied and this value must adhere to the following rules:
 - The value must be a positive, nonzero integer.
 - No leading zeroes are permitted.
 - The value must be an integer literal, and cannot not be an expression. For example, `PARTITIONS 0.2E+01` is not allowed, even though `0.2E+01` evaluates to 2. ([Bug#15890](#))

Note

The expression (`expr`) used in a `PARTITION BY` clause cannot refer to any columns not in the table being created; such references are specifically disallowed and cause the statement to fail with an error. ([Bug#29444](#))

Each partition may be individually defined using a `partition_definition` clause. The individual parts making up this clause are as follows:

- `PARTITION partition_name`: This specifies a logical name for the partition.
- A `VALUES` clause: For range partitioning, each partition must include a `VALUES LESS THAN` clause; for list partitioning, you must specify a `VALUES IN` clause for each partition. This is used to determine which rows are to be stored in this partition. See the discussions of partitioning types in [Chapter 17, Partitioning](#), for syntax examples.
- An optional `COMMENT` clause may be used to specify a string that describes the partition. Example:

```
COMMENT = 'Data for the years previous to 1999'
```

- `DATA DIRECTORY` and `INDEX DIRECTORY` may be used to indicate the directory where, respectively, the data and indexes for this partition are to be stored. Both the `data_dir` and the `index_dir` must be absolute system path names. Example:

```
CREATE TABLE th (id INT, name VARCHAR(30), adate DATE)
PARTITION BY LIST(YEAR(adata))
(
  PARTITION p1999 VALUES IN (1995, 1999, 2003)
  DATA DIRECTORY = '/var/appdata/95/data'
  INDEX DIRECTORY = '/var/appdata/95/idx',
  PARTITION p2000 VALUES IN (1996, 2000, 2004)
  DATA DIRECTORY = '/var/appdata/96/data'
  INDEX DIRECTORY = '/var/appdata/96/idx',
  PARTITION p2001 VALUES IN (1997, 2001, 2005)
  DATA DIRECTORY = '/var/appdata/97/data'
  INDEX DIRECTORY = '/var/appdata/97/idx',
  PARTITION p2000 VALUES IN (1998, 2002, 2006)
  DATA DIRECTORY = '/var/appdata/98/data'
  INDEX DIRECTORY = '/var/appdata/98/idx'
);
```

`DATA DIRECTORY` and `INDEX DIRECTORY` behave in the same way as in the `CREATE TABLE` statement's `table_option` clause as used for `MyISAM` tables.

One data directory and one index directory may be specified per partition. If left unspecified, the data and indexes are stored by default in the table's database directory.

On Windows, the `DATA DIRECTORY` and `INDEX DIRECTORY` options are not supported for individual partitions or subpartitions. These options are ignored on Windows, except that a warning is generated. ([Bug#30459](#))

Note

The `DATA DIRECTORY` and `INDEX DIRECTORY` options are ignored for creating partitioned tables if `NO_DIR_IN_CREATE` is in effect. ([Bug#24633](#))

- `MAX_ROWS` and `MIN_ROWS` may be used to specify, respectively, the maximum and minimum number of rows to be stored in the partition. The values for `max_number_of_rows` and `min_number_of_rows` must be positive integers. As with the table-level options with the same names, these act only as “suggestions” to the server and are not hard limits.
- The optional `TABLESPACE` clause may be used to designate a tablespace for the partition. Used for MySQL Cluster only.
- The partitioning handler accepts a `[STORAGE] ENGINE` option for both `PARTITION` and `SUBPARTITION`. Currently, the only way in which this can be used is to set all partitions or all subpartitions to the same storage engine, and an attempt to set different storage engines for partitions or subpartitions in the same table will give rise to the error `ERROR 1469 (HY000): THE MIX OF HANDLERS IN THE PARTITIONS IS NOT ALLOWED IN THIS VERSION OF MySQL`. We expect to lift this restriction on partitioning in a future MySQL release.
- The `NODEGROUP` option can be used to make this partition act as part of the node group identified by `node_group_id`. This option is applicable only to MySQL Cluster.
- The partition definition may optionally contain one or more `subpartition_definition` clauses. Each of these consists at a minimum of the `SUBPARTITION name`, where `name` is an identifier for the subpartition. Except for the replacement of the `PARTITION` keyword with `SUBPARTITION`, the syntax for a subpartition definition is identical to that for a partition definition.

Subpartitioning must be done by `HASH` or `KEY`, and can be done only on `RANGE` or `LIST` partitions. See [Section 17.2.5, “Subpartitioning”](#).

Partitions can be modified, merged, added to tables, and dropped from tables. For basic information about the MySQL statements to accomplish these tasks, see [Section 12.1.6, “ALTER TABLE Syntax”](#). For more detailed descriptions and examples, see [Section 17.3, “Partition Management”](#).

Important

The original `CREATE TABLE` statement, including all specifications and table options are stored by MySQL when the table is created. The information is retained so that if you change storage engines, collations or other settings using an `ALTER TABLE` statement, the original table options specified are retained. This allows you to change between `InnoDB` and `MyISAM` table types even though the row formats supported by the two engines are different.

Because the text of the original statement is retained, but due to the way that certain values and options may be silently reconfigured (such as the `ROW_FORMAT`), the active table definition (accessible through `DESCRIBE` or with `SHOW TABLE STATUS`) and the table creation string (accessible through `SHOW CREATE TABLE`) will report different values.

You can create one table from another by adding a `SELECT` statement at the end of the `CREATE TABLE` statement:

```
CREATE TABLE new_tbl SELECT * FROM orig_tbl;
```

MySQL creates new columns for all elements in the `SELECT`. For example:

```
mysql> CREATE TABLE test (a INT NOT NULL AUTO_INCREMENT,
-> PRIMARY KEY (a), KEY(b))
-> ENGINE=MyISAM SELECT b,c FROM test2;
```

This creates a `MyISAM` table with three columns, `a`, `b`, and `c`. Notice that the columns from the `SELECT` statement are appended to the right side of the table, not overlapped onto it. Take the following example:

```
mysql> SELECT * FROM foo;
+----+
| n |
+----+
| 1 |
+----+

mysql> CREATE TABLE bar (m INT) SELECT n FROM foo;
Query OK, 1 row affected (0.02 sec)
Records: 1 Duplicates: 0 Warnings: 0

mysql> SELECT * FROM bar;
+-----+-----+
| m | n |
+-----+-----+
| NULL | 1 |
+-----+-----+
1 row in set (0.00 sec)
```

For each row in table `foo`, a row is inserted in `bar` with the values from `foo` and default values for the new columns.

In a table resulting from `CREATE TABLE ... SELECT`, columns named only in the `CREATE TABLE` part come first. Columns named in both parts or only in the `SELECT` part come after that. The data type of `SELECT` columns can be overridden by also specifying the column in the `CREATE TABLE` part.

If any errors occur while copying the data to the table, it is automatically dropped and not created.

`CREATE TABLE ... SELECT` does not automatically create any indexes for you. This is done intentionally to make the statement as flexible as possible. If you want to have indexes in the created table, you should specify these before the `SELECT` statement:

```
mysql> CREATE TABLE bar (UNIQUE (n)) SELECT n FROM foo;
```

Some conversion of data types might occur. For example, the `AUTO_INCREMENT` attribute is not preserved, and `VARCHAR` columns can become `CHAR` columns. Retained attributes are `NULL` (or `NOT NULL`) and, for those columns that have them, `CHARACTER SET`, `COLLATION`, `COMMENT`, and the `DEFAULT` clause.

When creating a table with `CREATE ... SELECT`, make sure to alias any function calls or expressions in the query. If you do not, the `CREATE` statement might fail or result in undesirable column names.

```
CREATE TABLE artists_and_works
SELECT artist.name, COUNT(work.artist_id) AS number_of_works
FROM artist LEFT JOIN work ON artist.id = work.artist_id
GROUP BY artist.id;
```

You can also explicitly specify the data type for a generated column:

```
CREATE TABLE foo (a TINYINT NOT NULL) SELECT b+1 AS a FROM bar;
```

For `CREATE TABLE ... SELECT`, if `IF NOT EXISTS` is given and the table already exists, MySQL handles the statement as follows:

- The table definition given in the `CREATE TABLE` part is ignored. No error occurs, even if the definition does not match that of the existing table.
- If there is a mismatch between the number of columns in the table and the number of columns produced by the `SELECT` part, the selected values are assigned to the rightmost columns. For example, if the table contains n columns and the `SELECT` produces m columns, where $m < n$, the selected values are assigned to the m rightmost columns in the table. Each of the initial $n - m$ columns is assigned its default value, either that specified explicitly in the column definition or the implicit column data type default if the definition contains no default.

- If strict SQL mode is enabled and any of these initial columns do not have an explicit default value, the statement fails with an error.

The following example illustrates `IF NOT EXISTS` handling:

```
mysql> CREATE TABLE t1 (i1 INT DEFAULT 0, i2 INT, i3 INT, i4 INT);
Query OK, 0 rows affected (0.05 sec)

mysql> CREATE TABLE IF NOT EXISTS t1 (c1 CHAR(10)) SELECT 1, 2;
Query OK, 1 row affected, 1 warning (0.01 sec)
Records: 1 Duplicates: 0 Warnings: 0

mysql> SELECT * FROM t1;
+-----+-----+-----+-----+
| i1   | i2   | i3   | i4   |
+-----+-----+-----+-----+
| 0   | NULL | 1   | 2   |
+-----+-----+-----+-----+
1 row in set (0.00 sec)
```

Use `LIKE` to create an empty table based on the definition of another table, including any column attributes and indexes defined in the original table:

```
CREATE TABLE new_tbl LIKE orig_tbl;
```

The copy is created using the same version of the table storage format as the original table. The `SELECT` privilege is required on the original table.

`LIKE` works only for base tables, not for views.

`CREATE TABLE ... LIKE` does not preserve any `DATA DIRECTORY` or `INDEX DIRECTORY` table options that were specified for the original table, or any foreign key definitions.

You can precede the `SELECT` by `IGNORE` or `REPLACE` to indicate how to handle rows that duplicate unique key values. With `IGNORE`, new rows that duplicate an existing row on a unique key value are discarded. With `REPLACE`, new rows replace rows that have the same unique key value. If neither `IGNORE` nor `REPLACE` is specified, duplicate unique key values result in an error.

To ensure that the binary log can be used to re-create the original tables, MySQL does not allow concurrent inserts during `CREATE TABLE ... SELECT`.

12.1.14.1. Silent Column Specification Changes

In some cases, MySQL silently changes column specifications from those given in a `CREATE TABLE` or `ALTER TABLE` statement. These might be changes to a data type, to attributes associated with a data type, or to an index specification.

- `TIMESTAMP` display sizes are discarded.

Also note that `TIMESTAMP` columns are `NOT NULL` by default.

- Columns that are part of a `PRIMARY KEY` are made `NOT NULL` even if not declared that way.
- Trailing spaces are automatically deleted from `ENUM` and `SET` member values when the table is created.
- MySQL maps certain data types used by other SQL database vendors to MySQL types. See [Section 10.7, “Using Data Types from Other Database Engines”](#).
- If you include a `USING` clause to specify an index type that is not legal for a given storage engine, but there is another index type available that the engine can use without affecting query results, the engine uses the available type.
- If strict SQL mode is not enabled, a `VARCHAR` column with a length specification greater than 65535 is converted to `TEXT`, and a `VARBINARY` column with a length specification greater than 65535 is converted to `BLOB`. Otherwise, an error occurs in either of these cases.
- Specifying the `CHARACTER SET binary` attribute for a character data type causes the column to be created as the corresponding binary data type: `CHAR` becomes `BINARY`, `VARCHAR` becomes `VARBINARY`, and `TEXT` becomes `BLOB`. For the `ENUM` and `SET` data types, this does not occur; they are created as declared. Suppose that you specify a table using this definition:

```
CREATE TABLE t
(
  c1 VARCHAR(10) CHARACTER SET binary,
  c2 TEXT CHARACTER SET binary,
  c3 ENUM('a','b','c') CHARACTER SET binary
```

```
);
```

The resulting table has this definition:

```
CREATE TABLE t
(
  c1 VARBINARY(10),
  c2 BLOB,
  c3 ENUM('a', 'b', 'c') CHARACTER SET binary
);
```

To see whether MySQL used a data type other than the one you specified, issue a `DESCRIBE` or `SHOW CREATE TABLE` statement after creating or altering the table.

Certain other data type changes can occur if you compress a table using `mysampack`. See [Section 13.5.3.3, “Compressed Table Characteristics”](#).

12.1.15. CREATE TRIGGER Syntax

```
CREATE
[DEFINER = { user | CURRENT_USER }]
TRIGGER trigger_name trigger_time trigger_event
ON tbl_name FOR EACH ROW trigger_stmt
```

This statement creates a new trigger. A trigger is a named database object that is associated with a table, and that activates when a particular event occurs for the table. The trigger becomes associated with the table named `tbl_name`, which must refer to a permanent table. You cannot associate a trigger with a `TEMPORARY` table or a view.

MySQL Enterprise

For expert advice on creating triggers subscribe to the MySQL Enterprise Monitor. For more information, see <http://www.mysql.com/products/enterprise/advisors.html>.

`CREATE TRIGGER` requires the `TRIGGER` privilege for the table associated with the trigger.

The `DEFINER` clause determines the security context to be used when checking access privileges at trigger activation time.

`trigger_time` is the trigger action time. It can be `BEFORE` or `AFTER` to indicate that the trigger activates before or after each row to be modified.

`trigger_event` indicates the kind of statement that activates the trigger. The `trigger_event` can be one of the following:

- `INSERT`: The trigger is activated whenever a new row is inserted into the table; for example, through `INSERT`, `LOAD DATA`, and `REPLACE` statements.
- `UPDATE`: The trigger is activated whenever a row is modified; for example, through `UPDATE` statements.
- `DELETE`: The trigger is activated whenever a row is deleted from the table; for example, through `DELETE` and `REPLACE` statements. However, `DROP TABLE` and `TRUNCATE` statements on the table *do not* activate this trigger, because they do not use `DELETE`. Dropping a partition does not activate `DELETE` triggers, either. See [Section 12.2.10, “TRUNCATE Syntax”](#).

It is important to understand that the `trigger_event` does not represent a literal type of SQL statement that activates the trigger so much as it represents a type of table operation. For example, an `INSERT` trigger is activated by not only `INSERT` statements but also `LOAD DATA` statements because both statements insert rows into a table.

A potentially confusing example of this is the `INSERT INTO ... ON DUPLICATE KEY UPDATE ...` syntax: a `BEFORE INSERT` trigger will activate for every row, followed by either an `AFTER INSERT` trigger or both the `BEFORE UPDATE` and `AFTER UPDATE` triggers, depending on whether there was a duplicate key for the row.

There cannot be two triggers for a given table that have the same trigger action time and event. For example, you cannot have two `BEFORE UPDATE` triggers for a table. But you can have a `BEFORE UPDATE` and a `BEFORE INSERT` trigger, or a `BEFORE UPDATE` and an `AFTER UPDATE` trigger.

`trigger_stmt` is the statement to execute when the trigger activates. If you want to execute multiple statements, use the `BEGIN ... END` compound statement construct. This also enables you to use the same statements that are allowable within stored routines. See [Section 12.8.1, “BEGIN ... END Compound Statement Syntax”](#). Some statements are not allowed in triggers; see [Section D.1, “Restrictions on Stored Routines, Triggers, and Events”](#).

MySQL stores the `sql_mode` system variable setting that is in effect at the time a trigger is created, and always executes the trigger with this setting in force, *regardless of the current server SQL mode*.

Note

Currently, triggers are not activated by cascaded foreign key actions. This limitation will be lifted as soon as possible.

In MySQL 5.4, you can write triggers containing direct references to tables by name, such as the trigger named `testref` shown in this example:

```
CREATE TABLE test1(a1 INT);
CREATE TABLE test2(a2 INT);
CREATE TABLE test3(a3 INT NOT NULL AUTO_INCREMENT PRIMARY KEY);
CREATE TABLE test4(
  a4 INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
  b4 INT DEFAULT 0
);

delimiter |

CREATE TRIGGER testref BEFORE INSERT ON test1
FOR EACH ROW BEGIN
  INSERT INTO test2 SET a2 = NEW.a1;
  DELETE FROM test3 WHERE a3 = NEW.a1;
  UPDATE test4 SET b4 = b4 + 1 WHERE a4 = NEW.a1;
END;

delimiter ;

INSERT INTO test3 (a3) VALUES
  (NULL), (NULL), (NULL), (NULL), (NULL),
  (NULL), (NULL), (NULL), (NULL), (NULL);

INSERT INTO test4 (a4) VALUES
  (0), (0), (0), (0), (0), (0), (0), (0), (0), (0);
```

Suppose that you insert the following values into table `test1` as shown here:

```
mysql> INSERT INTO test1 VALUES
-> (1), (3), (1), (7), (1), (8), (4), (4);
Query OK, 8 rows affected (0.01 sec)
Records: 8 Duplicates: 0 Warnings: 0
```

As a result, the data in the four tables will be as follows:

```
mysql> SELECT * FROM test1;
+-----+
| a1 |
+-----+
| 1 |
| 3 |
| 1 |
| 7 |
| 1 |
| 8 |
| 4 |
| 4 |
+-----+
8 rows in set (0.00 sec)

mysql> SELECT * FROM test2;
+-----+
| a2 |
+-----+
| 1 |
| 3 |
| 1 |
| 7 |
| 1 |
| 8 |
| 4 |
| 4 |
+-----+
8 rows in set (0.00 sec)

mysql> SELECT * FROM test3;
+-----+
| a3 |
+-----+
| 2 |
| 5 |
| 6 |
| 9 |
| 10 |
+-----+
5 rows in set (0.00 sec)

mysql> SELECT * FROM test4;
```

a4	b4
1	3
2	0
3	1
4	2
5	0
6	0
7	1
8	1
9	0
10	0

10 rows in set (0.00 sec)

You can refer to columns in the subject table (the table associated with the trigger) by using the aliases `OLD` and `NEW`. `OLD.col_name` refers to a column of an existing row before it is updated or deleted. `NEW.col_name` refers to the column of a new row to be inserted or an existing row after it is updated.

The `DEFINER` clause specifies the MySQL account to be used when checking access privileges at trigger activation time. If a `user` value is given, it should be a MySQL account in '`user_name`'@'`host_name`' format (the same format used in the `GRANT` statement). The `user_name` and `host_name` values both are required. The definer can also be given as `CURRENT_USER` or `CURRENT_USER()`. The default `DEFINER` value is the user who executes the `CREATE TRIGGER` statement. (This is the same as `DEFINER = CURRENT_USER`.)

If you specify the `DEFINER` clause, these rules determine the legal `DEFINER` user values:

- If you do not have the `SUPER` privilege, the only legal `user` value is your own account, either specified literally or by using `CURRENT_USER`. You cannot set the definer to some other account.
- If you have the `SUPER` privilege, you can specify any syntactically legal account name. If the account does not actually exist, a warning is generated.
- Although it is possible to create triggers with a non-existent `DEFINER` value, it is not a good idea for such triggers to be activated until the definer actually does exist. Otherwise, the behavior with respect to privilege checking is undefined.

MySQL takes the `DEFINER` user into account when checking trigger privileges, as follows:

- At `CREATE TRIGGER` time, the user who issues the statement must have the `TRIGGER` privilege.
- At trigger activation time, privileges are checked against the `DEFINER` user. This user must have these privileges:
 - The `TRIGGER` privilege.
 - The `SELECT` privilege for the subject table if references to table columns occur via `OLD.col_name` or `NEW.col_name` in the trigger definition.
 - The `UPDATE` privilege for the subject table if table columns are targets of `SET NEW.col_name = value` assignments in the trigger definition.
 - Whatever other privileges normally are required for the statements executed by the trigger.

Within a trigger, the `CURRENT_USER()` function returns the account used to check privileges at trigger activation time. This is the `DEFINER` user, not the user whose actions caused the trigger to be activated. For information about user auditing within triggers, see [Section 5.5.9, “Auditing MySQL Account Activity”](#).

If you use `LOCK TABLES` to lock a table that has triggers, the tables used within the trigger are also locked, as described in [Section 12.4.5.2, “LOCK TABLES and Triggers”](#).

12.1.16. CREATE VIEW Syntax

```
CREATE
[OR REPLACE]
[ALGORITHM = {UNDEFINED | MERGE | TEMPTABLE}]
[DEFINER = { user | CURRENT_USER }]
[SQL SECURITY { DEFINER | INVOKER }]
VIEW view_name [(column_list)]
AS select_statement
[WITH [CASCADED | LOCAL] CHECK OPTION]
```

The `CREATE VIEW` statement creates a new view, or replaces an existing one if the `OR REPLACE` clause is given. If the view

does not exist, `CREATE OR REPLACE VIEW` is the same as `CREATE VIEW`. If the view does exist, `CREATE OR REPLACE VIEW` is the same as `ALTER VIEW`.

The *select_statement* is a `SELECT` statement that provides the definition of the view. (When you select from the view, you select in effect using the `SELECT` statement.) *select_statement* can select from base tables or other views.

The view definition is “frozen” at creation time, so changes to the underlying tables afterward do not affect the view definition. For example, if a view is defined as `SELECT *` on a table, new columns added to the table later do not become part of the view.

The `ALGORITHM` clause affects how MySQL processes the view. The `DEFINER` and `SQL SECURITY` clauses specify the security context to be used when checking access privileges at view invocation time. The `WITH CHECK OPTION` clause can be given to constrain inserts or updates to rows in tables referenced by the view. These clauses are described later in this section.

The `CREATE VIEW` statement requires the `CREATE VIEW` privilege for the view, and some privilege for each column selected by the `SELECT` statement. For columns used elsewhere in the `SELECT` statement you must have the `SELECT` privilege. If the `OR REPLACE` clause is present, you must also have the `DROP` privilege for the view.

A view belongs to a database. By default, a new view is created in the default database. To create the view explicitly in a given database, specify the name as *db_name.view_name* when you create it.

```
mysql> CREATE VIEW test.v AS SELECT * FROM t;
```

Base tables and views share the same namespace within a database, so a database cannot contain a base table and a view that have the same name.

Views must have unique column names with no duplicates, just like base tables. By default, the names of the columns retrieved by the `SELECT` statement are used for the view column names. To define explicit names for the view columns, the optional *column_list* clause can be given as a list of comma-separated identifiers. The number of names in *column_list* must be the same as the number of columns retrieved by the `SELECT` statement.

Columns retrieved by the `SELECT` statement can be simple references to table columns. They can also be expressions that use functions, constant values, operators, and so forth.

Unqualified table or view names in the `SELECT` statement are interpreted with respect to the default database. A view can refer to tables or views in other databases by qualifying the table or view name with the proper database name.

A view can be created from many kinds of `SELECT` statements. It can refer to base tables or other views. It can use joins, `UNION`, and subqueries. The `SELECT` need not even refer to any tables. The following example defines a view that selects two columns from another table, as well as an expression calculated from those columns:

```
mysql> CREATE TABLE t (qty INT, price INT);
mysql> INSERT INTO t VALUES(3, 50);
mysql> CREATE VIEW v AS SELECT qty, price, qty*price AS value FROM t;
mysql> SELECT * FROM v;
+-----+-----+-----+
| qty | price | value |
+-----+-----+-----+
| 3   | 50    | 150   |
+-----+-----+-----+
```

A view definition is subject to the following restrictions:

- The `SELECT` statement cannot contain a subquery in the `FROM` clause.
- The `SELECT` statement cannot refer to system or user variables.
- Within a stored program, the definition cannot refer to program parameters or local variables.
- The `SELECT` statement cannot refer to prepared statement parameters.
- Any table or view referred to in the definition must exist. However, after a view has been created, it is possible to drop a table or view that the definition refers to. In this case, use of the view results in an error. To check a view definition for problems of this kind, use the `CHECK TABLE` statement.
- The definition cannot refer to a `TEMPORARY` table, and you cannot create a `TEMPORARY` view.
- Any tables named in the view definition must exist at definition time.
- You cannot associate a trigger with a view.
- Aliases for column names in the `SELECT` statement are checked against the maximum column length of 64 characters (not the maximum alias length of 256 characters).

`ORDER BY` is allowed in a view definition, but it is ignored if you select from a view using a statement that has its own `ORDER BY`.

For other options or clauses in the definition, they are added to the options or clauses of the statement that references the view, but the effect is undefined. For example, if a view definition includes a `LIMIT` clause, and you select from the view using a statement that has its own `LIMIT` clause, it is undefined which limit applies. This same principle applies to options such as `ALL`, `DISTINCT`, or `SQL_SMALL_RESULT` that follow the `SELECT` keyword, and to clauses such as `INTO`, `FOR UPDATE`, `LOCK IN SHARE MODE`, and `PROCEDURE`.

If you create a view and then change the query processing environment by changing system variables, that may affect the results that you get from the view:

```
mysql> CREATE VIEW v (mycol) AS SELECT 'abc';
Query OK, 0 rows affected (0.01 sec)

mysql> SET sql_mode = '';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT "mycol" FROM v;
+-----+
| mycol |
+-----+
| mycol |
+-----+
1 row in set (0.01 sec)

mysql> SET sql_mode = 'ANSI_QUOTES';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT "mycol" FROM v;
+-----+
| mycol |
+-----+
| abc   |
+-----+
1 row in set (0.00 sec)
```

The `DEFINER` and `SQL SECURITY` clauses determine which MySQL account to use when checking access privileges for the view when a statement is executed that references the view. The legal `SQL SECURITY` characteristic values are `DEFINER` and `INVOKER`. These indicate that the required privileges must be held by the user who defined or invoked the view, respectively. The default `SQL SECURITY` value is `DEFINER`.

If a `user` value is given for the `DEFINER` clause, it should be a MySQL account in '`user_name`'@'`host_name`' format (the same format used in the `GRANT` statement). The `user_name` and `host_name` values both are required. The definer can also be given as `CURRENT_USER` or `CURRENT_USER()`. The default `DEFINER` value is the user who executes the `CREATE VIEW` statement. This is the same as specifying `DEFINER = CURRENT_USER` explicitly.

If you specify the `DEFINER` clause, these rules determine the legal `DEFINER` user values:

- If you do not have the `SUPER` privilege, the only legal `user` value is your own account, either specified literally or by using `CURRENT_USER`. You cannot set the definer to some other account.
- If you have the `SUPER` privilege, you can specify any syntactically legal account name. If the account does not actually exist, a warning is generated.
- If the `SQL SECURITY` value is `DEFINER` but the definer account does not exist when the view is referenced, an error occurs.

Within a view definition, `CURRENT_USER` returns the view's `DEFINER` value by default. For views defined with the `SQL SECURITY INVOKER` characteristic, `CURRENT_USER` returns the account for the view's invoker. For information about user auditing within views, see [Section 5.5.9, "Auditing MySQL Account Activity"](#).

Within a stored routine that is defined with the `SQL SECURITY DEFINER` characteristic, `CURRENT_USER` returns the routine's `DEFINER` value. This also affects a view defined within such a program, if the view definition contains a `DEFINER` value of `CURRENT_USER`.

View privileges are checked like this:

- At view definition time, the view creator must have the privileges needed to use the top-level objects accessed by the view. For example, if the view definition refers to table columns, the creator must have privileges for the columns, as described previously. If the definition refers to a stored function, only the privileges needed to invoke the function can be checked. The privileges required when the function runs can be checked only as it executes: For different invocations of the function, different execution paths within the function might be taken.
- When a view is referenced, privileges for objects accessed by the view are checked against the privileges held by the view cre-

ator or invoker, depending on whether the `SQL SECURITY` characteristic is `DEFINER` or `INVOKER`, respectively.

- If reference to a view causes execution of a stored function, privilege checking for statements executed within the function depend on whether the function is defined with a `SQL SECURITY` characteristic of `DEFINER` or `INVOKER`. If the security characteristic is `DEFINER`, the function runs with the privileges of its creator. If the characteristic is `INVOKER`, the function runs with the privileges determined by the view's `SQL SECURITY` characteristic.

Example: A view might depend on a stored function, and that function might invoke other stored routines. For example, the following view invokes a stored function `f()`:

```
CREATE VIEW v AS SELECT * FROM t WHERE t.id = f(t.name);
```

Suppose that `f()` contains a statement such as this:

```
IF name IS NULL then
  CALL p1();
ELSE
  CALL p2();
END IF;
```

The privileges required for executing statements within `f()` need to be checked when `f()` executes. This might mean that privileges are needed for `p1()` or `p2()`, depending on the execution path within `f()`. Those privileges must be checked at runtime, and the user who must possess the privileges is determined by the `SQL SECURITY` values of the view `v` and the function `f()`.

The `DEFINER` and `SQL SECURITY` clauses for views are extensions to standard SQL. In standard SQL, views are handled using the rules for `SQL SECURITY INVOKER`.

The optional `ALGORITHM` clause is a MySQL extension to standard SQL. It affects how MySQL processes the view. `ALGORITHM` takes three values: `MERGE`, `TEMPTABLE`, or `UNDEFINED`. The default algorithm is `UNDEFINED` if no `ALGORITHM` clause is present. For more information, see [Section 18.5.2, “View Processing Algorithms”](#).

Some views are updatable. That is, you can use them in statements such as `UPDATE`, `DELETE`, or `INSERT` to update the contents of the underlying table. For a view to be updatable, there must be a one-to-one relationship between the rows in the view and the rows in the underlying table. There are also certain other constructs that make a view non-updatable.

The `WITH CHECK OPTION` clause can be given for an updatable view to prevent inserts or updates to rows except those for which the `WHERE` clause in the `select_statement` is true.

In a `WITH CHECK OPTION` clause for an updatable view, the `LOCAL` and `CASCADE` keywords determine the scope of check testing when the view is defined in terms of another view. The `LOCAL` keyword restricts the `CHECK OPTION` only to the view being defined. `CASCADE` causes the checks for underlying views to be evaluated as well. When neither keyword is given, the default is `CASCADE`.

For more information about updatable views and the `WITH CHECK OPTION` clause, see [Section 18.5.3, “Updatable and Insertable Views”](#).

12.1.17. DROP DATABASE Syntax

```
DROP {DATABASE | SCHEMA} [IF EXISTS] db_name
```

`DROP DATABASE` drops all tables in the database and deletes the database. Be *very* careful with this statement! To use `DROP DATABASE`, you need the `DROP` privilege on the database. `DROP SCHEMA` is a synonym for `DROP DATABASE`.

Important

When a database is dropped, user privileges on the database are *not* automatically dropped. See [Section 12.5.1.3, “GRANT Syntax”](#).

`IF EXISTS` is used to prevent an error from occurring if the database does not exist.

If you use `DROP DATABASE` on a symbolically linked database, both the link and the original database are deleted.

`DROP DATABASE` returns the number of tables that were removed. This corresponds to the number of `.frm` files removed.

The `DROP DATABASE` statement removes from the given database directory those files and directories that MySQL itself may create during normal operation:

- All files with the following extensions.

<code>.BAK</code>	<code>.DAT</code>	<code>.HSH</code>	<code>.MRG</code>
<code>.MYD</code>	<code>.MYI</code>	<code>.TRG</code>	<code>.TRN</code>
<code>.db</code>	<code>.frm</code>	<code>.ibd</code>	<code>.ndb</code>
<code>.par</code>			

- The `db.opt` file, if it exists.

If other files or directories remain in the database directory after MySQL removes those just listed, the database directory cannot be removed. In this case, you must remove any remaining files or directories manually and issue the `DROP DATABASE` statement again.

You can also drop databases with `mysqladmin`. See [Section 4.5.2, “mysqladmin — Client for Administering a MySQL Server”](#).

12.1.18. DROP EVENT Syntax

```
DROP EVENT [IF EXISTS] event_name
```

This statement drops the event named *event_name*. The event immediately ceases being active, and is deleted completely from the server.

If the event does not exist, the error `ERROR 1517 (HY000): UNKNOWN EVENT 'EVENT_NAME'` results. You can override this and cause the statement to generate a warning for non-existent events instead using `IF EXISTS`.

This statement requires the `EVENT` privilege for the schema to which the event to be dropped belongs.

12.1.19. DROP FUNCTION Syntax

The `DROP FUNCTION` statement is used to drop stored functions and user-defined functions (UDFs):

- For information about dropping stored functions, see [Section 12.1.21, “DROP PROCEDURE and DROP FUNCTION Syntax”](#).
- For information about dropping user-defined functions, see [Section 12.5.3.2, “DROP FUNCTION Syntax”](#).

12.1.20. DROP INDEX Syntax

```
DROP [ONLINE|OFFLINE] INDEX index_name ON tbl_name
```

`DROP INDEX` drops the index named *index_name* from the table *tbl_name*. This statement is mapped to an `ALTER TABLE` statement to drop the index. See [Section 12.1.6, “ALTER TABLE Syntax”](#).

Indexes on variable-width columns are dropped online; that is, dropping the indexes does not require any copying of the table. For `NDBCLUSTER` tables, the table is not locked against access from other MySQL Cluster API nodes, although it is locked against other operations on the *same* API node for the duration of the online operation. This is done automatically by the server whenever it determines that it is possible to do so; you do not have to use any special SQL syntax or server options to cause it to happen.

In standard MySQL 5.4 releases, it is not possible to override the server when it determines that an index is to be dropped online. In MySQL Cluster, beginning with MySQL Cluster NDB 6.2.5 and MySQL Cluster NDB 6.3.3, you can drop indexes offline (which causes the table to be locked for all API nodes in the cluster) using the `OFFLINE` keyword. The rules and limitations governing on-line `DROP OFFLINE INDEX` and `DROP ONLINE INDEX` are the same as for `ALTER OFFLINE TABLE ... DROP INDEX` and `ALTER ONLINE TABLE ... DROP INDEX`. You cannot cause the online dropping of an index that would normally be dropped offline by using the `ONLINE` keyword (if it is not possible to perform the `DROP` operation online, then the `ONLINE` keyword is ignored). For more information, see [Section 12.1.6, “ALTER TABLE Syntax”](#).

Note

The `ONLINE` and `OFFLINE` keywords are available only in MySQL Cluster NDB 6.2 and MySQL Cluster NDB 6.3 releases beginning with versions 6.2.5 and 6.3.3, respectively; attempting to use them in earlier MySQL Cluster NDB 6.2 or 6.3 releases, standard MySQL 5.1 releases, or MySQL Cluster NDB 6.1 releases results in a syntax error.

12.1.21. DROP PROCEDURE and DROP FUNCTION Syntax

```
DROP {PROCEDURE | FUNCTION} [IF EXISTS] sp_name
```

This statement is used to drop a stored procedure or function. That is, the specified routine is removed from the server. You must have the `ALTER ROUTINE` privilege for the routine. (That privilege is granted automatically to the routine creator.)

The `IF EXISTS` clause is a MySQL extension. It prevents an error from occurring if the procedure or function does not exist. A warning is produced that can be viewed with `SHOW WARNINGS`.

`DROP FUNCTION` is also used to drop user-defined functions (see [Section 12.5.3.2, “DROP FUNCTION Syntax”](#)).

12.1.22. DROP SERVER Syntax

```
DROP SERVER [ IF EXISTS ] server_name
```

Drops the server definition for the server named *server_name*. The corresponding row within the `mysql.servers` table will be deleted. This statement requires the `SUPER` privilege.

Dropping a server for a table does not affect any `FEDERATED` tables that used this connection information when they were created. See [Section 12.1.13, “CREATE SERVER Syntax”](#).

`DROP SERVER` does not cause an automatic commit.

12.1.23. DROP TABLE Syntax

```
DROP [TEMPORARY] TABLE [IF EXISTS]
tbl_name [, tbl_name] ...
[RESTRICT | CASCADE]
```

`DROP TABLE` removes one or more tables. You must have the `DROP` privilege for each table. All table data and the table definition are *removed*, so *be careful* with this statement! If any of the tables named in the argument list do not exist, MySQL returns an error indicating by name which non-existing tables it was unable to drop, but it also drops all of the tables in the list that do exist.

Important

When a table is dropped, user privileges on the table are *not* automatically dropped. See [Section 12.5.1.3, “GRANT Syntax”](#).

Note that for a partitioned table, `DROP TABLE` permanently removes the table definition, all of its partitions, and all of the data which was stored in those partitions. It also removes the partitioning definition (`.par`) file associated with the dropped table.

Use `IF EXISTS` to prevent an error from occurring for tables that do not exist. A `NOTE` is generated for each non-existent table when using `IF EXISTS`. See [Section 12.5.5.41, “SHOW WARNINGS Syntax”](#).

`RESTRICT` and `CASCADE` are allowed to make porting easier. In MySQL 5.4, they do nothing.

Note

`DROP TABLE` automatically commits the current active transaction, unless you use the `TEMPORARY` keyword.

The `TEMPORARY` keyword has the following effects:

- The statement drops only `TEMPORARY` tables.
- The statement does not end an ongoing transaction.
- No access rights are checked. (A `TEMPORARY` table is visible only to the session that created it, so no check is necessary.)

Using `TEMPORARY` is a good way to ensure that you do not accidentally drop a non-`TEMPORARY` table.

12.1.24. DROP TRIGGER Syntax

```
DROP TRIGGER [IF EXISTS] [schema_name.]trigger_name
```

This statement drops a trigger. The schema (database) name is optional. If the schema is omitted, the trigger is dropped from the default schema. `DROP TRIGGER` was added in MySQL 5.0.2. Its use requires the `TRIGGER` privilege for the table associated with the trigger.

Use `IF EXISTS` to prevent an error from occurring for a trigger that does not exist. A `NOTE` is generated for a non-existent trigger when using `IF EXISTS`. See [Section 12.5.5.41](#), “`SHOW WARNINGS Syntax`”.

Triggers for a table are also dropped if you drop the table.

Note

When upgrading from a version of MySQL older than MySQL 5.0.10 to 5.0.10 or newer — including all MySQL 5.4 releases — you must drop all triggers *before upgrading* and re-create them afterward, or else `DROP TRIGGER` does not work after the upgrade. See [Section 2.12.1.1](#), “`Upgrading from MySQL 5.1 to 5.4`”, for a suggested upgrade procedure.

12.1.25. DROP VIEW Syntax

```
DROP VIEW [IF EXISTS]
view_name [, view_name] ...
[RESTRICT | CASCADE]
```

`DROP VIEW` removes one or more views. You must have the `DROP` privilege for each view. If any of the views named in the argument list do not exist, MySQL returns an error indicating by name which non-existing views it was unable to drop, but it also drops all of the views in the list that do exist.

The `IF EXISTS` clause prevents an error from occurring for views that don't exist. When this clause is given, a `NOTE` is generated for each non-existent view. See [Section 12.5.5.41](#), “`SHOW WARNINGS Syntax`”.

`RESTRICT` and `CASCADE`, if given, are parsed and ignored.

12.1.26. RENAME TABLE Syntax

```
RENAME TABLE tbl_name TO new_tbl_name
[, tbl_name2 TO new_tbl_name2] ...
```

This statement renames one or more tables.

The rename operation is done atomically, which means that no other session can access any of the tables while the rename is running. For example, if you have an existing table `old_table`, you can create another table `new_table` that has the same structure but is empty, and then replace the existing table with the empty one as follows (assuming that `backup_table` does not already exist):

```
CREATE TABLE new_table (...);
RENAME TABLE old_table TO backup_table, new_table TO old_table;
```

If the statement renames more than one table, renaming operations are done from left to right. If you want to swap two table names, you can do so like this (assuming that `tmp_table` does not already exist):

```
RENAME TABLE old_table TO tmp_table,
new_table TO old_table,
tmp_table TO new_table;
```

As long as two databases are on the same file system, you can use `RENAME TABLE` to move a table from one database to another:

```
RENAME TABLE current_db.tbl_name TO other_db.tbl_name;
```

If there are any triggers associated with a table which is moved to a different database using `RENAME TABLE`, then the statement fails with the error `TRIGGER IN WRONG SCHEMA`.

`RENAME TABLE` also works for views, as long as you do not try to rename a view into a different database.

Any privileges granted specifically for the renamed table or view are not migrated to the new name. They must be changed manually.

When you execute `RENAME`, you cannot have any locked tables or active transactions. You must also have the `ALTER` and `DROP` privileges on the original table, and the `CREATE` and `INSERT` privileges on the new table.

If MySQL encounters any errors in a multiple-table rename, it does a reverse rename for all renamed tables to return everything to its original state.

You cannot use `RENAME` to rename a `TEMPORARY` table. However, you can use `ALTER TABLE` instead:

```
mysql> ALTER TABLE orig_name RENAME new_name;
```

12.2. Data Manipulation Statements

12.2.1. CALL Syntax

```
CALL sp_name( [parameter[, ...]] )
CALL sp_name( )
```

The `CALL` statement invokes a stored procedure that was defined previously with `CREATE PROCEDURE`.

Stored procedures that take no arguments can be invoked without parentheses. That is, `CALL p()` and `CALL p` are equivalent.

`CALL` can pass back values to its caller using parameters that are declared as `OUT` or `INOUT` parameters. When the procedure returns, a client program can also obtain the number of rows affected for the final statement executed within the routine: At the SQL level, call the `ROW_COUNT()` function; from the C API, call the `mysql_affected_rows()` function.

To get back a value from a procedure using an `OUT` or `INOUT` parameter, pass the parameter by means of a user variable, and then check the value of the variable after the procedure returns. (If you are calling the procedure from within another stored procedure or function, you can also pass a routine parameter or local routine variable as an `IN` or `INOUT` parameter.) For an `INOUT` parameter, initialize its value before passing it to the procedure. The following procedure has an `OUT` parameter that the procedure sets to the current server version, and an `INOUT` value that the procedure increments by one from its current value:

```
CREATE PROCEDURE p (OUT ver_param VARCHAR(25), INOUT incr_param INT)
BEGIN
  # Set value of OUT parameter
  SELECT VERSION() INTO ver_param;
  # Increment value of INOUT parameter
  SET incr_param = incr_param + 1;
END;
```

Before calling the procedure, initialize the variable to be passed as the `INOUT` parameter. After calling the procedure, the values of the two variables will have been set or modified:

```
mysql> SET @increment = 10;
mysql> CALL p(@version, @increment);
mysql> SELECT @version, @increment;
+-----+-----+
| @version | @increment |
+-----+-----+
| 5.4.0-log | 11         |
+-----+-----+
```

In prepared `CALL` statements used with `PREPARE` and `EXECUTE`, placeholder support is available in MySQL 5.4 for `IN` parameters, but not for `OUT` or `INOUT` parameters. To work around this limitation for `OUT` and `INOUT` parameters, forego the use of placeholders; instead, refer to user variables in the `CALL` statement itself and do not specify them in the `EXECUTE` statement:

```
mysql> SET @increment = 10;
mysql> PREPARE s FROM 'CALL p(@version, @increment)';
mysql> EXECUTE s;
mysql> SELECT @version, @increment;
+-----+-----+
| @version | @increment |
+-----+-----+
| 5.4.0-log | 11         |
+-----+-----+
```

To write C programs that use the `CALL` SQL statement to execute stored procedures that produce result sets, the `CLIENT_MULTI_RESULTS` flag must be enabled. This is because each `CALL` returns a result to indicate the call status, in addition to any result sets that might be returned by statements executed within the procedure. `CLIENT_MULTI_RESULTS` must also be enabled if `CALL` is used to execute any stored procedure that contains prepared statements. It cannot be determined when such a procedure is loaded whether those statements will produce result sets, so it is necessary to assume that they will.

`CLIENT_MULTI_RESULTS` can be enabled when you call `mysql_real_connect()`, either explicitly by passing the `CLIENT_MULTI_RESULTS` flag itself, or implicitly by passing `CLIENT_MULTI_STATEMENTS` (which also enables `CLIENT_MULTI_RESULTS`).

To process the result of a `CALL` statement executed via `mysql_query()` or `mysql_real_query()`, use a loop that calls `mysql_next_result()` to determine whether there are more results. For an example, see [Section 20.10.12, “C API Support for Multiple Statement Execution”](#).

For programs written in a language that provides a MySQL interface, there is no native method for directly retrieving the results of `OUT` or `INOUT` parameters from `CALL` statements. To get the parameter values, pass user-defined variables to the procedure in the `CALL` statement and then execute a `SELECT` statement to produce a result set containing the variable values. To handle an `INOUT`

parameter, execute a statement prior to the `CALL` that sets the corresponding user variable to the value to be passed to the procedure.

The following example illustrates the technique (without error checking) for the stored procedure `p` described earlier that has an `OUT` parameter and an `INOUT` parameter:

```
mysql_query(mysql, "SET @increment = 10");
mysql_query(mysql, "CALL p(@version, @increment)");
mysql_query(mysql, "SELECT @version, @increment");
result = mysql_store_result(mysql);
row = mysql_fetch_row(result);
mysql_free_result(result);
```

After the preceding code executes, `row[0]` and `row[1]` contain the values of `@version` and `@increment`, respectively.

12.2.2. DELETE Syntax

Single-table syntax:

```
DELETE [LOW_PRIORITY] [QUICK] [IGNORE] FROM tbl_name
  [WHERE where_condition]
  [ORDER BY ...]
  [LIMIT row_count]
```

Multiple-table syntax:

```
DELETE [LOW_PRIORITY] [QUICK] [IGNORE]
  tbl_name [...] [, tbl_name [...]] ...
FROM table_references
  [WHERE where_condition]
```

Or:

```
DELETE [LOW_PRIORITY] [QUICK] [IGNORE]
  FROM tbl_name [...] [, tbl_name [...]] ...
  USING table_references
  [WHERE where_condition]
```

For the single-table syntax, the `DELETE` statement deletes rows from `tbl_name` and returns a count of the number of deleted rows. This count can be obtained by calling the `ROW_COUNT()` function (see [Section 11.11.3, “Information Functions”](#)). The `WHERE` clause, if given, specifies the conditions that identify which rows to delete. With no `WHERE` clause, all rows are deleted. If the `ORDER BY` clause is specified, the rows are deleted in the order that is specified. The `LIMIT` clause places a limit on the number of rows that can be deleted.

For the multiple-table syntax, `DELETE` deletes from each `tbl_name` the rows that satisfy the conditions. In this case, `ORDER BY` and `LIMIT` cannot be used.

`where_condition` is an expression that evaluates to true for each row to be deleted. It is specified as described in [Section 12.2.8, “SELECT Syntax”](#).

Currently, you cannot delete from a table and select from the same table in a subquery.

As stated, a `DELETE` statement with no `WHERE` clause deletes all rows. A faster way to do this, when you do not need to know the number of deleted rows, is to use `TRUNCATE TABLE`. However, within a transaction or if you have a lock on the table, `TRUNCATE TABLE` cannot be used whereas `DELETE` can. See [Section 12.2.10, “TRUNCATE Syntax”](#), and [Section 12.4.5, “LOCK TABLES and UNLOCK TABLES Syntax”](#).

If you delete the row containing the maximum value for an `AUTO_INCREMENT` column, the value is not reused for a `MyISAM` or `InnoDB` table. If you delete all rows in the table with `DELETE FROM tbl_name` (without a `WHERE` clause) in `autocommit` mode, the sequence starts over for all storage engines except `InnoDB` and `MyISAM`. There are some exceptions to this behavior for `InnoDB` tables, as discussed in [Section 13.6.4.3, “AUTO_INCREMENT Handling in InnoDB”](#).

For `MyISAM` tables, you can specify an `AUTO_INCREMENT` secondary column in a multiple-column key. In this case, reuse of values deleted from the top of the sequence occurs even for `MyISAM` tables. See [Section 3.6.9, “Using AUTO_INCREMENT”](#).

The `DELETE` statement supports the following modifiers:

- If you specify `LOW_PRIORITY`, the server delays execution of the `DELETE` until no other clients are reading from the table. This affects only storage engines that use only table-level locking (`MyISAM`, `MEMORY`, `MERGE`).
- For `MyISAM` tables, if you use the `QUICK` keyword, the storage engine does not merge index leaves during delete, which may speed up some kinds of delete operations.

- The `IGNORE` keyword causes MySQL to ignore all errors during the process of deleting rows. (Errors encountered during the parsing stage are processed in the usual manner.) Errors that are ignored due to the use of `IGNORE` are returned as warnings.

The speed of delete operations may also be affected by factors discussed in [Section 7.2.22, “Speed of DELETE Statements”](#).

In `MyISAM` tables, deleted rows are maintained in a linked list and subsequent `INSERT` operations reuse old row positions. To reclaim unused space and reduce file sizes, use the `OPTIMIZE TABLE` statement or the `myisamchk` utility to reorganize tables. `OPTIMIZE TABLE` is easier to use, but `myisamchk` is faster. See [Section 12.5.2.5, “OPTIMIZE TABLE Syntax”](#), and [Section 4.6.3, “myisamchk — MyISAM Table-Maintenance Utility”](#).

The `QUICK` modifier affects whether index leaves are merged for delete operations. `DELETE QUICK` is most useful for applications where index values for deleted rows are replaced by similar index values from rows inserted later. In this case, the holes left by deleted values are reused.

`DELETE QUICK` is not useful when deleted values lead to underfilled index blocks spanning a range of index values for which new inserts occur again. In this case, use of `QUICK` can lead to wasted space in the index that remains unreclaimed. Here is an example of such a scenario:

1. Create a table that contains an indexed `AUTO_INCREMENT` column.
2. Insert many rows into the table. Each insert results in an index value that is added to the high end of the index.
3. Delete a block of rows at the low end of the column range using `DELETE QUICK`.

In this scenario, the index blocks associated with the deleted index values become underfilled but are not merged with other index blocks due to the use of `QUICK`. They remain underfilled when new inserts occur, because new rows do not have index values in the deleted range. Furthermore, they remain underfilled even if you later use `DELETE` without `QUICK`, unless some of the deleted index values happen to lie in index blocks within or adjacent to the underfilled blocks. To reclaim unused index space under these circumstances, use `OPTIMIZE TABLE`.

If you are going to delete many rows from a table, it might be faster to use `DELETE QUICK` followed by `OPTIMIZE TABLE`. This rebuilds the index rather than performing many index block merge operations.

The MySQL-specific `LIMIT row_count` option to `DELETE` tells the server the maximum number of rows to be deleted before control is returned to the client. This can be used to ensure that a given `DELETE` statement does not take too much time. You can simply repeat the `DELETE` statement until the number of affected rows is less than the `LIMIT` value.

If the `DELETE` statement includes an `ORDER BY` clause, rows are deleted in the order specified by the clause. This is useful primarily in conjunction with `LIMIT`. For example, the following statement finds rows matching the `WHERE` clause, sorts them by `timestamp_column`, and deletes the first (oldest) one:

```
DELETE FROM somelog WHERE user = 'jcole'
ORDER BY timestamp_column LIMIT 1;
```

`ORDER BY` may also be useful in some cases to delete rows in an order required to avoid referential integrity violations.

If you are deleting many rows from a large table, you may exceed the lock table size for an `InnoDB` table. To avoid this problem, or simply to minimize the time that the table remains locked, the following strategy (which does not use `DELETE` at all) might be helpful:

1. Select the rows *not* to be deleted into an empty table that has the same structure as the original table:

```
INSERT INTO t_copy SELECT * FROM t WHERE ... ;
```

2. Use `RENAME TABLE` to atomically move the original table out of the way and rename the copy to the original name:

```
RENAME TABLE t TO t_old, t_copy TO t;
```

3. Drop the original table:

```
DROP TABLE t_old;
```

No other sessions can access the tables involved while `RENAME TABLE` executes, so the rename operation is not subject to concurrency problems. See [Section 12.1.26, “RENAME TABLE Syntax”](#).

You can specify multiple tables in a `DELETE` statement to delete rows from one or more tables depending on the particular condition in the `WHERE` clause. However, you cannot use `ORDER BY` or `LIMIT` in a multiple-table `DELETE`. The *table_references* clause lists the tables involved in the join. Its syntax is described in Section 12.2.8.1, “JOIN Syntax”.

For the first multiple-table syntax, only matching rows from the tables listed before the `FROM` clause are deleted. For the second multiple-table syntax, only matching rows from the tables listed in the `FROM` clause (before the `USING` clause) are deleted. The effect is that you can delete rows from many tables at the same time and have additional tables that are used only for searching:

```
DELETE t1, t2 FROM t1 INNER JOIN t2 INNER JOIN t3
WHERE t1.id=t2.id AND t2.id=t3.id;
```

Or:

```
DELETE FROM t1, t2 USING t1 INNER JOIN t2 INNER JOIN t3
WHERE t1.id=t2.id AND t2.id=t3.id;
```

These statements use all three tables when searching for rows to delete, but delete matching rows only from tables `t1` and `t2`.

The preceding examples use `INNER JOIN`, but multiple-table `DELETE` statements can use other types of join allowed in `SELECT` statements, such as `LEFT JOIN`. For example, to delete rows that exist in `t1` that have no match in `t2`, use a `LEFT JOIN`:

```
DELETE t1 FROM t1 LEFT JOIN t2 ON t1.id=t2.id WHERE t2.id IS NULL;
```

The syntax allows `.*` after each *tbl_name* for compatibility with `Access`.

If you use a multiple-table `DELETE` statement involving `InnoDB` tables for which there are foreign key constraints, the MySQL optimizer might process tables in an order that differs from that of their parent/child relationship. In this case, the statement fails and rolls back. Instead, you should delete from a single table and rely on the `ON DELETE` capabilities that `InnoDB` provides to cause the other tables to be modified accordingly.

Note

If you declare an alias for a table, you must use the alias when referring to the table:

```
DELETE t1 FROM test AS t1, test2 WHERE ...
```

Table aliases in a multiple-table `DELETE` statement should be declared only in the *table_references* part. Elsewhere in the statement, alias references are allowed but not alias declarations.

Correct:

```
DELETE a1, a2 FROM t1 AS a1 INNER JOIN t2 AS a2
WHERE a1.id=a2.id;

DELETE FROM a1, a2 USING t1 AS a1 INNER JOIN t2 AS a2
WHERE a1.id=a2.id;
```

Incorrect:

```
DELETE t1 AS a1, t2 AS a2 FROM t1 INNER JOIN t2
WHERE a1.id=a2.id;

DELETE FROM t1 AS a1, t2 AS a2 USING t1 INNER JOIN t2
WHERE a1.id=a2.id;
```

Declaration of aliases other than in the *table_references* part can lead to ambiguous statements that have unexpected results such as deleting rows from the wrong table. This is such a statement:

```
DELETE FROM t1 AS a2 USING t1 AS a1 INNER JOIN t2 AS a2;
```

Cross-database deletes are supported for multiple-table deletes, but you should be aware that in the list of tables from which to delete rows, aliases will have a default database unless one is specified explicitly. For example, if the current database is `test`, the following statement does not work because the unqualified alias `a1` has a default database of `test`:

```
DELETE a1, a2 FROM db1.t1 AS a1 INNER JOIN db2.t2 AS a2
WHERE a1.id=a2.id;
```

To correctly match the alias, you must explicitly qualify it with the database of the table being aliased:

```
DELETE db1.a1, db2.a2 FROM db1.t1 AS a1 INNER JOIN db2.t2 AS a2
WHERE a1.id=a2.id;
```

12.2.3. DO Syntax

```
DO expr [, expr] ...
```

`DO` executes the expressions but does not return any results. In most respects, `DO` is shorthand for `SELECT expr, ...`, but has the advantage that it is slightly faster when you do not care about the result.

`DO` is useful primarily with functions that have side effects, such as `RELEASE_LOCK()`.

12.2.4. HANDLER Syntax

```
HANDLER tbl_name OPEN [ [AS] alias ]
HANDLER tbl_name READ index_name { = | >= | <= | < } (value1,value2,...)
  [ WHERE where_condition ] [LIMIT ... ]
HANDLER tbl_name READ index_name { FIRST | NEXT | PREV | LAST }
  [ WHERE where_condition ] [LIMIT ... ]
HANDLER tbl_name READ { FIRST | NEXT }
  [ WHERE where_condition ] [LIMIT ... ]
HANDLER tbl_name CLOSE
```

The `HANDLER` statement provides direct access to table storage engine interfaces. It is available for `MyISAM` and `InnoDB` tables.

The `HANDLER ... OPEN` statement opens a table, making it accessible via subsequent `HANDLER ... READ` statements. This table object is not shared by other sessions and is not closed until the session calls `HANDLER ... CLOSE` or the session terminates. If you open the table using an alias, further references to the open table with other `HANDLER` statements must use the alias rather than the table name.

The first `HANDLER ... READ` syntax fetches a row where the index specified satisfies the given values and the `WHERE` condition is met. If you have a multiple-column index, specify the index column values as a comma-separated list. Either specify values for all the columns in the index, or specify values for a leftmost prefix of the index columns. Suppose that an index `my_idx` includes three columns named `col_a`, `col_b`, and `col_c`, in that order. The `HANDLER` statement can specify values for all three columns in the index, or for the columns in a leftmost prefix. For example:

```
HANDLER ... READ my_idx = (col_a_val,col_b_val,col_c_val) ...
HANDLER ... READ my_idx = (col_a_val,col_b_val) ...
HANDLER ... READ my_idx = (col_a_val) ...
```

To employ the `HANDLER` interface to refer to a table's `PRIMARY KEY`, use the quoted identifier ``PRIMARY``:

```
HANDLER tbl_name READ `PRIMARY` ...
```

The second `HANDLER ... READ` syntax fetches a row from the table in index order that matches the `WHERE` condition.

The third `HANDLER ... READ` syntax fetches a row from the table in natural row order that matches the `WHERE` condition. It is faster than `HANDLER tbl_name READ index_name` when a full table scan is desired. Natural row order is the order in which rows are stored in a `MyISAM` table data file. This statement works for `InnoDB` tables as well, but there is no such concept because there is no separate data file.

Without a `LIMIT` clause, all forms of `HANDLER ... READ` fetch a single row if one is available. To return a specific number of rows, include a `LIMIT` clause. It has the same syntax as for the `SELECT` statement. See [Section 12.2.8, “SELECT Syntax”](#).

`HANDLER ... CLOSE` closes a table that was opened with `HANDLER ... OPEN`.

There are several reasons to use the `HANDLER` interface instead of normal `SELECT` statements:

- `HANDLER` is faster than `SELECT`:
 - A designated storage engine handler object is allocated for the `HANDLER ... OPEN`. The object is reused for subsequent `HANDLER` statements for that table; it need not be reinitialized for each one.
 - There is less parsing involved.
 - There is no optimizer or query-checking overhead.
 - The table does not have to be locked between two handler requests.
 - The handler interface does not have to provide a consistent look of the data (for example, dirty reads are allowed), so the storage engine can use optimizations that `SELECT` does not normally allow.

- For applications that use a low-level [ISAM](#)-like interface, [HANDLER](#) makes it much easier to port them to MySQL.
- [HANDLER](#) enables you to traverse a database in a manner that is difficult (or even impossible) to accomplish with [SELECT](#). The [HANDLER](#) interface is a more natural way to look at data when working with applications that provide an interactive user interface to the database.

[HANDLER](#) is a somewhat low-level statement. For example, it does not provide consistency. That is, [HANDLER ... OPEN](#) does *not* take a snapshot of the table, and does *not* lock the table. This means that after a [HANDLER ... OPEN](#) statement is issued, table data can be modified (by the current session or other sessions) and these modifications might be only partially visible to [HANDLER ... NEXT](#) or [HANDLER ... PREV](#) scans.

An open handler can be closed and marked for reopen, in which case the handler loses its position in the table. This occurs when both of the following circumstances are true:

- Any session executes [FLUSH TABLES](#) or DDL statements on the handler's table.
- The session in which the handler is open executes non-[HANDLER](#) statements that use tables.

12.2.5. INSERT Syntax

```
INSERT [LOW_PRIORITY | DELAYED | HIGH_PRIORITY] [IGNORE]
[INTO] tbl_name [(col_name,...)]
{VALUES | VALUE} ({expr | DEFAULT},...),(...),...
[ ON DUPLICATE KEY UPDATE
  col_name=expr
  [, col_name=expr] ... ]
```

Or:

```
INSERT [LOW_PRIORITY | DELAYED | HIGH_PRIORITY] [IGNORE]
[INTO] tbl_name
SET col_name={expr | DEFAULT}, ...
[ ON DUPLICATE KEY UPDATE
  col_name=expr
  [, col_name=expr] ... ]
```

Or:

```
INSERT [LOW_PRIORITY | HIGH_PRIORITY] [IGNORE]
[INTO] tbl_name [(col_name,...)]
SELECT ...
[ ON DUPLICATE KEY UPDATE
  col_name=expr
  [, col_name=expr] ... ]
```

[INSERT](#) inserts new rows into an existing table. The [INSERT ... VALUES](#) and [INSERT ... SET](#) forms of the statement insert rows based on explicitly specified values. The [INSERT ... SELECT](#) form inserts rows selected from another table or tables. [INSERT ... SELECT](#) is discussed further in [Section 12.2.5.1, “INSERT ... SELECT Syntax”](#).

You can use [REPLACE](#) instead of [INSERT](#) to overwrite old rows. [REPLACE](#) is the counterpart to [INSERT IGNORE](#) in the treatment of new rows that contain unique key values that duplicate old rows: The new rows are used to replace the old rows rather than being discarded. See [Section 12.2.7, “REPLACE Syntax”](#).

[tbl_name](#) is the table into which rows should be inserted. The columns for which the statement provides values can be specified as follows:

- You can provide a comma-separated list of column names following the table name. In this case, a value for each named column must be provided by the [VALUES](#) list or the [SELECT](#) statement.
- If you do not specify a list of column names for [INSERT ... VALUES](#) or [INSERT ... SELECT](#), values for every column in the table must be provided by the [VALUES](#) list or the [SELECT](#) statement. If you do not know the order of the columns in the table, use [DESCRIBE tbl_name](#) to find out.
- The [SET](#) clause indicates the column names explicitly.

Column values can be given in several ways:

- If you are not running in strict SQL mode, any column not explicitly given a value is set to its default (explicit or implicit)

value. For example, if you specify a column list that does not name all the columns in the table, unnamed columns are set to their default values. Default value assignment is described in [Section 10.1.4, “Data Type Default Values”](#). See also [Section 1.7.6.2, “Constraints on Invalid Data”](#).

If you want an `INSERT` statement to generate an error unless you explicitly specify values for all columns that do not have a default value, you should use strict mode. See [Section 5.1.7, “Server SQL Modes”](#).

- Use the keyword `DEFAULT` to set a column explicitly to its default value. This makes it easier to write `INSERT` statements that assign values to all but a few columns, because it enables you to avoid writing an incomplete `VALUES` list that does not include a value for each column in the table. Otherwise, you would have to write out the list of column names corresponding to each value in the `VALUES` list.

You can also use `DEFAULT(col_name)` as a more general form that can be used in expressions to produce a given column's default value.

- If both the column list and the `VALUES` list are empty, `INSERT` creates a row with each column set to its default value:

```
INSERT INTO tbl_name () VALUES();
```

In strict mode, an error occurs if any column doesn't have a default value. Otherwise, MySQL uses the implicit default value for any column that does not have an explicitly defined default.

- You can specify an expression `expr` to provide a column value. This might involve type conversion if the type of the expression does not match the type of the column, and conversion of a given value can result in different inserted values depending on the data type. For example, inserting the string `'1999.0e-2'` into an `INT`, `FLOAT`, `DECIMAL(10,6)`, or `YEAR` column results in the values `1999`, `19.9921`, `19.992100`, and `1999` being inserted, respectively. The reason the value stored in the `INT` and `YEAR` columns is `1999` is that the string-to-integer conversion looks only at as much of the initial part of the string as may be considered a valid integer or year. For the floating-point and fixed-point columns, the string-to-floating-point conversion considers the entire string a valid floating-point value.

An expression `expr` can refer to any column that was set earlier in a value list. For example, you can do this because the value for `col2` refers to `col1`, which has previously been assigned:

```
INSERT INTO tbl_name (col1,col2) VALUES(15,col1*2);
```

But the following is not legal, because the value for `col1` refers to `col2`, which is assigned after `col1`:

```
INSERT INTO tbl_name (col1,col2) VALUES(col2*2,15);
```

One exception involves columns that contain `AUTO_INCREMENT` values. Because the `AUTO_INCREMENT` value is generated after other value assignments, any reference to an `AUTO_INCREMENT` column in the assignment returns a `0`.

`INSERT` statements that use `VALUES` syntax can insert multiple rows. To do this, include multiple lists of column values, each enclosed within parentheses and separated by commas. Example:

```
INSERT INTO tbl_name (a,b,c) VALUES(1,2,3),(4,5,6),(7,8,9);
```

The values list for each row must be enclosed within parentheses. The following statement is illegal because the number of values in the list does not match the number of column names:

```
INSERT INTO tbl_name (a,b,c) VALUES(1,2,3,4,5,6,7,8,9);
```

`VALUE` is a synonym for `VALUES` in this context. Neither implies anything about the number of values lists, and either may be used whether there is a single values list or multiple lists.

The affected-rows value for an `INSERT` can be obtained using the `ROW_COUNT()` function (see [Section 11.11.3, “Information Functions”](#)), or the `mysql_affected_rows()` C API function (see [Section 20.10.3.1, “mysql_affected_rows\(\)”](#)).

If you use an `INSERT ... VALUES` statement with multiple value lists or `INSERT ... SELECT`, the statement returns an information string in this format:

```
Records: 100 Duplicates: 0 Warnings: 0
```

`Records` indicates the number of rows processed by the statement. (This is not necessarily the number of rows actually inserted because `Duplicates` can be nonzero.) `Duplicates` indicates the number of rows that could not be inserted because they would duplicate some existing unique index value. `Warnings` indicates the number of attempts to insert column values that were problematic in some way. Warnings can occur under any of the following conditions:

- Inserting `NULL` into a column that has been declared `NOT NULL`. For multiple-row `INSERT` statements or `INSERT INTO ... SELECT` statements, the column is set to the implicit default value for the column data type. This is 0 for numeric types, the empty string (`' '`) for string types, and the “zero” value for date and time types. `INSERT INTO ... SELECT` statements are handled the same way as multiple-row inserts because the server does not examine the result set from the `SELECT` to see whether it returns a single row. (For a single-row `INSERT`, no warning occurs when `NULL` is inserted into a `NOT NULL` column. Instead, the statement fails with an error.)
- Setting a numeric column to a value that lies outside the column's range. The value is clipped to the closest endpoint of the range.
- Assigning a value such as `'10.34 a'` to a numeric column. The trailing non-numeric text is stripped off and the remaining numeric part is inserted. If the string value has no leading numeric part, the column is set to 0.
- Inserting a string into a string column (`CHAR`, `VARCHAR`, `TEXT`, or `BLOB`) that exceeds the column's maximum length. The value is truncated to the column's maximum length.
- Inserting a value into a date or time column that is illegal for the data type. The column is set to the appropriate zero value for the type.

If you are using the C API, the information string can be obtained by invoking the `mysql_info()` function. See [Section 20.10.3.35](#), “`mysql_info()`”.

If `INSERT` inserts a row into a table that has an `AUTO_INCREMENT` column, you can find the value used for that column by using the SQL `LAST_INSERT_ID()` function. From within the C API, use the `mysql_insert_id()` function. However, you should note that the two functions do not always behave identically. The behavior of `INSERT` statements with respect to `AUTO_INCREMENT` columns is discussed further in [Section 11.11.3](#), “[Information Functions](#)”, and [Section 20.10.3.37](#), “`mysql_insert_id()`”.

The `INSERT` statement supports the following modifiers:

- If you use the `DELAYED` keyword, the server puts the row or rows to be inserted into a buffer, and the client issuing the `INSERT DELAYED` statement can then continue immediately. If the table is in use, the server holds the rows. When the table is free, the server begins inserting rows, checking periodically to see whether there are any new read requests for the table. If there are, the delayed row queue is suspended until the table becomes free again. See [Section 12.2.5.2](#), “[INSERT DELAYED Syntax](#)”.

`DELAYED` is ignored with `INSERT ... SELECT` or `INSERT ... ON DUPLICATE KEY UPDATE`.

`DELAYED` is also disregarded for an `INSERT` that uses functions accessing tables or triggers, or that is called from a function or a trigger.

- If you use the `LOW_PRIORITY` keyword, execution of the `INSERT` is delayed until no other clients are reading from the table. This includes other clients that began reading while existing clients are reading, and while the `INSERT LOW_PRIORITY` statement is waiting. It is possible, therefore, for a client that issues an `INSERT LOW_PRIORITY` statement to wait for a very long time (or even forever) in a read-heavy environment. (This is in contrast to `INSERT DELAYED`, which lets the client continue at once. Note that `LOW_PRIORITY` should normally not be used with `MyISAM` tables because doing so disables concurrent inserts. See [Section 7.3.3](#), “[Concurrent Inserts](#)”.

If you specify `HIGH_PRIORITY`, it overrides the effect of the `--low-priority-updates` option if the server was started with that option. It also causes concurrent inserts not to be used. See [Section 7.3.3](#), “[Concurrent Inserts](#)”.

`LOW_PRIORITY` and `HIGH_PRIORITY` affect only storage engines that use only table-level locking (`MyISAM`, `MEMORY`, `MERGE`).

- If you use the `IGNORE` keyword, errors that occur while executing the `INSERT` statement are treated as warnings instead. For example, without `IGNORE`, a row that duplicates an existing `UNIQUE` index or `PRIMARY KEY` value in the table causes a duplicate-key error and the statement is aborted. With `IGNORE`, the row still is not inserted, but no error is issued.

`IGNORE` has a similar effect on inserts into partitioned tables where no partition matching a given value is found. Without `IGNORE`, such `INSERT` statements are aborted with an error; however, when `INSERT IGNORE` is used, the insert operation fails silently for the row containing the unmatched value, but any rows that are matched are inserted. For an example, see [Section 17.2.2](#), “[LIST Partitioning](#)”.

Data conversions that would trigger errors abort the statement if `IGNORE` is not specified. With `IGNORE`, invalid values are adjusted to the closest values and inserted; warnings are produced but the statement does not abort. You can determine with the `mysql_info()` C API function how many rows were actually inserted into the table.

- If you specify `ON DUPLICATE KEY UPDATE`, and a row is inserted that would cause a duplicate value in a `UNIQUE` index or `PRIMARY KEY`, an `UPDATE` of the old row is performed. The affected-rows value per row is 1 if the row is inserted as a

new row and 2 if an existing row is updated. See [Section 12.2.5.3, “INSERT ... ON DUPLICATE KEY UPDATE Syntax”](#).

Inserting into a table requires the `INSERT` privilege for the table. If the `ON DUPLICATE KEY UPDATE` clause is used and a duplicate key causes an `UPDATE` to be performed instead, the statement requires the `UPDATE` privilege for the columns to be updated. For columns that are read but not modified you need only the `SELECT` privilege (such as for a column referenced only on the right hand side of an `col_name=expr` assignment in an `ON DUPLICATE KEY UPDATE` clause).

12.2.5.1. INSERT ... SELECT Syntax

```
INSERT [LOW_PRIORITY | HIGH_PRIORITY] [IGNORE]
[INTO] tbl_name [(col_name,...)]
SELECT ...
[ ON DUPLICATE KEY UPDATE col_name=expr, ... ]
```

With `INSERT ... SELECT`, you can quickly insert many rows into a table from one or many tables. For example:

```
INSERT INTO tbl_temp2 (fld_id)
  SELECT tbl_temp1.fld_order_id
  FROM tbl_temp1 WHERE tbl_temp1.fld_order_id > 100;
```

The following conditions hold for a `INSERT ... SELECT` statements:

- Specify `IGNORE` to ignore rows that would cause duplicate-key violations.
- `DELAYED` is ignored with `INSERT ... SELECT`.
- The target table of the `INSERT` statement may appear in the `FROM` clause of the `SELECT` part of the query. (This was not possible in some older versions of MySQL.) In this case, MySQL creates a temporary table to hold the rows from the `SELECT` and then inserts those rows into the target table. However, it remains true that you cannot use `INSERT INTO t ... SELECT ... FROM t` when `t` is a `TEMPORARY` table, because `TEMPORARY` tables cannot be referred to twice in the same statement (see [Section B.1.7.3, “TEMPORARY Table Problems”](#)).
- `AUTO_INCREMENT` columns work as usual.
- To ensure that the binary log can be used to re-create the original tables, MySQL does not allow concurrent inserts for `INSERT ... SELECT` statements.
- Currently, you cannot insert into a table and select from the same table in a subquery.
- To avoid ambiguous column reference problems when the `SELECT` and the `INSERT` refer to the same table, provide a unique alias for each table used in the `SELECT` part, and qualify column names in that part with the appropriate alias.

In the values part of `ON DUPLICATE KEY UPDATE`, you can refer to columns in other tables, as long as you do not use `GROUP BY` in the `SELECT` part. One side effect is that you must qualify non-unique column names in the values part.

12.2.5.2. INSERT DELAYED Syntax

```
INSERT DELAYED ...
```

The `DELAYED` option for the `INSERT` statement is a MySQL extension to standard SQL that is very useful if you have clients that cannot or need not wait for the `INSERT` to complete. This is a common situation when you use MySQL for logging and you also periodically run `SELECT` and `UPDATE` statements that take a long time to complete.

When a client uses `INSERT DELAYED`, it gets an okay from the server at once, and the row is queued to be inserted when the table is not in use by any other thread.

Another major benefit of using `INSERT DELAYED` is that inserts from many clients are bundled together and written in one block. This is much faster than performing many separate inserts.

Note that `INSERT DELAYED` is slower than a normal `INSERT` if the table is not otherwise in use. There is also the additional overhead for the server to handle a separate thread for each table for which there are delayed rows. This means that you should use `INSERT DELAYED` only when you are really sure that you need it.

The queued rows are held only in memory until they are inserted into the table. This means that if you terminate `mysqld` forcibly (for example, with `kill -9`) or if `mysqld` dies unexpectedly, *any queued rows that have not been written to disk are lost*.

There are some constraints on the use of `DELAYED`:

- `INSERT DELAYED` works only with `MyISAM`, `MEMORY`, `ARCHIVE`, and `BLACKHOLE` tables. For engines that do not support `DELAYED`, an error occurs.
- An error occurs for `INSERT DELAYED` if used with a table that has been locked with `LOCK TABLES` because the insert must be handled by a separate thread, not by the session that holds the lock.
- For `MyISAM` tables, if there are no free blocks in the middle of the data file, concurrent `SELECT` and `INSERT` statements are supported. Under these circumstances, you very seldom need to use `INSERT DELAYED` with `MyISAM`.
- `INSERT DELAYED` should be used only for `INSERT` statements that specify value lists. The server ignores `DELAYED` for `INSERT ... SELECT` or `INSERT ... ON DUPLICATE KEY UPDATE` statements.
- Because the `INSERT DELAYED` statement returns immediately, before the rows are inserted, you cannot use `LAST_INSERT_ID()` to get the `AUTO_INCREMENT` value that the statement might generate.
- `DELAYED` rows are not visible to `SELECT` statements until they actually have been inserted.
- `INSERT DELAYED` is treated as a normal `INSERT` if the statement inserts multiple rows and binary logging is enabled and the global logging format is to use statement-based logging (`binlog_format` is set to `STATEMENT`). This restriction does not apply to row-based binary logging.
- `DELAYED` is ignored on slave replication servers, so that `INSERT DELAYED` is treated as a normal `INSERT` on slaves. This is because `DELAYED` could cause the slave to have different data than the master.
- Pending `INSERT DELAYED` statements are lost if a table is write locked and `ALTER TABLE` is used to modify the table structure.
- `INSERT DELAYED` is not supported for views.
- `INSERT DELAYED` is not supported for partitioned tables.

The following describes in detail what happens when you use the `DELAYED` option to `INSERT` or `REPLACE`. In this description, the “thread” is the thread that received an `INSERT DELAYED` statement and “handler” is the thread that handles all `INSERT DELAYED` statements for a particular table.

- When a thread executes a `DELAYED` statement for a table, a handler thread is created to process all `DELAYED` statements for the table, if no such handler already exists.
- The thread checks whether the handler has previously acquired a `DELAYED` lock; if not, it tells the handler thread to do so. The `DELAYED` lock can be obtained even if other threads have a `READ` or `WRITE` lock on the table. However, the handler waits for all `ALTER TABLE` locks or `FLUSH TABLES` statements to finish, to ensure that the table structure is up to date.
- The thread executes the `INSERT` statement, but instead of writing the row to the table, it puts a copy of the final row into a queue that is managed by the handler thread. Any syntax errors are noticed by the thread and reported to the client program.
- The client cannot obtain from the server the number of duplicate rows or the `AUTO_INCREMENT` value for the resulting row, because the `INSERT` returns before the insert operation has been completed. (If you use the C API, the `mysql_info()` function does not return anything meaningful, for the same reason.)
- The binary log is updated by the handler thread when the row is inserted into the table. In case of multiple-row inserts, the binary log is updated when the first row is inserted.
- Each time that `delayed_insert_limit` rows are written, the handler checks whether any `SELECT` statements are still pending. If so, it allows these to execute before continuing.
- When the handler has no more rows in its queue, the table is unlocked. If no new `INSERT DELAYED` statements are received within `delayed_insert_timeout` seconds, the handler terminates.
- If more than `delayed_queue_size` rows are pending in a specific handler queue, the thread requesting `INSERT DELAYED` waits until there is room in the queue. This is done to ensure that `mysqld` does not use all memory for the delayed memory queue.
- The handler thread shows up in the MySQL process list with `delayed_insert` in the `Command` column. It is killed if you execute a `FLUSH TABLES` statement or kill it with `KILL thread_id`. However, before exiting, it first stores all queued rows into the table. During this time it does not accept any new `INSERT` statements from other threads. If you execute an `INSERT DELAYED` statement after this, a new handler thread is created.

Note that this means that `INSERT DELAYED` statements have higher priority than normal `INSERT` statements if there is an `INSERT DELAYED` handler running. Other update statements have to wait until the `INSERT DELAYED` queue is empty,

someone terminates the handler thread (with `KILL thread_id`), or someone executes a `FLUSH TABLES`.

- The following status variables provide information about `INSERT DELAYED` statements.

Status Variable	Meaning
<code>Delayed_insert_threads</code>	Number of handler threads
<code>Delayed_writes</code>	Number of rows written with <code>INSERT DELAYED</code>
<code>Not_flushed_delayed_rows</code>	Number of rows waiting to be written

You can view these variables by issuing a `SHOW STATUS` statement or by executing a `mysqladmin extended-status` command.

12.2.5.3. `INSERT ... ON DUPLICATE KEY UPDATE` Syntax

If you specify `ON DUPLICATE KEY UPDATE`, and a row is inserted that would cause a duplicate value in a `UNIQUE` index or `PRIMARY KEY`, an `UPDATE` of the old row is performed. For example, if column `a` is declared as `UNIQUE` and contains the value `1`, the following two statements have identical effect:

```
INSERT INTO table (a,b,c) VALUES (1,2,3)
ON DUPLICATE KEY UPDATE c=c+1;

UPDATE table SET c=c+1 WHERE a=1;
```

With `ON DUPLICATE KEY UPDATE`, the affected-rows value per row is 1 if the row is inserted as a new row and 2 if an existing row is updated.

If column `b` is also unique, the `INSERT` is equivalent to this `UPDATE` statement instead:

```
UPDATE table SET c=c+1 WHERE a=1 OR b=2 LIMIT 1;
```

If `a=1 OR b=2` matches several rows, only *one* row is updated. In general, you should try to avoid using an `ON DUPLICATE KEY UPDATE` clause on tables with multiple unique indexes.

The `ON DUPLICATE KEY UPDATE` clause can contain multiple column assignments, separated by commas.

You can use the `VALUES(col_name)` function in the `UPDATE` clause to refer to column values from the `INSERT` portion of the `INSERT ... ON DUPLICATE KEY UPDATE` statement. In other words, `VALUES(col_name)` in the `ON DUPLICATE KEY UPDATE` clause refers to the value of `col_name` that would be inserted, had no duplicate-key conflict occurred. This function is especially useful in multiple-row inserts. The `VALUES()` function is meaningful only in `INSERT ... UPDATE` statements and returns `NULL` otherwise. Example:

```
INSERT INTO table (a,b,c) VALUES (1,2,3),(4,5,6)
ON DUPLICATE KEY UPDATE c=VALUES(a)+VALUES(b);
```

That statement is identical to the following two statements:

```
INSERT INTO table (a,b,c) VALUES (1,2,3)
ON DUPLICATE KEY UPDATE c=3;
INSERT INTO table (a,b,c) VALUES (4,5,6)
ON DUPLICATE KEY UPDATE c=9;
```

If a table contains an `AUTO_INCREMENT` column and `INSERT ... ON DUPLICATE KEY UPDATE` inserts or updates a row, the `LAST_INSERT_ID()` function returns the `AUTO_INCREMENT` value.

The `DELAYED` option is ignored when you use `ON DUPLICATE KEY UPDATE`.

12.2.6. `LOAD DATA INFILE` Syntax

```
LOAD DATA [LOW_PRIORITY | CONCURRENT] [LOCAL] INFILE 'file_name'
[REPLACE | IGNORE]
INTO TABLE tbl_name
[CHARACTER SET charset_name]
[ { FIELDS | COLUMNS }
  [TERMINATED BY 'string']
  [[OPTIONALLY] ENCLOSED BY 'char']
  [ESCAPED BY 'char']
]
[LINES
  [STARTING BY 'string']
  [TERMINATED BY 'string']
```

```

]
[IGNORE number LINES]
[(col_name_or_user_var,...)]
[SET col_name = expr,...]

```

The `LOAD DATA INFILE` statement reads rows from a text file into a table at a very high speed. The file name must be given as a literal string.

`LOAD DATA INFILE` is the complement of `SELECT ... INTO OUTFILE`. (See [Section 12.2.8, “SELECT Syntax”](#).) To write data from a table to a file, use `SELECT ... INTO OUTFILE`. To read the file back into a table, use `LOAD DATA INFILE`. The syntax of the `FIELDS` and `LINES` clauses is the same for both statements. Both clauses are optional, but `FIELDS` must precede `LINES` if both are specified.

For more information about the efficiency of `INSERT` versus `LOAD DATA INFILE` and speeding up `LOAD DATA INFILE`, see [Section 7.2.20, “Speed of INSERT Statements”](#).

The character set indicated by the `character_set_database` system variable is used to interpret the information in the file. `SET NAMES` and the setting of `character_set_client` do not affect interpretation of input. If the contents of the input file use a character set that differs from the default, it is usually preferable to specify the character set of the file by using the `CHARACTER SET` clause.

`LOAD DATA INFILE` interprets all fields in the file as having the same character set, regardless of the data types of the columns into which field values are loaded. For proper interpretation of file contents, you must ensure that it was written with the correct character set. For example, if you write a data file with `mysqldump -T` or by issuing a `SELECT ... INTO OUTFILE` statement in `mysql`, be sure to use a `--default-character-set` option with `mysqldump` or `mysql` so that output is written in the character set to be used when the file is loaded with `LOAD DATA INFILE`.

Note that it is currently not possible to load data files that use the `ucs2`, `utf16`, or `utf32` character set.

The `character_set_filesystem` system variable controls the interpretation of the file name.

You can also load data files by using the `mysqlimport` utility; it operates by sending a `LOAD DATA INFILE` statement to the server. The `--local` option causes `mysqlimport` to read data files from the client host. You can specify the `--compress` option to get better performance over slow networks if the client and server support the compressed protocol. See [Section 4.5.5, “mysqlimport — A Data Import Program”](#).

If you use `LOW_PRIORITY`, execution of the `LOAD DATA` statement is delayed until no other clients are reading from the table. This affects only storage engines that use only table-level locking (`MyISAM`, `MEMORY`, `MERGE`).

If you specify `CONCURRENT` with a `MyISAM` table that satisfies the condition for concurrent inserts (that is, it contains no free blocks in the middle), other threads can retrieve data from the table while `LOAD DATA` is executing. Using this option affects the performance of `LOAD DATA` a bit, even if no other thread is using the table at the same time.

`CONCURRENT` is not replicated when using statement-based replication; however, it is replicated when using row-based replication. See [Section 16.3.1.12, “Replication and LOAD DATA”](#), for more information.

The `LOCAL` keyword, if specified, is interpreted with respect to the client end of the connection:

- If `LOCAL` is specified, the file is read by the client program on the client host and sent to the server. The file can be given as a full path name to specify its exact location. If given as a relative path name, the name is interpreted relative to the directory in which the client program was started.
- If `LOCAL` is not specified, the file must be located on the server host and is read directly by the server. The server uses the following rules to locate the file:
 - If the file name is an absolute path name, the server uses it as given.
 - If the file name is a relative path name with one or more leading components, the server searches for the file relative to the server's data directory.
 - If a file name with no leading components is given, the server looks for the file in the database directory of the default database.

Note that, in the non-`LOCAL` case, these rules mean that a file named as `./myfile.txt` is read from the server's data directory, whereas the file named as `myfile.txt` is read from the database directory of the default database. For example, if `db1` is the default database, the following `LOAD DATA` statement reads the file `data.txt` from the database directory for `db1`, even though the statement explicitly loads the file into a table in the `db2` database:

```
LOAD DATA INFILE 'data.txt' INTO TABLE db2.my_table;
```

Windows path names are specified using forward slashes rather than backslashes. If you do use backslashes, you must double them.

For security reasons, when reading text files located on the server, the files must either reside in the database directory or be readable by all. Also, to use `LOAD DATA INFILE` on server files, you must have the `FILE` privilege. See [Section 5.4.1, “Privileges Provided by MySQL”](#). For non-`LOCAL` load operations, if the `secure_file_priv` system variable is set to a non-empty directory name, the file to be loaded must be located in that directory.

Using `LOCAL` is a bit slower than letting the server access the files directly, because the contents of the file must be sent over the connection by the client to the server. On the other hand, you do not need the `FILE` privilege to load local files.

With `LOCAL`, the default behavior is the same as if `IGNORE` is specified; this is because the server has no way to stop transmission of the file in the middle of the operation. `IGNORE` is explained further later in this section.

`LOCAL` works only if your server and your client both have been enabled to allow it. For example, if `mysqld` was started with `-local-infile=0`, `LOCAL` does not work. See [Section 5.3.4, “Security Issues with LOAD DATA LOCAL”](#).

On Unix, if you need `LOAD DATA` to read from a pipe, you can use the following technique (here we load the listing of the `/` directory into a table):

```
mkfifo /mysql/db/x/x
chmod 666 /mysql/db/x/x
find / -ls > /mysql/db/x/x &
mysql -e "LOAD DATA INFILE 'x' INTO TABLE x" x
```

Note that you must run the command that generates the data to be loaded and the `mysql` commands either on separate terminals, or run the data generation process in the background (as shown in the preceding example). If you do not do this, the pipe will block until data is read by the `mysql` process.

The `REPLACE` and `IGNORE` keywords control handling of input rows that duplicate existing rows on unique key values:

- If you specify `REPLACE`, input rows replace existing rows. In other words, rows that have the same value for a primary key or unique index as an existing row. See [Section 12.2.7, “REPLACE Syntax”](#).
- If you specify `IGNORE`, input rows that duplicate an existing row on a unique key value are skipped. If you do not specify either option, the behavior depends on whether the `LOCAL` keyword is specified. Without `LOCAL`, an error occurs when a duplicate key value is found, and the rest of the text file is ignored. With `LOCAL`, the default behavior is the same as if `IGNORE` is specified; this is because the server has no way to stop transmission of the file in the middle of the operation.

If you want to ignore foreign key constraints during the load operation, you can issue a `SET foreign_key_checks = 0` statement before executing `LOAD DATA`.

If you use `LOAD DATA INFILE` on an empty `MyISAM` table, all non-unique indexes are created in a separate batch (as for `REPAIR TABLE`). Normally, this makes `LOAD DATA INFILE` much faster when you have many indexes. In some extreme cases, you can create the indexes even faster by turning them off with `ALTER TABLE ... DISABLE KEYS` before loading the file into the table and using `ALTER TABLE ... ENABLE KEYS` to re-create the indexes after loading the file. See [Section 7.2.20, “Speed of INSERT Statements”](#).

For both the `LOAD DATA INFILE` and `SELECT ... INTO OUTFILE` statements, the syntax of the `FIELDS` and `LINES` clauses is the same. Both clauses are optional, but `FIELDS` must precede `LINES` if both are specified.

If you specify a `FIELDS` clause, each of its subclauses (`TERMINATED BY`, `[OPTIONALLY] ENCLOSED BY`, and `ESCAPED BY`) is also optional, except that you must specify at least one of them.

If you specify no `FIELDS` clause, the defaults are the same as if you had written this:

```
FIELDS TERMINATED BY '\t' ENCLOSED BY '' ESCAPED BY '\\'
```

If you specify no `LINES` clause, the defaults are the same as if you had written this:

```
LINES TERMINATED BY '\n' STARTING BY ''
```

In other words, the defaults cause `LOAD DATA INFILE` to act as follows when reading input:

- Look for line boundaries at newlines.
- Do not skip over any line prefix.
- Break lines into fields at tabs.

- Do not expect fields to be enclosed within any quoting characters.
- Interpret occurrences of tab, newline, or “\” preceded by “\” as literal characters that are part of field values.

Conversely, the defaults cause `SELECT ... INTO OUTFILE` to act as follows when writing output:

- Write tabs between fields.
- Do not enclose fields within any quoting characters.
- Use “\” to escape instances of tab, newline, or “\” that occur within field values.
- Write newlines at the ends of lines.

Backslash is the MySQL escape character within strings, so to write `FIELDS ESCAPED BY '\\'`, you must specify two backslashes for the value to be interpreted as a single backslash.

Note

If you have generated the text file on a Windows system, you might have to use `LINES TERMINATED BY '\r\n'` to read the file properly, because Windows programs typically use two characters as a line terminator. Some programs, such as `WordPad`, might use `\r` as a line terminator when writing files. To read such files, use `LINES TERMINATED BY '\r'`.

If all the lines you want to read in have a common prefix that you want to ignore, you can use `LINES STARTING BY 'prefix_string'` to skip over the prefix, *and anything before it*. If a line does not include the prefix, the entire line is skipped. Suppose that you issue the following statement:

```
LOAD DATA INFILE '/tmp/test.txt' INTO TABLE test
FIELDS TERMINATED BY ',' LINES STARTING BY 'xxx';
```

If the data file looks like this:

```
xxx"abc",1
something xxx"def",2
"ghi",3
```

The resulting rows will be `("abc" , 1)` and `("def" , 2)`. The third row in the file is skipped because it does not contain the prefix.

The `IGNORE number LINES` option can be used to ignore lines at the start of the file. For example, you can use `IGNORE 1 LINES` to skip over an initial header line containing column names:

```
LOAD DATA INFILE '/tmp/test.txt' INTO TABLE test IGNORE 1 LINES;
```

When you use `SELECT ... INTO OUTFILE` in tandem with `LOAD DATA INFILE` to write data from a database into a file and then read the file back into the database later, the field- and line-handling options for both statements must match. Otherwise, `LOAD DATA INFILE` will not interpret the contents of the file properly. Suppose that you use `SELECT ... INTO OUTFILE` to write a file with fields delimited by commas:

```
SELECT * INTO OUTFILE 'data.txt'
FIELDS TERMINATED BY ','
FROM table2;
```

To read the comma-delimited file back in, the correct statement would be:

```
LOAD DATA INFILE 'data.txt' INTO TABLE table2
FIELDS TERMINATED BY ',';
```

If instead you tried to read in the file with the statement shown following, it wouldn't work because it instructs `LOAD DATA INFILE` to look for tabs between fields:

```
LOAD DATA INFILE 'data.txt' INTO TABLE table2
FIELDS TERMINATED BY '\t';
```

The likely result is that each input line would be interpreted as a single field.

`LOAD DATA INFILE` can be used to read files obtained from external sources. For example, many programs can export data in

comma-separated values (CSV) format, such that lines have fields separated by commas and enclosed within double quotes. If lines in such a file are terminated by newlines, the statement shown here illustrates the field- and line-handling options you would use to load the file:

```
LOAD DATA INFILE 'data.txt' INTO TABLE tbl_name
  FIELDS TERMINATED BY ',' ENCLOSED BY '"'
  LINES TERMINATED BY '\n';
```

If the input values are not necessarily enclosed within quotes, use **OPTIONALLY** before the **ENCLOSED BY** keywords.

Any of the field- or line-handling options can specify an empty string (''). If not empty, the **FIELDS [OPTIONALLY] ENCLOSED BY** and **FIELDS ESCAPED BY** values must be a single character. The **FIELDS TERMINATED BY**, **LINES STARTING BY**, and **LINES TERMINATED BY** values can be more than one character. For example, to write lines that are terminated by carriage return/linefeed pairs, or to read a file containing such lines, specify a **LINES TERMINATED BY '\r\n'** clause.

To read a file containing jokes that are separated by lines consisting of %%, you can do this

```
CREATE TABLE jokes
  (a INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
  joke TEXT NOT NULL);
LOAD DATA INFILE '/tmp/jokes.txt' INTO TABLE jokes
  FIELDS TERMINATED BY ''
  LINES TERMINATED BY '\n%%\n' (joke);
```

FIELDS [OPTIONALLY] ENCLOSED BY controls quoting of fields. For output (**SELECT ... INTO OUTFILE**), if you omit the word **OPTIONALLY**, all fields are enclosed by the **ENCLOSED BY** character. An example of such output (using a comma as the field delimiter) is shown here:

```
"1","a string","100.20"
"2","a string containing a , comma","102.20"
"3","a string containing a \" quote","102.20"
"4","a string containing a \", quote and comma","102.20"
```

If you specify **OPTIONALLY**, the **ENCLOSED BY** character is used only to enclose values from columns that have a string data type (such as **CHAR**, **BINARY**, **TEXT**, or **ENUM**):

```
1,"a string",100.20
2,"a string containing a , comma",102.20
3,"a string containing a \" quote",102.20
4,"a string containing a \", quote and comma",102.20
```

Note that occurrences of the **ENCLOSED BY** character within a field value are escaped by prefixing them with the **ESCAPED BY** character. Also note that if you specify an empty **ESCAPED BY** value, it is possible to inadvertently generate output that cannot be read properly by **LOAD DATA INFILE**. For example, the preceding output just shown would appear as follows if the escape character is empty. Observe that the second field in the fourth line contains a comma following the quote, which (erroneously) appears to terminate the field:

```
1,"a string",100.20
2,"a string containing a , comma",102.20
3,"a string containing a " quote",102.20
4,"a string containing a ", quote and comma",102.20
```

For input, the **ENCLOSED BY** character, if present, is stripped from the ends of field values. (This is true regardless of whether **OPTIONALLY** is specified; **OPTIONALLY** has no effect on input interpretation.) Occurrences of the **ENCLOSED BY** character preceded by the **ESCAPED BY** character are interpreted as part of the current field value.

If the field begins with the **ENCLOSED BY** character, instances of that character are recognized as terminating a field value only if followed by the field or line **TERMINATED BY** sequence. To avoid ambiguity, occurrences of the **ENCLOSED BY** character within a field value can be doubled and are interpreted as a single instance of the character. For example, if **ENCLOSED BY ''** is specified, quotes are handled as shown here:

```
"The ""BIG"" boss" -> The "BIG" boss
The "BIG" boss    -> The "BIG" boss
The ""BIG"" boss  -> The "BIG" boss
```

FIELDS ESCAPED BY controls how to write or read special characters. If the **FIELDS ESCAPED BY** character is not empty, it is used to prefix the following characters on output:

- The **FIELDS ESCAPED BY** character
- The **FIELDS [OPTIONALLY] ENCLOSED BY** character

- The first character of the `FIELDS TERMINATED BY` and `LINES TERMINATED BY` values
- ASCII 0 (what is actually written following the escape character is ASCII “0”, not a zero-valued byte)

If the `FIELDS ESCAPED BY` character is empty, no characters are escaped and `NULL` is output as `NULL`, not `\N`. It is probably not a good idea to specify an empty escape character, particularly if field values in your data contain any of the characters in the list just given.

For input, if the `FIELDS ESCAPED BY` character is not empty, occurrences of that character are stripped and the following character is taken literally as part of a field value. Some two-character sequences that are exceptions, where the first character is the escape character. These sequences are shown in the following table (using “\” for the escape character). The rules for `NULL` handling are described later in this section.

<code>\0</code>	An ASCII NUL (0x00) character
<code>\b</code>	A backspace character
<code>\n</code>	A newline (linefeed) character
<code>\r</code>	A carriage return character
<code>\t</code>	A tab character.
<code>\Z</code>	ASCII 26 (Control-Z)
<code>\N</code>	NULL

For more information about “\”-escape syntax, see [Section 8.1, “Literal Values”](#).

In certain cases, field- and line-handling options interact:

- If `LINES TERMINATED BY` is an empty string and `FIELDS TERMINATED BY` is non-empty, lines are also terminated with `FIELDS TERMINATED BY`.
- If the `FIELDS TERMINATED BY` and `FIELDS ENCLOSED BY` values are both empty (‘ ’), a fixed-row (non-delimited) format is used. With fixed-row format, no delimiters are used between fields (but you can still have a line terminator). Instead, column values are read and written using a field width wide enough to hold all values in the field. For `TINYINT`, `SMALLINT`, `MEDIUMINT`, `INT`, and `BIGINT`, the field widths are 4, 6, 8, 11, and 20, respectively, no matter what the declared display width is.

`LINES TERMINATED BY` is still used to separate lines. If a line does not contain all fields, the rest of the columns are set to their default values. If you do not have a line terminator, you should set this to ‘ ’. In this case, the text file must contain all fields for each row.

Fixed-row format also affects handling of `NULL` values, as described later. Note that fixed-size format does not work if you are using a multi-byte character set.

Handling of `NULL` values varies according to the `FIELDS` and `LINES` options in use:

- For the default `FIELDS` and `LINES` values, `NULL` is written as a field value of `\N` for output, and a field value of `\N` is read as `NULL` for input (assuming that the `ESCAPED BY` character is “\”).
- If `FIELDS ENCLOSED BY` is not empty, a field containing the literal word `NULL` as its value is read as a `NULL` value. This differs from the word `NULL` enclosed within `FIELDS ENCLOSED BY` characters, which is read as the string ‘`NULL`’.
- If `FIELDS ESCAPED BY` is empty, `NULL` is written as the word `NULL`.
- With fixed-row format (which is used when `FIELDS TERMINATED BY` and `FIELDS ENCLOSED BY` are both empty), `NULL` is written as an empty string. Note that this causes both `NULL` values and empty strings in the table to be indistinguishable when written to the file because both are written as empty strings. If you need to be able to tell the two apart when reading the file back in, you should not use fixed-row format.

An attempt to load `NULL` into a `NOT NULL` column causes assignment of the implicit default value for the column's data type and a warning, or an error in strict SQL mode. Implicit default values are discussed in [Section 10.1.4, “Data Type Default Values”](#).

Some cases are not supported by `LOAD DATA INFILE`:

- Fixed-size rows (`FIELDS TERMINATED BY` and `FIELDS ENCLOSED BY` both empty) and `BLOB` or `TEXT` columns.
- If you specify one separator that is the same as or a prefix of another, `LOAD DATA INFILE` cannot interpret the input properly. For example, the following `FIELDS` clause would cause problems:

```
FIELDS TERMINATED BY '' ENCLOSED BY ''
```

- If `FIELDS ESCAPED BY` is empty, a field value that contains an occurrence of `FIELDS ENCLOSED BY` or `LINES TERMINATED BY` followed by the `FIELDS TERMINATED BY` value causes `LOAD DATA INFILE` to stop reading a field or line too early. This happens because `LOAD DATA INFILE` cannot properly determine where the field or line value ends.

The following example loads all columns of the `persondata` table:

```
LOAD DATA INFILE 'persondata.txt' INTO TABLE persondata;
```

By default, when no column list is provided at the end of the `LOAD DATA INFILE` statement, input lines are expected to contain a field for each table column. If you want to load only some of a table's columns, specify a column list:

```
LOAD DATA INFILE 'persondata.txt' INTO TABLE persondata (col1,col2,...);
```

You must also specify a column list if the order of the fields in the input file differs from the order of the columns in the table. Otherwise, MySQL cannot tell how to match input fields with table columns.

The column list can contain either column names or user variables. With user variables, the `SET` clause enables you to perform transformations on their values before assigning the result to columns.

User variables in the `SET` clause can be used in several ways. The following example uses the first input column directly for the value of `t1.column1`, and assigns the second input column to a user variable that is subjected to a division operation before being used for the value of `t1.column2`:

```
LOAD DATA INFILE 'file.txt'
  INTO TABLE t1
  (column1, @var1)
  SET column2 = @var1/100;
```

The `SET` clause can be used to supply values not derived from the input file. The following statement sets `column3` to the current date and time:

```
LOAD DATA INFILE 'file.txt'
  INTO TABLE t1
  (column1, column2)
  SET column3 = CURRENT_TIMESTAMP;
```

You can also discard an input value by assigning it to a user variable and not assigning the variable to a table column:

```
LOAD DATA INFILE 'file.txt'
  INTO TABLE t1
  (column1, @dummy, column2, @dummy, column3);
```

Use of the column/variable list and `SET` clause is subject to the following restrictions:

- Assignments in the `SET` clause should have only column names on the left hand side of assignment operators.
- You can use subqueries in the right hand side of `SET` assignments. A subquery that returns a value to be assigned to a column may be a scalar subquery only. Also, you cannot use a subquery to select from the table that is being loaded.
- Lines ignored by an `IGNORE` clause are not processed for the column/variable list or `SET` clause.
- User variables cannot be used when loading data with fixed-row format because user variables do not have a display width.

When processing an input line, `LOAD DATA` splits it into fields and uses the values according to the column/variable list and the `SET` clause, if they are present. Then the resulting row is inserted into the table. If there are `BEFORE INSERT` or `AFTER INSERT` triggers for the table, they are activated before or after inserting the row, respectively.

If an input line has too many fields, the extra fields are ignored and the number of warnings is incremented.

If an input line has too few fields, the table columns for which input fields are missing are set to their default values. Default value assignment is described in [Section 10.1.4, “Data Type Default Values”](#).

An empty field value is interpreted differently than if the field value is missing:

- For string types, the column is set to the empty string.
- For numeric types, the column is set to 0.
- For date and time types, the column is set to the appropriate “zero” value for the type. See [Section 10.3, “Date and Time Types”](#).

These are the same values that result if you assign an empty string explicitly to a string, numeric, or date or time type explicitly in an `INSERT` or `UPDATE` statement.

`TIMESTAMP` columns are set to the current date and time only if there is a `NULL` value for the column (that is, `\N`) and the column is not declared to allow `NULL` values, or if the `TIMESTAMP` column's default value is the current timestamp and it is omitted from the field list when a field list is specified.

`LOAD DATA INFILE` regards all input as strings, so you cannot use numeric values for `ENUM` or `SET` columns the way you can with `INSERT` statements. All `ENUM` and `SET` values must be specified as strings.

`BIT` values cannot be loaded using binary notation (for example, `b'011010'`). To work around this, specify the values as regular integers and use the `SET` clause to convert them so that MySQL performs a numeric type conversion and loads them into the `BIT` column properly:

```
shell> cat /tmp/bit_test.txt
2
127
shell> mysql test
mysql> LOAD DATA INFILE '/tmp/bit_test.txt'
-> INTO TABLE bit_test (@var1) SET b= CAST(@var1 AS UNSIGNED);
Query OK, 2 rows affected (0.00 sec)
Records: 2 Deleted: 0 Skipped: 0 Warnings: 0

mysql> SELECT BIN(b+0) FROM bit_test;
+-----+
| bin(b+0) |
+-----+
| 10       |
| 1111111 |
+-----+
2 rows in set (0.00 sec)
```

When the `LOAD DATA INFILE` statement finishes, it returns an information string in the following format:

```
Records: 1 Deleted: 0 Skipped: 0 Warnings: 0
```

If you are using the C API, you can get information about the statement by calling the `mysql_info()` function. See [Section 20.10.3.35, “mysql_info\(\)”](#).

Warnings occur under the same circumstances as when values are inserted via the `INSERT` statement (see [Section 12.2.5, “INSERT Syntax”](#)), except that `LOAD DATA INFILE` also generates warnings when there are too few or too many fields in the input row. The warnings are not stored anywhere; the number of warnings can be used only as an indication of whether everything went well.

You can use `SHOW WARNINGS` to get a list of the first `max_error_count` warnings as information about what went wrong. See [Section 12.5.5.41, “SHOW WARNINGS Syntax”](#).

12.2.7. REPLACE Syntax

```
REPLACE [LOW_PRIORITY | DELAYED]
[INTO] tbl_name [(col_name,...)]
{VALUES | VALUE} ({expr | DEFAULT},...),(...),...
```

Or:

```
REPLACE [LOW_PRIORITY | DELAYED]
[INTO] tbl_name
SET col_name={expr | DEFAULT}, ...
```

Or:

```
REPLACE [LOW_PRIORITY | DELAYED]
[INTO] tbl_name [(col_name,...)]
SELECT ...
```

REPLACE works exactly like **INSERT**, except that if an old row in the table has the same value as a new row for a **PRIMARY KEY** or a **UNIQUE** index, the old row is deleted before the new row is inserted. See [Section 12.2.5, “INSERT Syntax”](#).

REPLACE is a MySQL extension to the SQL standard. It either inserts, or *deletes* and inserts. For another MySQL extension to standard SQL — that either inserts or *updates* — see [Section 12.2.5.3, “INSERT ... ON DUPLICATE KEY UPDATE Syntax”](#).

Note that unless the table has a **PRIMARY KEY** or **UNIQUE** index, using a **REPLACE** statement makes no sense. It becomes equivalent to **INSERT**, because there is no index to be used to determine whether a new row duplicates another.

Values for all columns are taken from the values specified in the **REPLACE** statement. Any missing columns are set to their default values, just as happens for **INSERT**. You cannot refer to values from the current row and use them in the new row. If you use an assignment such as **SET col_name = col_name + 1**, the reference to the column name on the right hand side is treated as **DEFAULT(col_name)**, so the assignment is equivalent to **SET col_name = DEFAULT(col_name) + 1**.

To use **REPLACE**, you must have both the **INSERT** and **DELETE** privileges for the table.

The **REPLACE** statement returns a count to indicate the number of rows affected. This is the sum of the rows deleted and inserted. If the count is 1 for a single-row **REPLACE**, a row was inserted and no rows were deleted. If the count is greater than 1, one or more old rows were deleted before the new row was inserted. It is possible for a single row to replace more than one old row if the table contains multiple unique indexes and the new row duplicates values for different old rows in different unique indexes.

The affected-rows count makes it easy to determine whether **REPLACE** only added a row or whether it also replaced any rows: Check whether the count is 1 (added) or greater (replaced).

If you are using the C API, the affected-rows count can be obtained using the `mysql_affected_rows()` function.

Currently, you cannot replace into a table and select from the same table in a subquery.

MySQL uses the following algorithm for **REPLACE** (and **LOAD DATA ... REPLACE**):

1. Try to insert the new row into the table
2. While the insertion fails because a duplicate-key error occurs for a primary key or unique index:
 - a. Delete from the table the conflicting row that has the duplicate key value
 - b. Try again to insert the new row into the table

12.2.8. SELECT Syntax

```
SELECT
  [ALL | DISTINCT | DISTINCTROW ]
  [HIGH_PRIORITY]
  [STRAIGHT_JOIN]
  [SQL_SMALL_RESULT] [SQL_BIG_RESULT] [SQL_BUFFER_RESULT]
  [SQL_CACHE | SQL_NO_CACHE] [SQL_CALC_FOUND_ROWS]
  select_expr [, select_expr ...]
  [FROM table_references]
  [WHERE where_condition]
  [GROUP BY {col_name | expr | position}
  [ASC | DESC], ... [WITH ROLLUP]]
  [HAVING where_condition]
  [ORDER BY {col_name | expr | position}
  [ASC | DESC], ...]
  [LIMIT {[offset,] row_count | row_count OFFSET offset}]
  [PROCEDURE procedure_name(argument_list)]
  [INTO OUTFILE 'file_name' export_options
  | INTO DUMPFILE 'file_name'
  | INTO var_name [, var_name]]
  [FOR UPDATE | LOCK IN SHARE MODE]
```

SELECT is used to retrieve rows selected from one or more tables, and can include **UNION** statements and subqueries. See [Section 12.2.8.3, “UNION Syntax”](#), and [Section 12.2.9, “Subquery Syntax”](#).

The most commonly used clauses of **SELECT** statements are these:

- Each *select_expr* indicates a column that you want to retrieve. There must be at least one *select_expr*.
- *table_references* indicates the table or tables from which to retrieve rows. Its syntax is described in [Section 12.2.8.1, “JOIN Syntax”](#).

- The **WHERE** clause, if given, indicates the condition or conditions that rows must satisfy to be selected. *where_condition* is an expression that evaluates to true for each row to be selected. The statement selects all rows if there is no **WHERE** clause.

In the **WHERE** clause, you can use any of the functions and operators that MySQL supports, except for aggregate (summary) functions. See [Chapter 11, Functions and Operators](#).

SELECT can also be used to retrieve rows computed without reference to any table.

For example:

```
mysql> SELECT 1 + 1;
-> 2
```

You are allowed to specify **DUAL** as a dummy table name in situations where no tables are referenced:

```
mysql> SELECT 1 + 1 FROM DUAL;
-> 2
```

DUAL is purely for the convenience of people who require that all **SELECT** statements should have **FROM** and possibly other clauses. MySQL may ignore the clauses. MySQL does not require **FROM DUAL** if no tables are referenced.

In general, clauses used must be given in exactly the order shown in the syntax description. For example, a **HAVING** clause must come after any **GROUP BY** clause and before any **ORDER BY** clause. The exception is that the **INTO** clause can appear either as shown in the syntax description or immediately following the *select_expr* list.

The list of *select_expr* terms comprises the select list that indicates which columns to retrieve. Terms specify a column or expression or can use *****-shorthand:

- A select list consisting only of a single unqualified ***** can be used as shorthand to select all columns from all tables:

```
SELECT * FROM t1 INNER JOIN t2 ...
```

- tbl_name* . ***** can be used as a qualified shorthand to select all columns from the named table:

```
SELECT t1.*, t2.* FROM t1 INNER JOIN t2 ...
```

- Use of an unqualified ***** with other items in the select list may produce a parse error. To avoid this problem, use a qualified *tbl_name* . ***** reference

```
SELECT AVG(score), t1.* FROM t1 ...
```

The following list provides additional information about other **SELECT** clauses:

- A *select_expr* can be given an alias using **AS** *alias_name*. The alias is used as the expression's column name and can be used in **GROUP BY**, **ORDER BY**, or **HAVING** clauses. For example:

```
SELECT CONCAT(last_name,', ',first_name) AS full_name
FROM mytable ORDER BY full_name;
```

The **AS** keyword is optional when aliasing a *select_expr*. The preceding example could have been written like this:

```
SELECT CONCAT(last_name,', ',first_name) full_name
FROM mytable ORDER BY full_name;
```

However, because the **AS** is optional, a subtle problem can occur if you forget the comma between two *select_expr* expressions: MySQL interprets the second as an alias name. For example, in the following statement, *columnb* is treated as an alias name:

```
SELECT columna columnb FROM mytable;
```

For this reason, it is good practice to be in the habit of using **AS** explicitly when specifying column aliases.

It is not allowable to refer to a column alias in a **WHERE** clause, because the column value might not yet be determined when the **WHERE** clause is executed. See [Section B.1.5.4, "Problems with Column Aliases"](#).

- The `FROM table_references` clause indicates the table or tables from which to retrieve rows. If you name more than one table, you are performing a join. For information on join syntax, see [Section 12.2.8.1, “JOIN Syntax”](#). For each table specified, you can optionally specify an alias.

```
tbl_name [[AS] alias] [index_hint]
```

The use of index hints provides the optimizer with information about how to choose indexes during query processing. For a description of the syntax for specifying these hints, see [Section 12.2.8.2, “Index Hint Syntax”](#).

You can use `SET max_seeks_for_key=value` as an alternative way to force MySQL to prefer key scans instead of table scans. See [Section 5.1.3, “Server System Variables”](#).

- You can refer to a table within the default database as `tbl_name`, or as `db_name.tbl_name` to specify a database explicitly. You can refer to a column as `col_name`, `tbl_name.col_name`, or `db_name.tbl_name.col_name`. You need not specify a `tbl_name` or `db_name.tbl_name` prefix for a column reference unless the reference would be ambiguous. See [Section 8.2.1, “Identifier Qualifiers”](#), for examples of ambiguity that require the more explicit column reference forms.
- A table reference can be aliased using `tbl_name AS alias_name` or `tbl_name alias_name`:

```
SELECT t1.name, t2.salary FROM employee AS t1, info AS t2
WHERE t1.name = t2.name;

SELECT t1.name, t2.salary FROM employee t1, info t2
WHERE t1.name = t2.name;
```

- Columns selected for output can be referred to in `ORDER BY` and `GROUP BY` clauses using column names, column aliases, or column positions. Column positions are integers and begin with 1:

```
SELECT college, region, seed FROM tournament
ORDER BY region, seed;

SELECT college, region AS r, seed AS s FROM tournament
ORDER BY r, s;

SELECT college, region, seed FROM tournament
ORDER BY 2, 3;
```

To sort in reverse order, add the `DESC` (descending) keyword to the name of the column in the `ORDER BY` clause that you are sorting by. The default is ascending order; this can be specified explicitly using the `ASC` keyword.

If `ORDER BY` occurs within a subquery and also is applied in the outer query, the outermost `ORDER BY` takes precedence. For example, results for the following statement are sorted in descending order, not ascending order:

```
(SELECT ... ORDER BY a) ORDER BY a DESC;
```

Use of column positions is deprecated because the syntax has been removed from the SQL standard.

- If you use `GROUP BY`, output rows are sorted according to the `GROUP BY` columns as if you had an `ORDER BY` for the same columns. To avoid the overhead of sorting that `GROUP BY` produces, add `ORDER BY NULL`:

```
SELECT a, COUNT(b) FROM test_table GROUP BY a ORDER BY NULL;
```

- MySQL extends the `GROUP BY` clause so that you can also specify `ASC` and `DESC` after columns named in the clause:

```
SELECT a, COUNT(b) FROM test_table GROUP BY a DESC;
```

- MySQL extends the use of `GROUP BY` to allow selecting fields that are not mentioned in the `GROUP BY` clause. If you are not getting the results that you expect from your query, please read the description of `GROUP BY` found in [Section 11.12, “Functions and Modifiers for Use with GROUP BY Clauses”](#).
- `GROUP BY` allows a `WITH ROLLUP` modifier. See [Section 11.12.2, “GROUP BY Modifiers”](#).
- The `HAVING` clause is applied nearly last, just before items are sent to the client, with no optimization. (`LIMIT` is applied after `HAVING`.)

The SQL standard requires that `HAVING` must reference only columns in the `GROUP BY` clause or columns used in aggregate functions. However, MySQL supports an extension to this behavior, and allows `HAVING` to refer to columns in the `SELECT` list and columns in outer subqueries as well.

If the `HAVING` clause refers to a column that is ambiguous, a warning occurs. In the following statement, `col2` is ambiguous because it is used as both an alias and a column name:

```
SELECT COUNT(col1) AS col2 FROM t GROUP BY col2 HAVING col2 = 2;
```

Preference is given to standard SQL behavior, so if a `HAVING` column name is used both in `GROUP BY` and as an aliased column in the output column list, preference is given to the column in the `GROUP BY` column.

- Do not use `HAVING` for items that should be in the `WHERE` clause. For example, do not write the following:

```
SELECT col_name FROM tbl_name HAVING col_name > 0;
```

Write this instead:

```
SELECT col_name FROM tbl_name WHERE col_name > 0;
```

- The `HAVING` clause can refer to aggregate functions, which the `WHERE` clause cannot:

```
SELECT user, MAX(salary) FROM users
GROUP BY user HAVING MAX(salary) > 10;
```

(This did not work in some older versions of MySQL.)

- MySQL allows duplicate column names. That is, there can be more than one `select_expr` with the same name. This is an extension to standard SQL. Because MySQL also allows `GROUP BY` and `HAVING` to refer to `select_expr` values, this can result in an ambiguity:

```
SELECT 12 AS a, a FROM t GROUP BY a;
```

In that statement, both columns have the name `a`. To ensure that the correct column is used for grouping, use different names for each `select_expr`.

- MySQL resolves unqualified column or alias references in `ORDER BY` clauses by searching in the `select_expr` values, then in the columns of the tables in the `FROM` clause. For `GROUP BY` or `HAVING` clauses, it searches the `FROM` clause before searching in the `select_expr` values. (For `GROUP BY` and `HAVING`, this differs from the pre-MySQL 5.0 behavior that used the same rules as for `ORDER BY`.)
- The `LIMIT` clause can be used to constrain the number of rows returned by the `SELECT` statement. `LIMIT` takes one or two numeric arguments, which must both be non-negative integer constants (except when using prepared statements).

With two arguments, the first argument specifies the offset of the first row to return, and the second specifies the maximum number of rows to return. The offset of the initial row is 0 (not 1):

```
SELECT * FROM tbl LIMIT 5,10; # Retrieve rows 6-15
```

To retrieve all rows from a certain offset up to the end of the result set, you can use some large number for the second parameter. This statement retrieves all rows from the 96th row to the last:

```
SELECT * FROM tbl LIMIT 95,18446744073709551615;
```

With one argument, the value specifies the number of rows to return from the beginning of the result set:

```
SELECT * FROM tbl LIMIT 5; # Retrieve first 5 rows
```

In other words, `LIMIT row_count` is equivalent to `LIMIT 0, row_count`.

For prepared statements, you can use placeholders. The following statements will return one row from the `tbl` table:

```
SET @a=1;
PREPARE STMT FROM 'SELECT * FROM tbl LIMIT ?';
EXECUTE STMT USING @a;
```

The following statements will return the second to sixth row from the `tbl` table:

```
SET @skip=1; SET @numrows=5;
PREPARE STMT FROM 'SELECT * FROM tbl LIMIT ?, ?';
EXECUTE STMT USING @skip, @numrows;
```

For compatibility with PostgreSQL, MySQL also supports the `LIMIT row_count OFFSET offset` syntax.

If `LIMIT` occurs within a subquery and also is applied in the outer query, the outermost `LIMIT` takes precedence. For example, the following statement produces two rows, not one:

```
(SELECT ... LIMIT 1) LIMIT 2;
```

- A `PROCEDURE` clause names a procedure that should process the data in the result set. For an example, see [Section 21.4.1](#), “`PROCEDURE ANALYSE`”.
- The `SELECT ... INTO OUTFILE 'file_name'` form of `SELECT` writes the selected rows to a file. The file is created on the server host, so you must have the `FILE` privilege to use this syntax. `file_name` cannot be an existing file, which among other things prevents files such as `/etc/passwd` and database tables from being destroyed. The `character_set_filesystem` system variable controls the interpretation of the file name.

The `SELECT ... INTO OUTFILE` statement is intended primarily to let you very quickly dump a table to a text file on the server machine. If you want to create the resulting file on some client host other than the server host, you cannot use `SELECT ... INTO OUTFILE`. In that case, you should instead use a command such as `mysql -e "SELECT ..." > file_name` to generate the file on the client host.

`SELECT ... INTO OUTFILE` is the complement of `LOAD DATA INFILE`; the syntax for the `export_options` part of the statement consists of the same `FIELDS` and `LINES` clauses that are used with the `LOAD DATA INFILE` statement. See [Section 12.2.6](#), “`LOAD DATA INFILE Syntax`”.

Column values are dumped using the `binary` character set. In effect, there is no character set conversion. If a table contains columns in several character sets, the output data file will as well and you may not be able to reload the file correctly.

`FIELDS ESCAPED BY` controls how to write special characters. If the `FIELDS ESCAPED BY` character is not empty, it is used as a prefix that precedes following characters on output:

- The `FIELDS ESCAPED BY` character
- The `FIELDS [OPTIONALLY] ENCLOSED BY` character
- The first character of the `FIELDS TERMINATED BY` and `LINES TERMINATED BY` values
- ASCII `NUL` (the zero-valued byte; what is actually written following the escape character is ASCII “0”, not a zero-valued byte)

The `FIELDS TERMINATED BY`, `ENCLOSED BY`, `ESCAPED BY`, or `LINES TERMINATED BY` characters *must* be escaped so that you can read the file back in reliably. ASCII `NUL` is escaped to make it easier to view with some pagers.

The resulting file does not have to conform to SQL syntax, so nothing else need be escaped.

If the `FIELDS ESCAPED BY` character is empty, no characters are escaped and `NULL` is output as `NULL`, not `\N`. It is probably not a good idea to specify an empty escape character, particularly if field values in your data contain any of the characters in the list just given.

Here is an example that produces a file in the comma-separated values (CSV) format used by many programs:

```
SELECT a,b,a+b INTO OUTFILE '/tmp/result.txt'
  FIELDS TERMINATED BY ',' OPTIONALLY ENCLOSED BY '"'
  LINES TERMINATED BY '\n'
FROM test_table;
```

- If you use `INTO DUMPFILE` instead of `INTO OUTFILE`, MySQL writes only one row into the file, without any column or line termination and without performing any escape processing. This is useful if you want to store a `BLOB` value in a file.

Note

Any file created by `INTO OUTFILE` or `INTO DUMPFILE` is writable by all users on the server host. The reason for this is that the MySQL server cannot create a file that is owned by anyone other than the user under whose account it is running. (You should *never* run `mysqld` as `root` for this and other reasons.) The file thus must be world-writable so that you can manipulate its contents.

If the `secure_file_priv` system variable is set to a non-empty directory name, the file to be written must be located in that directory.

- The `INTO` clause can name a list of one or more variables, which can be user-defined variables, or parameters or local variables within a stored function or procedure body (see [Section 12.8.3.3](#), “`SELECT ... INTO Statement`”). The selected values are assigned to the variables. The number of variables must match the number of columns. The query should return a single row. If

the query returns no rows, a warning with error code 1329 occurs (`No data`), and the variable values remain unchanged. If the query returns multiple rows, error 1172 occurs (`Result consisted of more than one row`). If it is possible that the statement may retrieve multiple rows, you can use `LIMIT 1` to limit the result set to a single row.

In the context of such statements that occur as part of events executed by the Event Scheduler, diagnostics messages (not only errors, but also warnings) are written to the error log, and, on Windows, to the application event log. For additional information, see [Section 18.4.5, “Event Scheduler Status”](#).

- The `SELECT` syntax description at the beginning this section shows the `INTO` clause near the end of the statement. It is also possible to use `INTO` immediately following the `select_expr` list.
- An `INTO` clause should not be used in a nested `SELECT` because such a `SELECT` must return its result to the outer context.
- If you use `FOR UPDATE` with a storage engine that uses page or row locks, rows examined by the query are write-locked until the end of the current transaction. Using `LOCK IN SHARE MODE` sets a shared lock that allows other transactions to read the examined rows but not to update or delete them. See [Section 13.6.8.3, “SELECT ... FOR UPDATE and SELECT ... LOCK IN SHARE MODE Locking Reads”](#).

Following the `SELECT` keyword, you can use a number of options that affect the operation of the statement.

The `ALL`, `DISTINCT`, and `DISTINCTROW` options specify whether duplicate rows should be returned. If none of these options are given, the default is `ALL` (all matching rows are returned). `DISTINCT` and `DISTINCTROW` are synonyms and specify removal of duplicate rows from the result set.

`HIGH_PRIORITY`, `STRAIGHT_JOIN`, and options beginning with `SQL_` are MySQL extensions to standard SQL.

- `HIGH_PRIORITY` gives the `SELECT` higher priority than a statement that updates a table. You should use this only for queries that are very fast and must be done at once. A `SELECT HIGH_PRIORITY` query that is issued while the table is locked for reading runs even if there is an update statement waiting for the table to be free. This affects only storage engines that use only table-level locking (`MyISAM`, `MEMORY`, `MERGE`).

`HIGH_PRIORITY` cannot be used with `SELECT` statements that are part of a `UNION`.

- `STRAIGHT_JOIN` forces the optimizer to join the tables in the order in which they are listed in the `FROM` clause. You can use this to speed up a query if the optimizer joins the tables in non-optimal order. `STRAIGHT_JOIN` also can be used in the `table_references` list. See [Section 12.2.8.1, “JOIN Syntax”](#).

`STRAIGHT_JOIN` does not apply to any table that the optimizer treats as a `const` or `system` table. Such a table produces a single row, is read during the optimization phase of query execution, and references to its columns are replaced with the appropriate column values before query execution proceeds. These tables will appear first in the query plan displayed by `EXPLAIN`. See [Section 7.2.1, “Optimizing Queries with EXPLAIN”](#). This exception may not apply to `const` or `system` tables that are used on the `NULL`-complemented side of an outer join (that is, the right-side table of a `LEFT JOIN` or the left-side table of a `RIGHT JOIN`).

- `SQL_BIG_RESULT` can be used with `GROUP BY` or `DISTINCT` to tell the optimizer that the result set has many rows. In this case, MySQL directly uses disk-based temporary tables if needed, and prefers sorting to using a temporary table with a key on the `GROUP BY` elements.
- `SQL_BUFFER_RESULT` forces the result to be put into a temporary table. This helps MySQL free the table locks early and helps in cases where it takes a long time to send the result set to the client. This option can be used only for top-level `SELECT` statements, not for subqueries or following `UNION`.
- `SQL_SMALL_RESULT` can be used with `GROUP BY` or `DISTINCT` to tell the optimizer that the result set is small. In this case, MySQL uses fast temporary tables to store the resulting table instead of using sorting. This should not normally be needed.
- `SQL_CALC_FOUND_ROWS` tells MySQL to calculate how many rows there would be in the result set, disregarding any `LIMIT` clause. The number of rows can then be retrieved with `SELECT FOUND_ROWS()`. See [Section 11.11.3, “Information Functions”](#).
- The `SQL_CACHE` and `SQL_NO_CACHE` options affect caching of query results in the query cache (see [Section 7.5.5, “The MySQL Query Cache”](#)). `SQL_CACHE` tells MySQL to store the result in the query cache if it is cacheable and the value of the `query_cache_type` system variable is `2` or `DEMAND`. `SQL_NO_CACHE` tells MySQL not to store the result in the query cache. For a query that uses `UNION`, subqueries, or views, the following rules apply:
 - `SQL_NO_CACHE` applies if it appears in any `SELECT` in the query.
 - For a cacheable query, `SQL_CACHE` applies if it appears in the first `SELECT` of the query, or in the first `SELECT` of a view referred to by the query.

12.2.8.1. JOIN Syntax

MySQL supports the following `JOIN` syntaxes for the `table_references` part of `SELECT` statements and multiple-table `DELETE` and `UPDATE` statements:

```

table_references:
    table_reference [, table_reference] ...

table_reference:
    table_factor
  | join_table

table_factor:
    tbl_name [[AS] alias] [index_hint_list]
  | table_subquery [AS] alias
  | ( table_references )
  | { OJ table_reference LEFT OUTER JOIN table_reference
      ON conditional_expr }

join_table:
    table_reference [INNER | CROSS] JOIN table_factor [join_condition]
  | table_reference STRAIGHT_JOIN table_factor
  | table_reference STRAIGHT_JOIN table_factor ON conditional_expr
  | table_reference {LEFT|RIGHT} [OUTER] JOIN table_reference join_condition
  | table_reference NATURAL [{LEFT|RIGHT} [OUTER]] JOIN table_factor

join_condition:
    ON conditional_expr
  | USING (column_list)

index_hint_list:
    index_hint [, index_hint] ...

index_hint:
    USE {INDEX|KEY}
      [{FOR {JOIN|ORDER BY|GROUP BY}}] (index_list)
  | IGNORE {INDEX|KEY}
      [{FOR {JOIN|ORDER BY|GROUP BY}}] (index_list)
  | FORCE {INDEX|KEY}
      [{FOR {JOIN|ORDER BY|GROUP BY}}] (index_list)

index_list:
    index_name [, index_name] ...

```

A table reference is also known as a join expression.

The syntax of `table_factor` is extended in comparison with the SQL Standard. The latter accepts only `table_reference`, not a list of them inside a pair of parentheses.

This is a conservative extension if we consider each comma in a list of `table_reference` items as equivalent to an inner join. For example:

```

SELECT * FROM t1 LEFT JOIN (t2, t3, t4)
      ON (t2.a=t1.a AND t3.b=t1.b AND t4.c=t1.c)

```

is equivalent to:

```

SELECT * FROM t1 LEFT JOIN (t2 CROSS JOIN t3 CROSS JOIN t4)
      ON (t2.a=t1.a AND t3.b=t1.b AND t4.c=t1.c)

```

In MySQL, `CROSS JOIN` is a syntactic equivalent to `INNER JOIN` (they can replace each other). In standard SQL, they are not equivalent. `INNER JOIN` is used with an `ON` clause, `CROSS JOIN` is used otherwise.

In general, parentheses can be ignored in join expressions containing only inner join operations. MySQL also supports nested joins (see [Section 7.2.11, “Nested Join Optimization”](#)).

Index hints can be specified to affect how the MySQL optimizer makes use of indexes. For more information, see [Section 12.2.8.2, “Index Hint Syntax”](#).

The following list describes general factors to take into account when writing joins.

- A table reference can be aliased using `tbl_name AS alias_name` or `tbl_name alias_name`:

```

SELECT t1.name, t2.salary
  FROM employee AS t1 INNER JOIN info AS t2 ON t1.name = t2.name;

SELECT t1.name, t2.salary
  FROM employee t1 INNER JOIN info t2 ON t1.name = t2.name;

```

- A *table_subquery* is also known as a subquery in the `FROM` clause. Such subqueries *must* include an alias to give the subquery result a table name. A trivial example follows; see also [Section 12.2.9.8, “Subqueries in the FROM clause”](#).

```
SELECT * FROM (SELECT 1, 2, 3) AS t1;
```

- `INNER JOIN` and `,` (comma) are semantically equivalent in the absence of a join condition: both produce a Cartesian product between the specified tables (that is, each and every row in the first table is joined to each and every row in the second table).

However, the precedence of the comma operator is less than of `INNER JOIN`, `CROSS JOIN`, `LEFT JOIN`, and so on. If you mix comma joins with the other join types when there is a join condition, an error of the form `Unknown column 'col_name' in 'on clause'` may occur. Information about dealing with this problem is given later in this section.

- The *conditional_expr* used with `ON` is any conditional expression of the form that can be used in a `WHERE` clause. Generally, you should use the `ON` clause for conditions that specify how to join tables, and the `WHERE` clause to restrict which rows you want in the result set.
- If there is no matching row for the right table in the `ON` or `USING` part in a `LEFT JOIN`, a row with all columns set to `NULL` is used for the right table. You can use this fact to find rows in a table that have no counterpart in another table:

```
SELECT left_tbl.*
FROM left_tbl LEFT JOIN right_tbl ON left_tbl.id = right_tbl.id
WHERE right_tbl.id IS NULL;
```

This example finds all rows in `left_tbl` with an `id` value that is not present in `right_tbl` (that is, all rows in `left_tbl` with no corresponding row in `right_tbl`). This assumes that `right_tbl.id` is declared `NOT NULL`. See [Section 7.2.9, “LEFT JOIN and RIGHT JOIN Optimization”](#).

- The `USING(column_list)` clause names a list of columns that must exist in both tables. If tables `a` and `b` both contain columns `c1`, `c2`, and `c3`, the following join compares corresponding columns from the two tables:

```
a LEFT JOIN b USING (c1,c2,c3)
```

- The `NATURAL [LEFT] JOIN` of two tables is defined to be semantically equivalent to an `INNER JOIN` or a `LEFT JOIN` with a `USING` clause that names all columns that exist in both tables.
- `RIGHT JOIN` works analogously to `LEFT JOIN`. To keep code portable across databases, it is recommended that you use `LEFT JOIN` instead of `RIGHT JOIN`.
- The `{ OJ ... LEFT OUTER JOIN ... }` syntax shown in the join syntax description exists only for compatibility with ODBC. The curly braces in the syntax should be written literally; they are not metasyntax as used elsewhere in syntax descriptions.

```
SELECT left_tbl.*
FROM { OJ left_tbl LEFT OUTER JOIN right_tbl ON left_tbl.id = right_tbl.id }
WHERE right_tbl.id IS NULL;
```

You can use other types of joins within `{ OJ ... }`, such as `INNER JOIN` or `RIGHT OUTER JOIN`. This helps with compatibility with some third-party applications, but is not official ODBC syntax.

- `STRAIGHT_JOIN` is similar to `JOIN`, except that the left table is always read before the right table. This can be used for those (few) cases for which the join optimizer puts the tables in the wrong order.

Some join examples:

```
SELECT * FROM table1, table2;
SELECT * FROM table1 INNER JOIN table2 ON table1.id=table2.id;
SELECT * FROM table1 LEFT JOIN table2 ON table1.id=table2.id;
SELECT * FROM table1 LEFT JOIN table2 USING (id);
SELECT * FROM table1 LEFT JOIN table2 ON table1.id=table2.id
LEFT JOIN table3 ON table2.id=table3.id;
```

Join Processing Changes in MySQL 5.0.12

Note

Natural joins and joins with `USING`, including outer join variants, are processed according to the SQL:2003 standard. The goal was to align the syntax and semantics of MySQL with respect to `NATURAL JOIN` and `JOIN ... USING`

according to SQL:2003. However, these changes in join processing can result in different output columns for some joins. Also, some queries that appeared to work correctly in older versions (prior to 5.0.12) must be rewritten to comply with the standard.

These changes have five main aspects:

- The way that MySQL determines the result columns of **NATURAL** or **USING** join operations (and thus the result of the entire **FROM** clause).
- Expansion of **SELECT *** and **SELECT tbl_name.*** into a list of selected columns.
- Resolution of column names in **NATURAL** or **USING** joins.
- Transformation of **NATURAL** or **USING** joins into **JOIN ... ON**.
- Resolution of column names in the **ON** condition of a **JOIN ... ON**.

The following list provides more detail about several effects of current join processing versus join processing in older versions. The term “previously” means “prior to MySQL 5.0.12.”

- The columns of a **NATURAL** join or a **USING** join may be different from previously. Specifically, redundant output columns no longer appear, and the order of columns for **SELECT *** expansion may be different from before.

Consider this set of statements:

```
CREATE TABLE t1 (i INT, j INT);
CREATE TABLE t2 (k INT, j INT);
INSERT INTO t1 VALUES(1,1);
INSERT INTO t2 VALUES(1,1);
SELECT * FROM t1 NATURAL JOIN t2;
SELECT * FROM t1 JOIN t2 USING (j);
```

Previously, the statements produced this output:

```
+-----+-----+-----+-----+
| i     | j     | k     | j     |
+-----+-----+-----+-----+
| 1     | 1     | 1     | 1     |
+-----+-----+-----+-----+
| i     | j     | k     | j     |
+-----+-----+-----+-----+
| 1     | 1     | 1     | 1     |
+-----+-----+-----+-----+
```

In the first **SELECT** statement, column **j** appears in both tables and thus becomes a join column, so, according to standard SQL, it should appear only once in the output, not twice. Similarly, in the second **SELECT** statement, column **j** is named in the **USING** clause and should appear only once in the output, not twice. But in both cases, the redundant column is not eliminated. Also, the order of the columns is not correct according to standard SQL.

Now the statements produce this output:

```
+-----+-----+-----+
| j     | i     | k     |
+-----+-----+-----+
| 1     | 1     | 1     |
+-----+-----+-----+
| j     | i     | k     |
+-----+-----+-----+
| 1     | 1     | 1     |
+-----+-----+-----+
```

The redundant column is eliminated and the column order is correct according to standard SQL:

- First, coalesced common columns of the two joined tables, in the order in which they occur in the first table
- Second, columns unique to the first table, in order in which they occur in that table
- Third, columns unique to the second table, in order in which they occur in that table

The single result column that replaces two common columns is defined via the coalesce operation. That is, for two **t1.a** and **t2.a** the resulting single join column **a** is defined as **a = COALESCE(t1.a, t2.a)**, where:

```
COALESCE(x, y) = (CASE WHEN v1 IS NOT NULL THEN v1 ELSE v2 END)
```

If the join operation is any other join, the result columns of the join consists of the concatenation of all columns of the joined tables. This is the same as previously.

A consequence of the definition of coalesced columns is that, for outer joins, the coalesced column contains the value of the non-NULL column if one of the two columns is always NULL. If neither or both columns are NULL, both common columns have the same value, so it doesn't matter which one is chosen as the value of the coalesced column. A simple way to interpret this is to consider that a coalesced column of an outer join is represented by the common column of the inner table of a JOIN. Suppose that the tables `t1(a,b)` and `t2(a,c)` have the following contents:

```
t1    t2
----  ----
1 x   2 z
2 y   3 w
```

Then:

```
mysql> SELECT * FROM t1 NATURAL LEFT JOIN t2;
+-----+-----+-----+
| a     | b     | c     |
+-----+-----+-----+
| 1     | x     | NULL  |
| 2     | y     | z     |
+-----+-----+-----+
```

Here column `a` contains the values of `t1.a`.

```
mysql> SELECT * FROM t1 NATURAL RIGHT JOIN t2;
+-----+-----+-----+
| a     | c     | b     |
+-----+-----+-----+
| 2     | z     | y     |
| 3     | w     | NULL  |
+-----+-----+-----+
```

Here column `a` contains the values of `t2.a`.

Compare these results to the otherwise equivalent queries with `JOIN ... ON`:

```
mysql> SELECT * FROM t1 LEFT JOIN t2 ON (t1.a = t2.a);
+-----+-----+-----+-----+
| a     | b     | a     | c     |
+-----+-----+-----+-----+
| 1     | x     | NULL  | NULL  |
| 2     | y     | 2     | z     |
+-----+-----+-----+-----+
```

```
mysql> SELECT * FROM t1 RIGHT JOIN t2 ON (t1.a = t2.a);
+-----+-----+-----+-----+
| a     | b     | a     | c     |
+-----+-----+-----+-----+
| 2     | y     | 2     | z     |
| NULL | NULL | 3     | w     |
+-----+-----+-----+-----+
```

- Previously, a `USING` clause could be rewritten as an `ON` clause that compares corresponding columns. For example, the following two clauses were semantically identical:

```
a LEFT JOIN b USING (c1,c2,c3)
a LEFT JOIN b ON a.c1=b.c1 AND a.c2=b.c2 AND a.c3=b.c3
```

Now the two clauses no longer are quite the same:

- With respect to determining which rows satisfy the join condition, both joins remain semantically identical.
- With respect to determining which columns to display for `SELECT *` expansion, the two joins are not semantically identical. The `USING` join selects the coalesced value of corresponding columns, whereas the `ON` join selects all columns from all tables. For the preceding `USING` join, `SELECT *` selects these values:

```
COALESCE(a.c1,b.c1), COALESCE(a.c2,b.c2), COALESCE(a.c3,b.c3)
```

For the `ON` join, `SELECT *` selects these values:

```
a.c1, a.c2, a.c3, b.c1, b.c2, b.c3
```

With an inner join, `COALESCE(a.c1,b.c1)` is the same as either `a.c1` or `b.c1` because both columns will have the same value. With an outer join (such as `LEFT JOIN`), one of the two columns can be `NULL`. That column will be omitted from the result.

- The evaluation of multi-way natural joins differs in a very important way that affects the result of `NATURAL` or `USING` joins and that can require query rewriting. Suppose that you have three tables `t1(a,b)`, `t2(c,b)`, and `t3(a,c)` that each have one row: `t1(1,2)`, `t2(10,2)`, and `t3(7,10)`. Suppose also that you have this `NATURAL JOIN` on the three tables:

```
SELECT ... FROM t1 NATURAL JOIN t2 NATURAL JOIN t3;
```

Previously, the left operand of the second join was considered to be `t2`, whereas it should be the nested join `(t1 NATURAL JOIN t2)`. As a result, the columns of `t3` are checked for common columns only in `t2`, and, if `t3` has common columns with `t1`, these columns are not used as equi-join columns. Thus, previously, the preceding query was transformed to the following equi-join:

```
SELECT ... FROM t1, t2, t3
WHERE t1.b = t2.b AND t2.c = t3.c;
```

That join is missing one more equi-join predicate `(t1.a = t3.a)`. As a result, it produces one row, not the empty result that it should. The correct equivalent query is this:

```
SELECT ... FROM t1, t2, t3
WHERE t1.b = t2.b AND t2.c = t3.c AND t1.a = t3.a;
```

If you require the same query result in current versions of MySQL as in older versions, rewrite the natural join as the first equi-join.

- Previously, the comma operator `(,)` and `JOIN` both had the same precedence, so the join expression `t1, t2 JOIN t3` was interpreted as `((t1, t2) JOIN t3)`. Now `JOIN` has higher precedence, so the expression is interpreted as `(t1, (t2 JOIN t3))`. This change affects statements that use an `ON` clause, because that clause can refer only to columns in the operands of the join, and the change in precedence changes interpretation of what those operands are.

Example:

```
CREATE TABLE t1 (i1 INT, j1 INT);
CREATE TABLE t2 (i2 INT, j2 INT);
CREATE TABLE t3 (i3 INT, j3 INT);
INSERT INTO t1 VALUES(1,1);
INSERT INTO t2 VALUES(1,1);
INSERT INTO t3 VALUES(1,1);
SELECT * FROM t1, t2 JOIN t3 ON (t1.i1 = t3.i3);
```

Previously, the `SELECT` was legal due to the implicit grouping of `t1,t2` as `(t1,t2)`. Now the `JOIN` takes precedence, so the operands for the `ON` clause are `t2` and `t3`. Because `t1.i1` is not a column in either of the operands, the result is an `Unknown column 't1.i1' in 'on clause'` error. To allow the join to be processed, group the first two tables explicitly with parentheses so that the operands for the `ON` clause are `(t1,t2)` and `t3`:

```
SELECT * FROM (t1, t2) JOIN t3 ON (t1.i1 = t3.i3);
```

Alternatively, avoid the use of the comma operator and use `JOIN` instead:

```
SELECT * FROM t1 JOIN t2 JOIN t3 ON (t1.i1 = t3.i3);
```

This change also applies to statements that mix the comma operator with `INNER JOIN`, `CROSS JOIN`, `LEFT JOIN`, and `RIGHT JOIN`, all of which now have higher precedence than the comma operator.

- Previously, the `ON` clause could refer to columns in tables named to its right. Now an `ON` clause can refer only to its operands.

Example:

```
CREATE TABLE t1 (i1 INT);
CREATE TABLE t2 (i2 INT);
CREATE TABLE t3 (i3 INT);
SELECT * FROM t1 JOIN t2 ON (i1 = i3) JOIN t3;
```

Previously, the `SELECT` statement was legal. Now the statement fails with an `Unknown column 'i3' in 'on clause'` error because `i3` is a column in `t3`, which is not an operand of the `ON` clause. The statement should be rewritten as

follows:

```
SELECT * FROM t1 JOIN t2 JOIN t3 ON (i1 = i3);
```

- Resolution of column names in **NATURAL** or **USING** joins is different than previously. For column names that are outside the **FROM** clause, MySQL now handles a superset of the queries compared to previously. That is, in cases when MySQL formerly issued an error that some column is ambiguous, the query now is handled correctly. This is due to the fact that MySQL now treats the common columns of **NATURAL** or **USING** joins as a single column, so when a query refers to such columns, the query compiler does not consider them as ambiguous.

Example:

```
SELECT * FROM t1 NATURAL JOIN t2 WHERE b > 1;
```

Previously, this query would produce an error **ERROR 1052 (23000): Column 'b' in where clause is ambiguous**. Now the query produces the correct result:

b	c	y
4	2	3

One extension of MySQL compared to the SQL:2003 standard is that MySQL allows you to qualify the common (coalesced) columns of **NATURAL** or **USING** joins (just as previously), while the standard disallows that.

12.2.8.2. Index Hint Syntax

You can provide hints to give the optimizer information about how to choose indexes during query processing. [Section 12.2.8.1, “JOIN Syntax”](#), describes the general syntax for specifying tables in a **SELECT** statement. The syntax for an individual table, including that for index hints, looks like this:

```
tbl_name [[AS] alias] [index_hint_list]

index_hint_list:
  index_hint [, index_hint] ...

index_hint:
  USE {INDEX|KEY}
    [{FOR {JOIN|ORDER BY|GROUP BY}}] (index_list)
  | IGNORE {INDEX|KEY}
    [{FOR {JOIN|ORDER BY|GROUP BY}}] (index_list)
  | FORCE {INDEX|KEY}
    [{FOR {JOIN|ORDER BY|GROUP BY}}] (index_list)

index_list:
  index_name [, index_name] ...
```

By specifying **USE INDEX (index_list)**, you can tell MySQL to use only one of the named indexes to find rows in the table. The alternative syntax **IGNORE INDEX (index_list)** can be used to tell MySQL to not use some particular index or indexes. These hints are useful if **EXPLAIN** shows that MySQL is using the wrong index from the list of possible indexes.

You can also use **FORCE INDEX**, which acts like **USE INDEX (index_list)** but with the addition that a table scan is assumed to be *very* expensive. In other words, a table scan is used only if there is no way to use one of the given indexes to find rows in the table.

Each hint requires the names of *indexes*, not the names of columns. The name of a **PRIMARY KEY** is **PRIMARY**. To see the index names for a table, use **SHOW INDEX**.

An *index_name* value need not be a full index name. It can be an unambiguous prefix of an index name. If a prefix is ambiguous, an error occurs.

Examples:

```
SELECT * FROM table1 USE INDEX (col1_index,col2_index)
  WHERE col1=1 AND col2=2 AND col3=3;

SELECT * FROM table1 IGNORE INDEX (col3_index)
  WHERE col1=1 AND col2=2 AND col3=3;
```

The syntax for index hints has the following characteristics:

- It is syntactically valid to specify an empty *index_list* for `USE INDEX`, which means “use no indexes.” Specifying an empty *index_list* for `FORCE INDEX` or `IGNORE INDEX` is a syntax error.
- You can specify the scope of a index hint by adding a `FOR` clause to the hint. This provides more fine-grained control over the optimizer’s selection of an execution plan for various phases of query processing. To affect only the indexes used when MySQL decides how to find rows in the table and how to process joins, use `FOR JOIN`. To influence index usage for sorting or grouping rows, use `FOR ORDER BY` or `FOR GROUP BY`. (However, if there is a covering index for the table and it is used to access the table, the optimizer will ignore `IGNORE INDEX FOR {ORDER BY|GROUP BY}` hints that disable that index.)
- You can specify multiple index hints:

```
SELECT * FROM t1 USE INDEX (i1) IGNORE INDEX FOR ORDER BY (i2) ORDER BY a;
```

It is not a error to name the same index in several hints (even within the same hint):

```
SELECT * FROM t1 USE INDEX (i1) USE INDEX (i1,i1);
```

However, it is an error to mix `USE INDEX` and `FORCE INDEX` for the same table:

```
SELECT * FROM t1 USE INDEX FOR JOIN (i1) FORCE INDEX FOR JOIN (i2);
```

if you specify no `FOR` clause for an index hint, the hint by default applies to all parts of the statement. For example, this hint:

```
IGNORE INDEX (i1)
```

is equivalent to this combination of hints:

```
IGNORE INDEX FOR JOIN (i1)
IGNORE INDEX FOR ORDER BY (i1)
IGNORE INDEX FOR GROUP BY (i1)
```

To cause the server to use the older behavior for hint scope when no `FOR` clause is present (so that hints apply only to row retrieval), enable the `old` system variable at server startup. Take care about enabling this variable in a replication setup. With statement-based binary logging, having different modes for the master and slaves might lead to replication errors.

When index hints are processed, they are collected in a single list by type (`USE`, `FORCE`, `IGNORE`) and by scope (`FOR JOIN`, `FOR ORDER BY`, `FOR GROUP BY`). For example:

```
SELECT * FROM t1
  USE INDEX () IGNORE INDEX (i2) USE INDEX (i1) USE INDEX (i2);
```

is equivalent to:

```
SELECT * FROM t1
  USE INDEX (i1,i2) IGNORE INDEX (i2);
```

The index hints then are applied for each scope in the following order:

1. `{USE|FORCE} INDEX` is applied if present. (If not, the optimizer-determined set of indexes is used.)
2. `IGNORE INDEX` is applied over the result of the previous step. For example, the following two queries are equivalent:

```
SELECT * FROM t1 USE INDEX (i1) IGNORE INDEX (i2) USE INDEX (i2);
SELECT * FROM t1 USE INDEX (i1);
```

For `FULLTEXT` searches, index hints work as follows:

- For natural language mode searches, index hints are silently ignored. For example, `IGNORE INDEX(i)` is ignored with no warning and the index is still used.

For boolean mode searches, index hints with `FOR ORDER BY` or `FOR GROUP BY` are silently ignored. Index hints with `FOR JOIN` or no `FOR` modifier are honored. In contrast to how hints apply for non-`FULLTEXT` searches, the hint is used for all phases of query execution (finding rows and retrieval, grouping, and ordering). This is true even if the hint is given for a non-`FULLTEXT` index.

For example, the following two queries are equivalent:

```
SELECT * FROM t
  USE INDEX (index1)
  IGNORE INDEX (index1) FOR ORDER BY
  IGNORE INDEX (index1) FOR GROUP BY
  WHERE ... IN BOOLEAN MODE ... ;

SELECT * FROM t
  USE INDEX (index1)
  WHERE ... IN BOOLEAN MODE ... ;
```

Index hints are accepted but ignored for `UPDATE` statements.

12.2.8.3. UNION Syntax

```
SELECT ...
UNION [ALL | DISTINCT] SELECT ...
[UNION [ALL | DISTINCT] SELECT ...]
```

`UNION` is used to combine the result from multiple `SELECT` statements into a single result set.

The column names from the first `SELECT` statement are used as the column names for the results returned. Selected columns listed in corresponding positions of each `SELECT` statement should have the same data type. (For example, the first column selected by the first statement should have the same type as the first column selected by the other statements.)

If the data types of corresponding `SELECT` columns do not match, the types and lengths of the columns in the `UNION` result take into account the values retrieved by all of the `SELECT` statements. For example, consider the following:

```
mysql> SELECT REPEAT('a',1) UNION SELECT REPEAT('b',10);
+-----+
| REPEAT('a',1) |
+-----+
| a              |
| bbbbbbbbbbb   |
+-----+
```

(In some earlier versions of MySQL, only the type and length from the first `SELECT` would have been used and the second row would have been truncated to a length of 1.)

The `SELECT` statements are normal select statements, but with the following restrictions:

- Only the last `SELECT` statement can use `INTO OUTFILE`. (However, the entire `UNION` result is written to the file.)
- `HIGH_PRIORITY` cannot be used with `SELECT` statements that are part of a `UNION`. If you specify it for the first `SELECT`, it has no effect. If you specify it for any subsequent `SELECT` statements, a syntax error results.

The default behavior for `UNION` is that duplicate rows are removed from the result. The optional `DISTINCT` keyword has no effect other than the default because it also specifies duplicate-row removal. With the optional `ALL` keyword, duplicate-row removal does not occur and the result includes all matching rows from all the `SELECT` statements.

You can mix `UNION ALL` and `UNION DISTINCT` in the same query. Mixed `UNION` types are treated such that a `DISTINCT` union overrides any `ALL` union to its left. A `DISTINCT` union can be produced explicitly by using `UNION DISTINCT` or implicitly by using `UNION` with no following `DISTINCT` or `ALL` keyword.

To use an `ORDER BY` or `LIMIT` clause to sort or limit the entire `UNION` result, parenthesize the individual `SELECT` statements and place the `ORDER BY` or `LIMIT` after the last one. The following example uses both clauses:

```
(SELECT a FROM t1 WHERE a=10 AND B=1)
UNION
(SELECT a FROM t2 WHERE a=11 AND B=2)
ORDER BY a LIMIT 10;
```

This kind of `ORDER BY` cannot use column references that include a table name (that is, names in `tbl_name.col_name` format). Instead, provide a column alias in the first `SELECT` statement and refer to the alias in the `ORDER BY`. (Alternatively, refer to the column in the `ORDER BY` using its column position. However, use of column positions is deprecated.)

Also, if a column to be sorted is aliased, the `ORDER BY` clause *must* refer to the alias, not the column name. The first of the following statements will work, but the second will fail with an `Unknown column 'a' in 'order clause'` error:

```
(SELECT a AS b FROM t) UNION (SELECT ... ) ORDER BY b;
(SELECT a AS b FROM t) UNION (SELECT ... ) ORDER BY a;
```

To apply `ORDER BY` or `LIMIT` to an individual `SELECT`, place the clause inside the parentheses that enclose the `SELECT`:

```
(SELECT a FROM t1 WHERE a=10 AND B=1 ORDER BY a LIMIT 10)
UNION
(SELECT a FROM t2 WHERE a=11 AND B=2 ORDER BY a LIMIT 10);
```

However, use of `ORDER BY` for individual `SELECT` statements implies nothing about the order in which the rows appear in the final result because `UNION` by default produces an unordered set of rows. Therefore, the use of `ORDER BY` in this context is typically in conjunction with `LIMIT`, so that it is used to determine the subset of the selected rows to retrieve for the `SELECT`, even though it does not necessarily affect the order of those rows in the final `UNION` result. If `ORDER BY` appears without `LIMIT` in a `SELECT`, it is optimized away because it will have no effect anyway.

To cause rows in a `UNION` result to consist of the sets of rows retrieved by each `SELECT` one after the other, select an additional column in each `SELECT` to use as a sort column and add an `ORDER BY` following the last `SELECT`:

```
(SELECT 1 AS sort_col, col1a, col1b, ... FROM t1)
UNION
(SELECT 2, col2a, col2b, ... FROM t2) ORDER BY sort_col;
```

To additionally maintain sort order within individual `SELECT` results, add a secondary column to the `ORDER BY` clause:

```
(SELECT 1 AS sort_col, col1a, col1b, ... FROM t1)
UNION
(SELECT 2, col2a, col2b, ... FROM t2) ORDER BY sort_col, col1a;
```

Use of an additional column also enables you to determine which `SELECT` each row comes from. Extra columns can provide other identifying information as well, such as a string that indicates a table name.

12.2.9. Subquery Syntax

A subquery is a `SELECT` statement within another statement.

Starting with MySQL 4.1, all subquery forms and operations that the SQL standard requires are supported, as well as a few features that are MySQL-specific.

Here is an example of a subquery:

```
SELECT * FROM t1 WHERE column1 = (SELECT column1 FROM t2);
```

In this example, `SELECT * FROM t1 ...` is the *outer query* (or *outer statement*), and `(SELECT column1 FROM t2)` is the *subquery*. We say that the subquery is *nested* within the outer query, and in fact it is possible to nest subqueries within other subqueries, to a considerable depth. A subquery must always appear within parentheses.

The main advantages of subqueries are:

- They allow queries that are *structured* so that it is possible to isolate each part of a statement.
- They provide alternative ways to perform operations that would otherwise require complex joins and unions.
- They are, in many people's opinion, more readable than complex joins or unions. Indeed, it was the innovation of subqueries that gave people the original idea of calling the early SQL "Structured Query Language."

Here is an example statement that shows the major points about subquery syntax as specified by the SQL standard and supported in MySQL:

```
DELETE FROM t1
WHERE s11 > ANY
  (SELECT COUNT(*) /* no hint */ FROM t2
   WHERE NOT EXISTS
    (SELECT * FROM t3
     WHERE ROW(5*t2.s1,77)=
      (SELECT 50,11*s1 FROM t4 UNION SELECT 50,77 FROM
       (SELECT * FROM t5) AS t5)));
```

A subquery can return a scalar (a single value), a single row, a single column, or a table (one or more rows of one or more columns). These are called scalar, column, row, and table subqueries. Subqueries that return a particular kind of result often can be used only in certain contexts, as described in the following sections.

There are few restrictions on the type of statements in which subqueries can be used. A subquery can contain any of the keywords or clauses that an ordinary `SELECT` can contain: `DISTINCT`, `GROUP BY`, `ORDER BY`, `LIMIT`, joins, index hints, `UNION` con-

structs, comments, functions, and so on.

One restriction is that a subquery's outer statement must be one of: `SELECT`, `INSERT`, `UPDATE`, `DELETE`, `SET`, or `DO`. Another restriction is that currently you cannot modify a table and select from the same table in a subquery. This applies to statements such as `DELETE`, `INSERT`, `REPLACE`, `UPDATE`, and (because subqueries can be used in the `SET` clause) `LOAD DATA INFILE`.

A more comprehensive discussion of restrictions on subquery use, including performance issues for certain forms of subquery syntax, is given in [Section D.3, "Restrictions on Subqueries"](#).

12.2.9.1. The Subquery as Scalar Operand

In its simplest form, a subquery is a scalar subquery that returns a single value. A scalar subquery is a simple operand, and you can use it almost anywhere a single column value or literal is legal, and you can expect it to have those characteristics that all operands have: a data type, a length, an indication whether it can be `NULL`, and so on. For example:

```
CREATE TABLE t1 (s1 INT, s2 CHAR(5) NOT NULL);
INSERT INTO t1 VALUES(100, 'abcde');
SELECT (SELECT s2 FROM t1);
```

The subquery in this `SELECT` returns a single value ('abcde') that has a data type of `CHAR`, a length of 5, a character set and collation equal to the defaults in effect at `CREATE TABLE` time, and an indication that the value in the column can be `NULL`. In fact, almost all subqueries can be `NULL`. If the table used in the example were empty, the value of the subquery would be `NULL`.

There are a few contexts in which a scalar subquery cannot be used. If a statement allows only a literal value, you cannot use a subquery. For example, `LIMIT` requires literal integer arguments, and `LOAD DATA INFILE` requires a literal string file name. You cannot use subqueries to supply these values.

When you see examples in the following sections that contain the rather spartan construct `(SELECT column1 FROM t1)`, imagine that your own code contains much more diverse and complex constructions.

Suppose that we make two tables:

```
CREATE TABLE t1 (s1 INT);
INSERT INTO t1 VALUES (1);
CREATE TABLE t2 (s1 INT);
INSERT INTO t2 VALUES (2);
```

Then perform a `SELECT`:

```
SELECT (SELECT s1 FROM t2) FROM t1;
```

The result is 2 because there is a row in `t2` containing a column `s1` that has a value of 2.

A scalar subquery can be part of an expression, but remember the parentheses, even if the subquery is an operand that provides an argument for a function. For example:

```
SELECT UPPER((SELECT s1 FROM t1)) FROM t2;
```

12.2.9.2. Comparisons Using Subqueries

The most common use of a subquery is in the form:

```
non_subquery_operand comparison_operator (subquery)
```

Where *comparison_operator* is one of these operators:

```
= > < >= <= <> != <=>
```

For example:

```
... 'a' = (SELECT column1 FROM t1)
```

At one time the only legal place for a subquery was on the right side of a comparison, and you might still find some old DBMSs that insist on this.

Here is an example of a common-form subquery comparison that you cannot do with a join. It finds all the rows in table `t1` for which the `column1` value is equal to a maximum value in table `t2`:

```
SELECT * FROM t1
WHERE column1 = (SELECT MAX(column2) FROM t2);
```

Here is another example, which again is impossible with a join because it involves aggregating for one of the tables. It finds all rows in table `t1` containing a value that occurs twice in a given column:

```
SELECT * FROM t1 AS t
WHERE 2 = (SELECT COUNT(*) FROM t1 WHERE t1.id = t.id);
```

For a comparison of the subquery to a scalar, the subquery must return a scalar. For a comparison of the subquery to a row constructor, the subquery must be a row subquery that returns a row with the same number of values as the row constructor. See [Section 12.2.9.5, “Row Subqueries”](#).

12.2.9.3. Subqueries with **ANY**, **IN**, and **SOME**

Syntax:

```
operand comparison_operator ANY (subquery)
operand IN (subquery)
operand comparison_operator SOME (subquery)
```

The **ANY** keyword, which must follow a comparison operator, means “return **TRUE** if the comparison is **TRUE** for **ANY** of the values in the column that the subquery returns.” For example:

```
SELECT s1 FROM t1 WHERE s1 > ANY (SELECT s1 FROM t2);
```

Suppose that there is a row in table `t1` containing `(10)`. The expression is **TRUE** if table `t2` contains `(21, 14, 7)` because there is a value `7` in `t2` that is less than `10`. The expression is **FALSE** if table `t2` contains `(20, 10)`, or if table `t2` is empty. The expression is *unknown* if table `t2` contains `(NULL, NULL, NULL)`.

When used with a subquery, the word **IN** is an alias for **= ANY**. Thus, these two statements are the same:

```
SELECT s1 FROM t1 WHERE s1 = ANY (SELECT s1 FROM t2);
SELECT s1 FROM t1 WHERE s1 IN (SELECT s1 FROM t2);
```

IN and **= ANY** are not synonyms when used with an expression list. **IN** can take an expression list, but **= ANY** cannot. See [Section 11.2.3, “Comparison Functions and Operators”](#).

NOT IN is not an alias for **<> ANY**, but for **<> ALL**. See [Section 12.2.9.4, “Subqueries with ALL”](#).

The word **SOME** is an alias for **ANY**. Thus, these two statements are the same:

```
SELECT s1 FROM t1 WHERE s1 <> ANY (SELECT s1 FROM t2);
SELECT s1 FROM t1 WHERE s1 <> SOME (SELECT s1 FROM t2);
```

Use of the word **SOME** is rare, but this example shows why it might be useful. To most people's ears, the English phrase “a is not equal to any b” means “there is no b which is equal to a,” but that is not what is meant by the SQL syntax. The syntax means “there is some b to which a is not equal.” Using **<> SOME** instead helps ensure that everyone understands the true meaning of the query.

12.2.9.4. Subqueries with **ALL**

Syntax:

```
operand comparison_operator ALL (subquery)
```

The word **ALL**, which must follow a comparison operator, means “return **TRUE** if the comparison is **TRUE** for **ALL** of the values in the column that the subquery returns.” For example:

```
SELECT s1 FROM t1 WHERE s1 > ALL (SELECT s1 FROM t2);
```

Suppose that there is a row in table `t1` containing `(10)`. The expression is **TRUE** if table `t2` contains `(-5, 0, +5)` because `10` is greater than all three values in `t2`. The expression is **FALSE** if table `t2` contains `(12, 6, NULL, -100)` because there is a single value `12` in table `t2` that is greater than `10`. The expression is *unknown* (that is, **NULL**) if table `t2` contains `(0, NULL, 1)`.

Finally, if table `t2` is empty, the result is **TRUE**. So, the following statement is **TRUE** when table `t2` is empty:

```
SELECT * FROM t1 WHERE 1 > ALL (SELECT s1 FROM t2);
```

But this statement is **NULL** when table `t2` is empty:

```
SELECT * FROM t1 WHERE 1 > (SELECT s1 FROM t2);
```

In addition, the following statement is `NULL` when table `t2` is empty:

```
SELECT * FROM t1 WHERE 1 > ALL (SELECT MAX(s1) FROM t2);
```

In general, *tables containing `NULL` values* and *empty tables* are “edge cases.” When writing subquery code, always consider whether you have taken those two possibilities into account.

`NOT IN` is an alias for `<> ALL`. Thus, these two statements are the same:

```
SELECT s1 FROM t1 WHERE s1 <> ALL (SELECT s1 FROM t2);
SELECT s1 FROM t1 WHERE s1 NOT IN (SELECT s1 FROM t2);
```

12.2.9.5. Row Subqueries

The discussion to this point has been of scalar or column subqueries; that is, subqueries that return a single value or a column of values. A *row subquery* is a subquery variant that returns a single row and can thus return more than one column value. Legal operators for row subquery comparisons are:

```
= > < >= <= <> != <=>
```

Here are two examples:

```
SELECT * FROM t1 WHERE (1,2) = (SELECT column1, column2 FROM t2);
SELECT * FROM t1 WHERE ROW(1,2) = (SELECT column1, column2 FROM t2);
```

The queries here are both `TRUE` if table `t2` has a row where `column1 = 1` and `column2 = 2`.

The expressions `(1, 2)` and `ROW(1, 2)` are sometimes called *row constructors*. The two are equivalent. The row constructor and the row returned by the subquery must contain the same number of values.

Row constructors are legal in other contexts as well. For example, the following two statements are semantically equivalent:

```
SELECT * FROM t1 WHERE (column1,column2) = (1,1);
SELECT * FROM t1 WHERE column1 = 1 AND column2 = 1;
```

The normal use of row constructors is for comparisons with subqueries that return two or more columns. For example, the following query answers the request, “find all rows in table `t1` that also exist in table `t2`”:

```
SELECT column1,column2,column3
FROM t1
WHERE (column1,column2,column3) IN
      (SELECT column1,column2,column3 FROM t2);
```

12.2.9.6. EXISTS and NOT EXISTS

If a subquery returns any rows at all, `EXISTS subquery` is `TRUE`, and `NOT EXISTS subquery` is `FALSE`. For example:

```
SELECT column1 FROM t1 WHERE EXISTS (SELECT * FROM t2);
```

Traditionally, an `EXISTS` subquery starts with `SELECT *`, but it could begin with `SELECT 5` or `SELECT column1` or anything at all. MySQL ignores the `SELECT` list in such a subquery, so it makes no difference.

For the preceding example, if `t2` contains any rows, even rows with nothing but `NULL` values, the `EXISTS` condition is `TRUE`. This is actually an unlikely example because a `[NOT] EXISTS` subquery almost always contains correlations. Here are some more realistic examples:

- What kind of store is present in one or more cities?

```
SELECT DISTINCT store_type FROM stores
WHERE EXISTS (SELECT * FROM cities_stores
              WHERE cities_stores.store_type = stores.store_type);
```

- What kind of store is present in no cities?

```
SELECT DISTINCT store_type FROM stores
WHERE NOT EXISTS (SELECT * FROM cities_stores
                  WHERE cities_stores.store_type = stores.store_type);
```

- What kind of store is present in all cities?

```
SELECT DISTINCT store_type FROM stores s1
WHERE NOT EXISTS (
  SELECT * FROM cities WHERE NOT EXISTS (
    SELECT * FROM cities_stores
    WHERE cities_stores.city = cities.city
    AND cities_stores.store_type = stores.store_type));
```

The last example is a double-nested `NOT EXISTS` query. That is, it has a `NOT EXISTS` clause within a `NOT EXISTS` clause. Formally, it answers the question “does a city exist with a store that is not in `Stores`”? But it is easier to say that a nested `NOT EXISTS` answers the question “is x `TRUE` for all y ?”

12.2.9.7. Correlated Subqueries

A *correlated subquery* is a subquery that contains a reference to a table that also appears in the outer query. For example:

```
SELECT * FROM t1 WHERE column1 = ANY
(SELECT column1 FROM t2 WHERE t2.column2 = t1.column2);
```

Notice that the subquery contains a reference to a column of `t1`, even though the subquery's `FROM` clause does not mention a table `t1`. So, MySQL looks outside the subquery, and finds `t1` in the outer query.

Suppose that table `t1` contains a row where `column1 = 5` and `column2 = 6`; meanwhile, table `t2` contains a row where `column1 = 5` and `column2 = 7`. The simple expression `... WHERE column1 = ANY (SELECT column1 FROM t2)` would be `TRUE`, but in this example, the `WHERE` clause within the subquery is `FALSE` (because `(5, 6)` is not equal to `(5, 7)`), so the subquery as a whole is `FALSE`.

Scoping rule: MySQL evaluates from inside to outside. For example:

```
SELECT column1 FROM t1 AS x
WHERE x.column1 = (SELECT column1 FROM t2 AS x
WHERE x.column1 = (SELECT column1 FROM t3
WHERE x.column2 = t3.column1));
```

In this statement, `x.column2` must be a column in table `t2` because `SELECT column1 FROM t2 AS x ...` renames `t2`. It is not a column in table `t1` because `SELECT column1 FROM t1 ...` is an outer query that is *farther out*.

For subqueries in `HAVING` or `ORDER BY` clauses, MySQL also looks for column names in the outer select list.

For certain cases, a correlated subquery is optimized. For example:

```
val IN (SELECT key_val FROM tbl_name WHERE correlated_condition)
```

Otherwise, they are inefficient and likely to be slow. Rewriting the query as a join might improve performance.

Aggregate functions in correlated subqueries may contain outer references, provided the function contains nothing but outer references, and provided the function is not contained in another function or expression.

12.2.9.8. Subqueries in the `FROM` clause

Subqueries are legal in a `SELECT` statement's `FROM` clause. The actual syntax is:

```
SELECT ... FROM (subquery) [AS] name ...
```

The `[AS] name` clause is mandatory, because every table in a `FROM` clause must have a name. Any columns in the *subquery* select list must have unique names.

For the sake of illustration, assume that you have this table:

```
CREATE TABLE t1 (s1 INT, s2 CHAR(5), s3 FLOAT);
```

Here is how to use a subquery in the `FROM` clause, using the example table:

```
INSERT INTO t1 VALUES (1, '1', 1.0);
INSERT INTO t1 VALUES (2, '2', 2.0);
SELECT sb1, sb2, sb3
FROM (SELECT s1 AS sb1, s2 AS sb2, s3*2 AS sb3 FROM t1) AS sb
WHERE sb1 > 1;
```

Result: 2, '2', 4.0.

Here is another example: Suppose that you want to know the average of a set of sums for a grouped table. This does not work:

```
SELECT AVG(SUM(column1)) FROM t1 GROUP BY column1;
```

However, this query provides the desired information:

```
SELECT AVG(sum_column1)
FROM (SELECT SUM(column1) AS sum_column1
      FROM t1 GROUP BY column1) AS t1;
```

Notice that the column name used within the subquery (`sum_column1`) is recognized in the outer query.

Subqueries in the `FROM` clause can return a scalar, column, row, or table. Subqueries in the `FROM` clause cannot be correlated subqueries, unless used within the `ON` clause of a `JOIN` operation.

Subqueries in the `FROM` clause are executed even for the `EXPLAIN` statement (that is, derived temporary tables are built). This occurs because upper-level queries need information about all tables during the optimization phase, and the table represented by a subquery in the `FROM` clause is unavailable unless the subquery is executed.

It is possible under certain circumstances to modify table data using `EXPLAIN SELECT`. This can occur if the outer query accesses any tables and an inner query invokes a stored function that changes one or more rows of a table. For example, suppose there are two tables `t1` and `t2` in database `d1`, created as shown here:

```
mysql> CREATE DATABASE d1;
Query OK, 1 row affected (0.00 sec)

mysql> USE d1;
Database changed

mysql> CREATE TABLE t1 (c1 INT);
Query OK, 0 rows affected (0.15 sec)

mysql> CREATE TABLE t2 (c1 INT);
Query OK, 0 rows affected (0.08 sec)
```

Now we create a stored function `f1` which modifies `t2`:

```
mysql> DELIMITER //
mysql> CREATE FUNCTION f1(p1 INT) RETURNS INT
mysql> BEGIN
mysql>     INSERT INTO t2 VALUES (p1);
mysql>     RETURN p1;
mysql> END //
Query OK, 0 rows affected (0.01 sec)

mysql> DELIMITER ;
```

Referencing the function directly in an `EXPLAIN SELECT` does not have any effect on `t2`, as shown here:

```
mysql> SELECT * FROM t2;
Empty set (0.00 sec)

mysql> EXPLAIN SELECT f1(5);
+----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
| id | select_type | table | type | possible_keys | key | key_len | ref | rows | Extra |
+----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
| 1 | SIMPLE | NULL | NULL | NULL | NULL | NULL | NULL | NULL | No tables used |
+----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
1 row in set (0.00 sec)

mysql> SELECT * FROM t2;
Empty set (0.00 sec)
```

This is because the `SELECT` statement did not reference any tables, as can be seen in the `table` and `Extra` columns of the output. This is also true of the following nested `SELECT`:

```
mysql> EXPLAIN SELECT NOW() AS a1, (SELECT f1(5)) AS a2;
+----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
| id | select_type | table | type | possible_keys | key | key_len | ref | rows | Extra |
+----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
| 1 | PRIMARY | NULL | NULL | NULL | NULL | NULL | NULL | NULL | No tables used |
+----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
1 row in set, 1 warning (0.00 sec)

mysql> SHOW WARNINGS;
+-----+-----+-----+
| Level | Code | Message |
+-----+-----+-----+
| Note | 1249 | Select 2 was reduced during optimization |
+-----+-----+-----+
1 row in set (0.00 sec)

mysql> SELECT * FROM t2;
```

```
Empty set (0.00 sec)
```

However, if the outer `SELECT` references any tables, then the optimizer executes the statement in the subquery as well:

```
mysql> EXPLAIN SELECT * FROM t1 AS a1, (SELECT f1(5)) AS a2;
+----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
| id | select_type | table | type | possible_keys | key | key_len | ref | rows | Extra |
+----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
| 1  | PRIMARY    | a1    | system | NULL          | NULL | NULL    | NULL | 0    | const row not found |
| 1  | PRIMARY    | <derived2> | system | NULL          | NULL | NULL    | NULL | 1    | |
| 2  | DERIVED    | NULL  | NULL  | NULL          | NULL | NULL    | NULL | NULL | No tables used |
+----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
3 rows in set (0.00 sec)

mysql> SELECT * FROM t2;
+----+
| c1 |
+----+
| 5  |
+----+
1 row in set (0.00 sec)
```

This also means that an `EXPLAIN SELECT` statement such as the one shown here may take a long time to execute:

```
EXPLAIN SELECT * FROM t1 AS a1, (SELECT BENCHMARK(1000000, MD5(NOW())));
```

This is because the `BENCHMARK()` function is executed once for each row in `t1`.

12.2.9.9. Subquery Errors

There are some errors that apply only to subqueries. This section describes them.

- Unsupported subquery syntax:

```
ERROR 1235 (ER_NOT_SUPPORTED_YET)
SQLSTATE = 42000
Message = "This version of MySQL does not yet support
'LIMIT & IN/ALL/ANY/SOME subquery'"
```

This means that statements of the following form do not work yet:

```
SELECT * FROM t1 WHERE s1 IN (SELECT s2 FROM t2 ORDER BY s1 LIMIT 1)
```

- Incorrect number of columns from subquery:

```
ERROR 1241 (ER_OPERAND_COL)
SQLSTATE = 21000
Message = "Operand should contain 1 column(s)"
```

This error occurs in cases like this:

```
SELECT (SELECT column1, column2 FROM t2) FROM t1;
```

You may use a subquery that returns multiple columns, if the purpose is comparison. In other contexts, the subquery must be a scalar operand. See [Section 12.2.9.5, "Row Subqueries"](#).

- Incorrect number of rows from subquery:

```
ERROR 1242 (ER_SUBSELECT_NO_1_ROW)
SQLSTATE = 21000
Message = "Subquery returns more than 1 row"
```

This error occurs for statements where the subquery returns more than one row. Consider the following example:

```
SELECT * FROM t1 WHERE column1 = (SELECT column1 FROM t2);
```

If `SELECT column1 FROM t2` returns just one row, the previous query will work. If the subquery returns more than one row, error 1242 will occur. In that case, the query should be rewritten as:

```
SELECT * FROM t1 WHERE column1 = ANY (SELECT column1 FROM t2);
```

- Incorrectly used table in subquery:

```
Error 1093 (ER_UPDATE_TABLE_USED)
SQLSTATE = HY000
```

```
Message = "You can't specify target table 'x'
for update in FROM clause"
```

This error occurs in cases such as the following:

```
UPDATE t1 SET column2 = (SELECT MAX(column1) FROM t1);
```

You can use a subquery for assignment within an `UPDATE` statement because subqueries are legal in `UPDATE` and `DELETE` statements as well as in `SELECT` statements. However, you cannot use the same table (in this case, table `t1`) for both the subquery's `FROM` clause and the update target.

For transactional storage engines, the failure of a subquery causes the entire statement to fail. For non-transactional storage engines, data modifications made before the error was encountered are preserved.

12.2.9.10. Optimizing Subqueries

Development is ongoing, so no optimization tip is reliable for the long term. The following list provides some interesting tricks that you might want to play with:

- Use subquery clauses that affect the number or order of the rows in the subquery. For example:

```
SELECT * FROM t1 WHERE t1.column1 IN
  (SELECT column1 FROM t2 ORDER BY column1);
SELECT * FROM t1 WHERE t1.column1 IN
  (SELECT DISTINCT column1 FROM t2);
SELECT * FROM t1 WHERE EXISTS
  (SELECT * FROM t2 LIMIT 1);
```

- Replace a join with a subquery. For example, try this:

```
SELECT DISTINCT column1 FROM t1 WHERE t1.column1 IN (
  SELECT column1 FROM t2);
```

Instead of this:

```
SELECT DISTINCT t1.column1 FROM t1, t2
  WHERE t1.column1 = t2.column1;
```

- Some subqueries can be transformed to joins for compatibility with older versions of MySQL that do not support subqueries. However, in some cases, converting a subquery to a join may improve performance. See [Section 12.2.9.11, “Rewriting Subqueries as Joins”](#).
- Move clauses from outside to inside the subquery. For example, use this query:

```
SELECT * FROM t1
  WHERE s1 IN (SELECT s1 FROM t1 UNION ALL SELECT s1 FROM t2);
```

Instead of this query:

```
SELECT * FROM t1
  WHERE s1 IN (SELECT s1 FROM t1) OR s1 IN (SELECT s1 FROM t2);
```

For another example, use this query:

```
SELECT (SELECT column1 + 5 FROM t1) FROM t2;
```

Instead of this query:

```
SELECT (SELECT column1 FROM t1) + 5 FROM t2;
```

- Use a row subquery instead of a correlated subquery. For example, use this query:

```
SELECT * FROM t1
  WHERE (column1,column2) IN (SELECT column1,column2 FROM t2);
```

Instead of this query:

```
SELECT * FROM t1
WHERE EXISTS (SELECT * FROM t2 WHERE t2.column1=t1.column1
AND t2.column2=t1.column2);
```

- Use `NOT (a = ANY (...))` rather than `a <> ALL (...)`.
- Use `x = ANY (table containing (1,2))` rather than `x=1 OR x=2`.
- Use `= ANY` rather than `EXISTS`.
- For uncorrelated subqueries that always return one row, `IN` is always slower than `=`. For example, use this query:

```
SELECT * FROM t1 WHERE t1.col_name
= (SELECT a FROM t2 WHERE b = some_const);
```

Instead of this query:

```
SELECT * FROM t1 WHERE t1.col_name
IN (SELECT a FROM t2 WHERE b = some_const);
```

These tricks might cause programs to go faster or slower. Using MySQL facilities like the `BENCHMARK()` function, you can get an idea about what helps in your own situation. See [Section 11.11.3, “Information Functions”](#).

Some optimizations that MySQL itself makes are:

- MySQL executes uncorrelated subqueries only once. Use `EXPLAIN` to make sure that a given subquery really is uncorrelated.
- MySQL rewrites `IN`, `ALL`, `ANY`, and `SOME` subqueries in an attempt to take advantage of the possibility that the select-list columns in the subquery are indexed.
- MySQL replaces subqueries of the following form with an index-lookup function, which `EXPLAIN` describes as a special join type (`unique_subquery` or `index_subquery`):

```
... IN (SELECT indexed_column FROM single_table ...)
```

- MySQL enhances expressions of the following form with an expression involving `MIN()` or `MAX()`, unless `NULL` values or empty sets are involved:

```
value {ALL|ANY|SOME} {> | < | >= | <=} (uncorrelated subquery)
```

For example, this `WHERE` clause:

```
WHERE 5 > ALL (SELECT x FROM t)
```

might be treated by the optimizer like this:

```
WHERE 5 > (SELECT MAX(x) FROM t)
```

See also the MySQL Internals Manual chapter [How MySQL Transforms Subqueries](#).

12.2.9.11. Rewriting Subqueries as Joins

Although MySQL 5.4 supports subqueries (see [Section 12.2.9, “Subquery Syntax”](#)), it is still true that there are sometimes other ways to test membership in a set of values. It is also true that on some occasions, it is not only possible to rewrite a query without a subquery, but it can be more efficient to make use of some of these techniques rather than to use subqueries. One of these is the `IN()` construct:

For example, this query:

```
SELECT * FROM t1 WHERE id IN (SELECT id FROM t2);
```

Can be rewritten as:

```
SELECT DISTINCT t1.* FROM t1, t2 WHERE t1.id=t2.id;
```

The queries:

```
SELECT * FROM t1 WHERE id NOT IN (SELECT id FROM t2);
SELECT * FROM t1 WHERE NOT EXISTS (SELECT id FROM t2 WHERE t1.id=t2.id);
```

Can be rewritten as:

```
SELECT table1.*
FROM table1 LEFT JOIN table2 ON table1.id=table2.id
WHERE table2.id IS NULL;
```

A **LEFT [OUTER] JOIN** can be faster than an equivalent subquery because the server might be able to optimize it better — a fact that is not specific to MySQL Server alone. Prior to SQL-92, outer joins did not exist, so subqueries were the only way to do certain things. Today, MySQL Server and many other modern database systems offer a wide range of outer join types.

MySQL Server supports multiple-table **DELETE** statements that can be used to efficiently delete rows based on information from one table or even from many tables at the same time. Multiple-table **UPDATE** statements are also supported. See [Section 12.2.2](#), “**DELETE Syntax**”, and [Section 12.2.11](#), “**UPDATE Syntax**”.

12.2.10. TRUNCATE Syntax

```
TRUNCATE [TABLE] tbl_name
```

TRUNCATE TABLE empties a table completely. Logically, this is equivalent to a **DELETE** statement that deletes all rows, but there are practical differences under some circumstances.

For an **InnoDB** table, **InnoDB** processes **TRUNCATE TABLE** by deleting rows one by one if there are any **FOREIGN KEY** constraints that reference the table. If there are no **FOREIGN KEY** constraints, **InnoDB** performs fast truncation by dropping the original table and creating an empty one with the same definition, which is much faster than deleting rows one by one. The **AUTO_INCREMENT** counter is reset by **TRUNCATE TABLE**, regardless of whether there is a **FOREIGN KEY** constraint.

In the case that **FOREIGN KEY** constraints reference the table, **InnoDB** deletes rows one by one and processes the constraints on each one. If the **FOREIGN KEY** constraint specifies **DELETE CASCADE**, rows from the child (referenced) table are deleted, and the truncated table becomes empty. If the **FOREIGN KEY** constraint does *not* specify **CASCADE**, the **TRUNCATE** statement deletes rows one by one and stops if it encounters a parent row that is referenced by the child, returning this error:

```
ERROR 1451 (23000): Cannot delete or update a parent row: a foreign
key constraint fails (`test`.`child`, CONSTRAINT `child_ibfk_1`
FOREIGN KEY (`parent_id`) REFERENCES `parent` (`id`))
```

This is the same as a **DELETE** statement with no **WHERE** clause.

TRUNCATE is treated for purposes of binary logging and replication as **DROP TABLE** followed by **CREATE TABLE** — that is, as DDL rather than DML. This is due to the fact that, when using **InnoDB** and other transactional storage engines where the transaction isolation level does not allow for statement-based logging (**READ COMMITTED** or **READ UNCOMMITTED**), the statement was not logged and replicated when using **STATEMENT** or **MIXED** logging mode. ([Bug#36763](#)) However, it is still applied on replication slaves using **InnoDB** in the manner described previously.

The count of rows affected by **TRUNCATE TABLE** is accurate only when it is mapped to a **DELETE** statement.

For other storage engines, **TRUNCATE TABLE** differs from **DELETE** in the following ways in MySQL 5.4:

- Truncate operations drop and re-create the table, which is much faster than deleting rows one by one, particularly for large tables.
- Truncate operations are not transaction-safe; an error occurs when attempting one in the course of an active transaction or active table lock.
- Truncation operations do not return the number of deleted rows.
- As long as the table format file *tbl_name.frm* is valid, the table can be re-created as an empty table with **TRUNCATE TABLE**, even if the data or index files have become corrupted.
- The table handler does not remember the last used **AUTO_INCREMENT** value, but starts counting from the beginning. This is true even for **MyISAM** and **InnoDB**, which normally do not reuse sequence values.
- When used with partitioned tables, **TRUNCATE TABLE** preserves the partitioning; that is, the data and index files are dropped and re-created, while the partition definitions (*.par*) file is unaffected.

- Since truncation of a table does not make any use of `DELETE`, the `TRUNCATE` statement does not invoke `ON DELETE` triggers.

`TRUNCATE TABLE` requires the `DROP` privilege.

12.2.11. UPDATE Syntax

Single-table syntax:

```
UPDATE [LOW_PRIORITY] [IGNORE] table_reference
SET col_name1={expr1|DEFAULT} [, col_name2={expr2|DEFAULT}] ...
[WHERE where_condition]
[ORDER BY ...]
[LIMIT row_count]
```

Multiple-table syntax:

```
UPDATE [LOW_PRIORITY] [IGNORE] table_references
SET col_name1={expr1|DEFAULT} [, col_name2={expr2|DEFAULT}] ...
[WHERE where_condition]
```

For the single-table syntax, the `UPDATE` statement updates columns of existing rows in the named table with new values. The `SET` clause indicates which columns to modify and the values they should be given. Each value can be given as an expression, or the keyword `DEFAULT` to set a column explicitly to its default value. The `WHERE` clause, if given, specifies the conditions that identify which rows to update. With no `WHERE` clause, all rows are updated. If the `ORDER BY` clause is specified, the rows are updated in the order that is specified. The `LIMIT` clause places a limit on the number of rows that can be updated.

For the multiple-table syntax, `UPDATE` updates rows in each table named in `table_references` that satisfy the conditions. In this case, `ORDER BY` and `LIMIT` cannot be used.

`where_condition` is an expression that evaluates to true for each row to be updated.

`table_references` and `where_condition` are specified as described in [Section 12.2.8, “SELECT Syntax”](#).

The `UPDATE` statement supports the following modifiers:

- If you use the `LOW_PRIORITY` keyword, execution of the `UPDATE` is delayed until no other clients are reading from the table. This affects only storage engines that use only table-level locking ([MyISAM](#), [MEMORY](#), [MERGE](#)).
- If you use the `IGNORE` keyword, the update statement does not abort even if errors occur during the update. Rows for which duplicate-key conflicts occur are not updated. Rows for which columns are updated to values that would cause data conversion errors are updated to the closest valid values instead.

If you access a column from the table to be updated in an expression, `UPDATE` uses the current value of the column. For example, the following statement sets the `age` column to one more than its current value:

```
UPDATE persondata SET age=age+1;
```

Single-table `UPDATE` assignments are generally evaluated from left to right. For multiple-table updates, there is no guarantee that assignments are carried out in any particular order.

If you set a column to the value it currently has, MySQL notices this and does not update it.

If you update a column that has been declared `NOT NULL` by setting to `NULL`, an error occurs if strict SQL mode is enabled; otherwise, the column is set to the implicit default value for the column data type and the warning count is incremented. The implicit default value is `0` for numeric types, the empty string (`' '`) for string types, and the “zero” value for date and time types. See [Section 10.1.4, “Data Type Default Values”](#).

`UPDATE` returns the number of rows that were actually changed. The `mysql_info()` C API function returns the number of rows that were matched and updated and the number of warnings that occurred during the `UPDATE`.

You can use `LIMIT row_count` to restrict the scope of the `UPDATE`. A `LIMIT` clause is a rows-matched restriction. The statement stops as soon as it has found `row_count` rows that satisfy the `WHERE` clause, whether or not they actually were changed.

If an `UPDATE` statement includes an `ORDER BY` clause, the rows are updated in the order specified by the clause. This can be useful in certain situations that might otherwise result in an error. Suppose that a table `t` contains a column `id` that has a unique index. The following statement could fail with a duplicate-key error, depending on the order in which rows are updated:

```
UPDATE t SET id = id + 1;
```

For example, if the table contains 1 and 2 in the `id` column and 1 is updated to 2 before 2 is updated to 3, an error occurs. To avoid this problem, add an `ORDER BY` clause to cause the rows with larger `id` values to be updated before those with smaller values:

```
UPDATE t SET id = id + 1 ORDER BY id DESC;
```

You can also perform `UPDATE` operations covering multiple tables. However, you cannot use `ORDER BY` or `LIMIT` with a multiple-table `UPDATE`. The `table_references` clause lists the tables involved in the join. Its syntax is described in [Section 12.2.8.1, “JOIN Syntax”](#). Here is an example:

```
UPDATE items,month SET items.price=month.price
WHERE items.id=month.id;
```

The preceding example shows an inner join that uses the comma operator, but multiple-table `UPDATE` statements can use any type of join allowed in `SELECT` statements, such as `LEFT JOIN`.

You need the `UPDATE` privilege only for columns referenced in a multiple-table `UPDATE` that are actually updated. You need only the `SELECT` privilege for any columns that are read but not modified.

If you use a multiple-table `UPDATE` statement involving `InnoDB` tables for which there are foreign key constraints, the MySQL optimizer might process tables in an order that differs from that of their parent/child relationship. In this case, the statement fails and rolls back. Instead, update a single table and rely on the `ON UPDATE` capabilities that `InnoDB` provides to cause the other tables to be modified accordingly. See [Section 13.6.4.4, “FOREIGN KEY Constraints”](#).

Currently, you cannot update a table and select from the same table in a subquery.

Index hints (see [Section 12.2.8.2, “Index Hint Syntax”](#)) are accepted but ignored for `UPDATE` statements.

12.3. MySQL Utility Statements

12.3.1. DESCRIBE Syntax

```
{DESCRIBE | DESC} tbl_name [col_name | wild]
```

`DESCRIBE` provides information about the columns in a table. It is a shortcut for `SHOW COLUMNS FROM`. These statements also display information for views. (See [Section 12.5.5.6, “SHOW COLUMNS Syntax”](#).)

`col_name` can be a column name, or a string containing the SQL “`%`” and “`_`” wildcard characters to obtain output only for the columns with names matching the string. There is no need to enclose the string within quotes unless it contains spaces or other special characters.

```
mysql> DESCRIBE City;
```

Field	Type	Null	Key	Default	Extra
Id	int(11)	NO	PRI	NULL	auto_increment
Name	char(35)	NO			
Country	char(3)	NO	UNI		
District	char(20)	YES	MUL		
Population	int(11)	NO		0	

```
5 rows in set (0.00 sec)
```

The description for `SHOW COLUMNS` provides more information about the output columns (see [Section 12.5.5.6, “SHOW COLUMNS Syntax”](#)).

If the data types differ from what you expect them to be based on a `CREATE TABLE` statement, note that MySQL sometimes changes data types when you create or alter a table. The conditions under which this occurs are described in [Section 12.1.14.1, “Silent Column Specification Changes”](#).

The `DESCRIBE` statement is provided for compatibility with Oracle.

The `SHOW CREATE TABLE`, `SHOW TABLE STATUS`, and `SHOW INDEX` statements also provide information about tables. See [Section 12.5.5, “SHOW Syntax”](#).

12.3.2. EXPLAIN Syntax

```
EXPLAIN tbl_name
```

Or:

```
EXPLAIN [EXTENDED | PARTITIONS] SELECT select_options
```

The `EXPLAIN` statement can be used either as a synonym for `DESCRIBE` or as a way to obtain information about how MySQL executes a `SELECT` statement:

- `EXPLAIN tbl_name` is synonymous with `DESCRIBE tbl_name` or `SHOW COLUMNS FROM tbl_name`.

For a description of the `DESCRIBE` and `SHOW COLUMNS` statements, see [Section 12.3.1, “DESCRIBE Syntax”](#), and [Section 12.5.5.6, “SHOW COLUMNS Syntax”](#).

- When you precede a `SELECT` statement with the keyword `EXPLAIN`, MySQL displays information from the optimizer about the query execution plan. That is, MySQL explains how it would process the `SELECT`, including information about how tables are joined and in which order. `EXPLAIN EXTENDED` can be used to provide additional information.

For information regarding the use of `EXPLAIN` and `EXPLAIN EXTENDED` for obtaining query execution plan information, see [Section 7.2.1, “Optimizing Queries with EXPLAIN”](#).

- `EXPLAIN PARTITIONS` is useful only when examining queries involving partitioned tables.

For details, see [Section 17.3.4, “Obtaining Information About Partitions”](#).

12.3.3. HELP Syntax

```
HELP 'search_string'
```

The `HELP` statement returns online information from the MySQL Reference manual. Its proper operation requires that the help tables in the `mysql` database be initialized with help topic information (see [Section 5.1.8, “Server-Side Help”](#)).

The `HELP` statement searches the help tables for the given search string and displays the result of the search. The search string is not case sensitive.

The `HELP` statement understands several types of search strings:

- At the most general level, use `contents` to retrieve a list of the top-level help categories:

```
HELP 'contents'
```

- For a list of topics in a given help category, such as `Data Types`, use the category name:

```
HELP 'data types'
```

- For help on a specific help topic, such as the `ASCII()` function or the `CREATE TABLE` statement, use the associated keyword or keywords:

```
HELP 'ascii'
HELP 'create table'
```

In other words, the search string matches a category, many topics, or a single topic. You cannot necessarily tell in advance whether a given search string will return a list of items or the help information for a single help topic. However, you can tell what kind of response `HELP` returned by examining the number of rows and columns in the result set.

The following descriptions indicate the forms that the result set can take. Output for the example statements is shown using the familiar “tabular” or “vertical” format that you see when using the `mysql` client, but note that `mysql` itself reformats `HELP` result sets in a different way.

- Empty result set

No match could be found for the search string.

- Result set containing a single row with three columns

This means that the search string yielded a hit for the help topic. The result has three columns:

- **name**: The topic name.
- **description**: Descriptive help text for the topic.
- **example**: Usage example or examples. This column might be blank.

Example: `HELP 'replace'`

Yields:

```
name: REPLACE
description: Syntax:
REPLACE(str,from_str,to_str)

Returns the string str with all occurrences of the string from_str
replaced by the string to_str. REPLACE() performs a case-sensitive
match when searching for from_str.
example: mysql> SELECT REPLACE('www.mysql.com', 'w', 'Ww');
-> 'WwWwWw.mysql.com'
```

- Result set containing multiple rows with two columns

This means that the search string matched many help topics. The result set indicates the help topic names:

- **name**: The help topic name.
- **is_it_category**: **Y** if the name represents a help category, **N** if it does not. If it does not, the **name** value when specified as the argument to the `HELP` statement should yield a single-row result set containing a description for the named item.

Example: `HELP 'status'`

Yields:

name	is_it_category
SHOW	N
SHOW ENGINE	N
SHOW MASTER STATUS	N
SHOW PROCEDURE STATUS	N
SHOW SLAVE STATUS	N
SHOW STATUS	N
SHOW TABLE STATUS	N

- Result set containing multiple rows with three columns

This means the search string matches a category. The result set contains category entries:

- **source_category_name**: The help category name.
- **name**: The category or topic name
- **is_it_category**: **Y** if the name represents a help category, **N** if it does not. If it does not, the **name** value when specified as the argument to the `HELP` statement should yield a single-row result set containing a description for the named item.

Example: `HELP 'functions'`

Yields:

source_category_name	name	is_it_category
Functions	CREATE FUNCTION	N
Functions	DROP FUNCTION	N
Functions	Bit Functions	Y
Functions	Comparison operators	Y
Functions	Control flow functions	Y
Functions	Date and Time Functions	Y
Functions	Encryption Functions	Y
Functions	Information Functions	Y
Functions	Logical operators	Y
Functions	Miscellaneous Functions	Y
Functions	Numeric Functions	Y
Functions	String Functions	Y

12.3.4. USE Syntax

```
USE db_name
```

The `USE db_name` statement tells MySQL to use the *db_name* database as the default (current) database for subsequent statements. The database remains the default until the end of the session or another `USE` statement is issued:

```
USE db1;
SELECT COUNT(*) FROM mytable; # selects from db1.mytable
USE db2;
SELECT COUNT(*) FROM mytable; # selects from db2.mytable
```

Making a particular database the default by means of the `USE` statement does not preclude you from accessing tables in other databases. The following example accesses the `author` table from the `db1` database and the `editor` table from the `db2` database:

```
USE db1;
SELECT author_name,editor_name FROM author,db2.editor
WHERE author.editor_id = db2.editor.editor_id;
```

The `USE` statement is provided for compatibility with Sybase.

12.4. MySQL Transactional and Locking Statements

MySQL supports local transactions (within a given client session) through statements such as `SET autocommit`, `START TRANSACTION`, `COMMIT`, and `ROLLBACK`. See [Section 12.4.1, “START TRANSACTION, COMMIT, and ROLLBACK Syntax”](#). XA transaction support enables MySQL to participate in distributed transactions as well. See [Section 12.4.7, “XA Transactions”](#).

12.4.1. START TRANSACTION, COMMIT, and ROLLBACK Syntax

```
START TRANSACTION [WITH CONSISTENT SNAPSHOT] | BEGIN [WORK]
COMMIT [WORK] [AND [NO] CHAIN] [[NO] RELEASE]
ROLLBACK [WORK] [AND [NO] CHAIN] [[NO] RELEASE]
SET autocommit = {0 | 1}
```

The `START TRANSACTION` or `BEGIN` statement begins a new transaction. `COMMIT` commits the current transaction, making its changes permanent. `ROLLBACK` rolls back the current transaction, canceling its changes. The `SET autocommit` statement disables or enables the default autocommit mode for the current session.

The optional `WORK` keyword is supported for `COMMIT` and `ROLLBACK`, as are the `CHAIN` and `RELEASE` clauses. `CHAIN` and `RELEASE` can be used for additional control over transaction completion. The value of the `completion_type` system variable determines the default completion behavior. See [Section 5.1.3, “Server System Variables”](#).

Note

Within all stored programs (stored procedures and functions, triggers, and events), the parser treats `BEGIN [WORK]` as the beginning of a `BEGIN ... END` block. Begin a transaction in this context with `START TRANSACTION` instead.

The `AND CHAIN` clause causes a new transaction to begin as soon as the current one ends, and the new transaction has the same isolation level as the just-terminated transaction. The `RELEASE` clause causes the server to disconnect the current client session after terminating the current transaction. Including the `NO` keyword suppresses `CHAIN` or `RELEASE` completion, which can be useful if the `completion_type` system variable is set to cause chaining or release completion by default.

By default, MySQL runs with autocommit mode enabled. This means that as soon as you execute a statement that updates (modifies) a table, MySQL stores the update on disk to make it permanent. To disable autocommit mode, use the following statement:

```
SET autocommit=0;
```

After disabling autocommit mode by setting the `autocommit` variable to zero, changes to transaction-safe tables (such as those for `InnoDB` or `NDBCLUSTER`) are not made permanent immediately. You must use `COMMIT` to store your changes to disk or `ROLLBACK` to ignore the changes.

To disable autocommit mode for a single series of statements, use the `START TRANSACTION` statement:

```
START TRANSACTION;
SELECT @A:=SUM(salary) FROM table1 WHERE type=1;
UPDATE table2 SET summary=@A WHERE type=1;
COMMIT;
```

With `START TRANSACTION`, autocommit remains disabled until you end the transaction with `COMMIT` or `ROLLBACK`. The autocommit mode then reverts to its previous state.

`BEGIN` and `BEGIN WORK` are supported as aliases of `START TRANSACTION` for initiating a transaction. `START TRANSACTION` is standard SQL syntax and is the recommended way to start an ad-hoc transaction.

Important

Many APIs used for writing MySQL client applications (such as JDBC) provide their own methods for starting transactions that can (and sometimes should) be used instead of sending a `START TRANSACTION` statement from the client. See [Chapter 20, *Connectors and APIs*](#), or the documentation for your API, for more information.

The `BEGIN` statement differs from the use of the `BEGIN` keyword that starts a `BEGIN . . . END` compound statement. The latter does not begin a transaction. See [Section 12.8.1, “BEGIN . . . END Compound Statement Syntax”](#).

You can also begin a transaction like this:

```
START TRANSACTION WITH CONSISTENT SNAPSHOT;
```

The `WITH CONSISTENT SNAPSHOT` clause starts a consistent read for storage engines that are capable of it. This applies only to `InnoDB`. The effect is the same as issuing a `START TRANSACTION` followed by a `SELECT` from any `InnoDB` table. See [Section 13.6.8.2, “Consistent Non-Locking Reads”](#). The `WITH CONSISTENT SNAPSHOT` clause does not change the current transaction isolation level, so it provides a consistent snapshot only if the current isolation level is one that allows consistent read (`REPEATABLE READ` or `SERIALIZABLE`).

Beginning a transaction causes any pending transaction to be committed. See [Section 12.4.3, “Statements That Cause an Implicit Commit”](#), for more information.

Beginning a transaction also causes table locks acquired with `LOCK TABLES` to be released, as though you had executed `UNLOCK TABLES`. Beginning a transaction does not release a global read lock acquired with `FLUSH TABLES WITH READ LOCK`.

For best results, transactions should be performed using only tables managed by a single transaction-safe storage engine. Otherwise, the following problems can occur:

- If you use tables from more than one transaction-safe storage engine (such as `InnoDB` and `Falcon`), and the transaction isolation level is not `SERIALIZABLE`, it is possible that when one transaction commits, another ongoing transaction that uses the same tables will see only some of the changes made by the first transaction. That is, the atomicity of transactions is not guaranteed with mixed engines and inconsistencies can result. (If mixed-engine transactions are infrequent, you can use `SET TRANSACTION ISOLATION LEVEL` to set the isolation level to `SERIALIZABLE` on a per-transaction basis as necessary.)
- If you use tables that are not transaction-safe within a transaction, changes to those tables are stored at once, regardless of the status of autocommit mode.
- If you issue a `ROLLBACK` statement after updating a non-transactional table within a transaction, an `ER_WARNING_NOT_COMPLETE_ROLLBACK` warning occurs. Changes to transaction-safe tables are rolled back, but not changes to non-transaction-safe tables.

Each transaction is stored in the binary log in one chunk, upon `COMMIT`. Transactions that are rolled back are not logged. (**Exception:** Modifications to non-transactional tables cannot be rolled back. If a transaction that is rolled back includes modifications to non-transactional tables, the entire transaction is logged with a `ROLLBACK` statement at the end to ensure that modifications to the non-transactional tables are replicated.) See [Section 5.2.4, “The Binary Log”](#).

You can change the isolation level for transactions with `SET TRANSACTION ISOLATION LEVEL`. See [Section 12.4.6, “SET TRANSACTION Syntax”](#).

Rolling back can be a slow operation that may occur implicitly without the user having explicitly asked for it (for example, when an error occurs). Because of this, `SHOW PROCESSLIST` displays `Rolling back` in the `State` column for the session, not only for explicit rollbacks performed with the `ROLLBACK` statement but also for implicit rollbacks.

12.4.2. Statements That Cannot Be Rolled Back

Some statements cannot be rolled back. In general, these include data definition language (DDL) statements, such as those that create or drop databases, those that create, drop, or alter tables or stored routines.

You should design your transactions not to include such statements. If you issue a statement early in a transaction that cannot be rolled back, and then another statement later fails, the full effect of the transaction cannot be rolled back in such cases by issuing a `ROLLBACK` statement.

12.4.3. Statements That Cause an Implicit Commit

The statements listed in this section (and any synonyms for them) implicitly end a transaction, as if you had done a `COMMIT` before executing the statement.

- **Data definition language (DDL) statements that define or modify database objects.** `ALTER DATABASE ... UPGRADE DATA DIRECTORY NAME`, `ALTER EVENT`, `ALTER PROCEDURE`, `ALTER TABLE`, `ALTER VIEW`, `CREATE DATABASE`, `CREATE EVENT`, `CREATE INDEX`, `CREATE PROCEDURE`, `CREATE TABLE`, `CREATE TRIGGER`, `CREATE VIEW`, `DROP DATABASE`, `DROP EVENT`, `DROP INDEX`, `DROP PROCEDURE`, `DROP TABLE`, `DROP TRIGGER`, `DROP VIEW`, `RENAME TABLE`, `TRUNCATE TABLE`.

`commit`.

`ALTER FUNCTION`, `CREATE FUNCTION` and `DROP FUNCTION` also cause an implicit commit when used with stored functions, but not with UDFs. (`ALTER FUNCTION` can only be used with stored functions.)

`ALTER TABLE`, `CREATE TABLE`, and `DROP TABLE` do not commit a transaction if the `TEMPORARY` keyword is used. (This does not apply to other operations on temporary tables such as `CREATE INDEX`, which do cause a commit.) However, although no implicit commit occurs, neither can the statement be rolled back. Therefore, use of such statements will violate transaction atomicity: For example, if you use `CREATE TEMPORARY TABLE` and then roll back the transaction, the table remains in existence.

The `CREATE TABLE` statement in InnoDB is processed as a single transaction. This means that a `ROLLBACK` from the user does not undo `CREATE TABLE` statements the user made during that transaction.

`CREATE TABLE ... SELECT` causes an implicit commit before and after the statement is executed when you are creating non-temporary tables. (No commit occurs for `CREATE TEMPORARY TABLE ... SELECT`.) This is to prevent an issue during replication where the table could be created on the master after a rollback, but fail to be recorded in the binary log, and therefore not replicated to the slave. For more information, see [Bug#22865](#).

- **Statements that implicitly use or modify tables in the `mysql` database.** `CREATE USER`, `DROP USER`, `GRANT`, `RENAME USER`, `REVOKE`, `SET PASSWORD`.
- **Transaction-control and locking statements.** `BEGIN`, `LOCK TABLES`, `SET autocommit = 1` (if the value is not already 1), `START TRANSACTION`, `UNLOCK TABLES`.

`UNLOCK TABLES` commits a transaction only if any tables currently have been locked with `LOCK TABLES`. This does not occur for `UNLOCK TABLES` following `FLUSH TABLES WITH READ LOCK` because the latter statement does not acquire table-level locks.

Transactions cannot be nested. This is a consequence of the implicit commit performed for any current transaction when you issue a `START TRANSACTION` statement or one of its synonyms.

Statements that cause an implicit commit cannot be used in an XA transaction while the transaction is in an `ACTIVE` state.

The `BEGIN` statement differs from the use of the `BEGIN` keyword that starts a `BEGIN ... END` compound statement. The latter does not cause an implicit commit. See [Section 12.8.1, “BEGIN ... END Compound Statement Syntax”](#).

- **Data loading statements.** `LOAD DATA INFILE`. `LOAD DATA INFILE` causes an implicit commit only for tables using the NDB storage engine. For more information, see [Bug#11151](#).
- **Administrative statements.** `ANALYZE TABLE`, `CACHE INDEX`, `CHECK TABLE`, `LOAD INDEX INTO CACHE`, `OPTIMIZE TABLE`, `REPAIR TABLE`.

12.4.4. SAVEPOINT and ROLLBACK TO SAVEPOINT Syntax

```
SAVEPOINT identifier
ROLLBACK [WORK] TO [SAVEPOINT] identifier
RELEASE SAVEPOINT identifier
```

InnoDB supports the SQL statements `SAVEPOINT`, `ROLLBACK TO SAVEPOINT`, `RELEASE SAVEPOINT` and the optional `WORK` keyword for `ROLLBACK`.

The `SAVEPOINT` statement sets a named transaction savepoint with a name of *identifier*. If the current transaction has a savepoint with the same name, the old savepoint is deleted and a new one is set.

The `ROLLBACK TO SAVEPOINT` statement rolls back a transaction to the named savepoint without terminating the transaction. Modifications that the current transaction made to rows after the savepoint was set are undone in the rollback, but InnoDB does not release the row locks that were stored in memory after the savepoint. (For a new inserted row, the lock information is carried by

the transaction ID stored in the row; the lock is not separately stored in memory. In this case, the row lock is released in the undo.) Savepoints that were set at a later time than the named savepoint are deleted.

If the `ROLLBACK TO SAVEPOINT` statement returns the following error, it means that no savepoint with the specified name exists:

```
ERROR 1181: Got error 153 during ROLLBACK
```

The `RELEASE SAVEPOINT` statement removes the named savepoint from the set of savepoints of the current transaction. No commit or rollback occurs. It is an error if the savepoint does not exist.

All savepoints of the current transaction are deleted if you execute a `COMMIT`, or a `ROLLBACK` that does not name a savepoint.

A new savepoint level is created when a stored function is invoked or a trigger is activated. The savepoints on previous levels become unavailable and thus do not conflict with savepoints on the new level. When the function or trigger terminates, any savepoints it created are released and the previous savepoint level is restored.

12.4.5. LOCK TABLES and UNLOCK TABLES Syntax

```
LOCK TABLES
  tbl_name [[AS] alias] lock_type
  [, tbl_name [[AS] alias] lock_type] ...

lock_type:
  READ [LOCAL]
  | [LOW_PRIORITY] WRITE

UNLOCK TABLES
```

MySQL enables client sessions to acquire table locks explicitly for the purpose of cooperating with other sessions for access to tables, or to prevent other sessions from modifying tables during periods when a session requires exclusive access to them. A session can acquire or release locks only for itself. One session cannot acquire locks for another session or release locks held by another session.

Locks may be used to emulate transactions or to get more speed when updating tables. This is explained in more detail later in this section.

`LOCK TABLES` explicitly acquires table locks for the current client session. Table locks can be acquired for base tables or views. You must have the `LOCK TABLES` privilege, and the `SELECT` privilege for each object to be locked.

For view locking, `LOCK TABLES` adds all base tables used in the view to the set of tables to be locked and locks them automatically. If you lock a table explicitly with `LOCK TABLES`, any tables used in triggers are also locked implicitly, as described in [Section 12.4.5.2, “LOCK TABLES and Triggers”](#).

`UNLOCK TABLES` explicitly releases any table locks held by the current session.

Another use for `UNLOCK TABLES` is to release the global read lock acquired with the `FLUSH TABLES WITH READ LOCK` statement, which enables you to lock all tables in all databases. See [Section 12.5.6.3, “FLUSH Syntax”](#). (This is a very convenient way to get backups if you have a file system such as Veritas that can take snapshots in time.)

The following discussion applies only to non-`TEMPORARY` tables. `LOCK TABLES` is allowed (but ignored) for a `TEMPORARY` table. The table can be accessed freely by the session within which it was created, regardless of what other locking may be in effect. No lock is necessary because no other session can see the table.

The following general rules apply to acquisition and release of locks by a given session:

- Table locks are acquired with `LOCK TABLES`.
- If the `LOCK TABLES` statement must wait due to locks held by other sessions on any of the tables, it blocks until all locks can be acquired.
- Table locks are released explicitly with `UNLOCK TABLES`.
- Table locks are released implicitly under these conditions:
 - `LOCK TABLES` releases any table locks currently held by the session before acquiring new locks.
 - Beginning a transaction (for example, with `START TRANSACTION`) implicitly performs an `UNLOCK TABLES`. (Additional information about the interaction between table locking and transactions is given in [Section 12.4.5.1, “Interaction of Table Locking and Transactions”](#).)
 - If a client connection drops, the server releases table locks held by the client. If the client reconnects, the locks will no

longer be in effect. In addition, if the client had an active transaction, the server rolls back the transaction upon disconnect, and if reconnect occurs, the new session begins with autocommit enabled. For this reason, clients may wish to disable auto-reconnect. With auto-reconnect in effect, the client is not notified if reconnect occurs but any table locks or current transaction will have been lost. With auto-reconnect disabled, if the connection drops, an error occurs for the next statement issued. The client can detect the error and take appropriate action such as reacquiring the locks or redoing the transaction. See [Section 20.10.11, “Controlling Automatic Reconnection Behavior”](#).

Note

If you use `ALTER TABLE` on a locked table, it may become unlocked. See [Section B.1.7.1, “Problems with ALTER TABLE”](#).

A table lock protects only against inappropriate reads or writes by other clients. The client holding the lock, even a read lock, can perform table-level operations such as `DROP TABLE`. Truncate operations are not transaction-safe, so an error occurs if the client attempts one during an active transaction or while holding a table lock.

A session that requires locks must acquire all the locks that it needs in a single `LOCK TABLES` statement. While the locks thus obtained are held, the session can access only the locked tables. For example, in the following sequence of statements, an error occurs for the attempt to access `t2` because it was not locked in the `LOCK TABLES` statement:

```
mysql> LOCK TABLES t1 READ;
mysql> SELECT COUNT(*) FROM t1;
+-----+
| COUNT(*) |
+-----+
|          3 |
+-----+
mysql> SELECT COUNT(*) FROM t2;
ERROR 1100 (HY000): Table 't2' was not locked with LOCK TABLES
```

Tables in the `INFORMATION_SCHEMA` database are an exception. They can be accessed without being locked explicitly even while a session holds table locks obtained with `LOCK TABLES`.

You cannot refer to a locked table multiple times in a single query using the same name. Use aliases instead, and obtain a separate lock for the table and each alias:

```
mysql> LOCK TABLE t WRITE, t AS t1 READ;
mysql> INSERT INTO t SELECT * FROM t;
ERROR 1100: Table 't' was not locked with LOCK TABLES
mysql> INSERT INTO t SELECT * FROM t AS t1;
```

The error occurs for the first `INSERT` because there are two references to the same name for a locked table. The second `INSERT` succeeds because the references to the table use different names.

If your statements refer to a table by means of an alias, you must lock the table using that same alias. It does not work to lock the table without specifying the alias:

```
mysql> LOCK TABLE t READ;
mysql> SELECT * FROM t AS myalias;
ERROR 1100: Table 'myalias' was not locked with LOCK TABLES
```

Conversely, if you lock a table using an alias, you must refer to it in your statements using that alias:

```
mysql> LOCK TABLE t AS myalias READ;
mysql> SELECT * FROM t;
ERROR 1100: Table 't' was not locked with LOCK TABLES
mysql> SELECT * FROM t AS myalias;
```

If a session obtains a `READ` lock on a table, that session (and all other sessions) can only read from the table. If a session obtains a `WRITE` lock on a table, only the session holding the lock can write to the table (that session can also read from the table); other sessions are blocked from reading or writing the locked table until the lock has been released.

The difference between `READ` and `READ LOCAL` is that `READ LOCAL` allows non-conflicting `INSERT` statements (concurrent inserts) to execute while the lock is held. However, `READ LOCAL` cannot be used if you are going to manipulate the database using processes external to the server while you hold the lock. For `InnoDB` tables, `READ LOCAL` is the same as `READ`.

`WRITE` locks normally have higher priority than `READ` locks to ensure that updates are processed as soon as possible. This means that if one session obtains a `READ` lock and then another session requests a `WRITE` lock, subsequent `READ` lock requests wait until the session that requested the `WRITE` lock has obtained the lock and released it. A request for a `LOW_PRIORITY WRITE` lock, by contrast, allows subsequent `READ` lock requests by other sessions to be satisfied first if they occur while the `LOW_PRIORITY WRITE` request is waiting. You should use `LOW_PRIORITY WRITE` locks only if you are sure that eventually there will be a time

when no sessions have a `READ` lock. For `InnoDB` tables in transactional mode (`autocommit = 0`), a waiting `LOW_PRIORITY WRITE` lock acts like a regular `WRITE` lock and causes subsequent `READ` lock requests to wait.

`LOCK TABLES` acquires locks as follows:

1. Sort all tables to be locked in an internally defined order. From the user standpoint, this order is undefined.
2. If a table is to be locked with a read and a write lock, put the write lock request before the read lock request.
3. Lock one table at a time until the session gets all locks.

This policy ensures that table locking is deadlock free. There are, however, other things you need to be aware of about this policy: If you are using a `LOW_PRIORITY WRITE` lock for a table, it means only that MySQL waits for this particular lock until there are no other sessions that want a `READ` lock. When the session has gotten the `WRITE` lock and is waiting to get the lock for the next table in the lock table list, all other sessions wait for the `WRITE` lock to be released. If this becomes a serious problem with your application, you should consider converting some of your tables to transaction-safe tables.

12.4.5.1. Interaction of Table Locking and Transactions

`LOCK TABLES` and `UNLOCK TABLES` interact with the use of transactions as follows:

- `LOCK TABLES` is not transaction-safe and implicitly commits any active transaction before attempting to lock the tables.
- `UNLOCK TABLES` implicitly commits any active transaction, but only if `LOCK TABLES` has been used to acquire table locks. For example, in the following set of statements, `UNLOCK TABLES` releases the global read lock but does not commit the transaction because no table locks are in effect:

```
FLUSH TABLES WITH READ LOCK;
START TRANSACTION;
SELECT ...;
UNLOCK TABLES;
```

- Beginning a transaction (for example, with `START TRANSACTION`) implicitly commits any current transaction and releases existing locks.
- Other statements that implicitly cause transactions to be committed do not release existing locks. For a list of such statements, see [Section 12.4.3, “Statements That Cause an Implicit Commit”](#).
- The correct way to use `LOCK TABLES` and `UNLOCK TABLES` with transactional tables, such as `InnoDB` tables, is to begin a transaction with `SET autocommit = 0` (not `START TRANSACTION`) followed by `LOCK TABLES`, and to not call `UNLOCK TABLES` until you commit the transaction explicitly. For example, if you need to write to table `t1` and read from table `t2`, you can do this:

```
SET autocommit=0;
LOCK TABLES t1 WRITE, t2 READ, ...;
... do something with tables t1 and t2 here ...
COMMIT;
UNLOCK TABLES;
```

When you call `LOCK TABLES`, `InnoDB` internally takes its own table lock, and MySQL takes its own table lock. `InnoDB` releases its internal table lock at the next commit, but for MySQL to release its table lock, you have to call `UNLOCK TABLES`. You should not have `autocommit = 1`, because then `InnoDB` releases its internal table lock immediately after the call of `LOCK TABLES`, and deadlocks can very easily happen. `InnoDB` does not acquire the internal table lock at all if `autocommit = 1`, to help old applications avoid unnecessary deadlocks.

- `ROLLBACK` does not release table locks.
- `FLUSH TABLES WITH READ LOCK` acquires a global read lock and not table locks, so it is not subject to the same behavior as `LOCK TABLES` and `UNLOCK TABLES` with respect to table locking and implicit commits. See [Section 12.5.6.3, “FLUSH Syntax”](#).

12.4.5.2. LOCK TABLES and Triggers

If you lock a table explicitly with `LOCK TABLES`, any tables used in triggers are also locked implicitly:

- The locks are taken at the same time as those acquired explicitly with the `LOCK TABLES` statement.
- The lock on a table used in a trigger depends on whether the table is used only for reading. If so, a read lock suffices. Other-

wise, a write lock is used.

- If a table is locked explicitly for reading with `LOCK TABLES`, but needs to be locked for writing because it might be modified within a trigger, a write lock is taken rather than a read lock. (That is, an implicit write lock needed due to the table's appearance within a trigger causes an explicit read lock request for the table to be converted to a write lock request.)

Suppose that you lock two tables, `t1` and `t2`, using this statement:

```
LOCK TABLES t1 WRITE, t2 READ;
```

If `t1` or `t2` have any triggers, tables used within the triggers will also be locked. Suppose that `t1` has a trigger defined like this:

```
CREATE TRIGGER t1_a_ins AFTER INSERT ON t1 FOR EACH ROW
BEGIN
  UPDATE t4 SET count = count+1
    WHERE id = NEW.id AND EXISTS (SELECT a FROM t3);
  INSERT INTO t2 VALUES(1, 2);
END;
```

The result of the `LOCK TABLES` statement is that `t1` and `t2` are locked because they appear in the statement, and `t3` and `t4` are locked because they are used within the trigger:

- `t1` is locked for writing per the `WRITE` lock request.
- `t2` is locked for writing, even though the request is for a `READ` lock. This occurs because `t2` is inserted into within the trigger, so the `READ` request is converted to a `WRITE` request.
- `t3` is locked for reading because it is only read from within the trigger.
- `t4` is locked for writing because it might be updated within the trigger.

12.4.5.3. Other Table-Locking Notes

You can safely use `KILL` to terminate a session that is waiting for a table lock. See [Section 12.5.6.4, “KILL Syntax”](#).

You should *not* lock any tables that you are using with `INSERT DELAYED`. An `INSERT DELAYED` in this case results in an error because the insert must be handled by a separate thread, not by the session which holds the lock.

For some operations, system tables in the `mysql` database must be accessed. For example, the `HELP` statement requires the contents of the server-side help tables, and `CONVERT_TZ()` might need to read the time zone tables. The server implicitly locks the system tables for reading as necessary so that you need not lock them explicitly. These tables are treated as just described:

```
mysql.help_category
mysql.help_keyword
mysql.help_relation
mysql.help_topic
mysql.proc
mysql.time_zone
mysql.time_zone_leap_second
mysql.time_zone_name
mysql.time_zone_transition
mysql.time_zone_transition_type
```

If you want to explicitly place a `WRITE` lock on any of those tables with a `LOCK TABLES` statement, the table must be the only one locked; no other table can be locked with the same statement.

Normally, you do not need to lock tables, because all single `UPDATE` statements are atomic; no other session can interfere with any other currently executing SQL statement. However, there are a few cases when locking tables may provide an advantage:

- If you are going to run many operations on a set of `MyISAM` tables, it is much faster to lock the tables you are going to use. Locking `MyISAM` tables speeds up inserting, updating, or deleting on them because MySQL does not flush the key cache for the locked tables until `UNLOCK TABLES` is called. Normally, the key cache is flushed after each SQL statement.

The downside to locking the tables is that no session can update a `READ`-locked table (including the one holding the lock) and no session can access a `WRITE`-locked table other than the one holding the lock.

- If you are using tables for a non-transactional storage engine, you must use `LOCK TABLES` if you want to ensure that no other session modifies the tables between a `SELECT` and an `UPDATE`. The example shown here requires `LOCK TABLES` to execute safely:

```
LOCK TABLES trans READ, customer WRITE;
SELECT SUM(value) FROM trans WHERE customer_id=some_id;
UPDATE customer
  SET total_value=sum_from_previous_statement
  WHERE customer_id=some_id;
UNLOCK TABLES;
```

Without `LOCK TABLES`, it is possible that another session might insert a new row in the `trans` table between execution of the `SELECT` and `UPDATE` statements.

You can avoid using `LOCK TABLES` in many cases by using relative updates (`UPDATE customer SET value=value+new_value`) or the `LAST_INSERT_ID()` function. See [Section 1.7.5.2, “Transactions and Atomic Operations”](#).

You can also avoid locking tables in some cases by using the user-level advisory lock functions `GET_LOCK()` and `RELEASE_LOCK()`. These locks are saved in a hash table in the server and implemented with `pthread_mutex_lock()` and `pthread_mutex_unlock()` for high speed. See [Section 11.11.4, “Miscellaneous Functions”](#).

See [Section 7.3.1, “Internal Locking Methods”](#), for more information on locking policy.

12.4.6. SET TRANSACTION Syntax

```
SET [GLOBAL | SESSION] TRANSACTION ISOLATION LEVEL
{
  READ UNCOMMITTED
  READ COMMITTED
  REPEATABLE READ
  SERIALIZABLE
}
```

This statement sets the transaction isolation level globally, for the current session, or for the next transaction:

- With the `GLOBAL` keyword, the statement sets the default transaction level globally for all subsequent sessions. Existing sessions are unaffected.
- With the `SESSION` keyword, the statement sets the default transaction level for all subsequent transactions performed within the current session.
- Without any `SESSION` or `GLOBAL` keyword, the statement sets the isolation level for the next (not started) transaction performed within the current session.

A change to the global default isolation level requires the `SUPER` privilege. Any session is free to change its session isolation level (even in the middle of a transaction), or the isolation level for its next transaction.

To set the global default isolation level at server startup, use the `--transaction-isolation=level` option to `mysqld` on the command line or in an option file. Values of `level` for this option use dashes rather than spaces, so the allowable values are `READ-UNCOMMITTED`, `READ-COMMITTED`, `REPEATABLE-READ`, or `SERIALIZABLE`. For example, to set the default isolation level to `REPEATABLE READ`, use these lines in the `[mysqld]` section of an option file:

```
[mysqld]
transaction-isolation = REPEATABLE-READ
```

To determine the global and session transaction isolation levels at runtime, check the value of the `tx_isolation` system variable:

```
SELECT @@GLOBAL.tx_isolation, @@tx_isolation;
```

InnoDB supports each of the transaction isolation levels described here using different locking strategies. The default level is `REPEATABLE READ`. For additional information about InnoDB record-level locks and how it uses them to execute various types of statements, see [Section 13.6.8.4, “InnoDB Record, Gap, and Next-Key Locks”](#), and [Section 13.6.8.6, “Locks Set by Different SQL Statements in InnoDB”](#).

The following list describes how MySQL supports the different transaction levels:

- `READ UNCOMMITTED`
`SELECT` statements are performed in a non-locking fashion, but a possible earlier version of a row might be used. Thus, using

this isolation level, such reads are not consistent. This is also called a “dirty read.” Otherwise, this isolation level works like `READ COMMITTED`.

- `READ COMMITTED`

A somewhat Oracle-like isolation level with respect to consistent (non-locking) reads: Each consistent read, even within the same transaction, sets and reads its own fresh snapshot. See [Section 13.6.8.2, “Consistent Non-Locking Reads”](#).

For locking reads (`SELECT` with `FOR UPDATE` or `LOCK IN SHARE MODE`), `InnoDB` locks only index records, not the gaps before them, and thus allows the free insertion of new records next to locked records. For `UPDATE` and `DELETE` statements, locking depends on whether the statement uses a unique index with a unique search condition (such as `WHERE id = 100`), or a range-type search condition (such as `WHERE id > 100`). For a unique index with a unique search condition, `InnoDB` locks only the index record found, not the gap before it. For range-type searches, `InnoDB` locks the index range scanned, using gap locks or next-key (gap plus index-record) locks to block insertions by other sessions into the gaps covered by the range. This is necessary because “phantom rows” must be blocked for MySQL replication and recovery to work.

Note

In MySQL 5.4, if the `READ COMMITTED` isolation level is used or the `innodb_locks_unsafe_for_binlog` system variable is enabled, there is no `InnoDB` gap locking except for foreign-key constraint checking and duplicate-key checking. Also, record locks for non-matching rows are released after MySQL has evaluated the `WHERE` condition.

If you use `READ COMMITTED` or enable `innodb_locks_unsafe_for_binlog`, you *must* use row-based binary logging.

- `REPEATABLE READ`

This is the default isolation level for `InnoDB`. For consistent reads, there is an important difference from the `READ COMMITTED` isolation level: All consistent reads within the same transaction read the snapshot established by the first read. This convention means that if you issue several plain (non-locking) `SELECT` statements within the same transaction, these `SELECT` statements are consistent also with respect to each other. See [Section 13.6.8.2, “Consistent Non-Locking Reads”](#).

For locking reads (`SELECT` with `FOR UPDATE` or `LOCK IN SHARE MODE`), `UPDATE`, and `DELETE` statements, locking depends on whether the statement uses a unique index with a unique search condition, or a range-type search condition. For a unique index with a unique search condition, `InnoDB` locks only the index record found, not the gap before it. For other search conditions, `InnoDB` locks the index range scanned, using gap locks or next-key (gap plus index-record) locks to block insertions by other sessions into the gaps covered by the range.

- `SERIALIZABLE`

This level is like `REPEATABLE READ`, but `InnoDB` implicitly converts all plain `SELECT` statements to `SELECT ... LOCK IN SHARE MODE` if autocommit is disabled. If autocommit is enabled, the `SELECT` is its own transaction. It therefore is known to be read only and can be serialized if performed as a consistent (non-locking) read and need not block for other transactions. (This means that to force a plain `SELECT` to block if other transactions have modified the selected rows, you should disable autocommit.)

12.4.7. XA Transactions

Support for XA transactions is available for the `InnoDB` storage engine. The MySQL XA implementation is based on the X/Open CAE document *Distributed Transaction Processing: The XA Specification*. This document is published by The Open Group and available at <http://www.opengroup.org/public/pubs/catalog/c193.htm>. Limitations of the current XA implementation are described in [Section D.5, “Restrictions on XA Transactions”](#).

On the client side, there are no special requirements. The XA interface to a MySQL server consists of SQL statements that begin with the `XA` keyword. MySQL client programs must be able to send SQL statements and to understand the semantics of the XA statement interface. They do not need be linked against a recent client library. Older client libraries also will work.

Currently, among the MySQL Connectors, MySQL Connector/J 5.0.0 supports XA directly (by means of a class interface that handles the Xan SQL statement interface for you).

XA supports distributed transactions; that is, the ability to allow multiple separate transactional resources to participate in a global transaction. Transactional resources often are RDBMSs but may be other kinds of resources.

A global transaction involves several actions that are transactional in themselves, but that all must either complete successfully as a group, or all be rolled back as a group. In essence, this extends ACID properties “up a level” so that multiple ACID transactions can be executed in concert as components of a global operation that also has ACID properties. (However, for a distributed transaction, you must use the `SERIALIZABLE` isolation level to achieve ACID properties. It is enough to use `REPEATABLE READ` for a non-distributed transaction, but not for a distributed transaction.)

Some examples of distributed transactions:

- An application may act as an integration tool that combines a messaging service with an RDBMS. The application makes sure that transactions dealing with message sending, retrieval, and processing that also involve a transactional database all happen in a global transaction. You can think of this as “transactional email.”
- An application performs actions that involve different database servers, such as a MySQL server and an Oracle server (or multiple MySQL servers), where actions that involve multiple servers must happen as part of a global transaction, rather than as separate transactions local to each server.
- A bank keeps account information in an RDBMS and distributes and receives money via automated teller machines (ATMs). It is necessary to ensure that ATM actions are correctly reflected in the accounts, but this cannot be done with the RDBMS alone. A global transaction manager integrates the ATM and database resources to ensure overall consistency of financial transactions.

Applications that use global transactions involve one or more Resource Managers and a Transaction Manager:

- A Resource Manager (RM) provides access to transactional resources. A database server is one kind of resource manager. It must be possible to either commit or roll back transactions managed by the RM.
- A Transaction Manager (TM) coordinates the transactions that are part of a global transaction. It communicates with the RMs that handle each of these transactions. The individual transactions within a global transaction are “branches” of the global transaction. Global transactions and their branches are identified by a naming scheme described later.

The MySQL implementation of XA MySQL enables a MySQL server to act as a Resource Manager that handles XA transactions within a global transaction. A client program that connects to the MySQL server acts as the Transaction Manager.

To carry out a global transaction, it is necessary to know which components are involved, and bring each component to a point when it can be committed or rolled back. Depending on what each component reports about its ability to succeed, they must all commit or roll back as an atomic group. That is, either all components must commit, or all components must roll back. To manage a global transaction, it is necessary to take into account that any component or the connecting network might fail.

The process for executing a global transaction uses two-phase commit (2PC). This takes place after the actions performed by the branches of the global transaction have been executed.

1. In the first phase, all branches are prepared. That is, they are told by the TM to get ready to commit. Typically, this means each RM that manages a branch records the actions for the branch in stable storage. The branches indicate whether they are able to do this, and these results are used for the second phase.
2. In the second phase, the TM tells the RMs whether to commit or roll back. If all branches indicated when they were prepared that they will be able to commit, all branches are told to commit. If any branch indicated when it was prepared that it will not be able to commit, all branches are told to roll back.

In some cases, a global transaction might use one-phase commit (1PC). For example, when a Transaction Manager finds that a global transaction consists of only one transactional resource (that is, a single branch), that resource can be told to prepare and commit at the same time.

12.4.7.1. XA Transaction SQL Syntax

To perform XA transactions in MySQL, use the following statements:

```
XA {START|BEGIN} xid [JOIN|RESUME]
XA END xid [SUSPEND [FOR MIGRATE]]
XA PREPARE xid
XA COMMIT xid [ONE PHASE]
XA ROLLBACK xid
XA RECOVER
```

For XA **START**, the **JOIN** and **RESUME** clauses are not supported.

For XA **END** the **SUSPEND [FOR MIGRATE]** clause is not supported.

Each XA statement begins with the **XA** keyword, and most of them require an *xid* value. An *xid* is an XA transaction identifier. It

indicates which transaction the statement applies to. *xid* values are supplied by the client, or generated by the MySQL server. An *xid* value has from one to three parts:

```
xid: gtrid [, bqual [, formatID ]]
```

gtrid is a global transaction identifier, *bqual* is a branch qualifier, and *formatID* is a number that identifies the format used by the *gtrid* and *bqual* values. As indicated by the syntax, *bqual* and *formatID* are optional. The default *bqual* value is '' if not given. The default *formatID* value is 1 if not given.

gtrid and *bqual* must be string literals, each up to 64 bytes (not characters) long. *gtrid* and *bqual* can be specified in several ways. You can use a quoted string ('ab'), hex string (0x6162, X'ab'), or bit value (b'nnnn').

formatID is an unsigned integer.

The *gtrid* and *bqual* values are interpreted in bytes by the MySQL server's underlying XA support routines. However, while an SQL statement containing an XA statement is being parsed, the server works with some specific character set. To be safe, write *gtrid* and *bqual* as hex strings.

xid values typically are generated by the Transaction Manager. Values generated by one TM must be different from values generated by other TMs. A given TM must be able to recognize its own *xid* values in a list of values returned by the `XA RECOVER` statement.

MySQL Enterprise

For expert advice on XA Distributed Transaction Support subscribe to the MySQL Enterprise Monitor. For more information, see <http://www.mysql.com/products/enterprise/advisors.html>.

`XA START xid` starts an XA transaction with the given *xid* value. Each XA transaction must have a unique *xid* value, so the value must not currently be used by another XA transaction. Uniqueness is assessed using the *gtrid* and *bqual* values. All following XA statements for the XA transaction must be specified using the same *xid* value as that given in the `XA START` statement. If you use any of those statements but specify an *xid* value that does not correspond to some existing XA transaction, an error occurs.

One or more XA transactions can be part of the same global transaction. All XA transactions within a given global transaction must use the same *gtrid* value in the *xid* value. For this reason, *gtrid* values must be globally unique so that there is no ambiguity about which global transaction a given XA transaction is part of. The *bqual* part of the *xid* value must be different for each XA transaction within a global transaction. (The requirement that *bqual* values be different is a limitation of the current MySQL XA implementation. It is not part of the XA specification.)

The `XA RECOVER` statement returns information for those XA transactions on the MySQL server that are in the `PREPARED` state. (See Section 12.4.7.2, “XA Transaction States”.) The output includes a row for each such XA transaction on the server, regardless of which client started it.

`XA RECOVER` output rows look like this (for an example *xid* value consisting of the parts 'abc', 'def', and 7):

```
mysql> XA RECOVER;
+-----+-----+-----+-----+
| formatID | gtrid_length | bqual_length | data |
+-----+-----+-----+-----+
|          7 |              3 |              3 | abcdef |
+-----+-----+-----+-----+
```

The output columns have the following meanings:

- *formatID* is the *formatID* part of the transaction *xid*
- *gtrid_length* is the length in bytes of the *gtrid* part of the *xid*
- *bqual_length* is the length in bytes of the *bqual* part of the *xid*
- *data* is the concatenation of the *gtrid* and *bqual* parts of the *xid*

12.4.7.2. XA Transaction States

An XA transaction progresses through the following states:

1. Use `XA START` to start an XA transaction and put it in the `ACTIVE` state.
2. For an `ACTIVE` XA transaction, issue the SQL statements that make up the transaction, and then issue an `XA END` statement. `XA END` puts the transaction in the `IDLE` state.

3. For an **IDLE** XA transaction, you can issue either an **XA PREPARE** statement or an **XA COMMIT ... ONE PHASE** statement:
 - **XA PREPARE** puts the transaction in the **PREPARED** state. An **XA RECOVER** statement at this point will include the transaction's *xid* value in its output, because **XA RECOVER** lists all XA transactions that are in the **PREPARED** state.
 - **XA COMMIT ... ONE PHASE** prepares and commits the transaction. The *xid* value will not be listed by **XA RECOVER** because the transaction terminates.
4. For a **PREPARED** XA transaction, you can issue an **XA COMMIT** statement to commit and terminate the transaction, or **XA ROLLBACK** to roll back and terminate the transaction.

Here is a simple XA transaction that inserts a row into a table as part of a global transaction:

```
mysql> XA START 'xatest';
Query OK, 0 rows affected (0.00 sec)

mysql> INSERT INTO mytable (i) VALUES(10);
Query OK, 1 row affected (0.04 sec)

mysql> XA END 'xatest';
Query OK, 0 rows affected (0.00 sec)

mysql> XA PREPARE 'xatest';
Query OK, 0 rows affected (0.00 sec)

mysql> XA COMMIT 'xatest';
Query OK, 0 rows affected (0.00 sec)
```

Within the context of a given client connection, XA transactions and local (non-XA) transactions are mutually exclusive. For example, if **XA START** has been issued to begin an XA transaction, a local transaction cannot be started until the XA transaction has been committed or rolled back. Conversely, if a local transaction has been started with **START TRANSACTION**, no XA statements can be used until the transaction has been committed or rolled back.

Note that if an XA transaction is in the **ACTIVE** state, you cannot issue any statements that cause an implicit commit. That would violate the XA contract because you could not roll back the XA transaction. You will receive the following error if you try to execute such a statement:

```
ERROR 1399 (XAE07): XAER_RMFAIL: The command cannot be executed
when global transaction is in the ACTIVE state
```

Statements to which the preceding remark applies are listed at [Section 12.4.3, “Statements That Cause an Implicit Commit”](#).

12.5. Database Administration Statements

12.5.1. Account Management Statements

MySQL account information is stored in the tables of the `mysql` database. This database and the access control system are discussed extensively in [Chapter 5, *MySQL Server Administration*](#), which you should consult for additional details.

Important

Some releases of MySQL introduce changes to the structure of the grant tables to add new privileges or features. Whenever you update to a new version of MySQL, you should update your grant tables to make sure that they have the current structure so that you can take advantage of any new capabilities. See [Section 4.4.8, “mysql_upgrade — Check Tables for MySQL Upgrade”](#).

MySQL Enterprise

In a production environment it is always prudent to examine any changes to users' accounts. The MySQL Enterprise Monitor provides notification whenever users' privileges are altered. For more information, see <http://www.mysql.com/products/enterprise/advisors.html>.

12.5.1.1. CREATE USER Syntax

```
CREATE USER user [IDENTIFIED BY [PASSWORD] 'password']
[, user [IDENTIFIED BY [PASSWORD] 'password']] ...
```

The **CREATE USER** statement creates new MySQL accounts. To use it, you must have the global **CREATE USER** privilege or the **INSERT** privilege for the `mysql` database. For each account, **CREATE USER** creates a new row in the `mysql.user` table that has no privileges. An error occurs if the account already exists. Each account is named using the same format as for the **GRANT** statement; for example, '`jeffrey`'@'`localhost`'. If you specify only the user name part of the account name, a host name

part of '%' is used. For additional information about specifying account names, see [Section 12.5.1.3, “GRANT Syntax”](#).

The account can be given a password with the optional `IDENTIFIED BY` clause. The `user` value and the password are given the same way as for the `GRANT` statement. In particular, to specify the password in plain text, omit the `PASSWORD` keyword. To specify the password as the hashed value as returned by the `PASSWORD()` function, include the `PASSWORD` keyword. See [Section 12.5.1.3, “GRANT Syntax”](#).

Important

This statement may be recorded in a history file such as `~/.mysql_history`, which means that plaintext passwords may be read by anyone having read access to such files.

12.5.1.2. DROP USER Syntax

```
DROP USER user [, user] ...
```

The `DROP USER` statement removes one or more MySQL accounts. It removes privilege rows for the account from all grant tables. To use this statement, you must have the global `CREATE USER` privilege or the `DELETE` privilege for the `mysql` database. Each account is named using the same format as for the `GRANT` statement; for example, `'jeffrey'@'localhost'`. If you specify only the user name part of the account name, a host name part of '%' is used. For additional information about specifying account names, see [Section 12.5.1.3, “GRANT Syntax”](#).

With `DROP USER`, you can remove an account and its privileges as follows:

```
DROP USER user;
```

Important

`DROP USER` does not automatically close any open user sessions. Rather, in the event that a user with an open session is dropped, the statement does not take effect until that user's session is closed. Once the session is closed, the user is dropped, and that user's next attempt to log in will fail. *This is by design.*

`DROP USER` does not automatically delete or invalidate any database objects that the user created. This applies to tables, views, stored routines, triggers, and events.

12.5.1.3. GRANT Syntax

```
GRANT
  priv_type [(column_list)]
  [, priv_type [(column_list)] ...]
ON [object_type] priv_level
TO user [IDENTIFIED BY [PASSWORD] 'password']
  [, user [IDENTIFIED BY [PASSWORD] 'password']] ...
[REQUIRE {NONE | ssl_option [[AND] ssl_option] ...}]
[WITH with_option [with_option] ...]
```

object_type:

```
TABLE
FUNCTION
PROCEDURE
```

priv_level:

```
*
*.*
db_name.*
db_name.tbl_name
tbl_name
db_name.routine_name
```

with_option:

```
GRANT OPTION
MAX_QUERIES_PER_HOUR count
MAX_UPDATES_PER_HOUR count
MAX_CONNECTIONS_PER_HOUR count
MAX_USER_CONNECTIONS count
```

ssl_option:

```
SSL
X509
CIPHER 'cipher'
ISSUER 'issuer'
SUBJECT 'subject'
```

The `GRANT` statement enables system administrators to create MySQL user accounts and to grant rights to accounts. To use `GRANT`, you must have the `GRANT OPTION` privilege, and you must have the privileges that you are granting. The `REVOKE` statement is related and enables administrators to remove account privileges. To determine what privileges an account has, use `SHOW GRANTS`. See [Section 12.5.1.5, “REVOKE Syntax”](#), and [Section 12.5.5.22, “SHOW GRANTS Syntax”](#).

MySQL Enterprise

For automated notification of users with inappropriate privileges, subscribe to the MySQL Enterprise Monitor. For more information, see <http://www.mysql.com/products/enterprise/advisors.html>.

The following table summarizes the allowable `priv_type` privilege types that can be specified for the `GRANT` and `REVOKE` statements. For additional information about these privileges, see Section 5.4.1, “Privileges Provided by MySQL”.

Privilege	Meaning
<code>ALL [PRIVILEGES]</code>	Grant all privileges at specified access level except <code>GRANT OPTION</code>
<code>ALTER</code>	Enable use of <code>ALTER TABLE</code>
<code>ALTER ROUTINE</code>	Enable stored routines to be altered or dropped
<code>CREATE</code>	Enable database and table creation
<code>CREATE ROUTINE</code>	Enable stored routine creation
<code>CREATE TEMPORARY TABLES</code>	Enable use of <code>CREATE TEMPORARY TABLE</code>
<code>CREATE USER</code>	Enable use of <code>CREATE USER</code> , <code>DROP USER</code> , <code>RENAME USER</code> , and <code>REVOKE ALL PRIVILEGES</code>
<code>CREATE VIEW</code>	Enable views to be created or altered
<code>DELETE</code>	Enable use of <code>DELETE</code>
<code>DROP</code>	Enable databases, tables, and views to be dropped
<code>EVENT</code>	Enable use of events for the Event Scheduler
<code>EXECUTE</code>	Enable the user to execute stored routines
<code>FILE</code>	Enable the user to cause the server to read or write files
<code>GRANT OPTION</code>	Enable privileges to be granted to or removed from other accounts
<code>INDEX</code>	Enable indexes to be created or dropped
<code>INSERT</code>	Enable use of <code>INSERT</code>
<code>LOCK TABLES</code>	Enable use of <code>LOCK TABLES</code> on tables for which you have the <code>SELECT</code> privilege
<code>PROCESS</code>	Enable the user to see all processes with <code>SHOW PROCESSLIST</code>
<code>REFERENCES</code>	Not implemented
<code>RELOAD</code>	Enable use of <code>FLUSH</code> operations
<code>REPLICATION CLIENT</code>	Enable the user to ask where master or slave servers are
<code>REPLICATION SLAVE</code>	Enable replication slaves to read binary log events from the master
<code>SELECT</code>	Enable use of <code>SELECT</code>
<code>SHOW DATABASES</code>	Enable <code>SHOW DATABASES</code> to show all databases
<code>SHOW VIEW</code>	Enable use of <code>SHOW CREATE VIEW</code>
<code>SHUTDOWN</code>	Enable use of <code>mysqladmin shutdown</code>
<code>SUPER</code>	Enable use of <code>CHANGE MASTER TO</code> , <code>KILL</code> , <code>PURGE BINARY LOGS</code> , and <code>SET GLOBAL</code> statements, the <code>mysqladmin debug</code> command; allows you to connect (once) even if <code>max_connections</code> is reached
<code>TRIGGER</code>	Enable triggers to be created or dropped
<code>UPDATE</code>	Enable use of <code>UPDATE</code>
<code>USAGE</code>	Synonym for “no privileges”

A trigger is associated with a table, so to create or drop a trigger, you must have the `TRIGGER` privilege for the table, not the trigger.

`USAGE` can be specified when you want to create a user that has no privileges, or to modify the `REQUIRE` or `WITH` clauses for an account without changing its existing privileges.

MySQL account information is stored in the tables of the `mysql` database. This database and the access control system are discussed extensively in Chapter 5, *MySQL Server Administration*, which you should consult for additional details.

Important

Some releases of MySQL introduce changes to the structure of the grant tables to add new privileges or features. Whenever you update to a new version of MySQL, you should update your grant tables to make sure that they have

the current structure so that you can take advantage of any new capabilities. See [Section 4.4.8, “mysql_upgrade — Check Tables for MySQL Upgrade”](#).

If the grant tables hold privilege rows that contain mixed-case database or table names and the `lower_case_table_names` system variable is set to a nonzero value, `REVOKE` cannot be used to revoke these privileges. It will be necessary to manipulate the grant tables directly. (`GRANT` will not create such rows when `lower_case_table_names` is set, but such rows might have been created prior to setting the variable.)

Privileges can be granted at several levels, depending on the syntax used for the `ON` clause. For `REVOKE`, the same `ON` syntax specifies which privileges to take away. The examples shown here include no `IDENTIFIED BY 'password'` clause for brevity, but you should include one if the account does not already exist to avoid creating an account with no password.

Global privileges

Global privileges are administrative or apply to all databases on a given server. To assign global privileges, use `ON *.*` syntax:

```
GRANT ALL ON *.* TO 'someuser'@'somehost';
GRANT SELECT, INSERT ON *.* TO 'someuser'@'somehost';
```

Privileges also are assigned at the global level if you use `ON *` syntax and you have *not* selected a default database.

The `CREATE USER`, `FILE`, `PROCESS`, `RELOAD`, `REPLICATION CLIENT`, `REPLICATION SLAVE`, `SHOW DATABASES`, `SHUTDOWN`, and `SUPER` privileges are administrative and can only be granted globally.

Other privileges can be granted globally or at more specific levels.

Global privileges are stored in the `mysql.user` table.

Database privileges

Database privileges apply to all objects in a given database. To assign database-level privileges, use `ON db_name.*` syntax:

```
GRANT ALL ON mydb.* TO 'someuser'@'somehost';
GRANT SELECT, INSERT ON mydb.* TO 'someuser'@'somehost';
```

Privileges also are assigned at the database level if you use `ON *` syntax and you have selected a default database.

The `CREATE`, `DROP`, `EVENT`, and `GRANT OPTION` privileges can be specified at the database level. Table or routine privileges also can be specified at the database level, in which case they apply to all tables or routines in the database.

Database privileges are stored in the `mysql.db` and `mysql.host` tables. `GRANT` and `REVOKE` affect the `db` table, but not the `host` table, which is rarely used.

Table privileges

Table privileges apply to all columns in a given table. To assign table-level privileges, use `ON db_name.tbl_name` syntax:

```
GRANT ALL ON mydb.mytbl TO 'someuser'@'somehost';
GRANT SELECT, INSERT ON mydb.mytbl TO 'someuser'@'somehost';
```

If you specify `tbl_name` rather than `db_name.tbl_name`, the statement applies to `tbl_name` in the default database. An error occurs if there is no default database.

The allowable `priv_type` values for a table are `ALTER`, `CREATE VIEW`, `CREATE`, `DELETE`, `DROP`, `GRANT OPTION`, `INDEX`, `INSERT`, `SELECT`, `SHOW VIEW`, `TRIGGER`, and `UPDATE`.

Table privileges are stored in the `mysql.tables_priv` table.

Column privileges

Column privileges apply to single columns in a given table. Each privilege to be granted at the column level must be followed by the column or columns, enclosed within parentheses.

```
GRANT SELECT (col1), INSERT (col1,col2) ON mydb.mytbl TO 'someuser'@'somehost';
```

The allowable `priv_type` values for a column (that is, when you use a `column_list` clause) are `INSERT`, `SELECT`, and `UPDATE`.

Column privileges are stored in the `mysql.columns_priv` table.

Routine privileges

The `ALTER ROUTINE`, `CREATE ROUTINE`, `EXECUTE`, and `GRANT OPTION` privileges apply to stored routines (procedures and functions). They can be granted at the global and database levels. Except for `CREATE ROUTINE`, these privileges can be granted at the routine level for individual routines.

```
GRANT CREATE ROUTINE ON mydb.* TO 'someuser'@'somehost';
GRANT EXECUTE ON PROCEDURE mydb.myproc TO 'someuser'@'somehost';
```

The allowable *priv_type* values at the routine level are `ALTER ROUTINE`, `EXECUTE`, and `GRANT OPTION`. `CREATE ROUTINE` is not a routine-level privilege because you must have this privilege to create a routine in the first place.

Routine-level privileges are stored in the `mysql.procs_priv` table.

For the global, database, table, and routine levels, `GRANT ALL` assigns only the privileges that exist at the level you are granting. For example, `GRANT ALL ON db_name.*` is a database-level statement, so it does not grant any global-only privileges such as `FILE`.

The *object_type* clause, if present, should be specified as `TABLE`, `FUNCTION`, or `PROCEDURE` when the following object is a table, a stored function, or a stored procedure.

The privileges for a database, table, column, or routine are formed additively as the logical `OR` of the privileges at each of the privilege levels. For example, if a user has a global `SELECT` privilege, the privilege cannot be denied by an absence of the privilege at the database, table, or column level. Details of the privilege-checking procedure are presented in [Section 5.4.5, “Access Control, Stage 2: Request Verification”](#).

MySQL enables you to grant privileges even on database objects that do not exist. In such cases, the privileges to be granted must include the `CREATE` privilege. *This behavior is by design*, and is intended to enable the database administrator to prepare user accounts and privileges for database objects that are to be created at a later time.

Important

MySQL does not automatically revoke any privileges when you drop a database or table. However, if you drop a routine, any routine-level privileges granted for that routine are revoked.

The *user* value indicates which MySQL account to grant the privileges to. To accommodate granting rights to users from arbitrary hosts, MySQL supports specifying the *user* value in the form `user_name@host_name`. If a *user_name* or *host_name* value is legal as an unquoted identifier, you need not quote it. However, quotes are necessary to specify a *user_name* string containing special characters (such as “-”), or a *host_name* string containing special characters or wildcard characters (such as “%”); for example, `'test-user'@'%.com'`. Quote the user name and host name separately.

You can specify wildcards in the host name. For example, `user_name@'%.example.com'` applies to *user_name* for any host in the `example.com` domain, and `user_name@'192.168.1.%'` applies to *user_name* for any host in the `192.168.1` class C subnet.

The simple form `user_name` is a synonym for `user_name@'%'`.

MySQL does not support wildcards in user names. To refer to an anonymous user, specify an account with an empty user name with the `GRANT` statement:

```
GRANT ALL ON test.* TO ''@'localhost' ...
```

In this case, any user who connects from the local host with the correct password for the anonymous user will be allowed access, with the privileges associated with the anonymous-user account.

For additional information about user and host values in account names, see [Section 5.4.3, “Specifying Account Names”](#).

To specify quoted values, quote database, table, column, and routine names as identifiers, using backticks (“`”). Quote user names and host names as identifiers or as strings, using either backticks (“`”), single quotes (“'”), or double quotes (“”). Quote passwords as strings, using single quotes.

The “_” and “%” wildcards are allowed when specifying database names in `GRANT` statements that grant privileges at the global or database levels. This means, for example, that if you want to use a “_” character as part of a database name, you should specify it as “_” in the `GRANT` statement, to prevent the user from being able to access additional databases matching the wildcard pattern; for example, `GRANT ... ON `foo_bar`.* TO ...`

Warning

If you allow anonymous users to connect to the MySQL server, you should also grant privileges to all local users as `user_name@localhost`. Otherwise, the anonymous user account for `localhost` in the `mysql.user` table

(created during MySQL installation) is used when named users try to log in to the MySQL server from the local machine. For details, see [Section 5.4.4, “Access Control, Stage 1: Connection Verification”](#).

You can determine whether the preceding warning applies to you by executing the following query, which lists any anonymous users:

```
SELECT Host, User FROM mysql.user WHERE User='';
```

To avoid the problem just described, delete the local anonymous user account using this statement:

```
DROP USER ''@'localhost';
```

GRANT supports host names up to 60 characters long. Database, table, column, and routine names can be up to 64 characters. User names can be up to 16 characters.

Warning

The allowable length for user names cannot be changed by altering the `mysql.user` table. Attempting to do so results in unpredictable behavior which may even make it impossible for users to log in to the MySQL server. You should never alter any of the tables in the `mysql` database in any manner whatsoever except by means of the procedure prescribed by MySQL AB that is described in [Section 4.4.8, “mysql_upgrade — Check Tables for MySQL Upgrade”](#).

If the `NO_AUTO_CREATE_USER` SQL mode is not enabled and the account named in a **GRANT** statement does not exist in the `mysql.user` table, **GRANT** creates it. If you specify no `IDENTIFIED BY` clause or provide an empty password, the user has no password. *This is very insecure.*

If `NO_AUTO_CREATE_USER` is enabled and the account does not exist, **GRANT** fails and does not create the account unless the `IDENTIFIED BY` clause is given to provide a non-empty password.

When the `IDENTIFIED BY` clause is present and you have global grant privileges, the password becomes the new password for the account, even if the account exists and already has a password.

MySQL Enterprise

The MySQL Enterprise Monitor specifically guards against user accounts with no passwords. To find out more, see <http://www.mysql.com/products/enterprise/advisors.html>.

REVOKE does not remove `mysql.user` table entries; you must do that using `DROP USER` or `DELETE`.

Passwords can also be set with the `SET PASSWORD` statement. See [Section 12.5.1.6, “SET PASSWORD Syntax”](#).

In the `IDENTIFIED BY` clause, the password should be given as the literal password value. It is unnecessary to use the `PASSWORD()` function as it is for the `SET PASSWORD` statement. For example:

```
GRANT ... IDENTIFIED BY 'mypass';
```

If you do not want to send the password in clear text and you know the hashed value that `PASSWORD()` would return for the password, you can specify the hashed value preceded by the keyword `PASSWORD`:

```
GRANT ...
IDENTIFIED BY PASSWORD '*6C8989366EAF75BB670AD8EA7A7FC1176A95CEF4';
```

The `WITH` clause is used for several purposes:

- To enable a user to grant privileges to other users
- To specify resource-use limitations on a user
- To specify whether and how a user must use secure connections to the server

The `WITH GRANT OPTION` clause gives the user the ability to give to other users any privileges the user has at the specified privilege level. You should be careful to whom you give the `GRANT OPTION` privilege, because two users with different privileges may be able to combine privileges!

You cannot grant another user a privilege which you yourself do not have; the `GRANT OPTION` privilege enables you to assign only those privileges which you yourself possess.

Be aware that when you grant a user the `GRANT OPTION` privilege at a particular privilege level, any privileges the user possesses

(or may be given in the future) at that level can also be granted by that user to other users. Suppose that you grant a user the `INSERT` privilege on a database. If you then grant the `SELECT` privilege on the database and specify `WITH GRANT OPTION`, that user can give to other users not only the `SELECT` privilege, but also `INSERT`. If you then grant the `UPDATE` privilege to the user on the database, the user can grant `INSERT`, `SELECT`, and `UPDATE`.

For a non-administrative user, you should not grant the `ALTER` privilege globally or for the `mysql` database. If you do that, the user can try to subvert the privilege system by renaming tables!

For additional information about security risks associated with particular privileges, see [Section 5.4.1, “Privileges Provided by MySQL”](#).

The `MAX_QUERIES_PER_HOUR count`, `MAX_UPDATES_PER_HOUR count`, and `MAX_CONNECTIONS_PER_HOUR count` options limit the number of queries, updates, and logins a user can perform during any given one-hour period. (Queries for which results are served from the query cache do not count against the `MAX_QUERIES_PER_HOUR` limit.) If `count` is 0 (the default), this means that there is no limitation for that user.

The `MAX_USER_CONNECTIONS count` option limits the maximum number of simultaneous connections that the account can make. If `count` is 0 (the default), the `max_user_connections` system variable determines the number of simultaneous connections for the account.

To specify any of these resource-limit options for an existing user without affecting existing privileges, use `GRANT USAGE ON *.* ... WITH MAX_...`

For more information on restricting resources, see [Section 5.5.4, “Limiting Account Resources”](#).

MySQL can check X509 certificate attributes in addition to the usual authentication that is based on the user name and password. To specify SSL-related options for a MySQL account, use the `REQUIRE` clause of the `GRANT` statement. (For background information on the use of SSL with MySQL, see [Section 5.5.7, “Using SSL for Secure Connections”](#).)

There are a number of different possibilities for limiting connection types for a given account:

- `REQUIRE NONE` indicates that the account has no SSL or X509 requirements. This is the default if no SSL-related `REQUIRE` options are specified. Unencrypted connections are allowed if the user name and password are valid. However, encrypted connections can also be used, at the client's option, if the client has the proper certificate and key files. That is, the client need not specify any SSL command options, in which case the connection will be unencrypted. To use an encrypted connection, the client must specify either the `--ssl-ca` option, or all three of the `--ssl-ca`, `--ssl-key`, and `--ssl-cert` options.
- The `REQUIRE SSL` option tells the server to allow only SSL-encrypted connections for the account.

```
GRANT ALL PRIVILEGES ON test.* TO 'root'@'localhost'
  IDENTIFIED BY 'goodsecret' REQUIRE SSL;
```

To connect, the client must specify the `--ssl-ca` option, and may additionally specify the `--ssl-key` and `--ssl-cert` options.

- `REQUIRE X509` means that the client must have a valid certificate but that the exact certificate, issuer, and subject do not matter. The only requirement is that it should be possible to verify its signature with one of the CA certificates.

```
GRANT ALL PRIVILEGES ON test.* TO 'root'@'localhost'
  IDENTIFIED BY 'goodsecret' REQUIRE X509;
```

To connect, the client must specify the `--ssl-ca`, `--ssl-key`, and `--ssl-cert` options. This is also true for `ISSUER` and `SUBJECT` because those `REQUIRE` options imply `X509`.

- `REQUIRE ISSUER 'issuer'` places the restriction on connection attempts that the client must present a valid X509 certificate issued by CA `'issuer'`. If the client presents a certificate that is valid but has a different issuer, the server rejects the connection. Use of X509 certificates always implies encryption, so the `SSL` option is unnecessary in this case.

```
GRANT ALL PRIVILEGES ON test.* TO 'root'@'localhost'
  IDENTIFIED BY 'goodsecret'
  REQUIRE ISSUER '/C=FI/ST=Some-State/L=Helsinki/
  O=MySQL Finland AB/CN=Tonu Samuel/Email=tonu@example.com';
```

Note that the `'issuer'` value should be entered as a single string.

- `REQUIRE SUBJECT 'subject'` places the restriction on connection attempts that the client must present a valid X509 certificate containing the subject `subject`. If the client presents a certificate that is valid but has a different subject, the server rejects the connection.

```
GRANT ALL PRIVILEGES ON test.* TO 'root'@'localhost'
  IDENTIFIED BY 'goodsecret'
  REQUIRE SUBJECT '/C=EE/ST=Some-State/L=Tallinn/
```

```
O=MySQL demo client certificate/
CN=Tonu Samuel/Email=tonu@example.com';
```

Note that the `'subject'` value should be entered as a single string.

- `REQUIRE CIPHER 'cipher'` is needed to ensure that ciphers and key lengths of sufficient strength are used. SSL itself can be weak if old algorithms using short encryption keys are used. Using this option, you can ask that a specific cipher method is used to allow a connection.

```
GRANT ALL PRIVILEGES ON test.* TO 'root'@'localhost'
IDENTIFIED BY 'goodsecret'
REQUIRE CIPHER 'EDH-RSA-DES-CBC3-SHA';
```

The `SUBJECT`, `ISSUER`, and `CIPHER` options can be combined in the `REQUIRE` clause like this:

```
GRANT ALL PRIVILEGES ON test.* TO 'root'@'localhost'
IDENTIFIED BY 'goodsecret'
REQUIRE SUBJECT '/C=EE/ST=Some-State/L=Tallinn/
O=MySQL demo client certificate/
CN=Tonu Samuel/Email=tonu@example.com'
AND ISSUER '/C=FI/ST=Some-State/L=Helsinki/
O=MySQL Finland AB/CN=Tonu Samuel/Email=tonu@example.com'
AND CIPHER 'EDH-RSA-DES-CBC3-SHA';
```

The order of the options does not matter, but no option can be specified twice. The `AND` keyword is optional between `REQUIRE` options.

If you are using table, column, or routine privileges for even one user, the server examines table, column, and routine privileges for all users and this slows down MySQL a bit. Similarly, if you limit the number of queries, updates, or connections for any users, the server must monitor these values.

The biggest differences between the standard SQL and MySQL versions of `GRANT` are:

- In MySQL, privileges are associated with the combination of a host name and user name and not with only a user name.
- Standard SQL does not have global or database-level privileges, nor does it support all the privilege types that MySQL supports.
- MySQL does not support the standard SQL `UNDER` privilege.
- Standard SQL privileges are structured in a hierarchical manner. If you remove a user, all privileges the user has been granted are revoked. This is also true in MySQL if you use `DROP USER`. See [Section 12.5.1.2, “DROP USER Syntax”](#).
- In standard SQL, when you drop a table, all privileges for the table are revoked. In standard SQL, when you revoke a privilege, all privileges that were granted based on that privilege are also revoked. In MySQL, privileges can be dropped only with explicit `REVOKE` statements or by manipulating values stored in the MySQL grant tables.
- In MySQL, it is possible to have the `INSERT` privilege for only some of the columns in a table. In this case, you can still execute `INSERT` statements on the table, provided that you omit those columns for which you do not have the `INSERT` privilege. The omitted columns are set to their implicit default values if strict SQL mode is not enabled. In strict mode, the statement is rejected if any of the omitted columns have no default value. (Standard SQL requires you to have the `INSERT` privilege on all columns.) [Section 5.1.7, “Server SQL Modes”](#), discusses strict mode. [Section 10.1.4, “Data Type Default Values”](#), discusses implicit default values.

12.5.1.4. RENAME USER Syntax

```
RENAME USER old_user TO new_user
[, old_user TO new_user] ...
```

The `RENAME USER` statement renames existing MySQL accounts. To use it, you must have the global `CREATE USER` privilege or the `UPDATE` privilege for the `mysql` database. An error occurs if any old account does not exist or any new account exists. Each account is named using the same format as for the `GRANT` statement; for example, `'jeffrey'@'localhost'`. If you specify only the user name part of the account name, a host name part of `'%'` is used. For additional information about specifying account names, see [Section 12.5.1.3, “GRANT Syntax”](#).

`RENAME USER` does not automatically migrate any database objects that the user created, nor does it migrate any privileges that the user had prior to the renaming. This applies to tables, views, stored routines, triggers, and events.

12.5.1.5. REVOKE Syntax

```
REVOKE
  priv_type [(column_list)]
  [, priv_type [(column_list)]] ...
ON [object_type] priv_level
FROM user [, user] ...

REVOKE ALL PRIVILEGES, GRANT OPTION
FROM user [, user] ...
```

The **REVOKE** statement enables system administrators to revoke privileges from MySQL accounts. Each account is named using the same format as for the **GRANT** statement; for example, 'jeffrey'@'localhost'. If you specify only the user name part of the account name, a host name part of '%' is used. For details on the levels at which privileges exist, the allowable *priv_type* and *priv_level* values, and the syntax for specifying users and passwords, see [Section 12.5.1.3, “GRANT Syntax”](#)

To use the first **REVOKE** syntax, you must have the **GRANT OPTION** privilege, and you must have the privileges that you are revoking.

To revoke all privileges, use the second syntax, which drops all global, database, table, column, and routine privileges for the named user or users:

```
REVOKE ALL PRIVILEGES, GRANT OPTION FROM user [, user] ...
```

To use this **REVOKE** syntax, you must have the global **CREATE USER** privilege or the **UPDATE** privilege for the `mysql` database.

REVOKE removes privileges, but does not drop `mysql.user` table entries. To remove a user account entirely, use **DROP USER** (see [Section 12.5.1.2, “DROP USER Syntax”](#)) or **DELETE**.

If the grant tables hold privilege rows that contain mixed-case database or table names and the `lower_case_table_names` system variable is set to a nonzero value, **REVOKE** cannot be used to revoke these privileges. It will be necessary to manipulate the grant tables directly. (**GRANT** will not create such rows when `lower_case_table_names` is set, but such rows might have been created prior to setting the variable.)

To verify an account's privileges after a **REVOKE** operation, use **SHOW GRANTS**. See [Section 12.5.5.22, “SHOW GRANTS Syntax”](#).

12.5.1.6. SET PASSWORD Syntax

```
SET PASSWORD [FOR user] =
{
  PASSWORD('some password')
  | OLD_PASSWORD('some password')
  | 'encrypted password'
}
```

The **SET PASSWORD** statement assigns a password to an existing MySQL user account.

If the password is specified using the `PASSWORD()` or `OLD_PASSWORD()` function, the literal text of the password should be given. If the password is specified without using either function, the password should be the already-encrypted password value as returned by `PASSWORD()`.

With no **FOR** clause, this statement sets the password for the current user. Any client that has connected to the server using a non-anonymous account can change the password for that account.

With a **FOR** clause, this statement sets the password for a specific account on the current server host. Only clients that have the **UPDATE** privilege for the `mysql` database can do this. The *user* value should be given in `user_name@host_name` format, where *user_name* and *host_name* are exactly as they are listed in the `User` and `Host` columns of the `mysql.user` table entry. For example, if you had an entry with `User` and `Host` column values of 'bob' and '%.loc.gov', you would write the statement like this:

```
SET PASSWORD FOR 'bob'@'%.loc.gov' = PASSWORD('newpass');
```

That is equivalent to the following statements:

```
UPDATE mysql.user SET Password=PASSWORD('newpass')
WHERE User='bob' AND Host='%.loc.gov';
FLUSH PRIVILEGES;
```

Note

If you are connecting to a MySQL 4.1 or later server using a pre-4.1 client program, do not use the preceding **SET**

`PASSWORD` or `UPDATE` statement without reading [Section 5.5.6.3, “Password Hashing in MySQL”](#), first. The password format changed in MySQL 4.1, and under certain circumstances it is possible that if you change your password, you might not be able to connect to the server afterward.

You can see which account the server authenticated you as by executing `SELECT CURRENT_USER()`.

MySQL Enterprise

For automated notification of users without passwords, subscribe to the MySQL Enterprise Monitor. For more information, see <http://www.mysql.com/products/enterprise/advisors.html>.

12.5.2. Table Maintenance Statements

12.5.2.1. `ANALYZE TABLE` Syntax

```
ANALYZE [NO_WRITE_TO_BINLOG | LOCAL] TABLE
tbl_name [, tbl_name] ...
```

`ANALYZE TABLE` analyzes and stores the key distribution for a table. During the analysis, the table is locked with a read lock for `MyISAM`. For `InnoDB` the table is locked with a write lock. This statement works with `MyISAM`, and `InnoDB` tables. For `MyISAM` tables, this statement is equivalent to using `myisamchk --analyze`.

For more information on how the analysis works within `InnoDB`, see [Section 13.6.14, “Restrictions on InnoDB Tables”](#).

MySQL Enterprise

For expert advice on optimizing tables subscribe to the MySQL Enterprise Monitor. For more information, see <http://www.mysql.com/products/enterprise/advisors.html>.

MySQL uses the stored key distribution to decide the order in which tables should be joined when you perform a join on something other than a constant. In addition, key distributions can be used when deciding which indexes to use for a specific table within a query.

This statement requires `SELECT` and `INSERT` privileges for the table.

`ANALYZE TABLE` is supported for partitioned tables, and you can use `ALTER TABLE ... ANALYZE PARTITION` to analyze one or more partitions; for more information, see [Section 12.1.6, “ALTER TABLE Syntax”](#), and [Section 17.3.3, “Maintenance of Partitions”](#).

`ANALYZE TABLE` returns a result set with the following columns.

Column	Value
Table	The table name
Op	Always <code>analyze</code>
Msg_type	<code>status</code> , <code>error</code> , <code>info</code> , or <code>warning</code>
Msg_text	An informational message

You can check the stored key distribution with the `SHOW INDEX` statement. See [Section 12.5.5.23, “SHOW INDEX Syntax”](#).

If the table has not changed since the last `ANALYZE TABLE` statement, the table is not analyzed again.

By default, `ANALYZE TABLE` statements are written to the binary log so that they will be replicated to replication slaves. Logging can be suppressed with the optional `NO_WRITE_TO_BINLOG` keyword or its alias `LOCAL`.

12.5.2.2. `BACKUP TABLE` Syntax

```
BACKUP TABLE tbl_name [, tbl_name] ... TO '/path/to/backup/directory'
```

Note

This statement is deprecated. We are working on a better replacement for it that will provide online backup capabilities. In the meantime, the `mysqlhotcopy` script can be used instead.

`BACKUP TABLE` copies to the backup directory the minimum number of table files needed to restore the table, after flushing any buffered changes to disk. The statement works only for `MyISAM` tables. It copies the `.frm` definition and `.MYD` data files. The `.MYI` index file can be rebuilt from those two files. The directory should be specified as a full path name. To restore the table, use `RESTORE TABLE`.

During the backup, a read lock is held for each table, one at a time, as they are being backed up. If you want to back up several tables as a snapshot (preventing any of them from being changed during the backup operation), issue a `LOCK TABLES` statement first, to obtain a read lock for all tables in the group.

`BACKUP TABLE` returns a result set with the following columns.

Column	Value
Table	The table name
Op	Always <code>backup</code>
Msg_type	<code>status</code> , <code>error</code> , <code>info</code> , or <code>warning</code>
Msg_text	An informational message

12.5.2.3. CHECK TABLE Syntax

```
CHECK TABLE tbl_name [, tbl_name] ... [option] ...
option = {FOR UPGRADE | QUICK | FAST | MEDIUM | EXTENDED | CHANGED}
```

`CHECK TABLE` checks a table or tables for errors. `CHECK TABLE` works for `MyISAM`, `InnoDB`, `ARCHIVE`, and `CSV` tables. For `MyISAM` tables, the key statistics are updated as well.

`CHECK TABLE` can also check views for problems, such as tables that are referenced in the view definition that no longer exist.

`CHECK TABLE` is supported for partitioned tables, and you can use `ALTER TABLE ... CHECK PARTITION` to check one or more partitions; for more information, see [Section 12.1.6, “ALTER TABLE Syntax”](#), and [Section 17.3.3, “Maintenance of Partitions”](#).

`CHECK TABLE` returns a result set with the following columns.

Column	Value
Table	The table name
Op	Always <code>check</code>
Msg_type	One of <code>status</code> , <code>error</code> , <code>info</code> , or <code>warning</code>
Msg_text	The message

Note that the statement might produce many rows of information for each checked table. The last row has a `Msg_type` value of `status` and the `Msg_text` normally should be `OK`. If you don't get `OK`, or `Table is already up to date` you should normally run a repair of the table. See [Section 6.4, “Table Maintenance and Crash Recovery”](#). `Table is already up to date` means that the storage engine for the table indicated that there was no need to check the table.

The `FOR UPGRADE` option checks whether the named tables are compatible with the current version of MySQL. With `FOR UPGRADE`, the server checks each table to determine whether there have been any incompatible changes in any of the table's data types or indexes since the table was created. If not, the check succeeds. Otherwise, if there is a possible incompatibility, the server runs a full check on the table (which might take some time). If the full check succeeds, the server marks the table's `.frm` file with the current MySQL version number. Marking the `.frm` file ensures that further checks for the table with the same version of the server will be fast.

Incompatibilities might occur because the storage format for a data type has changed or because its sort order has changed. Our aim is to avoid these changes, but occasionally they are necessary to correct problems that would be worse than an incompatibility between releases.

Currently, `FOR UPGRADE` discovers these incompatibilities:

- The indexing order for end-space in `TEXT` columns for `InnoDB` and `MyISAM` tables changed between MySQL 4.1 and 5.0.
- The storage method of the new `DECIMAL` data type changed between MySQL 5.0.3 and 5.0.5.
- If your table was created by a different version of the MySQL server than the one you are currently running, `FOR UPGRADE` indicates that the table has an `.frm` file with an incompatible version. In this case, the result set returned by `CHECK TABLE` contains a line with a `Msg_type` value of `error` and a `Msg_text` value of `Table upgrade required. Please do "REPAIR TABLE `tbl_name`" to fix it!`
- Changes are sometimes made to character sets or collations that require table indexes to be rebuilt. For details about these

changes and when `FOR UPGRADE` detects them, see [Section 2.12.3, “Checking Whether Table Indexes Must Be Rebuilt”](#).

The other check options that can be given are shown in the following table. These options are passed to the storage engine, which may use them or not. `MyISAM` uses them; they are ignored for `InnoDB` tables and views.

Type	Meaning
<code>QUICK</code>	Do not scan the rows to check for incorrect links.
<code>FAST</code>	Check only tables that have not been closed properly.
<code>CHANGED</code>	Check only tables that have been changed since the last check or that have not been closed properly.
<code>MEDIUM</code>	Scan rows to verify that deleted links are valid. This also calculates a key checksum for the rows and verifies this with a calculated checksum for the keys.
<code>EXTENDED</code>	Do a full key lookup for all keys for each row. This ensures that the table is 100% consistent, but takes a long time.

If none of the options `QUICK`, `MEDIUM`, or `EXTENDED` are specified, the default check type for dynamic-format `MyISAM` tables is `MEDIUM`. This has the same result as running `myisamchk --medium-check tbl_name` on the table. The default check type also is `MEDIUM` for static-format `MyISAM` tables, unless `CHANGED` or `FAST` is specified. In that case, the default is `QUICK`. The row scan is skipped for `CHANGED` and `FAST` because the rows are very seldom corrupted.

You can combine check options, as in the following example that does a quick check on the table to determine whether it was closed properly:

```
CHECK TABLE test_table FAST QUICK;
```

Note

In some cases, `CHECK TABLE` changes the table. This happens if the table is marked as “corrupted” or “not closed properly” but `CHECK TABLE` does not find any problems in the table. In this case, `CHECK TABLE` marks the table as okay.

If a table is corrupted, it is most likely that the problem is in the indexes and not in the data part. All of the preceding check types check the indexes thoroughly and should thus find most errors.

If you just want to check a table that you assume is okay, you should use no check options or the `QUICK` option. The latter should be used when you are in a hurry and can take the very small risk that `QUICK` does not find an error in the data file. (In most cases, under normal usage, MySQL should find any error in the data file. If this happens, the table is marked as “corrupted” and cannot be used until it is repaired.)

`FAST` and `CHANGED` are mostly intended to be used from a script (for example, to be executed from `cron`) if you want to check tables from time to time. In most cases, `FAST` is to be preferred over `CHANGED`. (The only case when it is not preferred is when you suspect that you have found a bug in the `MyISAM` code.)

`EXTENDED` is to be used only after you have run a normal check but still get strange errors from a table when MySQL tries to update a row or find a row by key. This is very unlikely if a normal check has succeeded.

Use of `CHECK TABLE . . . EXTENDED` might influence the execution plan generated by the query optimizer.

Some problems reported by `CHECK TABLE` cannot be corrected automatically:

- `Found row where the auto_increment column has the value 0.`

This means that you have a row in the table where the `AUTO_INCREMENT` index column contains the value 0. (It is possible to create a row where the `AUTO_INCREMENT` column is 0 by explicitly setting the column to 0 with an `UPDATE` statement.)

This is not an error in itself, but could cause trouble if you decide to dump the table and restore it or do an `ALTER TABLE` on the table. In this case, the `AUTO_INCREMENT` column changes value according to the rules of `AUTO_INCREMENT` columns, which could cause problems such as a duplicate-key error.

To get rid of the warning, simply execute an `UPDATE` statement to set the column to some value other than 0.

- If `CHECK TABLE` finds a problem for an `InnoDB` table, the server shuts down to prevent error propagation. Details of the error will be written to the error log.

12.5.2.4. CHECKSUM TABLE Syntax

```
CHECKSUM TABLE tbl_name [, tbl_name] ... [ QUICK | EXTENDED ]
```

`CHECKSUM TABLE` reports a table checksum.

With `QUICK`, the live table checksum is reported if it is available, or `NULL` otherwise. This is very fast. A live checksum is enabled by specifying the `CHECKSUM=1` table option when you create the table; currently, this is supported only for `MyISAM` tables. See [Section 12.1.14, “CREATE TABLE Syntax”](#).

With `EXTENDED`, the entire table is read row by row and the checksum is calculated. This can be very slow for large tables.

If neither `QUICK` nor `EXTENDED` is specified, MySQL returns a live checksum if the table storage engine supports it and scans the table otherwise.

For a non-existent table, `CHECKSUM TABLE` returns `NULL` and generates a warning.

The checksum value depends on the table row format. If the row format changes, the checksum also changes. For example, the storage format for `VARCHAR` changed between MySQL 4.1 and 5.0, so if a 4.1 table is upgraded to MySQL 5.0, the checksum value may change.

Important

If the checksums for two tables are different, then the tables are different in some way. However, the fact that two tables produce the same checksum does *not* mean that the tables are identical.

12.5.2.5. OPTIMIZE TABLE Syntax

```
OPTIMIZE [NO_WRITE_TO_BINLOG | LOCAL] TABLE  
tbl_name [, tbl_name] ...
```

`OPTIMIZE TABLE` should be used if you have deleted a large part of a table or if you have made many changes to a table with variable-length rows (tables that have `VARCHAR`, `VARBINARY`, `BLOB`, or `TEXT` columns). Deleted rows are maintained in a linked list and subsequent `INSERT` operations reuse old row positions. You can use `OPTIMIZE TABLE` to reclaim the unused space and to defragment the data file.

This statement requires `SELECT` and `INSERT` privileges for the table.

`OPTIMIZE TABLE` is supported for partitioned tables, and you can use `ALTER TABLE ... OPTIMIZE PARTITION` to optimize one or more partitions; for more information, see [Section 12.1.6, “ALTER TABLE Syntax”](#), and [Section 17.3.3, “Maintenance of Partitions”](#).

In most setups, you need not run `OPTIMIZE TABLE` at all. Even if you do a lot of updates to variable-length rows, it is not likely that you need to do this more than once a week or month and only on certain tables.

`OPTIMIZE TABLE` works *only* for `MyISAM`, `InnoDB`, and `ARCHIVE` tables. It does *not* work for tables created using any other storage engine, including `NDBCLUSTER` Disk Data tables.

Beginning with MySQL Cluster NDB 6.3.7, `OPTIMIZE TABLE` is supported for dynamic columns of in-memory `NDBCLUSTER` tables. The performance of `OPTIMIZE` on Cluster tables can be tuned by adjusting the value of the `ndb_optimization_delay` system variable, which controls the number of milliseconds to wait between processing batches of rows by `OPTIMIZE TABLE`. See [Previous MySQL Cluster Issues Resolved in MySQL 5.1 and MySQL Cluster NDB 6.x](#), for more information.

Beginning with MySQL Cluster NDB 6.3.8, `OPTIMIZE TABLE` can be interrupted by (for example) killing the SQL thread performing the `OPTIMIZE` operation.

For `MyISAM` tables, `OPTIMIZE TABLE` works as follows:

1. If the table has deleted or split rows, repair the table.
2. If the index pages are not sorted, sort them.
3. If the table's statistics are not up to date (and the repair could not be accomplished by sorting the index), update them.

For `InnoDB` tables, `OPTIMIZE TABLE` is mapped to `ALTER TABLE`, which rebuilds the table to update index statistics and free unused space in the clustered index. This is displayed in the output of `OPTIMIZE TABLE` when you run it on an `InnoDB` table, as shown here:

```
mysql> OPTIMIZE TABLE foo;
```

Table	Op	Msg_type	Msg_text
test.foo	optimize	note	Table does not support optimize, doing recreate + analyze instead
test.foo	optimize	status	OK

You can make `OPTIMIZE TABLE` work on other storage engines by starting `mysqld` with the `--skip-new` or `--safe-mode` option. In this case, `OPTIMIZE TABLE` is just mapped to `ALTER TABLE`.

`OPTIMIZE TABLE` returns a result set with the following columns.

Column	Value
Table	The table name
Op	Always <code>optimize</code>
Msg_type	<code>status</code> , <code>error</code> , <code>info</code> , or <code>warning</code>
Msg_text	An informational message

Note that MySQL locks the table during the time `OPTIMIZE TABLE` is running.

By default, `OPTIMIZE TABLE` statements are written to the binary log so that they will be replicated to replication slaves. Logging can be suppressed with the optional `NO_WRITE_TO_BINLOG` keyword or its alias `LOCAL`.

`OPTIMIZE TABLE` does not sort R-tree indexes, such as spatial indexes on `POINT` columns. ([Bug#23578](#))

12.5.2.6. REPAIR TABLE Syntax

```
REPAIR [NO_WRITE_TO_BINLOG | LOCAL] TABLE
tbl_name [, tbl_name] ...
[QUICK] [EXTENDED] [USE_FRM]
```

`REPAIR TABLE` repairs a possibly corrupted table. By default, it has the same effect as `myisamchk --recover tbl_name`. `REPAIR TABLE` works for `MyISAM`, `ARCHIVE`, and `CSV` tables. See [Section 13.5, “The MyISAM Storage Engine”](#), and [Section 13.12, “The ARCHIVE Storage Engine”](#), and [Section 13.13, “The CSV Storage Engine”](#)

This statement requires `SELECT` and `INSERT` privileges for the table.

`REPAIR TABLE` is supported for partitioned tables. However, the `USE_FRM` option cannot be used with this statement on a partitioned table.

You can use `ALTER TABLE ... REPAIR PARTITION` to repair one or more partitions; for more information, see [Section 12.1.6, “ALTER TABLE Syntax”](#), and [Section 17.3.3, “Maintenance of Partitions”](#).

Normally, you should never have to run `REPAIR TABLE`. However, if disaster strikes, this statement is very likely to get back all your data from a `MyISAM` table. If your tables become corrupted often, you should try to find the reason for it, to eliminate the need to use `REPAIR TABLE`. See [Section B.1.4.2, “What to Do If MySQL Keeps Crashing”](#), and [Section 13.5.4, “MyISAM Table Problems”](#).

Caution

It is best to make a backup of a table before performing a table repair operation; under some circumstances the operation might cause data loss. Possible causes include but are not limited to file system errors.

Warning

If the server dies during a `REPAIR TABLE` operation, it is essential after restarting it that you immediately execute another `REPAIR TABLE` statement for the table before performing any other operations on it. In the worst case, you might have a new clean index file without information about the data file, and then the next operation you perform could overwrite the data file. This is an unlikely but possible scenario that underscores the value of making a backup first.

`REPAIR TABLE` returns a result set with the following columns.

Column	Value
Table	The table name
Op	Always <code>repair</code>

<code>Msg_type</code>	<code>status</code> , <code>error</code> , <code>info</code> , or <code>warning</code>
<code>Msg_text</code>	An informational message

The `REPAIR TABLE` statement might produce many rows of information for each repaired table. The last row has a `Msg_type` value of `status` and `Msg_text` normally should be `OK`. If you do not get `OK` for a `MyISAM` table, you should try repairing it with `myisamchk --safe-recover`. (`REPAIR TABLE` does not implement all the options of `myisamchk`.) With `myisamchk --safe-recover`, you can also use options that `REPAIR TABLE` does not support, such as `--max-record-length`.

If you use the `QUICK` option, `REPAIR TABLE` tries to repair only the index tree. This type of repair is like that done by `myisamchk --recover --quick`.

If you use the `EXTENDED` option, MySQL creates the index row by row instead of creating one index at a time with sorting. This type of repair is like that done by `myisamchk --safe-recover`.

The `USE_FRM` option is available for use if the `.MYI` index file is missing or if its header is corrupted. This option tells MySQL not to trust the information in the `.MYI` file header and to re-create it using information from the `.frm` file. This kind of repair cannot be done with `myisamchk`.

Note

Use the `USE_FRM` option *only* if you cannot use regular `REPAIR` modes! Telling the server to ignore the `.MYI` file makes important table metadata stored in the `.MYI` unavailable to the repair process, which can have deleterious consequences:

- The current `AUTO_INCREMENT` value is lost.
- The link to deleted records in the table is lost, which means that free space for deleted records will remain unoccupied thereafter.
- The `.MYI` header indicates whether the table is compressed. If the server ignores this information, it cannot tell that a table is compressed and repair can cause change or loss of table contents. This means that `USE_FRM` should not be used with compressed tables. That should not be necessary, anyway: Compressed tables are read only, so they should not become corrupt.

Caution

If you use `USE_FRM` for a table that was created by a different version of the MySQL server than the one you are currently running, `REPAIR TABLE` will not attempt to repair the table. In this case, the result set returned by `REPAIR TABLE` contains a line with a `Msg_type` value of `error` and a `Msg_text` value of `Failed repairing incompatible .FRM file`.

If `USE_FRM` is *not* used, `REPAIR TABLE` checks the table to see whether an upgrade is required. If so, it performs the upgrade, following the same rules as `CHECK TABLE ... FOR UPGRADE`. See [Section 12.5.2.3, “CHECK TABLE Syntax”](#), for more information. `REPAIR TABLE` without `USE_FRM` upgrades the `.frm` file to the current version.

By default, `REPAIR TABLE` statements are written to the binary log so that they will be replicated to replication slaves. Logging can be suppressed with the optional `NO_WRITE_TO_BINLOG` keyword or its alias `LOCAL`.

12.5.2.7. RESTORE TABLE Syntax

```
RESTORE TABLE tbl_name [, tbl_name] ... FROM '/path/to/backup/directory'
```

`RESTORE TABLE` restores the table or tables from a backup that was made with `BACKUP TABLE`. The directory should be specified as a full path name.

Existing tables are not overwritten; if you try to restore over an existing table, an error occurs. Just as for `BACKUP TABLE`, `RESTORE TABLE` currently works only for `MyISAM` tables. Restored tables are not replicated from master to slave.

The backup for each table consists of its `.frm` format file and `.MYD` data file. The restore operation restores those files, and then uses them to rebuild the `.MYI` index file. Restoring takes longer than backing up due to the need to rebuild the indexes. The more indexes the table has, the longer it takes.

`RESTORE TABLE` returns a result set with the following columns.

Column	Value
--------	-------

Table	The table name
Op	Always <code>restore</code>
Msg_type	One of <code>status</code> , <code>error</code> , <code>info</code> , or <code>warning</code>
Msg_text	The message

12.5.3. Plugin and User-Defined Function Statements

12.5.3.1. CREATE FUNCTION Syntax

```
CREATE [AGGREGATE] FUNCTION function_name RETURNS {STRING|INTEGER|REAL|DECIMAL}
SONAME shared_library_name
```

A user-defined function (UDF) is a way to extend MySQL with a new function that works like a native (built-in) MySQL function such as `ABS()` or `CONCAT()`.

function_name is the name that should be used in SQL statements to invoke the function. The `RETURNS` clause indicates the type of the function's return value. `DECIMAL` is a legal value after `RETURNS`, but currently `DECIMAL` functions return string values and should be written like `STRING` functions.

shared_library_name is the basename of the shared object file that contains the code that implements the function. The file must be located in the plugin directory. This directory is given by the value of the `plugin_dir` system variable.

To create a function, you must have the `INSERT` privilege for the `mysql` database. This is necessary because `CREATE FUNCTION` adds a row to the `mysql.func` system table that records the function's name, type, and shared library name. If you do not have this table, you should run the `mysql_upgrade` command to create it. See [Section 4.4.8, “mysql_upgrade — Check Tables for MySQL Upgrade”](#).

An active function is one that has been loaded with `CREATE FUNCTION` and not removed with `DROP FUNCTION`. All active functions are reloaded each time the server starts, unless you start `mysqld` with the `--skip-grant-tables` option. In this case, UDF initialization is skipped and UDFs are unavailable.

For instructions on writing user-defined functions, see [Section 21.3.2, “Adding a New User-Defined Function”](#). For the UDF mechanism to work, functions must be written in C or C++ (or another language that can use C calling conventions), your operating system must support dynamic loading and you must have compiled `mysqld` dynamically (not statically).

An `AGGREGATE` function works exactly like a native MySQL aggregate (summary) function such as `SUM` or `COUNT()`. For `AGGREGATE` to work, your `mysql.func` table must contain a `type` column. If your `mysql.func` table does not have this column, you should run the `mysql_upgrade` program to create it (see [Section 4.4.8, “mysql_upgrade — Check Tables for MySQL Upgrade”](#)).

Note

To upgrade the shared library associated with a UDF, issue a `DROP FUNCTION` statement, upgrade the shared library, and then issue a `CREATE FUNCTION` statement. If you upgrade the shared library first and then use `DROP FUNCTION`, the server may crash.

12.5.3.2. DROP FUNCTION Syntax

```
DROP FUNCTION function_name
```

This statement drops the user-defined function (UDF) named *function_name*.

To drop a function, you must have the `DELETE` privilege for the `mysql` database. This is because `DROP FUNCTION` removes a row from the `mysql.func` system table that records the function's name, type, and shared library name.

Note

To upgrade the shared library associated with a UDF, issue a `DROP FUNCTION` statement, upgrade the shared library, and then issue a `CREATE FUNCTION` statement. If you upgrade the shared library first and then use `DROP FUNCTION`, the server may crash.

`DROP FUNCTION` is also used to drop stored functions (see [Section 12.1.21, “DROP PROCEDURE and DROP FUNCTION Syntax”](#)).

12.5.3.3. INSTALL PLUGIN Syntax

```
INSTALL PLUGIN plugin_name SONAME 'plugin_library'
```

This statement installs a plugin.

plugin_name is the name of the plugin as defined in the plugin declaration structure contained in the library file. Plugin names are not case sensitive. For maximal compatibility, plugin names should be limited to ASCII letters, digits, and underscore, because they are used in C source files, shell command lines, M4 and Bourne shell scripts, and SQL environments.

plugin_library is the name of the shared library that contains the plugin code. The name includes the file name extension (for example, `libmyplugin.so` or `libmyplugin.dylib`).

The shared library must be located in the plugin directory (that is, the directory named by the `plugin_dir` system variable). The library must be in the plugin directory itself, not in a subdirectory. By default, `plugin_dir` is `plugin` directory under the directory named by the `pkglibdir` configuration variable, but it can be changed by setting the value of `plugin_dir` at server startup. For example, set its value in a `my.cnf` file:

```
[mysqld]
plugin_dir=/path/to/plugin/directory
```

If the value of `plugin_dir` is a relative path name, it is taken to be relative to the MySQL base directory (the value of the `basedir` system variable).

`INSTALL PLUGIN` adds a line to the `mysql.plugin` table that describes the `plugin`. This table contains the plugin name and library file name.

`INSTALL PLUGIN` causes the server to read option (`my.cnf`) files just as during server startup. This enables the plugin to pick up any relevant options from those files. It is possible to add plugin options to an option file even before loading a plugin (if the `loose` prefix is used). It is also possible to uninstall a plugin, edit `my.cnf`, and install the plugin again. Restarting the plugin this way enables it to the new option values without a server restart.

`INSTALL PLUGIN` also loads and initializes the plugin code to make the plugin available for use. A plugin is initialized by executing its initialization function, which handles any setup that the plugin must perform before it can be used.

To use `INSTALL PLUGIN`, you must have the `INSERT privilege` for the `mysql.plugin` table.

At server startup, the server loads and initializes any plugin that is listed in the `mysql.plugin` table. This means that a plugin is installed with `INSTALL PLUGIN` only once, not every time the server starts. Plugin loading at startup does not occur if the server is started with the `--skip-grant-tables` option.

When the server shuts down, it executes the deinitialization function for each plugin that is loaded so that the plugin has a chance to perform any final cleanup.

If you need to load plugins for a single server startup when the `--skip-grant-tables` option is given (which tells the server not to read system tables), use the `--plugin-load` option. See [Section 5.1.2, “Server Command Options”](#).

To remove a plugin entirely, use the `UNINSTALL PLUGIN` statement:

To see what plugins are installed, use the `SHOW PLUGIN` statement.

If you recompile a plugin library and need to reinstall it, you can use either of the following procedures:

- Use `UNINSTALL PLUGIN` to uninstall all plugins in the library, install the new plugin library file in the plugin directory, and then use `INSTALL PLUGIN` to install all plugins in the library. This procedure has the advantage that it can be used without stopping the server. However, if the plugin library contains many plugins, you must issue many `INSTALL PLUGIN` and `UNINSTALL PLUGIN` statements.
- Alternatively, stop the server, install the new plugin library file in the plugin directory, and then restart the server.

12.5.3.4. UNINSTALL PLUGIN Syntax

```
UNINSTALL PLUGIN plugin_name
```

This statement removes an installed plugin. You cannot uninstall a plugin if any table that uses it is open.

plugin_name must be the name of some plugin that is listed in the `mysql.plugin` table. The server executes the plugin's deinitialization function and removes the row for the plugin from the `mysql.plugin` table, so that subsequent server restarts will not load and initialize the plugin. `UNINSTALL PLUGIN` does not remove the plugin's shared library file.

To use `UNINSTALL PLUGIN`, you must have the `DELETE` privilege for the `mysql.plugin` table.

Plugin removal has implications for the use of associated tables. For example, if a full-text parser plugin is associated with a `FULLTEXT` index on the table, uninstalling the plugin makes the table unusable. Any attempt to access the table results in an error. The table cannot even be opened, so you cannot drop an index for which the plugin is used. This means that uninstalling a plugin is something to do with care unless you do not care about the table contents. If you are uninstalling a plugin with no intention of reinstalling it later and you care about the table contents, you should dump the table with `mysqldump` and remove the `WITH PARSER` clause from the dumped `CREATE TABLE` statement so that you can reload the table later. If you do not care about the table, `DROP TABLE` can be used even if any plugins associated with the table are missing.

12.5.4. SET Syntax

```
SET variable_assignment [, variable_assignment] ...

variable_assignment:
    user_var_name = expr
  | [GLOBAL | SESSION] system_var_name = expr
  | [@@global. | @@session. | @@]system_var_name = expr
```

The `SET` statement assigns values to different types of variables that affect the operation of the server or your client. Older versions of MySQL employed `SET OPTION`, but this syntax is deprecated in favor of `SET` without `OPTION`.

This section describes use of `SET` for assigning values to system variables or user variables. For general information about these types of variables, see [Section 5.1.3, “Server System Variables”](#), [Section 5.1.4, “Session System Variables”](#), and [Section 8.4, “User-Defined Variables”](#). System variables also can be set at server startup, as described in [Section 5.1.5, “Using System Variables”](#).

Some variants of `SET` syntax are used in other contexts:

- `SET CHARACTER SET` and `SET NAMES` assign values to character set and collation variables associated with the connection to the server. `SET ONESHOT` is used for replication. These variants are described later in this section.
- `SET PASSWORD` assigns account passwords. See [Section 12.5.1.6, “SET PASSWORD Syntax”](#).
- `SET TRANSACTION ISOLATION LEVEL` sets the isolation level for transaction processing. See [Section 12.4.6, “SET TRANSACTION Syntax”](#).
- `SET` is used within stored routines to assign values to local routine variables. See [Section 12.8.3.2, “Variable SET Statement”](#).

The following discussion shows the different `SET` syntaxes that you can use to set variables. The examples use the `=` assignment operator, but the `:=` operator also is allowable.

A user variable is written as `@var_name` and can be set as follows:

```
SET @var_name = expr;
```

Many system variables are dynamic and can be changed while the server runs by using the `SET` statement. For a list, see [Section 5.1.5.2, “Dynamic System Variables”](#). To change a system variable with `SET`, refer to it as `var_name`, optionally preceded by a modifier:

- To indicate explicitly that a variable is a global variable, precede its name by `GLOBAL` or `@@global..` The `SUPER` privilege is required to set global variables.
- To indicate explicitly that a variable is a session variable, precede its name by `SESSION`, `@@session..`, or `@@`. Setting a session variable requires no special privilege, but a client can change only its own session variables, not those of any other client.
- `LOCAL` and `@@local.` are synonyms for `SESSION` and `@@session..`
- If no modifier is present, `SET` changes the session variable.

MySQL Enterprise

The MySQL Enterprise Monitor makes extensive use of system variables to determine the state of your server. For more information, see <http://www.mysql.com/products/enterprise/advisors.html>.

A `SET` statement can contain multiple variable assignments, separated by commas. If you set several system variables, the most recent `GLOBAL` or `SESSION` modifier in the statement is used for following variables that have no modifier specified.

Examples:

```
SET sort_buffer_size=10000;
SET @@local.sort_buffer_size=100000;
SET GLOBAL sort_buffer_size=1000000, SESSION sort_buffer_size=1000000;
SET @@sort_buffer_size=1000000;
SET @@global.sort_buffer_size=1000000, @@local.sort_buffer_size=1000000;
```

The `@@var_name` syntax for system variables is supported for compatibility with some other database systems.

If you change a session system variable, the value remains in effect until your session ends or until you change the variable to a different value. The change is not visible to other clients.

If you change a global system variable, the value is remembered and used for new connections until the server restarts. (To make a global system variable setting permanent, you should set it in an option file.) The change is visible to any client that accesses that global variable. However, the change affects the corresponding session variable only for clients that connect after the change. The global variable change does not affect the session variable for any client that is currently connected (not even that of the client that issues the `SET GLOBAL` statement).

To prevent incorrect usage, MySQL produces an error if you use `SET GLOBAL` with a variable that can only be used with `SET SESSION` or if you do not specify `GLOBAL` (or `@@global.`) when setting a global variable.

To set a `SESSION` variable to the `GLOBAL` value or a `GLOBAL` value to the compiled-in MySQL default value, use the `DEFAULT` keyword. For example, the following two statements are identical in setting the session value of `max_join_size` to the global value:

```
SET max_join_size=DEFAULT;
SET @@session.max_join_size=@@global.max_join_size;
```

Not all system variables can be set to `DEFAULT`. In such cases, use of `DEFAULT` results in an error.

You can refer to the values of specific global or session system variables in expressions by using one of the `@@`-modifiers. For example, you can retrieve values in a `SELECT` statement like this:

```
SELECT @@global.sql_mode, @@session.sql_mode, @@sql_mode;
```

When you refer to a system variable in an expression as `@@var_name` (that is, when you do not specify `@@global.` or `@@session.`), MySQL returns the session value if it exists and the global value otherwise. (This differs from `SET @@var_name = value`, which always refers to the session value.)

Note

Some variables displayed by `SHOW VARIABLES` may not be available using `SELECT @@var_name` syntax; an `Unknown system variable` occurs. As a workaround in such cases, you can use `SHOW VARIABLES LIKE 'var_name'`.

Suffixes for specifying a value multiplier can be used when setting a variable at server startup, but not to set the value with `SET` at runtime. On the other hand, with `SET` you can assign a variable's value using an expression, which is not true when you set a variable at server startup. For example, the first of the following lines is legal at server startup, but the second is not:

```
shell> mysql --max_allowed_packet=16M
shell> mysql --max_allowed_packet=16*1024*1024
```

Conversely, the second of the following lines is legal at runtime, but the first is not:

```
mysql> SET GLOBAL max_allowed_packet=16M;
mysql> SET GLOBAL max_allowed_packet=16*1024*1024;
```

To display system variables names and values, use the `SHOW VARIABLES` statement. (See [Section 12.5.5.40](#), “`SHOW VARIABLES Syntax`”.)

The following list describes `SET` options that have non-standard syntax (that is, options that are not set with `name = value` syntax).

- `CHARACTER SET {charset_name | DEFAULT}`

This maps all strings from and to the client with the given mapping. You can add new mappings by editing `sql/convert.cc` in the MySQL source distribution. `SET CHARACTER SET` sets three session system variables: `character_set_client` and `character_set_results` are set to the given character set, and `character_set_connection` to the value of `character_set_database`. See [Section 9.1.4](#), “`Connection Character Sets and`

Collations”.

The default mapping can be restored by using the value `DEFAULT`. The default depends on the server configuration.

`ucs2` cannot be used as a client character set, which means that it does not work for `SET CHARACTER SET`.

- `NAMES { 'charset_name' [COLLATE 'collation_name'] | DEFAULT }`

`SET NAMES` sets the three session system variables `character_set_client`, `character_set_connection`, and `character_set_results` to the given character set. Setting `character_set_connection` to `charset_name` also sets `collation_connection` to the default collation for `charset_name`. The optional `COLLATE` clause may be used to specify a collation explicitly. See Section 9.1.4, “Connection Character Sets and Collations”.

The default mapping can be restored by using a value of `DEFAULT`. The default depends on the server configuration.

`ucs2` cannot be used as a client character set, which means that it does not work for `SET NAMES`.

- `ONE_SHOT`

This option is a modifier, not a variable. It can be used to influence the effect of variables that set the character set, the collation, and the time zone. `ONE_SHOT` is primarily used for replication purposes: `mysqlbinlog` uses `SET ONE_SHOT` to modify temporarily the values of character set, collation, and time zone variables to reflect at rollforward what they were originally. `ONE_SHOT` is for internal use only and is deprecated for MySQL 5.0 and up.

You cannot use `ONE_SHOT` with other than the allowed set of variables; if you try, you get an error like this:

```
mysql> SET ONE_SHOT max_allowed_packet = 1;
ERROR 1382 (HY000): The 'SET ONE_SHOT' syntax is reserved for purposes
internal to the MySQL server
```

If `ONE_SHOT` is used with the allowed variables, it changes the variables as requested, but only for the next non-`SET` statement. After that, the server resets all character set, collation, and time zone-related system variables to their previous values. Example:

```
mysql> SET ONE_SHOT character_set_connection = latin5;
mysql> SET ONE_SHOT collation_connection = latin5_turkish_ci;
mysql> SHOW VARIABLES LIKE '%_connection';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| character_set_connection | latin5 |
| collation_connection | latin5_turkish_ci |
+-----+-----+
mysql> SHOW VARIABLES LIKE '%_connection';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| character_set_connection | latin1 |
| collation_connection | latin1_swedish_ci |
+-----+-----+
```

12.5.5. SHOW Syntax

`SHOW` has many forms that provide information about databases, tables, columns, or status information about the server. This section describes those following:

```
SHOW AUTHORS
SHOW CHARACTER SET [like_or_where]
SHOW COLLATION [like_or_where]
SHOW [FULL] COLUMNS FROM tbl_name [FROM db_name] [like_or_where]
SHOW CONTRIBUTORS
SHOW CREATE DATABASE db_name
SHOW CREATE EVENT event_name
SHOW CREATE FUNCTION func_name
SHOW CREATE PROCEDURE proc_name
SHOW CREATE TABLE tbl_name
SHOW CREATE TRIGGER trigger_name
SHOW CREATE VIEW view_name
SHOW DATABASES [like_or_where]
SHOW ENGINE engine_name {STATUS | MUTEX}
SHOW [STORAGE] ENGINES
SHOW ERRORS [LIMIT [offset,] row_count]
SHOW [FULL] EVENTS
SHOW FUNCTION CODE func_name
SHOW FUNCTION STATUS [like_or_where]
SHOW GRANTS FOR user
SHOW INDEX FROM tbl_name [FROM db_name]
```

```

SHOW INNODB STATUS
SHOW OPEN TABLES [FROM db_name] [like_or_where]
SHOW PLUGINS
SHOW PROCEDURE CODE proc_name
SHOW PROCEDURE STATUS [like_or_where]
SHOW PRIVILEGES
SHOW [FULL] PROCESSLIST
SHOW PROFILE [types] [FOR QUERY n] [OFFSET n] [LIMIT n]
SHOW PROFILES
SHOW SCHEDULER STATUS
SHOW [GLOBAL | SESSION] STATUS [like_or_where]
SHOW TABLE STATUS [FROM db_name] [like_or_where]
SHOW TABLES [FROM db_name] [like_or_where]
SHOW TRIGGERS [FROM db_name] [like_or_where]
SHOW [GLOBAL | SESSION] VARIABLES [like_or_where]
SHOW WARNINGS [LIMIT [offset,] row_count]

like_or_where:
LIKE 'pattern'
| WHERE expr

```

If the syntax for a given `SHOW` statement includes a `LIKE 'pattern'` part, '*pattern*' is a string that can contain the SQL “%” and “_” wildcard characters. The pattern is useful for restricting statement output to matching values.

Several `SHOW` statements also accept a `WHERE` clause that provides more flexibility in specifying which rows to display. See [Section 19.28, “Extensions to SHOW Statements”](#).

Many MySQL APIs (such as PHP) allow you to treat the result returned from a `SHOW` statement as you would a result set from a `SELECT`; see [Chapter 20, Connectors and APIs](#), or your API documentation for more information. In addition, you can work in SQL with results from queries on tables in the `INFORMATION_SCHEMA` database, which you cannot easily do with results from `SHOW` statements. See [Chapter 19, INFORMATION_SCHEMA Tables](#).

12.5.5.1. SHOW AUTHORS Syntax

```
SHOW AUTHORS
```

The `SHOW AUTHORS` statement displays information about the people who work on MySQL. For each author, it displays `Name`, `Location`, and `Comment` values.

12.5.5.2. SHOW BINARY LOGS Syntax

```
SHOW BINARY LOGS
SHOW MASTER LOGS
```

Lists the binary log files on the server. This statement is used as part of the procedure described in [Section 12.6.1.1, “PURGE BINARY LOGS Syntax”](#), that shows how to determine which logs can be purged.

```

mysql> SHOW BINARY LOGS;
+-----+-----+
| Log_name | File_size |
+-----+-----+
| binlog.000015 | 724935 |
| binlog.000016 | 733481 |
+-----+-----+

```

`SHOW MASTER LOGS` is equivalent to `SHOW BINARY LOGS`.

12.5.5.3. SHOW BINLOG EVENTS Syntax

```

SHOW BINLOG EVENTS
  [IN 'log_name'] [FROM pos] [LIMIT [offset,] row_count]

```

Shows the events in the binary log. If you do not specify '*log_name*', the first binary log is displayed.

The `LIMIT` clause has the same syntax as for the `SELECT` statement. See [Section 12.2.8, “SELECT Syntax”](#).

Note

Issuing a `SHOW BINLOG EVENTS` with no `LIMIT` clause could start a very time- and resource-consuming process because the server returns to the client the complete contents of the binary log (which includes all statements executed by the server that modify data). As an alternative to `SHOW BINLOG EVENTS`, use the `mysqlbinlog` utility to save the binary log to a text file for later examination and analysis. See [Section 4.6.7, “mysqlbinlog — Utility for Processing Binary Log Files”](#).

Note

Events relating to the setting of variables are not included in the output from `SHOW BINLOG EVENTS`. To get complete coverage of events within a binary log, use `mysqlbinlog`.

12.5.5.4. SHOW CHARACTER SET Syntax

```
SHOW CHARACTER SET
[LIKE 'pattern' | WHERE expr]
```

The `SHOW CHARACTER SET` statement shows all available character sets. The `LIKE` clause, if present, indicates which character set names to match. The `WHERE` clause can be given to select rows using more general conditions, as discussed in [Section 19.28](#), “Extensions to SHOW Statements”. For example:

```
mysql> SHOW CHARACTER SET LIKE 'latin%';
+-----+-----+-----+-----+
| Charset | Description | Default collation | Maxlen |
+-----+-----+-----+-----+
| latin1  | cp1252 West European | latin1_swedish_ci | 1 |
| latin2  | ISO 8859-2 Central European | latin2_general_ci | 1 |
| latin5  | ISO 8859-9 Turkish | latin5_turkish_ci | 1 |
| latin7  | ISO 8859-13 Baltic | latin7_general_ci | 1 |
+-----+-----+-----+-----+
```

The `Maxlen` column shows the maximum number of bytes required to store one character.

12.5.5.5. SHOW COLLATION Syntax

```
SHOW COLLATION
[LIKE 'pattern' | WHERE expr]
```

The output from `SHOW COLLATION` includes all available character sets. The `LIKE` clause, if present, indicates which collation names to match. The `WHERE` clause can be given to select rows using more general conditions, as discussed in [Section 19.28](#), “Extensions to SHOW Statements”. For example:

```
mysql> SHOW COLLATION LIKE 'latin1%';
+-----+-----+-----+-----+-----+-----+
| Collation | Charset | Id | Default | Compiled | Sortlen |
+-----+-----+-----+-----+-----+-----+
| latin1_german1_ci | latin1 | 5 | Yes | Yes | 0 |
| latin1_swedish_ci | latin1 | 8 | Yes | Yes | 0 |
| latin1_danish_ci | latin1 | 15 | Yes | Yes | 0 |
| latin1_german2_ci | latin1 | 31 | Yes | Yes | 2 |
| latin1_bin | latin1 | 47 | Yes | Yes | 0 |
| latin1_general_ci | latin1 | 48 | Yes | Yes | 0 |
| latin1_general_cs | latin1 | 49 | Yes | Yes | 0 |
| latin1_spanish_ci | latin1 | 94 | Yes | Yes | 0 |
+-----+-----+-----+-----+-----+-----+
```

The `Default` column indicates whether a collation is the default for its character set. `Compiled` indicates whether the character set is compiled into the server. `Sortlen` is related to the amount of memory required to sort strings expressed in the character set.

To see the default collation for each character set, use the following statement. `Default` is a reserved word, so to use it as an identifier, it must be quoted as such:

```
mysql> SHOW COLLATION WHERE `Default` = 'Yes';
+-----+-----+-----+-----+-----+-----+
| Collation | Charset | Id | Default | Compiled | Sortlen |
+-----+-----+-----+-----+-----+-----+
| big5_chinese_ci | big5 | 1 | Yes | Yes | 1 |
| dec8_swedish_ci | dec8 | 3 | Yes | Yes | 1 |
| cp850_general_ci | cp850 | 4 | Yes | Yes | 1 |
| hp8_english_ci | hp8 | 6 | Yes | Yes | 1 |
| koi8r_general_ci | koi8r | 7 | Yes | Yes | 1 |
| latin1_swedish_ci | latin1 | 8 | Yes | Yes | 1 |
| ... | | | | | |
+-----+-----+-----+-----+-----+-----+
```

12.5.5.6. SHOW COLUMNS Syntax

```
SHOW [FULL] COLUMNS {FROM | IN} tbl_name [{FROM | IN} db_name]
[LIKE 'pattern' | WHERE expr]
```

`SHOW COLUMNS` displays information about the columns in a given table. It also works for views. The `LIKE` clause, if present, indicates which column names to match. The `WHERE` clause can be given to select rows using more general conditions, as discussed in [Section 19.28](#), “Extensions to SHOW Statements”.

```
mysql> SHOW COLUMNS FROM City;
+-----+-----+-----+-----+-----+-----+
| Field | Type | Null | Key | Default | Extra |
+-----+-----+-----+-----+-----+-----+
```

Id	int(11)	NO	PRI	NULL	auto_increment
Name	char(35)	NO			
Country	char(3)	NO	UNI		
District	char(20)	YES	MUL		
Population	int(11)	NO		0	

5 rows in set (0.00 sec)

If the data types differ from what you expect them to be based on a `CREATE TABLE` statement, note that MySQL sometimes changes data types when you create or alter a table. The conditions under which this occurs are described in [Section 12.1.14.1, “Silent Column Specification Changes”](#).

The `FULL` keyword causes the output to include the column collation and comments, as well as the privileges you have for each column.

You can use `db_name.tbl_name` as an alternative to the `tbl_name FROM db_name` syntax. In other words, these two statements are equivalent:

```
mysql> SHOW COLUMNS FROM mytable FROM mydb;
mysql> SHOW COLUMNS FROM mydb.mytable;
```

`SHOW COLUMNS` displays the following values for each table column:

Field indicates the column name.

Type indicates the column data type.

Collation indicates the collation for nonbinary string columns, or `NULL` for other columns. This value is displayed only if you use the `FULL` keyword.

The **Null** field contains `YES` if `NULL` values can be stored in the column, `NO` if not.

The **Key** field indicates whether the column is indexed:

- If **Key** is empty, the column either is not indexed or is indexed only as a secondary column in a multiple-column, non-unique index.
- If **Key** is `PRI`, the column is a `PRIMARY KEY` or is one of the columns in a multiple-column `PRIMARY KEY`.
- If **Key** is `UNI`, the column is the first column of a unique-valued index that cannot contain `NULL` values.
- If **Key** is `MUL`, multiple occurrences of a given value are allowed within the column. The column is the first column of a non-unique index or a unique-valued index that can contain `NULL` values.

If more than one of the **Key** values applies to a given column of a table, **Key** displays the one with the highest priority, in the order `PRI`, `UNI`, `MUL`.

A `UNIQUE` index may be displayed as `PRI` if it cannot contain `NULL` values and there is no `PRIMARY KEY` in the table. A `UNIQUE` index may display as `MUL` if several columns form a composite `UNIQUE` index; although the combination of the columns is unique, each column can still hold multiple occurrences of a given value.

The **Default** field indicates the default value that is assigned to the column.

The **Extra** field contains any additional information that is available about a given column. The value is `auto_increment` if the column was created with the `AUTO_INCREMENT` keyword and empty otherwise.

Privileges indicates the privileges you have for the column. This value is displayed only if you use the `FULL` keyword.

Comment indicates any comment the column has. This value is displayed only if you use the `FULL` keyword.

`SHOW FIELDS` is a synonym for `SHOW COLUMNS`. You can also list a table's columns with the `mysqlshow db_name tbl_name` command.

The `DESCRIBE` statement provides information similar to `SHOW COLUMNS`. See [Section 12.3.1, “DESCRIBE Syntax”](#).

The `SHOW CREATE TABLE`, `SHOW TABLE STATUS`, and `SHOW INDEX` statements also provide information about tables. See [Section 12.5.5, “SHOW Syntax”](#).

12.5.5.7. SHOW CONTRIBUTORS Syntax

```
SHOW CONTRIBUTORS
```

The `SHOW CONTRIBUTORS` statement displays information about the people who contribute to MySQL source or to causes that MySQL AB supports. For each contributor, it displays `Name`, `Location`, and `Comment` values.

12.5.5.8. SHOW CREATE DATABASE Syntax

```
SHOW CREATE {DATABASE | SCHEMA} db_name
```

Shows the `CREATE DATABASE` statement that creates the given database. `SHOW CREATE SCHEMA` is a synonym for `SHOW CREATE DATABASE`.

```
mysql> SHOW CREATE DATABASE test\G
***** 1. row *****
      Database: test
Create Database: CREATE DATABASE `test`
                  /*!40100 DEFAULT CHARACTER SET latin1 */

mysql> SHOW CREATE SCHEMA test\G
***** 1. row *****
      Database: test
Create Database: CREATE DATABASE `test`
                  /*!40100 DEFAULT CHARACTER SET latin1 */
```

`SHOW CREATE DATABASE` quotes table and column names according to the value of the `sql_quote_show_create` option. See Section 5.1.4, “Session System Variables”.

12.5.5.9. SHOW CREATE EVENT Syntax

```
SHOW CREATE EVENT event_name
```

This statement displays the `CREATE EVENT` statement needed to re-create a given event. For example (using the same event `e_daily` defined and then altered in Section 12.5.5.19, “SHOW EVENTS Syntax”):

```
mysql> SHOW CREATE EVENT test.e_daily\G
***** 1. row *****
      Event: e_daily
      sql_mode:
      time_zone: SYSTEM
Create Event: CREATE EVENT `e_daily`
              ON SCHEDULE EVERY 1 DAY
              STARTS CURRENT_TIMESTAMP + INTERVAL 6 HOUR
              ON COMPLETION NOT PRESERVE
              ENABLE
              COMMENT 'Saves total number of sessions then
                       clears the table each day'
              DO BEGIN
                INSERT INTO site_activity.totals (time, total)
                SELECT CURRENT_TIMESTAMP, COUNT(*)
                FROM site_activity.sessions;
                DELETE FROM site_activity.sessions;
              END
character_set_client: latin1
collation_connection: latin1_swedish_ci
Database Collation: latin1_swedish_ci
```

`character_set_client` is the session value of the `character_set_client` system variable when the event was created. `collation_connection` is the session value of the `collation_connection` system variable when the event was created. `Database Collation` is the collation of the database with which the event is associated.

Note that the output reflects the current status of the event (`ENABLE`) rather than the status with which it was created.

12.5.5.10. SHOW CREATE FUNCTION Syntax

```
SHOW CREATE FUNCTION func_name
```

This statement is similar to `SHOW CREATE PROCEDURE` but for stored functions. See Section 12.5.5.11, “SHOW CREATE PROCEDURE Syntax”.

12.5.5.11. SHOW CREATE PROCEDURE Syntax

```
SHOW CREATE PROCEDURE proc_name
```

This statement is a MySQL extension. It returns the exact string that can be used to re-create the named stored procedure. A similar statement, `SHOW CREATE FUNCTION`, displays information about stored functions (see Section 12.5.5.10, “SHOW CREATE

FUNCTION Syntax”).

Both statements require that you be the owner of the routine or have `SELECT` access to the `mysql.proc` table. If you do not have privileges for the routine itself, the value displayed for the `Create Procedure` or `Create Function` field will be `NULL`.

```
mysql> SHOW CREATE PROCEDURE test.simpleproc\G
***** 1. row *****
      Procedure: simpleproc
      sql_mode:
      Create Procedure: CREATE PROCEDURE `simpleproc`(OUT param1 INT)
                        BEGIN
                        SELECT COUNT(*) INTO param1 FROM t;
                        END
character_set_client: latin1
collation_connection: latin1_swedish_ci
  Database Collation: latin1_swedish_ci

mysql> SHOW CREATE FUNCTION test.hello\G
***** 1. row *****
      Function: hello
      sql_mode:
      Create Function: CREATE FUNCTION `hello`(s CHAR(20))
                      RETURNS CHAR(50)
                      RETURN CONCAT('Hello, ',s, '!')
character_set_client: latin1
collation_connection: latin1_swedish_ci
  Database Collation: latin1_swedish_ci
```

`character_set_client` is the session value of the `character_set_client` system variable when the routine was created. `collation_connection` is the session value of the `collation_connection` system variable when the routine was created. `Database Collation` is the collation of the database with which the routine is associated.

12.5.5.12. SHOW CREATE TABLE Syntax

```
SHOW CREATE TABLE tbl_name
```

Shows the `CREATE TABLE` statement that creates the given table. The statement requires the `SELECT` privilege for the table. This statement also works with views.

```
mysql> SHOW CREATE TABLE t\G
***** 1. row *****
      Table: t
      Create Table: CREATE TABLE t (
        id INT(11) default NULL auto_increment,
        s char(60) default NULL,
        PRIMARY KEY (id)
      ) ENGINE=MyISAM
```

`SHOW CREATE TABLE` quotes table and column names according to the value of the `sql_quote_show_create` option. See Section 5.1.4, “Session System Variables”.

12.5.5.13. SHOW CREATE TRIGGER Syntax

```
SHOW CREATE TRIGGER trigger_name
```

This statement shows a `CREATE TRIGGER` statement that creates the given trigger.

```
mysql> SHOW CREATE TRIGGER ins_sum\G
***** 1. row *****
      Trigger: ins_sum
      sql_mode:
      SQL Original Statement: CREATE DEFINER=`bob`@`localhost` TRIGGER ins_sum
                            BEFORE INSERT ON account
                            FOR EACH ROW SET @sum = @sum + NEW.amount
character_set_client: latin1
collation_connection: latin1_swedish_ci
  Database Collation: latin1_swedish_ci
```

You can also obtain information about trigger objects from `INFORMATION_SCHEMA`, which contains a `TRIGGERS` table. See Section 19.16, “The `INFORMATION_SCHEMA TRIGGERS` Table”.

12.5.5.14. SHOW CREATE VIEW Syntax

```
SHOW CREATE VIEW view_name
```

This statement shows a `CREATE VIEW` statement that creates the given view.

```
mysql> SHOW CREATE VIEW v\G
```

```

***** 1. row *****
View: v
Create View: CREATE ALGORITHM=UNDEFINED
            DEFINER=`bob`@`localhost`
            SQL SECURITY DEFINER VIEW
            `v` AS select 1 AS `a`,2 AS `b`
character_set_client: latin1
collation_connection: latin1_swedish_ci

```

`character_set_client` is the session value of the `character_set_client` system variable when the routine was created. `collation_connection` is the session value of the `collation_connection` system variable when the routine was created.

Use of `SHOW CREATE VIEW` requires the `SHOW VIEW` privilege and the `SELECT` privilege for the view in question.

You can also obtain information about view objects from `INFORMATION_SCHEMA`, which contains a `VIEWS` table. See [Section 19.15, “The INFORMATION_SCHEMA VIEWS Table”](#).

MySQL lets you use different `sql_mode` settings to tell the server the type of SQL syntax to support. For example, you might use the `ANSI SQL` mode to ensure MySQL correctly interprets the standard SQL concatenation operator, the double bar (`||`), in your queries. If you then create a view that concatenates items, you might worry that changing the `sql_mode` setting to a value different from `ANSI` could cause the view to become invalid. But this is not the case. No matter how you write out a view definition, MySQL always stores it the same way, in a canonical form. Here is an example that shows how the server changes a double bar concatenation operator to a `CONCAT()` function:

```

mysql> SET sql_mode = 'ANSI';
Query OK, 0 rows affected (0.00 sec)

mysql> CREATE VIEW test.v AS SELECT 'a' || 'b' as coll;
Query OK, 0 rows affected (0.01 sec)

mysql> SHOW CREATE VIEW test.v\G
***** 1. row *****
View: v
Create View: CREATE VIEW "v" AS select concat('a','b') AS "coll"
...
1 row in set (0.00 sec)

```

The advantage of storing a view definition in canonical form is that changes made later to the value of `sql_mode` will not affect the results from the view. However an additional consequence is that comments prior to `SELECT` are stripped from the definition by the server.

12.5.5.15. SHOW DATABASES Syntax

```

SHOW {DATABASES | SCHEMAS}
     [LIKE 'pattern' | WHERE expr]

```

`SHOW DATABASES` lists the databases on the MySQL server host. `SHOW SCHEMAS` is a synonym for `SHOW DATABASES`. The `LIKE` clause, if present, indicates which database names to match. The `WHERE` clause can be given to select rows using more general conditions, as discussed in [Section 19.28, “Extensions to SHOW Statements”](#).

You see only those databases for which you have some kind of privilege, unless you have the global `SHOW DATABASES` privilege. You can also get this list using the `mysqlshow` command.

If the server was started with the `--skip-show-database` option, you cannot use this statement at all unless you have the `SHOW DATABASES` privilege.

`SHOW SCHEMAS` can also be used.

12.5.5.16. SHOW ENGINE Syntax

```

SHOW ENGINE engine_name {STATUS | MUTEX}

```

`SHOW ENGINE` displays operational information about a storage engine. The following statements currently are supported:

```

SHOW ENGINE INNODB STATUS
SHOW ENGINE INNODB MUTEX
SHOW ENGINE {NDB | NDBCLUSTER} STATUS

```

Older (and now deprecated) synonyms are `SHOW INNODB STATUS` for `SHOW ENGINE INNODB STATUS` and `SHOW MUTEX STATUS` for `SHOW ENGINE INNODB MUTEX`.

In MySQL 5.1, `SHOW ENGINE INNODB MUTEX` is invoked as `SHOW MUTEX STATUS`. The latter statement displays similar information but in a somewhat different output format.

`SHOW ENGINE BDB LOGS` formerly displayed status information about `BDB` log files. The `BDB` storage engine is not supported, and this statement produces a warning.

`SHOW ENGINE INNODB STATUS` displays extensive information from the standard `InnoDB` Monitor about the state of the `InnoDB` storage engine. For information about the standard monitor and other `InnoDB` Monitors that provide information about `InnoDB` processing, see [Section 13.6.13.2, “SHOW ENGINE INNODB STATUS and the InnoDB Monitors”](#).

`SHOW ENGINE INNODB MUTEX` displays `InnoDB` mutex statistics. The statement displays the following output fields:

- **Type**

Always `InnoDB`.

- **Name**

The source file where the mutex is implemented, and the line number in the file where the mutex is created. The line number may change depending on your version of MySQL.

- **Status**

This field displays the same values as previously described (`count`, `spin_waits`, `spin_rounds`, `os_waits`, `os_yields`, `os_wait_times`), but only if `UNIV_DEBUG` was defined at MySQL compilation time (for example, in `include/univ.h` in the `InnoDB` part of the MySQL source tree). If `UNIV_DEBUG` was not defined, the statement displays only the `os_waits` value. In the latter case (without `UNIV_DEBUG`), the information on which the output is based is insufficient to distinguish regular mutexes and mutexes that protect rw-locks (which allow multiple readers or a single writer). Consequently, the output may appear to contain multiple rows for the same mutex.

Information from this statement can be used to diagnose system problems. For example, large values of `spin_waits` and `spin_rounds` may indicate scalability problems.

If the server has the `NDBCLUSTER` storage engine enabled, `SHOW ENGINE NDB STATUS` displays cluster status information such as the number of connected data nodes, the cluster connectstring, and cluster binlog epochs, as well as counts of various Cluster API objects created by the MySQL Server when connected to the cluster. Sample output from this statement is shown here:

```
mysql> SHOW ENGINE NDB STATUS;
+-----+-----+-----+
| Type | Name | Status |
+-----+-----+-----+
| ndbcluster | connection | cluster_node_id=7,
connected_host=192.168.0.103, connected_port=1186, number_of_data_nodes=4,
number_of_ready_data_nodes=3, connect_count=0 |
| ndbcluster | NdbTransaction | created=6, free=0, sizeof=212 |
| ndbcluster | NdbOperation | created=8, free=8, sizeof=660 |
| ndbcluster | NdbIndexScanOperation | created=1, free=1, sizeof=744 |
| ndbcluster | NdbIndexOperation | created=0, free=0, sizeof=664 |
| ndbcluster | NdbRecAttr | created=1285, free=1285, sizeof=60 |
| ndbcluster | NdbApiSignal | created=16, free=16, sizeof=136 |
| ndbcluster | NdbLabel | created=0, free=0, sizeof=196 |
| ndbcluster | NdbBranch | created=0, free=0, sizeof=24 |
| ndbcluster | NdbSubroutine | created=0, free=0, sizeof=68 |
| ndbcluster | NdbCall | created=0, free=0, sizeof=16 |
| ndbcluster | NdbBlob | created=1, free=1, sizeof=264 |
| ndbcluster | NdbReceiver | created=4, free=0, sizeof=68 |
| ndbcluster | binlog | latest_epoch=155467, latest_trans_epoch=148126,
latest_received_binlog_epoch=0, latest_handled_binlog_epoch=0,
latest_applied_binlog_epoch=0 |
+-----+-----+-----+
```

The `Status` column in each of these rows provides information about the MySQL server's connection to the cluster and about the cluster binary log's status, respectively. The `Status` information is in the form of comma-delimited set of name/value pairs.

The `connection` row's `Status` column contains the name/value pairs described in the following table.

Name	Value
<code>cluster_node_id</code>	The node ID of the MySQL server in the cluster
<code>connected_host</code>	The host name or IP address of the cluster management server to which the MySQL server is connected
<code>connected_port</code>	The port used by the MySQL server to connect to the management server (<code>connected_host</code>)
<code>number_of_data_nodes</code>	The number of data nodes configured for the cluster (that is, the number of <code>[ndbd]</code> sections in the cluster <code>config.ini</code> file)
<code>number_of_ready_data_nodes</code>	The number of data nodes in the cluster that are actually running

<code>connect_count</code>	The number of times this <code>mysqld</code> has connected or reconnected to cluster data nodes
----------------------------	---

The `binlog` row's `Status` column contains information relating to MySQL Cluster Replication. The name/value pairs it contains are described in the following table.

Name	Value
<code>latest_epoch</code>	The most recent epoch most recently run on this MySQL server (that is, the sequence number of the most recent transaction run on the server)
<code>latest_trans_epoch</code>	The most recent epoch processed by the cluster's data nodes
<code>latest_received_binlog_epoch</code>	The most recent epoch received by the binlog thread
<code>latest_handled_binlog_epoch</code>	The most recent epoch processed by the binlog thread (for writing to the binlog)
<code>latest_applied_binlog_epoch</code>	The most recent epoch actually written to the binlog

See [MySQL Cluster Replication](#), for more information.

The remaining rows from the output of `SHOW ENGINE NDB STATUS` which are most likely to prove useful in monitoring the cluster are listed here by `Name`:

- `NdbTransaction`: The number and size of `NdbTransaction` objects that have been created. An `NdbTransaction` is created each time a table schema operation (such as `CREATE TABLE` or `ALTER TABLE`) is performed on an `NDB` table.
- `NdbOperation`: The number and size of `NdbOperation` objects that have been created.
- `NdbIndexScanOperation`: The number and size of `NdbIndexScanOperation` objects that have been created.
- `NdbIndexOperation`: The number and size of `NdbIndexOperation` objects that have been created.
- `NdbRecAttr`: The number and size of `NdbRecAttr` objects that have been created. In general, one of these is created each time a data manipulation statement is performed by an SQL node.
- `NdbBlob`: The number and size of `NdbBlob` objects that have been created. An `NdbBlob` is created for each new operation involving a `BLOB` column in an `NDB` table.
- `NdbReceiver`: The number and size of any `NdbReceiver` object that have been created. The number in the `created` column is the same as the number of data nodes in the cluster to which the MySQL server has connected.

Note

`SHOW ENGINE NDB STATUS` returns an empty result if no operations involving `NDB` tables have been performed during the current session by the MySQL client accessing the SQL node on which this statement is run.

MySQL Enterprise

The `SHOW ENGINE engine_name STATUS` statement provides valuable information about the state of your server. For expert interpretation of this information, subscribe to the MySQL Enterprise Monitor. For more information, see <http://www.mysql.com/products/enterprise/advisors.html>.

12.5.5.17. SHOW ENGINES Syntax

```
SHOW [STORAGE] ENGINES
```

`SHOW ENGINES` displays status information about the server's storage engines. This is particularly useful for checking whether a storage engine is supported, or to see what the default engine is. `SHOW TABLE TYPES` is a deprecated synonym.

```
mysql> SHOW ENGINES\G
***** 1. row *****
  Engine: MEMORY
  Support: YES
  Comment: Hash based, stored in memory, useful for temporary tables
  Transactions: NO
    XA: NO
  Savepoints: NO
***** 2. row *****
  Engine: MyISAM
  Support: DEFAULT
```

```

Comment: Default engine as of MySQL 3.23 with great performance
Transactions: NO
  XA: NO
Savepoints: NO
***** 3. row *****
Engine: InnoDB
Support: YES
Comment: Supports transactions, row-level locking, and foreign keys
Transactions: YES
  XA: YES
Savepoints: YES
***** 4. row *****
Engine: EXAMPLE
Support: YES
Comment: Example storage engine
Transactions: NO
  XA: NO
Savepoints: NO
***** 5. row *****
Engine: ARCHIVE
Support: YES
Comment: Archive storage engine
Transactions: NO
  XA: NO
Savepoints: NO
***** 6. row *****
Engine: CSV
Support: YES
Comment: CSV storage engine
Transactions: NO
  XA: NO
Savepoints: NO
***** 7. row *****
Engine: BLACKHOLE
Support: YES
Comment: /dev/null storage engine (anything you write »
to it disappears)
Transactions: NO
  XA: NO
Savepoints: NO
***** 8. row *****
Engine: FEDERATED
Support: YES
Comment: Federated MySQL storage engine
Transactions: NO
  XA: NO
Savepoints: NO
***** 9. row *****
Engine: MRG_MYISAM
Support: YES
Comment: Collection of identical MyISAM tables
Transactions: NO
  XA: NO
Savepoints: NO

```

The output from `SHOW ENGINES` may vary according to the MySQL version used and other factors. The values shown in the `Support` column indicate the server's level of support for the storage engine, as shown in the following table.

Value	Meaning
YES	The engine is supported and is active
DEFAULT	Like YES, plus this is the default engine
NO	The engine is not supported
DISABLED	The engine is supported but has been disabled

A value of `NO` means that the server was compiled without support for the engine, so it cannot be activated at runtime.

A value of `DISABLED` occurs either because the server was started with an option that disables the engine, or because not all options required to enable it were given. In the latter case, the error log file should contain a reason indicating why the option is disabled. See [Section 5.2.2, “The Error Log”](#).

You might also see `DISABLED` for a storage engine if the server was compiled to support it, but was started with a `--skip-engine_name` option. For the `NDBCLUSTER` storage engine, `DISABLED` means the server was compiled with support for MySQL Cluster, but was not started with the `--ndbcluster` option.

All MySQL servers support `MyISAM` tables, because `MyISAM` is the default storage engine. It is not possible to disable `MyISAM`.

The `Transactions`, `XA`, and `Savepoints` columns indicate whether the storage engine supports transactions, XA transactions, and savepoints, respectively.

12.5.5.18. SHOW ERRORS Syntax

```
SHOW ERRORS [LIMIT [offset,] row_count]
```

```
SHOW COUNT(*) ERRORS
```

This statement is similar to `SHOW WARNINGS`, except that instead of displaying errors, warnings, and notes, it displays only errors.

The `LIMIT` clause has the same syntax as for the `SELECT` statement. See [Section 12.2.8, “SELECT Syntax”](#).

The `SHOW COUNT(*) ERRORS` statement displays the number of errors. You can also retrieve this number from the `error_count` variable:

```
SHOW COUNT(*) ERRORS;
SELECT @@error_count;
```

For more information, see [Section 12.5.5.41, “SHOW WARNINGS Syntax”](#).

12.5.5.19. SHOW EVENTS Syntax

```
SHOW EVENTS [{FROM | IN} schema_name]
             [LIKE 'pattern' | WHERE expr]
```

In its simplest form, `SHOW EVENTS` lists all of the events in the current schema:

```
mysql> SELECT CURRENT_USER(), SCHEMA();
+-----+-----+
| CURRENT_USER() | SCHEMA() |
+-----+-----+
| jon@ghidora    | myschema |
+-----+-----+
1 row in set (0.00 sec)

mysql> SHOW EVENTS\G
***** 1. row *****
      Db: myschema
      Name: e_daily
      Definer: jon@ghidora
      Time zone: SYSTEM
      Type: RECURRING
      Execute at: NULL
      Interval value: 10
      Interval field: SECOND
      Starts: 2006-02-09 10:41:23
      Ends: 0000-00-00 00:00:00
      Status: ENABLED
      Originator: 0
character_set_client: latin1
collation_connection: latin1_swedish_ci
Database Collation: latin1_swedish_ci
```

The `LIKE` clause, if present, indicates which event names to match. The `WHERE` clause can be given to select rows using more general conditions, as discussed in [Section 19.28, “Extensions to SHOW Statements”](#).

The columns in the output of `SHOW EVENTS` — which are similar to, but not identical to the columns in the `INFORMATION_SCHEMA.EVENTS` table — are shown here:

- **Db:** The schema (database) on which the event is defined.
- **Name:** The name of the event.
- **Time zone:** The time zone in effect when schedule for the event was last modified. If the event's schedule has not been modified since the event was created, then this is the time zone that was in effect at the event's creation. The default value is `SYSTEM`.
- **Definer:** The user account (`user_name@host_name`) which created the event.
- **Type:** One of the two values `ONE TIME` (transient) or `RECURRING`.
- **Execute At:** The date and time when a transient event is set to execute. Shown as a `DATETIME` value.
For a recurring event, the value of this column is always `NULL`.
- **Interval Value:** For a recurring event, the number of intervals to wait between event executions.
For a transient event, the value of this column is always `NULL`.
- **Interval Field:** The time units used for the interval which a recurring event waits before repeating.

For a transient event, the value of this column is always `NULL`.

- **Starts:** The start date and time for a recurring event. This is displayed as a `DATETIME` value, and is empty if no start date and time are defined for the event.

For a transient event, the value of this column is always `NULL`.

- **Ends:** The end date and time for a recurring event. This is displayed as a `DATETIME` value, and defaults to `'0000-00-00 00:00:00'` if no end date and time is defined for the event.

For a transient event, the value of this column is always `NULL`.

- **Status:** The event status. One of `ENABLED`, `DISABLED`, or `SLAVESIDE_DISABLED`.

`SLAVESIDE_DISABLED` indicates that the creation of the event occurred on another MySQL server acting as a replication master and replicated to the current MySQL server which is acting as a slave, but the event is not presently being executed on the slave.

- **Originator:** The server ID of the MySQL server on which the event was created. Defaults to 0.
- **character_set_client** is the session value of the `character_set_client` system variable when the routine was created. **collation_connection** is the session value of the `collation_connection` system variable when the routine was created. **Database Collation** is the collation of the database with which the routine is associated.

For more information about `SLAVE_DISABLED` and the `Originator` column, see [Section 16.3.1.7, “Replication of Invoked Features”](#).

Note that the action statement is not shown in the output of `SHOW EVENTS`.

These times are all given in terms of local time as determined by the MySQL server's `time_zone` setting. See also [Section 19.20, “The INFORMATION_SCHEMA EVENTS Table”](#).

To see events for a different schema, you can use the `FROM` clause. For example, if the `test` schema had been selected in the preceding example, you could view events defined on `myschema` using the following statement:

```
SHOW EVENTS FROM myschema;
```

You can filter the list returned by this statement on the event name using `LIKE` plus a pattern.

See also [Section 19.20, “The INFORMATION_SCHEMA EVENTS Table”](#).

12.5.5.20. SHOW FUNCTION CODE Syntax

```
SHOW FUNCTION CODE func_name
```

This statement is similar to `SHOW PROCEDURE CODE` but for stored functions. See [Section 12.5.5.29, “SHOW PROCEDURE CODE Syntax”](#).

12.5.5.21. SHOW FUNCTION STATUS Syntax

```
SHOW FUNCTION STATUS
[LIKE 'pattern' | WHERE expr]
```

This statement is similar to `SHOW PROCEDURE STATUS` but for stored functions. See [Section 12.5.5.30, “SHOW PROCEDURE STATUS Syntax”](#).

12.5.5.22. SHOW GRANTS Syntax

```
SHOW GRANTS [FOR user]
```

This statement lists the `GRANT` statement or statements that must be issued to duplicate the privileges that are granted to a MySQL user account. The account is named using the same format as for the `GRANT` statement; for example, `'jef-frey'@'localhost'`. If you specify only the user name part of the account name, a host name part of `'%'` is used. For additional information about specifying account names, see [Section 12.5.1.3, “GRANT Syntax”](#).

```
mysql> SHOW GRANTS FOR 'root'@'localhost';
+-----+
| Grants for root@localhost |
```

```
+-----+
| GRANT ALL PRIVILEGES ON *.* TO 'root'@'localhost' WITH GRANT OPTION |
+-----+
```

To list the privileges granted to the account that you are using to connect to the server, you can use any of the following statements:

```
SHOW GRANTS;
SHOW GRANTS FOR CURRENT_USER;
SHOW GRANTS FOR CURRENT_USER();
```

If `SHOW GRANTS FOR CURRENT_USER` (or any of the equivalent syntaxes) is used in `DEFINER` context, such as within a stored procedure that is defined with `SQL SECURITY DEFINER`, the grants displayed are those of the definer and not the invoker.

`SHOW GRANTS` displays only the privileges granted explicitly to the named account. Other privileges might be available to the account, but they are not displayed. For example, if an anonymous account exists, the named account might be able to use its privileges, but `SHOW GRANTS` will not display them.

`SHOW GRANTS` requires the `SELECT` privilege for the `mysql` database.

12.5.5.23. SHOW INDEX Syntax

```
SHOW {INDEX | INDEXES | KEYS}
     {FROM | IN} tbl_name
     [{FROM | IN} db_name]
```

`SHOW INDEX` returns table index information. The format resembles that of the `SQLStatistics` call in ODBC.

`SHOW INDEX` returns the following fields:

- `Table`
The name of the table.
- `Non_unique`
0 if the index cannot contain duplicates, 1 if it can.
- `Key_name`
The name of the index.
- `Seq_in_index`
The column sequence number in the index, starting with 1.
- `Column_name`
The column name.
- `Collation`
How the column is sorted in the index. In MySQL, this can have values “A” (Ascending) or `NULL` (Not sorted).
- `Cardinality`
An estimate of the number of unique values in the index. This is updated by running `ANALYZE TABLE` or `myisamchk -a`. `Cardinality` is counted based on statistics stored as integers, so the value is not necessarily exact even for small tables. The higher the cardinality, the greater the chance that MySQL uses the index when doing joins.
- `Sub_part`
The number of indexed characters if the column is only partly indexed, `NULL` if the entire column is indexed.
- `Packed`
Indicates how the key is packed. `NULL` if it is not.
- `Null`
Contains `YES` if the column may contain `NULL`. If not, the column contains `NO`.

Contains **YES** if the column may contain **NULL** values and **' '** if not.

- **Index_type**

The index method used (**BTREE**, **FULLTEXT**, **HASH**, **RTREE**).

- **Comment**

Various remarks.

You can use `db_name.tbl_name` as an alternative to the `tbl_name FROM db_name` syntax. These two statements are equivalent:

```
SHOW INDEX FROM mytable FROM mydb;
SHOW INDEX FROM mydb.mytable;
```

You can also list a table's indexes with the `mysqlshow -k db_name tbl_name` command.

12.5.5.24. SHOW INNODB STATUS Syntax

```
SHOW INNODB STATUS
```

In MySQL 5.4, this is a deprecated synonym for `SHOW ENGINE INNODB STATUS`. See [Section 12.5.5.16, “SHOW ENGINE Syntax”](#).

12.5.5.25. SHOW MASTER STATUS Syntax

```
SHOW MASTER STATUS
```

Provides status information about the binary log files of the master. Example:

```
mysql> SHOW MASTER STATUS;
+-----+-----+-----+-----+
| File           | Position | Binlog_Do_DB | Binlog_Ignore_DB |
+-----+-----+-----+-----+
| mysql-bin.003  | 73       | test         | manual,mysql      |
+-----+-----+-----+-----+
```

12.5.5.26. SHOW OPEN TABLES Syntax

```
SHOW OPEN TABLES [{FROM | IN} db_name]
[LIKE 'pattern' | WHERE expr]
```

`SHOW OPEN TABLES` lists the non-**TEMPORARY** tables that are currently open in the table cache. See [Section 7.4.7, “How MySQL Opens and Closes Tables”](#). The **FROM** clause, if present, restricts the tables shown to those present in the `db_name` database. The **LIKE** clause, if present, indicates which table names to match. The **WHERE** clause can be given to select rows using more general conditions, as discussed in [Section 19.28, “Extensions to SHOW Statements”](#).

`SHOW OPEN TABLES` returns the following columns:

- **Database**

The database containing the table.

- **Table**

The table name.

- **In_use**

The number of table locks or lock requests there are for the table. For example, if one client acquires a lock for a table using `LOCK TABLE t1 WRITE`, **In_use** will be 1. If another client issues `LOCK TABLE t1 WRITE` while the table remains locked, the client will block waiting for the lock, but the lock request causes **In_use** to be 2. If the count is zero, the table is open but not currently being used. **In_use** is also increased by the `HANDLER ... OPEN` statement and decreased by `HANDLER ... CLOSE`.

- **Name_locked**

Whether the table name is locked. Name locking is used for operations such as dropping or renaming tables.

12.5.5.27. SHOW PLUGINS Syntax

```
SHOW PLUGINS
```

`SHOW PLUGINS` displays information about known plugins.

```
mysql> SHOW PLUGINS;
+-----+-----+-----+-----+
| Name           | Status | Type           | Library |
+-----+-----+-----+-----+
| MEMORY         | ACTIVE | STORAGE ENGINE | NULL    |
| MyISAM         | ACTIVE | STORAGE ENGINE | NULL    |
| InnoDB         | ACTIVE | STORAGE ENGINE | NULL    |
| ARCHIVE        | ACTIVE | STORAGE ENGINE | NULL    |
| CSV            | ACTIVE | STORAGE ENGINE | NULL    |
| BLACKHOLE      | ACTIVE | STORAGE ENGINE | NULL    |
| FEDERATED      | ACTIVE | STORAGE ENGINE | NULL    |
| MRG_MYISAM     | ACTIVE | STORAGE ENGINE | NULL    |
+-----+-----+-----+-----+
```

12.5.5.28. SHOW PRIVILEGES Syntax

```
SHOW PRIVILEGES
```

`SHOW PRIVILEGES` shows the list of system privileges that the MySQL server supports. The exact list of privileges depends on the version of your server.

```
mysql> SHOW PRIVILEGES\G
***** 1. row *****
Privilege: Alter
Context: Tables
Comment: To alter the table
***** 2. row *****
Privilege: Alter routine
Context: Functions,Procedures
Comment: To alter or drop stored functions/procedures
***** 3. row *****
Privilege: Create
Context: Databases,Tables,Indexes
Comment: To create new databases and tables
***** 4. row *****
Privilege: Create routine
Context: Functions,Procedures
Comment: To use CREATE FUNCTION/PROCEDURE
***** 5. row *****
Privilege: Create temporary tables
Context: Databases
Comment: To use CREATE TEMPORARY TABLE
...
```

Privileges belonging to a specific user are displayed by the `SHOW GRANTS` statement. See [Section 12.5.5.22, “SHOW GRANTS Syntax”](#), for more information.

12.5.5.29. SHOW PROCEDURE CODE Syntax

```
SHOW PROCEDURE CODE proc_name
```

This statement is a MySQL extension that is available only for servers that have been built with debugging support. It displays a representation of the internal implementation of the named stored procedure. A similar statement, `SHOW FUNCTION CODE`, displays information about stored functions (see [Section 12.5.5.20, “SHOW FUNCTION CODE Syntax”](#)).

Both statements require that you be the owner of the routine or have `SELECT` access to the `mysql.proc` table.

If the named routine is available, each statement produces a result set. Each row in the result set corresponds to one “instruction” in the routine. The first column is `Pos`, which is an ordinal number beginning with 0. The second column is `Instruction`, which contains an SQL statement (usually changed from the original source), or a directive which has meaning only to the stored-routine handler.

```
mysql> DELIMITER //
mysql> CREATE PROCEDURE p1 ()
-> BEGIN
->   DECLARE fanta INT DEFAULT 55;
->   DROP TABLE t2;
->   LOOP
->     INSERT INTO t3 VALUES (fanta);
```

```

->      END LOOP;
->      END//
Query OK, 0 rows affected (0.00 sec)

mysql> SHOW PROCEDURE CODE p1//
+-----+-----+
| Pos | Instruction |
+-----+-----+
| 0   | set fanta@0 55 |
| 1   | stmt 9 "DROP TABLE t2" |
| 2   | stmt 5 "INSERT INTO t3 VALUES (fanta)" |
| 3   | jump 2 |
+-----+-----+
4 rows in set (0.00 sec)

```

In this example, the non-executable `BEGIN` and `END` statements have disappeared, and for the `DECLARE variable_name` statement, only the executable part appears (the part where the default is assigned). For each statement that is taken from source, there is a code word `stmt` followed by a type (9 means `DROP`, 5 means `INSERT`, and so on). The final row contains an instruction `jump 2`, meaning `GOTO instruction #2`.

12.5.5.30. SHOW PROCEDURE STATUS Syntax

```

SHOW PROCEDURE STATUS
[LIKE 'pattern' | WHERE expr]

```

This statement is a MySQL extension. It returns characteristics of a stored procedure, such as the database, name, type, creator, creation and modification dates, and character set information. A similar statement, `SHOW FUNCTION STATUS`, displays information about stored functions (see [Section 12.5.5.21](#), “`SHOW FUNCTION STATUS Syntax`”).

The `LIKE` clause, if present, indicates which procedure or function names to match. The `WHERE` clause can be given to select rows using more general conditions, as discussed in [Section 19.28](#), “`Extensions to SHOW Statements`”.

```

mysql> SHOW PROCEDURE STATUS LIKE 'sp1'\G
***** 1. row *****
      Db: test
      Name: sp1
      Type: PROCEDURE
      Definer: testuser@localhost
      Modified: 2004-08-03 15:29:37
      Created: 2004-08-03 15:29:37
      Security_type: DEFINER
      Comment:
character_set_client: latin1
collation_connection: latin1_swedish_ci
Database Collation: latin1_swedish_ci

```

`character_set_client` is the session value of the `character_set_client` system variable when the routine was created. `collation_connection` is the session value of the `collation_connection` system variable when the routine was created. `Database Collation` is the collation of the database with which the routine is associated.

You can also get information about stored routines from the `ROUTINES` table in `INFORMATION_SCHEMA`. See [Section 19.14](#), “`The INFORMATION_SCHEMA ROUTINES Table`”.

12.5.5.31. SHOW PROCESSLIST Syntax

```

SHOW [FULL] PROCESSLIST

```

`SHOW PROCESSLIST` shows you which threads are running. You can also get this information from the `INFORMATION_SCHEMA PROCESSLIST` table or the `mysqladmin processlist` command. If you have the `PROCESS` privilege, you can see all threads. Otherwise, you can see only your own threads (that is, threads associated with the MySQL account that you are using). If you do not use the `FULL` keyword, only the first 100 characters of each statement are shown in the `Info` field.

MySQL Enterprise

Subscribers to MySQL Enterprise Monitor receive instant notification and expert advice on resolution when there are too many concurrent processes. For more information, see <http://www.mysql.com/products/enterprise/advisors.html>.

This statement is very useful if you get the “too many connections” error message and want to find out what is going on. MySQL reserves one extra connection to be used by accounts that have the `SUPER` privilege, to ensure that administrators should always be able to connect and check the system (assuming that you are not giving this privilege to all your users).

Threads can be killed with the `KILL` statement. See [Section 12.5.6.4](#), “`KILL Syntax`”.

Here is an example of what `SHOW PROCESSLIST` output looks like:

```

mysql> SHOW FULL PROCESSLIST\G

```

```

***** 1. row *****
Id: 1
User: system user
Host:
db: NULL
Command: Connect
Time: 1030455
State: Waiting for master to send event
Info: NULL
***** 2. row *****
Id: 2
User: system user
Host:
db: NULL
Command: Connect
Time: 1004
State: Has read all relay log; waiting for the slave
      I/O thread to update it
Info: NULL
***** 3. row *****
Id: 3112
User: replikator
Host: artemis:2204
db: NULL
Command: Binlog Dump
Time: 2144
State: Has sent all binlog to slave; waiting for binlog to be updated
Info: NULL
***** 4. row *****
Id: 3113
User: replikator
Host: iconnect2:45781
db: NULL
Command: Binlog Dump
Time: 2086
State: Has sent all binlog to slave; waiting for binlog to be updated
Info: NULL
***** 5. row *****
Id: 3123
User: stefan
Host: localhost
db: apollon
Command: Query
Time: 0
State: NULL
Info: SHOW FULL PROCESSLIST
5 rows in set (0.00 sec)

```

The columns have the following meaning:

- **Id**

The connection identifier.

- **User**

The MySQL user who issued the statement. If this is `system user`, it refers to a non-client thread spawned by the server to handle tasks internally. This could be the I/O or SQL thread used on replication slaves or a delayed-row handler. `unauthenticated user` refers to a thread that has become associated with a client connection but for which authentication of the client user has not yet been done. `event_scheduler` refers to the thread that monitors scheduled events. For `system user` or `event_scheduler`, there is no host specified in the `Host` column.

- **Host**

The host name of the client issuing the statement (except for `system user` where there is no host). `SHOW PROCESSLIST` reports the host name for TCP/IP connections in `host_name:client_port` format to make it easier to determine which client is doing what.

- **db**

The default database, if one is selected, otherwise `NULL`.

- **Command**

The type of command the thread is executing. Descriptions for thread commands can be found at [Section 7.5.6, “Examining Thread Information”](#). The value of this column corresponds to the `COM_xxx` commands of the client/server protocol. See [Section 5.1.6, “Server Status Variables”](#)

- **Time**

The time in seconds that the thread has been in its current state.

- **State**

An action, event, or state that indicates what the thread is doing. Descriptions for *State* values can be found at [Section 7.5.6, “Examining Thread Information”](#).

Most states correspond to very quick operations. If a thread stays in a given state for many seconds, there might be a problem that needs to be investigated.

For the `SHOW PROCESSLIST` statement, the value of *State* is `NULL`.

- **Info**

The statement that the thread is executing, or `NULL` if it is not executing any statement. The statement might be the one sent to the server, or an innermost statement if the statement executes other statements. For example, if a `CALL p1()` statement executes a stored procedure `p1()`, and the procedure is executing a `SELECT` statement, the *Info* value shows the `SELECT` statement.

12.5.5.32. SHOW PROFILE Syntax

```
SHOW PROFILES
```

The `SHOW PROFILE` statement display profiling information that indicates resource usage for statements executed during the course of the current session. It is used together with `SHOW PROFILES`; see [Section 12.5.5.33, “SHOW PROFILES Syntax”](#).

12.5.5.33. SHOW PROFILES Syntax

```
SHOW PROFILE [type [, type] ... ]
  [FOR QUERY n]
  [LIMIT row_count [OFFSET offset]]

type:
  ALL
  BLOCK IO
  CONTEXT SWITCHES
  CPU
  IPC
  MEMORY
  PAGE FAULTS
  SOURCE
  SWAPS
```

The `SHOW PROFILES` and `SHOW PROFILE` statements display profiling information that indicates resource usage for statements executed during the course of the current session.

Profiling is controlled by the `profiling` session variable, which has a default value of 0 (`OFF`). Profiling is enabled by setting `profiling` to 1 or `ON`:

```
mysql> SET profiling = 1;
```

`SHOW PROFILES` displays a list of the most recent statements sent to the master. The size of the list is controlled by the `profiling_history_size` session variable, which has a default value of 15. The maximum value is 100. Setting the value to 0 has the practical effect of disabling profiling.

All statements are profiled except `SHOW PROFILES` and `SHOW PROFILE`, so you will find neither of those statements in the profile list. Malformed statements are profiled. For example, `SHOW PROFILING` is an illegal statement, and a syntax error occurs if you try to execute it, but it will show up in the profiling list.

`SHOW PROFILE` displays detailed information about a single statement. Without the `FOR QUERY n` clause, the output pertains to the most recently executed statement. If `FOR QUERY n` is included, `SHOW PROFILE` displays information for statement *n*. The values of *n* correspond to the `Query_ID` values displayed by `SHOW PROFILES`.

The `LIMIT row_count` clause may be given to limit the output to *row_count* rows. If `LIMIT` is given, `OFFSET offset` may be added to begin the output *offset* rows into the full set of rows.

By default, `SHOW PROFILE` displays `Status` and `Duration` columns. The `Status` values are like the `State` values displayed by `SHOW PROCESSLIST`, although there might be some minor differences in interpretation for the two statements for some status values (see [Section 7.5.6, “Examining Thread Information”](#)).

Optional *type* values may be specified to display specific additional types of information:

- `ALL` displays all information

- `BLOCK IO` displays counts for block input and output operations
- `CONTEXT SWITCHES` displays counts for voluntary and involuntary context switches
- `CPU` displays user and system CPU usage times
- `IPC` displays counts for messages sent and received
- `MEMORY` is not currently implemented
- `PAGE FAULTS` displays counts for major and minor page faults
- `SOURCE` displays the names of functions from the source code, together with the name and line number of the file in which the function occurs
- `SWAPS` displays swap counts

Profiling is enabled per session. When a session ends, its profiling information is lost.

```
mysql> SELECT @@profiling;
+-----+
| @@profiling |
+-----+
|           0 |
+-----+
1 row in set (0.00 sec)

mysql> SET profiling = 1;
Query OK, 0 rows affected (0.00 sec)

mysql> DROP TABLE IF EXISTS t1;
Query OK, 0 rows affected, 1 warning (0.00 sec)

mysql> CREATE TABLE T1 (id INT);
Query OK, 0 rows affected (0.01 sec)

mysql> SHOW PROFILES;
+-----+-----+-----+
| Query_ID | Duration | Query
+-----+-----+-----+
|         0 | 0.000088 | SET PROFILING = 1
|         1 | 0.000136 | DROP TABLE IF EXISTS t1
|         2 | 0.011947 | CREATE TABLE t1 (id INT)
+-----+-----+-----+
3 rows in set (0.00 sec)

mysql> SHOW PROFILE;
+-----+-----+
| Status | Duration |
+-----+-----+
| checking permissions | 0.000040 |
| creating table | 0.000056 |
| After create | 0.011363 |
| query end | 0.000375 |
| freeing items | 0.000089 |
| logging slow query | 0.000019 |
| cleaning up | 0.000005 |
+-----+-----+
7 rows in set (0.00 sec)

mysql> SHOW PROFILE FOR QUERY 1;
+-----+-----+
| Status | Duration |
+-----+-----+
| query end | 0.000107 |
| freeing items | 0.000008 |
| logging slow query | 0.000015 |
| cleaning up | 0.000006 |
+-----+-----+
4 rows in set (0.00 sec)

mysql> SHOW PROFILE CPU FOR QUERY 2;
+-----+-----+-----+-----+
| Status | Duration | CPU_user | CPU_system |
+-----+-----+-----+-----+
| checking permissions | 0.000040 | 0.000038 | 0.000002 |
| creating table | 0.000056 | 0.000028 | 0.000028 |
| After create | 0.011363 | 0.000217 | 0.001571 |
| query end | 0.000375 | 0.000013 | 0.000028 |
| freeing items | 0.000089 | 0.000010 | 0.000014 |
| logging slow query | 0.000019 | 0.000009 | 0.000010 |
| cleaning up | 0.000005 | 0.000003 | 0.000002 |
+-----+-----+-----+-----+
7 rows in set (0.00 sec)
```

Note

Profiling is only partially functional on some architectures. For values that depend on the `getrusage()` system call, `NULL` is returned on systems such as Windows that do not support the call. In addition, profiling is per process and not per thread. This means that activity on threads within the server other than your own may affect the timing information that you see.

You can also get profiling information from the `PROFILING` table in `INFORMATION_SCHEMA`. See Section 19.26, “The `INFORMATION_SCHEMA PROFILING Table`”. For example, the following queries produce the same result:

```
SHOW PROFILE FOR QUERY 2;

SELECT STATE, FORMAT(DURATION, 6) AS DURATION
FROM INFORMATION_SCHEMA.PROFILING
WHERE QUERY_ID = 2 ORDER BY SEQ;
```

12.5.5.34. SHOW SLAVE HOSTS Syntax

```
SHOW SLAVE HOSTS
```

Displays a list of replication slaves currently registered with the master. Only slaves started with the `--report-host=host_name` option are visible in this list.

The list is displayed on any server (not just the master server). The output looks like this:

```
mysql> SHOW SLAVE HOSTS;
+-----+-----+-----+-----+
| Server_id | Host      | Port | Master_id |
+-----+-----+-----+-----+
| 192168010 | iconnect2 | 3306 | 192168011 |
| 1921680101 | athena    | 3306 | 192168011 |
+-----+-----+-----+-----+
```

- **Server_id**: The unique server ID of the slave server, as configured in the server's option file, or on the command line with `--server-id=value`.
- **Host**: The host name of the slave server, as configured in the server's option file, or on the command line with `--report-host=host_name`. Note that this can differ from the machine name as configured in the operating system.
- **Port**: The port the slave server is listening on.
- **Master_id**: The unique server ID of the master server that the slave server is replicating from.

Some MySQL versions report another variable, `Rpl_recovery_rank`. This variable was never used, and was eventually removed.

12.5.5.35. SHOW SLAVE STATUS Syntax

```
SHOW SLAVE STATUS
```

This statement provides status information on essential parameters of the slave threads. If you issue this statement using the `mysql` client, you can use a `\G` statement terminator rather than a semicolon to obtain a more readable vertical layout:

```
mysql> SHOW SLAVE STATUS\G
***** 1. row *****
      Slave_IO_State: Waiting for master to send event
      Master_Host: localhost
      Master_User: root
      Master_Port: 3306
      Connect_Retry: 3
      Master_Log_File: gbichot-bin.005
      Read_Master_Log_Pos: 79
      Relay_Log_File: gbichot-relay-bin.005
      Relay_Log_Pos: 548
      Relay_Master_Log_File: gbichot-bin.005
      Slave_IO_Running: Yes
      Slave_SQL_Running: Yes
      Replicate_Do_DB:
      Replicate_Ignore_DB:
      Last_Errno: 0
      Last_Error:
      Skip_Counter: 0
      Exec_Master_Log_Pos: 79
      Relay_Log_Space: 552
      Until_Condition: None
      Until_Log_File:
      Until_Log_Pos: 0
      Master_SSL_Allowed: No
```

```

Master_SSL_CA_File:
Master_SSL_CA_Path:
Master_SSL_Cert:
Master_SSL_Cipher:
Master_SSL_Key:
Seconds_Behind_Master: 8
Master_SSL_Verify_Server_Cert: No
Last_IO_Errno: 0
Last_IO_Error:
Last_SQL_Errno: 0
Last_SQL_Error:

```

`SHOW SLAVE STATUS` returns the following fields:

- `Slave_IO_State`

A copy of the `State` field of the output of `SHOW PROCESSLIST` for the slave I/O thread. This tells you what the thread is doing: trying to connect to the master, waiting for events from the master, reconnecting to the master, and so on. Possible states are listed in [Section 16.4.1, “Replication Implementation Details”](#). It is necessary to check this field for older versions of MySQL which allowed the thread to continue running while unsuccessfully trying to connect to the master. If it is running, there is no problem; if it is not, you can find the error in the `Last_Error` field (described below).

- `Master_Host`

The current master host.

- `Master_User`

The current user used to connect to the master.

- `Master_Port`

The current master port.

- `Connect_Retry`

The number of seconds between connect retries (default 60). This may be set with the `CHANGE MASTER TO` statement or `--master-connect-retry` option.

- `Master_Log_File`

The name of the master binary log file from which the I/O thread is currently reading.

- `Read_Master_Log_Pos`

The position up to which the I/O thread has read in the current master binary log.

- `Relay_Log_File`

The name of the relay log file from which the SQL thread is currently reading and executing.

- `Relay_Log_Pos`

The position up to which the SQL thread has read and executed in the current relay log.

- `Relay_Master_Log_File`

The name of the master binary log file containing the most recent event executed by the SQL thread.

- `Slave_IO_Running`

Whether the I/O thread is started and has connected successfully to the master. Internally, the state of this thread is represented by one of 3 values; these are shown with their meanings in the following list:

- `MYSQL_SLAVE_NOT_RUN`. The slave I/O thread is not running.
- `MYSQL_SLAVE_RUN_NOT_CONNECT`. The slave I/O thread is running, but is not connected to a replication master.
- `MYSQL_SLAVE_RUN_CONNECT`. The slave I/O thread is running, and is connected to a replication master.

Different values are displayed for `Slave_IO_running` depending on the slave I/O thread's actual state and the version of MySQL used on the replication slave, as shown in the following table.

MySQL Version	MYSQL_SLAVE_NOT_RUN	MYSQL_SLAVE_RUN_NOT_CONNECT
4.1 (4.1.13 and earlier); 5.0 (5.0.11 and earlier)	No	Yes
4.1 (4.1.14 and later); 5.0 (5.0.12 and later)	No	No
5.1, 5.4 (all)	No	No
6.0 (6.0.10 and earlier)	No	No
6.0 (6.0.11 and later)	No	Connecting

- `Slave_SQL_Running`

Whether the SQL thread is started.

- `Replicate_Do_DB`, `Replicate_Ignore_DB`

The lists of databases that were specified with the `--replicate-do-db` and `--replicate-ignore-db` options, if any.

- `Replicate_Do_Table`, `Replicate_Ignore_Table`, `Replicate_Wild_Do_Table`, `Replicate_Wild_Ignore_Table`

The lists of tables that were specified with the `--replicate-do-table`, `--replicate-ignore-table`, `--replicate-wild-do-table`, and `--replicate-wild-ignore-table` options, if any.

- `Last_Errno`, `Last_Error`

These columns are aliases for `Last_SQL_Errno` and `Last_SQL_Error`.

Issuing `RESET MASTER` or `RESET SLAVE` resets the values shown in these columns.

Note

When the slave SQL thread receives an error, it reports the error first, then stops the SQL thread. This means that there is a small window of time during which `SHOW SLAVE STATUS` shows a nonzero value for `Last_Errno` even though `Slave_SQL_Running` still displays `Yes`.

- `Skip_Counter`

The most recently used value for `SQL_SLAVE_SKIP_COUNTER`.

- `Exec_Master_Log_Pos`

The position of the last event executed by the SQL thread from the master's binary log (`Relay_Master_Log_File`). (`Relay_Master_Log_File`, `Exec_Master_Log_Pos`) in the master's binary log corresponds to (`Relay_Log_File`, `Relay_Log_Pos`) in the relay log.

- `Relay_Log_Space`

The total combined size of all existing relay logs.

- `Until_Condition`, `Until_Log_File`, `Until_Log_Pos`

The values specified in the `UNTIL` clause of the `START SLAVE` statement.

`Until_Condition` has these values:

- `None` if no `UNTIL` clause was specified
- `Master` if the slave is reading until a given position in the master's binary logs
- `Relay` if the slave is reading until a given position in its relay logs

`Until_Log_File` and `Until_Log_Pos` indicate the log file name and position values that define the point at which the

SQL thread stops executing.

- `Master_SSL_Allowed`, `Master_SSL_CA_File`, `Master_SSL_CA_Path`, `Master_SSL_Cert`, `Master_SSL_Cipher`, `Master_SSL_Key`

These fields show the SSL parameters used by the slave to connect to the master, if any.

`Master_SSL_Allowed` has these values:

- `Yes` if an SSL connection to the master is permitted
- `No` if an SSL connection to the master is not permitted
- `Ignored` if an SSL connection is permitted but the slave server does not have SSL support enabled

The values of the other SSL-related fields correspond to the values of the `MASTER_SSL_CA`, `MASTER_SSL_CAPATH`, `MASTER_SSL_CERT`, `MASTER_SSL_CIPHER`, `MASTER_SSL_KEY`, and `MASTER_SSL_VERIFY_SERVER_CERT` options to the `CHANGE MASTER TO` statement. See [Section 12.6.2.1, “CHANGE MASTER TO Syntax”](#).

- `Seconds_Behind_Master`

This field is an indication of how “late” the slave is:

- When the slave SQL thread is actively running (processing updates), this field is the number of seconds that have elapsed since the timestamp of the most recent event on the master executed by that thread.
- When the SQL thread has caught up to the slave I/O thread and goes idle waiting for more events from the I/O thread, this field is zero.

In essence, this field measures the time difference in seconds between the slave SQL thread and the slave I/O thread.

If the network connection between master and slave is fast, the slave I/O thread is very close to the master, so this field is a good approximation of how late the slave SQL thread is compared to the master. If the network is slow, this is *not* a good approximation; the slave SQL thread may quite often be caught up with the slow-reading slave I/O thread, so `Seconds_Behind_Master` often shows a value of 0, even if the I/O thread is late compared to the master. In other words, *this column is useful only for fast networks*.

This time difference computation works even though the master and slave do not have identical clocks (the clock difference is computed when the slave I/O thread starts, and assumed to remain constant from then on). `Seconds_Behind_Master` is `NULL` (which means “unknown”) if the slave SQL thread is not running, or if the slave I/O thread is not running or not connected to master. For example if the slave I/O thread is sleeping for the number of seconds given by the `CHANGE MASTER TO` statement or `--master-connect-retry` option (default 60) before reconnecting, `NULL` is shown, as the slave cannot know what the master is doing, and so cannot say reliably how late it is.

This field has one limitation. The timestamp is preserved through replication, which means that, if a master M1 is itself a slave of M0, any event from M1's binlog which originates in replicating an event from M0's binlog has the timestamp of that event. This enables MySQL to replicate `TIMESTAMP` successfully. However, the problem for `Seconds_Behind_Master` is that if M1 also receives direct updates from clients, the value randomly deviates, because sometimes the last M1's event is from M0 and sometimes it is the most recent timestamp from a direct update.

- `Last_IO_Errno`, `Last_IO_Error`

The error number and error message of the last error that caused the I/O thread to stop. An error number of 0 and message of the empty string mean “no error.” If the `Last_IO_Error` value is not empty, it also appears as a message in the slave's error log.

Issuing `RESET MASTER` or `RESET SLAVE` resets the values shown in these columns.

- `Last_SQL_Errno`, `Last_SQL_Error`

The error number and error message of the last error that caused the SQL thread to stop. An error number of 0 and message of the empty string mean “no error.” If the `Last_IO_Error` value is not empty, it also appears as a message in the slave's error log.

Example:

```
Last_SQL_Errno: 1051
Last_SQL_Error: error 'Unknown table 'z'' on query 'drop table z'
```

The message indicates that the table `z` existed on the master and was dropped there, but it did not exist on the slave, so `DROP TABLE` failed on the slave. (This might occur, for example, if you forget to copy the table to the slave when setting up replica-

tion.)

Issuing `RESET MASTER` or `RESET SLAVE` resets the values shown in these columns.

12.5.5.36. SHOW STATUS Syntax

```
SHOW [GLOBAL | SESSION] STATUS
     [LIKE 'pattern' | WHERE expr]
```

`SHOW STATUS` provides server status information. This information also can be obtained using the `mysqladmin extended-status` command. The `LIKE` clause, if present, indicates which variable names to match. The `WHERE` clause can be given to select rows using more general conditions, as discussed in Section 19.28, “Extensions to `SHOW` Statements”.

Partial output is shown here. The list of names and values may be different for your server. The meaning of each variable is given in Section 5.1.6, “Server Status Variables”.

```
mysql> SHOW STATUS;
+-----+-----+
| Variable_name | Value |
+-----+-----+
| Aborted_clients | 0 |
| Aborted_connects | 0 |
| Bytes_received | 155372598 |
| Bytes_sent | 1176560426 |
| Connections | 30023 |
| Created_tmp_disk_tables | 0 |
| Created_tmp_tables | 8340 |
| Created_tmp_files | 60 |
| .. | .. |
| Open_tables | 1 |
| Open_files | 2 |
| Open_streams | 0 |
| Opened_tables | 44600 |
| Questions | 2026873 |
| .. | .. |
| Table_locks_immediate | 1920382 |
| Table_locks_waited | 0 |
| Threads_cached | 0 |
| Threads_created | 30022 |
| Threads_connected | 1 |
| Threads_running | 1 |
| Uptime | 80380 |
+-----+-----+
```

With a `LIKE` clause, the statement displays only rows for those variables with names that match the pattern:

```
mysql> SHOW STATUS LIKE 'Key%';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| Key_blocks_used | 14955 |
| Key_read_requests | 96854827 |
| Key_reads | 162040 |
| Key_write_requests | 7589728 |
| Key_writes | 3813196 |
+-----+-----+
```

With the `GLOBAL` modifier, `SHOW STATUS` displays the status values for all connections to MySQL. With `SESSION`, it displays the status values for the current connection. If no modifier is present, the default is `SESSION`. `LOCAL` is a synonym for `SESSION`.

Some status variables have only a global value. For these, you get the same value for both `GLOBAL` and `SESSION`. The scope for each status variable is listed at Section 5.1.6, “Server Status Variables”.

MySQL Enterprise

Status variables provide valuable clues to the state of your servers. For expert interpretation of the information provided by status variables, subscribe to the MySQL Enterprise Monitor. For more information, see <http://www.mysql.com/products/enterprise/advisors.html>.

12.5.5.37. SHOW TABLE STATUS Syntax

```
SHOW TABLE STATUS [{FROM | IN} db_name]
     [LIKE 'pattern' | WHERE expr]
```

`SHOW TABLE STATUS` works like `SHOW TABLES`, but provides a lot of information about each non-`TEMPORARY` table. You can also get this list using the `mysqlshow --status db_name` command. The `LIKE` clause, if present, indicates which table names to match. The `WHERE` clause can be given to select rows using more general conditions, as discussed in Section 19.28, “Extensions to `SHOW` Statements”.

This statement also displays information about views.

`SHOW TABLE STATUS` returns the following fields:

- `Name`
The name of the table.
- `Engine`
The storage engine for the table. See [Chapter 13, Storage Engines](#).
- `Version`
The version number of the table's `.frm` file.
- `Row_format`
The row storage format (`Fixed`, `Dynamic`, `Compressed`, `Redundant`, `Compact`). The format of `InnoDB` tables is reported as `Redundant` or `Compact`.
- `Rows`
The number of rows. Some storage engines, such as `MyISAM`, store the exact count. For other storage engines, such as `InnoDB`, this value is an approximation, and may vary from the actual value by as much as 40 to 50%. In such cases, use `SELECT COUNT(*)` to obtain an accurate count.

The `Rows` value is `NULL` for tables in the `INFORMATION_SCHEMA` database.
- `Avg_row_length`
The average row length.
- `Data_length`
The length of the data file.
- `Max_data_length`
The maximum length of the data file. This is the total number of bytes of data that can be stored in the table, given the data pointer size used.
- `Index_length`
The length of the index file.
- `Data_free`
The number of allocated but unused bytes.

This information is also shown for `InnoDB` tables (previously, it was in the `Comment` value). `InnoDB` tables report the free space of the tablespace to which the table belongs. For a table located in the shared tablespace, this is the free space of the shared tablespace. If you are using multiple tablespaces and the table has its own tablespace, the free space is for only that table. Free space means the number of completely free 1MB extents minus a safety margin. Even if free space displays as 0, it may be possible to insert rows as long as new extents need not be allocated.

For partitioned tables, this value is only an estimate and may not be absolutely correct. A more accurate method of obtaining this information in such cases is to query the `INFORMATION_SCHEMA.PARTITIONS` table, as shown in this example:

```
SELECT SUM(DATA_FREE)
FROM INFORMATION_SCHEMA.PARTITIONS
WHERE TABLE_SCHEMA = 'mydb'
AND TABLE_NAME = 'mytable';
```

For more information, see [Section 19.19, “The INFORMATION_SCHEMA PARTITIONS Table”](#).

- `Auto_increment`
The next `AUTO_INCREMENT` value.
- `Create_time`

When the table was created.

- `Update_time`

When the data file was last updated. For some storage engines, this value is `NULL`. For example, `InnoDB` stores multiple tables in its tablespace and the data file timestamp does not apply. For `MyISAM`, the data file timestamp is used; however, on Windows the timestamp is not updated by updates so the value is inaccurate.

- `Check_time`

When the table was last checked. Not all storage engines update this time, in which case the value is always `NULL`.

- `Collation`

The table's character set and collation.

- `Checksum`

The live checksum value (if any).

- `Create_options`

Extra options used with `CREATE TABLE`. The original options supplied when `CREATE TABLE` is called are retained and the options reported here may differ from the active table settings and options.

- `Comment`

The comment used when creating the table (or information as to why MySQL could not access the table information).

For `MEMORY` tables, the `Data_length`, `Max_data_length`, and `Index_length` values approximate the actual amount of allocated memory. The allocation algorithm reserves memory in large amounts to reduce the number of allocation operations.

For `NDBCLUSTER` tables, the output of this statement shows appropriate values for the `Avg_row_length` and `Data_length` columns, with the exception that `BLOB` columns are not taken into account.

For views, all the fields displayed by `SHOW TABLE STATUS` are `NULL` except that `Name` indicates the view name and `Comment` says `view`.

12.5.5.38. SHOW TABLES Syntax

```
SHOW [FULL] TABLES [{FROM | IN} db_name]
[LIKE 'pattern' | WHERE expr]
```

`SHOW TABLES` lists the non-`TEMPORARY` tables in a given database. You can also get this list using the `mysqlshow db_name` command. The `LIKE` clause, if present, indicates which table names to match. The `WHERE` clause can be given to select rows using more general conditions, as discussed in Section 19.28, “Extensions to SHOW Statements”.

This statement also lists any views in the database. The `FULL` modifier is supported such that `SHOW FULL TABLES` displays a second output column. Values for the second column are `BASE TABLE` for a table and `VIEW` for a view.

If you have no privileges for a base table or view, it does not show up in the output from `SHOW TABLES` or `mysqlshow db_name`.

12.5.5.39. SHOW TRIGGERS Syntax

```
SHOW TRIGGERS [{FROM | IN} db_name]
[LIKE 'pattern' | WHERE expr]
```

`SHOW TRIGGERS` lists the triggers currently defined for tables in a database (the default database unless a `FROM` clause is given). This statement requires the `TRIGGER` privilege. The `LIKE` clause, if present, indicates which table names to match and causes the statement to display triggers for those tables. The `WHERE` clause can be given to select rows using more general conditions, as discussed in Section 19.28, “Extensions to SHOW Statements”.

For the trigger `ins_sum` as defined in Section 18.3, “Using Triggers”, the output of this statement is as shown here:

```
mysql> SHOW TRIGGERS LIKE 'acc%' \G
***** 1. row *****
Trigger: ins_sum
Event: INSERT
Table: account
```

```

Statement: SET @sum = @sum + NEW.amount
Timing: BEFORE
Created: NULL
sql_mode:
Definer: myname@localhost
character_set_client: latin1
collation_connection: latin1_swedish_ci
Database Collation: latin1_swedish_ci

```

`character_set_client` is the session value of the `character_set_client` system variable when the trigger was created. `collation_connection` is the session value of the `collation_connection` system variable when the trigger was created. `Database Collation` is the collation of the database with which the trigger is associated.

Note

When using a `LIKE` clause with `SHOW TRIGGERS`, the expression to be matched (*expr*) is compared with the name of the table on which the trigger is declared, and not with the name of the trigger:

```

mysql> SHOW TRIGGERS LIKE 'ins%';
Empty set (0.01 sec)

```

A brief explanation of the columns in the output of this statement is shown here:

- **Trigger**
The name of the trigger.
- **Event**
The event that causes trigger activation: one of 'INSERT', 'UPDATE', or 'DELETE'.
- **Table**
The table for which the trigger is defined.
- **Statement**
The statement to be executed when the trigger is activated. This is the same as the text shown in the `ACTION_STATEMENT` column of `INFORMATION_SCHEMA.TRIGGERS`.
- **Timing**
One of the two values 'BEFORE' or 'AFTER'.
- **Created**
Currently, the value of this column is always `NULL`.
- **sql_mode**
The SQL mode in effect when the trigger executes.
- **Definer**
The account that created the trigger.

See also [Section 19.16, “The INFORMATION_SCHEMA TRIGGERS Table”](#).

12.5.5.40. SHOW VARIABLES Syntax

```

SHOW [GLOBAL | SESSION] VARIABLES
[LIKE 'pattern' | WHERE expr]

```

`SHOW VARIABLES` shows the values of MySQL system variables. This information also can be obtained using the `mysqladmin variables` command. The `LIKE` clause, if present, indicates which variable names to match. The `WHERE` clause can be given to select rows using more general conditions, as discussed in [Section 19.28, “Extensions to SHOW Statements”](#).

With the `GLOBAL` modifier, `SHOW VARIABLES` displays the values that are used for new connections to MySQL. With `SESSION`, it displays the values that are in effect for the current connection. If no modifier is present, the default is `SESSION`. `LOCAL` is a synonym for `SESSION`.

If the default system variable values are unsuitable, you can set them using command options when `mysqld` starts, and most can be changed at runtime with the `SET` statement. See [Section 5.1.5, “Using System Variables”](#), and [Section 12.5.4, “SET Syntax”](#).

Partial output is shown here. The list of names and values may be different for your server. [Section 5.1.3, “Server System Variables”](#), describes the meaning of each variable, and [Section 7.5.3, “Tuning Server Parameters”](#), provides information about tuning them.

```
mysql> SHOW VARIABLES;
```

Variable_name	Value
auto_increment_increment	1
auto_increment_offset	1
automatic_sp_privileges	ON
back_log	50
basedir	/home/jon/bin/mysql-5.1/
binlog_cache_size	32768
bulk_insert_buffer_size	8388608
character_set_client	latin1
character_set_connection	latin1
...	
max_user_connections	0
max_write_lock_count	4294967295
multi_range_count	256
mysam_data_pointer_size	6
mysam_max_sort_file_size	2147483647
mysam_recover_options	OFF
mysam_repair_threads	1
mysam_sort_buffer_size	8388608
ndb_autoincrement_prefetch_sz	32
ndb_cache_check_time	0
ndb_force_send	ON
...	
time_zone	SYSTEM
timed_mutexes	OFF
tmp_table_size	33554432
tmpdir	
transaction_alloc_block_size	8192
transaction_prealloc_size	4096
tx_isolation	REPEATABLE-READ
updatable_views_with_limit	YES
version	5.1.6-alpha-log
version_comment	Source distribution
version_compile_machine	i686
version_compile_os	suse-linux
wait_timeout	28800

With a `LIKE` clause, the statement displays only rows for those variables with names that match the pattern. To obtain the row for a specific variable, use a `LIKE` clause as shown:

```
SHOW VARIABLES LIKE 'max_join_size';
SHOW SESSION VARIABLES LIKE 'max_join_size';
```

To get a list of variables whose name match a pattern, use the “%” wildcard character in a `LIKE` clause:

```
SHOW VARIABLES LIKE '%size%';
SHOW GLOBAL VARIABLES LIKE '%size%';
```

Wildcard characters can be used in any position within the pattern to be matched. Strictly speaking, because “_” is a wildcard that matches any single character, you should escape it as “_” to match it literally. In practice, this is rarely necessary.

12.5.5.41. SHOW WARNINGS Syntax

```
SHOW WARNINGS [LIMIT [offset,] row_count]
SHOW COUNT(*) WARNINGS
```

`SHOW WARNINGS` shows the error, warning, and note messages that resulted from the last statement that generated messages in the current session. It shows nothing if the last statement used a table and generated no messages. (That is, a statement that uses a table but generates no messages clears the message list.) Statements that do not use tables and do not generate messages have no effect on the message list.

Warnings are generated for DML statements such as `INSERT`, `UPDATE`, and `LOAD DATA INFILE` as well as DDL statements such as `CREATE TABLE` and `ALTER TABLE`.

A related statement, `SHOW ERRORS`, shows only the errors. See [Section 12.5.5.18, “SHOW ERRORS Syntax”](#).

The `SHOW COUNT(*) WARNINGS` statement displays the total number of errors, warnings, and notes. You can also retrieve this number from the `warning_count` variable:

```
SHOW COUNT(*) WARNINGS;
SELECT @@warning_count;
```

The value of `warning_count` might be greater than the number of messages displayed by `SHOW WARNINGS` if the `max_error_count` system variable is set so low that not all messages are stored. An example shown later in this section demonstrates how this can happen.

The `LIMIT` clause has the same syntax as for the `SELECT` statement. See [Section 12.2.8, “SELECT Syntax”](#).

The MySQL server sends back the total number of errors, warnings, and notes resulting from the last statement. If you are using the C API, this value can be obtained by calling `mysql_warning_count()`. See [Section 20.10.3.72, “mysql_warning_count\(\)”](#).

The following `DROP TABLE` statement results in a note:

```
mysql> DROP TABLE IF EXISTS no_such_table;
mysql> SHOW WARNINGS;
+-----+-----+-----+
| Level | Code | Message |
+-----+-----+-----+
| Note  | 1051 | Unknown table 'no_such_table' |
+-----+-----+-----+
```

Here is a simple example that shows a syntax warning for `CREATE TABLE` and conversion warnings for `INSERT`:

```
mysql> CREATE TABLE t1 (a TINYINT NOT NULL, b CHAR(4)) TYPE=MyISAM;
Query OK, 0 rows affected, 1 warning (0.00 sec)
mysql> SHOW WARNINGS\G
***** 1. row *****
Level: Warning
Code: 1287
Message: 'TYPE=storage_engine' is deprecated, use
'ENGINE=storage_engine' instead
1 row in set (0.00 sec)

mysql> INSERT INTO t1 VALUES(10,'mysql'),(NULL,'test'),
-> (300,'Open Source');
Query OK, 3 rows affected, 4 warnings (0.01 sec)
Records: 3 Duplicates: 0 Warnings: 4

mysql> SHOW WARNINGS\G
***** 1. row *****
Level: Warning
Code: 1265
Message: Data truncated for column 'b' at row 1
***** 2. row *****
Level: Warning
Code: 1263
Message: Data truncated, NULL supplied to NOT NULL column 'a' at row 2
***** 3. row *****
Level: Warning
Code: 1264
Message: Data truncated, out of range for column 'a' at row 3
***** 4. row *****
Level: Warning
Code: 1265
Message: Data truncated for column 'b' at row 3
4 rows in set (0.00 sec)
```

The maximum number of error, warning, and note messages to store is controlled by the `max_error_count` system variable. By default, its value is 64. To change the number of messages you want stored, change the value of `max_error_count`. In the following example, the `ALTER TABLE` statement produces three warning messages, but only one is stored because `max_error_count` has been set to 1:

```
mysql> SHOW VARIABLES LIKE 'max_error_count';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| max_error_count | 64 |
+-----+-----+
1 row in set (0.00 sec)

mysql> SET max_error_count=1;
Query OK, 0 rows affected (0.00 sec)

mysql> ALTER TABLE t1 MODIFY b CHAR;
Query OK, 3 rows affected, 3 warnings (0.00 sec)
Records: 3 Duplicates: 0 Warnings: 3

mysql> SELECT @@warning_count;
+-----+
| @@warning_count |
+-----+
| 3 |
+-----+
1 row in set (0.01 sec)
```

```
mysql> SHOW WARNINGS;
+-----+-----+-----+
| Level | Code | Message                                     |
+-----+-----+-----+
| Warning | 1263 | Data truncated for column 'b' at row 1 |
+-----+-----+-----+
1 row in set (0.00 sec)
```

To disable warnings, set `max_error_count` to 0. In this case, `warning_count` still indicates how many warnings have occurred, but none of the messages are stored.

You can set the `sql_notes` session variable to 0 to cause `Note`-level warnings not to be recorded.

12.5.6. Other Administrative Statements

12.5.6.1. BINLOG Syntax

```
BINLOG 'str'
```

`BINLOG` is an internal-use statement. It is generated by the `mysqlbinlog` program as the printable representation of certain events in binary log files. (See [Section 4.6.7, “mysqlbinlog — Utility for Processing Binary Log Files”](#).) The `'str'` value is a base 64-encoded string that the server decodes to determine the data change indicated by the corresponding event. This statement requires the `SUPER` privilege.

12.5.6.2. CACHE INDEX Syntax

```
CACHE INDEX
tbl_index_list [, tbl_index_list] ...
IN key_cache_name

tbl_index_list:
tbl_name [[INDEX|KEY] (index_name[, index_name] ...)]
```

The `CACHE INDEX` statement assigns table indexes to a specific key cache. It is used only for `MyISAM` tables.

The following statement assigns indexes from the tables `t1`, `t2`, and `t3` to the key cache named `hot_cache`:

```
mysql> CACHE INDEX t1, t2, t3 IN hot_cache;
+-----+-----+-----+-----+
| Table | Op           | Msg_type | Msg_text |
+-----+-----+-----+-----+
| test.t1 | assign_to_keycache | status   | OK       |
| test.t2 | assign_to_keycache | status   | OK       |
| test.t3 | assign_to_keycache | status   | OK       |
+-----+-----+-----+-----+
```

The syntax of `CACHE INDEX` enables you to specify that only particular indexes from a table should be assigned to the cache. The current implementation assigns all the table's indexes to the cache, so there is no reason to specify anything other than the table name.

The key cache referred to in a `CACHE INDEX` statement can be created by setting its size with a parameter setting statement or in the server parameter settings. For example:

```
mysql> SET GLOBAL keycache1.key_buffer_size=128*1024;
```

Key cache parameters can be accessed as members of a structured system variable. See [Section 5.1.5.1, “Structured System Variables”](#).

A key cache must exist before you can assign indexes to it:

```
mysql> CACHE INDEX t1 IN non_existent_cache;
ERROR 1284 (HY000): Unknown key cache 'non_existent_cache'
```

By default, table indexes are assigned to the main (default) key cache created at the server startup. When a key cache is destroyed, all indexes assigned to it become assigned to the default key cache again.

Index assignment affects the server globally: If one client assigns an index to a given cache, this cache is used for all queries involving the index, no matter which client issues the queries.

12.5.6.3. FLUSH Syntax

```
FLUSH [NO_WRITE_TO_BINLOG | LOCAL]
flush_option [, flush_option] ...
```

The `FLUSH` statement clears or reloads various internal caches used by MySQL. To execute `FLUSH`, you must have the `RELOAD` privilege.

The `RESET` statement is similar to `FLUSH`. See [Section 12.5.6.6, “RESET Syntax”](#).

`flush_option` can be any of the following:

- `DES_KEY_FILE`

Reloads the DES keys from the file that was specified with the `--des-key-file` option at server startup time.

- `HOSTS`

Empties the host cache tables. You should flush the host tables if some of your hosts change IP number or if you get the error message `Host 'host_name' is blocked`. When more than `max_connect_errors` errors occur successively for a given host while connecting to the MySQL server, MySQL assumes that something is wrong and blocks the host from further connection requests. Flushing the host tables enables further connection attempts from the host. See [Section B.1.2.6, “Host 'host_name' is blocked”](#). You can start `mysqld` with `--max_connect_errors=999999999` to avoid this error message.

- `LOGS`

Closes and reopens all log files. If binary logging is enabled, the sequence number of the binary log file is incremented by one relative to the previous file. On Unix, this is the same thing as sending a `SIGHUP` signal to the `mysqld` server (except on some Mac OS X 10.3 versions where `mysqld` ignores `SIGHUP` and `SIGQUIT`).

If the server is writing error output to a named file (for example, if it was started with the `--log-error` option), `FLUSH LOGS` causes it to rename the current error log file with a suffix of `-old` and create a new empty log file. No renaming occurs if the server is not writing to a named file (for example, if it is writing errors to the console).

- `MASTER (DEPRECATED)`. Deletes all binary logs, resets the binary log index file and creates a new binary log. `FLUSH MASTER` is deprecated in favor of `RESET MASTER`, and is supported for backward compatibility only. See [Section 12.6.1.2, “RESET MASTER Syntax”](#).

- `PRIVILEGES`

Reloads the privileges from the grant tables in the `mysql` database. On Unix, this also occurs if the server receives a `SIGHUP` signal.

The server caches information in memory as a result of `GRANT`, `CREATE USER`, `CREATE SERVER`, and `INSTALL PLUGIN` statements. This memory is not released by the corresponding `REVOKE`, `DROP USER`, `DROP SERVER`, and `UNINSTALL PLUGIN` statements, so for a server that executes many instances of the statements that cause caching, there will be an increase in memory use. This cached memory can be freed with `FLUSH PRIVILEGES`.

- `QUERY CACHE`

Defragment the query cache to better utilize its memory. `FLUSH QUERY CACHE` does not remove any queries from the cache, unlike `FLUSH TABLES` or `RESET QUERY CACHE`.

- `SLAVE (DEPRECATED)`. Resets all replication slave parameters, including relay log files and replication position in the master's binary logs. `FLUSH SLAVE` is deprecated in favor of `RESET SLAVE`, and is supported for backward compatibility only. See [Section 12.6.2.5, “RESET SLAVE Syntax”](#).

- `STATUS`

This option adds the current thread's session status variable values to the global values and resets the session values to zero. It also resets the counters for key caches (default and named) to zero and sets `Max_used_connections` to the current number of open connections. This is something you should use only when debugging a query. See [Section 1.6, “How to Report Bugs or Problems”](#).

- `{TABLE | TABLES} [tbl_name [, tbl_name] ...]`

When no tables are named, closes all open tables, forces all tables in use to be closed, and flushes the query cache. With one or more table names, flushes only the given tables. `FLUSH TABLES` also removes all query results from the query cache, like the `RESET QUERY CACHE` statement. No error occurs if a named table does not exist.

- `TABLES WITH READ LOCK`

Closes all open tables and locks all tables for all databases with a read lock until you explicitly release the lock by executing

`UNLOCK TABLES`. This is very convenient way to get backups if you have a file system such as Veritas that can take snapshots in time.

`FLUSH TABLES WITH READ LOCK` acquires a global read lock and not table locks, so it is not subject to the same behavior as `LOCK TABLES` and `UNLOCK TABLES` with respect to table locking and implicit commits:

- `UNLOCK TABLES` implicitly commits any active transaction only if any tables currently have been locked with `LOCK TABLES`. The commit does not occur for `UNLOCK TABLES` following `FLUSH TABLES WITH READ LOCK` because the latter statement does not acquire table locks.
- Beginning a transaction causes table locks acquired with `LOCK TABLES` to be released, as though you had executed `UNLOCK TABLES`. Beginning a transaction does not release a global read lock acquired with `FLUSH TABLES WITH READ LOCK`.

`FLUSH TABLES WITH READ LOCK` does not prevent the server from inserting rows into the log tables (see [Section 5.2.1, “Selecting General Query and Slow Query Log Output Destinations”](#)).

- `USER_RESOURCES`

Resets all per-hour user resources to zero. This enables clients that have reached their hourly connection, query, or update limits to resume activity immediately. `FLUSH USER_RESOURCES` does not apply to the limit on maximum simultaneous connections. See [Section 12.5.1.3, “GRANT Syntax”](#).

By default, `FLUSH` statements are written to the binary log so that they will be replicated to replication slaves. Logging can be suppressed with the optional `NO_WRITE_TO_BINLOG` keyword or its alias `LOCAL`.

See also [Section 12.5.6.6, “RESET Syntax”](#), for information about how the `RESET` statement is used with replication.

Note

`FLUSH LOGS`, `FLUSH MASTER`, `FLUSH SLAVE`, and `FLUSH TABLES WITH READ LOCK` are not written to the binary log in any case because they would cause problems if replicated to a slave.

The `mysqladmin` utility provides a command-line interface to some flush operations, via the `flush-hosts`, `flush-logs`, `flush-privileges`, `flush-status`, and `flush-tables` commands.

Note

It is not possible in MySQL 5.4 to issue `FLUSH` statements within stored functions or triggers. However, you may use `FLUSH` in stored procedures, so long as these are not called from stored functions or triggers. See [Section D.1, “Restrictions on Stored Routines, Triggers, and Events”](#).

12.5.6.4. KILL Syntax

```
KILL [CONNECTION | QUERY] thread_id
```

Each connection to `mysqld` runs in a separate thread. You can see which threads are running with the `SHOW PROCESSLIST` statement and kill a thread with the `KILL thread_id` statement.

`KILL` allows the optional `CONNECTION` or `QUERY` modifier:

- `KILL CONNECTION` is the same as `KILL` with no modifier: It terminates the connection associated with the given *thread_id*.
- `KILL QUERY` terminates the statement that the connection is currently executing, but leaves the connection itself intact.

If you have the `PROCESS` privilege, you can see all threads. If you have the `SUPER` privilege, you can kill all threads and statements. Otherwise, you can see and kill only your own threads and statements.

You can also use the `mysqladmin processlist` and `mysqladmin kill` commands to examine and kill threads.

Note

You cannot use `KILL` with the Embedded MySQL Server library, because the embedded server merely runs inside the threads of the host application. It does not create any connection threads of its own.

When you use `KILL`, a thread-specific kill flag is set for the thread. In most cases, it might take some time for the thread to die, be-

cause the kill flag is checked only at specific intervals:

- In `SELECT`, `ORDER BY` and `GROUP BY` loops, the flag is checked after reading a block of rows. If the kill flag is set, the statement is aborted.
- During `ALTER TABLE`, the kill flag is checked before each block of rows are read from the original table. If the kill flag was set, the statement is aborted and the temporary table is deleted.
- During `UPDATE` or `DELETE` operations, the kill flag is checked after each block read and after each updated or deleted row. If the kill flag is set, the statement is aborted. Note that if you are not using transactions, the changes are not rolled back.
- `GET_LOCK()` aborts and returns `NULL`.
- An `INSERT DELAYED` thread quickly flushes (inserts) all rows it has in memory and then terminates.
- If the thread is in the table lock handler (state: `Locked`), the table lock is quickly aborted.
- If the thread is waiting for free disk space in a write call, the write is aborted with a “disk full” error message.

Warning

Killing a `REPAIR TABLE` or `OPTIMIZE TABLE` operation on a `MyISAM` table results in a table that is corrupted and unusable. Any reads or writes to such a table fail until you optimize or repair it again (without interruption).

12.5.6.5. LOAD INDEX INTO CACHE Syntax

```
LOAD INDEX INTO CACHE
  tbl_index_list [, tbl_index_list] ...

tbl_index_list:
  tbl_name
  [[INDEX|KEY] (index_name[, index_name] ...)]
  [IGNORE LEAVES]
```

The `LOAD INDEX INTO CACHE` statement preloads a table index into the key cache to which it has been assigned by an explicit `CACHE INDEX` statement, or into the default key cache otherwise. `LOAD INDEX INTO CACHE` is used only for `MyISAM` tables. It is not supported for tables having user-defined partitioning (see [Section 17.5, “Restrictions and Limitations on Partitioning”](#)).

The `IGNORE LEAVES` modifier causes only blocks for the non-leaf nodes of the index to be preloaded.

The following statement preloads nodes (index blocks) of indexes for the tables `t1` and `t2`:

```
mysql> LOAD INDEX INTO CACHE t1, t2 IGNORE LEAVES;
+-----+-----+-----+-----+
| Table | Op           | Msg_type | Msg_text |
+-----+-----+-----+-----+
| test.t1 | preload_keys | status   | OK       |
| test.t2 | preload_keys | status   | OK       |
+-----+-----+-----+-----+
```

This statement preloads all index blocks from `t1`. It preloads only blocks for the non-leaf nodes from `t2`.

The syntax of `LOAD INDEX INTO CACHE` enables you to specify that only particular indexes from a table should be preloaded. The current implementation preloads all the table's indexes into the cache, so there is no reason to specify anything other than the table name.

`LOAD INDEX INTO CACHE ... IGNORE LEAVES` fails unless all indexes in a table have the same block size. You can determine index block sizes for a table by using `myisamchk -dv` and checking the `Blocksize` column.

12.5.6.6. RESET Syntax

```
RESET reset_option [, reset_option] ...
```

The `RESET` statement is used to clear the state of various server operations. You must have the `RELOAD` privilege to execute `RESET`.

`RESET` acts as a stronger version of the `FLUSH` statement. See [Section 12.5.6.3, “FLUSH Syntax”](#).

`reset_option` can be any of the following:

- **MASTER**
Deletes all binary logs listed in the index file, resets the binary log index file to be empty, and creates a new binary log file.
- **QUERY CACHE**
Removes all query results from the query cache.
- **SLAVE**
Makes the slave forget its replication position in the master binary logs. Also resets the relay log by deleting any existing relay log files and beginning a new one.

12.6. Replication Statements

This section describes SQL statements related to replication. One group of statements is used for controlling master servers. The other is used for controlling slave servers.

12.6.1. SQL Statements for Controlling Master Servers

Replication can be controlled through the SQL interface. This section discusses statements for managing master replication servers. [Section 12.6.2, “SQL Statements for Controlling Slave Servers”](#), discusses statements for managing slave servers.

The following **SHOW** statements are used with master servers in replication:

- **SHOW BINARY LOGS**
- **SHOW BINLOG EVENTS**
- **SHOW MASTER STATUS**
- **SHOW SLAVE HOSTS**

For information about these statements, see [Section 12.5.5, “SHOW Syntax”](#).

12.6.1.1. PURGE BINARY LOGS Syntax

```
PURGE { BINARY | MASTER } LOGS
      { TO 'log_name' | BEFORE datetime_expr }
```

The binary log is a set of files that contain information about data modifications made by the MySQL server. The log consists of a set of binary log files, plus an index file.

The **PURGE BINARY LOGS** statement deletes all the binary log files listed in the log index file prior to the specified log file name or date. The log files also are removed from the list recorded in the index file, so that the given log file becomes the first.

This statement has no effect if the `--log-bin` option has not been enabled.

Examples:

```
PURGE BINARY LOGS TO 'mysql-bin.010';
PURGE BINARY LOGS BEFORE '2008-04-02 22:46:26';
```

The **BEFORE** variant's *datetime_expr* argument should evaluate to a **DATETIME** value (a value in `'YYYY-MM-DD hh:mm:ss'` format). **BINARY** and **MASTER** are synonyms.

This statement is safe to run while slaves are replicating. You do not need to stop them. If you have an active slave that currently is reading one of the logs you are trying to delete, this statement does nothing and fails with an error. However, if a slave is dormant and you happen to purge one of the logs it has yet to read, the slave will be unable to replicate after it comes up.

To safely purge logs, follow this procedure:

1. On each slave server, use **SHOW SLAVE STATUS** to check which log it is reading.
2. Obtain a listing of the binary logs on the master server with **SHOW BINARY LOGS**.
3. Determine the earliest log among all the slaves. This is the target log. If all the slaves are up to date, this is the last log on the

list.

4. Make a backup of all the logs you are about to delete. (This step is optional, but always advisable.)
5. Purge all logs up to but not including the target log.

You can also set the `expire_logs_days` system variable to expire binary log files automatically after a given number of days (see [Section 5.1.3, “Server System Variables”](#)). If you are using replication, you should set the variable no lower than the maximum number of days your slaves might lag behind the master.

`PURGE BINARY LOGS TO` and `PURGE BINARY LOGS BEFORE` both fail with an error when binary log files listed in the `.index` file had been removed from the system by some other means (such as using `rm` on Linux). ([Bug#18199](#), [Bug#18453](#)) You can handle such errors by editing the `.index` file (which is a simple text file) manually and insuring that it lists only the binary log files that are actually present, then running again the `PURGE BINARY LOGS` statement that failed.

12.6.1.2. RESET MASTER Syntax

```
RESET MASTER
```

Deletes all binary logs listed in the index file, resets the binary log index file to be empty, and creates a new binary log file. It is intended to be used only when the master is started for the first time.

Important

This effects of this statement differ from those of `PURGE BINARY LOGS` in 2 key ways:

1. `RESET MASTER` removes *all* binary logs that are listed in the index file, leaving only a single, empty binary log file named `master-bin.000001`, whereas the numbering is not reset by `PURGE BINARY LOGS`.
2. `RESET MASTER` is *not* intended to be used while any replication slaves are running. The behavior of `RESET MASTER` when used while slaves are running is undefined (and thus unsupported), whereas `PURGE BINARY LOGS` may be safely used while replication slaves are running.

See also [Section 12.6.1.1, “PURGE BINARY LOGS Syntax”](#).

`RESET MASTER` can prove useful when you first set up the master and the slave, so that you can verify the setup as follows:

1. Start the master and slave, and start replication (see [Section 16.1.1, “How to Set Up Replication”](#))
2. Execute a few test queries on the master
3. Check that the queries were replicated to the slave
4. When replication is running correctly, issue `STOP SLAVE` on the slave, followed by `RESET SLAVE`; verify that any unwanted data no longer exists on the slave
5. Issue `RESET MASTER` on the master to clean up the test queries

After verifying the setup and getting rid of any unwanted and logs generated by testing, you can start the slave and begin replicating.

12.6.1.3. SET sql_log_bin Syntax

```
SET sql_log_bin = {0|1}
```

Disables or enables binary logging for the current connection (`sql_log_bin` is a session variable) if the client has the `SUPER` privilege. The statement is refused with an error if the client does not have that privilege.

12.6.2. SQL Statements for Controlling Slave Servers

Replication can be controlled through the SQL interface. This section discusses statements for managing slave replication servers. [Section 12.6.1, “SQL Statements for Controlling Master Servers”](#), discusses statements for managing master servers.

`SHOW SLAVE STATUS` is also used with replication slaves. For information about this statement, see [Section 12.5.5.35, “SHOW](#)

SLAVE STATUS Syntax”.

12.6.2.1. CHANGE MASTER TO Syntax

```
CHANGE MASTER TO master_def [, master_def] ...

master_def:
MASTER_BIND = 'interface_name'
MASTER_HOST = 'host_name'
MASTER_USER = 'user_name'
MASTER_PASSWORD = 'password'
MASTER_PORT = port_num
MASTER_CONNECT_RETRY = interval
MASTER_HEARTBEAT_PERIOD = interval
MASTER_LOG_FILE = 'master_log_name'
MASTER_LOG_POS = master_log_pos
RELAY_LOG_FILE = 'relay_log_name'
RELAY_LOG_POS = relay_log_pos
MASTER_SSL = {0|1}
MASTER_SSL_CA = 'ca_file_name'
MASTER_SSL_CAPATH = 'ca_directory_name'
MASTER_SSL_CERT = 'cert_file_name'
MASTER_SSL_KEY = 'key_file_name'
MASTER_SSL_CIPHER = 'cipher_list'
MASTER_SSL_VERIFY_SERVER_CERT = {0|1}
```

`CHANGE MASTER TO` changes the parameters that the slave server uses for connecting to and communicating with the master server. It also updates the contents of the `master.info` and `relay-log.info` files.

`MASTER_USER`, `MASTER_PASSWORD`, `MASTER_SSL`, `MASTER_SSL_CA`, `MASTER_SSL_CAPATH`, `MASTER_SSL_CERT`, `MASTER_SSL_KEY`, `MASTER_SSL_CIPHER`, and `MASTER_SSL_VERIFY_SERVER_CERT` provide information to the slave about how to connect to its master. [Section 5.5.7.3, “SSL Command Options”](#).

`MASTER_CONNECT_RETRY` specifies how many seconds to wait between connect retries. The default is 60. The *number* of reconnection attempts is limited by the `--master-retry-count` server option; for more information, see [Section 16.1.3, “Replication and Binary Logging Options and Variables”](#).

The SSL options (`MASTER_SSL`, `MASTER_SSL_CA`, `MASTER_SSL_CAPATH`, `MASTER_SSL_CERT`, `MASTER_SSL_KEY`, `MASTER_SSL_CIPHER`), and `MASTER_SSL_VERIFY_SERVER_CERT` can be changed even on slaves that are compiled without SSL support. They are saved to the `master.info` file, but are ignored unless you use a server that has SSL support enabled.

If you don't specify a given parameter, it keeps its old value, except as indicated in the following discussion. For example, if the password to connect to your MySQL master has changed, you just need to issue these statements to tell the slave about the new password:

```
STOP SLAVE; -- if replication was running
CHANGE MASTER TO MASTER_PASSWORD='new3cret';
START SLAVE; -- if you want to restart replication
```

There is no need to specify the parameters that do not change (host, port, user, and so forth).

`MASTER_HOST` and `MASTER_PORT` are the host name (or IP address) of the master host and its TCP/IP port.

The next two options are available only in MySQL Cluster NDB 6.3 and 6.4; they are not supported in mainline MySQL 5.4:

- `MASTER_BIND` is for use on replication slaves having multiple network interfaces, and determines which of the slave's network interfaces is chosen for connecting to the master. It is also possible to determine which network interface is to be used in such cases by starting the slave `mysqld` process with the `--master-bind` option.

The ability to bind a replication slave to specific network interface was added in MySQL Cluster NDB 6.3.4.

- `MASTER_HEARTBEAT_PERIOD` is used to set the interval in seconds between replication heartbeats. Whenever the master's binlog is updated with an event, the waiting period for the next heartbeat is reset. *interval* is a decimal value having the range 0 to 4294967 seconds and a resolution to hundredths of a second; the smallest nonzero value is 0.001. Heartbeats are sent by the master only if there are no unsent events in the binlog file for a period longer than *interval*.

Setting *interval* to 0 disables heartbeats altogether. The default value for *interval* is equal to the value of `slave_net_timeout` divided by 2.

Note

Setting `@@global.slave_net_timeout` to a value less than that of the current heartbeat interval results in a warning being issued.

Issuing `RESET SLAVE` resets the heartbeat interval to the default.

`MASTER_HEARTBEAT_PERIOD` was added in MySQL Cluster NDB 6.3.4.

Note

Replication cannot use Unix socket files. You must be able to connect to the master MySQL server using TCP/IP.

If you specify `MASTER_HOST` or `MASTER_PORT`, the slave assumes that the master server is different from before (even if you specify a host or port value that is the same as the current value.) In this case, the old values for the master binary log name and position are considered no longer applicable, so if you do not specify `MASTER_LOG_FILE` and `MASTER_LOG_POS` in the statement, `MASTER_LOG_FILE=''` and `MASTER_LOG_POS=4` are silently appended to it.

Setting `MASTER_HOST=''` — that is, setting its value explicitly to an empty string — is *not* the same as not setting it at all. Setting this option to an empty string causes `START SLAVE` subsequently to fail. This issue is addressed in MySQL 6.0. ([Bug#28796](#))

`MASTER_LOG_FILE` and `MASTER_LOG_POS` are the coordinates at which the slave I/O thread should begin reading from the master the next time the thread starts. If you specify either of them, you cannot specify `RELAY_LOG_FILE` or `RELAY_LOG_POS`. If neither of `MASTER_LOG_FILE` or `MASTER_LOG_POS` are specified, the slave uses the last coordinates of the *slave SQL thread* before `CHANGE MASTER TO` was issued. This ensures that there is no discontinuity in replication, even if the slave SQL thread was late compared to the slave I/O thread, when you merely want to change, say, the password to use.

`CHANGE MASTER TO` deletes all relay log files and starts a new one, unless you specify `RELAY_LOG_FILE` or `RELAY_LOG_POS`. In that case, relay logs are kept; the `relay_log_purge` global variable is set silently to 0.

`CHANGE MASTER TO` is useful for setting up a slave when you have the snapshot of the master and have recorded the log and the offset corresponding to it. After loading the snapshot into the slave, you can run `CHANGE MASTER TO MASTER_LOG_FILE='log_name_on_master', MASTER_LOG_POS=log_offset_on_master` on the slave.

The following example changes the master and master's binary log coordinates. This is used when you want to set up the slave to replicate the master:

```
CHANGE MASTER TO
  MASTER_HOST='master2.mycompany.com',
  MASTER_USER='replication',
  MASTER_PASSWORD='big3cret',
  MASTER_PORT=3306,
  MASTER_LOG_FILE='master2-bin.001',
  MASTER_LOG_POS=4,
  MASTER_CONNECT_RETRY=10;
```

The next example shows an operation that is less frequently employed. It is used when the slave has relay logs that you want it to execute again for some reason. To do this, the master need not be reachable. You need only use `CHANGE MASTER TO` and start the SQL thread (`START SLAVE SQL_THREAD`):

```
CHANGE MASTER TO
  RELAY_LOG_FILE='slave-relay-bin.006',
  RELAY_LOG_POS=4025;
```

You can even use the second operation in a non-replication setup with a standalone, non-slave server for recovery following a crash. Suppose that your server has crashed and you have restored a backup. You want to replay the server's own binary logs (not relay logs, but regular binary logs), named (for example) `myhost-bin.*`. First, make a backup copy of these binary logs in some safe place, in case you don't exactly follow the procedure below and accidentally have the server purge the binary logs. Use `SET GLOBAL relay_log_purge=0` for additional safety. Then start the server without the `--log-bin` option. Instead, use the `--replicate-same-server-id`, `--relay-log=myhost-bin` (to make the server believe that these regular binary logs are relay logs) and `--skip-slave-start` options. After the server starts, issue these statements:

```
CHANGE MASTER TO
  RELAY_LOG_FILE='myhost-bin.153',
  RELAY_LOG_POS=410,
  MASTER_HOST='some_dummy_string';
START SLAVE SQL_THREAD;
```

The server reads and executes its own binary logs, thus achieving crash recovery. Once the recovery is finished, run `STOP SLAVE`, shut down the server, delete the `master.info` and `relay-log.info` files, and restart the server with its original options.

Specifying the `MASTER_HOST` option (even with a dummy value) is required to make the server think it is a slave.

12.6.2.2. LOAD DATA FROM MASTER Syntax

LOAD DATA FROM MASTER

This feature is deprecated. We recommend not using it anymore. It is subject to removal in a future version of MySQL.

Since the current implementation of `LOAD DATA FROM MASTER` and `LOAD TABLE FROM MASTER` is very limited, these statements are deprecated in versions 4.1 of MySQL and above. We will introduce a more advanced technique (called “online backup”) in a future version. That technique will have the additional advantage of working with more storage engines.

For MySQL 5.4 and earlier, the recommended alternative solution to using `LOAD DATA FROM MASTER` or `LOAD TABLE FROM MASTER` is using `mysqldump` or `mysqlhotcopy`. The latter requires Perl and two Perl modules (`DBI` and `DBD:mysql`) and works for `MyISAM` and `ARCHIVE` tables only. With `mysqldump`, you can create SQL dumps on the master and pipe (or copy) these to a `mysql` client on the slave. This has the advantage of working for all storage engines, but can be quite slow, since it works using `SELECT`.

This statement takes a snapshot of the master and copies it to the slave. It updates the values of `MASTER_LOG_FILE` and `MASTER_LOG_POS` so that the slave starts replicating from the correct position. Any table and database exclusion rules specified with the `--replicate-*do-*` and `--replicate-*ignore-*` options are honored. `--replicate-rewrite-db` is *not* taken into account because a user could use this option to set up a non-unique mapping such as `--replicate-rewrite-db="db1->db3"` and `--replicate-rewrite-db="db2->db3"`, which would confuse the slave when loading tables from the master.

Use of this statement is subject to the following conditions:

- It works only for `MyISAM` tables. Attempting to load a non-`MyISAM` table results in the following error:

```
ERROR 1189 (08S01): Net error reading from master
```

- It acquires a global read lock on the master while taking the snapshot, which prevents updates on the master during the load operation.

If you are loading large tables, you might have to increase the values of `net_read_timeout` and `net_write_timeout` on both the master and slave servers. See [Section 5.1.3, “Server System Variables”](#).

Note that `LOAD DATA FROM MASTER` does *not* copy any tables from the `mysql` database. This makes it easy to have different users and privileges on the master and the slave.

To use `LOAD DATA FROM MASTER`, the replication account that is used to connect to the master must have the `RELOAD` and `SUPER` privileges on the master and the `SELECT` privilege for all master tables you want to load. All master tables for which the user does not have the `SELECT` privilege are ignored by `LOAD DATA FROM MASTER`. This is because the master hides them from the user: `LOAD DATA FROM MASTER` calls `SHOW DATABASES` to know the master databases to load, but `SHOW DATABASES` returns only databases for which the user has some privilege. See [Section 12.5.5.15, “SHOW DATABASES Syntax”](#). On the slave side, the user that issues `LOAD DATA FROM MASTER` must have privileges for dropping and creating the databases and tables that are copied.

12.6.2.3. `LOAD TABLE tbl_name FROM MASTER` Syntax

LOAD TABLE `tbl_name` FROM MASTER

This feature is deprecated. We recommend not using it anymore. It is subject to removal in a future version of MySQL.

Since the current implementation of `LOAD DATA FROM MASTER` and `LOAD TABLE FROM MASTER` is very limited, these statements are deprecated in versions 4.1 of MySQL and above. We will introduce a more advanced technique (called “online backup”) in a future version. That technique will have the additional advantage of working with more storage engines.

For MySQL 5.4 and earlier, the recommended alternative solution to using `LOAD DATA FROM MASTER` or `LOAD TABLE FROM MASTER` is using `mysqldump` or `mysqlhotcopy`. The latter requires Perl and two Perl modules (`DBI` and `DBD:mysql`) and works for `MyISAM` and `ARCHIVE` tables only. With `mysqldump`, you can create SQL dumps on the master and pipe (or copy) these to a `mysql` client on the slave. This has the advantage of working for all storage engines, but can be quite slow, since it works using `SELECT`.

Transfers a copy of the table from the master to the slave. This statement is implemented mainly debugging `LOAD DATA FROM MASTER` operations. To use `LOAD TABLE`, the account used for connecting to the master server must have the `RELOAD` and `SUPER` privileges on the master and the `SELECT` privilege for the master table to load. On the slave side, the user that issues `LOAD TABLE FROM MASTER` must have privileges for dropping and creating the table.

The conditions for `LOAD DATA FROM MASTER` apply here as well. For example, `LOAD TABLE FROM MASTER` works only for `MyISAM` tables. The timeout notes for `LOAD DATA FROM MASTER` apply as well.

12.6.2.4. MASTER_POS_WAIT() Syntax

```
SELECT MASTER_POS_WAIT('master_log_file', master_log_pos [, timeout])
```

This is actually a function, not a statement. It is used to ensure that the slave has read and executed events up to a given position in the master's binary log. See [Section 11.11.4, “Miscellaneous Functions”](#), for a full description.

12.6.2.5. RESET SLAVE Syntax

```
RESET SLAVE
```

RESET SLAVE makes the slave forget its replication position in the master's binary logs. This statement is meant to be used for a clean start: It deletes the `master.info` and `relay-log.info` files, all the relay logs, and starts a new relay log.

Note

All relay logs are deleted, even if they have not been completely executed by the slave SQL thread. (This is a condition likely to exist on a replication slave if you have issued a **STOP SLAVE** statement or if the slave is highly loaded.)

Connection information stored in the `master.info` file is immediately reset using any values specified in the corresponding startup options. This information includes values such as master host, master port, master user, and master password. If the slave SQL thread was in the middle of replicating temporary tables when it was stopped, and **RESET SLAVE** is issued, these replicated temporary tables are deleted on the slave.

12.6.2.6. SET GLOBAL SQL_SLAVE_SKIP_COUNTER Syntax

```
SET GLOBAL SQL_SLAVE_SKIP_COUNTER = N
```

This statement skips the next *N* events from the master. This is useful for recovering from replication stops caused by a statement.

This statement is valid only when the slave thread is not running. Otherwise, it produces an error.

When using this statement, it is important to understand that the binary log is actually organized as a sequence of groups known as *event groups*. Each event group consists of a sequence of events.

- For transactional tables, an event group corresponds to a transaction.
- For non-transactional tables, an event group corresponds to a single SQL statement.

Note

A single transaction can contain changes to both transactional and non-transactional tables.

When you use **SET GLOBAL SQL_SLAVE_SKIP_COUNTER** to skip events and the result is in the middle of a group, the slave continues to skip events until it reaches the end of the group. Execution then starts with the next event group.

12.6.2.7. START SLAVE Syntax

```
START SLAVE [thread_type [, thread_type] ... ]
START SLAVE [SQL_THREAD] UNTIL
  MASTER_LOG_FILE = 'log_name', MASTER_LOG_POS = log_pos
START SLAVE [SQL_THREAD] UNTIL
  RELAY_LOG_FILE = 'log_name', RELAY_LOG_POS = log_pos
thread_type: IO_THREAD | SQL_THREAD
```

START SLAVE with no *thread_type* options starts both of the slave threads. The I/O thread reads queries from the master server and stores them in the relay log. The SQL thread reads the relay log and executes the queries. **START SLAVE** requires the **SUPER** privilege.

If **START SLAVE** succeeds in starting the slave threads, it returns without any error. However, even in that case, it might be that the slave threads start and then later stop (for example, because they do not manage to connect to the master or read its binary logs, or some other problem). **START SLAVE** does not warn you about this. You must check the slave's error log for error messages generated by the slave threads, or check that they are running satisfactorily with **SHOW SLAVE STATUS**.

START SLAVE sends an acknowledgement to the user after both the IO thread and the SQL thread have started. However, the IO

thread may not yet have connected. For this reason, a successful `START SLAVE` causes `SHOW SLAVE STATUS` to show `Slave_SQL_Running=Yes`, but this does not guarantee that `Slave_IO_Running=Yes` (because `Slave_IO_Running=Yes` only if the IO thread is running *and connected*). For more information, see [Section 12.5.5.35](#), “`SHOW SLAVE STATUS Syntax`”, and [Section 16.1.4.1](#), “`Checking Replication Status`”.

You can add `IO_THREAD` and `SQL_THREAD` options to the statement to name which of the threads to start.

An `UNTIL` clause may be added to specify that the slave should start and run until the SQL thread reaches a given point in the master binary logs or in the slave relay logs. When the SQL thread reaches that point, it stops. If the `SQL_THREAD` option is specified in the statement, it starts only the SQL thread. Otherwise, it starts both slave threads. If the SQL thread is running, the `UNTIL` clause is ignored and a warning is issued.

For an `UNTIL` clause, you must specify both a log file name and position. Do not mix master and relay log options.

Any `UNTIL` condition is reset by a subsequent `STOP SLAVE` statement, a `START SLAVE` statement that includes no `UNTIL` clause, or a server restart.

The `UNTIL` clause can be useful for debugging replication, or to cause replication to proceed until just before the point where you want to avoid having the slave replicate a statement. For example, if an unwise `DROP TABLE` statement was executed on the master, you can use `UNTIL` to tell the slave to execute up to that point but no farther. To find what the event is, use `mysqlbinlog` with the master logs or slave relay logs, or by using a `SHOW BINLOG EVENTS` statement.

If you are using `UNTIL` to have the slave process replicated queries in sections, it is recommended that you start the slave with the `--skip-slave-start` option to prevent the SQL thread from running when the slave server starts. It is probably best to use this option in an option file rather than on the command line, so that an unexpected server restart does not cause it to be forgotten.

The `SHOW SLAVE STATUS` statement includes output fields that display the current values of the `UNTIL` condition.

In old versions of MySQL (before 4.0.5), this statement was called `SLAVE START`. This usage is still accepted in MySQL 5.4 for backward compatibility, but is deprecated.

12.6.2.8. STOP SLAVE Syntax

```
STOP SLAVE [thread_type [, thread_type] ... ]
thread_type: IO_THREAD | SQL_THREAD
```

Stops the slave threads. `STOP SLAVE` requires the `SUPER` privilege.

Like `START SLAVE`, this statement may be used with the `IO_THREAD` and `SQL_THREAD` options to name the thread or threads to be stopped.

In old versions of MySQL (before 4.0.5), this statement was called `SLAVE STOP`. This usage is still accepted in MySQL 5.4 for backward compatibility, but is deprecated.

12.7. SQL Syntax for Prepared Statements

MySQL 5.4 provides support for server-side prepared statements. This support takes advantage of the efficient client/server binary protocol implemented in MySQL 4.1, provided that you use an appropriate client programming interface. Candidate interfaces include the MySQL C API client library (for C programs), MySQL Connector/J (for Java programs), and MySQL Connector/NET. For example, the C API provides a set of function calls that make up its prepared statement API. See [Section 20.10.4](#), “`C API Prepared Statements`”. Other language interfaces can provide support for prepared statements that use the binary protocol by linking in the C client library, one example being the `mysql_i extension`, available in PHP 5.0 and later.

An alternative SQL interface to prepared statements is available. This interface is not as efficient as using the binary protocol through a prepared statement API, but requires no programming because it is available directly at the SQL level:

- You can use it when no programming interface is available to you.
- You can use it from any program that allows you to send SQL statements to the server to be executed, such as the `mysql` client program.
- You can use it even if the client is using an old version of the client library. The only requirement is that you be able to connect to a server that is recent enough to support SQL syntax for prepared statements.

SQL syntax for prepared statements is intended to be used for situations such as these:

- You want to test how prepared statements work in your application before coding it.

- An application has problems executing prepared statements and you want to determine interactively what the problem is.
- You want to create a test case that describes a problem you are having with prepared statements, so that you can file a bug report.
- You need to use prepared statements but do not have access to a programming API that supports them.

SQL syntax for prepared statements is based on three SQL statements:

- `PREPARE` prepares a statement for execution (see [Section 12.7.1, “PREPARE Syntax”](#)).
- `EXECUTE` executes a prepared statement (see [Section 12.7.2, “EXECUTE Syntax”](#)).
- `DEALLOCATE PREPARE` releases a prepared statement (see [Section 12.7.3, “DEALLOCATE PREPARE Syntax”](#)).

The following examples show two equivalent ways of preparing a statement that computes the hypotenuse of a triangle given the lengths of the two sides.

The first example shows how to create a prepared statement by using a string literal to supply the text of the statement:

```
mysql> PREPARE stmt1 FROM 'SELECT SQRT(POW(?,2) + POW(?,2)) AS hypotenuse';
mysql> SET @a = 3;
mysql> SET @b = 4;
mysql> EXECUTE stmt1 USING @a, @b;
+-----+
| hypotenuse |
+-----+
|          5 |
+-----+
mysql> DEALLOCATE PREPARE stmt1;
```

The second example is similar, but supplies the text of the statement as a user variable:

```
mysql> SET @s = 'SELECT SQRT(POW(?,2) + POW(?,2)) AS hypotenuse';
mysql> PREPARE stmt2 FROM @s;
mysql> SET @a = 6;
mysql> SET @b = 8;
mysql> EXECUTE stmt2 USING @a, @b;
+-----+
| hypotenuse |
+-----+
|          10 |
+-----+
mysql> DEALLOCATE PREPARE stmt2;
```

Here is an additional example which demonstrates how to choose the table on which to perform a query at run time, by storing the name of the table as a user variable:

```
mysql> USE test;
mysql> CREATE TABLE t1 (a INT NOT NULL);
mysql> INSERT INTO t1 VALUES (4), (8), (11), (32), (80);

mysql> SET @table = 't1';
mysql> SET @s = CONCAT('SELECT * FROM ', @table);

mysql> PREPARE stmt3 FROM @s;
mysql> EXECUTE stmt3;
+-----+
| a |
+-----+
| 4 |
| 8 |
| 11|
| 32|
| 80|
+-----+
mysql> DEALLOCATE PREPARE stmt3;
```

A prepared statement is specific to the session in which it was created. If you terminate a session without deallocating a previously prepared statement, the server deallocates it automatically.

A prepared statement is also global to the session. If you create a prepared statement within a stored routine, it is not deallocated when the stored routine ends.

To guard against too many prepared statements being created simultaneously, set the `max_prepared_stmt_count` system variable. To prevent the use of prepared statements, set the value to 0.

The following SQL statements can be used in prepared statements:

```
ALTER TABLE
ANALYZE TABLE
CACHE INDEX
CALL
CHANGE MASTER
CHECKSUM {TABLE | TABLES}
COMMIT
{CREATE | DROP} DATABASE
{CREATE | RENAME | DROP} USER
CREATE INDEX
CREATE TABLE
DELETE
DO
DROP INDEX
DROP TABLE
FLUSH {TABLE | TABLES | TABLES WITH READ LOCK | HOSTS | PRIVILEGES
      | LOGS | STATUS | MASTER | SLAVE | DES_KEY_FILE | USER_RESOURCES}
GRANT
INSERT
INSTALL PLUGIN
KILL
LOAD INDEX INTO CACHE
OPTIMIZE TABLE
RENAME TABLE
REPAIR TABLE
REPLACE
RESET {MASTER | SLAVE | QUERY CACHE}
REVOKE
SELECT
SET
SHOW BINLOG EVENTS
SHOW CREATE {PROCEDURE | FUNCTION | EVENT | TABLE | VIEW}
SHOW {AUTHORS | CONTRIBUTORS | WARNINGS | ERRORS}
SHOW {MASTER | BINARY} LOGS
SHOW {MASTER | SLAVE} STATUS
SLAVE {START | STOP}
UNINSTALL PLUGIN
UPDATE
```

Other statements are not yet supported.

Statements not allowed in SQL prepared statements are generally also not permitted in stored routines. Any exceptions to this rule are noted in [Section 18.2, “Using Stored Routines \(Procedures and Functions\)”](#).

Placeholders can be used for the arguments of the `LIMIT` clause when using prepared statements. See [Section 12.2.8, “SELECT Syntax”](#).

In prepared `CALL` statements used with `PREPARE` and `EXECUTE`, placeholder support for `OUT` and `INOUT` parameters is not available in MySQL 5.4. See [Section 12.2.1, “CALL Syntax”](#), for an example and a workaround. Placeholders can be used for `IN` parameters regardless of version.

SQL syntax for prepared statements cannot be used in nested fashion. That is, a statement passed to `PREPARE` cannot itself be a `PREPARE`, `EXECUTE`, or `DEALLOCATE PREPARE` statement.

SQL syntax for prepared statements is distinct from using prepared statement API calls. For example, you cannot use the `mysql_stmt_prepare()` C API function to prepare a `PREPARE`, `EXECUTE`, or `DEALLOCATE PREPARE` statement.

SQL syntax for prepared statements can be used within stored procedures, but not in stored functions or triggers. However, a cursor cannot be used for a dynamic statement that is prepared and executed with `PREPARE` and `EXECUTE`. The statement for a cursor is checked at cursor creation time, so the statement cannot be dynamic.

SQL syntax for prepared statements does not support multi-statements (that is, multiple statements within a single string separated by “;” characters).

Prepared statements use the query cache under the conditions described in [Section 7.5.5.1, “How the Query Cache Operates”](#).

To write C programs that use the `CALL` SQL statement to execute stored procedures that contain prepared statements, the `CLIENT_MULTI_RESULTS` flag must be enabled. This is because each `CALL` returns a result to indicate the call status, in addition to any result sets that might be returned by statements executed within the procedure.

`CLIENT_MULTI_RESULTS` can be enabled when you call `mysql_real_connect()`, either explicitly by passing the `CLIENT_MULTI_RESULTS` flag itself, or implicitly by passing `CLIENT_MULTI_STATEMENTS` (which also enables `CLIENT_MULTI_RESULTS`). For additional information, see [Section 12.2.1, “CALL Syntax”](#).

12.7.1. PREPARE Syntax

```
PREPARE stmt_name FROM preparable_stmt
```

The `PREPARE` statement prepares a statement and assigns it a name, `stmt_name`, by which to refer to the statement later. Statement names are not case sensitive. `preparable_stmt` is either a string literal or a user variable that contains the text of the statement. The text must represent a single SQL statement, not multiple statements. Within the statement, “?” characters can be used as parameter markers to indicate where data values are to be bound to the query later when you execute it. The “?” characters should not be enclosed within quotes, even if you intend to bind them to string values. Parameter markers can be used only where data values should appear, not for SQL keywords, identifiers, and so forth.

If a prepared statement with the given name already exists, it is deallocated implicitly before the new statement is prepared. This means that if the new statement contains an error and cannot be prepared, an error is returned and no statement with the given name exists.

A prepared statement is executed with `EXECUTE` and released with `DEALLOCATE PREPARE`.

The scope of a prepared statement is the session within which it is created. Other sessions cannot see it.

For examples, see [Section 12.7, “SQL Syntax for Prepared Statements”](#).

12.7.2. EXECUTE Syntax

```
EXECUTE stmt_name
[USING @var_name [, @var_name] ...]
```

After preparing a statement with `PREPARE`, you execute it with an `EXECUTE` statement that refers to the prepared statement name. If the prepared statement contains any parameter markers, you must supply a `USING` clause that lists user variables containing the values to be bound to the parameters. Parameter values can be supplied only by user variables, and the `USING` clause must name exactly as many variables as the number of parameter markers in the statement.

You can execute a given prepared statement multiple times, passing different variables to it or setting the variables to different values before each execution.

For examples, see [Section 12.7, “SQL Syntax for Prepared Statements”](#).

12.7.3. DEALLOCATE PREPARE Syntax

```
{DEALLOCATE | DROP} PREPARE stmt_name
```

To deallocate a prepared statement produced with `PREPARE`, use a `DEALLOCATE PREPARE` statement that refers to the prepared statement name. Attempting to execute a prepared statement after deallocating it results in an error.

For examples, see [Section 12.7, “SQL Syntax for Prepared Statements”](#).

12.7.4. Automatic Prepared Statement Repreparation

Metadata changes to tables or views referred to by prepared statements are detected and cause automatic repreparation of the statement when it is next executed. This applies to prepared statements processed at the SQL level (using the `PREPARE` statement) and those processed using the binary client-server protocol (using the `mysql_stmt_prepare()` C API function).

Metadata changes occur for DDL statements such as those that create, drop, alter, rename, or truncate tables, or that analyze, optimize, or repair tables. Repreparation also occurs after referenced tables or views are flushed from the table definition cache, either implicitly to make room for new entries in the cache, or explicitly due to `FLUSH TABLES`.

Repreparation is automatic, but to the extent that it occurs, performance of prepared statements is diminished.

When a statement is reprepared, the default database and SQL mode that were in effect for the original preparation are used.

Table content changes (for example, with `INSERT` or `UPDATE`) do not cause repreparation, nor do `SELECT` statements.

An incompatibility with previous versions of MySQL is that a prepared statement may return a different set of columns or different column types from one execution to the next. For example, if the prepared statement is `SELECT * FROM t1`, altering `t1` to contain a different number of columns causes the next execution to return a number of columns different from the previous execution.

Older versions of the client library cannot handle this change in behavior. For applications that use prepared statements with a server that performs automatic repreparation, an upgrade to the new client library is strongly recommended.

The `Com_stmt_reprepare` status variable tracks the number of repreparations.

12.8. MySQL Compound-Statement Syntax

This section describes the syntax for the `BEGIN ... END` compound statement and other statements that can be used in the body of stored programs: Stored procedures and functions, triggers, and events. These objects are defined in terms of SQL code that is stored on the server for later invocation (see [Chapter 18, *Stored Programs and Views*](#)).

12.8.1. `BEGIN ... END` Compound Statement Syntax

```
[begin_label:] BEGIN
  [statement_list]
END [end_label]
```

`BEGIN ... END` syntax is used for writing compound statements, which can appear within stored programs. A compound statement can contain multiple statements, enclosed by the `BEGIN` and `END` keywords. `statement_list` represents a list of one or more statements, each terminated by a semicolon (`;`) statement delimiter. `statement_list` is optional, which means that the empty compound statement (`BEGIN END`) is legal.

Use of multiple statements requires that a client is able to send statement strings containing the `;` statement delimiter. This is handled in the `mysql` command-line client with the `delimiter` command. Changing the `;` end-of-statement delimiter (for example, to `//`) allows `;` to be used in a program body. For an example, see [Section 18.1, “Defining Stored Programs”](#).

A compound statement can be labeled. `end_label` cannot be given unless `begin_label` also is present. If both are present, they must be the same.

The optional `[NOT] ATOMIC` clause is not supported. This means that no transactional savepoint is set at the start of the instruction block and the `BEGIN` clause used in this context has no effect on the current transaction.

12.8.2. `DECLARE` Syntax

The `DECLARE` statement is used to define various items local to a program:

- Local variables. See [Section 12.8.3, “Variables in Stored Programs”](#).
- Conditions and handlers. See [Section 12.8.4, “Conditions and Handlers”](#).
- Cursors. See [Section 12.8.5, “Cursors”](#).

The `SIGNAL` and `RESIGNAL` statements are not supported until MySQL 6.0.

`DECLARE` is allowed only inside a `BEGIN ... END` compound statement and must be at its start, before any other statements.

Declarations must follow a certain order. Cursors must be declared before declaring handlers, and variables and conditions must be declared before declaring either cursors or handlers.

12.8.3. Variables in Stored Programs

You may declare and use variables within stored programs.

12.8.3.1. `DECLARE` for Local Variables

```
DECLARE var_name [, var_name] ... type [DEFAULT value]
```

This statement is used to declare local variables within stored programs. To provide a default value for the variable, include a `DEFAULT` clause. The value can be specified as an expression; it need not be a constant. If the `DEFAULT` clause is missing, the initial value is `NULL`.

Local variables are treated like stored routine parameters with respect to data type and overflow checking. See [Section 12.1.12, “CREATE PROCEDURE and CREATE FUNCTION Syntax”](#).

Local variable names are not case sensitive.

The scope of a local variable is within the `BEGIN ... END` block where it is declared. The variable can be referred to in blocks nested within the declaring block, except those blocks that declare a variable with the same name.

12.8.3.2. Variable `SET` Statement

```
SET var_name = expr [, var_name = expr] ...
```

The `SET` statement in stored programs is an extended version of the general `SET` statement (see [Section 12.5.4, “SET Syntax”](#)). Referenced variables may be ones declared inside a stored program, global system variables, or user-defined variables.

The `SET` statement in stored programs is implemented as part of the pre-existing `SET` syntax. This allows an extended syntax of `SET a=x, b=y, ...` where different variable types (locally declared variables, global and session server variables, user-defined variables) can be mixed. This also allows combinations of local variables and some options that make sense only for system variables; in that case, the options are recognized but ignored.

12.8.3.3. `SELECT ... INTO` Statement

```
SELECT col_name [, col_name] ...
      INTO var_name [, var_name] ...
      table_expr
```

`SELECT ... INTO` syntax enables selected columns to be stored directly into variables. The query should return a single row. If the query returns no rows, a warning with error code 1329 occurs (`No data`), and the variable values remain unchanged. If the query returns multiple rows, error 1172 occurs (`Result consisted of more than one row`). If it is possible that the statement may retrieve multiple rows, you can use `LIMIT 1` to limit the result set to a single row.

In the context of such statements that occur as part of events executed by the Event Scheduler, diagnostics messages (not only errors, but also warnings) are written to the error log, and, on Windows, to the application event log. For additional information, see [Section 18.4.5, “Event Scheduler Status”](#).

```
SELECT id,data INTO x,y FROM test.t1 LIMIT 1;
```

User variable names are not case sensitive. See [Section 8.4, “User-Defined Variables”](#).

12.8.3.4. Scope and Resolution of Local Variables

The scope of a local variable is within the `BEGIN ... END` block where it is declared. The variable can be referred to in blocks nested within the declaring block, except those blocks that declare a variable with the same name.

Local variable names should not be the same as column names. If an SQL statement, such as a `SELECT ... INTO` statement, contains a reference to a column and a declared local variable with the same name, MySQL currently interprets the reference as the name of a variable. For example, in the following statement, `xname` is interpreted as a reference to the `xname` variable rather than the `xname` column:

```
CREATE PROCEDURE sp1 (x VARCHAR(5))
  BEGIN
    DECLARE xname VARCHAR(5) DEFAULT 'bob';
    DECLARE newname VARCHAR(5);
    DECLARE xid INT;

    SELECT xname,id INTO newname,xid
      FROM table1 WHERE xname = xname;
    SELECT newname;
  END;
```

When this procedure is called, the `newname` variable returns the value `'bob'` regardless of the value of the `table1.xname` column.

See also [Section D.1, “Restrictions on Stored Routines, Triggers, and Events”](#).

12.8.4. Conditions and Handlers

Certain conditions may require specific handling. These conditions can relate to errors or warnings, as well as to general flow control inside a stored program.

12.8.4.1. `DECLARE` for Conditions

```
DECLARE condition_name CONDITION FOR condition_value
condition_value:
  SQLSTATE [VALUE] sqlstate_value
  | mysql_error_code
```

The `DECLARE ... CONDITION` statement defines a named error condition. It specifies a condition that needs specific handling and associates a name with that condition. The name can be referred to in a subsequence `DECLARE ... HANDLER` statement. See [Section 12.8.4.2, “DECLARE for Handlers”](#).

A `condition_value` for `DECLARE ... CONDITION` can be an SQLSTATE value (a 5-character string literal) or a MySQL

error code (a number). You should not use SQLSTATE value '00000' or MySQL error code 0, because those indicate success rather than an error condition. For a list of SQLSTATE values and MySQL error codes, see [Section B.3, “Server Error Codes and Messages”](#).

12.8.4.2. DECLARE for Handlers

```
DECLARE handler_type HANDLER
  FOR condition_value [, condition_value] ...
  statement

handler_type:
  CONTINUE
  EXIT
  UNDO

condition_value:
  SQLSTATE [VALUE] sqlstate_value
  condition_name
  SQLWARNING
  NOT FOUND
  SQLEXCEPTION
  mysql_error_code
```

The `DECLARE ... HANDLER` statement specifies handlers that each may deal with one or more conditions. If one of these conditions occurs, the specified *statement* is executed. *statement* can be a simple statement (for example, `SET var_name = value`), or it can be a compound statement written using `BEGIN` and `END` (see [Section 12.8.1, “BEGIN ... END Compound Statement Syntax”](#)).

For a `CONTINUE` handler, execution of the current program continues after execution of the handler statement. For an `EXIT` handler, execution terminates for the `BEGIN ... END` compound statement in which the handler is declared. (This is true even if the condition occurs in an inner block.) The `UNDO` handler type statement is not supported.

If a condition occurs for which no handler has been declared, the default action is `EXIT`.

A *condition_value* for `DECLARE ... HANDLER` can be any of the following values:

- An SQLSTATE value (a 5-character string literal) or a MySQL error code (a number). You should not use SQLSTATE value '00000' or MySQL error code 0, because those indicate success rather than an error condition. For a list of SQLSTATE values and MySQL error codes, see [Section B.3, “Server Error Codes and Messages”](#).
- A condition name previously specified with `DECLARE ... CONDITION`. See [Section 12.8.4.1, “DECLARE for Conditions”](#).
- `SQLWARNING` is shorthand for the class of SQLSTATE values that begin with '01'.
- `NOT FOUND` is shorthand for the class of SQLSTATE values that begin with '02'. This is relevant only in the context of cursors and is used to control what happens when a cursor reaches the end of a data set. If no more rows are available, a No Data condition occurs with SQLSTATE value 02000. To detect this condition, you can set up a handler for it (or for a `NOT FOUND` condition). An example is shown in [Section 12.8.5, “Cursors”](#). This condition also occurs for `SELECT ... INTO var_list` statements that retrieve no rows.
- `SQLEXCEPTION` is shorthand for the class of SQLSTATE values that do not begin with '00', '01', or '02'.

Example:

```
mysql> CREATE TABLE test.t (s1 INT, PRIMARY KEY (s1));
Query OK, 0 rows affected (0.00 sec)

mysql> delimiter //

mysql> CREATE PROCEDURE handlerdemo ()
-> BEGIN
->   DECLARE CONTINUE HANDLER FOR SQLSTATE '23000' SET @x2 = 1;
->   SET @x = 1;
->   INSERT INTO test.t VALUES (1);
->   SET @x = 2;
->   INSERT INTO test.t VALUES (1);
->   SET @x = 3;
-> END;
-> //
Query OK, 0 rows affected (0.00 sec)

mysql> CALL handlerdemo()//
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT @x//
+-----+
| @x    |
+-----+
| 3     |
+-----+
```

```
+-----+
1 row in set (0.00 sec)
```

The example associates a handler with SQLSTATE value '23000', which occurs for a duplicate-key error. Notice that @x is 3 after the procedure executes, which shows that execution continued to the end of the procedure. If the `DECLARE ... HANDLER` statement had not been present, MySQL would have taken the default path (`EXIT`) after the second `INSERT` failed due to the `PRIMARY KEY` constraint, and `SELECT @x` would have returned 2.

If you want to ignore a condition, you can declare a `CONTINUE` handler for it and associate it with an empty block. For example:

```
DECLARE CONTINUE HANDLER FOR SQLWARNING BEGIN END;
```

The statement associated with a handler cannot use `ITERATE` or `LEAVE` to refer to labels for blocks that enclose the handler declaration. That is, the scope of a block label does not include the code for handlers declared within the block. Consider the following example, where the `REPEAT` block has a label of `retry`:

```
CREATE PROCEDURE p ()
BEGIN
  DECLARE i INT DEFAULT 3;
  retry:
  REPEAT
  BEGIN
    DECLARE CONTINUE HANDLER FOR SQLWARNING
    BEGIN
      ITERATE retry; # illegal
    END;
  END;
  IF i < 0 THEN
    LEAVE retry; # legal
  END IF;
  SET i = i - 1;
  UNTIL FALSE END REPEAT;
END;
```

The label is in scope for the `IF` statement within the block. It is not in scope for the `CONTINUE` handler, so the reference there is invalid and results in an error:

```
ERROR 1308 (42000): LEAVE with no matching label: retry
```

To avoid using references to outer labels in handlers, you can use these strategies:

- To leave the block, use an `EXIT` handler:

```
DECLARE EXIT HANDLER FOR SQLWARNING BEGIN END;
```

- To iterate, set a status variable in the handler that can be checked in the enclosing block to determine whether the handler was invoked. The following example uses the variable `done` for this purpose:

```
CREATE PROCEDURE p ()
BEGIN
  DECLARE i INT DEFAULT 3;
  DECLARE done INT DEFAULT FALSE;
  retry:
  REPEAT
  BEGIN
    DECLARE CONTINUE HANDLER FOR SQLWARNING
    BEGIN
      SET done = TRUE;
    END;
  END;
  IF NOT done AND i < 0 THEN
    LEAVE retry;
  END IF;
  SET i = i - 1;
  UNTIL FALSE END REPEAT;
END;
```

12.8.5. Cursors

Cursors are supported inside stored routines, triggers, and events. The syntax is as in embedded SQL. Cursors in MySQL have these properties:

- Asensitive: The server may or may not make a copy of its result table
- Read only: Not updatable

- Non-scrollable: Can be traversed only in one direction and cannot skip rows

Cursors must be declared before declaring handlers. Variables and conditions must be declared before declaring either cursors or handlers.

Example:

```
CREATE PROCEDURE curdemo()
BEGIN
  DECLARE done INT DEFAULT 0;
  DECLARE a CHAR(16);
  DECLARE b,c INT;
  DECLARE cur1 CURSOR FOR SELECT id,data FROM test.t1;
  DECLARE cur2 CURSOR FOR SELECT i FROM test.t2;
  DECLARE CONTINUE HANDLER FOR NOT FOUND SET done = 1;

  OPEN cur1;
  OPEN cur2;

  REPEAT
    FETCH cur1 INTO a, b;
    FETCH cur2 INTO c;
    IF NOT done THEN
      IF b < c THEN
        INSERT INTO test.t3 VALUES (a,b);
      ELSE
        INSERT INTO test.t3 VALUES (a,c);
      END IF;
    END IF;
  UNTIL done END REPEAT;

  CLOSE cur1;
  CLOSE cur2;
END
```

12.8.5.1. DECLARE for Cursors

```
DECLARE cursor_name CURSOR FOR select_statement
```

This statement declares a cursor. Multiple cursors may be declared in a stored program, but each cursor in a given block must have a unique name.

The `SELECT` statement cannot have an `INTO` clause.

12.8.5.2. Cursor OPEN Statement

```
OPEN cursor_name
```

This statement opens a previously declared cursor.

12.8.5.3. Cursor FETCH Statement

```
FETCH cursor_name INTO var_name [, var_name] ...
```

This statement fetches the next row (if a row exists) using the specified open cursor, and advances the cursor pointer.

If no more rows are available, a No Data condition occurs with SQLSTATE value 02000. To detect this condition, you can set up a handler for it (or for a `NOT FOUND` condition). An example is shown in [Section 12.8.5, “Cursors”](#).

12.8.5.4. Cursor CLOSE Statement

```
CLOSE cursor_name
```

This statement closes a previously opened cursor.

If not closed explicitly, a cursor is closed at the end of the compound statement in which it was declared.

12.8.6. Flow Control Constructs

MySQL supports the `IF`, `CASE`, `ITERATE`, `LEAVE LOOP`, `WHILE`, and `REPEAT` constructs for flow control within stored programs.

Many of these constructs contain other statements, as indicated by the grammar specifications in the following sections. Such con-

structs may be nested. For example, an `IF` statement might contain a `WHILE` loop, which itself contains a `CASE` statement.

`FOR` loops are not supported.

12.8.6.1. `IF` Statement

```
IF search_condition THEN statement_list
  [ELSEIF search_condition THEN statement_list] ...
  [ELSE statement_list]
END IF
```

`IF` implements a basic conditional construct. If the *search_condition* evaluates to true, the corresponding SQL statement list is executed. If no *search_condition* matches, the statement list in the `ELSE` clause is executed. Each *statement_list* consists of one or more statements.

Note

There is also an `IF()` function, which differs from the `IF` statement described here. See [Section 11.3, “Control Flow Functions”](#).

An `IF ... END IF` block, like all other flow-control blocks used within stored programs, must be terminated with a semicolon, as shown in this example:

```
DELIMITER //
CREATE FUNCTION SimpleCompare(n INT, m INT)
  RETURNS VARCHAR(20)
  BEGIN
    DECLARE s VARCHAR(20);
    IF n > m THEN SET s = '>';
    ELSEIF n = m THEN SET s = '=';
    ELSE SET s = '<';
    END IF;
    SET s = CONCAT(n, ' ', s, ' ', m);
    RETURN s;
  END //
DELIMITER ;
```

As with other flow-control constructs, `IF ... END IF` blocks may be nested within other flow-control constructs, including other `IF` statements. Each `IF` must be terminated by its own `END IF` followed by a semicolon. You can use indentation to make nested flow-control blocks more easily readable by humans (although this is not required by MySQL), as shown here:

```
DELIMITER //
CREATE FUNCTION VerboseCompare (n INT, m INT)
  RETURNS VARCHAR(50)
  BEGIN
    DECLARE s VARCHAR(50);
    IF n = m THEN SET s = 'equals';
    ELSE
      IF n > m THEN SET s = 'greater';
      ELSE SET s = 'less';
      END IF;
    SET s = CONCAT('is ', s, ' than');
    END IF;
    SET s = CONCAT(n, ' ', s, ' ', m, '.');
    RETURN s;
  END //
DELIMITER ;
```

In this example, the inner `IF` is evaluated only if `n` is not equal to `m`.

12.8.6.2. `CASE` Statement

```
CASE case_value
  WHEN when_value THEN statement_list
  [WHEN when_value THEN statement_list] ...
  [ELSE statement_list]
END CASE
```

Or:

```

CASE
  WHEN search_condition THEN statement_list
  [WHEN search_condition THEN statement_list] ...
  [ELSE statement_list]
END CASE

```

The **CASE** statement for stored programs implements a complex conditional construct. If a *search_condition* evaluates to true, the corresponding SQL statement list is executed. If no search condition matches, the statement list in the **ELSE** clause is executed. Each *statement_list* consists of one or more statements.

If no *when_value* or *search_condition* matches the value tested and the **CASE** statement contains no **ELSE** clause, a **CASE NOT FOUND FOR CASE STATEMENT** error results.

Each *statement_list* consists of one or more statements; an empty *statement_list* is not allowed. To handle situations where no value is matched by any **WHEN** clause, use an **ELSE** containing an empty **BEGIN ... END** block, as shown in this example:

```

DELIMITER |
CREATE PROCEDURE p()
  BEGIN
    DECLARE v INT DEFAULT 1;

    CASE v
      WHEN 2 THEN SELECT v;
      WHEN 3 THEN SELECT 0;
      ELSE
        BEGIN
          END;
        END CASE;
    END;
  |

```

(The indentation used here in the **ELSE** clause is for purposes of clarity only, and is not otherwise significant.)

Note

The syntax of the **CASE statement** used inside stored programs differs slightly from that of the SQL **CASE expression** described in Section 11.3, “Control Flow Functions”. The **CASE** statement cannot have an **ELSE NULL** clause, and it is terminated with **END CASE** instead of **END**.

12.8.6.3. LOOP Statement

```

[begin_label:] LOOP
  statement_list
END LOOP [end_label]

```

LOOP implements a simple loop construct, enabling repeated execution of the statement list, which consists of one or more statements, each terminated by a semicolon (;) statement delimiter. The statements within the loop are repeated until the loop is exited; usually this is accomplished with a **LEAVE** statement.

A **LOOP** statement can be labeled. *end_label* cannot be given unless *begin_label* also is present. If both are present, they must be the same.

12.8.6.4. LEAVE Statement

```

LEAVE label

```

This statement is used to exit the flow control construct that has the given label. It can be used within **BEGIN ... END** or loop constructs (**LOOP**, **REPEAT**, **WHILE**).

12.8.6.5. ITERATE Statement

```

ITERATE label

```

ITERATE can appear only within **LOOP**, **REPEAT**, and **WHILE** statements. **ITERATE** means “do the loop again.”

Example:

```

CREATE PROCEDURE doiterate(p1 INT)
  BEGIN
    label1: LOOP
      SET p1 = p1 + 1;
      IF p1 < 10 THEN ITERATE label1; END IF;
      LEAVE label1;
    END LOOP label1;

```

```
SET @x = p1;
END
```

12.8.6.6. REPEAT Statement

```
[begin_label:] REPEAT
  statement_list
UNTIL search_condition
END REPEAT [end_label]
```

The statement list within a **REPEAT** statement is repeated until the *search_condition* is true. Thus, a **REPEAT** always enters the loop at least once. *statement_list* consists of one or more statements, each terminated by a semicolon (;) statement delimiter.

A **REPEAT** statement can be labeled. *end_label* cannot be given unless *begin_label* also is present. If both are present, they must be the same.

Example:

```
mysql> delimiter //

mysql> CREATE PROCEDURE dorepeat(p1 INT)
-> BEGIN
->   SET @x = 0;
->   REPEAT SET @x = @x + 1; UNTIL @x > p1 END REPEAT;
-> END
-> //
Query OK, 0 rows affected (0.00 sec)

mysql> CALL dorepeat(1000)//
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT @x//
+-----+
| @x    |
+-----+
| 1001  |
+-----+
1 row in set (0.00 sec)
```

12.8.6.7. WHILE Statement

```
[begin_label:] WHILE search_condition DO
  statement_list
END WHILE [end_label]
```

The statement list within a **WHILE** statement is repeated as long as the *search_condition* is true. *statement_list* consists of one or more statements.

A **WHILE** statement can be labeled. *end_label* cannot be given unless *begin_label* also is present. If both are present, they must be the same.

Example:

```
CREATE PROCEDURE dowhile()
BEGIN
  DECLARE v1 INT DEFAULT 5;

  WHILE v1 > 0 DO
    ...
    SET v1 = v1 - 1;
  END WHILE;
END
```

12.8.7. RETURN Syntax

```
RETURN expr
```

The **RETURN** statement terminates execution of a stored function and returns the value *expr* to the function caller. There must be at least one **RETURN** statement in a stored function. There may be more than one if the function has multiple exit points.

This statement is not used in stored procedures, triggers, or events.

Chapter 13. Storage Engines

MySQL supports several storage engines that act as handlers for different table types. MySQL storage engines include both those that handle transaction-safe tables and those that handle non-transaction-safe tables.

MySQL Server uses a pluggable storage engine architecture that allows storage engines to be loaded into and unloaded from a running MySQL server.

To determine which storage engines your server supports by using the `SHOW ENGINES` statement. The value in the `Support` column indicates whether an engine can be used. A value of `YES`, `NO`, or `DEFAULT` indicates that an engine is available, not available, or available and current set as the default storage engine.

```
mysql> SHOW ENGINES\G
***** 1. row *****
  Engine: FEDERATED
  Support: NO
  Comment: Federated MySQL storage engine
  Transactions: NULL
    XA: NULL
  Savepoints: NULL
***** 2. row *****
  Engine: MRG_MYISAM
  Support: YES
  Comment: Collection of identical MyISAM tables
  Transactions: NO
    XA: NO
  Savepoints: NO
***** 3. row *****
  Engine: MyISAM
  Support: DEFAULT
  Comment: Default engine as of MySQL 3.23 with great performance
  Transactions: NO
    XA: NO
  Savepoints: NO
...

```

This chapter describes each of the MySQL storage engines except for `NDBCLUSTER`, which is covered in [MySQL Cluster NDB 6.X/7.X](#). It also contains a description of the pluggable storage engine architecture (see [Section 13.4, “Overview of MySQL Storage Engine Architecture”](#)).

For information about storage engine support offered in commercial MySQL Server binaries, see [MySQL Enterprise Server 5.1](#), on the MySQL website. The storage engines available might depend on which edition of Enterprise Server you are using.

For answers to some commonly asked questions about MySQL storage engines, see [Section A.2, “MySQL 5.4 FAQ — Storage Engines”](#).

MySQL 5.4 supported storage engines

- **MyISAM** — The default MySQL storage engine and the one that is used the most in Web, data warehousing, and other application environments. **MyISAM** is supported in all MySQL configurations, and is the default storage engine unless you have configured MySQL to use a different one by default.
- **InnoDB** — A transaction-safe (ACID compliant) storage engine for MySQL that has commit, rollback, and crash-recovery capabilities to protect user data. **InnoDB** row-level locking (without escalation to coarser granularity locks) and Oracle-style consistent non-locking reads increase multi-user concurrency and performance. **InnoDB** stores user data in clustered indexes to reduce I/O for common queries based on primary keys. To maintain data integrity, **InnoDB** also supports **FOREIGN KEY** referential-integrity constraints.
- **Memory** — Stores all data in RAM for extremely fast access in environments that require quick lookups of reference and other like data. This engine was formerly known as the **HEAP** engine.
- **Merge** — Allows a MySQL DBA or developer to logically group a series of identical **MyISAM** tables and reference them as one object. Good for VLDB environments such as data warehousing.
- **Archive** — Provides the perfect solution for storing and retrieving large amounts of seldom-referenced historical, archived, or security audit information.
- **Federated** — Offers the ability to link separate MySQL servers to create one logical database from many physical servers. Very good for distributed or data mart environments.
- **CSV** — The CSV storage engine stores data in text files using comma-separated values format. You can use the CSV engine to easily exchange data between other software and applications that can import and export in CSV format.
- **Blackhole** — The Blackhole storage engine accepts but does not store data and retrievals always return an empty set. The

functionality can be used in distributed database design where data is automatically replicated, but not stored locally.

- **Example** — The Example storage engine is “stub” engine that does nothing. You can create tables with this engine, but no data can be stored in them or retrieved from them. The purpose of this engine is to serve as an example in the MySQL source code that illustrates how to begin writing new storage engines. As such, it is primarily of interest to developers.

It is important to remember that you are not restricted to using the same storage engine for an entire server or schema: you can use a different storage engine for each table in your schema.

Choosing a Storage Engine

The various storage engines provided with MySQL are designed with different use-cases in mind. To use the pluggable storage architecture effectively, it is good to have an idea of the advantages and disadvantages of the various storage engines. The following table provides an overview of some storage engines provided with MySQL:

Table 13.1. Storage Engine Features

Feature	MyISAM	Memory	InnoDB	Archive	NDB
Storage limits	256TB	RAM	64TB	None	384EB
Transactions	No	No	Yes	No	Yes
Locking granularity	Table	Table	Row	Row	Row
MVCC	No	No	Yes	No	No
Geospatial datatype support	Yes	No	Yes	Yes	Yes
Geospatial indexing support	Yes	No	No	No	No
B-tree indexes	Yes	Yes	Yes	No	Yes
Hash indexes	No	Yes	No	No	Yes
Full-text search indexes	Yes	No	No	No	No
Clustered indexes	No	No	Yes	No	No
Data caches	No	N/A	Yes	No	Yes
Index caches	Yes	N/A	Yes	No	Yes
Compressed data	Yes ^a	No	Yes ^b	Yes	No
Encrypted data ^c	Yes	Yes	Yes	Yes	Yes
Cluster database support	No	No	No	No	Yes
Replication support ^d	Yes	Yes	Yes	Yes	Yes
Foreign key support	No	No	Yes	No	No
Backup / point-in-time recovery ^e	Yes	Yes	Yes	Yes	Yes
Query cache support	Yes	Yes	Yes	Yes	Yes
Update statistics for data dictionary	Yes	Yes	Yes	Yes	Yes

^aCompressed MyISAM tables are supported only when using the compressed row format. Tables using the compressed row format with MyISAM are read only.

^bCompressed InnoDB tables are supported only by InnoDB Plugin.

^cImplemented in the server (via encryption functions), rather than in the storage engine.

^dImplemented in the server, rather than in the storage engine

^eImplemented in the server, rather than in the storage engine

13.1. Comparing Transaction and Non-Transaction Engines

Transaction-safe tables (TSTs) have several advantages over non-transaction-safe tables (NTSTs):

- They are safer. Even if MySQL crashes or you get hardware problems, you can get your data back, either by automatic recovery or from a backup plus the transaction log.
- You can combine many statements and accept them all at the same time with the `COMMIT` statement (if autocommit is disabled).
- You can execute `ROLLBACK` to ignore your changes (if autocommit is disabled).
- If an update fails, all of your changes are reverted. (With non-transaction-safe tables, all changes that have taken place are permanent.)
- Transaction-safe storage engines can provide better concurrency for tables that get many updates concurrently with reads.

You can combine transaction-safe and non-transaction-safe tables in the same statements to get the best of both worlds. However, although MySQL supports several transaction-safe storage engines, for best results, you should not mix different storage engines within a transaction with autocommit disabled. For example, if you do this, changes to non-transaction-safe tables still are committed immediately and cannot be rolled back. For information about this and other problems that can occur in transactions that use mixed storage engines, see [Section 12.4.1, “START TRANSACTION, COMMIT, and ROLLBACK Syntax”](#).

Non-transaction-safe tables have several advantages of their own, all of which occur because there is no transaction overhead:

- Much faster
- Lower disk space requirements
- Less memory required to perform updates

13.2. Other Storage Engines

Other storage engines may be available from third parties and community members that have used the Custom Storage Engine interface.

You can find more information on the list of third party storage engines on the [MySQL Forge Storage Engines](#) page.

Note

Third party engines are not supported by MySQL. For further information, documentation, installation guides, bug reporting or for any help or assistance with these engines, please contact the developer of the engine directly.

Third party engines that are known to be available include the following; please see the MySQL Forge links provided for more information:

- **PrimeBase XT (PBXT)** — PBXT has been designed for modern, web-based, high concurrency environments.
- **RitmarkFS** — RitmarkFS allows you to access and manipulate the file system using SQL queries. RitmarkFS also supports file system replication and directory change tracking.
- **Distributed Data Engine** — The Distributed Data Engine is an Open Source project that is dedicated to provide a Storage Engine for distributed data according to workload statistics.
- **mdbtools** — A pluggable storage engine that allows read-only access to Microsoft Access `.mdb` database files.
- **solidDB for MySQL** — solidDB Storage Engine for MySQL is an open source, transactional storage engine for MySQL Server. It is designed for mission-critical implementations that require a robust, transactional database. solidDB Storage Engine for MySQL is a multi-threaded storage engine that supports full ACID compliance with all expected transaction isolation levels, row-level locking, and Multi-Version Concurrency Control (MVCC) with non-blocking reads and writes.

- **BLOB Streaming Engine (MyBS)** — The Scalable BLOB Streaming infrastructure for MySQL will transform MySQL into a scalable media server capable of streaming pictures, films, MP3 files and other binary and text objects (BLOBs) directly in and out of the database.

For more information on developing a custom storage engine that can be used with the Pluggable Storage Engine Architecture, see [Writing a Custom Storage Engine](#) on [MySQL Forge](#).

13.3. Setting the Storage Engine

When you create a new table, you can specify which storage engine to use by adding an `ENGINE` table option to the `CREATE TABLE` statement:

```
CREATE TABLE t (i INT) ENGINE = INNODB;
```

If you omit the `ENGINE` or `TYPE` option, the default storage engine is used. Normally, this is `MyISAM`, but you can change it by using the `--default-storage-engine` or `--default-table-type` server startup option, or by setting the `default-storage-engine` or `default-table-type` option in the `my.cnf` configuration file.

You can set the default storage engine to be used during the current session by setting the `storage_engine` variable:

```
SET storage_engine=MYISAM;
```

When MySQL is installed on Windows using the MySQL Configuration Wizard, the `InnoDB` storage engine can be selected as the default instead of `MyISAM`. See [Section 2.3.4.5, “The Database Usage Dialog”](#).

To convert a table from one storage engine to another, use an `ALTER TABLE` statement that indicates the new engine:

```
ALTER TABLE t ENGINE = MYISAM;
```

See [Section 12.1.14, “CREATE TABLE Syntax”](#), and [Section 12.1.6, “ALTER TABLE Syntax”](#).

If you try to use a storage engine that is not compiled in or that is compiled in but deactivated, MySQL instead creates a table using the default storage engine, usually `MyISAM`. This behavior is convenient when you want to copy tables between MySQL servers that support different storage engines. (For example, in a replication setup, perhaps your master server supports transactional storage engines for increased safety, but the slave servers use only non-transactional storage engines for greater speed.)

This automatic substitution of the default storage engine for unavailable engines can be confusing for new MySQL users. A warning is generated whenever a storage engine is automatically changed.

For new tables, MySQL always creates an `.frm` file to hold the table and column definitions. The table's index and data may be stored in one or more other files, depending on the storage engine. The server creates the `.frm` file above the storage engine level. Individual storage engines create any additional files required for the tables that they manage. If a table name contains special characters, the names for the table files contain encoded versions of those characters as described in [Section 8.2.3, “Mapping of Identifiers to File Names”](#).

A database may contain tables of different types. That is, tables need not all be created with the same storage engine.

13.4. Overview of MySQL Storage Engine Architecture

The MySQL pluggable storage engine architecture allows a database professional to select a specialized storage engine for a particular application need while being completely shielded from the need to manage any specific application coding requirements. The MySQL server architecture isolates the application programmer and DBA from all of the low-level implementation details at the storage level, providing a consistent and easy application model and API. Thus, although there are different capabilities across different storage engines, the application is shielded from these differences.

The MySQL pluggable storage engine architecture is shown in [Figure 13.1, “MySQL Architecture with Pluggable Storage Engines”](#).

Figure 13.1. MySQL Architecture with Pluggable Storage Engines

The pluggable storage engine architecture provides a standard set of management and support services that are common among all underlying storage engines. The storage engines themselves are the components of the database server that actually perform actions on the underlying data that is maintained at the physical server level.

This efficient and modular architecture provides huge benefits for those wishing to specifically target a particular application need — such as data warehousing, transaction processing, or high availability situations — while enjoying the advantage of utilizing a set of interfaces and services that are independent of any one storage engine.

The application programmer and DBA interact with the MySQL database through Connector APIs and service layers that are above the storage engines. If application changes bring about requirements that demand the underlying storage engine change, or that one or more additional storage engines be added to support new needs, no significant coding or process changes are required to make things work. The MySQL server architecture shields the application from the underlying complexity of the storage engine by presenting a consistent and easy-to-use API that applies across storage engines.

13.4.1. Pluggable Storage Engine Architecture

MySQL Server uses a pluggable storage engine architecture that allows storage engines to be loaded into and unloaded from a running MySQL server.

Plugging in a Storage Engine

Before a storage engine can be used, the storage engine plugin shared library must be loaded into MySQL using the `INSTALL PLUGIN` statement. For example, if the `EXAMPLE` engine plugin is named `ha_example` and the shared library is named `ha_example.so`, you load it with the following statement:

```
mysql> INSTALL PLUGIN ha_example SONAME 'ha_example.so';
```

To install a pluggable storage engine, the plugin file must be located in the MySQL plugin directory, and the user issuing the `INSTALL PLUGIN` statement must have `INSERT` privilege for the `mysql.plugin` table.

The shared library must be located in the MySQL server plugin directory, the location of which is given by the `plugin_dir` system variable.

Unplugging a Storage Engine

To unplug a storage engine, use the `UNINSTALL PLUGIN` statement:

```
mysql> UNINSTALL PLUGIN ha_example;
```

If you unplug a storage engine that is needed by existing tables, those tables become inaccessible, but will still be present on disk (where applicable). Ensure that there are no tables using a storage engine before you unplug the storage engine.

13.4.2. The Common Database Server Layer

A MySQL pluggable storage engine is the component in the MySQL database server that is responsible for performing the actual data I/O operations for a database as well as enabling and enforcing certain feature sets that target a specific application need. A major benefit of using specific storage engines is that you are only delivered the features needed for a particular application, and therefore you have less system overhead in the database, with the end result being more efficient and higher database performance. This is one of the reasons that MySQL has always been known to have such high performance, matching or beating proprietary monolithic databases in industry standard benchmarks.

From a technical perspective, what are some of the unique supporting infrastructure components that are in a storage engine? Some of the key feature differentiations include:

- *Concurrency* — some applications have more granular lock requirements (such as row-level locks) than others. Choosing the right locking strategy can reduce overhead and therefore improve overall performance. This area also includes support for capabilities such as multi-version concurrency control or “snapshot” read.
- *Transaction Support* — Not every application needs transactions, but for those that do, there are very well defined requirements such as ACID compliance and more.
- *Referential Integrity* — The need to have the server enforce relational database referential integrity through DDL defined foreign keys.
- *Physical Storage* — This involves everything from the overall page size for tables and indexes as well as the format used for storing data to physical disk.
- *Index Support* — Different application scenarios tend to benefit from different index strategies. Each storage engine generally has its own indexing methods, although some (such as B-tree indexes) are common to nearly all engines.
- *Memory Caches* — Different applications respond better to some memory caching strategies than others, so although some memory caches are common to all storage engines (such as those used for user connections or MySQL's high-speed Query Cache), others are uniquely defined only when a particular storage engine is put in play.
- *Performance Aids* — This includes multiple I/O threads for parallel operations, thread concurrency, database checkpointing, bulk insert handling, and more.
- *Miscellaneous Target Features* — This may include support for geospatial operations, security restrictions for certain data manipulation operations, and other similar features.

Each set of the pluggable storage engine infrastructure components are designed to offer a selective set of benefits for a particular application. Conversely, avoiding a set of component features helps reduce unnecessary overhead. It stands to reason that understanding a particular application's set of requirements and selecting the proper MySQL storage engine can have a dramatic impact on overall system efficiency and performance.

13.5. The MyISAM Storage Engine

`MyISAM` is the default storage engine. It is based on the older `ISAM` code but has many useful extensions. (Note that MySQL 5.4 does *not* support `ISAM`.)

Table 13.2. MyISAM Features

Storage limits	256TB	Transactions	No	Locking granularity	Table
MVCC	No	Geospatial datatype support	Yes	Geospatial indexing support	Yes
B-tree indexes	Yes	Hash indexes	No	Full-text search indexes	Yes
Clustered indexes	No	Data caches	No	Index caches	Yes
Compressed data	Yes ^a	Encrypted data^b	Yes	Cluster database support	No
Replication support^c	Yes	Foreign key support	No	Backup / point-in-time re-	Yes

				covery ^d	
Query cache support	Yes	Update statistics for data dictionary	Yes		

^aCompressed MyISAM tables are supported only when using the compressed row format. Tables using the compressed row format with MyISAM are read only.

^bImplemented in the server (via encryption functions), rather than in the storage engine.

^cImplemented in the server, rather than in the storage engine

^dImplemented in the server, rather than in the storage engine

Each **MyISAM** table is stored on disk in three files. The files have names that begin with the table name and have an extension to indicate the file type. An `.frm` file stores the table format. The data file has an `.MYD` (**MYData**) extension. The index file has an `.MYI` (**MYIndex**) extension.

To specify explicitly that you want a **MyISAM** table, indicate that with an **ENGINE** table option:

```
CREATE TABLE t (i INT) ENGINE = MYISAM;
```

Normally, it is unnecessary to use **ENGINE** to specify the **MyISAM** storage engine. **MyISAM** is the default engine unless the default has been changed. To ensure that **MyISAM** is used in situations where the default might have been changed, include the **ENGINE** option explicitly.

You can check or repair **MyISAM** tables with the `mysqlcheck` client or `myisamchk` utility. You can also compress **MyISAM** tables with `myisampack` to take up much less space. See [Section 4.5.3, “mysqlcheck — A Table Maintenance Program”](#), [Section 6.4.1, “Using myisamchk for Crash Recovery”](#), and [Section 4.6.5, “myisampack — Generate Compressed, Read-Only MyISAM Tables”](#).

MyISAM tables have the following characteristics:

- All data values are stored with the low byte first. This makes the data machine and operating system independent. The only requirements for binary portability are that the machine uses two's-complement signed integers and IEEE floating-point format. These requirements are widely used among mainstream machines. Binary compatibility might not be applicable to embedded systems, which sometimes have peculiar processors.

There is no significant speed penalty for storing data low byte first; the bytes in a table row normally are unaligned and it takes little more processing to read an unaligned byte in order than in reverse order. Also, the code in the server that fetches column values is not time critical compared to other code.

- All numeric key values are stored with the high byte first to allow better index compression.
- Large files (up to 63-bit file length) are supported on file systems and operating systems that support large files.
- There is a limit of 2^{32} (~4.295E+09) rows in a **MyISAM** table. If you build MySQL with the `--with-big-tables` option, the row limitation is increased to $(2^{32})^2$ (1.844E+19) rows. See [Section 2.10.2, “Typical configure Options”](#). Binary distributions for Unix and Linux are built with this option.
- The maximum number of indexes per **MyISAM** table is 64. This can be changed by recompiling. You can configure the build by invoking `configure` with the `--with-max-indexes=N` option, where *N* is the maximum number of indexes to permit per **MyISAM** table. *N* must be less than or equal to 128.

The maximum number of columns per index is 16.

- The maximum key length is 1000 bytes. This can also be changed by changing the source and recompiling. For the case of a key longer than 250 bytes, a larger key block size than the default of 1024 bytes is used.
- When rows are inserted in sorted order (as when you are using an **AUTO_INCREMENT** column), the index tree is split so that the high node only contains one key. This improves space utilization in the index tree.
- Internal handling of one **AUTO_INCREMENT** column per table is supported. **MyISAM** automatically updates this column for **INSERT** and **UPDATE** operations. This makes **AUTO_INCREMENT** columns faster (at least 10%). Values at the top of the sequence are not reused after being deleted. (When an **AUTO_INCREMENT** column is defined as the last column of a multiple-column index, reuse of values deleted from the top of a sequence does occur.) The **AUTO_INCREMENT** value can be reset with `ALTER TABLE` or `myisamchk`.
- Dynamic-sized rows are much less fragmented when mixing deletes with updates and inserts. This is done by automatically combining adjacent deleted blocks and by extending blocks if the next block is deleted.
- **MyISAM** supports concurrent inserts: If a table has no free blocks in the middle of the data file, you can **INSERT** new rows into it at the same time that other threads are reading from the table. A free block can occur as a result of deleting rows or an update of a dynamic length row with more data than its current contents. When all free blocks are used up (filled in), future inserts become concurrent again. See [Section 7.3.3, “Concurrent Inserts”](#).

- You can put the data file and index file in different directories on different physical devices to get more speed with the `DATA DIRECTORY` and `INDEX DIRECTORY` table options to `CREATE TABLE`. See [Section 12.1.14, “CREATE TABLE Syntax”](#).
- `BLOB` and `TEXT` columns can be indexed.
- `NULL` values are allowed in indexed columns. This takes 0–1 bytes per key.
- Each character column can have a different character set. See [Section 9.1, “Character Set Support”](#).
- There is a flag in the `MyISAM` index file that indicates whether the table was closed correctly. If `mysqld` is started with the `--myisam-recover` option, `MyISAM` tables are automatically checked when opened, and are repaired if the table wasn't closed properly.
- `myisamchk` marks tables as checked if you run it with the `--update-state` option. `myisamchk --fast` checks only those tables that don't have this mark.
- `myisamchk --analyze` stores statistics for portions of keys, as well as for entire keys.
- `myisampack` can pack `BLOB` and `VARCHAR` columns.

`MyISAM` also supports the following features:

- Support for a true `VARCHAR` type; a `VARCHAR` column starts with a length stored in one or two bytes.
- Tables with `VARCHAR` columns may have fixed or dynamic row length.
- The sum of the lengths of the `VARCHAR` and `CHAR` columns in a table may be up to 64KB.
- Arbitrary length `UNIQUE` constraints.

Additional resources

- A forum dedicated to the `MyISAM` storage engine is available at <http://forums.mysql.com/list.php?21>.

13.5.1. MyISAM Startup Options

The following options to `mysqld` can be used to change the behavior of `MyISAM` tables. For additional information, see [Section 5.1.2, “Server Command Options”](#).

Table 13.3. `mysqld` MyISAM Option/Variable Reference

Name	Cmd-Line	Option file	System Var	Status Var	Var Scope	Dynamic
<code>bulk_insert_buffer_size</code>	Yes	Yes	Yes		Both	Yes
<code>concurrent_insert</code>	Yes	Yes	Yes		Global	Yes
<code>delay-key-write</code>	Yes	Yes			Global	Yes
- Variable: <code>delay_key_write</code>			Yes		Global	Yes
<code>have_rtree_keys</code>			Yes		Global	No
<code>key_buffer_size</code>	Yes	Yes	Yes		Global	Yes
<code>log-isam</code>	Yes	Yes				
<code>myisam-block-size</code>	Yes	Yes				
<code>myisam_data_pointer_size</code>	Yes	Yes	Yes		Global	Yes
<code>myisam_max_sort_file_size</code>	Yes	Yes	Yes		Global	Yes
<code>myisam-recover</code>	Yes	Yes				
<code>myisam_recover_options</code>			Yes		Global	No
<code>myisam_repair_threads</code>	Yes	Yes	Yes		Both	Yes
<code>myisam_sort_buffer_size</code>	Yes	Yes	Yes		Both	Yes
<code>myisam_stats_method</code>	Yes	Yes	Yes		Both	Yes

Name	Cmd-Line	Option file	System Var	Status Var	Var Scope	Dynamic
myisam_use_mmap	Yes	Yes	Yes		Global	Yes
skip-concurrent-insert	Yes	Yes				
- Variable: <code>concurrent_insert</code>						
tmp_table_size	Yes	Yes	Yes		Both	Yes

- `--myisam-recover=mode`

Set the mode for automatic recovery of crashed [MyISAM](#) tables.

- `--delay-key-write=ALL`

Don't flush key buffers between writes for any [MyISAM](#) table.

Note

If you do this, you should not access [MyISAM](#) tables from another program (such as from another MySQL server or with `myisamchk`) when the tables are in use. Doing so risks index corruption. Using `--external-locking` does not eliminate this risk.

The following system variables affect the behavior of [MyISAM](#) tables. For additional information, see [Section 5.1.3, “Server System Variables”](#).

- [bulk_insert_buffer_size](#)

The size of the tree cache used in bulk insert optimization.

Note

This is a limit *per thread*!

- [myisam_max_sort_file_size](#)

The maximum size of the temporary file that MySQL is allowed to use while re-creating a [MyISAM](#) index (during `REPAIR TABLE`, `ALTER TABLE`, or `LOAD DATA INFILE`). If the file size would be larger than this value, the index is created using the key cache instead, which is slower. The value is given in bytes.

- [myisam_sort_buffer_size](#)

Set the size of the buffer used when recovering tables.

Automatic recovery is activated if you start `mysqld` with the `--myisam-recover` option. In this case, when the server opens a [MyISAM](#) table, it checks whether the table is marked as crashed or whether the open count variable for the table is not 0 and you are running the server with external locking disabled. If either of these conditions is true, the following happens:

- The server checks the table for errors.
- If the server finds an error, it tries to do a fast table repair (with sorting and without re-creating the data file).
- If the repair fails because of an error in the data file (for example, a duplicate-key error), the server tries again, this time re-creating the data file.
- If the repair still fails, the server tries once more with the old repair option method (write row by row without sorting). This method should be able to repair any type of error and has low disk space requirements.

MySQL Enterprise

Subscribers to MySQL Enterprise Monitor receive notification if the `--myisam-recover` option has not been set. For more information, see <http://www.mysql.com/products/enterprise/advisors.html>.

If the recovery wouldn't be able to recover all rows from previously completed statements and you didn't specify `FORCE` in the value of the `--myisam-recover` option, automatic repair aborts with an error message in the error log:

```
Error: Couldn't repair table: test.g00pages
```

If you specify `FORCE`, a warning like this is written instead:

```
Warning: Found 344 of 354 rows when repairing ./test/g00pages
```

Note that if the automatic recovery value includes `BACKUP`, the recovery process creates files with names of the form `tbl_name-datetime.BAK`. You should have a `cron` script that automatically moves these files from the database directories to backup media.

13.5.2. Space Needed for Keys

`MyISAM` tables use B-tree indexes. You can roughly calculate the size for the index file as $(key_length+4)/0.67$, summed over all keys. This is for the worst case when all keys are inserted in sorted order and the table doesn't have any compressed keys.

String indexes are space compressed. If the first index part is a string, it is also prefix compressed. Space compression makes the index file smaller than the worst-case figure if a string column has a lot of trailing space or is a `VARCHAR` column that is not always used to the full length. Prefix compression is used on keys that start with a string. Prefix compression helps if there are many strings with an identical prefix.

In `MyISAM` tables, you can also prefix compress numbers by specifying the `PACK_KEYS=1` table option when you create the table. Numbers are stored with the high byte first, so this helps when you have many integer keys that have an identical prefix.

13.5.3. MyISAM Table Storage Formats

`MyISAM` supports three different storage formats. Two of them, fixed and dynamic format, are chosen automatically depending on the type of columns you are using. The third, compressed format, can be created only with the `myisampack` utility (see [Section 4.6.5, “myisampack — Generate Compressed, Read-Only MyISAM Tables”](#)).

When you use `CREATE TABLE` or `ALTER TABLE` for a table that has no `BLOB` or `TEXT` columns, you can force the table format to `FIXED` or `DYNAMIC` with the `ROW_FORMAT` table option.

See [Section 12.1.14, “CREATE TABLE Syntax”](#), for information about `ROW_FORMAT`.

You can decompress (unpack) compressed `MyISAM` tables using `myisamchk --unpack`; see [Section 4.6.3, “myisamchk — MyISAM Table-Maintenance Utility”](#), for more information.

13.5.3.1. Static (Fixed-Length) Table Characteristics

Static format is the default for `MyISAM` tables. It is used when the table contains no variable-length columns (`VARCHAR`, `VARBINARY`, `BLOB`, or `TEXT`). Each row is stored using a fixed number of bytes.

Of the three `MyISAM` storage formats, static format is the simplest and most secure (least subject to corruption). It is also the fastest of the on-disk formats due to the ease with which rows in the data file can be found on disk: To look up a row based on a row number in the index, multiply the row number by the row length to calculate the row position. Also, when scanning a table, it is very easy to read a constant number of rows with each disk read operation.

The security is evidenced if your computer crashes while the MySQL server is writing to a fixed-format `MyISAM` file. In this case, `myisamchk` can easily determine where each row starts and ends, so it can usually reclaim all rows except the partially written one. Note that `MyISAM` table indexes can always be reconstructed based on the data rows.

Note

Fixed-length row format is only available for tables without `BLOB` or `TEXT` columns. Creating a table with these columns with an explicit `ROW_FORMAT` clause will not raise an error or warning; the format specification will be ignored.

Static-format tables have these characteristics:

- `CHAR` and `VARCHAR` columns are space-padded to the specified column width, although the column type is not altered. `BINARY` and `VARBINARY` columns are padded with `0x00` bytes to the column width.
- Very quick.
- Easy to cache.
- Easy to reconstruct after a crash, because rows are located in fixed positions.

- Reorganization is unnecessary unless you delete a huge number of rows and want to return free disk space to the operating system. To do this, use `OPTIMIZE TABLE` or `myisamchk -r`.
- Usually require more disk space than dynamic-format tables.

13.5.3.2. Dynamic Table Characteristics

Dynamic storage format is used if a `MyISAM` table contains any variable-length columns (`VARCHAR`, `VARBINARY`, `BLOB`, or `TEXT`), or if the table was created with the `ROW_FORMAT=DYNAMIC` table option.

Dynamic format is a little more complex than static format because each row has a header that indicates how long it is. A row can become fragmented (stored in non-contiguous pieces) when it is made longer as a result of an update.

You can use `OPTIMIZE TABLE` or `myisamchk -r` to defragment a table. If you have fixed-length columns that you access or change frequently in a table that also contains some variable-length columns, it might be a good idea to move the variable-length columns to other tables just to avoid fragmentation.

Dynamic-format tables have these characteristics:

- All string columns are dynamic except those with a length less than four.
- Each row is preceded by a bitmap that indicates which columns contain the empty string (for string columns) or zero (for numeric columns). Note that this does not include columns that contain `NULL` values. If a string column has a length of zero after trailing space removal, or a numeric column has a value of zero, it is marked in the bitmap and not saved to disk. Non-empty strings are saved as a length byte plus the string contents.
- Much less disk space usually is required than for fixed-length tables.
- Each row uses only as much space as is required. However, if a row becomes larger, it is split into as many pieces as are required, resulting in row fragmentation. For example, if you update a row with information that extends the row length, the row becomes fragmented. In this case, you may have to run `OPTIMIZE TABLE` or `myisamchk -r` from time to time to improve performance. Use `myisamchk -ei` to obtain table statistics.
- More difficult than static-format tables to reconstruct after a crash, because rows may be fragmented into many pieces and links (fragments) may be missing.
- The expected row length for dynamic-sized rows is calculated using the following expression:

```
3
+ (number of columns + 7) / 8
+ (number of char columns)
+ (packed size of numeric columns)
+ (length of strings)
+ (number of NULL columns + 7) / 8
```

There is a penalty of 6 bytes for each link. A dynamic row is linked whenever an update causes an enlargement of the row. Each new link is at least 20 bytes, so the next enlargement probably goes in the same link. If not, another link is created. You can find the number of links using `myisamchk -ed`. All links may be removed with `OPTIMIZE TABLE` or `myisamchk -r`.

13.5.3.3. Compressed Table Characteristics

Compressed storage format is a read-only format that is generated with the `mysampack` tool. Compressed tables can be uncompressed with `myisamchk`.

Compressed tables have the following characteristics:

- Compressed tables take very little disk space. This minimizes disk usage, which is helpful when using slow disks (such as CD-ROMs).
- Each row is compressed separately, so there is very little access overhead. The header for a row takes up one to three bytes depending on the biggest row in the table. Each column is compressed differently. There is usually a different Huffman tree for each column. Some of the compression types are:
 - Suffix space compression.
 - Prefix space compression.

- Numbers with a value of zero are stored using one bit.
- If values in an integer column have a small range, the column is stored using the smallest possible type. For example, a `BIGINT` column (eight bytes) can be stored as a `TINYINT` column (one byte) if all its values are in the range from `-128` to `127`.
- If a column has only a small set of possible values, the data type is converted to `ENUM`.
- A column may use any combination of the preceding compression types.
- Can be used for fixed-length or dynamic-length rows.

Note

While a compressed table is read only, and you cannot therefore update or add rows in the table, DDL (Data Definition Language) operations are still valid. For example, you may still use `DROP` to drop the table, and `TRUNCATE` to empty the table.

13.5.4. MyISAM Table Problems

The file format that MySQL uses to store data has been extensively tested, but there are always circumstances that may cause database tables to become corrupted. The following discussion describes how this can happen and how to handle it.

13.5.4.1. Corrupted MyISAM Tables

Even though the `MyISAM` table format is very reliable (all changes to a table made by an SQL statement are written before the statement returns), you can still get corrupted tables if any of the following events occur:

- The `mysqld` process is killed in the middle of a write.
- An unexpected computer shutdown occurs (for example, the computer is turned off).
- Hardware failures.
- You are using an external program (such as `myisamchk`) to modify a table that is being modified by the server at the same time.
- A software bug in the MySQL or `MyISAM` code.

Typical symptoms of a corrupt table are:

- You get the following error while selecting data from the table:

```
Incorrect key file for table: '...'. Try to repair it
```

- Queries don't find rows in the table or return incomplete results.

You can check the health of a `MyISAM` table using the `CHECK TABLE` statement, and repair a corrupted `MyISAM` table with `REPAIR TABLE`. When `mysqld` is not running, you can also check or repair a table with the `myisamchk` command. See [Section 12.5.2.3, “CHECK TABLE Syntax”](#), [Section 12.5.2.6, “REPAIR TABLE Syntax”](#), and [Section 4.6.3, “myisamchk — MyISAM Table-Maintenance Utility”](#).

If your tables become corrupted frequently, you should try to determine why this is happening. The most important thing to know is whether the table became corrupted as a result of a server crash. You can verify this easily by looking for a recent `restarted mysqld` message in the error log. If there is such a message, it is likely that table corruption is a result of the server dying. Otherwise, corruption may have occurred during normal operation. This is a bug. You should try to create a reproducible test case that demonstrates the problem. See [Section B.1.4.2, “What to Do If MySQL Keeps Crashing”](#), and [MySQL Internals: Porting](#).

MySQL Enterprise

Find out about problems before they occur. Subscribe to the MySQL Enterprise Monitor for expert advice about the state of your servers. For more information, see <http://www.mysql.com/products/enterprise/advisors.html>.

13.5.4.2. Problems from Tables Not Being Closed Properly

Each `MyISAM` index file (`.MYI` file) has a counter in the header that can be used to check whether a table has been closed properly. If you get the following warning from `CHECK TABLE` or `myisamchk`, it means that this counter has gone out of sync:

```
clients are using or haven't closed the table properly
```

This warning doesn't necessarily mean that the table is corrupted, but you should at least check the table.

The counter works as follows:

- The first time a table is updated in MySQL, a counter in the header of the index files is incremented.
- The counter is not changed during further updates.
- When the last instance of a table is closed (because a `FLUSH TABLES` operation was performed or because there is no room in the table cache), the counter is decremented if the table has been updated at any point.
- When you repair the table or check the table and it is found to be okay, the counter is reset to zero.
- To avoid problems with interaction with other processes that might check the table, the counter is not decremented on close if it was zero.

In other words, the counter can become incorrect only under these conditions:

- A `MyISAM` table is copied without first issuing `LOCK TABLES` and `FLUSH TABLES`.
- MySQL has crashed between an update and the final close. (Note that the table may still be okay, because MySQL always issues writes for everything between each statement.)
- A table was modified by `myisamchk --recover` or `myisamchk --update-state` at the same time that it was in use by `mysqld`.
- Multiple `mysqld` servers are using the table and one server performed a `REPAIR TABLE` or `CHECK TABLE` on the table while it was in use by another server. In this setup, it is safe to use `CHECK TABLE`, although you might get the warning from other servers. However, `REPAIR TABLE` should be avoided because when one server replaces the data file with a new one, this is not known to the other servers.

In general, it is a bad idea to share a data directory among multiple servers. See [Section 5.6, “Running Multiple MySQL Servers on the Same Machine”](#), for additional discussion.

13.6. The `InnoDB` Storage Engine

`InnoDB` is a transaction-safe (ACID compliant) storage engine for MySQL that has commit, rollback, and crash-recovery capabilities to protect user data. `InnoDB` row-level locking (without escalation to coarser granularity locks) and Oracle-style consistent non-locking reads increase multi-user concurrency and performance. `InnoDB` stores user data in clustered indexes to reduce I/O for common queries based on primary keys. To maintain data integrity, `InnoDB` also supports `FOREIGN KEY` referential-integrity constraints. You can freely mix `InnoDB` tables with tables from other MySQL storage engines, even within the same statement.

To determine whether your server supports `InnoDB` use the `SHOW ENGINES` statement. See [Section 12.5.5.17, “SHOW ENGINES Syntax”](#).

Table 13.4. `InnoDB` Features

Storage limits	64TB	Transactions	Yes	Locking granularity	Row
MVCC	Yes	Geospatial datatype support	Yes	Geospatial indexing support	No
B-tree indexes	Yes	Hash indexes	No	Full-text search indexes	No
Clustered indexes	Yes	Data caches	Yes	Index caches	Yes
Compressed data	Yes ^a	Encrypted data^b	Yes	Cluster database support	No
Replication support^c	Yes	Foreign key support	Yes	Backup / point-in-time recovery^d	Yes
Query cache support	Yes	Update statistics for data dictionary	Yes		

^aCompressed InnoDB tables are supported only by InnoDB Plugin.

^bImplemented in the server (via encryption functions), rather than in the storage engine.

^cImplemented in the server, rather than in the storage engine

^dImplemented in the server, rather than in the storage engine

InnoDB has been designed for maximum performance when processing large data volumes. Its CPU efficiency is probably not matched by any other disk-based relational database engine.

The InnoDB storage engine maintains its own buffer pool for caching data and indexes in main memory. InnoDB stores its tables and indexes in a tablespace, which may consist of several files (or raw disk partitions). This is different from, for example, MyISAM tables where each table is stored using separate files. InnoDB tables can be very large even on operating systems where file size is limited to 2GB.

The Windows Essentials installer makes InnoDB the MySQL default storage engine on Windows, if the server being installed supports InnoDB.

InnoDB is used in production at numerous large database sites requiring high performance. The famous Internet news site Slashdot.org runs on InnoDB. Mytrix, Inc. stores more than 1TB of data in InnoDB, and another site handles an average load of 800 inserts/updates per second in InnoDB.

InnoDB is published under the same GNU GPL License Version 2 (of June 1991) as MySQL. For more information on MySQL licensing, see <http://www.mysql.com/company/legal/licensing/>.

Additional resources

- A forum dedicated to the InnoDB storage engine is available at <http://forums.mysql.com/list.php?22>.
- Innobase Oy also hosts several forums, available at <http://forums.innodb.com>.
- At the 2008 MySQL User Conference, Innobase announced availability of an InnoDB Plugin for MySQL. This plugin for MySQL exploits the “pluggable storage engine” architecture of MySQL, to permit users to replace the “built-in” version of InnoDB in MySQL 5.1 with a new release of InnoDB that offers new features, improved performance, enhanced reliability and new capabilities for flexibility and ease of use. Among the new features of the InnoDB Plugin are “Fast index creation”, table and index compression, file format management and new INFORMATION_SCHEMA tables.

For a general description of the InnoDB Plugin, see http://www.innodb.com/innodb_plugin/, and for an overview of its features, see http://www.innodb.com/innodb_plugin/features/. You can download the InnoDB Plugin from the InnoDB web site: http://www.innodb.com/innodb_plugin/download/. For the documentation for the InnoDB Plugin, see http://www.innodb.com/innodb_plugin/plugin-documentation/.

- InnoDB Hot Backup enables you to back up a running MySQL database, including InnoDB and MyISAM tables, with minimal disruption to operations while producing a consistent snapshot of the database. When InnoDB Hot Backup is copying InnoDB tables, reads and writes to both InnoDB and MyISAM tables can continue. During the copying of MyISAM tables, reads (but not writes) to those tables are permitted. In addition, InnoDB Hot Backup supports creating compressed backup files, and performing backups of subsets of InnoDB tables. In conjunction with MySQL’s binary log, users can perform point-in-time recovery. InnoDB Hot Backup is commercially licensed by Innobase Oy. For a more complete description of InnoDB Hot Backup, see <http://www.innodb.com/hot-backup/features/> or download the documentation from http://www.innodb.com/doc/hot_backup/manual.html. You can order trial, term, and perpetual licenses from Innobase at <http://www.innodb.com/hot-backup/order/>.

13.6.1. InnoDB Contact Information

Contact information for Innobase Oy, producer of the InnoDB engine:

Web site: <http://www.innodb.com/>

```
Innobase Oy Inc.
World Trade Center Helsinki
Aleksanterinkatu 17
P.O.Box 800
00101 Helsinki
Finland
```

13.6.2. InnoDB Configuration

If you do not want to use `InnoDB` tables, start the server with the `--skip-innodb` option to disable the `InnoDB` startup engine.

Caution

`InnoDB` is a transaction-safe (ACID compliant) storage engine for MySQL that has commit, rollback, and crash-recovery capabilities to protect user data. **However, it cannot do so** if the underlying operating system or hardware does not work as advertised. Many operating systems or disk subsystems may delay or reorder write operations to improve performance. On some operating systems, the very `fsync()` system call that should wait until all unwritten data for a file has been flushed might actually return before the data has been flushed to stable storage. Because of this, an operating system crash or a power outage may destroy recently committed data, or in the worst case, even corrupt the database because of write operations having been reordered. If data integrity is important to you, you should perform some “pull-the-plug” tests before using anything in production. On Mac OS X 10.3 and up, `InnoDB` uses a special `fcntl()` file flush method. Under Linux, it is advisable to **disable the write-back cache**.

On ATA/SATA disk drives, a command such `hdparm -W0 /dev/hda` may work to disable the write-back cache. **Beware that some drives or disk controllers may be unable to disable the write-back cache.**

Two important disk-based resources managed by the `InnoDB` storage engine are its tablespace data files and its log files. If you specify no `InnoDB` configuration options, MySQL creates an auto-extending 10MB data file named `ibdata1` and two 5MB log files named `ib_logfile0` and `ib_logfile1` in the MySQL data directory. To get good performance, you should explicitly provide `InnoDB` parameters as discussed in the following examples. Naturally, you should edit the settings to suit your hardware and requirements.

Caution

It is not a good idea to configure `InnoDB` to use data files or log files on NFS volumes. Otherwise, the files might be locked by other processes and become unavailable for use by MySQL.

MySQL Enterprise

For advice on settings suitable to your specific circumstances, subscribe to the MySQL Enterprise Monitor. For more information, see <http://www.mysql.com/products/enterprise/advisors.html>.

The examples shown here are representative. See Section 13.6.3, “`InnoDB` Startup Options and System Variables” for additional information about `InnoDB`-related configuration parameters.

To set up the `InnoDB` tablespace files, use the `innodb_data_file_path` option in the `[mysqld]` section of the `my.cnf` option file. On Windows, you can use `my.ini` instead. The value of `innodb_data_file_path` should be a list of one or more data file specifications. If you name more than one data file, separate them by semicolon (“;”) characters:

```
innodb_data_file_path=datafile_spec1[:datafile_spec2]...
```

For example, the following setting explicitly creates a tablespace having the same characteristics as the default:

```
[mysqld]
innodb_data_file_path=ibdata1:10M:autoextend
```

This setting configures a single 10MB data file named `ibdata1` that is auto-extending. No location for the file is given, so by default, `InnoDB` creates it in the MySQL data directory.

Sizes are specified using `K`, `M`, or `G` suffix letters to indicate units of KB, MB, or GB.

A tablespace containing a fixed-size 50MB data file named `ibdata1` and a 50MB auto-extending file named `ibdata2` in the data directory can be configured like this:

```
[mysqld]
innodb_data_file_path=ibdata1:50M;ibdata2:50M:autoextend
```

The full syntax for a data file specification includes the file name, its size, and several optional attributes:

```
file_name:file_size[:autoextend[:max:max_file_size]]
```

The `autoextend` and `max` attributes can be used only for the last data file in the `innodb_data_file_path` line.

If you specify the `autoextend` option for the last data file, `InnoDB` extends the data file if it runs out of free space in the tablespace. The increment is 8MB at a time by default. To modify the increment, change the `innodb_autoextend_increment`

system variable.

If the disk becomes full, you might want to add another data file on another disk. For tablespace reconfiguration instructions, see [Section 13.6.5, “Adding, Removing, or Resizing InnoDB Data and Log Files”](#).

InnoDB is not aware of the file system maximum file size, so be cautious on file systems where the maximum file size is a small value such as 2GB. To specify a maximum size for an auto-extending data file, use the `max` attribute following the `autoextend` attribute. The following configuration allows `ibdata1` to grow up to a limit of 500MB:

```
[mysqld]
innodb_data_file_path=ibdata1:10M:autoextend:max:500M
```

InnoDB creates tablespace files in the MySQL data directory by default. To specify a location explicitly, use the `innodb_data_home_dir` option. For example, to use two files named `ibdata1` and `ibdata2` but create them in the `/ibdata` directory, configure InnoDB like this:

```
[mysqld]
innodb_data_home_dir = /ibdata
innodb_data_file_path=ibdata1:50M;ibdata2:50M:autoextend
```

Note

InnoDB does not create directories, so make sure that the `/ibdata` directory exists before you start the server. This is also true of any log file directories that you configure. Use the Unix or DOS `mkdir` command to create any necessary directories.

Make sure that the MySQL server has the proper access rights to create files in the data directory. More generally, the server must have access rights in any directory where it needs to create data files or log files.

InnoDB forms the directory path for each data file by textually concatenating the value of `innodb_data_home_dir` to the data file name, adding a path name separator (slash or backslash) between values if necessary. If the `innodb_data_home_dir` option is not mentioned in `my.cnf` at all, the default value is the “dot” directory `./`, which means the MySQL data directory. (The MySQL server changes its current working directory to its data directory when it begins executing.)

If you specify `innodb_data_home_dir` as an empty string, you can specify absolute paths for the data files listed in the `innodb_data_file_path` value. The following example is equivalent to the preceding one:

```
[mysqld]
innodb_data_home_dir =
innodb_data_file_path=/ibdata/ibdata1:50M;/ibdata/ibdata2:50M:autoextend
```

A simple `my.cnf` example. Suppose that you have a computer with 512MB RAM and one hard disk. The following example shows possible configuration parameters in `my.cnf` or `my.ini` for InnoDB, including the `autoextend` attribute. The example suits most users, both on Unix and Windows, who do not want to distribute InnoDB data files and log files onto several disks. It creates an auto-extending data file `ibdata1` and two InnoDB log files `ib_logfile0` and `ib_logfile1` in the MySQL data directory.

```
[mysqld]
# You can write your other MySQL server options here
# ...
# Data files must be able to hold your data and indexes.
# Make sure that you have enough free disk space.
innodb_data_file_path = ibdata1:10M:autoextend
#
# Set buffer pool size to 50-80% of your computer's memory
innodb_buffer_pool_size=256M
innodb_additional_mem_pool_size=20M
#
# Set the log file size to about 25% of the buffer pool size
innodb_log_file_size=64M
innodb_log_buffer_size=8M
#
innodb_flush_log_at_trx_commit=1
```

Note that data files must be less than 2GB in some file systems. The combined size of the log files must be less than 4GB. The combined size of data files must be at least 10MB.

When you create an InnoDB tablespace for the first time, it is best that you start the MySQL server from the command prompt. InnoDB then prints the information about the database creation to the screen, so you can see what is happening. For example, on Windows, if `mysqld` is located in `C:\Program Files\MySQL\MySQL Server 5.4\bin`, you can start it like this:

```
C:\> "C:\Program Files\MySQL\MySQL Server 5.4\bin\mysqld" --console
```

If you do not send server output to the screen, check the server's error log to see what InnoDB prints during the startup process.

For an example of what the information displayed by InnoDB should look like, see [Section 13.6.2.3, “Creating the InnoDB Tablespace”](#).

You can place InnoDB options in the `[mysqld]` group of any option file that your server reads when it starts. The locations for option files are described in [Section 4.2.3.2, “Using Option Files”](#).

If you installed MySQL on Windows using the installation and configuration wizards, the option file will be the `my.ini` file located in your MySQL installation directory. See [The Location of the my.ini File](#).

If your PC uses a boot loader where the `C:` drive is not the boot drive, your only option is to use the `my.ini` file in your Windows directory (typically `C:\WINDOWS`). You can use the `SET` command at the command prompt in a console window to print the value of `WINDIR`:

```
C:\> SET WINDIR
windir=C:\WINDOWS
```

To make sure that `mysqld` reads options only from a specific file, use the `--defaults-file` option as the first option on the command line when starting the server:

```
mysqld --defaults-file=your_path_to_my_cnf
```

An advanced `my.cnf` example. Suppose that you have a Linux computer with 2GB RAM and three 60GB hard disks at directory paths `/`, `/dr2` and `/dr3`. The following example shows possible configuration parameters in `my.cnf` for InnoDB.

```
[mysqld]
# You can write your other MySQL server options here
# ...
innodb_data_home_dir =
#
# Data files must be able to hold your data and indexes
innodb_data_file_path = /db/ibdata1:2000M:/dr2/db/ibdata2:2000M:autoextend
#
# Set buffer pool size to 50-80% of your computer's memory,
# but make sure on Linux x86 total memory usage is < 2GB
innodb_buffer_pool_size=1G
innodb_additional_mem_pool_size=20M
innodb_log_group_home_dir = /dr3/iblogs
#
# Set the log file size to about 25% of the buffer pool size
innodb_log_file_size=250M
innodb_log_buffer_size=8M
#
innodb_flush_log_at_trx_commit=1
innodb_lock_wait_timeout=50
#
# Uncomment the next line if you want to use it
#innodb_thread_concurrency=5
```

In some cases, database performance improves if the data is not all placed on the same physical disk. Putting log files on a different disk from data is very often beneficial for performance. The example illustrates how to do this. It places the two data files on different disks and places the log files on the third disk. InnoDB fills the tablespace beginning with the first data file. You can also use raw disk partitions (raw devices) as InnoDB data files, which may speed up I/O. See [Section 13.6.2.2, “Using Raw Devices for the Shared Tablespace”](#).

Warning

On 32-bit GNU/Linux x86, you must be careful not to set memory usage too high. `glibc` may allow the process heap to grow over thread stacks, which crashes your server. It is a risk if the value of the following expression is close to or exceeds 2GB:

```
innodb_buffer_pool_size
+ key_buffer_size
+ max_connections*(sort_buffer_size+read_buffer_size+binlog_cache_size)
+ max_connections*2MB
```

Each thread uses a stack (often 2MB, but only 256KB in MySQL AB binaries) and in the worst case also uses `sort_buffer_size + read_buffer_size` additional memory.

Tuning other `mysqld` server parameters. The following values are typical and suit most users:

```
[mysqld]
skip-external-locking
max_connections=200
read_buffer_size=1M
sort_buffer_size=1M
#
# Set key_buffer to 5 - 50% of your RAM depending on how much
# you use MyISAM tables, but keep key_buffer_size + InnoDB
```

```
# buffer pool size < 80% of your RAM
key_buffer_size=value
```

On Linux, if the kernel is enabled for large page support, [InnoDB](#) can use large pages to allocate memory for its buffer pool and additional memory pool. See [Section 7.5.9, “Enabling Large Page Support”](#).

13.6.2.1. Using Per-Table Tablespaces

You can store each [InnoDB](#) table and its indexes in its own file. This feature is called “multiple tablespaces” because in effect each table has its own tablespace.

Using multiple tablespaces can be beneficial to users who want to move specific tables to separate physical disks or who wish to restore backups of single tables quickly without interrupting the use of other [InnoDB](#) tables.

To enable multiple tablespaces, start the server with the `--innodb_file_per_table` option. For example, add a line to the `[mysqld]` section of `my.cnf`:

```
[mysqld]
innodb_file_per_table
```

With multiple tablespaces enabled, [InnoDB](#) stores each newly created table into its own `tbl_name.ibd` file in the database directory where the table belongs. This is similar to what the [MyISAM](#) storage engine does, but [MyISAM](#) divides the table into a `tbl_name.MYD` data file and an `tbl_name.MYI` index file. For [InnoDB](#), the data and the indexes are stored together in the `.ibd` file. The `tbl_name.frm` file is still created as usual.

You cannot freely move `.ibd` files between database directories as you can with [MyISAM](#) table files. This is because the table definition that is stored in the [InnoDB](#) shared tablespace includes the database name, and because [InnoDB](#) must preserve the consistency of transaction IDs and log sequence numbers.

If you remove the `innodb_file_per_table` line from `my.cnf` and restart the server, [InnoDB](#) creates tables inside the shared tablespace files again.

The `--innodb_file_per_table` option affects only table creation, not access to existing tables. If you start the server with this option, new tables are created using `.ibd` files, but you can still access tables that exist in the shared tablespace. If you start the server without this option, new tables are created in the shared tablespace, but you can still access any tables that were created using multiple tablespaces.

Note

[InnoDB](#) always needs the shared tablespace because it puts its internal data dictionary and undo logs there. The `.ibd` files are not sufficient for [InnoDB](#) to operate.

To move an `.ibd` file and the associated table from one database to another, use a `RENAME TABLE` statement:

```
RENAME TABLE db1.tbl_name TO db2.tbl_name;
```

If you have a “clean” backup of an `.ibd` file, you can restore it to the MySQL installation from which it originated as follows:

1. Issue this `ALTER TABLE` statement to delete the current `.ibd` file:

```
ALTER TABLE tbl_name DISCARD TABLESPACE;
```

2. Copy the backup `.ibd` file to the proper database directory.
3. Issue this `ALTER TABLE` statement to tell [InnoDB](#) to use the new `.ibd` file for the table:

```
ALTER TABLE tbl_name IMPORT TABLESPACE;
```

In this context, a “clean” `.ibd` file backup is one for which the following requirements are satisfied:

- There are no uncommitted modifications by transactions in the `.ibd` file.
- There are no unmerged insert buffer entries in the `.ibd` file.
- Purge has removed all delete-marked index records from the `.ibd` file.

- `mysqld` has flushed all modified pages of the `.ibd` file from the buffer pool to the file.

You can make a clean backup `.ibd` file using the following method:

1. Stop all activity from the `mysqld` server and commit all transactions.
2. Wait until `SHOW ENGINE INNODB STATUS` shows that there are no active transactions in the database, and the main thread status of `InnoDB` is `Waiting for server activity`. Then you can make a copy of the `.ibd` file.

Another method for making a clean copy of an `.ibd` file is to use the commercial `InnoDB Hot Backup` tool:

1. Use `InnoDB Hot Backup` to back up the `InnoDB` installation.
2. Start a second `mysqld` server on the backup and let it clean up the `.ibd` files in the backup.

13.6.2.2. Using Raw Devices for the Shared Tablespace

You can use raw disk partitions as data files in the shared tablespace. By using a raw disk, you can perform non-buffered I/O on Windows and on some Unix systems without file system overhead. This may improve performance, but you are advised to perform tests with and without raw partitions to verify whether this is actually so on your system.

When you create a new data file, you must put the keyword `newraw` immediately after the data file size in `innodb_data_file_path`. The partition must be at least as large as the size that you specify. Note that 1MB in `InnoDB` is 1024×1024 bytes, whereas 1MB in disk specifications usually means 1,000,000 bytes.

```
[mysqld]
innodb_data_home_dir=
innodb_data_file_path=/dev/hdd1:3Gnewraw:/dev/hdd2:2Gnewraw
```

The next time you start the server, `InnoDB` notices the `newraw` keyword and initializes the new partition. However, do not create or change any `InnoDB` tables yet. Otherwise, when you next restart the server, `InnoDB` reinitializes the partition and your changes are lost. (As a safety measure `InnoDB` prevents users from modifying data when any partition with `newraw` is specified.)

After `InnoDB` has initialized the new partition, stop the server, change `newraw` in the data file specification to `raw`:

```
[mysqld]
innodb_data_home_dir=
innodb_data_file_path=/dev/hdd1:5Graw:/dev/hdd2:2Graw
```

Then restart the server and `InnoDB` allows changes to be made.

On Windows, you can allocate a disk partition as a data file like this:

```
[mysqld]
innodb_data_home_dir=
innodb_data_file_path=//./D:10Gnewraw
```

The `///` corresponds to the Windows syntax of `\\.\` for accessing physical drives.

When you use a raw disk partition, be sure that it has permissions that allow read and write access by the account used for running the MySQL server. For example, if you run the server as the `mysql` user, the partition must allow read and write access to `mysql`. If you run the server with the `--memlock` option, the server must be run as `root`, so the partition must allow access to `root`.

13.6.2.3. Creating the `InnoDB` Tablespace

Suppose that you have installed MySQL and have edited your option file so that it contains the necessary `InnoDB` configuration parameters. Before starting MySQL, you should verify that the directories you have specified for `InnoDB` data files and log files exist and that the MySQL server has access rights to those directories. `InnoDB` does not create directories, only files. Check also that you have enough disk space for the data and log files.

It is best to run the MySQL server `mysqld` from the command prompt when you first start the server with `InnoDB` enabled, not from `mysqld_safe` or as a Windows service. When you run from a command prompt you see what `mysqld` prints and what is happening. On Unix, just invoke `mysqld`. On Windows, start `mysqld` with the `--console` option to direct the output to the console window.

When you start the MySQL server after initially configuring `InnoDB` in your option file, `InnoDB` creates your data files and log

files, and prints something like this:

```
InnoDB: The first specified datafile /home/heikki/data/ibdata1
did not exist:
InnoDB: a new database to be created!
InnoDB: Setting file /home/heikki/data/ibdata1 size to 134217728
InnoDB: Database physically writes the file full: wait...
InnoDB: datafile /home/heikki/data/ibdata2 did not exist:
new to be created
InnoDB: Setting file /home/heikki/data/ibdata2 size to 262144000
InnoDB: Database physically writes the file full: wait...
InnoDB: Log file /home/heikki/data/logs/ib_logfile0 did not exist:
new to be created
InnoDB: Setting log file /home/heikki/data/logs/ib_logfile0 size
to 5242880
InnoDB: Log file /home/heikki/data/logs/ib_logfile1 did not exist:
new to be created
InnoDB: Setting log file /home/heikki/data/logs/ib_logfile1 size
to 5242880
InnoDB: Doublewrite buffer not found: creating new
InnoDB: Doublewrite buffer created
InnoDB: Creating foreign key constraint system tables
InnoDB: Foreign key constraint system tables created
InnoDB: Started
mysqld: ready for connections
```

At this point **InnoDB** has initialized its tablespace and log files. You can connect to the MySQL server with the usual MySQL client programs like `mysql`. When you shut down the MySQL server with `mysqladmin shutdown`, the output is like this:

```
010321 18:33:34 mysqld: Normal shutdown
010321 18:33:34 mysqld: Shutdown Complete
InnoDB: Starting shutdown...
InnoDB: Shutdown completed
```

You can look at the data file and log directories and you see the files created there. When MySQL is started again, the data files and log files have been created already, so the output is much briefer:

```
InnoDB: Started
mysqld: ready for connections
```

If you add the `innodb_file_per_table` option to `my.cnf`, **InnoDB** stores each table in its own `.ibd` file in the same MySQL database directory where the `.frm` file is created. See [Section 13.6.2.1, “Using Per-Table Tablespaces”](#).

13.6.2.4. Dealing with **InnoDB** Initialization Problems

If **InnoDB** prints an operating system error during a file operation, usually the problem has one of the following causes:

- You did not create the **InnoDB** data file directory or the **InnoDB** log directory.
- `mysqld` does not have access rights to create files in those directories.
- `mysqld` cannot read the proper `my.cnf` or `my.ini` option file, and consequently does not see the options that you specified.
- The disk is full or a disk quota is exceeded.
- You have created a subdirectory whose name is equal to a data file that you specified, so the name cannot be used as a file name.
- There is a syntax error in the `innodb_data_home_dir` or `innodb_data_file_path` value.

If something goes wrong when **InnoDB** attempts to initialize its tablespace or its log files, you should delete all files created by **InnoDB**. This means all `ibdata` files and all `ib_logfile` files. In case you have already created some **InnoDB** tables, delete the corresponding `.frm` files for these tables (and any `.ibd` files if you are using multiple tablespaces) from the MySQL database directories as well. Then you can try the **InnoDB** database creation again. It is best to start the MySQL server from a command prompt so that you see what is happening.

13.6.3. **InnoDB** Startup Options and System Variables

This section describes the **InnoDB**-related command options and system variables. System variables that are true or false can be enabled at server startup by naming them, or disabled by using a `--skip` prefix. For example, to enable or disable **InnoDB** checksums, you can use `--innodb_checksums` or `--skip-innodb_checksums` on the command line, or `innodb_checksums` or `skip-innodb_checksums` in an option file. System variables that take a numeric value can be specified as `--var_name=value` on the command line or as `var_name=value` in option files. For more information on specifying options and system variables, see [Section 4.2.3, “Specifying Program Options”](#). Many of the system variables can be changed at runtime (see [Section 5.1.5.2, “Dynamic System Variables”](#)).

MySQL Enterprise

The MySQL Enterprise Monitor provides expert advice on InnoDB start-up options and related system variables. For more information, see <http://www.mysql.com/products/enterprise/advisors.html>.

Table 13.5. `mysqld` InnoDB Option/Variable Reference

Name	Cmd-Line	Option file	System Var	Status Var	Var Scope	Dynamic

InnoDB command options:

- [--ignore-builtin-innodb](#)

This option causes the server to behave as if the built-in InnoDB is not present. It causes other InnoDB options not to be recognized.

- [--innodb](#)

Enables the InnoDB storage engine, if the server was compiled with InnoDB support. Use [--skip-innodb](#) to disable InnoDB.

- [--innodb_status_file](#)

Controls whether InnoDB creates a file named `innodb_status.<pid>` in the MySQL data directory. If enabled, InnoDB periodically writes the output of `SHOW ENGINE INNODB STATUS` to this file.

By default, the file is not created. To create it, start `mysqld` with the [--innodb_status_file=1](#) option. The file is deleted during normal shutdown.

InnoDB system variables:

- [ignore_builtin_innodb](#)

Whether the server was started with the [--ignore-builtin-innodb](#) option, which causes the server to behave as if the built-in InnoDB is not present.

- [innodb_adaptive_hash_index](#)

Whether InnoDB adaptive hash indexes are enabled or disabled (see [Section 13.6.10.4, “Adaptive Hash Indexes”](#)). This variable is enabled by default. Use [--skip-innodb_adaptive_hash_index](#) at server startup to disable it.

- [innodb_additional_mem_pool_size](#)

The size in bytes of a memory pool InnoDB uses to store data dictionary information and other internal data structures. The more tables you have in your application, the more memory you need to allocate here. If InnoDB runs out of memory in this pool, it starts to allocate memory from the operating system and writes warning messages to the MySQL error log. The default value is 8MB.

- [innodb_autoextend_increment](#)

The increment size (in MB) for extending the size of an auto-extending tablespace file when it becomes full. The default value is 64.

- [innodb_autoinc_lock_mode](#)

The locking mode to use for generating auto-increment values. The allowable values are 0, 1, or 2, for “traditional”, “consecutive”, or “interleaved” lock mode, respectively. [Section 13.6.4.3, “AUTO_INCREMENT Handling in InnoDB”](#), describes the characteristics of these modes.

This variable has a default of 1 (“consecutive” lock mode).

- [innodb_buffer_pool_size](#)

The size in bytes of the memory buffer InnoDB uses to cache data and indexes of its tables. The default value is 1GB. The larger you set this value, the less disk I/O is needed to access data in tables. On a dedicated database server, you may set this to up to 80% of the machine physical memory size. However, do not set it too large because competition for physical memory might cause paging in the operating system.

- [innodb_checksums](#)

InnoDB can use checksum validation on all pages read from the disk to ensure extra fault tolerance against broken hardware or

data files. This validation is enabled by default. However, under some rare circumstances (such as when running benchmarks) this extra safety feature is unneeded and can be disabled with `--skip-innodb-checksums`.

- `innodb_commit_concurrency`

The number of threads that can commit at the same time. A value of 0 (the default) allows any number of transactions to commit simultaneously.

- `innodb_concurrency_tickets`

The number of threads that can enter `InnoDB` concurrently is determined by the `innodb_thread_concurrency` variable. A thread is placed in a queue when it tries to enter `InnoDB` if the number of threads has already reached the concurrency limit. When a thread is allowed to enter `InnoDB`, it is given a number of “free tickets” equal to the value of `innodb_concurrency_tickets`, and the thread can enter and leave `InnoDB` freely until it has used up its tickets. After that point, the thread again becomes subject to the concurrency check (and possible queuing) the next time it tries to enter `InnoDB`. The default value is 500.

- `innodb_data_file_path`

The paths to individual data files and their sizes. The full directory path to each data file is formed by concatenating `innodb_data_home_dir` to each path specified here. The file sizes are specified in KB, MB, or GB (1024MB) by appending `K`, `M`, or `G` to the size value. The sum of the sizes of the files must be at least 10MB. If you do not specify `innodb_data_file_path`, the default behavior is to create a single 10MB auto-extending data file named `ibdata1`. The size limit of individual files is determined by your operating system. You can set the file size to more than 4GB on those operating systems that support big files. You can also use raw disk partitions as data files. For detailed information on configuring `InnoDB` tablespace files, see [Section 13.6.2, “InnoDB Configuration”](#).

- `innodb_data_home_dir`

The common part of the directory path for all `InnoDB` data files. The default value is the MySQL data directory. If you specify the value as an empty string, you can use absolute file paths in `innodb_data_file_path`.

- `innodb_doublewrite`

If this variable is enabled (the default), `InnoDB` stores all data twice, first to the doublewrite buffer, and then to the actual data files. This variable can be turned off with `--skip-innodb_doublewrite` for benchmarks or cases when top performance is needed rather than concern for data integrity or possible failures.

- `innodb_extra_dirty_writes`

This variable is used in conjunction with `innodb_max_dirty_pages_pct`. The latter variable specifies the percentage of pages that must be dirty before `InnoDB` flushes them. If `innodb_extra_dirty_writes` is enabled (the default), flushing of dirty pages may occur when the server is idle, even if the percentage of dirty pages has not reached the normally required percentage. This can help reduce the amount of flushing that must be done when the server is not idle and has fewer resources to spare. When `innodb_extra_dirty_writes` is disabled, extra flushing does not occur.

- `innodb_fast_shutdown`

The `InnoDB` shutdown mode. By default, the value is 1, which causes a “fast” shutdown (the normal type of shutdown). If the value is 0, `InnoDB` does a full purge and an insert buffer merge before a shutdown. These operations can take minutes, or even hours in extreme cases. If the value is 1, `InnoDB` skips these operations at shutdown. If the value is 2, `InnoDB` will just flush its logs and then shut down cold, as if MySQL had crashed; no committed transaction will be lost, but crash recovery will be done at the next startup. A value of 2 cannot be used on NetWare.

- `innodb_file_per_table`

If `innodb_file_per_table` is disabled (the default), `InnoDB` creates tables in the shared tablespace. If `innodb_file_per_table` is enabled, `InnoDB` creates each new table using its own `.ibd` file for storing data and indexes, rather than in the shared tablespace. See [Section 13.6.2.1, “Using Per-Table Tablespaces”](#).

- `innodb_flush_log_at_trx_commit`

If the value of `innodb_flush_log_at_trx_commit` is 0, the log buffer is written out to the log file once per second and the flush to disk operation is performed on the log file, but nothing is done at a transaction commit. When the value is 1 (the default), the log buffer is written out to the log file at each transaction commit and the flush to disk operation is performed on the log file. When the value is 2, the log buffer is written out to the file at each commit, but the flush to disk operation is not performed on it. However, the flushing on the log file takes place once per second also when the value is 2. Note that the once-per-second flushing is not 100% guaranteed to happen every second, due to process scheduling issues.

The default value of 1 is the value required for ACID compliance. You can achieve better performance by setting the value different from 1, but then you can lose at most one second worth of transactions in a crash. With a value of 0, any `mysql` pro-

cess crash can erase the last second of transactions. With a value of 2, then only an operating system crash or a power outage can erase the last second of transactions. However, **InnoDB's** crash recovery is not affected and thus crash recovery does work regardless of the value.

For the greatest possible durability and consistency in a replication setup using **InnoDB** with transactions, use `innodb_flush_log_at_trx_commit = 1` and `sync_binlog = 1` in your master server `my.cnf` file.

Caution

Many operating systems and some disk hardware fool the flush-to-disk operation. They may tell `mysqld` that the flush has taken place, even though it has not. Then the durability of transactions is not guaranteed even with the setting 1, and in the worst case a power outage can even corrupt the **InnoDB** database. Using a battery-backed disk cache in the SCSI disk controller or in the disk itself speeds up file flushes, and makes the operation safer. You can also try using the Unix command `hdparm` to disable the caching of disk writes in hardware caches, or use some other command specific to the hardware vendor.

- `innodb_flush_method`

By default, **InnoDB** uses `fsync()` to flush both the data and log files. If `innodb_flush_method` option is set to `O_DSYNC`, **InnoDB** uses `O_SYNC` to open and flush the log files, and `fsync()` to flush the data files. If `O_DIRECT` is specified (available on some GNU/Linux versions, FreeBSD, and Solaris), **InnoDB** uses `O_DIRECT` (or `directio()` on Solaris) to open the data files, and uses `fsync()` to flush both the data and log files. Note that **InnoDB** uses `fsync()` instead of `fdatasync()`, and it does not use `O_DSYNC` by default because there have been problems with it on many varieties of Unix. This variable is relevant only for Unix. On Windows, the flush method is always `async_unbuffered` and cannot be changed.

Different values of this variable can have a marked effect on **InnoDB** performance. For example, on some systems where **InnoDB** data and log files are located on a SAN, it has been found that setting `innodb_flush_method` to `O_DIRECT` can degrade performance of simple `SELECT` statements by a factor of three.

Formerly it was possible to specify a value of `fdatasync` to obtain the default behavior. This is no longer possible because it can be confusing that a value of `fdatasync` causes use of `fsync()` rather than `fdatasync()` for flushing.

- `innodb_force_recovery`

The crash recovery mode. Possible values are from 0 to 6. The meanings of these values are described in [Section 13.6.6.2, “Forcing InnoDB Recovery”](#).

Warning

This variable should be set greater than 0 only in an emergency situation when you want to dump your tables from a corrupt database! As a safety measure, **InnoDB** prevents any changes to its data when this variable is greater than 0.

- `innodb_io_capacity`

The maximum number of I/O operations per second that **InnoDB** will perform. This variable can be set at server startup, which enables higher values to be selected for systems capable of higher I/O rates. Having a higher I/O rate can help the server handle a higher rate of row changes because it may be able to increase dirty-page flushing, deleted-row removal, and application of changes to the insert buffer. The default value of `innodb_io_capacity` is 200. In general, you can increase the value as a function of the number of drives used for **InnoDB** I/O.

The ability to raise the I/O limit should be especially beneficial on platforms that support many IOPS. For example, systems that use multiple disks or solid-state disks for **InnoDB** are likely to benefit from the ability to control this parameter.

- `innodb_lock_wait_timeout`

The timeout in seconds an **InnoDB** transaction may wait for a row lock before giving up. The default value is 50 seconds. A transaction that tries to access a row that is locked by another **InnoDB** transaction will hang for at most this many seconds before issuing the following error:

```
ERROR 1205 (HY000): Lock wait timeout exceeded; try restarting transaction
```

When a lock wait timeout occurs, the current statement is not executed. The current transaction is *not* rolled back. (To have the entire transaction roll back, start the server with the `--innodb_rollback_on_timeout` option. See also [Section 13.6.12, “InnoDB Error Handling”](#).)

`innodb_lock_wait_timeout` applies to **InnoDB** row locks only. A MySQL table lock does not happen inside **InnoDB** and this timeout does not apply to waits for table locks.

InnoDB does detect transaction deadlocks in its own lock table immediately and rolls back one transaction. The lock wait

timeout value does not apply to such a wait.

- [innodb_locks_unsafe_for_binlog](#)

This variable affects how **InnoDB** uses gap locking for searches and index scans. Normally, **InnoDB** uses an algorithm called *next-key locking* that combines index-row locking with gap locking. **InnoDB** performs row-level locking in such a way that when it searches or scans a table index, it sets shared or exclusive locks on the index records it encounters. Thus, the row-level locks are actually index-record locks. In addition, a next-key lock on an index record also affects the “gap” before that index record. That is, a next-key lock is an index-record lock plus a gap lock on the gap preceding the index record. If one session has a shared or exclusive lock on record **R** in an index, another session cannot insert a new index record in the gap immediately before **R** in the index order. See [Section 13.6.8.4, “InnoDB Record, Gap, and Next-Key Locks”](#).

By default, the value of [innodb_locks_unsafe_for_binlog](#) is 0 (disabled), which means that gap locking is enabled: **InnoDB** uses next-key locks for searches and index scans. To enable the variable, set it to 1. This causes gap locking to be disabled: **InnoDB** uses only index-record locks for searches and index scans.

Enabling [innodb_locks_unsafe_for_binlog](#) does not disable the use of gap locking for foreign-key constraint checking or duplicate-key checking.

The effect of enabling [innodb_locks_unsafe_for_binlog](#) is similar to but not identical to setting the transaction isolation level to `READ COMMITTED`:

- Enabling [innodb_locks_unsafe_for_binlog](#) is a global setting and affects all sessions, whereas the isolation level can be set globally for all sessions, or individually per session.
- [innodb_locks_unsafe_for_binlog](#) can be set only at server startup, whereas the isolation level can be set at startup or changed at runtime.

`READ COMMITTED` therefore offers finer and more flexible control than [innodb_locks_unsafe_for_binlog](#). For additional details about the effect of isolation level on gap locking, see [Section 12.4.6, “SET TRANSACTION Syntax”](#).

Enabling [innodb_locks_unsafe_for_binlog](#) may cause phantom problems because other sessions can insert new rows into the gaps when gap locking is disabled. Suppose that there is an index on the `id` column of the `child` table and that you want to read and lock all rows from the table having an identifier value larger than 100, with the intention of updating some column in the selected rows later:

```
SELECT * FROM child WHERE id > 100 FOR UPDATE;
```

The query scans the index starting from the first record where `id` is greater than 100. If the locks set on the index records in that range do not lock out inserts made in the gaps, another session can insert a new row into the table. Consequently, if you were to execute the same `SELECT` again within the same transaction, you would see a new row in the result set returned by the query. This also means that if new items are added to the database, **InnoDB** does not guarantee serializability. Therefore, if [innodb_locks_unsafe_for_binlog](#) is enabled, **InnoDB** guarantees at most an isolation level of `READ COMMITTED`. (Conflict serializability is still guaranteed.) For additional information about phantoms, see [Section 13.6.8.5, “Avoiding the Phantom Problem Using Next-Key Locking”](#).

Enabling [innodb_locks_unsafe_for_binlog](#) has additional effects:

- For `UPDATE` or `DELETE` statements, **InnoDB** holds locks only for rows that it updates or deletes. Record locks for non-matching rows are released after MySQL has evaluated the `WHERE` condition. This greatly reduces the probability of deadlocks, but they can still happen.
- For `UPDATE` statements, if a row is already locked, **InnoDB** performs a “semi-consistent” read, returning the latest committed version to MySQL so that MySQL can determine whether the row matches the `WHERE` condition of the `UPDATE`. If the row matches (must be updated), MySQL reads the row again and this time **InnoDB** either locks it or waits for a lock on it.

Consider the following example, beginning with this table:

```
CREATE TABLE t (a INT NOT NULL, b INT) ENGINE = InnoDB;
INSERT INTO t VALUES (1,2), (2,3), (3,2), (4,3), (5,2);
COMMIT;
```

In this case, table has no indexes, so searches and index scans use the hidden clustered index for record locking (see [Section 13.6.10.1, “Clustered and Secondary Indexes”](#)).

Suppose that one client performs an `UPDATE` using these statements:

```
SET autocommit = 0;
UPDATE t SET b = 5 WHERE b = 3;
```

Suppose also that a second client performs an `UPDATE` by executing these statements following those of the first client:

```
SET autocommit = 0;
UPDATE t SET b = 4 WHERE b = 2;
```

As `InnoDB` executes each `UPDATE`, it first acquires an exclusive lock for each row, and then determines whether to modify it. If `InnoDB` does not modify the row and `innodb_locks_unsafe_for_binlog` is enabled, it releases the lock. Otherwise, `InnoDB` retains the lock until the end of the transaction. This affects transaction processing as follows.

If `innodb_locks_unsafe_for_binlog` is disabled, the first `UPDATE` acquires x-locks and does not release any of them:

```
x-lock(1,2); retain x-lock
x-lock(2,3); update(2,3) to (2,5); retain x-lock
x-lock(3,2); retain x-lock
x-lock(4,3); update(4,3) to (4,5); retain x-lock
x-lock(5,2); retain x-lock
```

The second `UPDATE` blocks as soon as it tries to acquire any locks (because first update has retained locks on all rows), and does not proceed until the first `UPDATE` commits or rolls back:

```
x-lock(1,2); block and wait for first UPDATE to commit or roll back
```

If `innodb_locks_unsafe_for_binlog` is enabled, the first `UPDATE` acquires x-locks and releases those for rows that it does not modify:

```
x-lock(1,2); unlock(1,2)
x-lock(2,3); update(2,3) to (2,5); retain x-lock
x-lock(3,2); unlock(3,2)
x-lock(4,3); update(4,3) to (4,5); retain x-lock
x-lock(5,2); unlock(5,2)
```

For the second `UPDATE`, `InnoDB` does a “semi-consistent” read, returning the latest committed version of each row to MySQL so that MySQL can determine whether the row matches the `WHERE` condition of the `UPDATE`:

```
x-lock(1,2); update(1,2) to (1,4); retain x-lock
x-lock(2,3); unlock(2,3)
x-lock(3,2); update(3,2) to (3,4); retain x-lock
x-lock(4,3); unlock(4,3)
x-lock(5,2); update(5,2) to (5,4); retain x-lock
```

- `innodb_log_buffer_size`

The size in bytes of the buffer that `InnoDB` uses to write to the log files on disk. The default value is 1MB. Sensible values range from 1MB to 8MB. A large log buffer allows large transactions to run without a need to write the log to disk before the transactions commit. Thus, if you have big transactions, making the log buffer larger saves disk I/O.

- `innodb_log_file_size`

The size in bytes of each log file in a log group. The combined size of log files must be less than 4GB. The default value is 5MB. Sensible values range from 1MB to 1/*N*-th of the size of the buffer pool, where *N* is the number of log files in the group. The larger the value, the less checkpoint flush activity is needed in the buffer pool, saving disk I/O. But larger log files also mean that recovery is slower in case of a crash.

- `innodb_log_files_in_group`

The number of log files in the log group. `InnoDB` writes to the files in a circular fashion. The default (and recommended) value is 3.

- `innodb_log_group_home_dir`

The directory path to the `InnoDB` log files. If you do not specify any `InnoDB` log variables, the default is to create two 5MB files names `ib_logfile0` and `ib_logfile1` in the MySQL data directory.

- `innodb_max_dirty_pages_pct`

This is an integer in the range from 0 to 99. The default value is 75. The main thread in `InnoDB` tries to write pages from the buffer pool so that the percentage of dirty (not yet written) pages will not exceed this value.

- `innodb_max_merged_io`

The maximum number of background I/O requests that will be merged to issue a larger I/O request in a more contiguous man-

ner. The default value is 64.

- `innodb_max_purge_lag`

This variable controls how to delay `INSERT`, `UPDATE`, and `DELETE` operations when purge operations are lagging (see [Section 13.6.9, “InnoDB Multi-Versioning”](#)). The default value 0 (no delays).

The InnoDB transaction system maintains a list of transactions that have delete-marked index records by `UPDATE` or `DELETE` operations. Let the length of this list be `purge_lag`. When `purge_lag` exceeds `innodb_max_purge_lag`, each `INSERT`, `UPDATE`, and `DELETE` operation is delayed by $((\text{purge_lag}/\text{innodb_max_purge_lag}) \times 10) - 5$ milliseconds. The delay is computed in the beginning of a purge batch, every ten seconds. The operations are not delayed if purge cannot run because of an old consistent read view that could see the rows to be purged.

A typical setting for a problematic workload might be 1 million, assuming that transactions are small, only 100 bytes in size, and it is allowable to have 100MB of unpurged InnoDB table rows.

- `innodb_mirrored_log_groups`

The number of identical copies of log groups to keep for the database. This should be set to 1.

- `innodb_open_files`

This variable is relevant only if you use multiple tablespaces in InnoDB. It specifies the maximum number of `.ibd` files that InnoDB can keep open at one time. The minimum value is 10. The default value is 300.

The file descriptors used for `.ibd` files are for InnoDB only. They are independent of those specified by the `-open-files-limit` server option, and do not affect the operation of the table cache.

- `innodb_read_io_threads`

The number of I/O threads for read operations in InnoDB. The default value is 8.

- `innodb_rollback_on_timeout`

In MySQL 5.4, InnoDB rolls back only the last statement on a transaction timeout by default. If `-innodb_rollback_on_timeout` is specified, a transaction timeout causes InnoDB to abort and roll back the entire transaction (the same behavior as in MySQL 4.1).

- `innodb_stats_on_metadata`

When this variable is enabled (which is the default, as before the variable was created), InnoDB updates statistics during metadata statements such as `SHOW TABLE STATUS` or `SHOW INDEX`, or when accessing the `INFORMATION_SCHEMA` tables `TABLES` or `STATISTICS`. (These updates are similar to what happens for `ANALYZE TABLE`.) When disabled, InnoDB does not update statistics during these operations. Disabling this variable can improve access speed for schemas that have a large number of tables or indexes. It can also improve the stability of execution plans for queries that involve InnoDB tables.

- `innodb_support_xa`

When the variable is enabled (the default), InnoDB support for two-phase commit in XA transactions is enabled, which causes an extra disk flush for transaction preparation.

If you do not wish to use XA transactions, you can disable this variable to reduce the number of disk flushes and get better InnoDB performance.

Having `innodb_support_xa` enabled on a replication master — or on any MySQL server where binary logging is in use — ensures that the binary log does not get out of sync compared to the table data.

- `innodb_sync_spin_loops`

The number of times a thread waits for an InnoDB mutex to be freed before the thread is suspended. The default value is 20.

- `innodb_table_locks`

If `autocommit = 0`, InnoDB honors `LOCK TABLES`; MySQL does not return from `LOCK TABLES ... WRITE` until all other threads have released all their locks to the table. The default value of `innodb_table_locks` is 1, which means that `LOCK TABLES` causes InnoDB to lock a table internally if `autocommit = 0`.

- `innodb_thread_concurrency`

InnoDB tries to keep the number of operating system threads concurrently inside **InnoDB** less than or equal to the limit given by this variable. Once the number of threads reaches this limit, additional threads are placed into a wait state within a FIFO queue for execution. Threads waiting for locks are not counted in the number of concurrently executing threads.

The correct value for this variable is dependent on environment and workload. You will need to try a range of different values to determine what value works for your applications.

The range of this variable is 0 to 1000. A value of 0 is interpreted as infinite concurrency (no concurrency checking). Disabling thread concurrency checking allows **InnoDB** to create as many threads as it needs. The default value is 0.

- `innodb_thread_concurrency_timer_based`

If this variable is enabled, use a lock-free timer-based method of handling thread concurrency. If disabled, the original mutex-based method is used. For the lock-free concurrency method to be used, two requirements must be satisfied:

- The `innodb_thread_concurrency` system variable must be set to a number greater than 0. The default value in MySQL 5.4 is 0, so you must change it to use the lock-free concurrency method.
- Atomic instructions must be available. That is, the `InnoDB_have_sync_atomic` status variable must be `ON`.

If `innodb_thread_concurrency` is 0 or `InnoDB_have_sync_atomic` is `OFF`, enabling `innodb_thread_concurrency_timer_based` has no effect.

- `innodb_thread_sleep_delay`

How long **InnoDB** threads sleep before joining the **InnoDB** queue, in microseconds. The default value is 10,000. A value of 0 disables sleep.

- `innodb_write_io_threads`

The number of I/O threads for write operations in **InnoDB**. The default value is 8.

- `sync_binlog`

If the value of this variable is greater than 0, the MySQL server synchronizes its binary log to disk (using `fdatasync()`) after every `sync_binlog` writes to the binary log. There is one write to the binary log per statement if autocommit is enabled, and one write per transaction otherwise. The default value of `sync_binlog` is 0, which does no synchronizing to disk. A value of 1 is the safest choice, because in the event of a crash you lose at most one statement or transaction from the binary log. However, it is also the slowest choice (unless the disk has a battery-backed cache, which makes synchronization very fast).

13.6.4. Creating and Using **InnoDB** Tables

To create an **InnoDB** table, specify an `ENGINE = InnoDB` option in the `CREATE TABLE` statement:

```
CREATE TABLE customers (a INT, b CHAR (20), INDEX (a)) ENGINE=InnoDB;
```

The statement creates a table and an index on column `a` in the **InnoDB** tablespace that consists of the data files that you specified in `my.cnf`. In addition, MySQL creates a file `customers.frm` in the `test` directory under the MySQL database directory. Internally, **InnoDB** adds an entry for the table to its own data dictionary. The entry includes the database name. For example, if `test` is the database in which the `customers` table is created, the entry is for `'test/customers'`. This means you can create a table of the same name `customers` in some other database, and the table names do not collide inside **InnoDB**.

You can query the amount of free space in the **InnoDB** tablespace by issuing a `SHOW TABLE STATUS` statement for any **InnoDB** table. The amount of free space in the tablespace appears in the `Data_free` section in the output of `SHOW TABLE STATUS`. For example:

```
SHOW TABLE STATUS FROM test LIKE 'customers'
```

The statistics `SHOW` displays for **InnoDB** tables are only approximate. They are used in SQL optimization. Table and index reserved sizes in bytes are accurate, though.

13.6.4.1. How to Use Transactions in **InnoDB** with Different APIs

By default, each client that connects to the MySQL server begins with autocommit mode enabled, which automatically commits every SQL statement as you execute it. To use multiple-statement transactions, you can switch autocommit off with the SQL statement `SET autocommit = 0` and end each transaction with either `COMMIT` or `ROLLBACK`. If you want to leave autocommit on, you can begin your transactions within `START TRANSACTION` and end them with `COMMIT` or `ROLLBACK`. The following ex-

ample shows two transactions. The first is committed; the second is rolled back.

```
shell> mysql test

mysql> CREATE TABLE customer (a INT, b CHAR (20), INDEX (a))
-> ENGINE=InnoDB;
Query OK, 0 rows affected (0.00 sec)
mysql> START TRANSACTION;
Query OK, 0 rows affected (0.00 sec)
mysql> INSERT INTO customer VALUES (10, 'Heikki');
Query OK, 1 row affected (0.00 sec)
mysql> COMMIT;
Query OK, 0 rows affected (0.00 sec)
mysql> SET autocommit=0;
Query OK, 0 rows affected (0.00 sec)
mysql> INSERT INTO customer VALUES (15, 'John');
Query OK, 1 row affected (0.00 sec)
mysql> ROLLBACK;
Query OK, 0 rows affected (0.00 sec)
mysql> SELECT * FROM customer;
+-----+-----+
| a     | b     |
+-----+-----+
| 10    | Heikki |
+-----+-----+
1 row in set (0.00 sec)
mysql>
```

In APIs such as PHP, Perl DBI, JDBC, ODBC, or the standard C call interface of MySQL, you can send transaction control statements such as `COMMIT` to the MySQL server as strings just like any other SQL statements such as `SELECT` or `INSERT`. Some APIs also offer separate special transaction commit and rollback functions or methods.

13.6.4.2. Converting Tables from Other Storage Engines to InnoDB

To convert a non-InnoDB table to use InnoDB use `ALTER TABLE`:

```
ALTER TABLE t1 ENGINE=InnoDB;
```

Important

Do not convert MySQL system tables in the `mysql` database (such as `user` or `host`) to the InnoDB type. This is an unsupported operation. The system tables must always be of the `MyISAM` type.

InnoDB does not have a special optimization for separate index creation the way the `MyISAM` storage engine does. Therefore, it does not pay to export and import the table and create indexes afterward. The fastest way to alter a table to InnoDB is to do the inserts directly to an InnoDB table. That is, use `ALTER TABLE ... ENGINE=INNODB`, or create an empty InnoDB table with identical definitions and insert the rows with `INSERT INTO ... SELECT * FROM ...`

If you have `UNIQUE` constraints on secondary keys, you can speed up a table import by turning off the uniqueness checks temporarily during the import operation:

```
SET unique_checks=0;
... import operation ...
SET unique_checks=1;
```

For big tables, this saves a lot of disk I/O because InnoDB can then use its insert buffer to write secondary index records as a batch. Be certain that the data contains no duplicate keys. `unique_checks` allows but does not require storage engines to ignore duplicate keys.

To get better control over the insertion process, it might be good to insert big tables in pieces:

```
INSERT INTO newtable SELECT * FROM oldtable
WHERE yourkey > something AND yourkey <= somethingelse;
```

After all records have been inserted, you can rename the tables.

During the conversion of big tables, you should increase the size of the InnoDB buffer pool to reduce disk I/O. Do not use more than 80% of the physical memory, though. You can also increase the sizes of the InnoDB log files.

Make sure that you do not fill up the tablespace: InnoDB tables require a lot more disk space than `MyISAM` tables. If an `ALTER TABLE` operation runs out of space, it starts a rollback, and that can take hours if it is disk-bound. For inserts, InnoDB uses the insert buffer to merge secondary index records to indexes in batches. That saves a lot of disk I/O. For rollback, no such mechanism is used, and the rollback can take 30 times longer than the insertion.

In the case of a runaway rollback, if you do not have valuable data in your database, it may be advisable to kill the database process rather than wait for millions of disk I/O operations to complete. For the complete procedure, see [Section 13.6.6.2, “Forcing InnoDB Recovery”](#).

If you want all your (non-system) tables to be created as `InnoDB` tables, add the line `default-storage-engine=innodb` to the `[mysqld]` section of your server option file.

13.6.4.3. `AUTO_INCREMENT` Handling in `InnoDB`

`InnoDB` provides a locking strategy that significantly improves scalability and performance of SQL statements that add rows to tables with `AUTO_INCREMENT` columns. This section provides background information on the original (“traditional”) implementation of auto-increment locking in `InnoDB`, explains the configurable locking mechanism, documents the parameter for configuring the mechanism, and describes its behavior and interaction with replication.

13.6.4.3.1. “Traditional” `InnoDB` Auto-Increment Locking

The original implementation of auto-increment handling in `InnoDB` uses the following strategy to prevent problems when using the binary log for statement-based replication or for certain recovery scenarios.

If you specify an `AUTO_INCREMENT` column for an `InnoDB` table, the table handle in the `InnoDB` data dictionary contains a special counter called the auto-increment counter that is used in assigning new values for the column. This counter is stored only in main memory, not on disk.

`InnoDB` uses the following algorithm to initialize the auto-increment counter for a table `t` that contains an `AUTO_INCREMENT` column named `ai_col`: After a server startup, for the first insert into a table `t`, `InnoDB` executes the equivalent of this statement:

```
SELECT MAX(ai_col) FROM t FOR UPDATE;
```

`InnoDB` increments by one the value retrieved by the statement and assigns it to the column and to the auto-increment counter for the table. If the table is empty, `InnoDB` uses the value `1`. If a user invokes a `SHOW TABLE STATUS` statement that displays output for the table `t` and the auto-increment counter has not been initialized, `InnoDB` initializes but does not increment the value and stores it for use by later inserts. This initialization uses a normal exclusive-locking read on the table and the lock lasts to the end of the transaction.

`InnoDB` follows the same procedure for initializing the auto-increment counter for a freshly created table.

After the auto-increment counter has been initialized, if a user does not explicitly specify a value for an `AUTO_INCREMENT` column, `InnoDB` increments the counter by one and assigns the new value to the column. If the user inserts a row that explicitly specifies the column value, and the value is bigger than the current counter value, the counter is set to the specified column value.

When accessing the auto-increment counter, `InnoDB` uses a special table-level `AUTO-INC` lock that it keeps to the end of the current SQL statement, not to the end of the transaction. The special lock release strategy was introduced to improve concurrency for inserts into a table containing an `AUTO_INCREMENT` column. Nevertheless, two transactions cannot have the `AUTO-INC` lock on the same table simultaneously, which can have a performance impact if the `AUTO-INC` lock is held for a long time. That might be the case for a statement such as `INSERT INTO t1 ... SELECT ... FROM t2` that inserts all rows from one table into another.

`InnoDB` uses the in-memory auto-increment counter as long as the server runs. When the server is stopped and restarted, `InnoDB` reinitializes the counter for each table for the first `INSERT` to the table, as described earlier.

You may see gaps in the sequence of values assigned to the `AUTO_INCREMENT` column if you roll back transactions that have generated numbers using the counter.

If a user specifies `NULL` or `0` for the `AUTO_INCREMENT` column in an `INSERT`, `InnoDB` treats the row as if the value had not been specified and generates a new value for it.

The behavior of the auto-increment mechanism is not defined if a user assigns a negative value to the column or if the value becomes bigger than the maximum integer that can be stored in the specified integer type.

An `AUTO_INCREMENT` column must appear as the first column in an index on an `InnoDB` table.

`InnoDB` supports the `AUTO_INCREMENT = N` table option in `CREATE TABLE` and `ALTER TABLE` statements, to set the initial counter value or alter the current counter value. The effect of this option is canceled by a server restart, for reasons discussed earlier in this section.

13.6.4.3.2. Configurable `InnoDB` Auto-Increment Locking

As described in the previous section, `InnoDB` uses a special lock called the table-level `AUTO-INC` lock for inserts into tables with `AUTO_INCREMENT` columns. This lock is normally held to the end of the statement (not to the end of the transaction), to ensure that auto-increment numbers are assigned in a predictable and repeatable order for a given sequence of `INSERT` statements.

In the case of statement-based replication, this means that when an SQL statement is replicated on a slave server, the same values are used for the auto-increment column as on the master server. The result of execution of multiple `INSERT` statements is determ-

istic, and the slave reproduces the same data as on the master. If auto-increment values generated by multiple `INSERT` statements were interleaved, the result of two concurrent `INSERT` statements would be non-deterministic, and could not reliably be propagated to a slave server using statement-based replication.

To make this clear, consider an example that uses this table:

```
CREATE TABLE t1 (
  c1 INT(11) NOT NULL AUTO_INCREMENT,
  c2 VARCHAR(10) DEFAULT NULL,
  PRIMARY KEY (c1)
) ENGINE=InnoDB;
```

Suppose that there are two transactions running, each inserting rows into a table with an `AUTO_INCREMENT` column. One transaction is using an `INSERT ... SELECT` statement that inserts 1000 rows, and another is using a simple `INSERT` statement that inserts one row:

```
Tx1: INSERT INTO t1 (c2) SELECT 1000 rows from another table ...
Tx2: INSERT INTO t1 (c2) VALUES ('xxx');
```

`InnoDB` cannot tell in advance how many rows will be retrieved from the `SELECT` in the `INSERT` statement in Tx1, and it assigns the auto-increment values one at a time as the statement proceeds. With a table-level lock, held to the end of the statement, only one `INSERT` statement referring to table `t1` can execute at a time, and the generation of auto-increment numbers by different statements is not interleaved. The auto-increment value generated by the Tx1 `INSERT ... SELECT` statement will be consecutive, and the (single) auto-increment value used by the `INSERT` statement in Tx2 will either be smaller or larger than all those used for Tx1, depending on which statement executes first.

As long as the SQL statements execute in the same order when replayed from the binary log (when using statement-based replication, or in recovery scenarios), the results will be the same as they were when Tx1 and Tx2 first ran. Thus, table-level locks held until the end of a statement make `INSERT` statements using auto-increment safe for use with statement-based replication. However, those locks limit concurrency and scalability when multiple transactions are executing insert statements at the same time.

In the preceding example, if there were no table-level lock, the value of the auto-increment column used for the `INSERT` in Tx2 depends on precisely when the statement executes. If the `INSERT` of Tx2 executes while the `INSERT` of Tx1 is running (rather than before it starts or after it completes), the specific auto-increment values assigned by the two `INSERT` statements are non-deterministic, and may vary from run to run.

`InnoDB` can avoid using the table-level `AUTO-INC` lock for a class of `INSERT` statements where the number of rows is known in advance, and still preserve deterministic execution and safety for statement-based replication. Further, if you are not using the binary log to replay SQL statements as part of recovery or replication, you can entirely eliminate use of the table-level `AUTO-INC` lock for even greater concurrency and performance—at the cost of permitting gaps in auto-increment numbers assigned by a statement and potentially having the numbers assigned by concurrently executing statements interleaved.

For `INSERT` statements where the number of rows to be inserted is known at the beginning of processing the statement, `InnoDB` quickly allocates the required number of auto-increment values without taking any lock, but only if there is no concurrent session already holding the table-level `AUTO-INC` lock (because that other statement will be allocating auto-increment values one-by-one as it proceeds). More precisely, such an `INSERT` statement obtains auto-increment values under the control of a mutex (a lightweight lock) that is *not* held until the statement completes, but only for the duration of the allocation process.

This new locking scheme allows much greater scalability, but it does introduce some subtle differences in how auto-increment values are assigned compared to the original mechanism. To describe the way auto-increment works in `InnoDB`, the following discussion defines some terms, and explains how `InnoDB` behaves using different settings of the new `innodb_autoinc_lock_mode` configuration parameter. Additional considerations are described following the explanation of auto-increment locking behavior.

First, some definitions:

- “`INSERT-like`” statements

All statements that generate new rows in a table, including `INSERT`, `INSERT ... SELECT`, `REPLACE`, `REPLACE ... SELECT`, and `LOAD DATA`.

- “Simple inserts”

Statements for which the number of rows to be inserted can be determined in advance (when the statement is initially processed). This includes single-row and multiple-row `INSERT` and `REPLACE` statements that do not have a nested subquery, but not `INSERT ... ON DUPLICATE KEY UPDATE`.

- “Bulk inserts”

Statements for which the number of rows to be inserted (and the number of required auto-increment values) is not known in advance. This includes `INSERT ... SELECT`, `REPLACE ... SELECT`, and `LOAD DATA` statements. `InnoDB` will assign

new values for the `AUTO_INCREMENT` column one at a time as each row is processed.

- “Mixed-mode inserts”

These are “simple insert” statements that specify the auto-increment value for some (but not all) of the new rows. An example follows, where `c1` is an `AUTO_INCREMENT` column of table `t1`:

```
INSERT INTO t1 (c1,c2) VALUES (1,'a'), (NULL,'b'), (5,'c'), (NULL,'d');
```

Another type of “mixed-mode insert” is `INSERT ... ON DUPLICATE KEY UPDATE`, which in the worst case is in effect an `INSERT` followed by a `UPDATE`, where the allocated value for the `AUTO_INCREMENT` column may or may not be used during the update phase.

In MySQL 5.4, there is a configuration parameter that controls how `InnoDB` uses locking when generating values for `AUTO_INCREMENT` columns. This parameter can be set using the `--innodb-autoinc-lock-mode` option at `mysqld` startup.

In general, if you encounter problems with the way auto-increment works (which will most likely involve replication), you can force use of the original behavior by setting the lock mode to 0.

There are three possible settings for the `innodb_autoinc_lock_mode` parameter:

- `innodb_autoinc_lock_mode = 0` (“traditional” lock mode)

This lock mode provides the same behavior as before `innodb_autoinc_lock_mode` existed. For all “`INSERT`-like” statements, a special table-level `AUTO-INC` lock is obtained and held to the end of the statement. This assures that the auto-increment values assigned by any given statement are consecutive (although “gaps” can exist within a table if a transaction that generated auto-increment values is rolled back, as discussed later).

This lock mode is provided only for backward compatibility and performance testing. There is little reason to use this lock mode unless you use “mixed-mode inserts” and care about the important difference in semantics described later.

- `innodb_autoinc_lock_mode = 1` (“consecutive” lock mode)

This is the default lock mode. In this mode, “bulk inserts” use the special `AUTO-INC` table-level lock and hold it until the end of the statement. This applies to all `INSERT ... SELECT`, `REPLACE ... SELECT`, and `LOAD DATA` statements. Only one statement holding the `AUTO-INC` lock can execute at a time.

With this lock mode, “simple inserts” (only) use a new locking model where a light-weight mutex is used during the allocation of auto-increment values, and no table-level `AUTO-INC` lock is used, unless an `AUTO-INC` lock is held by another transaction. If another transaction does hold an `AUTO-INC` lock, a “simple insert” waits for the `AUTO-INC` lock, as if it too were a “bulk insert.”

This lock mode ensures that, in the presence of `INSERT` statements where the number of rows is not known in advance (and where auto-increment numbers are assigned as the statement progresses), all auto-increment values assigned by any “`INSERT`-like” statement are consecutive, and operations are safe for statement-based replication.

Simply put, the important impact of this lock mode is significantly better scalability. This mode is safe for use with statement-based replication. Further, as with “traditional” lock mode, auto-increment numbers assigned by any given statement are *consecutive*. In this mode, there is *no change* in semantics compared to “traditional” mode for any statement that uses auto-increment, with one important exception.

The exception is for “mixed-mode inserts”, where the user provides explicit values for an `AUTO_INCREMENT` column for some, but not all, rows in a multiple-row “simple insert.” For such inserts, `InnoDB` will allocate more auto-increment values than the number of rows to be inserted. However, all values automatically assigned are consecutively generated (and thus higher than) the auto-increment value generated by the most recently executed previous statement. “Excess” numbers are lost.

A similar situation exists if you use `INSERT ... ON DUPLICATE KEY UPDATE`. This statement is also classified as a “mixed-mode insert” since an auto-increment value is not necessarily generated for each row. Because `InnoDB` allocates the auto-increment value before the insert is actually attempted, it cannot know whether an inserted value will be a duplicate of an existing value and thus cannot know whether the auto-increment value it generates will be used for a new row. Therefore, if you are using statement-based replication, you must either avoid `INSERT ... ON DUPLICATE KEY UPDATE` or use `innodb_autoinc_lock_mode = 0` (“traditional” lock mode).

- `innodb_autoinc_lock_mode = 2` (“interleaved” lock mode)

In this lock mode, no “`INSERT`-like” statements use the table-level `AUTO-INC` lock, and multiple statements can execute at the same time. This is the fastest and most scalable lock mode, but it is *not safe* when using statement-based replication or re-

covery scenarios when SQL statements are replayed from the binary log.

In this lock mode, auto-increment values are guaranteed to be unique and monotonically increasing across all concurrently executing “INSERT-like” statements. However, because multiple statements can be generating numbers at the same time (that is, allocation of numbers is *interleaved* across statements), the values generated for the rows inserted by any given statement may not be consecutive.

If the only statements executing are “simple inserts” where the number of rows to be inserted is known ahead of time, there will be no gaps in the numbers generated for a single statement, except for “mixed-mode inserts.” However, when “bulk inserts” are executed, there may be gaps in the auto-increment values assigned by any given statement.

The auto-increment locking modes provided by `innodb_autoinc_lock_mode` have several usage implications:

- Using auto-increment with replication

If you are using statement-based replication, you should set `innodb_autoinc_lock_mode` to 0 or 1 and use the same value on the master and its slaves. Auto-increment values are not ensured to be the same on the slaves as on the master if you use `innodb_autoinc_lock_mode = 2` (“interleaved”) or configurations where the master and slaves do not use the same lock mode.

If you are using row-based replication, all of the auto-increment lock modes are safe. Row-based replication is not sensitive to the order of execution of the SQL statements.

- “Lost” auto-increment values and sequence gaps

In all lock modes (0, 1, and 2), if a transaction that generated auto-increment values rolls back, those auto-increment values are “lost.” Once a value is generated for an auto-increment column, it cannot be rolled back, whether or not the “INSERT-like” statement is completed, and whether or not the containing transaction is rolled back. Such lost values are not reused. Thus, there may be gaps in the values stored in an `AUTO_INCREMENT` column of a table.

- Auto-increment values assigned by “mixed-mode inserts”

Consider a “mixed-mode insert,” where a “simple insert” specifies the auto-increment value for some (but not all) resulting rows. Such a statement will behave differently in lock modes 0, 1, and 2. For example, assume `c1` is an `AUTO_INCREMENT` column of table `t1`, and that the most recent automatically generated sequence number is 100. Consider the following “mixed-mode insert” statement:

```
INSERT INTO t1 (c1,c2) VALUES (1,'a'), (NULL,'b'), (5,'c'), (NULL,'d');
```

With `innodb_autoinc_lock_mode` set to 0 (“traditional”), the four new rows will be:

c1	c2
1	a
101	b
5	c
102	d

The next available auto-increment value will be 103 because the auto-increment values are allocated one at a time, not all at once at the beginning of statement execution. This result is true whether or not there are concurrently executing “INSERT-like” statements (of any type).

With `innodb_autoinc_lock_mode` set to 1 (“consecutive”), the four new rows will also be:

c1	c2
1	a
101	b
5	c
102	d

However, in this case, the next available auto-increment value will be 105, not 103 because four auto-increment values are allocated at the time the statement is processed, but only two are used. This result is true whether or not there are concurrently executing “INSERT-like” statements (of any type).

With `innodb_autoinc_lock_mode` set to mode 2 (“interleaved”), the four new rows will be:

```
+-----+-----+
```

c1	c2
1	a
<i>x</i>	b
5	c
<i>y</i>	d

The values of *x* and *y* will be unique and larger than any previously generated rows. However, the specific values of *x* and *y* will depend on the number of auto-increment values generated by concurrently executing statements.

Finally, consider the following statement, issued when the most-recently generated sequence number was the value 4:

```
INSERT INTO t1 (c1,c2) VALUES (1,'a'), (NULL,'b'), (5,'c'), (NULL,'d');
```

With any `innodb_autoinc_lock_mode` setting, this statement will generate a duplicate-key error 23000 (`Can't write; duplicate key in table`) because 5 will be allocated for the row `(NULL, 'b')` and insertion of the row `(5, 'c')` will fail.

- Gaps in auto-increment values for “bulk inserts”

With `innodb_autoinc_lock_mode` set to 0 (“traditional”) or 1 (“consecutive”), the auto-increment values generated by any given statement will be consecutive, without gaps, because the table-level `AUTO-INC` lock is held until the end of the statement, and only one such statement can execute at a time.

With `innodb_autoinc_lock_mode` set to 2 (“interleaved”), there may be gaps in the auto-increment values generated by “bulk inserts,” but only if there are concurrently executing “`INSERT`-like” statements.

13.6.4.4. FOREIGN KEY Constraints

InnoDB supports foreign key constraints. The syntax for a foreign key constraint definition in InnoDB looks like this:

```
[CONSTRAINT symbol] FOREIGN KEY
  [index_name] (index_col_name, ...)
REFERENCES tbl_name (index_col_name, ...)
[ON DELETE reference_option]
[ON UPDATE reference_option]

reference_option:
  RESTRICT | CASCADE | SET NULL | NO ACTION
```

index_name represents a foreign key ID. If given, this is ignored if an index for the foreign key is defined explicitly. Otherwise, if InnoDB creates an index for the foreign key, it uses *index_name* for the index name.

Foreign key definitions are subject to the following conditions:

- Both tables must be InnoDB tables and they must not be `TEMPORARY` tables.
- Corresponding columns in the foreign key and the referenced key must have similar internal data types inside InnoDB so that they can be compared without a type conversion. *The size and sign of integer types must be the same.* The length of string types need not be the same. For nonbinary (character) string columns, the character set and collation must be the same.
- InnoDB requires indexes on foreign keys and referenced keys so that foreign key checks can be fast and not require a table scan. In the referencing table, there must be an index where the foreign key columns are listed as the *first* columns in the same order. Such an index is created on the referencing table automatically if it does not exist. (This is in contrast to some older versions, in which indexes had to be created explicitly or the creation of foreign key constraints would fail.) *index_name*, if given, is used as described previously.
- InnoDB allows a foreign key to reference any index column or group of columns. However, in the referenced table, there must be an index where the referenced columns are listed as the *first* columns in the same order.
- Index prefixes on foreign key columns are not supported. One consequence of this is that `BLOB` and `TEXT` columns cannot be included in a foreign key because indexes on those columns must always include a prefix length.
- If the `CONSTRAINT symbol` clause is given, the *symbol* value must be unique in the database. If the clause is not given, InnoDB creates the name automatically.

InnoDB rejects any `INSERT` or `UPDATE` operation that attempts to create a foreign key value in a child table if there is no a matching candidate key value in the parent table. The action InnoDB takes for any `UPDATE` or `DELETE` operation that attempts to

update or delete a candidate key value in the parent table that has some matching rows in the child table is dependent on the *referential action* specified using `ON UPDATE` and `ON DELETE` subclauses of the `FOREIGN KEY` clause. When the user attempts to delete or update a row from a parent table, and there are one or more matching rows in the child table, `InnoDB` supports five options regarding the action to be taken. If `ON DELETE` or `ON UPDATE` are not specified, the default action is `RESTRICT`.

- `CASCADE`: Delete or update the row from the parent table and automatically delete or update the matching rows in the child table. Both `ON DELETE CASCADE` and `ON UPDATE CASCADE` are supported. Between two tables, you should not define several `ON UPDATE CASCADE` clauses that act on the same column in the parent table or in the child table.

Note

Currently, cascaded foreign key actions do not activate triggers.

- `SET NULL`: Delete or update the row from the parent table and set the foreign key column or columns in the child table to `NULL`. This is valid only if the foreign key columns do not have the `NOT NULL` qualifier specified. Both `ON DELETE SET NULL` and `ON UPDATE SET NULL` clauses are supported.

If you specify a `SET NULL` action, *make sure that you have not declared the columns in the child table as `NOT NULL`*.

- `NO ACTION`: In standard SQL, `NO ACTION` means *no action* in the sense that an attempt to delete or update a primary key value is not allowed to proceed if there is a related foreign key value in the referenced table. `InnoDB` rejects the delete or update operation for the parent table.
- `RESTRICT`: Rejects the delete or update operation for the parent table. Specifying `RESTRICT` (or `NO ACTION`) is the same as omitting the `ON DELETE` or `ON UPDATE` clause. (Some database systems have deferred checks, and `NO ACTION` is a deferred check. In MySQL, foreign key constraints are checked immediately, so `NO ACTION` is the same as `RESTRICT`.)
- `SET DEFAULT`: This action is recognized by the parser, but `InnoDB` rejects table definitions containing `ON DELETE SET DEFAULT` or `ON UPDATE SET DEFAULT` clauses.

`InnoDB` supports foreign key references within a table. In these cases, “child table records” really refers to dependent records within the same table.

Here is a simple example that relates `parent` and `child` tables through a single-column foreign key:

```
CREATE TABLE parent (id INT NOT NULL,
                     PRIMARY KEY (id))
ENGINE=INNODB;
CREATE TABLE child (id INT, parent_id INT,
                    INDEX par_ind (parent_id),
                    FOREIGN KEY (parent_id) REFERENCES parent(id)
                    ON DELETE CASCADE)
ENGINE=INNODB;
```

A more complex example in which a `product_order` table has foreign keys for two other tables. One foreign key references a two-column index in the `product` table. The other references a single-column index in the `customer` table:

```
CREATE TABLE product (category INT NOT NULL, id INT NOT NULL,
                      price DECIMAL,
                      PRIMARY KEY(category, id)) ENGINE=INNODB;
CREATE TABLE customer (id INT NOT NULL,
                       PRIMARY KEY (id)) ENGINE=INNODB;
CREATE TABLE product_order (no INT NOT NULL AUTO_INCREMENT,
                             product_category INT NOT NULL,
                             product_id INT NOT NULL,
                             customer_id INT NOT NULL,
                             PRIMARY KEY(no),
                             INDEX (product_category, product_id),
                             FOREIGN KEY (product_category, product_id)
                             REFERENCES product(category, id)
                             ON UPDATE CASCADE ON DELETE RESTRICT,
                             INDEX (customer_id),
                             FOREIGN KEY (customer_id)
                             REFERENCES customer(id)) ENGINE=INNODB;
```

`InnoDB` allows you to add a new foreign key constraint to a table by using `ALTER TABLE`:

```
ALTER TABLE tbl_name
ADD [CONSTRAINT [symbol]] FOREIGN KEY
[index_name] (index_col_name, ...)
REFERENCES tbl_name (index_col_name, ...)
[ON DELETE reference_option]
[ON UPDATE reference_option]
```

The foreign key can be self referential (referring to the same table). When you add a foreign key constraint to a table using `ALTER TABLE`, *remember to create the required indexes first*.

InnoDB supports the use of `ALTER TABLE` to drop foreign keys:

```
ALTER TABLE tbl_name DROP FOREIGN KEY fk_symbol;
```

If the `FOREIGN KEY` clause included a `CONSTRAINT` name when you created the foreign key, you can refer to that name to drop the foreign key. Otherwise, the `fk_symbol` value is internally generated by InnoDB when the foreign key is created. To find out the symbol value when you want to drop a foreign key, use the `SHOW CREATE TABLE` statement. For example:

```
mysql> SHOW CREATE TABLE ibtest11c\G
***** 1. ROW *****
      Table: ibtest11c
Create Table: CREATE TABLE `ibtest11c` (
  `A` int(11) NOT NULL auto_increment,
  `D` int(11) NOT NULL default '0',
  `B` varchar(200) NOT NULL default '',
  `C` varchar(175) default NULL,
  PRIMARY KEY (`A`,`D`,`B`),
  KEY `B` (`B`,`C`),
  KEY `C` (`C`),
  CONSTRAINT `0_38775` FOREIGN KEY (`A`, `D`)
REFERENCES `ibtest11a` (`A`, `D`)
ON DELETE CASCADE ON UPDATE CASCADE,
  CONSTRAINT `0_38776` FOREIGN KEY (`B`, `C`)
REFERENCES `ibtest11a` (`B`, `C`)
ON DELETE CASCADE ON UPDATE CASCADE
) ENGINE=INNODB CHARSET=latin1
1 row in set (0.01 sec)

mysql> ALTER TABLE ibtest11c DROP FOREIGN KEY `0_38775`;
```

You cannot add a foreign key and drop a foreign key in separate clauses of a single `ALTER TABLE` statement. Separate statements are required.

If `ALTER TABLE` for an InnoDB table results in changes to column values (for example, because a column is truncated), InnoDB's `FOREIGN KEY` constraint checks do not notice possible violations caused by changing the values.

The InnoDB parser allows table and column identifiers in a `FOREIGN KEY ... REFERENCES ...` clause to be quoted with in backticks. (Alternatively, double quotes can be used if the `ANSI_QUOTES SQL` mode is enabled.) The InnoDB parser also takes into account the setting of the `lower_case_table_names` system variable.

InnoDB returns a table's foreign key definitions as part of the output of the `SHOW CREATE TABLE` statement:

```
SHOW CREATE TABLE tbl_name;
```

`mysqldump` also produces correct definitions of tables in the dump file, and does not forget about the foreign keys.

You can also display the foreign key constraints for a table like this:

```
SHOW TABLE STATUS FROM db_name LIKE 'tbl_name';
```

The foreign key constraints are listed in the `Comment` column of the output.

When performing foreign key checks, InnoDB sets shared row-level locks on child or parent records it has to look at. InnoDB checks foreign key constraints immediately; the check is not deferred to transaction commit.

To make it easier to reload dump files for tables that have foreign key relationships, `mysqldump` automatically includes a statement in the dump output to set `foreign_key_checks` to 0. This avoids problems with tables having to be reloaded in a particular order when the dump is reloaded. It is also possible to set this variable manually:

```
mysql> SET foreign_key_checks = 0;
mysql> SOURCE dump_file_name;
mysql> SET foreign_key_checks = 1;
```

This allows you to import the tables in any order if the dump file contains tables that are not correctly ordered for foreign keys. It also speeds up the import operation. Setting `foreign_key_checks` to 0 can also be useful for ignoring foreign key constraints during `LOAD DATA` and `ALTER TABLE` operations. However, even if `foreign_key_checks = 0`, InnoDB does not allow the creation of a foreign key constraint where a column references a non-matching column type. Also, if an InnoDB table has foreign key constraints, `ALTER TABLE` cannot be used to change the table to use another storage engine. To alter the storage engine, you must drop any foreign key constraints first.

InnoDB does not allow you to drop a table that is referenced by a `FOREIGN KEY` constraint, unless you do `SET foreign_key_checks = 0`. When you drop a table, the constraints that were defined in its create statement are also dropped.

If you re-create a table that was dropped, it must have a definition that conforms to the foreign key constraints referencing it. It must have the right column names and types, and it must have indexes on the referenced keys, as stated earlier. If these are not sat-

ified, MySQL returns error number 1005 and refers to error 150 in the error message.

If MySQL reports an error number 1005 from a `CREATE TABLE` statement, and the error message refers to error 150, table creation failed because a foreign key constraint was not correctly formed. Similarly, if an `ALTER TABLE` fails and it refers to error 150, that means a foreign key definition would be incorrectly formed for the altered table. You can use `SHOW ENGINE INNODB STATUS` to display a detailed explanation of the most recent InnoDB foreign key error in the server.

Important

For users familiar with the ANSI/ISO SQL Standard, please note that no storage engine, including InnoDB, recognizes or enforces the `MATCH` clause used in referential-integrity constraint definitions. Use of an explicit `MATCH` clause will not have the specified effect, and also causes `ON DELETE` and `ON UPDATE` clauses to be ignored. For these reasons, specifying `MATCH` should be avoided.

The `MATCH` clause in the SQL standard controls how `NULL` values in a composite (multiple-column) foreign key are handled when comparing to a primary key. InnoDB essentially implements the semantics defined by `MATCH SIMPLE`, which allow a foreign key to be all or partially `NULL`. In that case, the (child table) row containing such a foreign key is allowed to be inserted, and does not match any row in the referenced (parent) table. It is possible to implement other semantics using triggers.

Additionally, MySQL and InnoDB require that the referenced columns be indexed for performance. However, the system does not enforce a requirement that the referenced columns be `UNIQUE` or be declared `NOT NULL`. The handling of foreign key references to non-unique keys or keys that contain `NULL` values is not well defined for operations such as `UPDATE` or `DELETE CASCADE`. You are advised to use foreign keys that reference only `UNIQUE` and `NOT NULL` keys.

Furthermore, InnoDB does not recognize or support “inline `REFERENCES` specifications” (as defined in the SQL standard) where the references are defined as part of the column specification. InnoDB accepts `REFERENCES` clauses only when specified as part of a separate `FOREIGN KEY` specification. For other storage engines, MySQL Server parses and ignores foreign key specifications.

Deviation from SQL standards: If there are several rows in the parent table that have the same referenced key value, InnoDB acts in foreign key checks as if the other parent rows with the same key value do not exist. For example, if you have defined a `RESTRICT` type constraint, and there is a child row with several parent rows, InnoDB does not allow the deletion of any of those parent rows.

InnoDB performs cascading operations through a depth-first algorithm, based on records in the indexes corresponding to the foreign key constraints.

Deviation from SQL standards: A `FOREIGN KEY` constraint that references a non-`UNIQUE` key is not standard SQL. It is an InnoDB extension to standard SQL.

Deviation from SQL standards: If `ON UPDATE CASCADE` or `ON UPDATE SET NULL` recurses to update the *same table* it has previously updated during the cascade, it acts like `RESTRICT`. This means that you cannot use self-referential `ON UPDATE CASCADE` or `ON UPDATE SET NULL` operations. This is to prevent infinite loops resulting from cascaded updates. A self-referential `ON DELETE SET NULL`, on the other hand, is possible, as is a self-referential `ON DELETE CASCADE`. Cascading operations may not be nested more than 15 levels deep.

Deviation from SQL standards: Like MySQL in general, in an SQL statement that inserts, deletes, or updates many rows, InnoDB checks `UNIQUE` and `FOREIGN KEY` constraints row-by-row. According to the SQL standard, the default behavior should be deferred checking. That is, constraints are only checked after the *entire SQL statement* has been processed. Until InnoDB implements deferred constraint checking, some things will be impossible, such as deleting a record that refers to itself via a foreign key.

13.6.4.5. InnoDB and MySQL Replication

MySQL replication works for InnoDB tables as it does for MyISAM tables. It is also possible to use replication in a way where the storage engine on the slave is not the same as the original storage engine on the master. For example, you can replicate modifications to an InnoDB table on the master to a MyISAM table on the slave.

To set up a new slave for a master, you have to make a copy of the InnoDB tablespace and the log files, as well as the `.frm` files of the InnoDB tables, and move the copies to the slave. If the `innodb_file_per_table` variable is enabled, you must also copy the `.ibd` files as well. For the proper procedure to do this, see Section 13.6.6, “Backing Up and Recovering an InnoDB Database”.

If you can shut down the master or an existing slave, you can take a cold backup of the InnoDB tablespace and log files and use that to set up a slave. To make a new slave without taking down any server you can also use the commercial InnoDB Hot Backup tool.

You cannot set up replication for InnoDB using the `LOAD TABLE FROM MASTER` statement, which works only for MyISAM

tables. There are two possible workarounds:

- Dump the table on the master and import the dump file into the slave.
- Use `ALTER TABLE tbl_name ENGINE=MyISAM` on the master before setting up replication with `LOAD TABLE tbl_name FROM MASTER`, and then use `ALTER TABLE` to convert the master table back to `InnoDB` afterward. However, this should not be done for tables that have foreign key definitions because the definitions will be lost.

Transactions that fail on the master do not affect replication at all. MySQL replication is based on the binary log where MySQL writes SQL statements that modify data. A transaction that fails (for example, because of a foreign key violation, or because it is rolled back) is not written to the binary log, so it is not sent to slaves. See [Section 12.4.1, “START TRANSACTION, COMMIT, and ROLLBACK Syntax”](#).

Replication and CASCADE. Cascading actions for `InnoDB` tables on the master are replicated on the slave *only* if the tables sharing the foreign key relation use `InnoDB` on both the master and slave. This is true whether you are using statement-based or row-based replication. For example, suppose you have started replication, and then create two tables on the master using the following `CREATE TABLE` statements:

```
CREATE TABLE fc1 (
  i INT PRIMARY KEY,
  j INT
) ENGINE = InnoDB;

CREATE TABLE fc2 (
  m INT PRIMARY KEY,
  n INT,
  FOREIGN KEY ni (n) REFERENCES fc1 (i)
  ON DELETE CASCADE
) ENGINE = InnoDB;
```

Suppose that the slave does not have `InnoDB` support enabled. If this is the case, then the tables on the slave are created, but they use the `MyISAM` storage engine, and the `FOREIGN KEY` option is ignored. Now we insert some rows into the tables on the master:

```
master> INSERT INTO fc1 VALUES (1, 1), (2, 2);
Query OK, 2 rows affected (0.09 sec)
Records: 2 Duplicates: 0 Warnings: 0

master> INSERT INTO fc2 VALUES (1, 1), (2, 2), (3, 1);
Query OK, 3 rows affected (0.19 sec)
Records: 3 Duplicates: 0 Warnings: 0
```

At this point, on both the master and the slave, table `fc1` contains 2 rows, and table `fc2` contains 3 rows, as shown here:

```
master> SELECT * FROM fc1;
+----+----+
| i  | j  |
+----+----+
| 1  | 1  |
| 2  | 2  |
+----+----+
2 rows in set (0.00 sec)

master> SELECT * FROM fc2;
+----+----+
| m  | n  |
+----+----+
| 1  | 1  |
| 2  | 2  |
| 3  | 1  |
+----+----+
3 rows in set (0.00 sec)

slave> SELECT * FROM fc1;
+----+----+
| i  | j  |
+----+----+
| 1  | 1  |
| 2  | 2  |
+----+----+
2 rows in set (0.00 sec)

slave> SELECT * FROM fc2;
+----+----+
| m  | n  |
+----+----+
| 1  | 1  |
| 2  | 2  |
| 3  | 1  |
+----+----+
3 rows in set (0.00 sec)
```

Now suppose that you perform the following `DELETE` statement on the master:

```
master> DELETE FROM fc1 WHERE i=1;
Query OK, 1 row affected (0.09 sec)
```

Due to the cascade, table `fc2` on the master now contains only 1 row:

```
master> SELECT * FROM fc2;
+----+----+
| m | n |
+----+----+
| 2 | 2 |
+----+----+
1 row in set (0.00 sec)
```

However, the cascade does not propagate on the slave because on the slave the `DELETE` for `fc1` deletes no rows from `fc2`. The slave's copy of `fc2` still contains all of the rows that were originally inserted:

```
slave> SELECT * FROM fc2;
+----+----+
| m | n |
+----+----+
| 1 | 1 |
| 3 | 1 |
| 2 | 2 |
+----+----+
3 rows in set (0.00 sec)
```

This difference is due to the fact that the cascading deletes are handled internally by the `InnoDB` storage engine, which means that none of the changes are logged.

13.6.5. Adding, Removing, or Resizing `InnoDB` Data and Log Files

This section describes what you can do when your `InnoDB` tablespace runs out of room or when you want to change the size of the log files.

The easiest way to increase the size of the `InnoDB` tablespace is to configure it from the beginning to be auto-extending. Specify the `autoextend` attribute for the last data file in the tablespace definition. Then `InnoDB` increases the size of that file automatically in 8MB increments when it runs out of space. The increment size can be changed by setting the value of the `innodb_autoextend_increment` system variable, which is measured in MB.

Alternatively, you can increase the size of your tablespace by adding another data file. To do this, you have to shut down the MySQL server, change the tablespace configuration to add a new data file to the end of `innodb_data_file_path`, and start the server again.

If your last data file was defined with the keyword `autoextend`, the procedure for reconfiguring the tablespace must take into account the size to which the last data file has grown. Obtain the size of the data file, round it down to the closest multiple of 1024×1024 bytes (= 1MB), and specify the rounded size explicitly in `innodb_data_file_path`. Then you can add another data file. Remember that only the last data file in the `innodb_data_file_path` can be specified as auto-extending.

As an example, assume that the tablespace has just one auto-extending data file `ibdata1`:

```
innodb_data_home_dir =
innodb_data_file_path = /ibdata/ibdata1:10M:autoextend
```

Suppose that this data file, over time, has grown to 988MB. Here is the configuration line after modifying the original data file to not be auto-extending and adding another auto-extending data file:

```
innodb_data_home_dir =
innodb_data_file_path = /ibdata/ibdata1:988M;/disk2/ibdata2:50M:autoextend
```

When you add a new file to the tablespace configuration, make sure that it does not exist. `InnoDB` will create and initialize the file when you restart the server.

Currently, you cannot remove a data file from the tablespace. To decrease the size of your tablespace, use this procedure:

1. Use `mysqldump` to dump all your `InnoDB` tables.
2. Stop the server.
3. Remove all the existing tablespace files, including the `ibdata` and `ib_log` files. If you want to keep a backup copy of the information, then copy all the `ib*` files to another location before the removing the files in your MySQL installation.
4. Remove any `.frm` files for `InnoDB` tables.
5. Configure a new tablespace.
6. Restart the server.
7. Import the dump files.

If you want to change the number or the size of your `InnoDB` log files, use the following instructions. The procedure to use depends on the value of `innodb_fast_shutdown`:

- If `innodb_fast_shutdown` is not set to 2: Stop the MySQL server and make sure that it shuts down without errors (to ensure that there is no information for outstanding transactions in the log). Copy the old log files into a safe place in case something went wrong during the shutdown and you need them to recover the tablespace. Delete the old log files from the log file directory, edit `my.cnf` to change the log file configuration, and start the MySQL server again. `mysqld` sees that no `InnoDB` log files exist at startup and creates new ones.
- If `innodb_fast_shutdown` is set to 2: Set `innodb_fast_shutdown` to 1:

```
mysql> SET GLOBAL innodb_fast_shutdown = 1;
```

Then follow the instructions in the previous item.

13.6.6. Backing Up and Recovering an `InnoDB` Database

The key to safe database management is making regular backups.

`InnoDB Hot Backup` enables you to back up a running MySQL database, including `InnoDB` and `MyISAM` tables, with minimal disruption to operations while producing a consistent snapshot of the database. When `InnoDB Hot Backup` is copying `InnoDB` tables, reads and writes to both `InnoDB` and `MyISAM` tables can continue. During the copying of `MyISAM` tables, reads (but not writes) to those tables are permitted. In addition, `InnoDB Hot Backup` supports creating compressed backup files, and performing backups of subsets of `InnoDB` tables. In conjunction with MySQL's binary log, users can perform point-in-time recovery. `InnoDB Hot Backup` is commercially licensed by Innobase Oy. For a more complete description of `InnoDB Hot Backup`, see <http://www.innodb.com/hot-backup/features/> or download the documentation from http://www.innodb.com/doc/hot_backup/manual.html. You can order trial, term, and perpetual licenses from Innobase at <http://www.innodb.com/hot-backup/order/>.

If you are able to shut down your MySQL server, you can make a binary backup that consists of all files used by `InnoDB` to manage its tables. Use the following procedure:

1. Shut down your MySQL server and make sure that it shuts down without errors.
2. Copy all your data files (`ibdata` files and `.ibd` files) into a safe place.
3. Copy all your `ib_logfile` files to a safe place.
4. Copy your `my.cnf` configuration file or files to a safe place.
5. Copy all the `.frm` files for your `InnoDB` tables to a safe place.

Replication works with `InnoDB` tables, so you can use MySQL replication capabilities to keep a copy of your database at database sites requiring high availability.

In addition to making binary backups as just described, you should also regularly make dumps of your tables with `mysqldump`. The reason for this is that a binary file might be corrupted without you noticing it. Dumped tables are stored into text files that are human-readable, so spotting table corruption becomes easier. Also, because the format is simpler, the chance for serious data corruption is smaller. `mysqldump` also has a `--single-transaction` option that you can use to make a consistent snapshot without locking out other clients. See [Section 6.2.1, "Backup Policy"](#).

To be able to recover your `InnoDB` database to the present from the binary backup just described, you have to run your MySQL server with binary logging turned on. To achieve point-in-time recovery after restoring a backup, you can apply changes from the binary log that occurred after the backup was made. See [Section 6.3, "Point-in-Time Recovery"](#).

To recover from a crash of your MySQL server, the only requirement is to restart it. `InnoDB` automatically checks the logs and performs a roll-forward of the database to the present. `InnoDB` automatically rolls back uncommitted transactions that were present at the time of the crash. During recovery, `mysqld` displays output something like this:

```
InnoDB: Database was not shut down normally.
InnoDB: Starting recovery from log files...
InnoDB: Starting log scan based on checkpoint at
InnoDB: log sequence number 0 13674004
InnoDB: Doing recovery: scanned up to log sequence number 0 13739520
InnoDB: Doing recovery: scanned up to log sequence number 0 13805056
InnoDB: Doing recovery: scanned up to log sequence number 0 13870592
InnoDB: Doing recovery: scanned up to log sequence number 0 13936128
...
InnoDB: Doing recovery: scanned up to log sequence number 0 20555264
```

```
InnoDB: Doing recovery: scanned up to log sequence number 0 20620800
InnoDB: Doing recovery: scanned up to log sequence number 0 20664692
InnoDB: 1 uncommitted transaction(s) which must be rolled back
InnoDB: Starting rollback of uncommitted transactions
InnoDB: Rolling back trx no 16745
InnoDB: Rolling back of trx no 16745 completed
InnoDB: Rollback of uncommitted transactions completed
InnoDB: Starting an apply batch of log records to the database...
InnoDB: Apply batch completed
InnoDB: Started
mysqld: ready for connections
```

If your database gets corrupted or your disk fails, you have to do the recovery from a backup. In the case of corruption, you should first find a backup that is not corrupted. After restoring the base backup, do the recovery from the binary log files using `mysql-binlog` and `mysql` to restore the changes that occurred after the backup was made.

In some cases of database corruption it is enough just to dump, drop, and re-create one or a few corrupt tables. You can use the `CHECK TABLE` SQL statement to check whether a table is corrupt, although `CHECK TABLE` naturally cannot detect every possible kind of corruption. You can use the Tablespace Monitor to check the integrity of the file space management inside the tablespace files.

In some cases, apparent database page corruption is actually due to the operating system corrupting its own file cache, and the data on disk may be okay. It is best first to try restarting your computer. Doing so may eliminate errors that appeared to be database page corruption.

13.6.6.1. The InnoDB Recovery Process

InnoDB crash recovery consists of several steps. The first step, redo log application, is performed during the initialization, before accepting any connections. If all changes were flushed from the buffer pool to the tablespaces (`ibdata*` and `*.ibd` files) at the time of the shutdown or crash, the redo log application can be skipped. If the redo log files are missing at startup, InnoDB skips the redo log application.

The remaining steps after redo log application do not depend on the redo log (other than for logging the writes) and are performed in parallel with normal processing. These include:

- Rolling back incomplete transactions: Any transactions that were active at the time of crash or fast shutdown.
- Insert buffer merge: Applying changes from the insert buffer tree (from the shared tablespace) to leaf pages of secondary indexes as the index pages are read to the buffer pool.
- Purge: Deleting delete-marked records that are no longer visible for any active transaction.

Of these, only rollback of incomplete transactions is special to crash recovery. The insert buffer merge and the purge are performed during normal processing.

13.6.6.2. Forcing InnoDB Recovery

If there is database page corruption, you may want to dump your tables from the database with `SELECT INTO ... OUTFILE`. Usually, most of the data obtained in this way is intact. However, it is possible that the corruption might cause `SELECT * FROM tbl_name` statements or InnoDB background operations to crash or assert, or even cause InnoDB roll-forward recovery to crash. In such cases, you can use the `innodb_force_recovery` option to force the InnoDB storage engine to start up while preventing background operations from running, so that you are able to dump your tables. For example, you can add the following line to the `[mysqld]` section of your option file before restarting the server:

```
[mysqld]
innodb_force_recovery = 4
```

`innodb_force_recovery` is 0 by default (normal startup without forced recovery) The allowable nonzero values for `innodb_force_recovery` follow. A larger number includes all precautions of smaller numbers. If you are able to dump your tables with an option value of at most 4, then you are relatively safe that only some data on corrupt individual pages is lost. A value of 6 is more drastic because database pages are left in an obsolete state, which in turn may introduce more corruption into B-trees and other database structures.

- 1 (`SRV_FORCE_IGNORE_CORRUPT`)

Let the server run even if it detects a corrupt page. Try to make `SELECT * FROM tbl_name` jump over corrupt index records and pages, which helps in dumping tables.

- 2 (`SRV_FORCE_NO_BACKGROUND`)

Prevent the main thread from running. If a crash would occur during the purge operation, this recovery value prevents it.

- 3 (`SRV_FORCE_NO_TRX_UNDO`)

Do not run transaction rollbacks after recovery.

- 4 (`SRV_FORCE_NO_IBUF_MERGE`)

Prevent insert buffer merge operations. If they would cause a crash, do not do them. Do not calculate table statistics.

- 5 (`SRV_FORCE_NO_UNDO_LOG_SCAN`)

Do not look at undo logs when starting the database: `InnoDB` treats even incomplete transactions as committed.

- 6 (`SRV_FORCE_NO_LOG_REDO`)

Do not do the log roll-forward in connection with recovery.

The database must not otherwise be used with any nonzero value of `innodb_force_recovery`. As a safety measure, `InnoDB` prevents users from performing `INSERT`, `UPDATE`, or `DELETE` operations when `innodb_force_recovery` is greater than 0.

You can `SELECT` from tables to dump them, or `DROP` or `CREATE` tables even if forced recovery is used. If you know that a given table is causing a crash on rollback, you can drop it. You can also use this to stop a runaway rollback caused by a failing mass import or `ALTER TABLE`. You can kill the `mysqld` process and set `innodb_force_recovery` to 3 to bring the database up without the rollback, then `DROP` the table that is causing the runaway rollback.

13.6.6.3. `InnoDB` Checkpoints

`InnoDB` implements a checkpoint mechanism known as “fuzzy” checkpointing. `InnoDB` flushes modified database pages from the buffer pool in small batches. There is no need to flush the buffer pool in one single batch, which would in practice stop processing of user SQL statements during the checkpointing process.

During crash recovery, `InnoDB` looks for a checkpoint label written to the log files. It knows that all modifications to the database before the label are present in the disk image of the database. Then `InnoDB` scans the log files forward from the checkpoint, applying the logged modifications to the database.

`InnoDB` writes to its log files on a rotating basis. All committed modifications that make the database pages in the buffer pool different from the images on disk must be available in the log files in case `InnoDB` has to do a recovery. This means that when `InnoDB` starts to reuse a log file, it has to make sure that the database page images on disk contain the modifications logged in the log file that `InnoDB` is going to reuse. In other words, `InnoDB` must create a checkpoint and this often involves flushing of modified database pages to disk.

The preceding description explains why making your log files very large may reduce disk I/O in checkpointing. It often makes sense to set the total size of the log files as large as the buffer pool or even larger. The disadvantage of using large log files is that crash recovery can take longer because there is more logged information to apply to the database.

13.6.7. Moving an `InnoDB` Database to Another Machine

On Windows, `InnoDB` always stores database and table names internally in lowercase. To move databases in a binary format from Unix to Windows or from Windows to Unix, you should create all databases and tables using lowercase names. A convenient way to accomplish this is to add the following line to the `[mysqld]` section of your `my.cnf` or `my.ini` file before creating any databases or tables:

```
[mysqld]
lower_case_table_names=1
```

Like `MyISAM` data files, `InnoDB` data and log files are binary-compatible on all platforms having the same floating-point number format. You can move an `InnoDB` database simply by copying all the relevant files listed in [Section 13.6.6, “Backing Up and Recovering an `InnoDB` Database”](#). If the floating-point formats differ but you have not used `FLOAT` or `DOUBLE` data types in your tables, then the procedure is the same: simply copy the relevant files. If you use `mysqldump` to dump your tables on one machine and then import the dump files on the other machine, it does not matter whether the formats differ or your tables contain floating-point data.

One way to increase performance is to switch off autocommit mode when importing data, assuming that the tablespace has enough space for the big rollback segment that the import transactions generate. Do the commit only after importing a whole table or a segment of a table.

13.6.8. The InnoDB Transaction Model and Locking

In the InnoDB transaction model, the goal is to combine the best properties of a multi-versioning database with traditional two-phase locking. InnoDB does locking on the row level and runs queries as non-locking consistent reads by default, in the style of Oracle. The lock table in InnoDB is stored so space-efficiently that lock escalation is not needed: Typically several users are allowed to lock every row in InnoDB tables, or any random subset of the rows, without causing InnoDB memory exhaustion.

In InnoDB, all user activity occurs inside a transaction. If autocommit mode is enabled, each SQL statement forms a single transaction on its own. By default, MySQL starts the session for each new connection with autocommit enabled, so MySQL does a commit after each SQL statement if that statement did not return an error. If a statement returns an error, the commit or rollback behavior depends on the error. See [Section 13.6.12, “InnoDB Error Handling”](#).

A session that has autocommit enabled can perform a multiple-statement transaction by starting it with an explicit `START TRANSACTION` or `BEGIN` statement and ending it with a `COMMIT` or `ROLLBACK` statement.

If autocommit mode is disabled within a session with `SET autocommit = 0`, the session always has a transaction open. A `COMMIT` or `ROLLBACK` statement ends the current transaction and a new one starts.

A `COMMIT` means that the changes made in the current transaction are made permanent and become visible to other sessions. A `ROLLBACK` statement, on the other hand, cancels all modifications made by the current transaction. Both `COMMIT` and `ROLLBACK` release all InnoDB locks that were set during the current transaction.

In terms of the SQL:1992 transaction isolation levels, the default InnoDB level is `REPEATABLE READ`. InnoDB offers all four transaction isolation levels described by the SQL standard: `READ UNCOMMITTED`, `READ COMMITTED`, `REPEATABLE READ`, and `SERIALIZABLE`.

A user can change the isolation level for a single session or for all subsequent connections with the `SET TRANSACTION` statement. To set the server's default isolation level for all connections, use the `--transaction-isolation` option on the command line or in an option file. For detailed information about isolation levels and level-setting syntax, see [Section 12.4.6, “SET TRANSACTION Syntax”](#).

In row-level locking, InnoDB normally uses next-key locking. That means that besides index records, InnoDB can also lock the “gap” preceding an index record to block insertions by other sessions in the gap immediately before the index record. A next-key lock refers to a lock that locks an index record and the gap before it. A gap lock refers to a lock that locks only the gap before some index record.

For more information about row-level locking, and the circumstances under which gap locking is disabled, see [Section 13.6.8.4, “InnoDB Record, Gap, and Next-Key Locks”](#).

13.6.8.1. InnoDB Lock Modes

InnoDB implements standard row-level locking where there are two types of locks:

- A shared (*S*) lock allows a transaction to read a row.
- An exclusive (*X*) lock allows a transaction to update or delete a row.

If transaction *T1* holds a shared (*S*) lock on row *r*, then requests from some distinct transaction *T2* for a lock on row *r* are handled as follows:

- A request by *T2* for an *S* lock can be granted immediately. As a result, both *T1* and *T2* hold an *S* lock on *r*.
- A request by *T2* for an *X* lock cannot be granted immediately.

If a transaction *T1* holds an exclusive (*X*) lock on row *r*, a request from some distinct transaction *T2* for a lock of either type on *r* cannot be granted immediately. Instead, transaction *T2* has to wait for transaction *T1* to release its lock on row *r*.

Additionally, InnoDB supports *multiple granularity locking* which allows coexistence of record locks and locks on entire tables. To make locking at multiple granularity levels practical, additional types of locks called *intention locks* are used. Intention locks are table locks in InnoDB. The idea behind intention locks is for a transaction to indicate which type of lock (shared or exclusive) it will require later for a row in that table. There are two types of intention locks used in InnoDB (assume that transaction *T* has requested a lock of the indicated type on table *t*):

- Intention shared (*IS*): Transaction *T* intends to set *S* locks on individual rows in table *t*.
- Intention exclusive (*IX*): Transaction *T* intends to set *X* locks on those rows.

For example, `SELECT ... LOCK IN SHARE MODE` sets an *IS* lock and `SELECT ... FOR UPDATE` sets an *IX* lock.

The intention locking protocol is as follows:

- Before a transaction can acquire an *S* lock on a row in table *t*, it must first acquire an *IS* or stronger lock on *t*.
- Before a transaction can acquire an *X* lock on a row, it must first acquire an *IX* lock on *t*.

These rules can be conveniently summarized by means of the following *lock type compatibility matrix*.

	<i>X</i>	<i>IX</i>	<i>S</i>	<i>IS</i>
<i>X</i>	Conflict	Conflict	Conflict	Conflict
<i>IX</i>	Conflict	Compatible	Conflict	Compatible
<i>S</i>	Conflict	Conflict	Compatible	Compatible
<i>IS</i>	Conflict	Compatible	Compatible	Compatible

A lock is granted to a requesting transaction if it is compatible with existing locks, but not if it conflicts with existing locks. A transaction waits until the conflicting existing lock is released. If a lock request conflicts with an existing lock and cannot be granted because it would cause deadlock, an error occurs.

Thus, intention locks do not block anything except full table requests (for example, `LOCK TABLES ... WRITE`). The main purpose of *IX* and *IS* locks is to show that someone is locking a row, or going to lock a row in the table.

The following example illustrates how an error can occur when a lock request would cause a deadlock. The example involves two clients, A and B.

First, client A creates a table containing one row, and then begins a transaction. Within the transaction, A obtains an *S* lock on the row by selecting it in share mode:

```
mysql> CREATE TABLE t (i INT) ENGINE = InnoDB;
Query OK, 0 rows affected (1.07 sec)

mysql> INSERT INTO t (i) VALUES(1);
Query OK, 1 row affected (0.09 sec)

mysql> START TRANSACTION;
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT * FROM t WHERE i = 1 LOCK IN SHARE MODE;
+-----+
| i     |
+-----+
| 1     |
+-----+
1 row in set (0.10 sec)
```

Next, client B begins a transaction and attempts to delete the row from the table:

```
mysql> START TRANSACTION;
Query OK, 0 rows affected (0.00 sec)

mysql> DELETE FROM t WHERE i = 1;
```

The delete operation requires an *X* lock. The lock cannot be granted because it is incompatible with the *S* lock that client A holds, so the request goes on the queue of lock requests for the row and client B blocks.

Finally, client A also attempts to delete the row from the table:

```
mysql> DELETE FROM t WHERE i = 1;
ERROR 1213 (40001): Deadlock found when trying to get lock;
try restarting transaction
```

Deadlock occurs here because client A needs an *X* lock to delete the row. However, that lock request cannot be granted because client B already has a request for an *X* lock and is waiting for client A to release its *S* lock. Nor can the *S* lock held by A be upgraded to an *X* lock because of the prior request by B for an *X* lock. As a result, *InnoDB* generates an error for client A and releases its locks. At that point, the lock request for client B can be granted and B deletes the row from the table.

13.6.8.2. Consistent Non-Locking Reads

A consistent read means that *InnoDB* uses multi-versioning to present to a query a snapshot of the database at a point in time. The

query sees the changes made by transactions that committed before that point of time, and no changes made by later or uncommitted transactions. The exception to this rule is that the query sees the changes made by earlier statements within the same transaction. This exception causes the following anomaly: If you update some rows in a table, a `SELECT` will see the latest version of the updated rows, but it might also see older versions of any rows. If other sessions simultaneously update the same table, the anomaly means that you may see the table in a state that never existed in the database.

If the transaction isolation level is `REPEATABLE READ` (the default level), all consistent reads within the same transaction read the snapshot established by the first such read in that transaction. You can get a fresher snapshot for your queries by committing the current transaction and after that issuing new queries.

With `READ COMMITTED` isolation level, each consistent read within a transaction sets and reads its own fresh snapshot.

Consistent read is the default mode in which `InnoDB` processes `SELECT` statements in `READ COMMITTED` and `REPEATABLE READ` isolation levels. A consistent read does not set any locks on the tables it accesses, and therefore other sessions are free to modify those tables at the same time a consistent read is being performed on the table.

Suppose that you are running in the default `REPEATABLE READ` isolation level. When you issue a consistent read (that is, an ordinary `SELECT` statement), `InnoDB` gives your transaction a timepoint according to which your query sees the database. If another transaction deletes a row and commits after your timepoint was assigned, you do not see the row as having been deleted. Inserts and updates are treated similarly.

You can advance your timepoint by committing your transaction and then doing another `SELECT`.

This is called *multi-versioned concurrency control*.

In the following example, session A sees the row inserted by B only when B has committed the insert and A has committed as well, so that the timepoint is advanced past the commit of B.

	Session A	Session B
time	<code>SET autocommit=0;</code>	<code>SET autocommit=0;</code>
	<code>SELECT * FROM t;</code> empty set	<code>INSERT INTO t VALUES (1, 2);</code>
v	<code>SELECT * FROM t;</code> empty set	<code>COMMIT;</code>
	<code>SELECT * FROM t;</code> empty set	
	<code>COMMIT;</code>	
	<code>SELECT * FROM t;</code>	
	----- 1 2 -----	
	1 row in set	

If you want to see the “freshest” state of the database, you should use either the `READ COMMITTED` isolation level or a locking read:

```
SELECT * FROM t LOCK IN SHARE MODE;
```

With `READ COMMITTED` isolation level, each consistent read within a transaction sets and reads its own fresh snapshot. With `LOCK IN SHARE MODE`, a locking read occurs instead: A `SELECT` blocks until the transaction containing the freshest rows ends (see [Section 13.6.8.3](#), “`SELECT ... FOR UPDATE` and `SELECT ... LOCK IN SHARE MODE` Locking Reads”).

Consistent read does not work over `DROP TABLE` or over `ALTER TABLE`:

- Consistent read does not work over `DROP TABLE` because MySQL cannot use a table that has been dropped and `InnoDB` destroys the table.
- Consistent read does not work over `ALTER TABLE` because `ALTER TABLE` works by making a temporary copy of the original table and deleting the original table when the temporary copy is built. When you reissue a consistent read within a transaction, rows in the new table are not visible because those rows did not exist when the transaction's snapshot was taken.

`InnoDB` uses a consistent read for select in clauses like `INSERT INTO ... SELECT`, `UPDATE ... (SELECT)`, and `CREATE TABLE ... SELECT` that do not specify `FOR UPDATE` or `LOCK IN SHARE MODE` if the `innodb_locks_unsafe_for_binlog` option is set and the isolation level of the transaction is not set to `SERIALIZABLE`. Thus, no locks are set on rows read from the selected table. Otherwise, `InnoDB` uses stronger locks and the `SELECT` part acts like `READ COMMITTED`, where each consistent read, even within the same transaction, sets and reads its own fresh snapshot.

13.6.8.3. `SELECT ... FOR UPDATE` and `SELECT ... LOCK IN SHARE MODE` Locking Reads

In some circumstances, a consistent (non-locking) read is not convenient and a locking read is required instead. InnoDB supports two types of locking reads:

- `SELECT ... LOCK IN SHARE MODE` sets a shared mode lock on the rows read. A shared mode lock enables other sessions to read the rows but not to modify them. The rows read are the latest available, so if they belong to another transaction that has not yet committed, the read blocks until that transaction ends.
- For index records the search encounters, `SELECT ... FOR UPDATE` blocks other sessions from doing `SELECT ... LOCK IN SHARE MODE` or from reading in certain transaction isolation levels. Consistent reads will ignore any locks set on the records that exist in the read view. (Old versions of a record cannot be locked; they will be reconstructed by applying undo logs on an in-memory copy of the record.)

Locks set by `LOCK IN SHARE MODE` and `FOR UPDATE` reads are released when the transaction is committed or rolled back.

As an example of a situation in which a locking read is useful, suppose that you want to insert a new row into a table `child`, and make sure that the child row has a parent row in table `parent`. The following discussion describes how to implement referential integrity in application code.

Suppose that you use a consistent read to read the table `parent` and indeed see the parent row of the to-be-inserted child row in the table. Can you safely insert the child row to table `child`? No, because it is possible for some other session to delete the parent row from the table `parent` in the meantime without you being aware of it.

The solution is to perform the `SELECT` in a locking mode using `LOCK IN SHARE MODE`:

```
SELECT * FROM parent WHERE NAME = 'Jones' LOCK IN SHARE MODE;
```

A read performed with `LOCK IN SHARE MODE` reads the latest available data and sets a shared mode lock on the rows read. A shared mode lock prevents others from updating or deleting the row read. Also, if the latest data belongs to a yet uncommitted transaction of another session, we wait until that transaction ends. After we see that the `LOCK IN SHARE MODE` query returns the parent 'Jones', we can safely add the child record to the `child` table and commit our transaction.

Let us look at another example: We have an integer counter field in a table `child_codes` that we use to assign a unique identifier to each child added to table `child`. It is not a good idea to use either consistent read or a shared mode read to read the present value of the counter because two users of the database may then see the same value for the counter, and a duplicate-key error occurs if two users attempt to add children with the same identifier to the table.

Here, `LOCK IN SHARE MODE` is not a good solution because if two users read the counter at the same time, at least one of them ends up in deadlock when it attempts to update the counter.

In this case, there are two good ways to implement reading and incrementing the counter:

- First update the counter by incrementing it by 1, and then read it.
- First perform a locking read of the counter using `FOR UPDATE`, and then increment the counter.

The latter approach can be implemented as follows:

```
SELECT counter_field FROM child_codes FOR UPDATE;
UPDATE child_codes SET counter_field = counter_field + 1;
```

A `SELECT ... FOR UPDATE` reads the latest available data, setting exclusive locks on each row it reads. Thus, it sets the same locks a searched SQL `UPDATE` would set on the rows.

The preceding description is merely an example of how `SELECT ... FOR UPDATE` works. In MySQL, the specific task of generating a unique identifier actually can be accomplished using only a single access to the table:

```
UPDATE child_codes SET counter_field = LAST_INSERT_ID(counter_field + 1);
SELECT LAST_INSERT_ID();
```

The `SELECT` statement merely retrieves the identifier information (specific to the current connection). It does not access any table.

■ Note

Locking of rows for update using `SELECT FOR UPDATE` only applies when autocommit is disabled (either by beginning transaction with `START TRANSACTION` or by setting `autocommit` to 0. If autocommit is enabled, the rows matching the specification are not locked.

13.6.8.4. InnoDB Record, Gap, and Next-Key Locks

InnoDB has several types of record-level locks:

- Record lock: This is a lock on an index record.
- Gap lock: This is a lock on a gap between index records, or a lock on the gap before the first or after the last index record.
- Next-key lock: This is a combination of a record lock on the index record and a gap lock on the gap before the index record.

Record locks always lock index records, even if a table is defined with no indexes. For such cases, InnoDB creates a hidden clustered index and uses this index for record locking. See [Section 13.6.10.1, “Clustered and Secondary Indexes”](#).

By default, InnoDB operates in `REPEATABLE READ` transaction isolation level and with the `innodb_locks_unsafe_for_binlog` system variable disabled. In this case, InnoDB uses next-key locks for searches and index scans, which prevents phantom rows (see [Section 13.6.8.5, “Avoiding the Phantom Problem Using Next-Key Locking”](#)).

Next-key locking combines index-row locking with gap locking. InnoDB performs row-level locking in such a way that when it searches or scans a table index, it sets shared or exclusive locks on the index records it encounters. Thus, the row-level locks are actually index-record locks. In addition, a next-key lock on an index record also affects the “gap” before that index record. That is, a next-key lock is an index-record lock plus a gap lock on the gap preceding the index record. If one session has a shared or exclusive lock on record `R` in an index, another session cannot insert a new index record in the gap immediately before `R` in the index order.

Suppose that an index contains the values 10, 11, 13, and 20. The possible next-key locks for this index cover the following intervals, where `(` or `)` denote exclusion of the interval endpoint and `[` or `]` denote inclusion of the endpoint:

```
(negative infinity, 10]
(10, 11]
(11, 13]
(13, 20]
(20, positive infinity)
```

For the last interval, the next-key lock locks the gap above the largest value in the index and the “supremum” pseudo-record having a value higher than any value actually in the index. The supremum is not a real index record, so, in effect, this next-key lock locks only the gap following the largest index value.

The preceding example shows that a gap might span a single index value, multiple index values, or even be empty.

Gap locking is not needed for statements that lock rows using a unique index to search for a unique row. For example, if the `id` column has a unique index, the following statement uses only an index-record lock for the row having `id` value 100 and it does not matter whether other sessions insert rows in the preceding gap:

```
SELECT * FROM child WHERE id = 100;
```

If `id` is not indexed or has a non-unique index, the statement does lock the preceding gap.

A type of gap lock called an insertion intention gap lock is set by `INSERT` operations prior to row insertion. This lock signals the intent to insert in such a way that multiple transactions inserting into the same index gap need not wait for each other if they are not inserting at the same position within the gap. Suppose that there are index records with values of 4 and 7. Separate transactions that attempt to insert values of 5 and 6 each lock the gap between 4 and 7 with insert intention locks prior to obtaining the exclusive lock on the inserted row, but do not block each other because the rows are non-conflicting.

Gap locking can be disabled explicitly. This occurs if you change the transaction isolation level to `READ COMMITTED` or enable the `innodb_locks_unsafe_for_binlog` system variable. Under these circumstances, gap locking is disabled for searches and index scans and is used only for foreign-key constraint checking and duplicate-key checking.

There are also other effects of using the `READ COMMITTED` isolation level or enabling `innodb_locks_unsafe_for_binlog`: Record locks for non-matching rows are released after MySQL has evaluated the `WHERE` condition. For `UPDATE` statements, InnoDB does a “semi-consistent” read, such that it returns the latest committed version to MySQL so that MySQL can determine whether the row matches the `WHERE` condition of the `UPDATE`.

13.6.8.5. Avoiding the Phantom Problem Using Next-Key Locking

The so-called *phantom* problem occurs within a transaction when the same query produces different sets of rows at different times.

For example, if a `SELECT` is executed twice, but returns a row the second time that was not returned the first time, the row is a “phantom” row.

Suppose that there is an index on the `id` column of the `child` table and that you want to read and lock all rows from the table having an identifier value larger than 100, with the intention of updating some column in the selected rows later:

```
SELECT * FROM child WHERE id > 100 FOR UPDATE;
```

The query scans the index starting from the first record where `id` is bigger than 100. Let the table contain rows having `id` values of 90 and 102. If the locks set on the index records in the scanned range do not lock out inserts made in the gaps (in this case, the gap between 90 and 102), another session can insert a new row into the table with an `id` of 101. If you were to execute the same `SELECT` within the same transaction, you would see a new row with an `id` of 101 (a “phantom”) in the result set returned by the query. If we regard a set of rows as a data item, the new phantom child would violate the isolation principle of transactions that a transaction should be able to run so that the data it has read does not change during the transaction.

To prevent phantoms, `InnoDB` uses an algorithm called *next-key locking* that combines index-row locking with gap locking. `InnoDB` performs row-level locking in such a way that when it searches or scans a table index, it sets shared or exclusive locks on the index records it encounters. Thus, the row-level locks are actually index-record locks. In addition, a next-key lock on an index record also affects the “gap” before that index record. That is, a next-key lock is an index-record lock plus a gap lock on the gap preceding the index record. If one session has a shared or exclusive lock on record `R` in an index, another session cannot insert a new index record in the gap immediately before `R` in the index order.

When `InnoDB` scans an index, it can also lock the gap after the last record in the index. Just that happens in the preceding example: To prevent any insert into the table where `id` would be bigger than 100, the locks set by `InnoDB` include a lock on the gap following `id` value 102.

You can use next-key locking to implement a uniqueness check in your application: If you read your data in share mode and do not see a duplicate for a row you are going to insert, then you can safely insert your row and know that the next-key lock set on the successor of your row during the read prevents anyone meanwhile inserting a duplicate for your row. Thus, the next-key locking allows you to “lock” the non-existence of something in your table.

Gap locking can be disabled as discussed in [Section 13.6.8.4, “InnoDB Record, Gap, and Next-Key Locks”](#). This may cause phantom problems because other sessions can insert new rows into the gaps when gap locking is disabled.

13.6.8.6. Locks Set by Different SQL Statements in `InnoDB`

A locking read, an `UPDATE`, or a `DELETE` generally set record locks on every index record that is scanned in the processing of the SQL statement. It does not matter whether there are `WHERE` conditions in the statement that would exclude the row. `InnoDB` does not remember the exact `WHERE` condition, but only knows which index ranges were scanned. The locks are normally next-key locks that also block inserts into the “gap” immediately before the record. However, gap locking can be disabled explicitly, which causes next-key locking not to be used. For more information, see [Section 13.6.8.4, “InnoDB Record, Gap, and Next-Key Locks”](#).

Differences between shared and exclusive locks are described in [Section 13.6.8.1, “InnoDB Lock Modes”](#).

If you have no indexes suitable for your statement and MySQL must scan the entire table to process the statement, every row of the table becomes locked, which in turn blocks all inserts by other users to the table. It is important to create good indexes so that your queries do not unnecessarily scan many rows.

For `SELECT ... FOR UPDATE` or `SELECT ... LOCK IN SHARE MODE`, locks are acquired for scanned rows, and expected to be released for rows that do not qualify for inclusion in the result set (for example, if they do not meet the criteria given in the `WHERE` clause). However, in some cases, rows might not be unlocked immediately because the relationship between a result row and its original source is lost during query execution. For example, in a `UNION`, scanned (and locked) rows from a table might be inserted into a temporary table before evaluation whether they qualify for the result set. In this circumstance, the relationship of the rows in the temporary table to the rows in the original table is lost and the latter rows are not unlocked until the end of query execution.

`InnoDB` sets specific types of locks as follows. If a secondary index is used in the search and index record locks to be set are exclusive, `InnoDB` also retrieves the corresponding clustered index records and sets locks on them.

- `SELECT ... FROM` is a consistent read, reading a snapshot of the database and setting no locks unless the transaction isolation level is set to `SERIALIZABLE`. For `SERIALIZABLE` level, the search sets shared next-key locks on the index records it encounters.
- `SELECT ... FROM ... LOCK IN SHARE MODE` sets shared next-key locks on all index records the search encounters.
- For index records the search encounters, `SELECT ... FROM ... FOR UPDATE` blocks other sessions from doing `SELECT ... FROM ... LOCK IN SHARE MODE` or from reading in certain transaction isolation levels. Consistent reads will ignore any locks set on the records that exist in the read view.
- `UPDATE ... WHERE ...` sets an exclusive next-key lock on every record the search encounters.

- `DELETE FROM ... WHERE ...` sets an exclusive next-key lock on every record the search encounters.
- `INSERT` sets an exclusive lock on the inserted row. This lock is an index-record lock, not a next-key lock (that is, there is no gap lock) and does not prevent other sessions from inserting into the gap before the inserted row.

Prior to inserting the row, a type of gap lock called an insertion intention gap lock is set. This lock signals the intent to insert in such a way that multiple transactions inserting into the same index gap need not wait for each other if they are not inserting at the same position within the gap. Suppose that there are index records with values of 4 and 7. Separate transactions that attempt to insert values of 5 and 6 each lock the gap between 4 and 7 with insert intention locks prior to obtaining the exclusive lock on the inserted row, but do not block each other because the rows are non-conflicting.

If a duplicate-key error occurs, a shared lock on the duplicate index record is set. This use of a shared lock can result in deadlock should there be multiple sessions trying to insert the same row if another session already has an exclusive lock. This can occur if another session deletes the row. Suppose that an `InnoDB` table `t1` has the following structure:

```
CREATE TABLE t1 (i INT, PRIMARY KEY (i)) ENGINE = InnoDB;
```

Now suppose that three sessions perform the following operations in order:

Session 1:

```
START TRANSACTION;
INSERT INTO t1 VALUES(1);
```

Session 2:

```
START TRANSACTION;
INSERT INTO t1 VALUES(1);
```

Session 3:

```
START TRANSACTION;
INSERT INTO t1 VALUES(1);
```

Session 1:

```
ROLLBACK;
```

The first operation by session 1 acquires an exclusive lock for the row. The operations by sessions 2 and 3 both result in a duplicate-key error and they both request a shared lock for the row. When session 1 rolls back, it releases its exclusive lock on the row and the queued shared lock requests for sessions 2 and 3 are granted. At this point, sessions 2 and 3 deadlock: Neither can acquire an exclusive lock for the row because of the shared lock held by the other.

A similar situation occurs if the table already contains a row with key value 1 and three sessions perform the following operations in order:

Session 1:

```
START TRANSACTION;
DELETE FROM t1 WHERE i = 1;
```

Session 2:

```
START TRANSACTION;
INSERT INTO t1 VALUES(1);
```

Session 3:

```
START TRANSACTION;
INSERT INTO t1 VALUES(1);
```

Session 1:

```
COMMIT;
```

The first operation by session 1 acquires an exclusive lock for the row. The operations by sessions 2 and 3 both result in a duplicate-key error and they both request a shared lock for the row. When session 1 commits, it releases its exclusive lock on the row and the queued shared lock requests for sessions 2 and 3 are granted. At this point, sessions 2 and 3 deadlock: Neither can acquire an exclusive lock for the row because of the shared lock held by the other.

- `REPLACE` is done like an `INSERT` if there is no collision on a unique key. Otherwise, an exclusive next-key lock is placed on the row that must be updated.
- `INSERT INTO T SELECT ... FROM S WHERE ...` sets an exclusive index record without a gap lock on each row inserted into `T`. If `innodb_locks_unsafe_for_binlog` is enabled or the transaction isolation level is `READ COMMITTED`, `InnoDB` does the search on `S` as a consistent read (no locks). Otherwise, `InnoDB` sets shared next-key locks on rows from `S`. `InnoDB` has to set locks in the latter case: In roll-forward recovery from a backup, every SQL statement must be executed in exactly the same way it was done originally.

`CREATE TABLE ... SELECT ...` performs the `SELECT` with shared next-key locks or as a consistent read, as for `INSERT ... SELECT`.

For `REPLACE INTO T SELECT ... FROM S WHERE ...`, `InnoDB` sets shared next-key locks on rows from `S`.

- While initializing a previously specified `AUTO_INCREMENT` column on a table, `InnoDB` sets an exclusive lock on the end of the index associated with the `AUTO_INCREMENT` column. In accessing the auto-increment counter, `InnoDB` uses a specific `AUTO-INC` table lock mode where the lock lasts only to the end of the current SQL statement, not to the end of the entire transaction. Other sessions cannot insert into the table while the `AUTO-INC` table lock is held; see [Section 13.6.8, “The InnoDB Transaction Model and Locking”](#).

`InnoDB` fetches the value of a previously initialized `AUTO_INCREMENT` column without setting any locks.

- If a `FOREIGN KEY` constraint is defined on a table, any insert, update, or delete that requires the constraint condition to be checked sets shared record-level locks on the records that it looks at to check the constraint. `InnoDB` also sets these locks in the case where the constraint fails.
- `LOCK TABLES` sets table locks, but it is the higher MySQL layer above the `InnoDB` layer that sets these locks. `InnoDB` is aware of table locks if `innodb_table_locks = 1` (the default) and `autocommit = 0`, and the MySQL layer above `InnoDB` knows about row-level locks.

Otherwise, `InnoDB`'s automatic deadlock detection cannot detect deadlocks where such table locks are involved. Also, because in this case the higher MySQL layer does not know about row-level locks, it is possible to get a table lock on a table where another session currently has row-level locks. However, this does not endanger transaction integrity, as discussed in [Section 13.6.8.8, “Deadlock Detection and Rollback”](#). See also [Section 13.6.14, “Restrictions on InnoDB Tables”](#).

13.6.8.7. Implicit Transaction Commit and Rollback

By default, MySQL starts the session for each new connection with autocommit mode enabled, so MySQL does a commit after each SQL statement if that statement did not return an error. If a statement returns an error, the commit or rollback behavior depends on the error. See [Section 13.6.12, “InnoDB Error Handling”](#).

If a session that has autocommit disabled ends without explicitly committing the final transaction, MySQL rolls back that transaction.

Some statements implicitly end a transaction, as if you had done a `COMMIT` before executing the statement. For details, see [Section 12.4.3, “Statements That Cause an Implicit Commit”](#).

13.6.8.8. Deadlock Detection and Rollback

`InnoDB` automatically detects transaction deadlocks and rolls back a transaction or transactions to break the deadlock. `InnoDB` tries to pick small transactions to roll back, where the size of a transaction is determined by the number of rows inserted, updated, or deleted.

`InnoDB` is aware of table locks if `innodb_table_locks = 1` (the default) and `autocommit = 0`, and the MySQL layer above it knows about row-level locks. Otherwise, `InnoDB` cannot detect deadlocks where a table lock set by a MySQL `LOCK TABLES` statement or a lock set by a storage engine other than `InnoDB` is involved. You must resolve these situations by setting the value of the `innodb_lock_wait_timeout` system variable.

When `InnoDB` performs a complete rollback of a transaction, all locks set by the transaction are released. However, if just a single SQL statement is rolled back as a result of an error, some of the locks set by the statement may be preserved. This happens because `InnoDB` stores row locks in a format such that it cannot know afterward which lock was set by which statement.

If a `SELECT` calls a stored function in a transaction, and a statement within the function fails, that statement rolls back. Furthermore, if `ROLLBACK` is executed after that, the entire transaction rolls back.

13.6.8.9. How to Cope with Deadlocks

Deadlocks are a classic problem in transactional databases, but they are not dangerous unless they are so frequent that you cannot run certain transactions at all. Normally, you must write your applications so that they are always prepared to re-issue a transaction

if it gets rolled back because of a deadlock.

InnoDB uses automatic row-level locking. You can get deadlocks even in the case of transactions that just insert or delete a single row. That is because these operations are not really “atomic”; they automatically set locks on the (possibly several) index records of the row inserted or deleted.

You can cope with deadlocks and reduce the likelihood of their occurrence with the following techniques:

- Use `SHOW ENGINE INNODB STATUS` to determine the cause of the latest deadlock. That can help you to tune your application to avoid deadlocks.
- Always be prepared to re-issue a transaction if it fails due to deadlock. Deadlocks are not dangerous. Just try again.
- Commit your transactions often. Small transactions are less prone to collision.
- If you are using locking reads (`SELECT ... FOR UPDATE` or `SELECT ... LOCK IN SHARE MODE`), try using a lower isolation level such as `READ COMMITTED`.
- Access your tables and rows in a fixed order. Then transactions form well-defined queues and do not deadlock.
- Add well-chosen indexes to your tables. Then your queries need to scan fewer index records and consequently set fewer locks. Use `EXPLAIN SELECT` to determine which indexes the MySQL server regards as the most appropriate for your queries.
- Use less locking. If you can afford to allow a `SELECT` to return data from an old snapshot, do not add the clause `FOR UPDATE` or `LOCK IN SHARE MODE` to it. Using the `READ COMMITTED` isolation level is good here, because each consistent read within the same transaction reads from its own fresh snapshot.
- If nothing else helps, serialize your transactions with table-level locks. The correct way to use `LOCK TABLES` with transactional tables, such as **InnoDB** tables, is to begin a transaction with `SET autocommit = 0` (not `START TRANSACTION`) followed by `LOCK TABLES`, and to not call `UNLOCK TABLES` until you commit the transaction explicitly. For example, if you need to write to table `t1` and read from table `t2`, you can do this:

```
SET autocommit=0;
LOCK TABLES t1 WRITE, t2 READ, ...;
... do something with tables t1 and t2 here ...
COMMIT;
UNLOCK TABLES;
```

Table-level locks make your transactions queue nicely and avoid deadlocks.

- Another way to serialize transactions is to create an auxiliary “semaphore” table that contains just a single row. Have each transaction update that row before accessing other tables. In that way, all transactions happen in a serial fashion. Note that the **InnoDB** instant deadlock detection algorithm also works in this case, because the serializing lock is a row-level lock. With MySQL table-level locks, the timeout method must be used to resolve deadlocks.

13.6.9. **InnoDB** Multi-Versioning

Because **InnoDB** is a multi-versioned storage engine, it must keep information about old versions of rows in the tablespace. This information is stored in a data structure called a *rollback segment* (after an analogous data structure in Oracle).

Internally, **InnoDB** adds three fields to each row stored in the database. A 6-byte `DB_TRX_ID` field indicates the transaction identifier for the last transaction that inserted or updated the row. Also, a deletion is treated internally as an update where a special bit in the row is set to mark it as deleted. Each row also contains a 7-byte `DB_ROLL_PTR` field called the roll pointer. The roll pointer points to an undo log record written to the rollback segment. If the row was updated, the undo log record contains the information necessary to rebuild the content of the row before it was updated. A 6-byte `DB_ROW_ID` field contains a row ID that increases monotonically as new rows are inserted. If **InnoDB** generates a clustered index automatically, the index contains row ID values. Otherwise, the `DB_ROW_ID` column does not appear in any index.

InnoDB uses the information in the rollback segment to perform the undo operations needed in a transaction rollback. It also uses the information to build earlier versions of a row for a consistent read.

Undo logs in the rollback segment are divided into insert and update undo logs. Insert undo logs are needed only in transaction rollback and can be discarded as soon as the transaction commits. Update undo logs are used also in consistent reads, but they can be discarded only after there is no transaction present for which **InnoDB** has assigned a snapshot that in a consistent read could need the information in the update undo log to build an earlier version of a database row.

You must remember to commit your transactions regularly, including those transactions that issue only consistent reads. Otherwise, **InnoDB** cannot discard data from the update undo logs, and the rollback segment may grow too big, filling up your tablespace.

The physical size of an undo log record in the rollback segment is typically smaller than the corresponding inserted or updated row. You can use this information to calculate the space need for your rollback segment.

In the [InnoDB](#) multi-versioning scheme, a row is not physically removed from the database immediately when you delete it with an SQL statement. Only when [InnoDB](#) can discard the update undo log record written for the deletion can it also physically remove the corresponding row and its index records from the database. This removal operation is called a purge, and it is quite fast, usually taking the same order of time as the SQL statement that did the deletion.

In a scenario where the user inserts and deletes rows in smallish batches at about the same rate in the table, it is possible that the purge thread starts to lag behind, and the table grows bigger and bigger, making everything disk-bound and very slow. Even if the table carries just 10MB of useful data, it may grow to occupy 10GB with all the “dead” rows. In such a case, it would be good to throttle new row operations and allocate more resources to the purge thread. The `innodb_max_purge_lag` system variable exists for exactly this purpose. See [Section 13.6.3, “InnoDB Startup Options and System Variables”](#), for more information.

13.6.10. InnoDB Table and Index Structures

MySQL stores its data dictionary information for tables in `.frm` files in database directories. This is true for all MySQL storage engines, but every [InnoDB](#) table also has its own entry in the [InnoDB](#) internal data dictionary inside the tablespace. When MySQL drops a table or a database, it has to delete one or more `.frm` files as well as the corresponding entries inside the [InnoDB](#) data dictionary. Consequently, you cannot move [InnoDB](#) tables between databases simply by moving the `.frm` files.

13.6.10.1. Clustered and Secondary Indexes

Every [InnoDB](#) table has a special index called the *clustered index* where the data for the rows is stored:

- If you define a [PRIMARY KEY](#) on your table, [InnoDB](#) uses it as the clustered index.
- If you do not define a [PRIMARY KEY](#) for your table, MySQL picks the first [UNIQUE](#) index that has only [NOT NULL](#) columns as the primary key and [InnoDB](#) uses it as the clustered index.
- If the table has no [PRIMARY KEY](#) or suitable [UNIQUE](#) index, [InnoDB](#) internally generates a hidden clustered index on a synthetic column containing row ID values. The rows are ordered by the ID that [InnoDB](#) assigns to the rows in such a table. The row ID is a 6-byte field that increases monotonically as new rows are inserted. Thus, the rows ordered by the row ID are physically in insertion order.

Accessing a row through the clustered index is fast because the row data is on the same page where the index search leads. If a table is large, the clustered index architecture often saves a disk I/O operation when compared to storage organizations that store row data using a different page from the index record. (For example, [MyISAM](#) uses one file for data rows and another for index records.)

In [InnoDB](#), the records in non-clustered indexes (also called secondary indexes) contain the primary key columns for the row that are not in the secondary index. [InnoDB](#) uses this primary key value to search for the row in the clustered index. If the primary key is long, the secondary indexes use more space, so it is advantageous to have a short primary key.

13.6.10.2. Physical Structure of an Index

All [InnoDB](#) indexes are B-trees where the index records are stored in the leaf pages of the tree. The default size of an index page is 16KB. When new records are inserted, [InnoDB](#) tries to leave 1/16 of the page free for future insertions and updates of the index records.

If index records are inserted in a sequential order (ascending or descending), the resulting index pages are about 15/16 full. If records are inserted in a random order, the pages are from 1/2 to 15/16 full. If the fill factor of an index page drops below 1/2, [InnoDB](#) tries to contract the index tree to free the page.

13.6.10.3. Insert Buffering

It is a common situation in database applications that the primary key is a unique identifier and new rows are inserted in the ascending order of the primary key. Thus, insertions into the clustered index do not require random reads from a disk.

On the other hand, secondary indexes are usually non-unique, and insertions into secondary indexes happen in a relatively random order. This would cause a lot of random disk I/O operations without a special mechanism used in [InnoDB](#).

If an index record should be inserted into a non-unique secondary index, [InnoDB](#) checks whether the secondary index page is in the buffer pool. If that is the case, [InnoDB](#) does the insertion directly to the index page. If the index page is not found in the buffer pool, [InnoDB](#) inserts the record to a special insert buffer structure. The insert buffer is kept so small that it fits entirely in the buffer pool, and insertions can be done very fast.

Periodically, the insert buffer is merged into the secondary index trees in the database. Often it is possible to merge several insertions into the same page of the index tree, saving disk I/O operations. It has been measured that the insert buffer can speed up insertions into a table up to 15 times.

The insert buffer merging may continue to happen *after* the inserting transaction has been committed. In fact, it may continue to happen after a server shutdown and restart (see [Section 13.6.6.2, “Forcing InnoDB Recovery”](#)).

Insert buffer merging may take many hours when many secondary indexes must be updated and many rows have been inserted. During this time, disk I/O will be increased, which can cause significant slowdown on disk-bound queries. Another significant background I/O operation is the purge thread (see [Section 13.6.9, “InnoDB Multi-Versioning”](#)).

13.6.10.4. Adaptive Hash Indexes

If a table fits almost entirely in main memory, the fastest way to perform queries on it is to use hash indexes. [InnoDB](#) has a mechanism that monitors index searches made to the indexes defined for a table. If [InnoDB](#) notices that queries could benefit from building a hash index, it does so automatically.

The hash index is always built based on an existing B-tree index on the table. [InnoDB](#) can build a hash index on a prefix of any length of the key defined for the B-tree, depending on the pattern of searches that [InnoDB](#) observes for the B-tree index. A hash index can be partial: It is not required that the whole B-tree index is cached in the buffer pool. [InnoDB](#) builds hash indexes on demand for those pages of the index that are often accessed.

In a sense, [InnoDB](#) tailors itself through the adaptive hash index mechanism to ample main memory, coming closer to the architecture of main-memory databases.

13.6.10.5. Physical Row Structure

The physical row structure for an [InnoDB](#) table depends on the row format specified when the table was created. [InnoDB](#) uses the [COMPACT](#) format by default, but the [REDUNDANT](#) format is available to retain compatibility with older versions of MySQL. To check the row format of an [InnoDB](#) table, use `SHOW TABLE STATUS`.

The compact row format decreases row storage space by about 20% at the cost of increasing CPU use for some operations. If your workload is a typical one that is limited by cache hit rates and disk speed, compact format is likely to be faster. If the workload is a rare case that is limited by CPU speed, compact format might be slower.

Rows in [InnoDB](#) tables that use [REDUNDANT](#) row format have the following characteristics:

- Each index record contains a six-byte header. The header is used to link together consecutive records, and also in row-level locking.
- Records in the clustered index contain fields for all user-defined columns. In addition, there is a six-byte transaction ID field and a seven-byte roll pointer field.
- If no primary key was defined for a table, each clustered index record also contains a six-byte row ID field.
- Each secondary index record also contains all the primary key fields defined for the clustered index key that are not in the secondary index.
- A record contains a pointer to each field of the record. If the total length of the fields in a record is less than 128 bytes, the pointer is one byte; otherwise, two bytes. The array of these pointers is called the record directory. The area where these pointers point is called the data part of the record.
- Internally, [InnoDB](#) stores fixed-length character columns such as `CHAR(10)` in a fixed-length format. [InnoDB](#) does not truncate trailing spaces from [VARCHAR](#) columns.
- An SQL `NULL` value reserves one or two bytes in the record directory. Besides that, an SQL `NULL` value reserves zero bytes in the data part of the record if stored in a variable length column. In a fixed-length column, it reserves the fixed length of the column in the data part of the record. Reserving the fixed space for `NULL` values enables an update of the column from `NULL` to a non-`NULL` value to be done in place without causing fragmentation of the index page.

Rows in [InnoDB](#) tables that use [COMPACT](#) row format have the following characteristics:

- Each index record contains a five-byte header that may be preceded by a variable-length header. The header is used to link together consecutive records, and also in row-level locking.
- The variable-length part of the record header contains a bit vector for indicating `NULL` columns. If the number of columns in the index that can be `NULL` is N , the bit vector occupies $(N+7)/8$ bytes. Columns that are `NULL` do not occupy space other than

the bit in this vector. The variable-length part of the header also contains the lengths of variable-length columns. Each length takes one or two bytes, depending on the maximum length of the column. If all columns in the index are `NOT NULL` and have a fixed length, the record header has no variable-length part.

- For each non-`NULL` variable-length field, the record header contains the length of the column in one or two bytes. Two bytes will only be needed if part of the column is stored externally in overflow pages or the maximum length exceeds 255 bytes and the actual length exceeds 127 bytes. For an externally stored column, the two-byte length indicates the length of the internally stored part plus the 20-byte pointer to the externally stored part. The internal part is 768 bytes, so the length is 768+20. The 20-byte pointer stores the true length of the column.
- The record header is followed by the data contents of the non-`NULL` columns.
- Records in the clustered index contain fields for all user-defined columns. In addition, there is a six-byte transaction ID field and a seven-byte roll pointer field.
- If no primary key was defined for a table, each clustered index record also contains a six-byte row ID field.
- Each secondary index record also contains all the primary key fields defined for the clustered index key that are not in the secondary index. If any of these primary key fields are variable length, the record header for each secondary index will have a variable-length part to record their lengths, even if the secondary index is defined on fixed-length columns.
- Internally, `InnoDB` stores fixed-length, fixed-width character columns such as `CHAR(10)` in a fixed-length format. `InnoDB` does not truncate trailing spaces from `VARCHAR` columns.
- Internally, `InnoDB` attempts to store UTF-8 `CHAR(N)` columns in N bytes by trimming trailing spaces. (With `REDUNDANT` row format, such columns occupy $3 \times N$ bytes.) Reserving the minimum space N in many cases enables column updates to be done in place without causing fragmentation of the index page.

13.6.11. `InnoDB` Disk I/O and File Space Management

13.6.11.1. `InnoDB` Disk I/O

`InnoDB` uses simulated asynchronous disk I/O: `InnoDB` creates a number of threads to take care of I/O operations, such as read-ahead.

There are two read-ahead heuristics in `InnoDB`:

- In sequential read-ahead, if `InnoDB` notices that the access pattern to a segment in the tablespace is sequential, it posts in advance a batch of reads of database pages to the I/O system.
- In random read-ahead, if `InnoDB` notices that some area in a tablespace seems to be in the process of being fully read into the buffer pool, it posts the remaining reads to the I/O system.

`InnoDB` uses a novel file flush technique called *doublewrite*. It adds safety to recovery following an operating system crash or a power outage, and improves performance on most varieties of Unix by reducing the need for `fsync()` operations.

Doublewrite means that before writing pages to a data file, `InnoDB` first writes them to a contiguous tablespace area called the doublewrite buffer. Only after the write and the flush to the doublewrite buffer has completed does `InnoDB` write the pages to their proper positions in the data file. If the operating system crashes in the middle of a page write, `InnoDB` can later find a good copy of the page from the doublewrite buffer during recovery.

13.6.11.2. File Space Management

The data files that you define in the configuration file form the `InnoDB` tablespace. The files are simply concatenated to form the tablespace. There is no striping in use. Currently, you cannot define where within the tablespace your tables are allocated. However, in a newly created tablespace, `InnoDB` allocates space starting from the first data file.

The tablespace consists of database pages with a default size of 16KB. The pages are grouped into extents of size 1MB (64 consecutive pages). The “files” inside a tablespace are called *segments* in `InnoDB`. The term “rollback segment” is somewhat confusing because it actually contains many tablespace segments.

When a segment grows inside the tablespace, `InnoDB` allocates the first 32 pages to it individually. After that, `InnoDB` starts to allocate whole extents to the segment. `InnoDB` can add up to 4 extents at a time to a large segment to ensure good sequentiality of data.

Two segments are allocated for each index in `InnoDB`. One is for non-leaf nodes of the B-tree, the other is for the leaf nodes. The idea here is to achieve better sequentiality for the leaf nodes, which contain the data.

Some pages in the tablespace contain bitmaps of other pages, and therefore a few extents in an `InnoDB` tablespace cannot be allocated to segments as a whole, but only as individual pages.

When you ask for available free space in the tablespace by issuing a `SHOW TABLE STATUS` statement, `InnoDB` reports the extents that are definitely free in the tablespace. `InnoDB` always reserves some extents for cleanup and other internal purposes; these reserved extents are not included in the free space.

When you delete data from a table, `InnoDB` contracts the corresponding B-tree indexes. Whether the freed space becomes available for other users depends on whether the pattern of deletes frees individual pages or extents to the tablespace. Dropping a table or deleting all rows from it is guaranteed to release the space to other users, but remember that deleted rows are physically removed only in an (automatic) purge operation after they are no longer needed for transaction rollbacks or consistent reads. (See [Section 13.6.9, “InnoDB Multi-Versioning”](#).)

The maximum row length, except for variable-length columns (`VARBINARY`, `VARCHAR`, `BLOB` and `TEXT`), is slightly less than half of a database page. That is, the maximum row length is about 8000 bytes. `LONGBLOB` and `LONGTEXT` columns must be less than 4GB, and the total row length, including `BLOB` and `TEXT` columns, must be less than 4GB.

If a row is less than half a page long, all of it is stored locally within the page. If it exceeds half a page, variable-length columns are chosen for external off-page storage until the row fits within half a page. For a column chosen for off-page storage, `InnoDB` stores the first 768 bytes locally in the row, and the rest externally into overflow pages. Each such column has its own list of overflow pages. The 768-byte prefix is accompanied by a 20-byte value that stores the true length of the column and points into the overflow list where the rest of the value is stored.

To see information about the tablespace, use the Tablespace Monitor. See [Section 13.6.13.2, “SHOW ENGINE INNODB STATUS and the InnoDB Monitors”](#).

13.6.11.3. Defragmenting a Table

If there are random insertions into or deletions from the indexes of a table, the indexes may become fragmented. Fragmentation means that the physical ordering of the index pages on the disk is not close to the index ordering of the records on the pages, or that there are many unused pages in the 64-page blocks that were allocated to the index.

One symptom of fragmentation is that a table takes more space than it “should” take. How much that is exactly, is difficult to determine. All `InnoDB` data and indexes are stored in B-trees, and their fill factor may vary from 50% to 100%. Another symptom of fragmentation is that a table scan such as this takes more time than it “should” take:

```
SELECT COUNT(*) FROM t WHERE a_non_indexed_column <> 12345;
```

(In the preceding query, we are “fooling” the SQL optimizer into scanning the clustered index rather than a secondary index.) Most disks can read 10MB/s to 50MB/s, which can be used to estimate how fast a table scan should be.

It can speed up index scans if you periodically perform a “null” `ALTER TABLE` operation, which causes MySQL to rebuild the table:

```
ALTER TABLE tbl_name ENGINE=INNODB
```

Another way to perform a defragmentation operation is to use `mysqldump` to dump the table to a text file, drop the table, and reload it from the dump file.

If the insertions into an index are always ascending and records are deleted only from the end, the `InnoDB` filespace management algorithm guarantees that fragmentation in the index does not occur.

13.6.12. InnoDB Error Handling

Error handling in `InnoDB` is not always the same as specified in the SQL standard. According to the standard, any error during an SQL statement should cause rollback of that statement. `InnoDB` sometimes rolls back only part of the statement, or the whole transaction. The following items describe how `InnoDB` performs error handling:

- If you run out of file space in the tablespace, a MySQL `Table is full` error occurs and `InnoDB` rolls back the SQL statement.
- A transaction deadlock causes `InnoDB` to roll back the entire transaction. You should normally retry the whole transaction when this happens.

A lock wait timeout causes `InnoDB` to roll back only the single statement that was waiting for the lock and encountered the timeout. (To have the entire transaction roll back, start the server with the `--innodb_rollback_on_timeout` option.) You should normally retry the statement if using the current behavior or the entire transaction if using `--innodb_rollback_on_timeout`.

Both deadlocks and lock wait timeouts are normal on busy servers and it is necessary for applications to be aware that they may happen and handle them by retrying. You can make them less likely by doing as little work as possible between the first change to data during a transaction and the commit, so the locks are held for the shortest possible time and for the smallest possible number of rows. Sometimes splitting work between different transactions may be practical and helpful.

When a transaction rollback occurs due to a deadlock or lock wait timeout, it cancels the effect of the statements within the transaction. But if the start-transaction statement was `START TRANSACTION` or `BEGIN` statement, rollback does not cancel that statement. Further SQL statements become part of the transaction until the occurrence of `COMMIT`, `ROLLBACK`, or some SQL statement that causes an implicit commit.

- A duplicate-key error rolls back the SQL statement, if you have not specified the `IGNORE` option in your statement.
- A `row too long error` rolls back the SQL statement.
- Other errors are mostly detected by the MySQL layer of code (above the `InnoDB` storage engine level), and they roll back the corresponding SQL statement. Locks are not released in a rollback of a single SQL statement.

During implicit rollbacks, as well as during the execution of an explicit `ROLLBACK SQL` statement, `SHOW PROCESSLIST` displays `Rolling back` in the `State` column for the relevant connection.

13.6.12.1. InnoDB Error Codes

The following is a non-exhaustive list of common `InnoDB`-specific errors that you may encounter, with information about why each occurs and how to resolve the problem.

- `1005 (ER_CANT_CREATE_TABLE)`
Cannot create table. If the error message refers to error 150, table creation failed because a foreign key constraint was not correctly formed. If the error message refers to error -1, table creation probably failed because the table includes a column name that matched the name of an internal `InnoDB` table.
- `1016 (ER_CANT_OPEN_FILE)`
Cannot find the `InnoDB` table from the `InnoDB` data files, although the `.frm` file for the table exists. See [Section 13.6.13.4, “Troubleshooting InnoDB Data Dictionary Operations”](#).
- `1114 (ER_RECORD_FILE_FULL)`
`InnoDB` has run out of free space in the tablespace. You should reconfigure the tablespace to add a new data file.
- `1205 (ER_LOCK_WAIT_TIMEOUT)`
Lock wait timeout expired. Transaction was rolled back.
- `1213 (ER_LOCK_DEADLOCK)`
Transaction deadlock. You should rerun the transaction.
- `1216 (ER_NO_REFERENCED_ROW)`
You are trying to add a row but there is no parent row, and a foreign key constraint fails. You should add the parent row first.
- `1217 (ER_ROW_IS_REFERENCED)`
You are trying to delete a parent row that has children, and a foreign key constraint fails. You should delete the children first.

13.6.12.2. Operating System Error Codes

To print the meaning of an operating system error number, use the `pererror` program that comes with the MySQL distribution.

The following table provides a list of some common Linux system error codes. For a more complete list, see [Linux source code](#).

- `1 (EPERM)`
Operation not permitted

- 2 (ENOENT)
No such file or directory
- 3 (ESRCH)
No such process
- 4 (EINTR)
Interrupted system call
- 5 (EIO)
I/O error
- 6 (ENXIO)
No such device or address
- 7 (E2BIG)
Arg list too long
- 8 (ENOEXEC)
Exec format error
- 9 (EBADF)
Bad file number
- 10 (ECHILD)
No child processes
- 11 (EAGAIN)
Try again
- 12 (ENOMEM)
Out of memory
- 13 (EACCES)
Permission denied
- 14 (EFAULT)
Bad address
- 15 (ENOTBLK)
Block device required
- 16 (EBUSY)
Device or resource busy
- 17 (EEXIST)
File exists
- 18 (EXDEV)
Cross-device link
- 19 (ENODEV)
No such device

- 20 (ENOTDIR)
Not a directory
- 21 (EISDIR)
Is a directory
- 22 (EINVAL)
Invalid argument
- 23 (ENFILE)
File table overflow
- 24 (EMFILE)
Too many open files
- 25 (ENOTTY)
Inappropriate ioctl for device
- 26 (ETXTBSY)
Text file busy
- 27 (EFBIG)
File too large
- 28 (ENOSPC)
No space left on device
- 29 (ESPIPE)
Illegal seek
- 30 (EROFS)
Read-only file system
- 31 (EMLINK)
Too many links

The following table provides a list of some common Windows system error codes. For a complete list, see the [Microsoft Web site](#).

- 1 (ERROR_INVALID_FUNCTION)
Incorrect function.
- 2 (ERROR_FILE_NOT_FOUND)
The system cannot find the file specified.
- 3 (ERROR_PATH_NOT_FOUND)
The system cannot find the path specified.
- 4 (ERROR_TOO_MANY_OPEN_FILES)
The system cannot open the file.
- 5 (ERROR_ACCESS_DENIED)
Access is denied.

- 6 (`ERROR_INVALID_HANDLE`)
The handle is invalid.
- 7 (`ERROR_ARENA_TRASHED`)
The storage control blocks were destroyed.
- 8 (`ERROR_NOT_ENOUGH_MEMORY`)
Not enough storage is available to process this command.
- 9 (`ERROR_INVALID_BLOCK`)
The storage control block address is invalid.
- 10 (`ERROR_BAD_ENVIRONMENT`)
The environment is incorrect.
- 11 (`ERROR_BAD_FORMAT`)
An attempt was made to load a program with an incorrect format.
- 12 (`ERROR_INVALID_ACCESS`)
The access code is invalid.
- 13 (`ERROR_INVALID_DATA`)
The data is invalid.
- 14 (`ERROR_OUTOFMEMORY`)
Not enough storage is available to complete this operation.
- 15 (`ERROR_INVALID_DRIVE`)
The system cannot find the drive specified.
- 16 (`ERROR_CURRENT_DIRECTORY`)
The directory cannot be removed.
- 17 (`ERROR_NOT_SAME_DEVICE`)
The system cannot move the file to a different disk drive.
- 18 (`ERROR_NO_MORE_FILES`)
There are no more files.
- 19 (`ERROR_WRITE_PROTECT`)
The media is write protected.
- 20 (`ERROR_BAD_UNIT`)
The system cannot find the device specified.
- 21 (`ERROR_NOT_READY`)
The device is not ready.
- 22 (`ERROR_BAD_COMMAND`)
The device does not recognize the command.
- 23 (`ERROR_CRC`)
Data error (cyclic redundancy check).

- 24 (`ERROR_BAD_LENGTH`)
The program issued a command but the command length is incorrect.
- 25 (`ERROR_SEEK`)
The drive cannot locate a specific area or track on the disk.
- 26 (`ERROR_NOT_DOS_DISK`)
The specified disk or diskette cannot be accessed.
- 27 (`ERROR_SECTOR_NOT_FOUND`)
The drive cannot find the sector requested.
- 28 (`ERROR_OUT_OF_PAPER`)
The printer is out of paper.
- 29 (`ERROR_WRITE_FAULT`)
The system cannot write to the specified device.
- 30 (`ERROR_READ_FAULT`)
The system cannot read from the specified device.
- 31 (`ERROR_GEN_FAILURE`)
A device attached to the system is not functioning.
- 32 (`ERROR_SHARING_VIOLATION`)
The process cannot access the file because it is being used by another process.
- 33 (`ERROR_LOCK_VIOLATION`)
The process cannot access the file because another process has locked a portion of the file.
- 34 (`ERROR_WRONG_DISK`)
The wrong diskette is in the drive. Insert %2 (Volume Serial Number: %3) into drive %1.
- 36 (`ERROR_SHARING_BUFFER_EXCEEDED`)
Too many files opened for sharing.
- 38 (`ERROR_HANDLE_EOF`)
Reached the end of the file.
- 39 (`ERROR_HANDLE_DISK_FULL`)
The disk is full.
- 87 (`ERROR_INVALID_PARAMETER`)
The parameter is incorrect.
- 112 (`ERROR_DISK_FULL`)
The disk is full.
- 123 (`ERROR_INVALID_NAME`)
The file name, directory name, or volume label syntax is incorrect.
- 1450 (`ERROR_NO_SYSTEM_RESOURCES`)
Insufficient system resources exist to complete the requested service.

13.6.13. InnoDB Performance Tuning and Troubleshooting

13.6.13.1. InnoDB Performance Tuning Tips

- In **InnoDB**, having a long **PRIMARY KEY** wastes a lot of disk space because its value must be stored with every secondary index record. (See [Section 13.6.10, “InnoDB Table and Index Structures”](#).) Create an **AUTO_INCREMENT** column as the primary key if your primary key is long.
- If you have **UNIQUE** constraints on secondary keys, you can speed up table imports by temporarily turning off the uniqueness checks during the import session:

```
SET unique_checks=0;
... import operation ...
SET unique_checks=1;
```

For big tables, this saves a lot of disk I/O because **InnoDB** can use its insert buffer to write secondary index records in a batch. Be certain that the data contains no duplicate keys.

- If you have **FOREIGN KEY** constraints in your tables, you can speed up table imports by turning the foreign key checks off for the duration of the import session:

```
SET foreign_key_checks=0;
... import operation ...
SET foreign_key_checks=1;
```

For big tables, this can save a lot of disk I/O.

- If the Unix **top** tool or the Windows Task Manager shows that the CPU usage percentage with your workload is less than 70%, your workload is probably disk-bound. Maybe you are making too many transaction commits, or the buffer pool is too small. Making the buffer pool bigger can help, but do not set it equal to more than 80% of physical memory.
- Wrap several modifications into a single transaction to reduce the number of flush operations. **InnoDB** must flush the log to disk at each transaction commit if that transaction made modifications to the database. The rotation speed of a disk is typically at most 167 revolutions/second, which constrains the number of commits to the same 167th of a second if the disk does not “fool” the operating system.
- If you can afford the loss of some of the latest committed transactions if a crash occurs, you can set the **innodb_flush_log_at_trx_commit** parameter to 0. **InnoDB** tries to flush the log once per second anyway, although the flush is not guaranteed. You should also set the value of **innodb_support_xa** to 0, which will reduce the number of disk flushes due to synchronizing on disk data and the binary log.
- Make your log files big, even as big as the buffer pool. When **InnoDB** has written the log files full, it must write the modified contents of the buffer pool to disk in a checkpoint. Small log files cause many unnecessary disk writes. The disadvantage of big log files is that the recovery time is longer.
- Make the log buffer quite large as well (on the order of 8MB).
- Use the **VARCHAR** data type instead of **CHAR** if you are storing variable-length strings or if the column may contain many **NULL** values. A **CHAR(N)** column always takes *N* characters to store data, even if the string is shorter or its value is **NULL**. Smaller tables fit better in the buffer pool and reduce disk I/O.

When using **COMPACT** row format (the default **InnoDB** format in MySQL 5.4) and variable-length character sets, such as **utf8** or **sjis**, **CHAR(N)** will occupy a variable amount of space, at least *N* bytes.

- In some versions of GNU/Linux and Unix, flushing files to disk with the Unix **fsync()** call (which **InnoDB** uses by default) and other similar methods is surprisingly slow. If you are dissatisfied with database write performance, you might try setting the **innodb_flush_method** parameter to **O_DSYNC**. The **O_DSYNC** flush method seems to perform slower on most systems, but yours might not be one of them.
- When using the **InnoDB** storage engine on Solaris 10 for x86_64 architecture (AMD Opteron), it is important to mount any file systems used for storing **InnoDB**-related files using the **forcedirectio** option. (The default on Solaris 10/x86_64 is *not* to use this option.) Failure to use **forcedirectio** causes a serious degradation of **InnoDB**'s speed and performance on this platform.

When using the **InnoDB** storage engine with a large **innodb_buffer_pool_size** value on any release of Solaris 2.6 and up and any platform (sparc/x86/x64/amd64), a significant performance gain might be achieved by placing **InnoDB** data files and log files on raw devices or on a separate direct I/O UFS file system (using the **forcedirectio** mount option; see **mount_ufs(1M)**). Users of the Veritas file system VxFS should use the **convosync=direct** mount option. You are advised to perform tests with and without raw partitions or direct I/O file systems to verify whether performance is improved on your system.

Other MySQL data files, such as those for [MyISAM](#) tables, should not be placed on a direct I/O file system. Executables or libraries *must not* be placed on a direct I/O file system.

- When importing data into [InnoDB](#), make sure that MySQL does not have autocommit mode enabled because that requires a log flush to disk for every insert. To disable autocommit during your import operation, surround it with `SET autocommit` and `COMMIT` statements:

```
SET autocommit=0;
... SQL import statements ...
COMMIT;
```

If you use the `mysqldump` option `--opt`, you get dump files that are fast to import into an [InnoDB](#) table, even without wrapping them with the `SET autocommit` and `COMMIT` statements.

- Beware of big rollbacks of mass inserts: [InnoDB](#) uses the insert buffer to save disk I/O in inserts, but no such mechanism is used in a corresponding rollback. A disk-bound rollback can take 30 times as long to perform as the corresponding insert. Killing the database process does not help because the rollback starts again on server startup. The only way to get rid of a run-away rollback is to increase the buffer pool so that the rollback becomes CPU-bound and runs fast, or to use a special procedure. See [Section 13.6.6.2, “Forcing InnoDB Recovery”](#).
- Beware also of other big disk-bound operations. Use `DROP TABLE` and `CREATE TABLE` to empty a table, not `DELETE FROM tbl_name`.
- Use the multiple-row `INSERT` syntax to reduce communication overhead between the client and the server if you need to insert many rows:

```
INSERT INTO yourtable VALUES (1,2), (5,5), ...;
```

This tip is valid for inserts into any table, not just [InnoDB](#) tables.

- If you often have recurring queries for tables that are not updated frequently, enable the query cache:

```
[mysqld]
query_cache_type = 1
query_cache_size = 10M
```

- Unlike [MyISAM](#), [InnoDB](#) does not store an index cardinality value in its tables. Instead, [InnoDB](#) computes a cardinality for a table the first time it accesses it after startup. With a large number of tables, this might take significant time. It is the initial table open operation that is important, so to “warm up” a table for later use, access it immediately after startup by issuing a statement such as `SELECT 1 FROM tbl_name LIMIT 1`.

MySQL Enterprise

For optimization recommendations geared to your specific circumstances subscribe to the MySQL Enterprise Monitor. For more information, see <http://www.mysql.com/products/enterprise/advisors.html>.

13.6.13.2. SHOW ENGINE INNODB STATUS and the InnoDB Monitors

[InnoDB](#) Monitors provide information about the [InnoDB](#) internal state. This information is useful for performance tuning. Each Monitor can be enabled by creating a table with a special name, which causes [InnoDB](#) to write Monitor output periodically. Also, output for the standard [InnoDB](#) Monitor is available on demand via the `SHOW ENGINE INNODB STATUS` SQL statement.

There are several types of [InnoDB](#) Monitors:

- The standard [InnoDB](#) Monitor displays the following types of information:
 - Table and record locks held by each active transaction
 - Lock waits of a transactions
 - Semaphore waits of threads
 - Pending file I/O requests
 - Buffer pool statistics
 - Purge and insert buffer merge activity of the main [InnoDB](#) thread

For a discussion of [InnoDB](#) lock modes, see [Section 13.6.8.1, “InnoDB Lock Modes”](#).

To enable the standard `InnoDB` Monitor for periodic output, create a table named `innodb_monitor`. To obtain Monitor output on demand, use the `SHOW ENGINE INNODB STATUS` SQL statement to fetch the output to your client program. If you are using the `mysql` interactive client, the output is more readable if you replace the usual semicolon statement terminator with `\G`:

```
mysql> SHOW ENGINE INNODB STATUS\G
```

- The `InnoDB` Lock Monitor is like the standard Monitor but also provides extensive lock information. To enable this Monitor for periodic output, create a table named `innodb_lock_monitor`.
- The `InnoDB` Tablespace Monitor prints a list of file segments in the shared tablespace and validates the tablespace allocation data structures. To enable this Monitor for periodic output, create a table named `innodb_tablespace_monitor`.
- The `InnoDB` Table Monitor prints the contents of the `InnoDB` internal data dictionary. To enable this Monitor for periodic output, create a table named `innodb_table_monitor`.

To enable an `InnoDB` Monitor for periodic output, use a `CREATE TABLE` statement to create the table associated with the Monitor. For example, to enable the standard `InnoDB` Monitor, create the `innodb_monitor` table:

```
CREATE TABLE innodb_monitor (a INT) ENGINE=INNODB;
```

To stop the Monitor, drop the table:

```
DROP TABLE innodb_monitor;
```

The `CREATE TABLE` syntax is just a way to pass a command to the `InnoDB` engine through MySQL's SQL parser: The only things that matter are the table name `innodb_monitor` and that it be an `InnoDB` table. The structure of the table is not relevant at all for the `InnoDB` Monitor. If you shut down the server, the Monitor does not restart automatically when you restart the server. You must drop the Monitor table and issue a new `CREATE TABLE` statement to start the Monitor. (This syntax may change in a future release.)

The `PROCESS` privilege is required to start or stop the `InnoDB` Monitor tables.

When you enable `InnoDB` Monitors for periodic output, `InnoDB` writes their output to the `mysqld` server standard error output (`stderr`). In this case, no output is sent to clients. When switched on, `InnoDB` Monitors print data about every 15 seconds. Server output usually is directed to the error log (see [Section 5.2.2, “The Error Log”](#)). This data is useful in performance tuning. On Windows, you must start the server from a command prompt in a console window with the `--console` option if you want to direct the output to the window rather than to the error log.

`InnoDB` sends diagnostic output to `stderr` or to files rather than to `stdout` or fixed-size memory buffers, to avoid potential buffer overflows. As a side effect, the output of `SHOW ENGINE INNODB STATUS` is written to a status file in the MySQL data directory every fifteen seconds. The name of the file is `innodb_status.pid`, where `pid` is the server process ID. `InnoDB` removes the file for a normal shutdown. If abnormal shutdowns have occurred, instances of these status files may be present and must be removed manually. Before removing them, you might want to examine them to see whether they contain useful information about the cause of abnormal shutdowns. The `innodb_status.pid` file is created only if the configuration option `innodb_status_file=1` is set.

`InnoDB` Monitors should be enabled only when you actually want to see Monitor information because output generation does result in some performance decrement. Also, if you enable monitor output by creating the associated table, your error log may become quite large if you forget to remove the table later.

For additional information about `InnoDB` monitors, see the following resources:

- Mark Leith: [InnoDB Table and Tablespace Monitors](#)
- MySQL Performance Blog: [SHOW INNODB STATUS walk through](#)

Each monitor begins with a header containing a timestamp and the monitor name. For example:

```
=====
090407 12:06:19 INNODB TABLESPACE MONITOR OUTPUT
=====
```

The header for the standard Monitor (`INNODB MONITOR OUTPUT`) is also used for the Lock Monitor because the latter produces the same output with the addition of extra lock information.

The following sections describe the output for each Monitor.

13.6.13.2.1. InnoDB Standard Monitor and Lock Monitor Output

The Lock Monitor is the same as the standard Monitor except that it includes additional lock information. Enabling either monitor for periodic output by creating the associated InnoDB table turns on the same output stream, but the stream includes the extra information if the Lock Monitor is enabled. For example, if you create the `innodb_monitor` and `innodb_lock_monitor` tables, that turns on a single output stream. The stream includes extra lock information until you disable the Lock Monitor by removing the `innodb_lock_monitor` table.

Example InnoDB Monitor output:

```
mysql> SHOW ENGINE INNODB STATUS\G
***** 1. row *****
Status:
-----
030709 13:00:59 INNODB MONITOR OUTPUT
-----
Per second averages calculated from the last 18 seconds

END OF INNODB MONITOR OUTPUT
-----
```

InnoDB Monitor output is limited to 64,000 bytes when produced via the `SHOW ENGINE INNODB STATUS` statement. This limit does not apply to output written to the server's error output.

Some notes on the output sections:

- [SEMAPHORES](#)

This section reports threads waiting for a semaphore and statistics on how many times threads have needed a spin or a wait on a mutex or a rw-lock semaphore. A large number of threads waiting for semaphores may be a result of disk I/O, or contention problems inside InnoDB. Contention can be due to heavy parallelism of queries or problems in operating system thread scheduling. Setting the `innodb_thread_concurrency` system variable smaller than the default value might help in such situations.

- [LATEST FOREIGN KEY ERROR](#)

This section provides information about the most recent foreign key constraint error. It is not present if no such error has occurred. The contents include the statement that failed as well as information about the constraint that failed and the referenced and referencing tables.

- [LATEST DETECTED DEADLOCK](#)

This section provides information about the most recent deadlock. It is not present if no deadlock has occurred. The contents show which transactions are involved, the statement each was attempting to execute, the locks they have and need, and which transaction InnoDB decided to roll back to break the deadlock. The lock modes reported in this section are explained in [Section 13.6.8.1, “InnoDB Lock Modes”](#).

- [TRANSACTIONS](#)

If this section reports lock waits, your applications might have lock contention. The output can also help to trace the reasons for transaction deadlocks.

- [FILE I/O](#)

This section provides information about threads that InnoDB uses to perform various types of I/O. The first few of these are dedicated to general InnoDB processing. The contents also display information for pending I/O operations and statistics for I/O performance.

The number of these threads are controlled by the `innodb_read_io_threads` and `innodb_write_io_threads` parameters. See [Section 13.6.3, “InnoDB Startup Options and System Variables”](#).

- [INSERT BUFFER AND ADAPTIVE HASH INDEX](#)

This section shows the status of the InnoDB insert buffer and adaptive hash index. (See [Section 13.6.10.3, “Insert Buffering”](#), and [Section 13.6.10.4, “Adaptive Hash Indexes”](#).) The contents include the number of operations performed for each, plus statistics for hash index performance.

- [LOG](#)

This section displays information about the InnoDB log. The contents include the current log sequence number, how far the log has been flushed to disk, and the position at which InnoDB last took a checkpoint. (See [Section 13.6.6.3, “InnoDB Checkpoints”](#).) The section also displays information about pending writes and write performance statistics.

- [BUFFER POOL AND MEMORY](#)

This section gives you statistics on pages read and written. You can calculate from these numbers how many data file I/O operations your queries currently are doing.

- [ROW OPERATIONS](#)

This section shows what the main thread is doing, including the number and performance rate for each type of row operation.

In MySQL 5.4, output from the standard Monitor includes additional sections compared to the output for previous versions. For details, see [Section 1.4.2.4, “Diagnostic and Monitoring Capabilities”](#).

13.6.13.2.2. InnoDB Tablespace Monitor Output

The **InnoDB** Tablespace Monitor prints information about the file segments in the shared tablespace and validates the tablespace allocation data structures. If you use individual tablespaces by enabling `innodb_file_per_table`, the Tablespace Monitor does not describe those tablespaces.

Example **InnoDB** Tablespace Monitor output:

```

=====
090408 21:28:09 INNODB TABLESPACE MONITOR OUTPUT

Validating tablespace
Validation ok
-----
END OF INNODB TABLESPACE MONITOR OUTPUT
=====

```

The Tablespace Monitor output includes information about the shared tablespace as a whole, followed by a list containing a breakdown for each segment within the tablespace.

The tablespace consists of database pages with a default size of 16KB. The pages are grouped into extents of size 1MB (64 consecutive pages).

The initial part of the output that displays overall tablespace information has this format:

```

FILE SPACE INFO: id 0
size 13440, free limit 3136, free extents 28
not full frag extents 2: used pages 78, full frag extents 3
first seg id not used 0 23845

```

Overall tablespace information includes these values:

- `id`: The tablespace ID. A value of 0 refers to the shared tablespace.
- `size`: The current tablespace size in pages.
- `free limit`: The minimum page number for which the free list has not been initialized. Pages at or above this limit are free.
- `free extents`: The number of free extents.
- `not full frag extents, used pages`: The number of fragment extents that are not completely filled, and the number of pages in those extents that have been allocated.
- `full frag extents`: The number of completely full fragment extents.
- `first seg id not used`: The first unused segment ID.

Individual segment information has this format:

```

SEGMENT id 0 15 space 0; page 2; res 160 used 160; full ext 2
fragm pages 32; free extents 0; not full extents 0: pages 0

```

Segment information includes these values:

id: The segment ID.

space, page: The tablespace number and page within the tablespace where the segment “inode” is located. A tablespace number of 0 indicates the shared tablespace. **InnoDB** uses inodes to keep track of segments in the tablespace. The other fields displayed for a segment (**id**, **res**, and so forth) are derived from information in the inode.

res: The number of pages allocated (reserved) for the segment.

used: The number of allocated pages in use by the segment.

full ext: The number of extents allocated for the segment that are completely used.

fragm pages: The number of initial pages that have been allocated to the segment.

free extents: The number of extents allocated for the segment that are completely unused.

not full extents: The number of extents allocated for the segment that are partially used.

pages: The number of pages used within the not-full extents.

When a segment grows, it starts as a single page, and **InnoDB** allocates the first pages for it individually, up to 32 pages (this is the **fragm pages** value). After that, **InnoDB** allocates complete 64-page extents. **InnoDB** can add up to 4 extents at a time to a large segment to ensure good sequentiality of data.

For the example segment shown earlier, it has 32 fragment pages, plus 2 full extents (64 pages each), for a total of 160 pages used out of 160 pages allocated. The following segment has 32 fragment pages and one partially full extent using 14 pages for a total of 46 pages used out of 96 pages allocated:

```
SEGMENT id 0 1 space 0; page 2; res 96 used 46; full ext 0
fragm pages 32; free extents 0; not full extents 1: pages 14
```

It is possible for a segment that has extents allocated to it to have a **fragm pages** value less than 32 if some of the individual pages have been deallocated subsequent to extent allocation.

13.6.13.2.3. InnoDB Table Monitor Output

The **InnoDB** Table Monitor prints the contents of the **InnoDB** internal data dictionary.

The output contains one section per table. The **SYS_FOREIGN** and **SYS_FOREIGN_COLS** sections are for internal data dictionary tables that maintain information about foreign keys. There are also sections for the Table Monitor table and each user-created **InnoDB** table. Suppose that the following two tables have been created in the **test** database:

```
CREATE TABLE parent
(
  par_id      INT NOT NULL,
  fname      CHAR(20),
  lname      CHAR(20),
  PRIMARY KEY (par_id),
  UNIQUE INDEX (lname, fname)
) ENGINE = INNODB;

CREATE TABLE child
(
  par_id      INT NOT NULL,
  child_id   INT NOT NULL,
  name       VARCHAR(40),
  birth      DATE,
  weight     DECIMAL(10,2),
  misc_info  VARCHAR(255),
  last_update TIMESTAMP,
  PRIMARY KEY (par_id, child_id),
  INDEX (name),
  FOREIGN KEY (par_id) REFERENCES parent (par_id)
  ON DELETE CASCADE
  ON UPDATE CASCADE
) ENGINE = INNODB;
```

Then the Table Monitor output will look something like this (reformatted slightly):

```
=====
090420 12:09:32 INNODB TABLE MONITOR OUTPUT

-----
END OF INNODB TABLE MONITOR OUTPUT
=====

```

For each table, Table Monitor output contains a section that displays general information about the table and specific information about its columns, indexes, and foreign keys.

The general information for each table includes the table name (in *db_name/tbl_name* format except for internal tables), its ID, the number of columns and indexes, and an approximate row count.

The **COLUMNS** part of a table section lists each column in the table. Information for each column indicates its name and data type characteristics. Some internal columns are added by InnoDB, such as **DB_ROW_ID** (row ID), **DB_TRX_ID** (transaction ID), and **DB_ROLL_PTR** (a pointer to the rollback/undo data).

- **DATA_XXX**: These symbols indicate the data type. There may be multiple **DATA_XXX** symbols for a given column.
- **prtype**: The column's "precise" type. This field includes information such as the column data type, character set code, nullability, signedness, and whether it is a binary string. This field is described in the `innobase/include/data0type.h` source file.
- **len**: The column length in bytes.

Each `INDEX` part of the table section provides the name and characteristics of one table index:

- `name`: The index name. If the name is `PRIMARY`, the index is a primary key. If the name is `GEN_CLUST_INDEX`, the index is the clustered index that is created automatically if the table definition doesn't include a primary key or non-NULL unique index. See [Section 13.6.10.1, “Clustered and Secondary Indexes”](#).
- `id`: The index ID.
- `fields`: The number of fields in the index, as a value in `m/n` format:
 - `m` is the number of user-defined columns; that is, the number of columns you would see in the index definition in a `CREATE TABLE` statement.
 - `n` is the total number of index columns, including those added internally. For the clustered index, the total includes the other columns in the table definition, plus any columns added internally. For a secondary index, the total includes the columns from the primary key that are not part of the secondary index.
- `uniq`: The number of leading fields that are enough to determine index values uniquely.
- `type`: The index type. This is a bit field. For example, 1 indicates a clustered index and 2 indicates a unique index, so a clustered index (which always contains unique values), will have a `type` value of 3. An index with a `type` value of 0 is neither clustered nor unique. The flag values are defined in the `innobase/include/dict0mem.h` source file.
- `root page`: The index root page number.
- `appr. key vals`: The approximate index cardinality.
- `leaf pages`: The approximate number of leaf pages in the index.
- `size pages`: The approximate total number of pages in the index.
- `FIELDS`: The names of the fields in the index. For a clustered index that was generated automatically, the field list begins with the internal `DB_ROW_ID` (row ID) field. `DB_TRX_ID` and `DB_ROLL_PTR` are always added internally to the clustered index, following the fields that comprise the primary key. For a secondary index, the final fields are those from the primary key that are not part of the secondary index.

The end of the table section lists the `FOREIGN KEY` definitions that apply to the table. This information appears whether the table is a referencing or referenced table.

13.6.13.3. InnoDB General Troubleshooting

The following general guidelines apply to troubleshooting `InnoDB` problems:

- When an operation fails or you suspect a bug, you should look at the MySQL server error log (see [Section 5.2.2, “The Error Log”](#)).
- When troubleshooting, it is usually best to run the MySQL server from the command prompt, rather than through `mysqld_safe` or as a Windows service. You can then see what `mysqld` prints to the console, and so have a better grasp of what is going on. On Windows, start `mysqld` with the `--console` option to direct the output to the console window.
- Use the `InnoDB` Monitors to obtain information about a problem (see [Section 13.6.13.2, “SHOW ENGINE INNODB STATUS and the InnoDB Monitors”](#)). If the problem is performance-related, or your server appears to be hung, you should use the standard Monitor to print information about the internal state of `InnoDB`. If the problem is with locks, use the Lock Monitor. If the problem is in creation of tables or other data dictionary operations, use the Table Monitor to print the contents of the `InnoDB` internal data dictionary. To see tablespace information use the Tablespace Monitor.
- If you suspect that a table is corrupt, run `CHECK TABLE` on that table.

MySQL Enterprise

The MySQL Enterprise Monitor provides a number of advisors specifically designed for monitoring `InnoDB` tables. In some cases, these advisors can anticipate potential problems. For more information, see <http://www.mysql.com/products/enterprise/advisors.html>.

13.6.13.4. Troubleshooting `InnoDB` Data Dictionary Operations

A specific issue with tables is that the MySQL server keeps data dictionary information in `.frm` files it stores in the database dir-

ectories, whereas [InnoDB](#) also stores the information into its own data dictionary inside the tablespace files. If you move `.frm` files around, or if the server crashes in the middle of a data dictionary operation, the locations of the `.frm` files may end up out of synchrony with the locations recorded in the [InnoDB](#) internal data dictionary.

A symptom of an out-of-sync data dictionary is that a `CREATE TABLE` statement fails. If this occurs, you should look in the server's error log. If the log says that the table already exists inside the [InnoDB](#) internal data dictionary, you have an orphaned table inside the [InnoDB](#) tablespace files that has no corresponding `.frm` file. The error message looks like this:

```
InnoDB: Error: table test/parent already exists in InnoDB internal
InnoDB: data dictionary. Have you deleted the .frm file
InnoDB: and not used DROP TABLE? Have you used DROP DATABASE
InnoDB: for InnoDB tables in MySQL version <= 3.23.43?
InnoDB: See the Restrictions section of the InnoDB manual.
InnoDB: You can drop the orphaned table inside InnoDB by
InnoDB: creating an InnoDB table with the same name in another
InnoDB: database and moving the .frm file to the current database.
InnoDB: Then MySQL thinks the table exists, and DROP TABLE will
InnoDB: succeed.
```

You can drop the orphaned table by following the instructions given in the error message. If you are still unable to use `DROP TABLE` successfully, the problem may be due to name completion in the `mysql` client. To work around this problem, start the `mysql` client with the `--skip-auto-rehash` option and try `DROP TABLE` again. (With name completion on, `mysql` tries to construct a list of table names, which fails when a problem such as just described exists.)

Another symptom of an out-of-sync data dictionary is that MySQL prints an error that it cannot open a `.InnoDB` file:

```
ERROR 1016: Can't open file: 'child2.InnoDB'. (errno: 1)
```

In the error log you can find a message like this:

```
InnoDB: Cannot find table test/child2 from the internal data dictionary
InnoDB: of InnoDB though the .frm file for the table exists. Maybe you
InnoDB: have deleted and recreated InnoDB data files but have forgotten
InnoDB: to delete the corresponding .frm files of InnoDB tables?
```

This means that there is an orphaned `.frm` file without a corresponding table inside [InnoDB](#). You can drop the orphaned `.frm` file by deleting it manually.

If MySQL crashes in the middle of an `ALTER TABLE` operation, you may end up with an orphaned temporary table inside the [InnoDB](#) tablespace. Using the Table Monitor, you can see listed a table with a name that begins with `#sql-`. You can perform SQL statements on tables whose name contains the character “#” if you enclose the name within backticks. Thus, you can drop such an orphaned table like any other orphaned table using the method described earlier. To copy or rename a file in the Unix shell, you need to put the file name in double quotes if the file name contains “#”.

13.6.14. Restrictions on [InnoDB](#) Tables

Warning

Do *not* convert MySQL system tables in the `mysql` database from [MyISAM](#) to [InnoDB](#) tables! This is an unsupported operation. If you do this, MySQL does not restart until you restore the old system tables from a backup or regenerate them with the `mysql_install_db` script.

Warning

It is not a good idea to configure [InnoDB](#) to use data files or log files on NFS volumes. Otherwise, the files might be locked by other processes and become unavailable for use by MySQL.

- A table cannot contain more than 1000 columns.
- The [InnoDB](#) internal maximum key length is 3500 bytes, but MySQL itself restricts this to 3072 bytes.
- Index key prefixes can be up to 767 bytes. See [Section 12.1.11](#), “`CREATE INDEX Syntax`”.
- The maximum row length, except for variable-length columns ([VARBINARY](#), [VARCHAR](#), [BLOB](#) and [TEXT](#)), is slightly less than half of a database page. That is, the maximum row length is about 8000 bytes. [LONGBLOB](#) and [LONGTEXT](#) columns must be less than 4GB, and the total row length, including [BLOB](#) and [TEXT](#) columns, must be less than 4GB.

If a row is less than half a page long, all of it is stored locally within the page. If it exceeds half a page, variable-length columns are chosen for external off-page storage until the row fits within half a page, as described in [Section 13.6.11.2](#), “[File Space Management](#)”.

- Although [InnoDB](#) supports row sizes larger than 65535 internally, you cannot define a row containing [VARBINARY](#) or

`VARCHAR` columns with a combined size larger than 65535:

```
mysql> CREATE TABLE t (a VARCHAR(8000), b VARCHAR(10000),
-> c VARCHAR(10000), d VARCHAR(10000), e VARCHAR(10000),
-> f VARCHAR(10000), g VARCHAR(10000)) ENGINE=InnoDB;
ERROR 1118 (42000): Row size too large. The maximum row size for the
used table type, not counting BLOBs, is 65535. You have to change some
columns to TEXT or BLOBs
```

- On some older operating systems, files must be less than 2GB. This is not a limitation of `InnoDB` itself, but if you require a large tablespace, you will need to configure it using several smaller data files rather than one or a file large data files.
- The combined size of the `InnoDB` log files must be less than 4GB.
- The minimum tablespace size is 10MB. The maximum tablespace size is four billion database pages (64TB). This is also the maximum size for a table.
- `InnoDB` tables do not support `FULLTEXT` indexes.
- `InnoDB` tables support spatial data types, but not indexes on them.
- `ANALYZE TABLE` determines index cardinality (as displayed in the `Cardinality` column of `SHOW INDEX` output) by doing ten random dives to each of the index trees and updating index cardinality estimates accordingly. Because these are only estimates, repeated runs of `ANALYZE TABLE` may produce different numbers. This makes `ANALYZE TABLE` fast on `InnoDB` tables but not 100% accurate because it does not take all rows into account.

MySQL uses index cardinality estimates only in join optimization. If some join is not optimized in the right way, you can try using `ANALYZE TABLE`. In the few cases that `ANALYZE TABLE` does not produce values good enough for your particular tables, you can use `FORCE INDEX` with your queries to force the use of a particular index, or set the `max_seeks_for_key` system variable to ensure that MySQL prefers index lookups over table scans. See [Section 5.1.3, “Server System Variables”](#), and [Section B.1.6, “Optimizer-Related Issues”](#).

- `SHOW TABLE STATUS` does not give accurate statistics on `InnoDB` tables, except for the physical size reserved by the table. The row count is only a rough estimate used in SQL optimization.
- `InnoDB` does not keep an internal count of rows in a table. (In practice, this would be somewhat complicated due to multi-versioning.) To process a `SELECT COUNT(*) FROM t` statement, `InnoDB` must scan an index of the table, which takes some time if the index is not entirely in the buffer pool. If your table does not change often, using the MySQL query cache is a good solution. To get a fast count, you have to use a counter table you create yourself and let your application update it according to the inserts and deletes it does. `SHOW TABLE STATUS` also can be used if an approximate row count is sufficient. See [Section 13.6.13.1, “InnoDB Performance Tuning Tips”](#).
- On Windows, `InnoDB` always stores database and table names internally in lowercase. To move databases in a binary format from Unix to Windows or from Windows to Unix, you should create all databases and tables using lowercase names.
- For an `AUTO_INCREMENT` column, you must always define an index for the table, and that index must contain just the `AUTO_INCREMENT` column. In `MyISAM` tables, the `AUTO_INCREMENT` column may be part of a multi-column index.
- While initializing a previously specified `AUTO_INCREMENT` column on a table, `InnoDB` sets an exclusive lock on the end of the index associated with the `AUTO_INCREMENT` column. In accessing the auto-increment counter, `InnoDB` uses a specific table lock mode `AUTO-INC` where the lock lasts only to the end of the current SQL statement, not to the end of the entire transaction. Other clients cannot insert into the table while the `AUTO-INC` table lock is held; see [Section 13.6.4.3, “AUTO_INCREMENT Handling in InnoDB”](#).
- When you restart the MySQL server, `InnoDB` may reuse an old value that was generated for an `AUTO_INCREMENT` column but never stored (that is, a value that was generated during an old transaction that was rolled back).
- When an `AUTO_INCREMENT` column runs out of values, `InnoDB` wraps a `BIGINT` to `-9223372036854775808` and `BIGINT UNSIGNED` to `1`. However, `BIGINT` values have 64 bits, so if you were to insert one million rows per second, it would still take nearly three hundred thousand years before `BIGINT` reached its upper bound. With all other integer type columns, a duplicate-key error results. This is similar to how `MyISAM` works, because it is mostly general MySQL behavior and not about any storage engine in particular.
- `DELETE FROM tbl_name` does not regenerate the table but instead deletes all rows, one by one.
- Under some conditions, `TRUNCATE tbl_name` for an `InnoDB` table is mapped to `DELETE FROM tbl_name`. See [Section 12.2.10, “TRUNCATE Syntax”](#).
- In MySQL 5.4, the MySQL `LOCK TABLES` operation acquires two locks on each table if `innodb_table_locks = 1` (the default). In addition to a table lock on the MySQL layer, it also acquires an `InnoDB` table lock. Older versions of MySQL did not acquire `InnoDB` table locks; the old behavior can be selected by setting `innodb_table_locks = 0`. If no `InnoDB` table lock is acquired, `LOCK TABLES` completes even if some records of the tables are being locked by other transac-

tions.

- All `InnoDB` locks held by a transaction are released when the transaction is committed or aborted. Thus, it does not make much sense to invoke `LOCK TABLES` on `InnoDB` tables in `autocommit = 1` mode, because the acquired `InnoDB` table locks would be released immediately.
- Sometimes it would be useful to lock further tables in the course of a transaction. Unfortunately, `LOCK TABLES` in MySQL performs an implicit `COMMIT` and `UNLOCK TABLES`. An `InnoDB` variant of `LOCK TABLES` has been planned that can be executed in the middle of a transaction.
- The `LOAD TABLE FROM MASTER` statement for setting up replication slave servers does not work for `InnoDB` tables. A workaround is to alter the table to `MyISAM` on the master, then do the load, and after that alter the master table back to `InnoDB`. Do not do this if the tables use `InnoDB`-specific features such as foreign keys.
- The default database page size in `InnoDB` is 16KB. By recompiling the code, you can set it to values ranging from 8KB to 64KB. You must update the values of `UNIV_PAGE_SIZE` and `UNIV_PAGE_SIZE_SHIFT` in the `univ.i` source file.
- Currently, cascaded foreign key actions do not activate triggers.
- You cannot create a table with a column name that matches the name of an internal `InnoDB` column (including `DB_ROW_ID`, `DB_TRX_ID`, `DB_ROLL_PTR`, and `DB_MIX_ID`). The server will report error 1005 and refers to error -1 in the error message. This limitation applies only to use of the names in uppercase.
- `InnoDB` has a limit of 1023 concurrent transactions that have created undo records by modifying data. Workarounds include keeping transactions as small and fast as possible, delaying changes until near the end of the transaction, and using stored routines to reduce client-server latency delays. Applications should commit transactions before doing time-consuming client-side operations.

13.7. The `IBMDB2I` Storage Engine

The `IBMDB2I` storage engine is designed as a fully-featured transaction-capable storage engine that enables MySQL to store its data in DB2 tables running on IBM i. With the `IBMDB2I` storage engine, data can be shared between MySQL applications and applications coded for native DB2 for i interfaces.

`IBMDB2I` provides ACID-compliant transactions, support for foreign key constraints, full crash recovery, radix-tree-based indexes, and the unique ability to allow DB2 for i applications to see and update table data in real time.

More information about the storage engine and its interaction with DB2 for i can be found in IBM's *Using DB2 for i as a Storage Engine for MySQL* Redbook publication, at [IBM DB2 for i a Storage Engine for MySQL Redbook](#).

13.7.1. Installation

Because it relies on features specific to the IBM i operating system running on IBM Power systems, the `IBMDB2I` storage engine is only available on builds of MySQL specifically created for the IBM i operating system.

IBM i 5.4 or later is required to run `IBMDB2I`. Some features may require IBM i 6.1 or later versions. As well, a set of program temporary fixes (PTFs) must be installed. Information about the specific PTF numbers can be obtained from http://www-912.ibm.com/n_dir/nas4apar.nsf/c79815e083182fec862564c00079d117/67d12878076e4827862574e2003c6d4a?OpenDocument.

The engine is built as a dynamic plugin and so must be installed by using the following command: `INSTALL PLUGIN ibmdb2i SONAME ha_ibmdb2i.so;`

13.7.2. Configuration Options

Table 13.6. `ibmdb2i` Option/Variable Reference

Name	Cmd-Line	Option file	System Var	Status Var	Var Scope	Dynamic
<code>ibmdb2i_assume_exclusive_use</code>	Yes	Yes	Yes		Global	Yes
<code>ibmdb2i_async_enabled</code>	Yes	Yes	Yes		Both	Yes
<code>ibmdb2i_compat_opt_allow_zero_date_vals</code>	Yes	Yes	Yes		Both	Yes
<code>ibmdb2i_compat_opt_blob_cols</code>	Yes	Yes	Yes		Both	Yes
<code>ibmdb2i_compat_opt_time_as_duration</code>	Yes	Yes	Yes		Both	Yes
<code>ibmdb2i_compat_opt_year_as_int</code>	Yes	Yes	Yes		Both	Yes

Name	Cmd-Line	Option file	System Var	Status Var	Var Scope	Dynamic
ibmdb2i_create_index_option	Yes	Yes	Yes		Both	Yes
ibmdb2i_lob_alloc_size	Yes	Yes	Yes		Both	Yes
ibmdb2i_max_read_buffer_size	Yes	Yes	Yes		Both	Yes
ibmdb2i_max_write_buffer_size	Yes	Yes	Yes		Both	Yes
ibmdb2i_propagate_default_col_vals	Yes	Yes	Yes		Both	Yes
ibmdb2i_rdb_name	Yes	Yes	Yes		Global	No
ibmdb2i_system_trace_level	Yes	Yes	Yes		Global	Yes
ibmdb2i_transaction_unsafe	Yes	Yes	Yes		Both	Yes

- [ibmdb2i_assume_exclusive_use](#)

Command Line Format	ibmdb2i_assume_exclusive_use	
Config File Format	ibmdb2i_assume_exclusive_use	
Variable Name	ibmdb2i_assume_exclusive_use	
Variable Scope	Global	
Dynamic Variable	Yes	
Value Set	Type (ibmsystemi)	boolean
	Default	off

Specifies whether an external interface (such as DB2 for i) may be altering the data accessible by the **IBMDB2I** engine. This is an advisory value that may improve performance when correctly set to ON. When the value is ON, **IBMDB2I** may perform some internal caching of table statistics. When the value is set to OFF, **IBMDB2I** must assume that the table rows could be inserted and deleted without its direct knowledge and must call DB2 to obtain accurate statistics before each operation.

Default Value: OFF

- [ibmdb2i_async_enabled](#)

Command Line Format	ibmdb2i_assume_exclusive_use	
Config File Format	ibmdb2i_assume_exclusive_use	
Variable Name	ibmdb2i_assume_exclusive_use	
Variable Scope	Global	
Dynamic Variable	Yes	
Value Set	Type (ibmsystemi)	boolean
	Default	off

Specifies whether buffering between **IBMDB2I** and the QSQSRVR jobs responsible for fetching row data should be done in an asynchronous manner. Asynchronous reads are enabled by default and provide optimal performance. Under normal circumstances, this value will never need to be modified.

Default Value: ON

- [ibmdb2i_create_index_option](#)

Command Line Format	ibmdb2i_assume_exclusive_use	
Config File Format	ibmdb2i_assume_exclusive_use	
Variable Name	ibmdb2i_assume_exclusive_use	
Variable Scope	Global	
Dynamic Variable	Yes	
Value Set	Type (ibmsystemi)	boolean
	Default	off

Controls whether additional indexes are created for use by traditional DB2 for i interfaces. When the value is 0, no additional indexes will be created. When the value is 1 and the index created on behalf of MySQL is ASCII-based, an additional index is created based on EBCDIC hexadecimal sorting. The additional index may be useful for traditional DB2 for i interfaces which expect indexes to use EBCDIC-based sort sequences.

Default Value: 0

- `ibmdb2i_compat_opt_time_as_duration`

Command Line Format	<code>ibmdb2i_assume_exclusive_use</code>	
Config File Format	<code>ibmdb2i_assume_exclusive_use</code>	
Variable Name	<code>ibmdb2i_assume_exclusive_use</code>	
Variable Scope	Global	
Dynamic Variable	Yes	
Value Set	Type (ibmsystemi)	<code>boolean</code>
	Default	<code>off</code>

Controls how MySQL TIME columns are mapped to DB2 data types when creating or altering an `IBMDB2I` table. When the value is `ON`, the column is mapped to an `INTEGER` type in DB2 and supports the full range of values defined by MySQL for `TIME` types. When the value is `OFF`, the column is mapped to a DB2 `TIME` type and supports values in the range of '00:00:00' to '23:59:59'. This option is provided to allow enhanced interoperability with DB2 for i interfaces.

Default Value: OFF

- `ibmdb2i_system_trace_level`

Command Line Format	<code>ibmdb2i_assume_exclusive_use</code>	
Config File Format	<code>ibmdb2i_assume_exclusive_use</code>	
Variable Name	<code>ibmdb2i_assume_exclusive_use</code>	
Variable Scope	Global	
Dynamic Variable	Yes	
Value Set	Type (ibmsystemi)	<code>boolean</code>
	Default	<code>off</code>

Specifies what kind of debugging information is to be gathered for `QSQRVR` jobs servicing MySQL connections. Multiple sources of information may be specified by summing the respective values. Changes to this option only affect new connections. Valid values include

- 0 — No information (Default)
- 2 — `STRDBMON`
- 4 — `STRDBG`
- 8 — `DSPJOBLOG`
- 16 — `STRTRC`
- 32 — `PRTSQLINF`

The most useful sources of information are `DSPJOBLOG`, which will capture the job log for each `QSQRVR` job in a spoolfile, and `STRDBG`, which will increase the diagnostic information in each job log.

Default Value: 0

- `ibmdb2i_compat_opt_allow_zero_date_vals`

Command Line Format	<code>ibmdb2i_compat_opt_allow_zero_date_vals</code>	
Config File Format	<code>ibmdb2i_compat_opt_allow_zero_date_vals</code>	
Variable Name	<code>ibmdb2i_compat_opt_allow_zero_date_vals</code>	

Variable Scope	Both	
Dynamic Variable	Yes	
Value Set	Type (ibmsystemi)	boolean
	Default	0

Specifies whether the storage engine should allow the 0000-00-00 date in `DATETIME`, `TIMESTAMP` and `DATE` columns. When the option is 0, attempts to insert a row containing this zero date into an `IBMDB2I` table will fail. As well, a warning will be generated when creating a column with this zero value as the default value. When this option is 1, the zero value will be substituted with 0001-01-01 when stored in DB2, and a 0001-01-01 value will be translated to 0000-00-00 when read from DB2. Similarly, when a column with a default zero value is created, the DB2 default value will be '0001-01-01'. Users must be aware that, when this option is 1, all values of 0001-01-01 in DB2 will be interpreted as 0000-00-00. This option is primarily added for compatibility with applications which rely on the zero date.

Default Value: 0

- `ibmdb2i_propagate_default_col_vals`

Command Line Format	<code>ibmdb2i_propagate_default_col_vals</code>	
Config File Format	<code>ibmdb2i_propagate_default_col_vals</code>	
Variable Name	<code>ibmdb2i_propagate_default_col_vals</code>	
Variable Scope	Both	
Dynamic Variable	Yes	
Value Set	Type (ibmsystemi)	boolean
	Default	on

Specifies whether `DEFAULT` value associated with each column should be propagated to the DB2 definition of the table when a table is created or altered. The default value is ON. This ensures that rows inserted from a standard DB2 interface will use the same default values as when inserted from MySQL.

Default Value: ON

- `ibmdb2i_compat_opt_year_as_int`

Command Line Format	<code>ibmdb2i_compat_opt_year_as_int</code>	
Config File Format	<code>ibmdb2i_compat_opt_year_as_int</code>	
Variable Name	<code>ibmdb2i_compat_opt_year_as_int</code>	
Variable Scope	Both	
Dynamic Variable	Yes	
Value Set	Type (ibmsystemi)	boolean
	Default	0

Controls how `YEAR` columns are stored in DB2. The default is 0 and causes `YEAR` columns to be created as `CHAR(4) CC-SID 1208` columns in DB2. Setting this option to 1 causes the `YEAR` columns to be created as `SMALLINT` columns. This provides a slight performance increase and enables indexes that combine a `YEAR` column with a character column.

Default Value: 0

- `ibmdb2i_lob_alloc_size`

Command Line Format	<code>ibmdb2i_lob_alloc_size</code>	
Config File Format	<code>ibmdb2i_lob_alloc_size</code>	
Variable Name	<code>ibmdb2i_lob_alloc_size</code>	
Variable Scope	Both	
Dynamic Variable	Yes	
Value Set	Type (ibmsystemi)	numeric
	Default	

	Default	2MB
--	----------------	-----

Controls how much space is allocated by default for reading data from a `BLOB` or `TEXT` field. If an application consistently uses `BLOB` or `TEXT` fields that contain more than 2 MB of data, read performance may be improved if this value is increased. Conversely, an application which uses smaller `BLOB` or `TEXT` fields may find that the MySQL memory footprint is reduced if a smaller value is specified for this option.

Default Value: 2 MB

- `ibmdb2i_compat_opt_blob_cols`

Command Line Format	<code>ibmdb2i_compat_opt_blob_cols</code>	
Config File Format	<code>ibmdb2i_compat_opt_blob_cols</code>	
Variable Name	<code>ibmdb2i_compat_opt_blob_cols</code>	
Variable Scope	Both	
Dynamic Variable	Yes	
Value Set	Type (ibmsystemi)	numeric
	Default	0

Specifies how MySQL `TEXT` and `BLOB` columns larger than 255 characters are mapped when creating `IBMDB2I` tables. When the value is 0, `TEXT` columns are mapped to `CLOB` or `DBCLOB` columns for DB2 for i. This allows the column to contain the maximum size documented for `TEXT` columns (64K characters), but the column can not be included in an index. When the value is 1, `TEXT` columns are mapped to `LONG VARCHAR/VARGRAPHIC` columns, and `BLOB` columns are mapped to `LONG VARBINARY`. This permits indexes to be created over the column, but it reduces the amount of storage available to the column below the documented maximum for `TEXT` columns. This option was provided to enable applications which relied on the ability to create prefix indexes over `TEXT` columns.

Default Value: 0

- `ibmdb2i_max_read_buffer_size`

Command Line Format	<code>ibmdb2i_max_read_buffer_size</code>	
Config File Format	<code>ibmdb2i_max_read_buffer_size</code>	
Variable Name	<code>ibmdb2i_max_read_buffer_size</code>	
Variable Scope	Both	
Dynamic Variable	Yes	
Value Set	Type (ibmsystemi)	numeric
	Default	1MB

Controls the maximum amount of memory allocated for buffering row data when doing reads from an `IBMDB2I` table. This buffering is done independently of any row buffering done within MySQL proper. Setting this value too low may reduce read performance, while setting it too high may increase memory usage and may also reduce read performance.

Default Value: 1 MB

- `ibmdb2i_max_write_buffer_size`

Command Line Format	<code>ibmdb2i_max_write_buffer_size</code>	
Config File Format	<code>ibmdb2i_max_write_buffer_size</code>	
Variable Name	<code>ibmdb2i_max_write_buffer_size</code>	
Variable Scope	Both	
Dynamic Variable	Yes	
Value Set	Type (ibmsystemi)	numeric
	Default	8MB

Controls the maximum amount of memory allocated for buffering row data when inserting multiple rows into an `IBMDB2I` table. This buffering is done independently of any row buffering done within MySQL proper. Setting this value too low may reduce write performance, while setting it too high may increase memory usage.

Default Value: 8 MB

- `ibmdb2i_rdb_name`

Command Line Format	<code>ibmdb2i_rdb_name</code>	
Config File Format	<code>ibmdb2i_rdb_name</code>	
Variable Name	<code>ibmdb2i_rdb_name</code>	
Variable Scope	Global	
Dynamic Variable	No	
Value Set	Type (ibmsystemi)	<code>string</code>
	Default	

The name of a local DB2 for i relational database that will act as a container for all `IBMDB2I` tables. This allows an independent auxiliary storage pool (IASP) to be selected for usage. If no value is specified, the system database (`*SYSBAS`) is used.

Default Value: <blank>

- `ibmdb2i_transaction_unsafe`

Command Line Format	<code>ibmdb2i_transaction_unsafe</code>	
Config File Format	<code>ibmdb2i_transaction_unsafe</code>	
Variable Name	<code>ibmdb2i_transaction_unsafe</code>	
Variable Scope	Both	
Dynamic Variable	Yes	
Value Set	Type (ibmsystemi)	<code>boolean</code>
	Default	<code>off</code>

Controls whether `IBMDB2I` honors the transactional commands and isolation levels specified for MySQL. If the value is `OFF`, transactions are fully supported. If the value is `ON`, transactional behavior is not implemented. This may provide a moderate performance increase for applications that do not rely on transactional guarantees.

Default Value: `OFF`

The values specified for `ibmdb2i_create_index_option`, `ibmdb2i_create_time_columns_as_tod`, `ibmdb2i_map_blob_to_varchar`, `ibmdb2i_compat_opt_allow_zero_date_vals`, `ibmdb2i_propagate_default_col_vals`, and `ibmdb2i_propagate_default_col_val` will be applied whenever an `IBMDB2I` table is created. Tables are implicitly destroyed and re-created when an `offline ALTER TABLE` is performed on an `IBMDB2I` table. Therefore it is highly recommended that the values of these variables be consistent across the lifetime of a table to prevent an `ALTER TABLE` from running under a different set of options than were used to originally create the table. If this recommendation is not followed, the `ALTER TABLE` may fail upon encountering incompatible data when re-creating the table.

13.7.3. Creating schemas and tables

`IBMDB2I` tables are created by specifying the `ENGINE=IBMDB2I` option on a `CREATE TABLE` or `ALTER TABLE` statement. These tables are stored as DB2 for i objects in the `QSYS.LIB` file system. Therefore, in contrast to the behavior of other storage engines, `IBMDB2I` table and index data does not reside beneath the `datadir` directory with other MySQL table data.

When the first `IBMDB2I` table is created in a MySQL schema, the corresponding DB2 schema will be created (if it does not already exist).

Note that--if the user profile running MySQL has sufficient authority--dropping a MySQL schema will drop a DB2 schema of the same name even if the schema never contained any `IBMDB2I` tables and contains objects not related to MySQL. Therefore, it is recommended that extreme caution be used when dropping MySQL schemas when the `IBMDB2I` plugin is installed.

13.7.3.1. Identifier names

DB2 for i file objects have both a short (10-character) system name and an SQL name. The DB2 for i SQL name is always the same as the MySQL name. However, because MySQL's sensitivity to the letter case of schema and table names depends on the file system containing the datadir, mapping the MySQL name to the system name of the corresponding DB2 for i object must account for several factors, described below.

When MySQL is operating in a case-sensitive mode (i.e. datadir is in a case-sensitive file-system like (/QOpenSys), the case of the system name of the `IBMDB2I` object reflects the case of the name specified to MySQL. If the object has all uppercase characters and is equal to or less than 10 characters in length, the system name will be undelimited and in uppercase. If the object name has mixed or lower-case letters, the IBM i system name will contain up to 8 characters of the name in the specified case and will be delimited by surrounding quotation marks. If the MySQL name has more characters than can fit in the delimited system name, the system name will be generated as a mangled name delimited by surrounding quotation marks.

Examples of this naming behavior are given below:

Table 13.7. Naming Behavior in DB2 Storage Engine

MySQL name	DB2 for i SQL name	IBM i System name
mytable	mytable	"mytable"
mylongertable	mylongertable	"mylo0001"
UPPERTABLE	UPPERTABLE	UPPERTABLE
UPPERLONGTABLE	UPPERLONGTABLE	UPPER00001
MixedTab	MixedTab	"MixedTab"
MixedlongerTab	MixedlongerTab	"Mixe0001"

If MySQL is operating in a case-insensitive mode, the IBM i system name will contain up to 8 characters of the name in lower case and will be delimited by surrounding quotation marks. If the MySQL name has more characters than can fit in the delimited system name, the system name will be generated as a mangled name delimited by surrounding quotation marks.

Note that IBM i system names are not changed when a `RENAME TABLE` command is executed. Only the DB2 for i SQL name changes.

13.7.3.2. Index names

Unlike MySQL, DB2 for i requires that index names be unique to an entire schema. In order to support MySQL indexes, `IBMDB2I` creates the DB2 for i indexes with modified file names. The generated name is a concatenation of the index name, three underscores (`_`), and the table name. For example, `CREATE INDEX idx1 ON tab1 (a, b)` would create a DB2 index named `idx___tab1`. If the `ibmdb2i_create_index_option` value is set to 1, an additional index may be created which is named with an additional `H_` marker between the index and table names (e.g. `idx___H_tab1`). These generated names are then mangled to create the an IBM i system name, as described above.

If a table is renamed, the indexes will also be renamed.

This index name generation scheme also has implications for the length of index and table names; to permit the generated name and allow for delimiting quotes, the combined length of the index and table names must be less than or equal to 121 characters.

13.7.3.2.1. Data type mapping

When creating a table, `IBMDB2I` may map the MySQL types specified on a `CREATE TABLE` statement into a corresponding or compatible DB2 for i type. Examples include the `BIT` type, which is stored as a `BINARY` field, or the `MEDIUMINT` type, which is stored as an `INTEGER` field. For most data types, this mapping is transparent. Data types which have restrictions unique to `IBM-DB2I` are documented in [Notes and Limitations](#)

13.7.4. Database/metadata management

When an `IBMDB2I` table is created, a File Level ID (FID) file is created in the database directory. This file has an extension `.FID` and contains the last known FID of the associated DB2 for i physical file. The `IBMDB2I` engine uses this FID value to determine whether incompatible changes have been made to the table by an external (non-MySQL) interface. If the physical file is altered, DB2 for i automatically generates a new FID. The next time `IBMDB2I` attempts to access the file, it will detect that the new FID does not match the known FID, and it will prevent MySQL from using the table.

In some cases, the changes to the physical file that cause the FID to be updated may not adversely affect access through MySQL and `IBMDB2I`. In this case, a user may wish to override the FID check that `IBMDB2I` performs. A user with appropriate permissions may do so simply by deleting the `.FID` file associated with the table and performing a `FLUSH TABLE` command against the table. `IBMDB2I` will then regenerate the file with the new FID the next time the table is accessed from MySQL.

If triggers or constraints are applied to the table from a native DB2 interface, they will be respected when accessing the table from MySQL, but MySQL will have no knowledge of the triggers or constraints. Likewise, views and indexes can be created over the tables from a DB2 interface, but the indexes will not be accessible from MySQL.

13.7.5. Transaction behavior

The `IBMDB2I` storage engine supports row-level transaction management. All MySQL isolation levels are supported by the engine, and where highest performance is required, transaction support can be disabled globally or per session by modifying the `ibmdb2i_transaction_unsafe` configuration option.

`IBMDB2I` uses the underlying DB2 for i transaction support to implement MySQL isolation levels. DB2 for i uses table and row locks to implement the various isolation levels, as described below:

Table 13.8. `IBMDB2I` Isolation Levels

Isolation level	Read-only (SELECT)		Read-write (UPDATE, DELETE)	
	Lock enforcement	Visibility of uncommitted work on behalf of other connections	Lock enforcement	Visibility of uncommitted work on behalf of other connections
SERIALIZABLE	Table is locked until end of transaction. Other connections may read rows while locked.	N/A	Table is locked until end of transaction. Other connections may read rows while locked.	N/A
REPEATABLE READ	Rows that have been read are locked until end of transaction. Other connections may read and insert rows while locked.	Rows cannot be read until work is committed.	Rows that have been read are locked until end of transaction. Other connections may read and insert rows while locked.	Rows cannot be read until work is committed.
READ COMMITTED	Row is locked while cursor is positioned on that row. Other connections may read and insert rows while locked.	Rows cannot be read until work is committed.	Row is locked while cursor is positioned on that row. Other connections may read and insert rows while locked.	Rows cannot be read until work is committed.
READ UNCOMMITTED	Row is locked while cursor is positioned on that row. Other connections may read and insert rows while locked.	Rows can be read before work is committed.	Row is locked while cursor is positioned on that row. Other connections may read and insert rows while locked.	Rows can be read before work is committed.
<code>transaction_unsafe</code>	No locks	Full access	Table is locked until end of transaction. Other connections may read rows while locked.	Unrestricted access

Attempts to access locked rows time out according to the timeout value associated with the underlying DB2 physical file. This timeout wait is 30 seconds by default. Refer to <http://publib.boulder.ibm.com/infocenter/iserics/v5r4/index.jsp?topic=/dbp/rbafconrec.htm> for more information.

Because `IBMDB2I` does not multi-version rows under commitment control, row lock contention may occur under certain scenarios. In particular, when multiple connections attempt to read overlapping ranges of rows while performing a statement that does updates, the connections may contend for the same row locks. This may lead to delays until the row lock timeout expires. Creating appropriate indexes and increasing query selectivity to reduce range overlap may help to alleviate this contention.

13.7.6. Principles and Terminology

`AUTO_INCREMENT`

The MySQL `auto_increment` column attribute can be used to generate a unique identity for new rows. The `IBMDB2I` storage engine maps the MySQL `auto_increment` attribute to the DB2 for i identity attribute

For most MySQL storage engines, the `auto_increment` value is determined by adding one to the maximum value stored in the table for the column. For the `IBMDB2I` storage engine, DB2 for i generates the identity value by adding one to the last generated value. Following are some example MySQL statements to illustrate the point.

```
create table t1 (a int auto increment, primary key(a)) engine = ibmdb2i;
insert into t1 values(3);
insert into t1 values(null),(null);
```

For the first INSERT statement, an explicit value of 3 is specified for the auto_increment column, so the value 3 is stored in the inserted row. For the second INSERT statement null is specified, so generated values 1 and 2 will be stored in the rows.

Duplicate key failures can occur in DB2 for i if a MySQL application mixes explicit auto_increment values with generated values within a table. For the example above, if one more record is inserted into the table for which an auto_increment value is generated, a duplicate key error will occur because the value 3 (that is, the last generated value plus one) already exists in the table. To effect the MySQL behavior for auto_increment columns, the `IBMDB2I` storage engine will detect a duplicate key error, alter the restart value for the DB2 identity column to the maximum value plus one, and retry the failed insert, but only if the following conditions are true:

- The duplicate key error occurred on an index for which the auto_increment column is a key field
- An exclusive (LENR) lock can be acquired on the table
- The error occurred on the first or only row of the `INSERT` statement.

The `IBMDB2I` storage engine does not support the following usage of auto_increment columns:

1. Any MySQL global or session variable that affects the start, increment, or offset for generated auto_increment values.
2. Any MySQL feature that returns the *next value to be used* for an auto_increment column.
3. An auto_increment column on a MySQL partitioned table.

13.7.7. Notes and Limitations

- `IBMDB2I` honors the `CASCADE/RESTRICT` option on the `DROP TABLE` command.
- The use of `FLUSH TABLES WITH READ LOCK` is discouraged when using `IBMDB2I` tables. Due to differences in internal locking implementations, `FLUSH TABLES WITH READ LOCK` may produce deadlocks on `IBMDB2I` tables.
- Row-based replication is supported by `IBMDB2I`. Statement-based replication is not supported.
- Schema name lengths are limited to 10 characters in IBM i 5.4 and 30 characters in IBM i 6.1. If the schema name is mixed- or lower-case, two characters must be subtracted from the limit to account for surrounding quotes.
- The `RENAME TABLE` command cannot be used to move `IBMDB2I` tables from one database to another.
- The maximum length of the internal row format for `IBMDB2I` is 32767 bytes. Because the internal row format may differ from the MySQL row format due to data mapping differences (see Creating schemas and tables section), anticipating this limit may be difficult.
- The combined length of the index and table names must be less than or equal to 121 characters.
- Indexes over TEXT or BLOB columns with a maximum length greater than 255 characters are not supported. The `ibm-db2i_map_blob_to_varchar` option can be used to work around this limitation for TEXT fields up to 64K characters.
- Specific restrictions apply to certain data types as described in the following chart:

Table 13.9. Data type restrictions in `IBMDB2I`

MySQL data type	Restriction
<code>LONGBLOB</code> or <code>LONG-TEXT</code>	The maximum length of a DB2 BLOB data type is 2GB.
<code>DATE</code>	<code>IBMDB2I</code> does not support the special date value of '0000-00-00'. The restrictions on <code>DATE</code> and <code>DATETIME</code> columns can be removed by setting the value of <code>ibm-db2i_compat_opt_allow_zero_date_vals</code> to 1.
<code>DATETIME</code>	<code>IBMDB2I</code> does not support the special datetime value of '0000-00-00 00:00:00'. The restrictions on <code>DATE</code> and <code>DATETIME</code> columns can be removed by setting the value of <code>ibm-db2i_compat_opt_allow_zero_date_vals</code> to 1.
<code>DECIMAL(p, s)</code> or <code>NUMERIC(p, s)</code>	If p is greater than 63 and s is greater than (p-63), the field definition is truncated to <code>DECIMAL(63, s-(p-63))</code> . If p is greater than 63 and s is less than or equal to (p-63), the definition is not supported.

MySQL data type	Restriction
TIME	By default, <code>IBMDB2I</code> only supports times in the range '00:00:00' to '23:59:59.' See the <code>ibm-db2i_create_time_columns_as_tod</code> option for more information.

- These MySQL statements are not supported by the `IBMDB2I` Engine:
 - `CACHE INDEX` and `LOAD INDEX INTO CACHE`
 - `HANDLER`
 - `CHECK TABLE`
 - `REPAIR TABLE`
 - `BACKUP-RESTORE TABLE`
- The `ucs2_spanish2_ci` and `utf8_spanish2_ci` collations are not supported by `IBMDB2I`. There are no plans to support these collations.
- The `ucs2_swedish_ci` and `utf8_swedish_ci` collations are not supported by `IBMDB2I`. This will be fixed in a subsequent release of the storage engine; as with other language-specific unicode collations, the support will be only be available on IBM i 6.1 and later releases.

13.7.8. Character sets and collations

DB2 for i only supports a single collation per index or foreign key constraint. A foreign key constraint must have the same collation as a primary key constraint, if one exists..

Character sets and collations supported by `IBMDB2I` are described in the list below. IBM i 6.1 is required for the most comprehensive collation support. Note that Chinese, Japanese, and Korean character sets are converted to UTF-16 for storage in DB2 for i; `utf8_general_ci` is converted to `UCS2` for storage in DB2 for i.

Table 13.10. Collation compatibility in `IBMDB2I` and MySQL

13.7.9. Error codes and trouble-shooting information

Errors reported by the **IBMDB2I** engine may originate from two locations. Error values under 2500 originate in DB2 for i. Error values over 2500 originate in the storage engine itself. Occasionally, errors are reported by **IBMDB2I** but, due to the architecture of MySQL, cannot be directly exposed to MySQL client interfaces. In these cases, issuing a **SHOW ERRORS** command or referring to the MySQL error log may be necessary to determine the cause of a failure. Errors which originate in DB2 for i are usually encountered in the DB2 for i SQL Server Mode job (QSQRVR) which services the MySQL client connection; additional information about failures can often be found by looking in the job log of the associated QSQRVR job.

Following is the list of codes and messages for errors that occur in DB2 for i that are reported by the **IBMDB2I** engine. %d and %s represent numbers and strings, respectively, that are replaced when the message is displayed.

Table 13.11. Error codes from **IBMDB2I**

Error Code Number	Error Message Text
0	Successful
2016	Thread ID is too long
2017	Error creating a SPACE memory object
2018	Error creating a FILE memory object
2019	Error creating a SPACE synchronization token
2020	Error creating a FILE synchronization token
2021	See message %-.7s in joblog for job %-.6s/%-.10s/%-.10s.
2022	Error unlocking a synchronization token when closing a connection
2023	Invalid action specified for an 'object lock' request
2024	Invalid action specified for a savepoint request
2025	Partial keys are not supported with an ICU sort sequence
2026	Error retrieving an ICU sort key
2027	Error converting single-byte sort sequence to UCS-2
2028	An unsupported collation was specified
2029	Validation failed for referenced table of foreign key constraint
2030	Error extracting table for constraint information
2031	Error extracting referenced table for constraint information
2032	Invalid action specified for a 'commitment control' request
2033	Invalid commitment control isolation level specified on 'open' request
2034	Invalid file handle
2036	Invalid option specified for returning data on 'read' request
2037	Invalid orientation specified for 'read' request
2038	Invalid option type specified for 'read' request
2039	Invalid isolation level for starting commitment control
2040	Error unlocking a synchronization token in module QMYALC
2041	Length of space for returned format is not long enough
2042	SQL XA transactions are currently unsupported by this interface
2043	The associated QSQRVR job was killed or ended unexpectedly.

Error Code Number	Error Message Text
2044	Error unlocking a synchronization token in module QMYSEI
2045	Error unlocking a synchronization token in module QMYSPO
2046	Error converting input CCSID from short form to long form
2048	Error getting associated CCSID for CCSID conversion
2049	Error converting a string from one CCSID to another
2050	Error unlocking a synchronization token
2051	Error destroying a synchronization token
2052	Error locking a synchronization token
2053	Error recreating a synchronization token
2054	A space handle was not specified for a constraint request
2055	An SQL cursor was specified for a delete request
2057	Error on delete request because current UFCB for connection is not open
2058	An SQL cursor was specified for an object initialization request
2059	An SQL cursor was specified for an object override request
2060	A space handle was not specified for an object override request
2061	An SQL cursor was specified for an information request
2062	An SQL cursor was specified for an object lock request
2063	An SQL cursor was specified for an optimize request
2064	A data handle was not specified for a read request
2065	A row number handle was not specified for a read request
2066	A key handle was not specified for a read request
2067	An SQL cursor was specified for an row estimation request
2068	A space handle was not specified for a row estimation request
2069	An SQL cursor was specified for a release record request
2070	A statement handle was not specified for an 'execute immediate' request
2071	A statement handle was not specified for a 'prepare open' request
2072	An SQL cursor was specified for an update request
2073	The UFCB was not open for read
2074	Error on update request because current UFCB for connection is not open
2075	A data handle was not specified for an update request
2076	An SQL cursor was specified for a write request
2077	A data handle was not specified for a write request
2078	An unknown function was specified on a process request
2079	A share definition was not specified for an 'allocate share' request
2080	A share handle was not specified for an 'allocate share' request
2081	A use count handle was not specified for an 'allocate share' request
2082	A 'records per key' handle was not specified for an information request
2083	Error resolving LOB addresss
2084	Length of a LOB space is too small
2085	An unknown function was specified for a server request
2086	Object authorization failed. See message %-.7s in joblog for job %-.6s/%-.10s/%-.10s. for more information.
2088	Error locking mutex on server
2089	Error unlocking mutex on server
2090	Error checking for RDB name in RDB Directory
2091	Error creating mutex on server
2094	Error unlocking mutex
2095	Error connecting to server job

Error Code Number	Error Message Text
2096	Error connecting to server job
2098	Function check occurred while registering parameter spaces. See job log.
2101	End of block
2102	The file has changed and might not be compatible with the MySQL table definition
2103	Error giving pipe to server job
2104	There are open object locks when attempting to deallocate
2105	There is no open lock
2108	The maximum value for the auto_increment data type was exceeded
2109	Error occurred closing the pipe
2110	Error occurred taking a descriptor for the pipe
2111	Error writing to pipe
2112	Server was interrupted
2113	No pipe descriptor exists for reuse
2114	Error occurred during an SQL prepare statement
2115	Error occurred during an SQL open
2122	An unspecified error was returned from the system.

Following is the list of error codes and messages that occur within the [IBMDB2I](#) storage engine.

Table 13.12. Error codes and messages in [IBMDB2I](#)

Error Code Number	Error Message Text
2501	Error opening codeset conversion from %.64s to %.64s (errno = %d). Resolution: Alter the table definition to specify a character set that is supported by the IBMDB2I engine.
2502	Invalid %-.10s name '%-.128s'. Resolution: If a field name, ensure that it is less than the maximum length of 126 characters. If an index name, ensure that the length of the index name plus the length of the table name is less than 121 characters.
2503	Unsupported move from '%-.128s' to '%-.128s' on RENAME TABLE statement. Resolution: Moving a table from one schema to another is not supported by the IBMDB2I engine. Create a new table in the 'to' schema, copy the data to the new table, and then drop the old table.
2505	Auto_increment is not allowed for a partitioned table. Resolution: Remove the auto_increment attribute from the table or do not partition the table.
2506	Character set conversion error due to unknown encoding scheme %d. Resolution: Alter the table definition to ensure that character sets assigned to columns are supported by the IBMDB2I engine.
2508	Table '%-.128s' was not found by the storage engine. Resolution: A table definition exists in MySQL, but the corresponding table in DB2 for i is not found. Delete the MySQL table or restore the DB2 table.
2509	Could not resolve to %-.128s in library %-.10s type %-.10s (errno = %d). Resolution: Restore the missing IBM i object to the system.
2510	Error on _PGMCALL for program %-.10s in library %-.10s (error = %d). Resolution: This is an internal error.
2511	Error on _ILECALL for API '%.128s' (error = %d). Resolution: This is an internal error.
2512	Error in iconv() function during character set conversion (errno = %d). Resolution: Ensure the text being inserted contains only valid code points for the associated character set. This may be caused by using ENCRYPT or COMPRESS on a text field, resulting in binary data containing invalid characters.
2513	Error from Get Encoding Scheme (QTQGESp) API: %d, %d, %d Resolution: This is an internal error.
2514	Error from Get Related Default CCSID (QTQGRDC) API: %d, %d, %d. Resolution: This is an internal error.
2515	Data out of range for column '%.192s'. Resolution: DB2 for i does not support a zero value for DATE and DATE-TIME data types. Specify a new value for the column.
2516	Schema name '%.128s' exceeds maximum length of %d characters. Resolution: Change the schema name so that its

Error Code Number	Error Message Text
	length does not exceed the maximum. For mixed case or lower case names, allow 2 characters for outer quotes.
2517	Multiple collations not supported in a single index. Resolution: DB2 for i only supports sort sequences at the table or index level, so all character-based columns in the primary key or index must be using the same collation. Alter the table definition so that all columns use the same collation.
2518	Sort sequence was not found. Resolution: Alter the table to use a collation that is supported by the <code>IBMDB2I</code> engine.
2519	One or more characters in column <code>%.128s</code> were substituted during conversion. Resolution: This is a warning that during the conversion of data from MySQL to DB2 some characters were replaced with substitute characters.
2520	A decimal column exceeded the maximum precision. Data may be truncated. Resolution: A decimal column specified on a <code>CREATE TABLE</code> or <code>ALTER TABLE</code> command has greater precision than DB2 allows. Data stored in this column may be truncated. Change the column specification to have a precision less than or equal to 63.
2521	Some data returned by DB2 for table <code>%s</code> could not be converted for MySQL. Resolution: This is a warning that some data could not be converted from DB2 to MySQL. Data was likely inserted into the table using DB2 interfaces that is valid data for DB2 but is invalid for MySQL.
2523	Column <code>%.128s</code> contains characters that cannot be converted. Resolution: An error occurred converting data from the MySQL character set to the associated DB2 coded character set identifier (CCSID). Omit the incompatible characters or alter the table to specify a different character set for the column.
2524	An invalid name was specified for <code>ibmdb2i_rdb_name</code> . Resolution: Specify a valid relational database (RDB) name.
2525	A duplicate key was encountered for index <code>%.128s</code> . Resolution: : Specify a unique key value for the row. Generally, this error occurs if a unique constraint or index has been applied to the table from a non-MySQL interface.
2528	Some attribute(s) defined for column <code>%.128s</code> may not be honored by accesses from DB2.

13.8. The `MERGE` Storage Engine

The `MERGE` storage engine, also known as the `MRG_MyISAM` engine, is a collection of identical `MyISAM` tables that can be used as one. “Identical” means that all tables have identical column and index information. You cannot merge `MyISAM` tables in which the columns are listed in a different order, do not have exactly the same columns, or have the indexes in different order. However, any or all of the `MyISAM` tables can be compressed with `myisampack`. See [Section 4.6.5, “myisampack — Generate Compressed, Read-Only MyISAM Tables”](#). Differences in table options such as `AVG_ROW_LENGTH`, `MAX_ROWS`, or `PACK_KEYS` do not matter.

When you create a `MERGE` table, MySQL creates two files on disk. The files have names that begin with the table name and have an extension to indicate the file type. An `.frm` file stores the table format, and an `.MRG` file contains the names of the tables that should be used as one. The tables do not have to be in the same database as the `MERGE` table itself.

You can use `SELECT`, `DELETE`, `UPDATE`, and `INSERT` on `MERGE` tables. You must have `SELECT`, `UPDATE`, and `DELETE` privileges on the `MyISAM` tables that you map to a `MERGE` table.

Note

The use of `MERGE` tables entails the following security issue: If a user has access to `MyISAM` table `t`, that user can create a `MERGE` table `m` that accesses `t`. However, if the user's privileges on `t` are subsequently revoked, the user can continue to access `t` by doing so through `m`.

If you `DROP` the `MERGE` table, you are dropping only the `MERGE` specification. The underlying tables are not affected.

To create a `MERGE` table, you must specify a `UNION=(list-of-tables)` clause that indicates which `MyISAM` tables you want to use as one. You can optionally specify an `INSERT_METHOD` option if you want inserts for the `MERGE` table to take place in the first or last table of the `UNION` list. Use a value of `FIRST` or `LAST` to cause inserts to be made in the first or last table, respectively. If you do not specify an `INSERT_METHOD` option or if you specify it with a value of `NO`, attempts to insert rows into the `MERGE` table result in an error.

The following example shows how to create a `MERGE` table:

```
mysql> CREATE TABLE t1 (
->   a INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
->   message CHAR(20)) ENGINE=MyISAM;
mysql> CREATE TABLE t2 (
->   a INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
->   message CHAR(20)) ENGINE=MyISAM;
mysql> INSERT INTO t1 (message) VALUES ('Testing'),('table'),('t1');
mysql> INSERT INTO t2 (message) VALUES ('Testing'),('table'),('t2');
mysql> CREATE TABLE total (
->   a INT NOT NULL AUTO_INCREMENT,
```

```
-> message CHAR(20), INDEX(a))
-> ENGINE=MERGE UNION=(t1,t2) INSERT_METHOD=LAST;
```

Note that the `a` column is indexed as a `PRIMARY KEY` in the underlying `MyISAM` tables, but not in the `MERGE` table. There it is indexed but not as a `PRIMARY KEY` because a `MERGE` table cannot enforce uniqueness over the set of underlying tables.

When a table that is part of a `MERGE` table is opened, the following checks are applied before opening each table. If any table fails the conformance checks, then the operation that triggered the opening of the table will fail. The conformance checks applied to each table are:

- Table must have exactly the same amount of columns that `MERGE` table has.
- Column order in the `MERGE` table must match the column order in the underlying tables.
- Additionally, the specification for each column in the parent `MERGE` table and the underlying table are compared. For each column, MySQL checks:
 - Column type in the underlying table equals the column type of `MERGE` table.
 - Column length in the underlying table equals the column length of `MERGE` table.
 - Column of underlying table and column of `MERGE` table can be `NULL`.
- Underlying table must have at least the same amount of keys that merge table has. The underlying table may have more keys than the `MERGE` table, but cannot have less.

Note

A known issue exists that keys on the some columns must be identical in order in both the `MERGE` table and the underlying `MyISAM` table. See [Bug#33653](#).

For each key:

- Check if the key type of underlying table equals the key type of merge table.
- Check if number of key parts (i.e. multiple columns within a compound key) in the underlying table key definition equals the number of key parts in merge table key definition.
- For each key part:
 - Check if key part lengths are equal.
 - Check if key part types are equal.
 - Check if key part languages are equal.
 - Check if key part can be `NULL`.

After creating the `MERGE` table, you can issue queries that operate on the group of tables as a whole:

```
mysql> SELECT * FROM total;
+-----+-----+
| a | message |
+-----+-----+
| 1 | Testing |
| 2 | table   |
| 3 | t1      |
| 1 | Testing |
| 2 | table   |
| 3 | t2      |
+-----+-----+
```

To remap a `MERGE` table to a different collection of `MyISAM` tables, you can use one of the following methods:

- `DROP` the `MERGE` table and re-create it.
- Use `ALTER TABLE tbl_name UNION=(...)` to change the list of underlying tables.

It is also possible to use `ALTER TABLE ... UNION=()` (that is, with an empty `UNION` clause) to remove all of the underlying tables. ([Bug#28248](#))

MERGE tables can help you solve the following problems:

- Easily manage a set of log tables. For example, you can put data from different months into separate tables, compress some of them with **mysampack**, and then create a **MERGE** table to use them as one.
- Obtain more speed. You can split a big read-only table based on some criteria, and then put individual tables on different disks. A **MERGE** table on this could be much faster than using the big table.
- Perform more efficient searches. If you know exactly what you are looking for, you can search in just one of the split tables for some queries and use a **MERGE** table for others. You can even have many different **MERGE** tables that use overlapping sets of tables.
- Perform more efficient repairs. It is easier to repair individual tables that are mapped to a **MERGE** table than to repair a single large table.
- Instantly map many tables as one. A **MERGE** table need not maintain an index of its own because it uses the indexes of the individual tables. As a result, **MERGE** table collections are *very* fast to create or remap. (Note that you must still specify the index definitions when you create a **MERGE** table, even though no indexes are created.)
- If you have a set of tables from which you create a large table on demand, you should instead create a **MERGE** table on them on demand. This is much faster and saves a lot of disk space.
- Exceed the file size limit for the operating system. Each **MyISAM** table is bound by this limit, but a collection of **MyISAM** tables is not.
- You can create an alias or synonym for a **MyISAM** table by defining a **MERGE** table that maps to that single table. There should be no really notable performance impact from doing this (only a couple of indirect calls and `memcpy()` calls for each read).

The disadvantages of **MERGE** tables are:

- You can use only identical **MyISAM** tables for a **MERGE** table.
- You cannot use a number of **MyISAM** features in **MERGE** tables. For example, you cannot create **FULLTEXT** indexes on **MERGE** tables. (You can, of course, create **FULLTEXT** indexes on the underlying **MyISAM** tables, but you cannot search the **MERGE** table with a full-text search.)
- If the **MERGE** table is non-temporary, all underlying **MyISAM** tables must be non-temporary, too. If the **MERGE** table is temporary, the **MyISAM** tables can be any mix of temporary and non-temporary.
- **MERGE** tables use more file descriptors. If 10 clients are using a **MERGE** table that maps to 10 tables, the server uses $(10 \times 10) + 10$ file descriptors. (10 data file descriptors for each of the 10 clients, and 10 index file descriptors shared among the clients.)
- Key reads are slower. When you read a key, the **MERGE** storage engine needs to issue a read on all underlying tables to check which one most closely matches the given key. To read the next key, the **MERGE** storage engine needs to search the read buffers to find the next key. Only when one key buffer is used up does the storage engine need to read the next key block. This makes **MERGE** keys much slower on **eq_ref** searches, but not much slower on **ref** searches. See [Section 12.3.2, “EXPLAIN Syntax”](#), for more information about **eq_ref** and **ref**.

Additional resources

- A forum dedicated to the **MERGE** storage engine is available at <http://forums.mysql.com/list.php?93>.

13.8.1. **MERGE** Table Problems

The following are known problems with **MERGE** tables:

- If you use **ALTER TABLE** to change a **MERGE** table to another storage engine, the mapping to the underlying tables is lost. Instead, the rows from the underlying **MyISAM** tables are copied into the altered table, which then uses the specified storage engine.
- **REPLACE** does not work as expected because the **MERGE** engine cannot enforce uniqueness over the set of underlying tables. The two key facts are:
 - **REPLACE** can detect unique key violations only in the underlying table to which it is going to write (which is determined

by `INSERT_METHOD`). This differs from violations in the `MERGE` table itself.

- If `REPLACE` detects such a violation, it will only change the corresponding row in the first underlying table in which the row is present, whereas a row with the same unique key value may be present in all underlying tables.

Similar considerations apply for `INSERT ... ON DUPLICATE KEY UPDATE`.

- `MERGE` tables do not support partitioning. That is, you cannot partition a `MERGE` table, nor can any of a `MERGE` table's underlying `MyISAM` tables be partitioned.
- You cannot use `REPAIR TABLE`, `OPTIMIZE TABLE`, `DROP TABLE`, `ALTER TABLE`, `DELETE` without a `WHERE` clause, `TRUNCATE TABLE`, or `ANALYZE TABLE` on any of the tables that are mapped into an open `MERGE` table. If you do so, the `MERGE` table may still refer to the original table, which yields unexpected results. The easiest way to work around this deficiency is to ensure that no `MERGE` tables remain open by issuing a `FLUSH TABLES` statement prior to performing any of those operations.

The unexpected results include the possibility that the operation on the `MERGE` table will report table corruption. However, if this occurs after operations on the underlying `MyISAM` tables such as those listed in the previous paragraph (`REPAIR TABLE`, `OPTIMIZE TABLE`, and so forth), the corruption message is spurious. To deal with this, issue a `FLUSH TABLES` statement after modifying the `MyISAM` tables.

- `DROP TABLE` on a table that is in use by a `MERGE` table does not work on Windows because the `MERGE` storage engine's table mapping is hidden from the upper layer of MySQL. Windows does not allow open files to be deleted, so you first must flush all `MERGE` tables (with `FLUSH TABLES`) or drop the `MERGE` table before dropping the table.
- A `MERGE` table cannot maintain uniqueness constraints over the entire table. When you perform an `INSERT`, the data goes into the first or last `MyISAM` table (depending on the value of the `INSERT_METHOD` option). MySQL ensures that unique key values remain unique within that `MyISAM` table, but not across all the tables in the collection.
- The `INSERT_METHOD` table option for a `MERGE` table indicates which underlying `MyISAM` table to use for inserts into the `MERGE` table. However, use of the `AUTO_INCREMENT` table option for that `MyISAM` table has no effect for inserts into the `MERGE` table until at least one row has been inserted directly into the `MyISAM` table.
- The definition of the `MyISAM` tables and the `MERGE` table are checked when the tables are accessed (for example, as part of a `SELECT` or `INSERT` statement). The checks ensure that the definitions of the tables and the parent `MERGE` table definition match by comparing column order, types, sizes and associated indexes. If there is a difference between the tables then an error will be returned and the statement will fail.

Because these checks take place when the tables are opened, any changes to the definition of a single table, including column changes, column ordering and engine alterations will cause the statement to fail.

- The order of indexes in the `MERGE` table and its underlying tables should be the same. If you use `ALTER TABLE` to add a `UNIQUE` index to a table used in a `MERGE` table, and then use `ALTER TABLE` to add a non-unique index on the `MERGE` table, the index ordering is different for the tables if there was already a non-unique index in the underlying table. (This happens because `ALTER TABLE` puts `UNIQUE` indexes before non-unique indexes to facilitate rapid detection of duplicate keys.) Consequently, queries on tables with such indexes may return unexpected results.
- If you encounter an error message similar to `ERROR 1017 (HY000): CAN'T FIND FILE: 'MM.MRG' (ERRNO: 2)` it generally indicates that some of the base tables are not using the `MyISAM` storage engine. Confirm that all of these tables are `MyISAM`.
- The maximum number of rows in a `MERGE` table is 2^{64} (~1.844E+19; the same as for a `MyISAM` table), provided that the server was built using the `--with-big-tables` option. (All standard MySQL 5.4 standard binaries are built with this option; for more information, see [Section 2.10.2, "Typical configure Options"](#).) It is not possible to merge multiple `MyISAM` tables into a single `MERGE` table that would have more than this number of rows.
- The `MERGE` storage engine does not support `INSERT DELAYED` statements.
- Using different underlying row formats in `MyISAM` tables with a parent `MERGE` table is currently known to fail. See [Bug#32364](#).
- If a `MERGE` table cannot be opened or used because of a problem with an underlying table, `CHECK TABLE` displays information about which table caused the problem.
- You cannot change the union list of a non-temporary `MERGE` table when `LOCK TABLES` is in effect. The following does *not* work:

```
CREATE TABLE m1 ... ENGINE=MRG_MYISAM ...;
LOCK TABLES t1 WRITE, t2 WRITE, m1 WRITE;
ALTER TABLE m1 ... UNION=(t1,t2) ...;
```

However, you can do this with a temporary `MERGE` table.

- You cannot create a `MERGE` table with `CREATE ... SELECT`, neither as a temporary `MERGE` table, nor as a non-temporary `MERGE` table. For example:

```
CREATE TABLE m1 ... ENGINE=MRG_MYISAM ... SELECT ...;
```

Gives error message: table is not `BASE TABLE`.

13.9. The `MEMORY (HEAP)` Storage Engine

The `MEMORY` storage engine creates tables with contents that are stored in memory. Formerly, these were known as `HEAP` tables. `MEMORY` is the preferred term, although `HEAP` remains supported for backward compatibility.

Table 13.13. Memory Features

Storage limits	RAM	Transactions	No	Locking granularity	Table
MVCC	No	Geospatial datatype support	No	Geospatial indexing support	No
B-tree indexes	Yes	Hash indexes	Yes	Full-text search indexes	No
Clustered indexes	No	Data caches	N/A	Index caches	N/A
Compressed data	No	Encrypted data ^a	Yes	Cluster database support	No
Replication support ^b	Yes	Foreign key support	No	Backup / point-in-time recovery ^c	Yes
Query cache support	Yes	Update statistics for data dictionary	Yes		

^aImplemented in the server (via encryption functions), rather than in the storage engine.

^bImplemented in the server, rather than in the storage engine

^cImplemented in the server, rather than in the storage engine

Each `MEMORY` table is associated with one disk file. The file name begins with the table name and has an extension of `.frm` to indicate that it stores the table definition.

To specify explicitly that you want to create a `MEMORY` table, indicate that with an `ENGINE` table option:

```
CREATE TABLE t (i INT) ENGINE = MEMORY;
```

As indicated by the name, `MEMORY` tables are stored in memory. They use hash indexes by default, which makes them very fast, and very useful for creating temporary tables. However, when the server shuts down, all rows stored in `MEMORY` tables are lost. The tables themselves continue to exist because their definitions are stored in `.frm` files on disk, but they are empty when the server restarts.

This example shows how you might create, use, and remove a `MEMORY` table:

```
mysql> CREATE TABLE test ENGINE=MEMORY
-> SELECT ip,SUM(downloads) AS down
-> FROM log_table GROUP BY ip;
mysql> SELECT COUNT(ip),AVG(down) FROM test;
mysql> DROP TABLE test;
```

`MEMORY` tables have the following characteristics:

- Space for `MEMORY` tables is allocated in small blocks. Tables use 100% dynamic hashing for inserts. No overflow area or extra key space is needed. No extra space is needed for free lists. Deleted rows are put in a linked list and are reused when you insert new data into the table. `MEMORY` tables also have none of the problems commonly associated with deletes plus inserts in hashed tables.
- `MEMORY` tables can have up to 32 indexes per table, 16 columns per index and a maximum key length of 500 bytes.
- The `MEMORY` storage engine implements both `HASH` and `BTREE` indexes. You can specify one or the other for a given index by adding a `USING` clause as shown here:

```
CREATE TABLE lookup
(id INT, INDEX USING HASH (id))
ENGINE = MEMORY;
CREATE TABLE lookup
```

```
(id INT, INDEX USING BTREE (id))
ENGINE = MEMORY;
```

General characteristics of B-tree and hash indexes are described in [Section 7.4.4, “How MySQL Uses Indexes”](#).

- You can have non-unique keys in a `MEMORY` table. (This is an uncommon feature for implementations of hash indexes.)
- If you have a hash index on a `MEMORY` table that has a high degree of key duplication (many index entries containing the same value), updates to the table that affect key values and all deletes are significantly slower. The degree of this slowdown is proportional to the degree of duplication (or, inversely proportional to the index cardinality). You can use a `BTREE` index to avoid this problem.
- Columns that are indexed can contain `NULL` values.
- `MEMORY` tables use a fixed-length row storage format.
- `MEMORY` tables cannot contain `BLOB` or `TEXT` columns.
- `MEMORY` includes support for `AUTO_INCREMENT` columns.
- You can use `INSERT DELAYED` with `MEMORY` tables. See [Section 12.2.5.2, “INSERT DELAYED Syntax”](#).
- `MEMORY` tables are shared among all clients (just like any other non-`TEMPORARY` table).
- `MEMORY` table contents are stored in memory, which is a property that `MEMORY` tables share with internal tables that the server creates on the fly while processing queries. However, the two types of tables differ in that `MEMORY` tables are not subject to storage conversion, whereas internal tables are:
 - If an internal table becomes too large, the server automatically converts it to an on-disk table. The size limit is determined by the value of the `tmp_table_size` system variable.
 - `MEMORY` tables are never converted to disk tables.
 - The maximum size of `MEMORY` tables is limited by the `max_heap_table_size` system variable, which has a default value of 16MB. To have larger (or smaller) `MEMORY` tables, you must change the value of this variable. The value in effect at the time a `MEMORY` table is created is the value used for the life of the table. (If you use `ALTER TABLE` or `TRUNCATE TABLE`, the value in effect at that time becomes the new maximum size for the table. A server restart also sets the maximum size of existing `MEMORY` tables to the global `max_heap_table_size` value.) You can set the size for individual tables as described later in this section.
- The server needs sufficient memory to maintain all `MEMORY` tables that are in use at the same time.
- Memory used by a `MEMORY` table is not reclaimed if you delete individual rows from the table. Memory is only reclaimed when the entire table is deleted. Memory that was previously used for rows that have been deleted will be re-used for new rows only within the same table. To free up the memory used by rows that have been deleted you should use `ALTER TABLE ENGINE=MEMORY` to force a table rebuild.

To free all the memory used by a `MEMORY` table when you no longer require its contents, you should execute `DELETE` or `TRUNCATE TABLE`, or remove the table altogether using `DROP TABLE`.

- If you want to populate a `MEMORY` table when the MySQL server starts, you can use the `--init-file` option. For example, you can put statements such as `INSERT INTO ... SELECT` or `LOAD DATA INFILE` into this file to load the table from a persistent data source. See [Section 5.1.2, “Server Command Options”](#), and [Section 12.2.6, “LOAD DATA INFILE Syntax”](#).
- If you are using replication, the master server's `MEMORY` tables become empty when it is shut down and restarted. However, a slave is not aware that these tables have become empty, so it returns out-of-date content if you select data from them. When a `MEMORY` table is used on the master for the first time since the master was started, a `DELETE` statement is written to the master's binary log automatically, thus synchronizing the slave to the master again. Note that even with this strategy, the slave still has outdated data in the table during the interval between the master's restart and its first use of the table. However, if you use the `--init-file` option to populate the `MEMORY` table on the master at startup, it ensures that this time interval is zero.
- The memory needed for one row in a `MEMORY` table is calculated using the following expression:

```
SUM_OVER_ALL_BTREE_KEYS(max_length_of_key + sizeof(char*) × 4)
+ SUM_OVER_ALL_HASH_KEYS(sizeof(char*) × 2)
+ ALIGN(length_of_row+1, sizeof(char*))
```

`ALIGN()` represents a round-up factor to cause the row length to be an exact multiple of the `char` pointer size. `sizeof(char*)` is 4 on 32-bit machines and 8 on 64-bit machines.

As mentioned earlier, the `max_heap_table_size` system variable sets the limit on the maximum size of `MEMORY` tables. To control the maximum size for individual tables, set the session value of this variable before creating each table. (Do not change the global `max_heap_table_size` value unless you intend the value to be used for `MEMORY` tables created by all clients.) The following example creates two `MEMORY` tables, with a maximum size of 1MB and 2MB, respectively:

```
mysql> SET max_heap_table_size = 1024*1024;
Query OK, 0 rows affected (0.00 sec)

mysql> CREATE TABLE t1 (id INT, UNIQUE(id)) ENGINE = MEMORY;
Query OK, 0 rows affected (0.01 sec)

mysql> SET max_heap_table_size = 1024*1024*2;
Query OK, 0 rows affected (0.00 sec)

mysql> CREATE TABLE t2 (id INT, UNIQUE(id)) ENGINE = MEMORY;
Query OK, 0 rows affected (0.00 sec)
```

Both tables will revert to the server's global `max_heap_table_size` value if the server restarts.

You can also specify a `MAX_ROWS` table option in `CREATE TABLE` statements for `MEMORY` tables to provide a hint about the number of rows you plan to store in them. This does not allow the table to grow beyond the `max_heap_table_size` value, which still acts as a constraint on maximum table size. For maximum flexibility in being able to use `MAX_ROWS`, set `max_heap_table_size` at least as high as the value to which you want each `MEMORY` table to be able to grow.

Additional resources

- A forum dedicated to the `MEMORY` storage engine is available at <http://forums.mysql.com/list.php?92>.

13.10. The `EXAMPLE` Storage Engine

The `EXAMPLE` storage engine is a stub engine that does nothing. Its purpose is to serve as an example in the MySQL source code that illustrates how to begin writing new storage engines. As such, it is primarily of interest to developers.

To enable the `EXAMPLE` storage engine if you build MySQL from source, invoke `configure` with the `--with-example-storage-engine` option.

To examine the source for the `EXAMPLE` engine, look in the `storage/example` directory of a MySQL source distribution.

When you create an `EXAMPLE` table, the server creates a table format file in the database directory. The file begins with the table name and has an `.frm` extension. No other files are created. No data can be stored into the table. Retrievals return an empty result.

```
mysql> CREATE TABLE test (i INT) ENGINE = EXAMPLE;
Query OK, 0 rows affected (0.78 sec)

mysql> INSERT INTO test VALUES(1),(2),(3);
ERROR 1031 (HY000): Table storage engine for 'test' doesn't >
      have this option

mysql> SELECT * FROM test;
Empty set (0.31 sec)
```

The `EXAMPLE` storage engine does not support indexing.

13.11. The `FEDERATED` Storage Engine

The `FEDERATED` storage engine enables data to be accessed from a remote MySQL database on a local server without using replication or cluster technology. When using a `FEDERATED` table, queries on the local server are automatically executed on the remote (federated) tables. No data is stored on the local tables.

To include the `FEDERATED` storage engine if you build MySQL from source, invoke `configure` with the `--with-federated-storage-engine` option.

The `FEDERATED` storage engine is not enabled by default in the running server; to enable `FEDERATED`, you must start the MySQL server binary using the `--federated` option.

To examine the source for the `FEDERATED` engine, look in the `storage/federated` directory of a MySQL source distribution.

MySQL Enterprise

MySQL Enterprise subscribers will find MySQL Knowledge Base articles about the `FEDERATED` storage engine at [FEDERATED Storage Engine](#). Access to the Knowledge Base collection of articles is one of the ad-

vantages of subscribing to MySQL Enterprise. For more information, see <http://www.mysql.com/products/enterprise/advisors.html>.

13.11.1. FEDERATED Storage Engine Overview

When you create a table using one of the standard storage engines (such as `MyISAM`, `CSV` or `InnoDB`), the table consists of the table definition and the associated data. When you create a `FEDERATED` table, the table definition is the same, but the physical storage of the data is handled on a remote server.

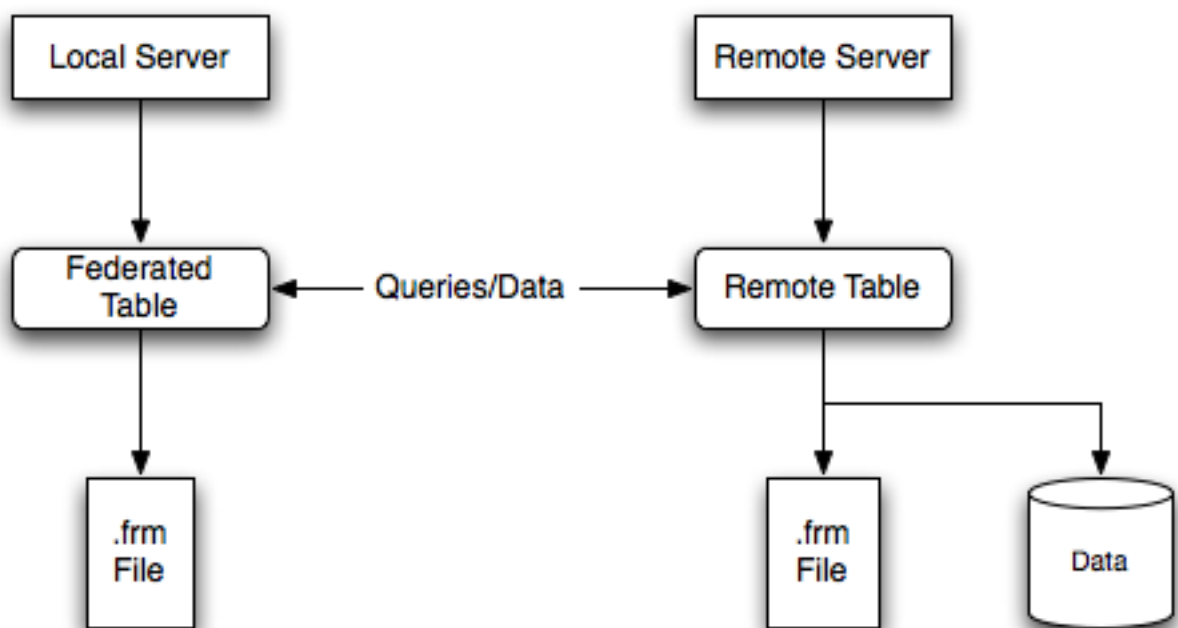

A `FEDERATED` table consists of two elements:

- A *remote server* with a database table, which in turn consists of the table definition (stored in the `.frm` file) and the associated table. The table type of the remote table may be any type supported by the remote `mysqld` server, including `MyISAM` or `InnoDB`.
- A *local server* with a database table, where the table definition matches that of the corresponding table on the remote server. The table definition is stored within the `.frm` file. However, there is no data file on the local server. Instead, the table definition includes a connection string that points to the remote table.

When executing queries and statements on a `FEDERATED` table on the local server, the operations that would normally insert, update or delete information from a local data file are instead sent to the remote server for execution, where they update the data file on the remote server or return matching rows from the remote server.

The basic structure of a `FEDERATED` table setup is shown in [Figure 13.2, “FEDERATED table structure”](#).

Figure 13.2. FEDERATED table structure

When a client issues an SQL statement that refers to a `FEDERATED` table, the flow of information between the local server (where the SQL statement is executed) and the remote server (where the data is physically stored) is as follows:

1. The storage engine looks through each column that the `FEDERATED` table has and constructs an appropriate SQL statement that refers to the remote table.
2. The statement is sent to the remote server using the MySQL client API.
3. The remote server processes the statement and the local server retrieves any result that the statement produces (an affected-rows count or a result set).

4. If the statement produces a result set, each column is converted to internal storage engine format that the **FEDERATED** engine expects and can use to display the result to the client that issued the original statement.

The local server communicates with the remote server using MySQL client C API functions. It invokes `mysql_real_query()` to send the statement. To read a result set, it uses `mysql_store_result()` and fetches rows one at a time using `mysql_fetch_row()`.

13.11.2. How to Create **FEDERATED** Tables

To create a **FEDERATED** table you should follow these steps:

1. Create the table on the remote server. Alternatively, make a note of the table definition of an existing table, perhaps using the `SHOW CREATE TABLE` statement.
2. Create the table on the local server with an identical table definition, but adding the connection information that links the local table to the remote table.

For example, you could create the following table on the remote server:

```
CREATE TABLE test_table (
  id      INT(20) NOT NULL AUTO_INCREMENT,
  name    VARCHAR(32) NOT NULL DEFAULT '',
  other   INT(20) NOT NULL DEFAULT '0',
  PRIMARY KEY (id),
  INDEX name (name),
  INDEX other_key (other)
)
ENGINE=MyISAM
DEFAULT CHARSET=latin1;
```

To create the local table that will be federated to the remote table, there are two options available. You can either create the local table and specify the connection string (containing the server name, login, password) to be used to connect to the remote table using the **CONNECTION**, or you can use an existing connection that you have previously created using the **CREATE SERVER** statement.

Important

When you create the local table it *must* have an identical field definition to the remote table.

Note

You can improve the performance of a **FEDERATED** table by adding indexes to the table on the host, even though the tables will not actually be created locally. The optimization will occur because the query sent to the remote server will include the contents of the **WHERE** clause will be sent to the remote server and executed locally. This reduces the network traffic that would otherwise request the entire table from the server for local processing.

13.11.2.1. Creating a **FEDERATED** Table Using **CONNECTION**

To use the first method, you must specify the **CONNECTION** string after the engine type in a `CREATE TABLE` statement. For example:

```
CREATE TABLE federated_table (
  id      INT(20) NOT NULL AUTO_INCREMENT,
  name    VARCHAR(32) NOT NULL DEFAULT '',
  other   INT(20) NOT NULL DEFAULT '0',
  PRIMARY KEY (id),
  INDEX name (name),
  INDEX other_key (other)
)
ENGINE=FEDERATED
DEFAULT CHARSET=latin1
CONNECTION='mysql://fed_user@remote_host:9306/federated/test_table';
```

Note

CONNECTION replaces the **COMMENT** used in some previous versions of MySQL.

The **CONNECTION** string contains the information required to connect to the remote server containing the table that will be used to physically store the data. The connection string specifies the server name, login credentials, port number and database/table information. In the example, the remote table is on the server `remote_host`, using port 9306. The name and port number should match the host name (or IP address) and port number of the remote MySQL server instance you want to use as your remote table.

The format the connection string is as follows:

```
scheme://user_name[:password]@host_name[:port_num]/db_name/tbl_name
```

Where:

- *scheme* — is a recognized connection protocol. Only `mysql` is supported as the *scheme* value at this point.
- *user_name* — the user name for the connection. This user must have been created on the remote server, and must have suitable privileges to perform the required actions (`SELECT`, `INSERT`, `UPDATE`, and so forth) on the remote table.
- *password* — (optional) the corresponding password for *user_name*.
- *host_name* — the host name or IP address of the remote server.
- *port_num* — (optional) the port number for the remote server. The default is 3306.
- *db_name* — the name of the database holding the remote table.
- *tbl_name* — the name of the remote table. The name of the local and the remote table do not have to match.

Sample connection strings:

```
CONNECTION='mysql://username:password@hostname:port/database/tablename'
CONNECTION='mysql://username@hostname/database/tablename'
CONNECTION='mysql://username:password@hostname/database/tablename'
```

13.11.2.2. Creating a **FEDERATED** Table Using **CREATE SERVER**

If you are creating a number of **FEDERATED** tables on the same server, or if you want to simplify the process of creating **FEDERATED** tables, you can use the **CREATE SERVER** statement to define the server connection parameters, just as you would with the **CONNECTION** string.

The format of the **CREATE SERVER** statement is:

```
CREATE SERVER
server_name
FOREIGN DATA WRAPPER wrapper_name
OPTIONS (option [, option] ...)
```

The *server_name* is used in the connection string when creating a new **FEDERATED** table.

For example, to create a server connection identical to the **CONNECTION** string:

```
CONNECTION='mysql://fed_user@remote_host:9306/federated/test_table';
```

You would use the following statement:

```
CREATE SERVER fedlink
FOREIGN DATA WRAPPER mysql
OPTIONS (USER 'fed_user', HOST 'remote_host', PORT 9306, DATABASE 'federated');
```

To create a **FEDERATED** table that uses this connection, you still use the **CONNECTION** keyword, but specify the name you used in the **CREATE SERVER** statement.

```
CREATE TABLE test_table (
  id      INT(20) NOT NULL AUTO_INCREMENT,
  name    VARCHAR(32) NOT NULL DEFAULT '',
  other   INT(20) NOT NULL DEFAULT '0',
  PRIMARY KEY (id),
  INDEX name (name),
  INDEX other_key (other)
)
ENGINE=FEDERATED
DEFAULT CHARSET=latin1
CONNECTION='fedlink/test_table';
```

The connection name in this example contains the name of the connection (`fedlink`) and the name of the table (`test_table`) to link to, separated by a slash. If you specify only the connection name without a table name, the table name of the local table is used instead.

For more information on `CREATE SERVER`, see [Section 12.1.13, “CREATE SERVER Syntax”](#).

The `CREATE SERVER` statement accepts the same arguments as the `CONNECTION` string. The `CREATE SERVER` statement updates the rows in the `mysql.servers` table. See the following table for information on the correspondence between parameters in a connection string, options in the `CREATE SERVER` statement, and the columns in the `mysql.servers` table. For reference, the format of the `CONNECTION` string is as follows:

```
scheme://user_name[:password]@host_name[:port_num]/db_name/tbl_name
```

Description	CONNECTION string	CREATE SERVER option	mysql.servers column
Connection scheme	<i>scheme</i>	<code>wrapper_name</code>	<code>Wrapper</code>
Remote user	<i>user_name</i>	<code>USER</code>	<code>Username</code>
Remote password	<i>password</i>	<code>PASSWORD</code>	<code>Password</code>
Remote host	<i>host_name</i>	<code>HOST</code>	<code>Host</code>
Remote port	<i>port_num</i>	<code>PORT</code>	<code>Port</code>
Remote database	<i>db_name</i>	<code>DATABASE</code>	<code>Db</code>

13.11.3. FEDERATED Storage Engine Notes and Tips

You should be aware of the following points when using the `FEDERATED` storage engine:

- `FEDERATED` tables may be replicated to other slaves, but you must ensure that the slave servers are able to use the user/password combination that is defined in the `CONNECTION` string (or the row in the `mysql.servers` table) to connect to the remote server.

The following items indicate features that the `FEDERATED` storage engine does and does not support:

- The remote server must be a MySQL server. Support by `FEDERATED` for other database engines may be added in the future.
- The remote table that a `FEDERATED` table points to *must* exist before you try to access the table through the `FEDERATED` table.
- It is possible for one `FEDERATED` table to point to another, but you must be careful not to create a loop.
- A `FEDERATED` table does not support indexes per se. Because access to the table is handled remotely, it is the remote table that supports the indexes. Care should be taken when creating a `FEDERATED` table since the index definition from an equivalent `MyISAM` or other table may not be supported. For example, creating a `FEDERATED` table with an index prefix on `VARCHAR`, `TEXT` or `BLOB` columns will fail. The following definition in `MyISAM` is valid:

```
CREATE TABLE `T1`(`A` VARCHAR(100),UNIQUE KEY(`A`(30))) ENGINE=MYISAM;
```

The key prefix in this example is incompatible with the `FEDERATED` engine, and the equivalent statement will fail:

```
CREATE TABLE `T1`(`A` VARCHAR(100),UNIQUE KEY(`A`(30))) ENGINE=FEDERATED
CONNECTION='MYSQL://127.0.0.1:3306/TEST/T1';
```

If possible, you should try to separate the column and index definition when creating tables on both the remote server and the local server to avoid these index issues.

- Internally, the implementation uses `SELECT`, `INSERT`, `UPDATE`, and `DELETE`, but not `HANDLER`.
- The `FEDERATED` storage engine supports `SELECT`, `INSERT`, `UPDATE`, `DELETE`, `TRUNCATE`, and indexes. It does not support `ALTER TABLE`, or any Data Definition Language statements that directly affect the structure of the table, other than `DROP TABLE`. The current implementation does not use prepared statements.
- `FEDERATED` accepts `INSERT ... ON DUPLICATE KEY UPDATE` statements, but if a duplicate-key violation occurs, the statement fails with an error.
- Performance on a `FEDERATED` table when performing bulk inserts (for example, on a `INSERT INTO ... SELECT ...` statement) is slower than with other table types because each selected row is treated as an individual `INSERT` statement on the `FEDERATED` table.

- Transactions are not supported.
- **FEDERATED** performs bulk-insert handling such that multiple rows are sent to the remote table in a batch. This provides a performance improvement and enables the remote table to perform improvement. Also, if the remote table is transactional, it enables the remote storage engine to perform statement rollback properly should an error occur. This capability has the following limitations:
 - The size of the insert cannot exceed the maximum packet size between servers. If the insert exceeds this size, it is broken into multiple packets and the rollback problem can occur.
 - Bulk-insert handling does not occur for `INSERT ... ON DUPLICATE KEY UPDATE`.
- There is no way for the **FEDERATED** engine to know if the remote table has changed. The reason for this is that this table must work like a data file that would never be written to by anything other than the database system. The integrity of the data in the local table could be breached if there was any change to the remote database.
- When using a **CONNECTION** string, you cannot use an '@' character in the password. You can get round this limitation by using the `CREATE SERVER` statement to create a server connection.
- The `insert_id` and `timestamp` options are not propagated to the data provider.
- Any `DROP TABLE` statement issued against a **FEDERATED** table drops only the local table, not the remote table.
- **FEDERATED** tables do not work with the query cache.
- User-defined partitioning is not supported for **FEDERATED** tables.

Some of these limitations may be lifted in future versions of the **FEDERATED** handler.

13.11.4. **FEDERATED** Storage Engine Resources

The following additional resources are available for the **FEDERATED** storage engine:

- A forum dedicated to the **FEDERATED** storage engine is available at <http://forums.mysql.com/list.php?105>.

13.12. The **ARCHIVE** Storage Engine

The **ARCHIVE** storage engine is used for storing large amounts of data without indexes in a very small footprint.

Table 13.14. Archive Features

Storage limits	None	Transactions	No	Locking granularity	Row
MVCC	No	Geospatial datatype support	Yes	Geospatial indexing support	No
B-tree indexes	No	Hash indexes	No	Full-text search indexes	No
Clustered indexes	No	Data caches	No	Index caches	No
Compressed data	Yes	Encrypted data^a	Yes	Cluster database support	No
Replication support^b	Yes	Foreign key support	No	Backup / point-in-time recovery^c	Yes
Query cache support	Yes	Update statistics for data dictionary	Yes		

^aImplemented in the server (via encryption functions), rather than in the storage engine.

^bImplemented in the server, rather than in the storage engine

^cImplemented in the server, rather than in the storage engine

The **ARCHIVE** storage engine is included in MySQL binary distributions. To enable this storage engine if you build MySQL from source, invoke `configure` with the `--with-archive-storage-engine` option.

To examine the source for the **ARCHIVE** engine, look in the `storage/archive` directory of a MySQL source distribution.

You can check whether the **ARCHIVE** storage engine is available with the `SHOW ENGINES` statement.

When you create an **ARCHIVE** table, the server creates a table format file in the database directory. The file begins with the table

name and has an `.frm` extension. The storage engine creates other files, all having names beginning with the table name. The data file has an extension of `.ARZ`. An `.ARN` file may appear during optimization operations.

The `ARCHIVE` engine supports `INSERT` and `SELECT`, but not `DELETE`, `REPLACE`, or `UPDATE`. It does support `ORDER BY` operations, `BLOB` columns, and basically all but spatial data types (see [Section 11.13.4.1, “MySQL Spatial Data Types”](#)). The `ARCHIVE` engine uses row-level locking.

The `ARCHIVE` engine supports the `AUTO_INCREMENT` column attribute. The `AUTO_INCREMENT` column can have either a unique or non-unique index. Attempting to create an index on any other column results in an error. The `ARCHIVE` engine also supports the `AUTO_INCREMENT` table option in `CREATE TABLE` and `ALTER TABLE` statements to specify the initial sequence value for a new table or reset the sequence value for an existing table, respectively.

The `ARCHIVE` engine ignores `BLOB` columns if they are not requested and scans past them while reading.

Storage: Rows are compressed as they are inserted. The `ARCHIVE` engine uses `zlib` lossless data compression (see <http://www.zlib.net/>). You can use `OPTIMIZE TABLE` to analyze the table and pack it into a smaller format (for a reason to use `OPTIMIZE TABLE`, see later in this section). The engine also supports `CHECK TABLE`. There are several types of insertions that are used:

- An `INSERT` statement just pushes rows into a compression buffer, and that buffer flushes as necessary. The insertion into the buffer is protected by a lock. A `SELECT` forces a flush to occur, unless the only insertions that have come in were `INSERT DELAYED` (those flush as necessary). See [Section 12.2.5.2, “INSERT DELAYED Syntax”](#).
- A bulk insert is visible only after it completes, unless other inserts occur at the same time, in which case it can be seen partially. A `SELECT` never causes a flush of a bulk insert unless a normal insert occurs while it is loading.

Retrieval: On retrieval, rows are uncompressed on demand; there is no row cache. A `SELECT` operation performs a complete table scan: When a `SELECT` occurs, it finds out how many rows are currently available and reads that number of rows. `SELECT` is performed as a consistent read. Note that lots of `SELECT` statements during insertion can deteriorate the compression, unless only bulk or delayed inserts are used. To achieve better compression, you can use `OPTIMIZE TABLE` or `REPAIR TABLE`. The number of rows in `ARCHIVE` tables reported by `SHOW TABLE STATUS` is always accurate. See [Section 12.5.2.5, “OPTIMIZE TABLE Syntax”](#), [Section 12.5.2.6, “REPAIR TABLE Syntax”](#), and [Section 12.5.5.37, “SHOW TABLE STATUS Syntax”](#).

Additional resources

- A forum dedicated to the `ARCHIVE` storage engine is available at <http://forums.mysql.com/list.php?112>.

13.13. The `CSV` Storage Engine

The `CSV` storage engine stores data in text files using comma-separated values format.

To enable the `CSV` storage engine if you build MySQL from source, invoke `configure` with the `-with-csv-storage-engine` option.

To examine the source for the `CSV` engine, look in the `storage/csv` directory of a MySQL source distribution.

When you create a `CSV` table, the server creates a table format file in the database directory. The file begins with the table name and has an `.frm` extension. The storage engine also creates a data file. Its name begins with the table name and has a `.CSV` extension. The data file is a plain text file. When you store data into the table, the storage engine saves it into the data file in comma-separated values format.

```
mysql> CREATE TABLE test (i INT NOT NULL, c CHAR(10) NOT NULL)
-> ENGINE = CSV;
Query OK, 0 rows affected (0.12 sec)

mysql> INSERT INTO test VALUES(1,'record one'),(2,'record two');
Query OK, 2 rows affected (0.00 sec)
Records: 2 Duplicates: 0 Warnings: 0

mysql> SELECT * FROM test;
+-----+-----+
| i     | c           |
+-----+-----+
| 1     | record one  |
| 2     | record two  |
+-----+-----+
2 rows in set (0.00 sec)
```

Creating a `CSV` table also creates a corresponding Metafile that stores the state of the table and the number of rows that exist in the table. The name of this file is the same as the name of the table with the extension `CSM`.

If you examine the `test.CSV` file in the database directory created by executing the preceding statements, its contents should look like this:

```
"1","record one"
"2","record two"
```

This format can be read, and even written, by spreadsheet applications such as Microsoft Excel or StarOffice Calc.

13.13.1. Repairing and Checking CSV Tables

The CSV storage engines supports the `CHECK` and `REPAIR` commands to verify and if possible repair a damaged CSV table.

When running the `CHECK` command, the CSV file will be checked for validity by looking for the correct field separators, escaped fields (matching quotes and/or missing quotes), the correct number of fields compared to the table definition and the existence of a corresponding CSV metafile. The first invalid row discovered will report an error. Checking a valid table produces output like that shown below:

```
mysql> check table csvtest;
+-----+-----+-----+-----+
| Table      | Op    | Msg_type | Msg_text |
+-----+-----+-----+-----+
| test.csvtest | check | status   | OK       |
+-----+-----+-----+-----+
1 row in set (0.00 sec)
```

A check on a corrupted table returns a fault:

```
mysql> check table csvtest;
+-----+-----+-----+-----+
| Table      | Op    | Msg_type | Msg_text |
+-----+-----+-----+-----+
| test.csvtest | check | error    | Corrupt  |
+-----+-----+-----+-----+
1 row in set (0.01 sec)
```

If the check fails, the table is marked as crashed (corrupt). Once a table has been marked as corrupt, it is automatically repaired when you next run `CHECK` or execute a `SELECT` statement. The corresponding corrupt status and new status will be displayed when running `CHECK`:

```
mysql> check table csvtest;
+-----+-----+-----+-----+
| Table      | Op    | Msg_type | Msg_text |
+-----+-----+-----+-----+
| test.csvtest | check | warning  | Table is marked as crashed |
| test.csvtest | check | status   | OK       |
+-----+-----+-----+-----+
2 rows in set (0.08 sec)
```

To repair a table you can use `REPAIR`, this copies as many valid rows from the existing CSV data as possible, and then replaces the existing CSV file with the recovered rows. Any rows beyond the corrupted data are lost.

```
mysql> repair table csvtest;
+-----+-----+-----+-----+
| Table      | Op    | Msg_type | Msg_text |
+-----+-----+-----+-----+
| test.csvtest | repair | status   | OK       |
+-----+-----+-----+-----+
1 row in set (0.02 sec)
```

Warning

Note that during repair, only the rows from the CSV file up to the first damaged row are copied to the new table. All other rows from the first damaged row to the end of the table are removed, even valid rows.

13.13.2. CSV Limitations

Important

The `CSV` storage engine does not support indexing.

Partitioning is not supported for tables using the `CSV` storage engine.

Tables using the `CSV` storage engine cannot be created with `NULL` columns. However, for backward compatibility, you can continue to use such tables that were created in previous MySQL releases. ([Bug#32050](#))

13.14. The **BLACKHOLE** Storage Engine

The **BLACKHOLE** storage engine acts as a “black hole” that accepts data but throws it away and does not store it. Retrievals always return an empty result:

```
mysql> CREATE TABLE test(i INT, c CHAR(10)) ENGINE = BLACKHOLE;
Query OK, 0 rows affected (0.03 sec)

mysql> INSERT INTO test VALUES(1,'record one'),(2,'record two');
Query OK, 2 rows affected (0.00 sec)
Records: 2 Duplicates: 0 Warnings: 0

mysql> SELECT * FROM test;
Empty set (0.00 sec)
```

To enable the **BLACKHOLE** storage engine if you build MySQL from source, invoke `configure` with the `--with-blackhole-storage-engine` option.

To examine the source for the **BLACKHOLE** engine, look in the `sql` directory of a MySQL source distribution.

When you create a **BLACKHOLE** table, the server creates a table format file in the database directory. The file begins with the table name and has an `.frm` extension. There are no other files associated with the table.

The **BLACKHOLE** storage engine supports all kinds of indexes. That is, you can include index declarations in the table definition.

You can check whether the **BLACKHOLE** storage engine is available with the `SHOW ENGINES` statement.

Inserts into a **BLACKHOLE** table do not store any data, but if the binary log is enabled, the SQL statements are logged (and replicated to slave servers). This can be useful as a repeater or filter mechanism. For example, suppose that your application requires slave-side filtering rules, but transferring all binary log data to the slave first results in too much traffic. In such a case, it is possible to set up on the master host a “dummy” slave process whose default storage engine is **BLACKHOLE**, depicted as follows:

The master writes to its binary log. The “dummy” `mysqld` process acts as a slave, applying the desired combination of `replicate-do-*` and `replicate-ignore-*` rules, and writes a new, filtered binary log of its own. (See [Section 16.1.3, “Replication and Binary Logging Options and Variables”](#).) This filtered log is provided to the slave.

The dummy process does not actually store any data, so there is little processing overhead incurred by running the additional `mysqld` process on the replication master host. This type of setup can be repeated with additional replication slaves.

`INSERT` triggers for **BLACKHOLE** tables work as expected. However, because the **BLACKHOLE** table does not actually store any data, `UPDATE` and `DELETE` triggers are not activated: The `FOR EACH ROW` clause in the trigger definition does not apply because there are no rows.

Other possible uses for the **BLACKHOLE** storage engine include:

- Verification of dump file syntax.
- Measurement of the overhead from binary logging, by comparing performance using **BLACKHOLE** with and without binary

logging enabled.

- **BLACKHOLE** is essentially a “no-op” storage engine, so it could be used for finding performance bottlenecks not related to the storage engine itself.

The **BLACKHOLE** engine is transaction-aware, in the sense that committed transactions are written to the binary log and rolled-back transactions are not.

Chapter 14. High Availability and Scalability

When using MySQL you may need to ensure the availability or scalability of your MySQL installation. Availability refers to the ability to cope with, and if necessary recover from, failures on the host, including failures of MySQL, the operating system, or the hardware. Scalability refers to the ability to spread the load of your application queries across multiple MySQL servers. As your application and usage increases, you may need to spread the queries for the application across multiple servers to improve response times.

There are a number of solutions available for solving issues of availability and scalability. The two primary solutions supported by MySQL are MySQL Replication and MySQL Cluster. Further options are available using third-party solutions such as DRBD (Distributed Replicated Block Device) and Heartbeat, and more complex scenarios can be solved through a combination of these technologies. These tools work in different ways:

- *MySQL Replication* enables statements and data from one MySQL server instance to be replicated to another MySQL server instance. Without using more complex setups, data can only be replicated from a single master server to any number of slaves. The replication is asynchronous, so the synchronization does not take place in real time, and there is no guarantee that data from the master will have been replicated to the slaves.
 - **Advantages**
 - MySQL Replication is available on all platforms supported by MySQL, and since it isn't operating system-specific it can operate across different platforms.
 - Replication is asynchronous and can be stopped and restarted at any time, making it suitable for replicating over slower links, partial links and even across geographical boundaries.
 - Data can be replicated from one master to any number of slaves, making replication suitable in environments with heavy reads, but light writes (for example, many web applications), by spreading the load across multiple slaves.
 - **Disadvantages**
 - Data can only be written to the master. In advanced configurations, though, you can set up a multiple-master configuration where the data is replicated around a ring configuration.
 - There is no guarantee that data on master and slaves will be consistent at a given point in time. Because replication is asynchronous there may be a small delay between data being written to the master and it being available on the slaves. This can cause problems in applications where a write to the master must be available for a read on the slaves (for example a web application).
 - **Recommended uses**
 - Scale-out solutions that require a large number of reads but fewer writes (for example, web serving).
 - Logging/data analysis of live data. By replicating live data to a slave you can perform queries on the slave without affecting the operation of the master.
 - Online backup (availability), where you need an active copy of the data available. You need to combine this with other tools, such as custom scripts or Heartbeat. However, because of the asynchronous architecture, the data may be incomplete.
 - Offline backup. You can use replication to keep a copy of the data. By replicating the data to a slave, you take the slave down and get a reliable snapshot of the data (without MySQL running), then restart MySQL and replication to catch up. The master (and any other slaves) can be kept running during this period.

For information on setting up and configuring replication, see [Chapter 16, Replication](#).

- *MySQL Cluster* is a synchronous solution that enables multiple MySQL instances to share database information. Unlike replication, data in a cluster can be read from or written to any node within the cluster, and information will be distributed to the other nodes.
 - **Advantages**
 - Offers multiple read and write nodes for data storage.
 - Provides automatic failover between nodes. Only transaction information for the active node being used is lost in the event of a failure.
 - Data on nodes is instantaneously distributed to the other data nodes.

- **Disadvantages**

- Available on a limited range of platforms.
- Nodes within a cluster should be connected via a LAN; geographically separate nodes are not supported. However, you can replicate from one cluster to another using MySQL Replication, although the replication in this case is still asynchronous.

- **Recommended uses**

- Applications that need very high availability, such as telecoms and banking.
- Applications that require an equal or higher number of writes compared to reads.

For information on MySQL Cluster, see [MySQL Cluster NDB 6.X/7.X](#).

- *DRBD (Distributed Replicated Block Device)* is a solution from Linbit supported only on Linux. DRBD creates a virtual block device (which is associated with an underlying physical block device) that can be replicated from the primary server to a secondary server. You create a file system on the virtual block device, and this information is then replicated, at the block level, to the secondary server.

Because the block device, not the data you are storing on it, is being replicated the validity of the information is more reliable than with data-only replication solutions. DRBD can also ensure data integrity by only returning from a write operation on the primary server when the data has been written to the underlying physical block device on both the primary and secondary servers.

- **Advantages**

- Provides high availability and data integrity across two servers in the event of hardware or system failure.
- Can ensure data integrity by enforcing write consistency on the primary and secondary nodes.

- **Disadvantages**

- Only provides a method for duplicating data across the nodes. Secondary nodes cannot use the DRBD device while data is being replicated, and so the MySQL on the secondary node cannot be simultaneously active.
- Can not be used to scale performance, since you can not redirect reads to the secondary node.

- **Recommended uses**

- High availability situations where concurrent access to the data is not required, but instant access to the active data in the event of a system or hardware failure is required.

For information on configuring DRBD and configuring MySQL for use with a DRBD device, see [Section 14.1, “Using MySQL with DRBD”](#).

- *memcached* is a simple, yet highly-scalable key-based cache that stores data and objects wherever dedicated or spare RAM is available for very quick access by applications. You use *memcached* in combination with your application and MySQL to reduce the number of reads from the database.

When writing your application, you first try to load the data from the *memcached* cache, if the data you are looking for cannot be found, you then load the data from the MySQL database as normal, and populate the cache with the information that you loaded. Because *memcached* can be used to store entire objects that might normally consist of multiple table lookups and aggregations, you can significantly increase the speed of your application because the requirement to load data directly from the database is reduced or even eliminated. Because the cache is entirely in RAM, the response time is very fast, and the information can be distributed among many servers to make the best use of any spare RAM capacity.

- **Advantages**

- Very fast, RAM based, cache.
- Reduces load on the MySQL server, allowing MySQL to concentrate on persistent storage and data writes.
- Highly distributable and scalable, allowing multiple servers to be part of the cache group.
- Highly portable - the *memcached* interface is supported by many languages and systems, including Perl, Python, PHP, Ruby, Java and the MySQL server.

- **Disadvantages**

- Data is not persistent - you should only use the cache to store information that can otherwise be loaded from a MySQL database.
- Fault tolerance is implied, rather than explicit. If a [memcached](#) node fails then your application must be capable of loading the data from MySQL and updating the cache.
- **Recommended uses**
 - High scalability situations where you have a very high number of reads, particularly of complex data objects that can easily be cached in the final, usable, form directly within the cache.

For information on installing, configuring and using [memcached](#), including using the many APIs available for communicating with [memcached](#), see [Section 14.5, “Using MySQL with memcached”](#).

- *Heartbeat* is a software solution for Linux. It is not a data replication or synchronization solution, but a solution for monitoring servers and switching active MySQL servers automatically in the event of failure. Heartbeat needs to be combined with MySQL Replication or DRBD to provide automatic failover.

For more information on configuring Heartbeat for use with MySQL and DRBD, see [Section 14.2, “Using Linux HA Heartbeat”](#).

The information and suitability of the various technologies and different scenarios is summarized in the following table.

Requirements	MySQL Replication	MySQL Replication + Heartbeat	MySQL Heartbeat + DRBD	MySQL Cluster	MySQL + memcached
Availability					
Automated IP failover	No	Yes	Yes	No	No
Automated database failover	No	No	Yes	Yes	No
Typical failover time	User/ script-dependent	Varies	< 30 seconds	< 3 seconds	App dependent
Automatic resynchronization of data	No	No	Yes	Yes	No
Geographic redundancy support	Yes	Yes	Yes, when combined with MySQL Replication	Yes, when combined with MySQL Replication	No
Scalability					
Built-in load balancing	No	No	No	Yes	Yes
Supports Read-intensive applications	Yes	Yes	Yes, when combined with MySQL Replication	Yes	Yes
Supports Write-intensive applications	No	No	Yes	Yes	No
Maximum number of nodes per group	One master, multiple slaves	One master, multiple slaves	One active (primary), one passive (secondary) node	255	Unlimited
Maximum number of slaves	Unlimited (reads only)	Unlimited (reads only)	One (failover only)	Unlimited (reads only)	Unlimited

14.1. Using MySQL with DRBD

The Distributed Replicated Block Device (DRBD) is a Linux Kernel module that constitutes a distributed storage system. You can use DRBD to share block devices between Linux servers and, in turn, share file systems and data.

DRBD implements a block device which can be used for storage and which is replicated from a primary server to one or more secondary servers. The distributed block device is handled by the DRBD service. Writes to the DRBD block device are distributed among the servers. Each DRBD service writes the information from the DRBD block device to a local physical block device (hard disk).

On the primary data writes are written both to the underlying physical block device and distributed to the secondary DRBD services. On the secondary, the writes received through DRBD and written to the local physical block device. On both the primary and the secondary, reads from the DRBD block device are handled by the underlying physical block device. The information is shared between the primary DRBD server and the secondary DRBD server synchronously and at a block level, and this means that DRBD can be used in high-availability solutions where you need failover support.

Figure 14.1. DRBD Architecture Overview

When used with MySQL, DRBD can be used to ensure availability in the event of a failure. MySQL is configured to store information on the DRBD block device, with one server acting as the primary and a second machine available to operate as an immediate replacement in the event of a failure.

For automatic failover support you can combine DRBD with the Linux Heartbeat project, which will manage the interfaces on the two servers and automatically configure the secondary (passive) server to replace the primary (active) server in the event of a failure. You can also combine DRBD with MySQL Replication to provide both failover and scalability within your MySQL environment.

For information on how to configure DRBD and MySQL, including Heartbeat support, see [Section 14.1.1, “Configuring the DRBD Environment”](#).

An FAQ for using DRBD and MySQL is available. See [Section A.14, “MySQL 5.4 FAQ — MySQL, DRBD, and Heartbeat”](#).

Note

Because DRBD is a Linux Kernel module it is currently not supported on platforms other than Linux.

14.1.1. Configuring the DRBD Environment

To set up DRBD, MySQL and Heartbeat you need to follow a number of steps that affect the operating system, DRBD and your MySQL installation.

Before starting the installation process, you should be aware of the following information, terms and requirements on using DRBD:

- DRBD is a solution for enabling high-availability, and therefore you need to ensure that the two machines within your DRBD setup are as identically configured as possible so that the secondary machine can act as a direct replacement for the primary machine in the event of system failure.
- DRBD works through two (or more) servers, each called a *node*
- The node that contains the primary data, has read/write access to the data, and in an HA environment is the currently active node is called the *primary*.
- The server to which the data is replicated is referred as *secondary*.

- A collection of nodes that are sharing information are referred to as a *DRBD cluster*.
- For DRBD to operate you must have a block device on which the information can be stored on *each* DRBD node. The *lower level* block device can be a physical disk partition, a partition from a volume group or RAID device or any other block device.

Typically you use a spare partition on which the physical data will be stored. On the primary node, this disk will hold the raw data that you want replicated. On the secondary nodes, the disk will hold the data replicated to the secondary server by the DRBD service. Ideally, the size of the partition on the two DRBD servers should be identical, but this is not necessary as long as there is enough space to hold the data that you want distributed between the two servers.

- For the distribution of data to work, DRBD is used to create a logical block device that uses the lower level block device for the actual storage of information. To store information on the distributed device, a file system is created on the DRBD logical block device.
- When used with MySQL, once the file system has been created, you move the MySQL data directory (including InnoDB data files and binary logs) to the new file system.
- When you set up the secondary DRBD server, you set up the physical block device and the DRBD logical block device that will store the data. The block device data is then copied from the primary to the secondary server.

The overview for the installation and configuration sequence is as follows:

1. First you need to set up your operating system and environment. This includes setting the correct host name, updating the system and preparing the available packages and software required by DRBD, and configuring a physical block device to be used with the DRBD block device. See [Section 14.1.1.1, “Setting Up Your Operating System for DRBD”](#).
2. Installing DRBD requires installing or compiling the DRBD source code and then configuring the DRBD service to set up the block devices that will be shared. See [Section 14.1.1.2, “Installing and Configuring DRBD”](#).
3. Once DRBD has been configured, you must alter the configuration and storage location of the MySQL data. See [Section 14.1.2, “Configuring MySQL for DRBD”](#).

You may optionally want to configure high availability using the Linux Heartbeat service. See [Section 14.2, “Using Linux HA Heartbeat”](#), for more information.

14.1.1.1. Setting Up Your Operating System for DRBD

To set your Linux environment for using DRBD there are a number of system configuration steps that you must follow.

- Make sure that the primary and secondary DRBD servers have the correct host name, and that the host names are unique. You can verify this by using the `uname` command:

```
shell> uname -n
drbd-one
```

If the host name is not set correctly, edit the appropriate file (usually `/etc/sysconfig/network`, `/etc/hostname`, or `/etc/conf.d/hostname`) and set the name correctly.

- Each DRBD node must have a unique IP address. Make sure that the IP address information is set correctly within the network configuration and that the host name and IP address has been set correctly within the `/etc/hosts` file.
- Although you can rely on the DNS or NIS system for host resolving, in the event of a major network failure these services may not be available. If possible, add the IP address and host name of each DRBD node into the `/etc/hosts` file for each machine. This will ensure that the node information can always be determined even if the DNS/NIS servers are unavailable.
- As a general rule, the faster your network connection the better. Because the block device data is exchanged over the network, everything that will be written to the local disk on the DRBD primary will also be written to the network for distribution to the DRBD secondary.

For tips on configuring a faster network connection see [Section 14.1.3, “Optimizing Performance and Reliability”](#).

- You must have a spare disk or disk partition that you can use as the physical storage location for the DRBD data that will be replicated. You do not have to have a complete disk available, a partition on an existing disk is acceptable.

If the disk is unpartitioned, partition the disk using `fdisk`, `cfdisk` or other partitioning solution. Do not create a file system on the new partition.

Remember that you must have a physical disk available for the storage of the replicated information on each DRBD node. Ideally the partitions that will be used on each node should be of an identical size, although this is not strictly necessary. Do, however, ensure that the physical partition on the DRBD secondary is at least as big as the partitions on the DRBD primary node.

- If possible, upgrade your system to the latest available Linux kernel for your distribution. Once the kernel has been installed, you must reboot to make the kernel active. To use DRBD you will also need to install the relevant kernel development and header files that are required for building kernel modules. Platform specification information for this is available later in this section.

Before you compile or install DRBD, you must make sure the following tools and files are in place:

- Kernel header files
- Kernel source files
- GCC Compiler
- `glib 2`
- `flex`

Here are some operating system specific tips for setting up your installation:

- **Tips for Red Hat (including CentOS and Fedora):**

Use `up2date` or `yum` to update and install the latest kernel and kernel header files:

```
root-shell> up2date kernel-smp-devel kernel-smp
```

Reboot. If you are going to build DRBD from source, then update your system with the required development packages:

```
root-shell> up2date glib-devel openssl-devel libgcrypt-devel glib2-devel \  
pkgconfig ncurses-devel rpm-build rpm-devel redhat-rpm-config gcc \  
gcc-c++ bison flex gnutls-devel lm_sensors-devel net-snmp-devel \  
python-devel bzip2-devel libselinux-devel perl-DBI
```

If you are going to use the pre-built DRBD RPMs:

```
root-shell> up2date gnutls lm_sensors net-snmp ncurses libgcrypt glib2 openssl glib
```

- **Tips for Debian, Ubuntu, Kubuntu:**

Use `apt-get` to install the kernel packages

```
root-shell> apt-get install linux-headers linux-image-server
```

If you are going to use the pre-built Debian packages for DRBD then you should not need any additional packages.

If you want to build DRBD from source, you will need to use the following command to install the required components:

```
root-shell> apt-get install devscripts flex bison build-essential \  
dpkg-dev kernel-package debconf-utils dpatch debhelper \  
libnet1-dev e2fslibs-dev libglib2.0-dev automake1.9 \  
libgnutls-dev libtool libltdl3 libltdl3-dev
```

- **Tips for Gentoo:**

Gentoo is a source based Linux distribution and therefore many of the source files and components that you will need are either already installed or will be installed automatically by `emerge`.

To install DRBD 0.8.x, you must unmask the `sys-cluster/drbd` build by adding the following line to `/etc/portage/package.keywords`:

```
sys-cluster/drbd ~x86  
sys-cluster/drbd-kernel ~x86
```

If your kernel does not already have the userspace to kernelspace linker enabled, then you will need to rebuild the kernel with this option. The best way to do this is to use `genkernel` with the `--menuconfig` option to select the option and then rebuild the kernel. For example, at the command line as `root`:

```
root-shell> genkernel --menuconfig all
```

Then through the menu options, select **DEVICE DRIVERS, CONNECTOR - UNIFIED USERSPACE <-> KERNELSPACE LINKER** and finally press 'y' or 'space' to select the **CONNECTOR - UNIFIED USERSPACE <-> KERNELSPACE LINKER** option. Then exit the menu configuration. The kernel will be rebuilt and installed. If this is a new kernel, make sure you update your bootloader accordingly. Now reboot to enable the new kernel.

14.1.1.2. Installing and Configuring DRBD

To install DRBD you can choose either the pre-built binary installation packages or you can use the source packages and build from source. If you want to build from source you must have installed the source and development packages.

If you are installing using a binary distribution then you must ensure that the kernel version number of the binary package matches your currently active kernel. You can use `uname` to find out this information:

```
shell> uname -r
2.6.20-gentoo-r6
```

Once DRBD has been built and installed, you need to edit the `/etc/drbd.conf` file and then run a number of commands to build the block device and set up the replication.

Although the steps below are split into those for the primary node and the secondary node, it should be noted that the configuration files for all nodes should be identical, and many of the same steps have to be repeated on each node to enable the DRBD block device.

Building from source:

To download and install from the source code:

1. Download the source code.
2. Unpack the package:

```
shell> tar xzf drbd-8.3.0.tar.gz
```

3. Change to the extracted directory, and then run `make` to build the DRBD driver:

```
shell> cd drbd-8.3.0
shell> make
```

4. Install the kernel driver and commands:

```
shell> make install
```

Binary Installation:

- **SUSE Linux Enterprise Server (SLES)**

For SUSE, use `yast`:

```
shell> yast -i drbd
```

Alternatively:

```
shell> rug install drbd
```

- **Debian**

Use `apt-get` to install the modules. You do not need to install any other components.

```
shell> apt-get install drbd8-utils drbd8-module
```

- **Debian 3.1 and 4.0**

You must install the `module-assistant` to build the DRBD kernel module, in addition to the DRBD components.

```
shell> apt-get install drbd0.7-utils drbd0.7-module-source \
  build-essential module-assistant
shell> module-assistant auto-install drbd0.7
```

- **CentOS**

DRBD can be installed using yum:

```
shell> yum install drbd kmod-drbd
```

- **Ubuntu**

You must enable the universe component for your preferred Ubuntu mirror in `/etc/apt/sources.list`, and then issue these commands:

```
shell> apt-get update
shell> apt-get install drbd8-utils drbd8-module-source \
  build-essential module-assistant
shell> module-assistant auto-install drbd8
```

- **Gentoo**

You can now `emerge` DRBD 0.8.x into your Gentoo installation:

```
root-shell> emerge drbd
```

Once `drbd` has been downloaded and installed, you need to decompress and copy the default configuration file from `/usr/share/doc/drbd-8.0.7/drbd.conf.bz2` into `/etc/drbd.conf`.

14.1.1.3. Setting Up a DRBD Primary Node

To set up a DRBD primary node you need to configure the DRBD service, create the first DRBD block device and then create a file system on the device so that you can store files and data.

The DRBD configuration file `/etc/drbd.conf` defines a number of parameters for your DRBD configuration, including the frequency of updates and block sizes, security information and the definition of the DRBD devices that you want to create.

The key elements to configure are the `on` sections which specify the configuration of each node.

To follow the configuration, the sequence below shows only the changes from the default `drbd.conf` file. Configurations within the file can be both global or tied to specific resource.

1. Set the synchronization rate between the two nodes. This is the rate at which devices are synchronized in the background after a disk failure, device replacement or during the initial setup. You should keep this in check compared to the speed of your network connection. Gigabit Ethernet can support up to 125 MB/second, 100Mbps Ethernet slightly less than a tenth of that (12MBps). If you are using a shared network connection, rather than a dedicated, then you should gauge accordingly.

To set the synchronization rate, edit the `rate` setting within the `syncer` block:

```
syncer {
  rate 10M;
}
```

You may additionally want to set the `al-extents` parameter. The default for this parameter is 257.

For more detailed information on synchronization, the effects of the synchronization rate and the effects on network performance, see [Section 14.1.3.2, “Optimizing the Synchronization Rate”](#).

2. Set up some basic authentication. DRBD supports a simple password hash exchange mechanism. This helps to ensure that only those hosts with the same shared secret are able to join the DRBD node group.

```
cram-hmac-alg "sha1";
```

```
shared-secret "shared-string";
```

- Now you must configure the host information. Remember that you must have the node information for the primary and secondary nodes in the `drbd.conf` file on each host. You need to configure the following information for each node:
 - `device` — the path of the logical block device that will be created by DRBD.
 - `disk` — the block device that will be used to store the data.
 - `address` — the IP address and port number of the host that will hold this DRBD device.
 - `meta-disk` — the location where the metadata about the DRBD device will be stored. You can set this to `internal` and DRBD will use the physical block device to store the information, by recording the metadata within the last sections of the disk. The exact size will depend on the size of the logical block device you have created, but it may involve up to 128MB.

A sample configuration for our primary server might look like this:

```
on drbd-one {
device /dev/drbd0;
disk /dev/hdd1;
address 192.168.0.240:8888;
meta-disk internal;
}
```

The `on` configuration block should be repeated for the secondary node (and any further) nodes:

```
on drbd-two {
device /dev/drbd0;
disk /dev/hdd1;
address 192.168.0.241:8888;
meta-disk internal;
}
```

The IP address of each `on` block must match the IP address of the corresponding host. Do not set this value to the IP address of the corresponding primary or secondary in each case.

- Before starting the primary node, you should create the metadata for the devices:

```
root-shell> drbdadm create-md all
```

- You are now ready to start DRBD:

```
root-shell> /etc/init.d/drbd start
```

DRBD should now start and initialize, creating the DRBD devices that you have configured.

- DRBD creates a standard block device - to make it usable, you must create a file system on the block device just as you would with any standard disk partition. Before you can create the file system, you must mark the new device as the primary device (i.e. where the data will be written and stored), and initialize the device. Because this is a destructive operation, you must specify the command line option to overwrite the raw data:

```
root-shell> drbdadm -- --overwrite-data-of-peer primary all
```

If you are using a version of DRBD 0.7.x or earlier, then you need to use a different command-line option:

```
root-shell> drbdadm -- --do-what-I-say primary all
```

Now create a file system using your chosen file system type:

```
root-shell> mkfs.ext3 /dev/drbd0
```

- You can now mount the file system and if necessary copy files to the mount point:

```
root-shell> mkdir /mnt/drbd
root-shell> mount /dev/drbd0 /mnt/drbd
root-shell> echo "DRBD Device" >/mnt/drbd/samplefile
```

Your primary node is now ready to use. You should now configure your secondary node or nodes.

14.1.1.4. Setting Up a DRBD Secondary Node

The configuration process for setting up a secondary node is the same as for the primary node, except that you do not have to create the file system on the secondary node device, as this information will automatically be transferred from the primary node.

To set up a secondary node:

1. Copy the `/etc/drbd.conf` file from your primary node to your secondary node. It should already contain all the information and configuration that you need, since you had to specify the secondary node IP address and other information for the primary node configuration.
2. Create the DRBD metadata on the underlying disk device:

```
root-shell> drbdadm create-md all
```

3. Start DRBD:

```
root-shell> /etc/init.d/drbd start
```

Once DRBD has started, it will start the copy the data from the primary node to the secondary node. Even with an empty file system this will take some time, since DRBD is copying the block information from a block device, not simply copying the file system data.

You can monitor the progress of the copy between the primary and secondary nodes by viewing the output of `/proc/drbd`:

```
root-shell> cat /proc/drbd
version: 8.0.4 (api:86/proto:86)
SVN Revision: 2947 build by root@drbd-one, 2007-07-30 16:43:05
0: cs:SyncSource st:Primary/Secondary ds:UpToDate/Inconsistent C r---
ns:252284 nr:0 dw:0 dr:257280 al:0 bm:15 lo:0 pe:7 ua:157 ap:0
[==>.....] sync'ed: 12.3% (1845088/2097152)K
finish: 0:06:06 speed: 4,972 (4,580) K/sec
resync: used:1/31 hits:15901 misses:16 starving:0 dirty:0 changed:16
act_log: used:0/257 hits:0 misses:0 starving:0 dirty:0 changed:0
```

You can monitor the synchronization process by using the `watch` command to run the command at specific intervals:

```
root-shell> watch -n 10 'cat /proc/drbd'
```

14.1.1.5. Monitoring DRBD Device

Once the primary and secondary machines are configured and synchronized, you can get the status information about your DRBD device by viewing the output from `/proc/drbd`:

```
root-shell> cat /proc/drbd
version: 8.0.4 (api:86/proto:86)
SVN Revision: 2947 build by root@drbd-one, 2007-07-30 16:43:05
0: cs:Connected st:Primary/Secondary ds:UpToDate/UpToDate C r---
ns:2175704 nr:0 dw:99192 dr:2076641 al:33 bm:128 lo:0 pe:0 ua:0 ap:0
resync: used:0/31 hits:134841 misses:135 starving:0 dirty:0 changed:135
act_log: used:0/257 hits:24765 misses:33 starving:0 dirty:0 changed:33
```

The first line provides the version/revision and build information.

The second line starts the detailed status information for an individual resource. The individual field headings are as follows:

- `cs` — connection state
- `st` — node state (local/remote)
- `ld` — local data consistency
- `ds` — data consistency
- `ns` — network send
- `nr` — network receive
- `dw` — disk write

- `dr` — disk read
- `pe` — pending (waiting for ack)
- `ua` — unack'd (still need to send ack)
- `al` — access log write count

In the previous example, the information shown indicates that the nodes are connected, the local node is the primary (because it is listed first), and the local and remote data is up to date with each other. The remainder of the information is statistical data about the device, and the data exchanged that kept the information up to date.

You can also get the status information for DRBD by using the startup script with the `status` option:

```
root-shell> /etc/init.d/drbd status
* status: started
* drbd driver loaded OK; device status: ...
version: 8.3.0 (api:88/proto:86-89)
GIT-hash: 9ba8b93e24d842f0dd3fblf9b90e8348ddb95829 build by root@gentool.vmbear, 2009-03-14 23:00:06
0: cs:Connected ro:Secondary/Secondary ds:UpToDate/UpToDate C r---
   ns:0 nr:0 dw:0 dr:8385604 al:0 bm:0 lo:0 pe:0 ua:0 ap:0 ep:1 wo:b oos:0
```

The information and statistics are the same.

14.1.1.6. Managing your DRBD Installation

For administration, the main command is `drbdadm`. There are a number of commands supported by this tool to control the connectivity and status of the DRBD devices.

Note

For convenience, a bash completion script is available. This will provide tab completion for options to `drbdadm`. The file `drbdadm.bash_completion` can be found within the standard DRBD source package within the `scripts` directory. To enable, copy the file to `/etc/bash_completion.d/drbdadm`. You can load it manually by using:

```
shell> source /etc/bash_completion.d/drbdadm
```

The most common commands are those to set the primary/secondary status of the local device. You can manually set this information for a number of reasons, including when you want to check the physical status of the secondary device (since you cannot mount a DRBD device in primary mode), or when you are temporarily moving the responsibility of keeping the data in check to a different machine (for example, during an upgrade or physical move of the normal primary node). You can set state of all local device to be the primary using this command:

```
root-shell> drbdadm primary all
```

Or switch the local device to be the secondary using:

```
root-shell> drbdadm secondary all
```

To change only a single DRBD resource, specify the resource name instead of `all`.

You can temporarily disconnect the DRBD nodes:

```
root-shell> drbdadm disconnect all
```

Reconnect them using `connect`:

```
root-shell> drbdadm connect all
```

For other commands and help with `drbdadm` see the DRBD documentation.

14.1.1.7. Additional DRBD Configuration Options

Additional options you may want to configure:

- `protocol` — specifies the level of consistency to be used when information is written to the block device. The option is similar in principle to the `innodb_flush_log_at_trx_commit` option within MySQL. Three levels are supported:

- **A** — data is considered written when the information reaches the TCP send buffer and the local physical disk. There is no guarantee that the data has been written to the remote server or the remote physical disk.
- **B** — data is considered written when the data has reached the local disk and the remote node's network buffer. The data has reached the remote server, but there is no guarantee it has reached the remote server's physical disk.
- **C** — data is considered written when the data has reached the local disk and the remote node's physical disk.

The preferred and recommended protocol is C, as it is the only protocol which ensures the consistency of the local and remote physical storage.

- **size** — if you do not want to use the entire partition space with your DRBD block device then you can specify the size of the DRBD device to be created. The size specification can include a quantifier. For example, to set the maximum size of the DRBD partition to 1GB you would use:

```
size 1G;
```

With the configuration file suitably configured and ready to use, you now need to populate the lower-level device with the metadata information, and then start the DRBD service.

14.1.2. Configuring MySQL for DRBD

Once you have configured DRBD and have an active DRBD device and file system, you can configure MySQL to use the chosen device to store the MySQL data.

When performing a new installation of MySQL, you can either select to install MySQL entirely onto the DRBD device, or just configure the data directory to be located on the new file system.

In either case, the files and installation must take place on the primary node, because that is the only DRBD node on which you can mount the DRBD device file system as read/write.

You should store the following files and information on your DRBD device:

- MySQL data files, including the binary log, and InnoDB data files.
- MySQL configuration file (`my.cnf`).

To set up MySQL to use your new DRBD device and file system:

1. If you are migrating an existing MySQL installation, stop MySQL:

```
shell> mysqladmin shutdown
```

2. Copy the `my.cnf` onto the DRBD device. If you are not already using a configuration file, copy one of the sample configuration files from the MySQL distribution.

```
root-shell> mkdir /mnt/drbd/mysql
root-shell> cp /etc/my.cnf /mnt/drbd/mysql
```

3. Copy your MySQL data directory to the DRBD device and mounted file system.

```
root-shell> cp -R /var/lib/mysql /drbd/mysql/data
```

4. Edit the configuration file to reflect the change of directory by setting the value of the `datadir` option. If you have not already enabled the binary log, also set the value of the `log-bin` option.

```
datadir = /drbd/mysql/data
log-bin = mysql-bin
```

5. Create a symbolic link from `/etc/my.cnf` to the new configuration file on the DRBD device file system.

```
root-shell> ln -s /drbd/mysql/my.cnf /etc/my.cnf
```

6. Now start MySQL and check that the data that you copied to the DRBD device file system is present.

```
root-shell> /etc/init.d/mysql start
```

Your MySQL data should now be located on the file system running on your DRBD device. The data will be physically stored on the underlying device that you configured for the DRBD device. Meanwhile, the content of your MySQL databases will be copied to the secondary DRBD node.

Note that you cannot access the information on your secondary node, as a DRBD device working in secondary mode is not available for use.

14.1.3. Optimizing Performance and Reliability

Because of the nature of the DRBD system, the critical requirements are for a very fast exchange of the information between the two hosts. To ensure that your DRBD setup is available to switch over in the event of a failure as quickly as possible, you must transfer the information between the two hosts using the fastest method available.

Typically, a dedicated network circuit should be used for exchanging DRBD data between the two hosts. You should then use a separate, additional, network interface for your standard network connection. For an example of this layout, see [Figure 14.2, “DRBD Architecture Using Separate Network Interfaces”](#).

Figure 14.2. DRBD Architecture Using Separate Network Interfaces

The dedicated DRBD network interfaces should be configured to use a non-routed TCP/IP network configuration. For example, you might want to set the primary to use 192.168.0.1 and the secondary 192.168.0.2. These networks and IP addresses should not be part of normal network subnet.

Note

The preferred setup, whenever possible, is to use a direct cable connection (using a crossover cable with Ethernet, for example) between the two machines. This eliminates the risk of loss of connectivity due to switch failures.

14.1.3.1. Using Bonded Ethernet Network Interfaces

For a set-up where there is a high-throughput of information being written, you may want to use bonded network interfaces. This is where you combine the connectivity of more than one network port, increasing the throughput linearly according to the number of bonded connections.

Bonding also provides an additional benefit in that with multiple network interfaces effectively supporting the same communications channel, a fault within a single network interface in a bonded group does not stop communication. For example, imagine you have a bonded setup with four network interfaces providing a single interface channel between two DRBD servers. If one network interface fails, communication can continue on the other three without interruption, although it will be at a lower speed.

To enable bonded connections you must enable bonding within the kernel. You then need to configure the module to specify the bonded devices and then configure each new bonded device just as you would a standard network device:

- To configure the bonded devices, you need to edit the `/etc/modprobe.conf` file (RedHat) or add a file to the `/etc/modprobe.d` directory. In each case you will define the parameters for the kernel module. First, you need to specify each bonding device:

```
alias bond0 bonding
```

You can then configure additional parameters for the kernel module. Typical parameters are the `mode` option and the `miimon` option.

The `mode` option specifies how the network interfaces are used. The default setting is 0, which means that each network interface is used in a round-robin fashion (this supports aggregation and fault tolerance). Using setting 1 sets the bonding mode to active-backup. This means that only one network interface is used as a time, but that the link will automatically failover to a new interface if the primary interface fails. This settings only supports fault-tolerance.

The `miimon` option enables the MII link monitoring. A positive value greater than zero indicates the monitoring frequency in milliseconds for checking each slave network interface that is configured as part of the bonded interface. A typical value is 100.

You set th options within the module parameter file, and you must set the options for each bonded device individually:

```
options bond0 miimon=100 mode=1
```

- Reboot your server to enable the bonded devices.
- Configure the network device parameters. There are two parts to this, you need to setup the bonded device configuration, and then configure the original network interfaces as 'slaves' of the new bonded interface.

- For RedHat Linux:

Edit the configuration file for the bonded device. For device `bond0` this would be `/etc/sysconfig/network-scripts/ifcfg-bond0`:

```
DEVICE=bond0
BOOTPROTO=none
ONBOOT=yes
GATEWAY=192.168.0.254
NETWORK=192.168.0.0
NETMASK=255.255.255.0
IPADDR=192.168.0.1
USERCTL=no
```

Then for each network interface that you want to be part of the bonded device, configure the interface as a slave to the 'master' bond. For example, the configuration of `eth0` in `/etc/sysconfig/network-scripts/ifcfg-eth0` might look like this::

```
DEVICE=eth0
BOOTPROTO=none
HWADDR=00:11:22:33:44:55
ONBOOT=yes
TYPE=Ethernet
MASTER=bond0
SLAVE=yes
```

- For Debian Linux:

Edit the `/etc/iftab` file and configure the logical name and MAC address for each devices. For example:

```
eth0 mac 00:11:22:33:44:55
```

Now you need to set the configuration of the devices in `/etc/network/interfaces`:

```
auto bond0
iface bond0 inet static
address 192.168.0.1
netmask 255.255.255.0
network 192.168.0.0
gateway 192.168.0.254
up /sbin/ifenslave bond0 eth0
up /sbin/ifenslave bond0 eth1
```

- For Gentoo:

Use `emerge` to add the `net-misc/ifenslave` package to your system.

Edit the `/etc/conf.d/net` file and specify the network interface slaves in a bond, the dependencies and then the configuration for the bond itself. A sample configuration might look like this:

```
slaves_bond0="eth0 eth1 eth2"

config_bond0=( "192.168.0.1 netmask 255.255.255.0" )

depend_bond0() {
  need net.eth0 net.eth1 net.eth2
}
```

Then make sure that you add the new network interface to list of interfaces configured during boot:

```
root-shell> rc-update add default net.bond0
```

Once the bonded devices are configured you should reboot your systems.

You can monitor the status of a bonded connection using the `/proc` file system:

```
root-shell> cat /proc/net/bonding/bond0
Bonding Mode: fault-tolerance (active-backup)
Primary Slave: None
Currently Active Slave: eth1
MII Status: up
MII Polling Interval (ms): 100
Up Delay (ms): 200
Down Delay (ms): 200
Slave Interface: eth1
MII Status: up
Link Failure Count: 0
Permanent HW addr: 00:11:22:33:44:55
Slave Interface: eth2
MII Status: up
Link Failure Count: 0
Permanent HW addr: 00:11:22:33:44:56
```

14.1.3.2. Optimizing the Synchronization Rate

The `syncer rate` configuration parameter should be configured with care as the synchronization rate can have a significant effect on the performance of the DRBD setup in the event of a node or disk failure where the information is being synchronized from the Primary to the Secondary node.

In DRBD, there are two distinct ways of data being transferred between peer nodes:

- *Replication* refers to the transfer of modified blocks being transferred from the primary to the secondary node. This happens automatically when the block is modified on the primary node, and the replication process uses whatever bandwidth is available over the replication link. The replication process cannot be throttled, because you want to transfer of the block information to happen as quickly as possible during normal operation.
- *Synchronization* refers to the process of bringing peers back in sync after some sort of outage, due to manual intervention, node failure, disk swap, or the initial setup. Synchronization is limited to the `syncer rate` configured for the DRBD device.

Both replication and synchronization can take place at the same time. For example, the block devices can be being synchronized while they are actively being used by the primary node. Any I/O that updates on the primary node will automatically trigger replication of the modified block. In the event of a failure within an HA environment, it is highly likely that synchronization and replication will take place at the same time.

Unfortunately, if the synchronization rate is set too high, then the synchronization process will use up all the available network bandwidth between the primary and secondary nodes. In turn, the bandwidth available for replication of changed blocks is zero, which means replication will stall and I/O will block, and ultimately the application will fail or degrade.

To avoid enabling the `syncer rate` to consume the available network bandwidth and prevent the replication of changed blocks you should set the `syncer rate` to less than the maximum network bandwidth.

You should avoid setting the sync rate to more than 30% of the maximum bandwidth available to your device and network bandwidth. For example, if your network bandwidth is based on Gigabit ethernet, you should achieve 110MB/s. Assuming your disk interface is capable of handling data at 110MB/s or more, then the sync rate should be configured as `33M` (33MB/s). If your disk sys-

tem works at a rate lower than your network interface, use 30% of your disk interface speed.

Depending on the application, you may wish to limit the synchronization rate. For example, on a busy server you may wish to configure a significantly slower synchronization rate to ensure the replication rate is not affected.

The `al-extents` parameter controls the number of 4MB blocks of the underlying disk that can be written to at the same time. Increasing this parameter lowers the frequency of the meta data transactions required to log the changes to the DRBD device, which in turn lowers the number of interruptions in your I/O stream when synchronizing changes. This can lower the latency of changes to the DRBD device. However, if a crash occurs on your primary, then all of the blocks in the activity log (i.e. the number of `al-extents` blocks) will need to be completely resynchronized before replication can continue.

14.2. Using Linux HA Heartbeat

The Heartbeat program provides a basis for verifying the availability of resources on one or more systems within a cluster. In this context a resource includes MySQL, the file systems on which the MySQL data is being stored and, if you are using DRBD, the DRBD device being used for the file system. Heartbeat also manages a virtual IP address, and the virtual IP address should be used for all communication to the MySQL instance.

A cluster within the context of Heartbeat is defined as two computers notionally providing the same service. By definition, each computer in the cluster is physically capable of providing the same services as all the others in the cluster. However, because the cluster is designed for high-availability, only one of the servers is actively providing the service at any one time. Each additional server within the cluster is a “hot-spare” that can be brought into service in the event of a failure of the master, its next connectivity or the connectivity of the network in general.

The basics of Heartbeat are very simple. Within the Heartbeat cluster (see [Figure 14.3, “Heartbeat Architecture”](#)), each machine sends a 'heartbeat' signal to the other hosts in the cluster. The other cluster nodes monitor this heartbeat. The heartbeat can be transmitted over many different systems, including shared network devices, dedicated network interfaces and serial connections. Failure to get a heartbeat from a node is treated as failure of the node. Although we do not know the reason for the failure (it could be an OS failure, a hardware failure in the server, or a failure in the network switch), it is safe to assume that if no heartbeat is produced there is a fault.

Figure 14.3. Heartbeat Architecture

In addition to checking the heartbeat from the server, the system can also check the connectivity (using `ping`) to another host on the network, such as the network router. This allows Heartbeat to detect a failure of communication between a server and the router (and therefore failure of the server, since it is no longer capable of providing the necessary service), even if the heartbeat between the servers in the clusters is working fine.

In the event of a failure, the resources on the failed host are disabled, and the resources on one of the replacement hosts is enabled instead. In addition, the Virtual IP address for the cluster is redirected to the new host in place of the failed device.

When used with MySQL and DRBD, the MySQL data is replicated from the master to the slave using the DRBD device, but MySQL is only running on the master. When the master fails, the slave switches the DRBD devices to be primary, the file systems on those devices are mounted, and MySQL is started. The original master (if still available) has its resources disabled, which means shutting down MySQL and unmounting the file systems and switching the DRBD device to secondary.

14.2.1. Heartbeat Configuration

Heartbeat configuration requires three files located in `/etc/ha.d`. The `ha.cf` contains the main heartbeat configuration, including the list of the nodes and times for identifying failures. `haresources` contains the list of resources to be managed within the cluster. The `authkeys` file contains the security information for the cluster.

The contents of these files should be identical on each host within the Heartbeat cluster. It is important that you keep these files in sync across all the hosts. Any changes in the information on one host should be copied to the all the others.

For these examples an example of the `ha.cf` file is shown below:

```
logfacility local0
keepalive 500ms
deadtime 10
warntime 5
initdead 30
mcast bond0 225.0.0.1 694 2 0
mcast bond1 225.0.0.2 694 1 0
auto_failback off
```

```
node drbd1
node drbd2
```

The individual lines in the file can be identified as follows:

- `logfacility` — sets the logging, in this case setting the logging to use `syslog`.
- `keepalive` — defines how frequently the heartbeat signal is sent to the other hosts.
- `deadtime` — the delay in seconds before other hosts in the cluster are considered 'dead' (failed).
- `warntime` — the delay in seconds before a warning is written to the log that a node cannot be contacted.
- `initdead` — the period in seconds to wait during system startup before the other host is considered to be down.
- `mcast` — defines a method for sending a heartbeat signal. In the above example, a multicast network address is being used over a bonded network device. If you have multiple clusters then the multicast address for each cluster should be unique on your network. Other choices for the heartbeat exchange exist, including a serial connection.

If you are using multiple network interfaces (for example, one interface for your server connectivity and a secondary and/or bonded interface for your DRBD data exchange) then you should use both interfaces for your heartbeat connection. This decreases the chance of a transient failure causing an invalid failure event.

- `auto_failback` — sets whether the original (preferred) server should be enabled again if it becomes available. Switching this to `on` may cause problems if the preferred went offline and then comes back on line again. If the DRBD device has not been synced properly, or if the problem with the original server happens again you may end up with two different datasets on the two servers, or with a continually changing environment where the two servers flip-flop as the preferred server reboots and then starts again.
- `node` — sets the nodes within the Heartbeat cluster group. There should be one `node` for each server.

An optional additional set of information provides the configuration for a ping test that will check the connectivity to another host. You should use this to ensure that you have connectivity on the public interface for your servers, so the ping test should be to a reliable host such as a router or switch. The additional lines specify the destination machine for the `ping`, which should be specified as an IP address, rather than a host name; the command to run when a failure occurs, the authority for the failure and the timeout before a non-response triggers a failure. A sample configure is shown below:

```
ping 10.0.0.1
respawn hacluster /usr/lib64/heartbeat/ipfail
apiauth ipfail gid=haclient uid=hacluster
deadping 5
```

In the above example, the `ipfail` command, which is part of the Heartbeat solution, is called on a failure and 'fakes' a fault on the currently active server. You need to configure the user and group ID under which the command should be executed (using the `apiauth`). The failure will be triggered after 5 seconds.

Note

The `deadping` value must be less than the `deadtime` value.

The `authkeys` file holds the authorization information for the Heartbeat cluster. The authorization relies on a single unique 'key' that is used to verify the two machines in the Heartbeat cluster. The file is used only to confirm that the two machines are in the same cluster and is used to ensure that the multiple clusters can co-exist within the same network.

14.2.2. Using Heartbeat with MySQL and DRBD

To use Heartbeat in combination with MySQL you should be using DRBD (see [Section 14.1, “Using MySQL with DRBD”](#)) or another solution that allows for sharing of the MySQL database files in event of a system failure. In these examples, DRBD is used as the data sharing solution.

Heartbeat manages the configuration of different resources to manage the switching between two servers in the event of a failure. The resource configuration defines the individual services that should be brought up (or taken down) in the event of a failure.

The `haresources` file within `/etc/ha.d` defines the resources that should be managed, and the individual resource mentioned in this file in turn relates to scripts located within `/etc/ha.d/resource.d`. The resource definition is defined all on one line:

```
drbd1 drbddisk Filesystem::/dev/drbd0::/drbd::ext3 mysql 10.0.0.100
```

The line is notionally split by whitespace. The first entry (`drbd1`) is the name of the preferred host, i.e. the server that is normally responsible for handling the service. The last field is virtual IP address or name that should be used to share the service. This is the IP address that should be used to connect to the MySQL server. It will automatically be allocated to the server that is active when Heartbeat starts.

The remaining fields between these two fields define the resources that should be managed. Each Field should contain the name of the resource (and each name should refer to a script within `/etc/ha.d/resource.d`). In the event of a failure, these resources are started on the backup server by calling the corresponding script (with a single argument, `start`), in order from left to right. If there are additional arguments to the script, you can use a double colon to separate each additional argument.

In the above example, we manage the following resources:

- `drbddisk` — the DRBD resource script, this will switch the DRBD disk on the secondary host into primary mode, making the device read/write.
- `Filesystem` — manages the Filesystem resource. In this case we have supplied additional arguments to specify the DRBD device, mount point and file system type. When executed this should mount the specified file system.
- `mysql` — manages the MySQL instances and starts the MySQL server. You should copy the `mysql.resource` file from the `support-files` directory from any MySQL release into the `/etc/ha.d/resources.d` directory.

If this file is not available in your distribution, you can use the following as the contents of the `/etc/ha.d/resource.d/mysql.resource` file:

```
#!/bin/bash
#
# This script is intended to be used as resource script by heartbeat
#
# Mar 2006 by Monty Taylor
#
###
. /etc/ha.d/shellfuncs
case "$1" in
  start)
    res=`/etc/init.d/mysql start`
    ret=$?
    ha_log $res
    exit $ret
    ;;
  stop)
    res=`/etc/init.d/mysql stop`
    ret=$?
    ha_log $res
    exit $ret
    ;;
  status)
    if [ `ps -ef | grep '[mysqld]'` ]; then
      echo "running"
    else
      echo "stopped"
    fi
    ;;
  *)
    echo "Usage: mysql {start|stop|status}"
    exit 1
    ;;
esac
exit 0
```

If you want to be notified of the failure by email, you can add another line to the `haresources` file with the address for warnings and the warning text:

```
MailTo::youremail@address.com::DRBDFailure
```

With the Heartbeat configuration in place, copy the `haresources`, `authkeys` and `ha.cf` files from your primary and secondary servers to make sure that the configuration is identical. Then start the Heartbeat service, either by calling `/etc/init.d/heartbeat start` or by rebooting both primary and secondary servers.

You can test the configuration by running a manual failover, connect to the primary node and run:

```
root-shell> /usr/lib64/heartbeat/hb_standby
```

This will cause the current node to relinquish its resources cleanly to the other node.

14.2.3. Using Heartbeat with DRBD and `dopd`

As a further extension to using DRBD and Heartbeat together, you can enable `dopd`. The `dopd` daemon handles the situation where a DRBD node is out of date compared to the master and prevents the slave from being promoted to master in the event of a failure. This stops a situation where you have two machines that have been masters ending up with different data on the underlying device.

For example, imagine that you have a two server DRBD setup, master and slave. If the DRBD connectivity between master and slave fails then the slave would be out of the sync with the master. If Heartbeat identifies a connectivity issue for master and then switches over to the slave, the slave DRBD device will be promoted to the primary device, even though the data on the slave and the master is not in synchronization.

In this situation, with `dopd` enabled, the connectivity failure between the master and slave would be identified and the metadata on the slave would be set to `Outdated`. Heartbeat will then refuse to switch over to the slave even if the master failed. In a dual-host solution this would effectively render the cluster out of action, as there is no additional fail over server. In an HA cluster with three or more servers, control would be passed to the slave that has an up to date version of the DRBD device data.

To enable `dopd`, you need to modify the Heartbeat configuration and specify `dopd` as part of the commands executed during the monitoring process. Add the following lines to your `ha.cf` file:

```
respawn hacluster /usr/lib/heartbeat/dopd
apiauth dopd gid=haclient uid=hacluster
```

Make sure you make the same modification on both your primary and secondary nodes.

You will need to reload the Heartbeat configuration:

```
root-shell> /etc/init.d/heartbeat reload
```

You will also need to modify your DRBD configuration by configuration the `outdate-peer` option. You will need to add the configuration line into the `common` section of `/etc/drbd.conf` on both hosts. An example of the full block is shown below:

```
common {
  handlers {
    outdate-peer "/usr/lib/heartbeat/drbd-peer-outdater";
  }
}
```

Finally, set the `fencing` option on your DRBD configured resources:

```
resource my-resource {
  disk {
    fencing resource-only;
  }
}
```

Now reload your DRBD configuration:

```
root-shell> drbdadmin adjust all
```

You can test the system by unplugging your DRBD link and monitoring the output from `/proc/drbd`.

14.2.4. Dealing with System Level Errors

Because a kernel panic or oops may indicate potential problem with your server, you should configure your server to remove itself from the cluster in the event of a problem. Typically on a kernel panic your system will automatically trigger a hard reboot. For a kernel oops a reboot may not happen automatically, but the issue that caused that oops may still lead to potential problems.

You can force a reboot by setting the `kernel.panic` and `kernel.panic_on_oops` parameters of the kernel control file `/etc/sysctl.conf`. For example:

```
kernel.panic_on_oops = 1
kernel.panic = 1
```

You can also set these parameters during runtime by using the `sysctl` command. You can either specify the parameters on the command line:

```
shell> sysctl -w kernel.panic=1
```

Or you can edit your `sysctl.conf` file and then reload the configuration information:

```
shell> sysctl -p
```

By setting both these parameters to a positive value (actually the number of seconds to wait before triggering the reboot), the system will reboot. Your second heartbeat node should then detect that the server is down and then switch over to the failover host.

14.3. MySQL and Virtualization

Using virtualization can be an effective way of better utilizing the hardware of your machine when using MySQL, or to provide improved security or isolation of different instances of MySQL on the same machine. In some circumstances, virtualization may be a suitable solution for scaling out your database environment by enabling you to easily deploy additional instances of a pre-configured MySQL server and application environment to new virtualization hosts.

With any virtualization solution there is often a tradeoff between the flexibility and ease of deployment and performance, or between the potential performance advantage and complexities of effectively configuring multiple instances of MySQL to reside within a single physical host.

Different issues are experienced according to the virtualization environment you are using. Virtualization generally falls into one of the following categories:

- **Native virtualization**, including products like VMware Workstation, Parallels Desktop/Parallels Workstation, Microsoft Virtual PC and VirtualBox, all work by acting as an application that runs within an existing operating system environment. Recent versions can take advantage of the virtualization extensions in the Intel and AMD CPUs to help improve performance.

The application-based solutions have a number of advantages, including the ability to prioritize CPU usage (including multiple CPUs) and easily run multiple virtualized environments simultaneously.

With these solutions, you also have the ability to easily create a virtualized environment that can be packaged and shared among different virtualization hosts. For example, you can create a MySQL environment and configuration that can be deployed multiple times to help extend an existing scalability or HA environment.

The major disadvantage of this type of virtualization environment is the effect of the host on the performance of the virtualization instances. Disk storage is typically provided by using one or more files on the host OS which are then emulated to provide physical disks within the virtual instance. Other resources on the host are similarly shared, including CPU, network interfaces and additional devices (USB). It is also difficult to directly share lower-level components, such as PCI devices and that the ability to take advantage of RAID storage solutions.

- **Paravirtualization (Hypervisor)**, including Xen, Solaris xVM (based on Xen), VMware ESX Server, Windows Server 2008 Hyper-V, and Solaris Logical Domains (LDOM), work by running a specialized version of the host operating system. The host OS then allows slightly modified versions of different operating systems to run within the virtualized environment.

With paravirtualization, the level of performance and the control over the underlying hardware used to support the virtualized environments is higher than native virtualization solutions. For example, using paravirtualization you can dedicate individual CPU cores, RAM, disk drives and even PCI devices to be accessible to individual and specific virtual instances.

For example, within a paravirtualized environment you could dedicate a physical disk drive or subsystem to a particular virtual environment and gain a performance benefit over a typical file-based solution virtual disk.

- **Operating system-level virtualization**, including BSD jails, and Solaris Containers/Zones, offer methods for isolating different instances of an operating system environment while sharing the same hardware environment. Unlike the other virtualization solutions, operating system level virtualization is not normally used to run other operating systems, but instead to provide a level of security isolation and resource control within the core operating environment.

The isolation of these different instances is the key advantage of this type of virtualization. Each virtualized instance sees its environment as if it were completely different system. The solution can be an effective method to provide isolated computing resources for different departments or users, or to provide unique instances for testing and development.

The main reasons for using virtualization, particularly with a database or an application stack that includes a database component, include:

- **Security** — separate instances of different operating systems running within a single host but with effective isolation from each other. When used with MySQL, you can provide an increased level of security between different instances of each server.
- **Consolidation** — merging a number of individual systems with a relatively small load onto a single, larger, server. This can help reduce footprint and energy costs, or make more efficient use of a larger machine. Performance is the main issue with this

solution as the load of many MySQL databases running in individual virtual instances on a single machine can be considerable.

- **Development/QA/Testing** — by creating different instances of different environments and operating systems you can test your MySQL-based application in different environments.
- **Scalability** — although using virtualization imposes a performance hit, many virtualization solutions allow you to create a packaged version of an environment, including MySQL and the other application components. By distributing the virtualization environment package to new hosts you can often very quickly scale out by adding new hosts and deploying the virtualized environment.

The remainder of this chapter looks at common issues with using MySQL in a virtualized environment and tips for using MySQL within different virtualization tools.

For advice on common issues and problems, including performance and configuration issues, when using virtualized instances, see [Section 14.3.1, “Common Issues with Virtualization”](#).

14.3.1. Common Issues with Virtualization

There are many issues related to using MySQL within a virtualized environment that are common across the different virtualization types. Most are directly related to the performance or security of the environment in which you are deploying the MySQL server compared to the host on which you are running the virtualization solution.

Before deciding to use virtualization as a solution for your database, you should ensure that the expected load for the server and the expected performance when run in a virtualized environment meet your needs and requirements.

To help you determine the issues and some of the potential solutions, use the following sections:

- For general performance issues, problems and the probable causes, see [Section 14.3.1.1, “Virtualization Performance Issues”](#).
- Disk and storage concerns directly affect database storage because most database access is limited by the I/O bandwidth. For some examples and issues, see [Section 14.3.1.2, “Virtualization Storage Issues”](#).
- Issues related to network configuration and performance may need more careful planning, especially if you are using network-specific technologies such as MySQL replication. For further examples and details, see [Section 14.3.1.3, “Virtualization Networking Issues”](#).

14.3.1.1. Virtualization Performance Issues

Often the biggest consideration is the performance of a virtualized environment once hosted. In most cases, the virtualized environment involves some level of emulation of one or more of the hardware interfaces (CPU, network or disk) of the host environment. The effect is to reduce the effective performance of the virtualized environment compared to running an application natively on the host.

Some core resourcing issues to be aware of include:

- Using virtualization does not reduce the amount of CPU required to support a particular application or environment. If your application stack requires 2GB of RAM on an individual machine, the same RAM requirement will apply within your virtualized environment. The additional overhead of the virtualization layer and host operating system or environment often mean that you will need 2.5GB or 3GB of RAM to run the same application within the virtualized environment.

You should configure your virtualization environment with the correct RAM allocation according to your applications needs, and not to maximize the number of virtualized environments that you can execute within the virtualization host.

- Virtualization of the CPU resources is more complex. If your MySQL database and application stack do not have a high CPU load, then consolidating multiple environments onto a single host is often more efficient. You should keep in mind that at peak times your application and database CPU requirement may need to grow beyond your default allocation.

With some virtualization environments (Xen, Solaris Containers, Solaris LDOMs) you can dedicate CPU or core to a virtual instance. You should use this functionality to improve performance for database or application loads that have a high constant CPU requirement as the performance benefit will outweigh the flexibility of dynamic allocation of the CPU resources.

- Contention of resources within the host should be taken into account. In a system with high CPU loads, even when dedicating RAM and CPU resources, the I/O channels and interfaces to storage and networking resources may exceed the capacity of the host. Solutions such as Xen and Solaris LDOMs dedicate specific resources to individual virtual instances, but this will not eliminate the effects of the overall load on the host.

- If your database application is time sensitive, including logging and real-time database applications, or you are using MySQL Cluster, then the effects of virtualization may severely reduce the performance of your application. Because of the way the virtualized instances are executed and shared between CPUs and the effects of load on other resources, the response times for your database or application may be much higher than normal. This is especially true if you are running a large number of virtualized instances on a single host.
- Be aware of the limitation of using a single host to run multiple virtualized instances. In the event of a machine or component failure, the problem will affect more than just one database instance. For example, a failure in a storage device could bring down all your virtualized instances. Using a RAID solution that supports fault tolerance (RAID levels 1,3,4,5 or 6) will help protect you from the effects of this.

14.3.1.2. Virtualization Storage Issues

Due to the random I/O nature of any database solution, running MySQL within a virtualized environment places a heavy load on the storage solution you are using. To help keep the performance of your virtualized solution at the highest level, you should use the following notes to help configure your systems.

- Some virtualization solutions allow you to use a physical disk directly within your virtual host as if it were a local disk. You should use this whenever possible to ensure that disk contention issues do not affect the performance of your virtual environment.

When running multiple virtual machines, you should use an individual disk for each virtual instance. Using a single disk and multiple partitions, with each partition dedicated to a virtual host, will lead to the same contention issues.

- If you are using standard file-based storage for your virtualized disks:
 - File-based storage is subject to fragmentation on the host disk. To prevent fragmentation, create a fixed-size disk (that is, one where the entire space for the disk file is preallocated) instead of a dynamic disk that will grow with usage. Also be prepared to defragment the disk hosting the files at regular intervals to reduce the fragmentation.
 - Use separate disk files for the operating system and database disks, and try to avoid partitioning a disk file as this increases the contention within the file.
 - Use a high-performance disk solution, such as RAID or SAN, to store the disk files for your virtualized environments. This will improve the performance of what is essentially a large single file on a physical device.
 - When running a number of different virtualized environments within a single host, do not use the same physical host drive for multiple virtual disks. Instead, spread the virtual disks among multiple physical disks. Even when using a RAID device, be aware that each virtual host is equivalent to increasing the load linearly on the host RAID device.

14.3.1.3. Virtualization Networking Issues

When running multiple virtual machines on a host, you should be aware of the networking implications of each virtualized instance. If your host machine has only one network card, then you will be sharing the networking throughput for all of your machines through only one card, and this may severely limit the performance of your virtual environments.

If possible, you should use multiple network cards to support your virtualized instances. Depending on the expected load of each instance, you should dedicate or spread the allocation of the virtual network devices across these physical devices to ensure that you do not reach saturation.

If you are using packaged virtual machines as the basis for deployment of your MySQL database solution, you should make sure that the network interfaces are correctly reconfigured. Some solutions duplicate the hardware MAC address which will cause problems when you start up additional instances of the same virtualized environment.

14.3.2. Using MySQL within an Amazon EC2 Instance

The Amazon Elastic Compute Cloud (EC2) service provides virtual servers that you can build and deploy to run a variety of different applications and services, including MySQL. The EC2 service is based around the Xen framework, supporting x86, Linux based, platforms with individual instances of a virtual machine referred to as an Amazon Machine Image (AMI). You have complete (root) access to the AMI instance that you create, allowing you to configure and install your AMI in any way you choose.

To use EC2, you create an AMI based on the configuration and applications that you want to use and upload the AMI to the Amazon Simple Storage Service (S3). From the S3 resource, you can deploy one or more copies of the AMI to run as an instance within the EC2 environment. The EC2 environment provides management and control of the instance and contextual information about the instance while it is running.

Because you can create and control the AMI, the configuration, and the applications, you can deploy and create any environment

you choose. This includes a basic MySQL server in addition to more extensive replication, HA and scalability scenarios that enable you to take advantage of the EC2 environment, and the ability to deploy additional instances as the demand for your MySQL services and applications grow.

To aid the deployment and distribution of work, three different Amazon EC2 instances are available, small (identified as `m1.small`), large (`m1.large`) and extra large (`m1.xlarge`). The different types provide different levels of computing power measured in EC2 computer units (ECU). A summary of the different instance configurations is shown here.

	Small	Large	Extra Large
Platform	32-bit	64-bit	64-bit
CPU cores	1	2	4
ECUs	1	4	8
RAM	1.7GB	7.5GB	15GB
Storage	150GB	840GB	1680GB
I/O Performance	Medium	High	High

The typical model for deploying and using MySQL within the EC2 environment is to create a basic AMI that you can use to hold your database data and application. Once the basic environment for your database and application has been created you can then choose to deploy the AMI to a suitable instance. Here the flexibility of having an AMI that can be re-deployed from the small to the large or extra large EC2 instance makes it easy to upgrade the hardware environment without rebuilding your application or database stack.

To get started with MySQL on EC2, including information on how to set up and install MySQL within an EC2 installation and how to port and migrate your data to the running instance, see [Section 14.3.2.1, “Setting Up MySQL on an EC2 AMI”](#).

For tips and advice on how to create a scalable EC2 environment using MySQL, including guides on setting up replication, see [Section 14.3.2.3, “Deploying a MySQL Database Using EC2”](#).

14.3.2.1. Setting Up MySQL on an EC2 AMI

There are many different ways of setting up an EC2 AMI with MySQL, including using any of the pre-configured AMIs supplied by Amazon.

The default *Getting Started* AMI provided by Amazon uses Fedora Core 4, and you can install MySQL by using `yum`:

```
shell> yum install mysql
```

This will install both the MySQL server and the Perl DBD::mysql driver for the Perl DBI API.

Alternatively, you can use one of the AMIs that include MySQL within the standard installation.

Finally, you can also install a standard version of MySQL downloaded from the MySQL website. The installation process and instructions are identical to any other installation of MySQL on Linux. See [Chapter 2, *Installing and Upgrading MySQL*](#).

The standard configuration for MySQL places the data files in the default location, `/var/lib/mysql`. The default data directory on an EC2 instance is `/mnt` (although on the large and extra large instance you can alter this configuration). You must edit `/etc/my.cnf` to set the `datadir` option to point to the larger storage area.

Important

The first time you use the main storage location within an EC2 instance it needs to be initialized. The initialization process starts automatically the first time you write to the device. You can start using the device right away, but the write performance of the new device is significantly lower on the initial writes until the initialization process has finished.

To avoid this problem when setting up a new instance, you should start the initialization process before populating your MySQL database. One way to do this is to use `dd` to write to the file system:

```
root-shell> dd if=/dev/zero of=initialize bs=1024M count=50
```

The preceding will create a 50GB on the file system and start the initialization process. You should delete the file once the process has finished.

The initialization process can be time-consuming. On the small instance, initialization will take between two and three hours. For the large and extra large drives, the initialization will be 10 or 20 hours, respectively.

In addition to configuring the correct storage location for your MySQL data files, you should also consider setting the following other settings in your instance before you save the instance configuration for deployment:

- Set the MySQL server ID so that when you use it for replication the ID information is set correctly.
- Enabling binary logging so that replication can be initialized without starting and stopping the server.
- Set the caching and memory parameters for your storage engines. There are no limitations or restrictions on what storage engines you use in your EC2 environment. Choose a configuration, possibly using one of the standard configurations provided with MySQL appropriate for the instance on which you expect to deploy. The large and extra large instances have RAM that can be dedicated to caching. Be aware that if you choose to install [memcached](#) on the servers as part of your application stack you must ensure there is enough memory for both MySQL and [memcached](#).

Once you have configured your AMI with MySQL and the rest of your application stack, you should save the AMI so that you can deploy and reuse the instance.

Once you have your application stack configured in an AMI, populating your MySQL database with data should be performed by creating a dump of your database using [mysqldump](#), transferring the dump to the EC2 instance, and then reloading the information into the EC2 instance database.

Before using your instance with your application in a production situation you should be aware of the limitations of the EC2 instance environment. See [Section 14.3.2.2, “EC2 Instance Limitations”](#). To begin using your MySQL AMI, you should consult the notes on deployment. See [Section 14.3.2.3, “Deploying a MySQL Database Using EC2”](#).

14.3.2.2. EC2 Instance Limitations

There are some limitations of the EC2 instances that you should be aware of before deploying your applications. Although these shouldn't affect your ability to deploy within the Amazon EC2 environment, they may alter the way you setup and configure your environment to support your application.

- Data stored within instances is not persistent. If you create an instance and populate the instance with data, then the data will only remain in place while the machine is running. The data will survive a reboot. If you shut down the instance, any data it contained will be lost.

To ensure that you do not lose information, take regular backups using [mysqldump](#). If the data being stored is critical, consider using replication to keep a “live” backup of your data in the event of a failure. When creating a backup, write the data to the Amazon S3 service to avoid the transfer charges applied when copying data offsite.

- EC2 instances are not persistent. If the hardware on which an instance is running fails, then the instance will be shut down. This can lead to loss of data or service.
- If you want to use replication with your EC2 instances to a non-EC2 environment, be aware of the transfer costs to and from the EC2 service. Data transfer between different EC2 instances is free, so using replication within the EC2 environment does not incur additional charges.
- Certain HA features are either not directly supported, or have limiting factors or problems that may reduce their utility. For example, using DRBD or MySQL Cluster may not work. The default storage configuration is also not redundant. You can use software-based RAID to improve redundancy, but this implies a further performance hit.

14.3.2.3. Deploying a MySQL Database Using EC2

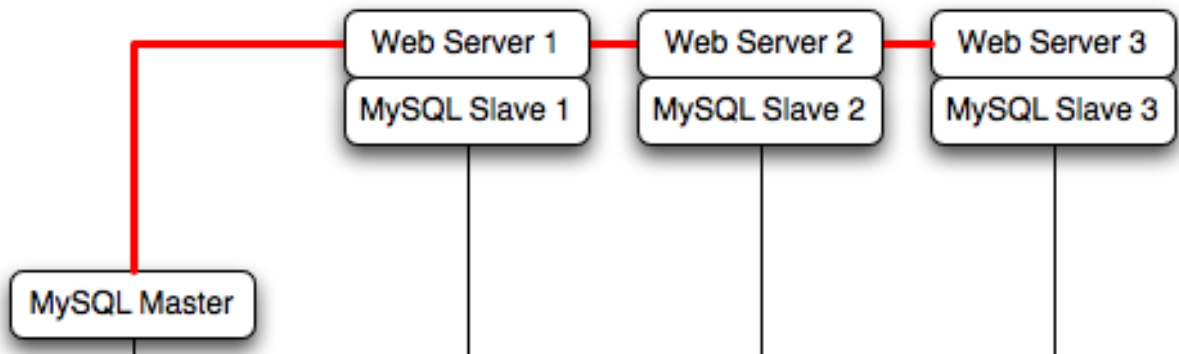

Because you cannot guarantee the uptime and availability of your EC2 instances, when deploying MySQL within the EC2 environment you should use an approach that enables you to easily distribute work among your EC2 instances. There are a number of ways of doing this. Using sharding techniques, where you split the application across multiple servers dedicating specific blocks of your dataset and users to different servers is an effective way of doing this. As a general rule, it is easier to create more EC2 instances to support more users than to upgrade the instance to a larger machine.

The EC2 architecture means that you should treat the EC2 instances as temporary, cache-based solutions, rather than as a long-term, high availability solution. In addition to using multiple machines, you should also take advantage of other services, such as [memcached](#) to provide additional caching for your application to help reduce the load on the MySQL server so that it can concentrate on writes. On the large and extra large instances within EC2, the RAM available can be used to provide a large memory cache for data.

Most types of scale out topology that you would use with your own hardware can be used and applied within the EC2 environment. However, you should be use the limitations and advice already given to ensure that any potential failures do not lose you any data. Also, because the relative power of each EC2 instance is so low, you should be prepared to alter your application to use sharding

and add further EC2 instances to improve the performance of your application.

For example, take the typical scale-out environment shown following, where a single master replicates to one or more slaves (three in this example), with a web server running on each replication slave.

You can reproduce this structure completely within the EC2 environment, using an EC2 instance for the master, and one instance for each of the web and MySQL slave servers.

Note

Within the EC2 environment, internal (private) IP addresses used by the EC2 instances are constant. You should always use these internal addresses and names when communicating between instances. Only use public IP addresses when communicating with the outside world - for example, when publicizing your application.

To ensure reliability of your database, you should add at least one replication slave dedicated to providing an active backup and storage to the Amazon S3 facility. You can see an example of this in the following topology.

Using [memcached](#) within your EC2 instances should provide better performance. The large and extra large instances have a significant amount of RAM. To use [memcached](#) in your application, when loading information from the database, first check whether the item exists in the cache. If the data you are looking for exists in the cache, use it. If not, reload the data from the database and populate the cache.

Sharding divides up data in your entire database by allocating individual machines or machine groups to provide a unique set of data according to an appropriate group. For example, you might put all users with a surname ending in the letters A-D onto a single server. When a user connects to the application and their surname is known, queries can be redirected to the appropriate MySQL server.

When using sharding with EC2 you should separate the web server and MySQL server into separate EC2 instances, and then apply the sharding decision logic into your application. Once you know which MySQL server you should be using for accessing the data you then distribute queries to the appropriate server. You can see a sample of this in the following illustration.

**Warning**

With sharding and EC2 you should be careful that the potential for failure of an instance does not affect your application. If the EC2 instance that provides the MySQL server for a particular shard fails, then all of the data on that shard will be unavailable.

14.3.3. Virtualization Resources

For more information on virtualization, see the following links:

- [MySQL Virtualization Forum](#)
- [Amazon Elastic Compute Cloud \(Amazon EC2\)](#)
- [MySQL and Cloud Computing](#)
- [MySQL Enterprise for Amazon EC2](#)

14.4. Using ZFS Replication

To support high availability environments, providing an instant copy of the information on both the currently active machine and the hot backup is a critical part of the HA solution. There are many solutions to this problem, including [Chapter 16, Replication](#) and [Section 14.1, “Using MySQL with DRBD”](#).

The ZFS filesystem provides functionality that allows you to create a snapshot of the filesystem contents and to then transfer the snapshot to another machine and extract the snapshot to recreate the filesystem. You can create a snapshot at any time, and you can create as many snapshots as you like. By continually creating, transferring and restoring snapshots you can provide synchronization between one or more machines in a fashion similar to DRBD.

To understand the replication solution within ZFS, you must first understand the ZFS environment. Below is a simple OpenSolaris system running with two pools, the `root` pool and another pool mounted at `/opt`:

```

Filesystem      size  used  avail capacity  Mounted on
rpool/ROOT/opensolaris-1
                 7.3G  3.6G  508M   88%      /
  
```

/devices	0K	0K	0K	0%	/devices
/dev	0K	0K	0K	0%	/dev
ctfs	0K	0K	0K	0%	/system/contract
proc	0K	0K	0K	0%	/proc
mnttab	0K	0K	0K	0%	/etc/mnttab
swap	465M	312K	465M	1%	/etc/svc/volatile
objfs	0K	0K	0K	0%	/system/object
sharefs	0K	0K	0K	0%	/etc/dfs/sharetab
/usr/lib/libc/libc_hwcapi.so.1					
	4.1G	3.6G	508M	88%	/lib/libc.so.1
fd	0K	0K	0K	0%	/dev/fd
swap	466M	744K	465M	1%	/tmp
swap	465M	40K	465M	1%	/var/run
rpool/export	7.3G	19K	508M	1%	/export
rpool/export/home	7.3G	1.5G	508M	75%	/export/home
rpool	7.3G	60K	508M	1%	/rpool
rpool/ROOT	7.3G	18K	508M	1%	/rpool/ROOT
opt	7.8G	1.0G	6.8G	14%	/opt

The MySQL data will be stored in a directory on `/opt`. To help demonstrate some of the basic replication functionality, there are also other items stored in `/opt` as well:

```
total 17
drwxr-xr-x  31 root   bin          50 Jul 21 07:32 DTT/
drwxr-xr-x   4 root   bin           5 Jul 21 07:32 SUNWmlib/
drwxr-xr-x  14 root   sys          16 Nov  5 09:56 SUNWspro/
drwxrwxrwx  19 1000  1000         40 Nov  6 19:16 emacs-22.1/
```

To create a snapshot of the filesystem, you use `zfs snapshot`, and then specify the pool and the snapshot name:

```
root-shell> zfs snapshot opt@snap1
```

To get a list of snapshots already taken:

```
root-shell> zfs list -t snapshot
NAME                                USED  AVAIL  REFER  MOUNTPOINT
opt@snap1                           0      -    1.03G  -
rpool@install                        19.5K  -      55K   -
rpool/ROOT@install                   15K    -      18K   -
rpool/ROOT/opensolaris-1@install     59.8M  -     2.22G  -
rpool/ROOT/opensolaris-1@opensolaris-1 100M   -     2.29G  -
rpool/ROOT/opensolaris-1/opt@install  0      -     3.61M  -
rpool/ROOT/opensolaris-1/opt@opensolaris-1 0      -     3.61M  -
rpool/export@install                 15K    -      19K   -
rpool/export/home@install            20K    -      21K   -
```

The snapshots themselves are stored within the filesystem metadata, and the space required to keep them will vary as time goes on because of the way the snapshots are created. The initial creation of a snapshot is really quick, because instead of taking an entire copy of the data and metadata required to hold the entire snapshot, ZFS merely records the point in time and metadata of when the snapshot was created.

As more changes to the original filesystem are made, the size of the snapshot increases because more space is required to keep the record of the old blocks. Furthermore, if you create lots of snapshots, say one per day, and then delete the snapshots from earlier in the week, the size of the newer snapshots may also increase, as the changes that make up the newer state have to be included in the more recent snapshots, rather than being spread over the seven snapshots that make up the week.

The only issue, from a backup perspective, is that snapshots exist within the confines of the original filesystem. To get the snapshot out into a format that you can copy to another filesystem, tape, etc. you use the `zfs send` command to create a stream version of the snapshot.

For example, to write out the snapshot to a file:

```
root-shell> zfs send opt@snap1 >/backup/opt-snap1
```

Or tape:

```
root-shell> zfs send opt@snap1 >/dev/rmt/0
```

You can also write out the incremental changes between two snapshots using `zfs send`:

```
root-shell> zfs send opt@snap1 opt@snap2 >/backup/opt-changes
```

To recover a snapshot, you use `zfs recv` which applies the snapshot information either to a new filesystem, or to an existing one.

14.4.1. Using ZFS for Filesystem Replication

Because `zfs send` and `zfs recv` use streams to exchange data, you can use them to replicate information from one system to another by combining `zfs send`, `ssh`, and `zfs recv`.

For example, if a snapshot of the `opt` filesystem has been created and this needs to be copied to a new system or filesystem called `slavepool`. You would use the following command, combining the snapshot of `opt`, the transmission to the slave machine (using `ssh`), and the recovery of the snapshot on the slave using `zfs recv`:

```
root-shell> zfs send opt@snap1 | ssh mc@slave pfexec zfs recv -F slavepool
```

The first part, `zfs send opt@snap1`, streams the snapshot, the second, `ssh mc@slave`, and the third, `pfexec zfs recv -F slavepool`, receives the streamed snapshot data and writes it to `slavepool`. In this instance, I've specified the `-F` option which forces the snapshot data to be applied, and is therefore destructive. This is fine, as I'm creating the first version of my replicated filesystem.

On the slave machine, the replicated filesystem contains the exact same content:

```
root-shell> ls -al /slavepool/
total 23
drwxr-xr-x  6 root  root      7 Nov  8 09:13 ./
drwxr-xr-x 29 root  root     34 Nov  9 07:06 ../
drwxr-xr-x 31 root  bin     50 Jul 21 07:32 DTT/
drwxr-xr-x  4 root  bin     5 Jul 21 07:32 SUNWmlib/
drwxr-xr-x 14 root  sys    16 Nov  5 09:56 SUNWspro/
drwxrwxrwx 19 1000 1000   40 Nov  6 19:16 emacs-22.1/
```

Once a snapshot has been created, to synchronize the filesystem again, you need to create a new snapshot, and then use the incremental snapshot feature of `zfs send` to send the changes between the two snapshots to the slave machine again:

```
root-shell> zfs send -i opt@snapshot1 opt@snapshot2 | ssh mc@192.168.0.93 pfexec zfs recv slavepool
```

Without further modification, this operation will fail. The reason is that the filesystem on the slave machine can currently be modified, and you can't apply the incremental changes to a destination filesystem that has changed. It is the metadata that has changed. The metadata about the filesystem, like the last time it was accessed - in this case, it will have been our `ls` that caused the problem.

To prevent changes on the slave filesystem, you must set the filesystem on the slave to be read-only:

```
root-shell> zfs set readonly=on slavepool
```

Setting `readonly` means that you cannot change the filesystem on the slave by normal means, including the filesystem metadata. Operations that would normally update metadata (like our `ls`) will silently perform their function without attempting to update the filesystem state.

In essence, the slave filesystem is nothing but a static copy of the original filesystem. However, even when configured to be read-only, a filesystem can have snapshots applied to it. Now the filesystem is read only, re-run the initial copy:

```
root-shell> zfs send opt@snap1 | ssh mc@slave pfexec zfs recv -F slavepool
```

Now you can make changes to the original filesystem and replicate them to the slave.

14.4.2. Configuring MySQL for ZFS Replication

Configuring MySQL on the source filesystem is a case of creating the data on the filesystem that you will be replicating. The configuration file in the example below has been updated to use `/opt/mysql-data` as the data directory, and now I can initialize the tables:

```
root-shell> mysql_install_db --defaults-file=/etc/mysql/5.0/my.cnf --user=mysql
```

To synchronize the initial information, perform a new snapshot and then send an incremental snapshot to the slave using `zfs send`:

```
root-shell> zfs snapshot opt@snap2
root-shell> zfs send -i opt@snap1 opt@snap2 | ssh mc@192.168.0.93 pfexec zfs recv slavepool
```

Double check that the slave has the data by looking at the MySQL data directory on the `slavepool`:

```
root-shell> ls -al /slavepool/mysql-data/
```

Now we can start up MySQL, create some data, and then replicate the changes using `zfs send/ zfs recv` to the slave to synchronize the changes.

The rate at which you perform the synchronization is dependent on your application and environment. The limitation is the speed required to perform the snapshot and then to send the changes over the network.

To automate the process, you should create a script that performs the snapshot, send, and receive operation, and then use `cron` to synchronize the changes at set times or intervals. For automated operations, see [Tim Foster's zfs replication tool](#).

14.4.3. Handling MySQL Recovery with ZFS

When using ZFS replication to provide a constant copy of your data, you should ensure that you can recover your tables, either manually or automatically, in the event of a failure of the original system.

In the event of a failure, you should follow this sequence:

1. Stop the script on the master, if it is still up and running.
2. Set the slave filesystem to be read/write:

```
root-shell> zfs set readonly=off slavepool
```

3. Start up `mysqld` on the slave. If you are using `InnoDB`, `Falcon` or `Maria` you should get auto-recovery, if it is needed, to make sure the table data is correct, as shown here when I started up from our mid-INSERT snapshot:

```
InnoDB: The log sequence number in ibdata files does not match
InnoDB: the log sequence number in the ib_logfiles!
081109 15:59:59 InnoDB: Database was not shut down normally!
InnoDB: Starting crash recovery.
InnoDB: Reading tablespace information from the .ibd files...
InnoDB: Restoring possible half-written data pages from the doublewrite
InnoDB: buffer...
081109 16:00:03 InnoDB: Started; log sequence number 0 1142807951
081109 16:00:03 [Note] /slavepool/mysql-5.0.67-solaris10-i386/bin/mysqld: ready for connections.
Version: '5.0.67' socket: '/tmp/mysql.sock' port: 3306 MySQL Community Server (GPL)
```

On MyISAM, or other tables, you may need to run `REPAIR TABLE`, and you might even have lost some information. You should use a recovery-capable storage engine and a regular synchronization schedule to reduce the risk for significant data loss.

14.5. Using MySQL with `memcached`

The largest problem with scalability within a typical environment is the speed with which you can access information. For frequently accessed information, using MySQL can be slow because each access of information requires execution of the SQL query and recovery of the information from the database. This also means that queries on tables that are locked or blocking may delay your query and reduce the speed of recovery of information.

`memcached` is a simple, yet highly-scalable key-based cache that stores data and objects wherever dedicated or spare RAM is available for very quick access by applications. To use, you run `memcached` on one or more hosts and then use the shared cache to store objects. Because each host's RAM is storing information, the access speed will be much faster than having to load the information from disk. This can provide a significant performance boost in retrieving data versus loading the data natively from a database. Also, because the cache is just a repository for information, you can use the cache to store any data, including complex structures that would normally require a significant amount of effort to create, but in a ready-to-use format, helping to reduce the load on your MySQL servers.

The typical usage environment is to modify your application so that information is read from the cache provided by `memcached`. If the information isn't in `memcached`, then the data is loaded from the MySQL database and written into the cache so that future requests for the same object benefit from the cached data.

For a typical deployment layout, see [Figure 14.4, "memcached Architecture Overview"](#).

Figure 14.4. `memcached` Architecture Overview

In the example structure, any of the clients can contact one of the `memcached` servers to request a given key. Each client is configured to talk to all of the servers shown in the illustration. Within the client, when the request is made to store the information, the key used to reference the data is hashed and this hash is then used to select one of the `memcached` servers. The selection of the `memcached` server takes place on the client before the server is contacted, keeping the process lightweight.

The same algorithm is used again when a client requests the same key. The same key will generate the same hash, and the same `memcached` server will be selected as the source for the data. Using this method, the cached data is spread among all of the `memcached` servers, and the cached information is accessible from any client. The result is a distributed, memory-based, cache that can return information, particularly complex data and structures, much faster than natively reading the information from the database.

The data held within a `memcached` server is never stored on disk (only in RAM, which means there is no persistence of data), and the RAM cache is always populated from the backing store (a MySQL database). If a `memcached` server fails, the data can always be recovered from the MySQL database, albeit at a slower speed than loading the information from the cache.

14.5.1. Installing `memcached`

You can build and install `memcached` from the source code directly, or you can use an existing operating system package or installation.

Installing `memcached` from a Binary Distribution

To install `memcached` on a RedHat, Fedora or CentOS host, use `yum`:

```
root-shell> yum install memcached
```

To install `memcached` on a Debian or Ubuntu host, use `apt-get`:

```
root-shell> apt-get install memcached
```

To install `memcached` on a Gentoo host, use `emerge`:

```
root-shell> emerge install memcached
```

To install on OpenSolaris, use the `pkg` command to install the `SUNWmemcached` package:

```
root-shell> pkg install SUNWmemcached
```

You may also find `memcached` in the Coolstack project. For more details, see <http://cooltools.sunsource.net/coolstack/>.

Building `memcached` from Source

On other Unix-based platforms, including Solaris, AIX, HP-UX and Mac OS X, and Linux distributions not mentioned already, you will need to install from source. For Linux, make sure you have a 2.6-based kernel, which includes the improved `epoll` interface. For all platforms, ensure that you have `libevent` 1.1 or higher installed. You can obtain `libevent` from [libevent web page](#).

You can obtain the source for `memcached` from [memcached website](#).

To build `memcached`, follow these steps:

1. Extract the `memcached` source package:

```
shell> gunzip -c memcached-1.2.5.tar.gz | tar xf -
```

2. Change to the `memcached-1.2.5` directory:

```
shell> cd memcached-1.2.5
```

3. Run `configure`

```
shell> ./configure
```

Some additional options you may want to specify to `configure`:

- `--prefix`

If you want to specify a different installation directory, use the `--prefix` option:

```
shell> ./configure --prefix=/opt
```

The default is to use the `/usr/local` directory.

- `--with-libevent`

If you have installed `libevent` and `configure` cannot find the library, use the `--with-libevent` option to specify the location of the installed library.

- `--enable-64bit`

To build a 64-bit version of `memcached` (which will allow you to use a single instance with a large RAM allocation), use `--enable-64bit`.

- `--enable-threads`

To enable multi-threading support in `memcached`, which will improve the response times on servers with a heavy load, use `--enable-threads`. You must have support for the POSIX threads within your operating system to enable thread support. For more information on the threading support, see [Section 14.5.2.7, “memcached thread Support”](#).

- `--enable-dtrace`

`memcached` includes a range of DTrace threads that can be used to monitor and benchmark a `memcached` instance. For more information, see [Section 14.5.2.5, “Using memcached and DTrace”](#).

4. Run `make` to build `memcached`:

```
shell> make
```

5. Run `make install` to install `memcached`:

```
shell> make install
```

14.5.2. Using `memcached`

To start using `memcached`, you must start the `memcached` service on one or more servers. Running `memcached` sets up the server, allocates the memory and starts listening for connections from clients.

■ Note

You do not need to be privileged user (`root`) to run `memcached` unless you want to listen on one of the privileged TCP/IP ports (below 1024). You must, however, use a user that has not had their memory limits restricted using `setrlimit` or similar.

To start the server, run `memcached` as a non-privileged (i.e. non-root) user:

```
shell> memcached
```

By default, `memcached` uses the following settings:

- Memory allocation of 64MB
- Listens for connections on all network interfaces, using port 11211
- Supports a maximum of 1024 simultaneous connections

Typically, you would specify the full combination of options that you want when starting `memcached`, and normally provide a startup script to handle the initialization of `memcached`. For example, the following line starts `memcached` with a maximum of 1024MB RAM for the cache, listening on port 11211 on the IP address 192.168.0.110, running as a background daemon:

```
shell> memcached -d -m 1024 -p 11211 -l 192.168.0.110
```

To ensure that `memcached` is started up on boot you should check the init script and configuration parameters. On OpenSolaris, `memcached` is controlled by SMF. You can enable it by using:

```
root-shell> svcadm enable memcached
```

`memcached` supports the following options:

- `-u user`

If you start `memcached` as `root`, use the `-u` option to specify the user for executing `memcached`:

```
shell> memcached -u memcache
```

- `-m memory`

Set the amount of memory allocated to `memcached` for object storage. Default is 64MB.

To increase the amount of memory allocated for the cache, use the `-m` option to specify the amount of RAM to be allocated (in megabytes). The more RAM you allocate, the more data you can store and therefore the more effective your cache will be.

Warning

Do not specify a memory allocation larger than your available RAM. If you specify too large a value, then some RAM allocated for `memcached` will be using swap space, and not physical RAM. This may lead to delays when storing and retrieving values, because data will be swapped to disk, instead of storing the data directly in RAM.

You can use the output of the `vmstat` command to get the free memory, as shown in `free` column:

```
shell> vmstat
kthr      memory          page        disk          faults         cpu
r  b  w    swap free  re  mf  pi  po  fr  de  sr  sl  s2  --  --   in  sy   cs us  sy id
0  0  0  5170504 3450392 2   7   2  0  0  0  4  0  0  0  0  296  54  199  0  0 100
```

For example, to allocate 3GB of RAM:

```
shell> memcached -m 3072
```

On 32-bit x86 systems where you are using PAE to access memory above the 4GB limit, you will be unable to allocate RAM beyond the maximum process size. You can get around this by running multiple instances of `memcached`, each listening on a different port:

```
shell> memcached -m 1024 -p11211
shell> memcached -m 1024 -p11212
shell> memcached -m 1024 -p11213
```

- `-l interface`

Specify a network interface/address to listen for connections. The default is to listen on all available address (`INADDR_ANY`).

```
shell> memcached -l 192.168.0.110
```

Support for IPv6 address support was added in `memcached` 1.2.5.

- `-p port`

Specify the TCP port to use for connections. Default is 18080.

```
shell> memcached -p 18080
```

- `-U port`

Specify the UDP port to use for connections. Default is 0 (off).

```
shell> memcached -U 18080
```

- `-s socket`

Specify a Unix socket to listen on.

If you are running `memcached` on the same server as the clients, you can disable the network interface and use a local UNIX socket using the `-s` option:

```
shell> memcached -s /tmp/memcached
```

Using a UNIX socket automatically disables network support, and saves network ports (allowing more ports to be used by your web server or other process).

- `-a mask`

Specify the access mask to be used for the Unix socket, in octal. Default is 0700.

- `-c connections`

Specify the maximum number of simultaneous connections to the `memcached` service. The default is 1024.

```
shell> memcached -c 2048
```

You should use this option, either to reduce the number of connections (to prevent overloading `memcached` service) or to increase the number to make more effective use of the server running `memcached` server.

- `-t threads`

Specify the number of threads to use when processing incoming requests.

By default, `memcached` is configured to use 4 concurrent threads. The threading improves the performance of storing and retrieving data in the cache, using a locking system to prevent different threads overwriting or updating the same values. You may want to increase or decrease the number of threads, use the `-t` option:

```
shell> memcached -t 8
```

- `-d`

Run `memcached` as a daemon (background) process:

```
shell> memcached -d
```

- `-r`

Maximize the size of the core file limit. In the event of a failure, this will attempt to dump the entire memory space to disk as a core file, up to any limits imposed by `setrlimit`.

- `-M`

Return an error to the client when the memory has been exhausted. This replaces the normal behavior of removing older items

from the cache to make way for new items.

- `-k`

Lock down all paged memory.

Note

There is a user-level limit on how much memory you may lock. Trying to allocate more than the available memory will fail. You can set the limit for the user you started the daemon with (not for the `-u user` user) within the shell by using `ulimit -S -l NUM_KB`

- `-v`

Verbose mode. Prints errors and warnings while executing the main event loop.

- `-vv`

Very verbose mode. In addition to information printed by `-v`, also prints each client command and the response.

- `-h`

Print the help message and exit.

- `-i`

Print the `memcached` and `libevent` license.

- `-b`

Run a managed instance.

- `-P pidfile`

Save the process ID of the `memcached` instance into `file`.

- `-f`

Set the chunk size growth factor. When allocating new memory chunks, the allocated size of new chunks will be determined by multiple the default slab size by this factor.

- `-n bytes`

The minimum space allocated for the key+value+flags information. The default is 48 bytes.

- `-L`

On systems that support large memory pages, enables large memory page use. Using large memory pages enables `memcached` to allocate the item cache in one large chunk, which can improve the performance by reducing the number misses when accessing memory.

14.5.2.1. `memcached` Deployment

When using `memcached` you can use a number of different potential deployment strategies and topologies. The exact strategy you use will depend on your application and environment. When developing a system for deploying `memcached` within your system, you should keep in mind the following points:

- `memcached` is only a caching mechanism. It shouldn't be used to store information that you cannot otherwise afford to lose and then load from a different location.
- There is no security built into the `memcached` protocol. At a minimum you should make sure that the servers running `memcached` are only accessible from inside your network, and that the network ports being used are blocked (using a firewall or similar). If the information on the `memcached` servers that is being stored is any sensitive, then encrypt the information before storing it in `memcached`.
- `memcached` does not provide any sort of failover. Because there is no communication between different `memcached` instances. If an instance fails, your application must be capable of removing it from the list, reloading the data and then writing data to another `memcached` instance.

- Latency between the clients and the `memcached` can be a problem if you are using different physical machines for these tasks. If you find that the latency is a problem, move the `memcached` instances to be on the clients.
- Key length is determined by the `memcached` server. The default maximum key size is 250 bytes.
- Using a single `memcached` instance, especially for multiple clients, is generally a bad idea as it introduces a single point of failure. Instead provide at least two `memcached` instances so that a failure can be handled appropriately. If possible, you should create as many `memcached` nodes as possible. When adding and removing `memcached` instances from a pool, the hashing and distribution of key/value pairs may be affected. For information on how to avoid problems, see [Section 14.5.2.4, “memcached Distribution Types”](#).

14.5.2.2. Using namespaces

The `memcached` cache is a very simple massive key/value storage system, and as such there is no way of compartmentalizing data automatically into different sections. For example, if you are storing information by the unique ID returned from a MySQL database, then storing the data from two different tables will run into issues because the same ID will probably be valid in both tables.

Some interfaces provide an automated mechanism for creating *namespaces* when storing information into the cache. In practice, these namespaces are merely a prefix before a given ID that is applied every time a value is stored or retrieve from the cache.

You can implement the same basic principle by using keys that describe the object and the unique identifier within the key that you supply when the object is stored. For example, when storing user data, prefix the ID of the user with `user:` or `user-`.

Note

Using namespaces or prefixes only controls the keys stored/retrieved. There is no security within `memcached`, and therefore no way to enforce that a particular client only accesses keys with a particular namespace. Namespaces are only useful as a method of identifying data and preventing corruption of key/value pairs.

14.5.2.3. Data Expiry

There are two types of data expiry within a `memcached` instance. The first type is applied at the point when you store a new key/value pair into the `memcached` instance. If there is not enough space within a suitable slab to store the value, then an existing least recently used (LRU) object is removed (evicted) from the cache to make room for the new item.

The LRU algorithm ensures that the object that is removed is one that is either no longer in active use or that was used so long ago that its data is potentially out of date or of little value. However, in a system where the memory allocated to `memcached` is smaller than the number of regularly used objects required in the cache you will see a lot of expired items being removed from the cache even though they are in active use. You use the statistics mechanism to get a better idea of the level of evictions (expired objects). For more information, see [Section 14.5.4, “Getting memcached Statistics”](#).

You can change this eviction behavior by setting the `-M` command-line option when starting `memcached`. This option forces an error to be returned when the memory has been exhausted, instead of automatically evicting older data.

The second type of expiry system is an explicit mechanism that you can set when a key/value pair is inserted into the cache, or when deleting an item from the cache. Using an expiration time can be a useful way of ensuring that the data in the cache is up to date and in line with your application needs and requirements.

A typical scenario for explicitly setting the expiry time might include caching session data for a user when accessing a website. `memcached` uses a lazy expiry mechanism where the explicit expiry time that has been set is compared with the current time when the object is requested. Only objects that have not expired are returned.

You can also set the expiry time when explicitly deleting an object from the cache. In this case, the expiry time is really a timeout and indicates the period when any attempts to set the value for a given key are rejected.

14.5.2.4. memcached Distribution Types

The `memcached` client interface supports a number of different distribution algorithms that are used in multi-server configurations to determine which host should be used when setting or getting data from a given `memcached` instance. When you get or set a value, a hash is constructed from the supplied key and then used to select a host from the list of configured servers. Because the hashing mechanism uses the supplied key as the basis for the hash, the selected server will be the same during both set and get operations.

For example, if you have three servers, A, B, and C, and you set the value `myid`, then the `memcached` client will create a hash based on the ID and select server B. When the same key is requested, the same hash is generated, and the same server, B, will be selected to request the value.

Because the hashing mechanism is part of the client interface, not the server interface, the hashing process and selection is very fast. By performing the hashing on the client, it also means that if you want to access the same data by the same ID from the same

list of servers but from different client interfaces, you must use the same or compatible hashing mechanisms. If you do not use the same hashing mechanism then the same data may be recorded on different servers by different interfaces, both wasting space on your `memcached` and leading to potential differences in the information.

Note

One way to use a multi-interface compatible hashing mechanism is to use the `libmemcached` library and the associated interfaces. Because the interfaces for the different languages (including C, Ruby, Perl and Python) are using the same client library interface, they will always generate the same hash code from the ID.

One issue with the client-side hashing mechanism is that when using multiple servers and extending or shrinking the list of servers that you have configured for use with `memcached`, the resulting hash may change. For example, if you have servers A, B, and C; the computed hash for key `myid` may equate to server B. If you add another server, D, into this list, then computing the hash for the same ID again may result in the selection of server D for that key.

This means that servers B and D both contain the information for key `myid`, but there may be differences between the data held by the two instances. A more significant problem is that you will get a much higher number of cache-misses when retrieving data as the addition of a new server will change the distribution of keys, and this will in turn require rebuilding the cached data on the `memcached` instances and require an increase in database reads.

For this reason, there are two common types of hashing algorithm, *consistent* and *modula*.

With *consistent* hashing algorithms, the same key when applied to a list of servers will always use the same server to store or retrieve the keys, even if the list of configured servers changes. This means that you can add and remove servers from the configure list and always use the same server for a given key. There are two types of consistent hashing algorithms available, Ketama and Wheel. Both types are supported by `libmemcached`, and implementations are available for PHP and Java.

There are some limitations with any consistent hashing algorithm. When adding servers to an existing list of configured servers, then keys will be distributed to the new servers as part of the normal distribution. When removing servers from the list, the keys will be re-allocated to another server within the list, which will mean that the cache will need to be re-populated with the information. Also, a consistent hashing algorithm does not resolve the issue where you want consistent selection of a server across multiple clients, but where each client contains a different list of servers. The consistency is enforced only within a single client.

With a *modula* hashing algorithm, the client will select a server by first computing the hash and then choosing a server from the list of configured servers. As the list of servers changes, so the server selected when using a modula hashing algorithm will also change. The result is the behavior described above; changes to the list of servers will mean different servers are selected when retrieving data leading to cache misses and increase in database load as the cache is re-seeded with information.

If you use only a single `memcached` instance for each client, or your list of `memcached` servers configured for a client never changes, then the selection of a hashing algorithm is irrelevant, as you will not notice the effect.

If you change your servers regularly, or you use a common set of servers that are shared among a large number of clients, then using a consistent hashing algorithm should help to ensure that your cache data is not duplicated and the data is evenly distributed.

14.5.2.5. Using `memcached` and DTrace

`memcached` includes a number of different DTrace probes that can be used to monitor the operation of the server. The probes included can monitor individual connections, slab allocations, and modifications to the hash table when a key/value pair is added, updated, or removed.

For more information on DTrace and writing DTrace scripts, read the [DTrace User Guide](#).

Support for DTrace probes was added to `memcached` 1.2.6 includes a number of DTrace probes that can be used to help monitor your application. DTrace is supported on Solaris 10, OpenSolaris, Mac OS X 10.5 and FreeBSD. To enable the DTrace probes in `memcached`, you should build from source and use the `--enable-dtrace` option. For more information, see [Section 14.5.1, "Installing memcached"](#).

The probes supported by `memcached` are:

- `conn-allocate(connid)`

Fired when a connection object is allocated from the connection pool.

- `connid` — the connection id
- `conn-release(connid)`

Fired when a connection object is released back to the connection pool.

Arguments:

- `connid` — the connection id
- `conn-create(ptr)`

Fired when a new connection object is being created (i.e. there are no free connection objects in the connection pool).

Arguments:

- `ptr` — pointer to the connection object
- `conn-destroy(ptr)`

Fired when a connection object is being destroyed.

Arguments:

- `ptr` — pointer to the connection object
- `conn-dispatch(connid, threadid)`

Fired when a connection is dispatched from the main or connection-management thread to a worker thread.

Arguments:

- `connid` — the connection id
- `threadid` — the thread id
- `slabs-allocate(size, slabclass, slabsize, ptr)`

Allocate memory from the slab allocator

Arguments:

- `size` — the requested size
- `slabclass` — the allocation will be fulfilled in this class
- `slabsize` — the size of each item in this class
- `ptr` — pointer to allocated memory
- `slabs-allocate-failed(size, slabclass)`

Failed to allocate memory (out of memory)

Arguments:

- `size` — the requested size
- `slabclass` — the class that failed to fulfill the request
- `slabs-slabclass-allocate(slabclass)`

Fired when a slab class needs more space

Arguments:

- `slabclass` — class that needs more memory
- `slabs-slabclass-allocate-failed(slabclass)`

Failed to allocate memory (out of memory)

Arguments:

- `slabclass` — the class that failed grab more memory
- `slabs-free(size, slabclass, ptr)`

Release memory

Arguments:

- `size` — the size of the memory
- `slabclass` — the class the memory belongs to
- `ptr` — pointer to the memory to release
- `assoc-find(key, depth)`

Fired when the when we have searched the hash table for a named key. These two elements provide an insight in how well the hash function operates. Traversals are a sign of a less optimal function, wasting cpu capacity.

Arguments:

- `key` — the key searched for
- `depth` — the depth in the list of hash table
- `assoc-insert(key, nokeys)`

Fired when a new item has been inserted.

Arguments:

- `key` — the key just inserted
- `nokeys` — the total number of keys currently being stored, including the key for which insert was called.
- `assoc-delete(key, nokeys)`

Fired when a new item has been removed.

Arguments:

- `key` — the key just deleted
- `nokeys` — the total number of keys currently being stored, excluding the key for which delete was called.
- `item-link(key, size)`

Fired when an item is being linked in the cache

Arguments:

- `key` — the items key
- `size` — the size of the data
- `item-unlink(key, size)`

Fired when an item is being deleted

Arguments:

- `key` — the items key
- `size` — the size of the data
- `item-remove(key, size)`

Fired when the refcount for an item is reduced

Arguments:

- `key` — the items key
- `size` — the size of the data

- `item-update(key, size)`

Fired when the "last referenced" time is updated

Arguments:

- `key` — the items key
- `size` — the size of the data

- `item-replace(oldkey, oldsize, newkey, newsize)`

Fired when an item is being replaced with another item

Arguments:

- `oldkey` — the key of the item to replace
- `oldsize` — the size of the old item
- `newkey` — the key of the new item
- `newsize` — the size of the new item

- `process-command-start(connid, request, size)`

Fired when the processing of a command starts

Arguments:

- `connid` — the connection id
- `request` — the incoming request
- `size` — the size of the request

- `process-command-end(connid, response, size)`

Fired when the processing of a command is done

Arguments:

- `connid` — the connection id
- `response` — the response to send back to the client
- `size` — the size of the response

- `command-get(connid, key, size)`

Fired for a get-command

Arguments:

- `connid` — connection id
- `key` — requested key
- `size` — size of the key's data (or -1 if not found)

- `command-gets(connid, key, size, casid)`

Fired for a gets command

Arguments:

- `connid` — connection id
- `key` — requested key
- `size` — size of the key's data (or -1 if not found)

- `casid` — the casid for the item
- `command-add(connid, key, size)`
Fired for a add-command
Arguments:
 - `connid` — connection id
 - `key` — requested key
 - `size` — the new size of the key's data (or -1 if not found)
- `command-set(connid, key, size)`
Fired for a set-command
Arguments:
 - `connid` — connection id
 - `key` — requested key
 - `size` — the new size of the key's data (or -1 if not found)
- `command-replace(connid, key, size)`
Fired for a replace-command
Arguments:
 - `connid` — connection id
 - `key` — requested key
 - `size` — the new size of the key's data (or -1 if not found)
- `command-prepend(connid, key, size)`
Fired for a prepend-command
Arguments:
 - `connid` — connection id
 - `key` — requested key
 - `size` — the new size of the key's data (or -1 if not found)
- `command-append(connid, key, size)`
Fired for a append-command
Arguments:
 - `connid` — connection id
 - `key` — requested key
 - `size` — the new size of the key's data (or -1 if not found)
- `command-cas(connid, key, size, casid)`
Fired for a cas-command
Arguments:
 - `connid` — connection id
 - `key` — requested key

- `size` — size of the key's data (or -1 if not found)
- `casid` — the cas id requested
- `command-incr(connid, key, val)`

Fired for incr command

Arguments:

- `connid` — connection id
- `key` — the requested key
- `val` — the new value
- `command-decr(connid, key, val)`

Fired for decr command

Arguments:

- `connid` — connection id
- `key` — the requested key
- `val` — the new value
- `command-delete(connid, key, exptime)`

Fired for a delete command

Arguments:

- `connid` — connection id
- `key` — the requested key
- `exptime` — the expiry time

14.5.2.6. Memory allocation within `memcached`

When you first start `memcached`, the memory that you have configured is not automatically allocated. Instead, `memcached` only starts allocating and reserving physical memory once you start saving information into the cache.

When you start to store data into the cache, `memcached` does not allocate the memory for the data on an item by item basis. Instead, a slab allocation is used to optimize memory usage and prevent memory fragmentation when information expires from the cache.

With slab allocation, memory is reserved in blocks of 1MB. The slab is divided up into a number of blocks of equal size. When you try to store a value into the cache, `memcached` checks the size of the value that you are adding to the cache and determines which slab contains the right size allocation for the item. If a slab with the item size already exists, the item is written to the block within the slab.

If the new item is bigger than the size of any existing blocks, then a new slab is created, divided up into blocks of a suitable size. If an existing slab with the right block size already exists, but there are no free blocks, a new slab is created. If you update an existing item with data that is larger than the existing block allocation for that key, then the key is re-allocated into a suitable slab.

For example, the default size for the smallest block is 88 bytes (40 bytes of value, and the default 48 bytes for the key and flag data). If the size of the first item you store into the cache is less than 40 bytes, then a slab with a block size of 88 bytes is created and the value stored.

If the size of the data that you want to store is larger than this value, then the block size is increased by the chunk size factor until a block size large enough to hold the value is determined. The block size is always a function of the scale factor, rounded up to a block size which is exactly divisible into the chunk size.

For a sample of the structure, see [Figure 14.5, “Memory Allocation in `memcached`”](#).

Figure 14.5. Memory Allocation in `memcached`

The result is that you have multiple pages allocated within the range of memory allocated to `memcached`. Each page is 1MB in size (by default), and will be split into a different number of chunks, according to the chunk size required to store the key/value pairs. Each instance will have multiple pages allocated, and a page will always be created when a new item needs to be created requiring a chunk of a particular size. A slab may consist of multiple pages, and each page within a slab will contain an equal number of chunks.

The chunk size of a new slab is determined by the base chunk size combined with the chunk size growth factor. For example, if the initial chunks are 104 bytes in size, and the default chunk size growth factor is used (1.25), then the next chunk size allocated would be the best power of 2 fit for $104 * 1.25$, or 136 bytes.

Allocating the pages in this way ensures that memory does not get fragmented. However, depending on the distribution of the objects that you want to store, it may lead to an inefficient distribution of the slabs and chunks if you have significantly different sized items. For example, having a relatively small number of items within each chunk size may waste a lot of memory with just few chunks in each allocated page.

You can tune the growth factor to reduce this effect by using the `-f` command line option. This will adapt the growth factor applied to make more effective use of the chunks and slabs allocated. For information on how to determine the current slab allocation statistics, see [Section 14.5.4.2, “memcached Slabs Statistics”](#).

If your operating system supports it, you can also start `memcached` with the `-L` command line option. With this option enabled, it will preallocate all the memory during startup using large memory pages. This can improve performance by reducing the number of misses in the CPU memory cache.

14.5.2.7. `memcached` thread Support

If you enable the thread implementation within when building `memcached` from source, then `memcached` will use multiple threads in addition to the `libevent` system to handle requests.

When enabled, the threading implementation operates as follows:

- Threading is handled by wrapping functions within the code to provide basic protection from updating the same global structures at the same time.
- Each thread uses its own instance of the `libevent` to help improve performance.
- TCP/IP connections are handled with a single thread listening on the TCP/IP socket. Each connection is then distribution to one of the active threads on a simple round-robin basis. Each connection then operates solely within this thread while the connection remains open.
- For UDP connections, all the threads listen to a single UDP socket for incoming requests. Threads that are not currently dealing with another request ignore the incoming packet. One of the remaining, non-busy, threads will read the request and send the response. This implementation can lead to increased CPU load as threads will wake from sleep to potentially process the request.

Using threads can increase the performance on servers that have multiple CPU cores available, as the requests to update the hash table can be spread between the individual threads. However, because of the locking mechanism employed you may want to experiment with different thread values to achieve the best performance based on the number and type of requests within your given workload.

14.5.3. `memcached` Interfaces

A number of interfaces from different languages exist for interacting with `memcached` servers and storing and retrieving information. Interfaces for the most common language platforms including Perl, PHP, Python, Ruby, C and Java.

Data stored into a `memcached` server is referred to by a single string (the key), with storage into the cache and retrieval from the cache using the key as the reference. The cache therefore operates like a large associative array or hash. It is not possible to structure or otherwise organize the information stored in the cache. If you want to store information in a structured way, you must use 'formatted' keys.

The following tips may be useful to you when using `memcached`:

The general sequence for using `memcached` in any language as a caching solution is as follows:

1. Request the item from the cache.
2. If the item exists, use the item data.
3. If the item does not exist, load the data from MySQL, and store the value into the cache. This means the value will be available to the next client that requests it from the cache.

For a flow diagram of this sequence, see [Figure 14.6, "Typical `memcached` Application Flowchart"](#).

Figure 14.6. Typical `memcached` Application Flowchart

The interface to `memcached` supports the following methods for storing and retrieving information in the cache, and these are consistent across all the different APIs, even though the language specific mechanics may be different:

- `get(key)` — retrieves information from the cache. Returns the value if it exists, or `NULL`, `nil`, or `undefined` or the closest equivalent in the corresponding language, if the specified key does not exist.
- `set(key, value [, expiry])` — sets the key in the cache to the specified value. Note that this will either update an existing key if it already exists, or add a new key/value pair if the key doesn't exist. If the expiry time is specified, then the key will expire (be deleted) when the expiry time is reached. The time should be specified in seconds, and is taken as a relative time if the value is less than 30 days ($30*24*60*60$), or an absolute time (epoch) if larger than this value.
- `add(key, value [, expiry])` — adds the key to the cache, if the specified key doesn't already exist.
- `replace(key, value [, expiry])` — replace the `value` of the specified `key`, only if the key already exists.
- `delete(key [, time])` — Deletes the `key` from the cache. If you supply a `time`, then adding a value with the specified `key` is blocked for the specified period.
- `incr(key [, value])` — Increment the specified `key` by one or the specified `value`.
- `decr(key [, value])` — Decrement the specified `key` by one or the specified `value`.
- `flush_all` — invalidates (or expires) all the current items in the cache. Technically they will still exist (they are not deleted), but they will be silently destroyed the next time you try to access them.

In all implementations, most or all of these functions are duplicated through the corresponding native language interface.

For all languages and interfaces, you should use `memcached` to store full items, rather than simply caching single rows of information from the database. For example, when displaying a record about an object (invoice, user history, or blog post), all the data for the associated entry should be loaded from the database, and compiled into the internal structure that would normally be required by the application. You then save the complete object into the cache.

Data cannot be stored directly, it needs to be serialized, and most interfaces will serialize the data for you. Perl uses `Storable`, PHP uses `serialize`, Python uses `cPickle` (or `Pickle`) and Java uses the `Serializable` interface. In most cases, the serialization interface used is customizable. If you want to share data stored in `memcached` instances between different language interfaces, consider using a common serialization solution such as JSON (Javascript Object Notation).

14.5.3.1. Using `libmemcached`

The `libmemcached` library provides both C and C++ interfaces to `memcached` and is also the basis for a number of different additional API implementations, including Perl, Python and Ruby. Understanding the core `libmemcached` functions can help when using these other interfaces.

The C library is the most comprehensive interface library for `memcached` and provides a wealth of functions and operational systems not always exposed in the other interfaces not based on the `libmemcached` library.

The different functions can be divided up according to their basic operation. In addition to functions that interface to the core API, there are a number of utility functions that provide extended functionality, such as appending and prepending data.

To build and install `libmemcached`, download the `libmemcached` package, run configure, and then build and install:

```
shell> tar xjf libmemcached-0.21.tar.gz
shell> cd libmemcached-0.21
shell> ./configure
shell> make
shell> make install
```

On many Linux operating systems, you can install the corresponding `libmemcached` package through the usual `yum`, `apt-get` or similar commands. On OpenSolaris, use `pkg` to install the `SUNWlibmemcached` package.

To build an application that uses the library, you need to first set the list of servers. You can do this either by directly manipulating the servers configured within the main `memcached_st` structure, or by separately populating a list of servers, and then adding this list to the `memcached_st` structure. The latter method is used in the following example. Once the server list has been set, you can call the functions to store or retrieve data. A simple application for setting a preset value to localhost is provided here:

```
#include <stdio.h>
#include <string.h>
#include <unistd.h>
#include <libmemcached/memcached.h>

int main(int argc, char *argv[])
{
    memcached_server_st *servers = NULL;
    memcached_st *memc;
    memcached_return rc;
    char *key= "keystring";
    char *value= "keyvalue";

    memcached_server_st *memcached_servers_parse (char *server_strings);
    memc= memcached_create(NULL);

    servers= memcached_server_list_append(servers, "localhost", 11211, &rc);
    rc= memcached_server_push(memc, servers);

    if (rc == MEMCACHED_SUCCESS)
        fprintf(stderr, "Added server successfully\n");
    else
        fprintf(stderr, "Couldn't add server: %s\n", memcached_strerror(memc, rc));

    rc= memcached_set(memc, key, strlen(key), value, strlen(value), (time_t)0, (uint32_t)0);

    if (rc == MEMCACHED_SUCCESS)
        fprintf(stderr, "Key stored successfully\n");
    else
        fprintf(stderr, "Couldn't store key: %s\n", memcached_strerror(memc, rc));

    return 0;
}
```

You can test the success of an operation by using the return value, or populated result code, for a given function. The value will always be set to `MEMCACHED_SUCCESS` if the operation succeeded. In the event of a failure, use the `memcached_strerror()` function to translate the result code into a printable string.

To build the application, you must specify the `memcached` library:

```
shell> gcc -o memc_basic memc_basic.c -lmemcached
```

Running the above sample application, after starting a `memcached` server, should return a success message:

```
shell> memc_basic
Added server successfully
Key stored successfully
```

14.5.3.1.1. libmemcached Base Functions

The base `libmemcached` functions allow you to create, destroy and clone the main `memcached_st` structure that is used to interface to the `memcached` servers. The main functions are defined below:

```
memcached_st *memcached_create (memcached_st *ptr);
```

Creates a new `memcached_st` structure for use with the other `libmemcached` API functions. You can supply an existing, static, `memcached_st` structure, or `NULL` to have a new structured allocated. Returns a pointer to the created structure, or `NULL` on failure.

```
void memcached_free (memcached_st *ptr);
```

Free the structure and memory allocated to a previously created `memcached_st` structure.

```
memcached_st *memcached_clone(memcached_st *clone, memcached_st *source);
```

Clone an existing `memcached` structure from the specified `source`, copying the defaults and list of servers defined in the structure.

14.5.3.1.2. libmemcached Server Functions

The `libmemcached` API uses a list of servers, stored within the `memcached_server_st` structure, to act as the list of servers used by the rest of the functions. To use `memcached`, you first create the server list, and then apply the list of servers to a valid `libmemcached` object.

Because the list of servers, and the list of servers within an active `libmemcached` object can be manipulated separately, you can update and manage server lists while an active `libmemcached` interface is running.

The functions for manipulating the list of servers within a `memcached_st` structure are given below:

```
memcached_return
memcached_server_add (memcached_st *ptr,
                    char *hostname,
                    unsigned int port);
```

Add a server, using the given `hostname` and `port` into the `memcached_st` structure given in `ptr`.

```
memcached_return
memcached_server_add_unix_socket (memcached_st *ptr,
                                char *socket);
```

Add a Unix socket to the list of servers configured in the `memcached_st` structure.

```
unsigned int memcached_server_count (memcached_st *ptr);
```

Return a count of the number of configured servers within the `memcached_st` structure.

```
memcached_server_st *
memcached_server_list (memcached_st *ptr);
```

Returns an array of all the defined hosts within a `memcached_st` structure.

```
memcached_return
memcached_server_push (memcached_st *ptr,
                    memcached_server_st *list);
```

Pushes an existing list of servers onto list of servers configured for a current `memcached_st` structure. This adds servers to the end of the existing list, and duplicates are not checked.

The `memcached_server_st` structure can be used to create a list of `memcached` servers which can then be applied individu-

ally to `memcached_st` structures.

```
memcached_server_st *
    memcached_server_list_append (memcached_server_st *ptr,
                                  char *hostname,
                                  unsigned int port,
                                  memcached_return *error);
```

Add a server, with `hostname` and `port`, to the server list in `ptr`. The result code is handled by the `error` argument, which should point to an existing `memcached_return` variable. The function returns a pointer to the returned list.

```
unsigned int memcached_server_list_count (memcached_server_st *ptr);
```

Return the number of the servers in the server list.

```
void memcached_server_list_free (memcached_server_st *ptr);
```

Free up the memory associated with a server list.

```
memcached_server_st *memcached_servers_parse (char *server_strings);
```

Parses a string containing a list of servers, where individual servers are separated by a comma and/or space, and where individual servers are of the form `server[:port]`. The return value is a server list structure.

14.5.3.1.3. libmemcached Set Functions

The set related functions within `libmemcached` provide the same functionality as the core functions supported by the `memcached` protocol. The full definition for the different functions is the same for all the base functions (add, replace, prepend, append). For example, the function definition for `memcached_set()` is:

```
memcached_return
    memcached_set (memcached_st *ptr,
                  const char *key,
                  size_t key_length,
                  const char *value,
                  size_t value_length,
                  time_t expiration,
                  uint32_t flags);
```

The `ptr` is the `memcached_st` structure. The `key` and `key_length` define the key name and length, and `value` and `value_length` the corresponding value and length. You can also set the expiration and optional flags. For more information, see [Section 14.5.3.1.5, “libmemcached Behaviors”](#).

The following table outlines the remainder of the set-related functions.

libmemcached Function	Equivalent to
<code>memcached_set(memc, key, key_length, value, value_length, expiration, flags)</code>	Generic <code>set()</code> operation.
<code>memcached_add(memc, key, key_length, value, value_length, expiration, flags)</code>	Generic <code>add()</code> function.
<code>memcached_replace(memc, key, key_length, value, value_length, expiration, flags)</code>	Generic <code>replace()</code> .
<code>memcached_prepend(memc, key, key_length, value, value_length, expiration, flags)</code>	Prepends the specified <code>value</code> before the current value of the specified <code>key</code> .
<code>memcached_append(memc, key, key_length, value, value_length, expiration, flags)</code>	Appends the specified <code>value</code> after the current value of the specified <code>key</code> .
<code>memcached_cas(memc, key, key_length, value, value_length, expiration, flags, cas)</code>	Overwrites the data for a given key as long as the corresponding <code>cas</code> value is still the same within the server.
<code>memcached_set_by_key(memc, master_key, master_key_length, key, key_length, value, value_length, expiration, flags)</code>	Similar to the generic <code>set()</code> , but has the option of an additional master key that can be used to identify an individual server.
<code>memcached_add_by_key(memc, master_key, master_key_length, key, key_length, value, value_length, expiration, flags)</code>	Similar to the generic <code>add()</code> , but has the option of an additional master key that can be used to identify an individual server.
<code>memcached_replace_by_key(memc, master_key, master_key_length, key, key_length, value, value_length, expiration, flags)</code>	Similar to the generic <code>replace()</code> , but has the option of an additional master key that can be used to identify an individual server.

libmemcached Function	Equivalent to
<code>memcached_prepend_by_key(memc, master_key, master_key_length, key, key_length, value, value_length, expiration, flags)</code>	Similar to the <code>memcached_prepend()</code> , but has the option of an additional master key that can be used to identify an individual server.
<code>memcached_append_by_key(memc, master_key, master_key_length, key, key_length, value, value_length, expiration, flags)</code>	Similar to the <code>memcached_append()</code> , but has the option of an additional master key that can be used to identify an individual server.
<code>memcached_cas_by_key(memc, master_key, master_key_length, key, key_length, value, value_length, expiration, flags)</code>	Similar to the <code>memcached_cas()</code> , but has the option of an additional master key that can be used to identify an individual server.

The `by_key` methods add two further arguments, the master key, to be used and applied during the hashing stage for selecting the servers. You can see this in the following definition:

```
memcached_return
memcached_set_by_key(memcached_st *ptr,
                    const char *master_key,
                    size_t master_key_length,
                    const char *key,
                    size_t key_length,
                    const char *value,
                    size_t value_length,
                    time_t expiration,
                    uint32_t flags);
```

All the functions return a value of type `memcached_return`, which you can compare against the `MEMCACHED_SUCCESS` constant.

14.5.3.1.4. libmemcached Get Functions

The `libmemcached` functions provide both direct access to a single item, and a multiple-key request mechanism that provides much faster responses when fetching a large number of keys simultaneously.

The main get-style function, which is equivalent to the generic `get()` is `memcached_get()`. The function a string pointer to the returned value for a corresponding key.

```
char *memcached_get (memcached_st *ptr,
                    const char *key, size_t key_length,
                    size_t *value_length,
                    uint32_t *flags,
                    memcached_return *error);
```

A multi-key get, `memcached_mget()`, is also available. Using a multiple key get operation is much quicker to do in one block than retrieving the key values with individual calls to `memcached_get()`. To start the multi-key get, you need to call `memcached_mget()`:

```
memcached_return
memcached_mget (memcached_st *ptr,
                char **keys, size_t *key_length,
                unsigned int number_of_keys);
```

The return value is the success of the operation. The `keys` parameter should be an array of strings containing the keys, and `key_length` an array containing the length of each corresponding key. `number_of_keys` is the number of keys supplied in the array.

To fetch the individual values, you need to use `memcached_fetch()` to get each corresponding value.

```
char *memcached_fetch (memcached_st *ptr,
                      const char *key, size_t *key_length,
                      size_t *value_length,
                      uint32_t *flags,
                      memcached_return *error);
```

The function returns the key value, with the `key`, `key_length` and `value_length` parameters being populated with the corresponding key and length information. The function returns `NULL` when there are no more values to be returned. A full example, including the populating of the key data and the return of the information is provided here.

```
#include <stdio.h>
#include <sstring.h>
#include <unistd.h>
#include <libmemcached/memcached.h>

int main(int argc, char *argv[])
```

```

{
    memcached_server_st *servers = NULL;
    memcached_st *memc;
    memcached_return rc;
    char *keys[] = {"huey", "dewey", "louie"};
    size_t key_length[3];
    char *values[] = {"red", "blue", "green"};
    size_t value_length[3];
    unsigned int x;
    uint32_t flags;

    char return_key[MEMCACHED_MAX_KEY];
    size_t return_key_length;
    char *return_value;
    size_t return_value_length;

    memc= memcached_create(NULL);

    servers= memcached_server_list_append(servers, "localhost", 11211, &rc);
    rc= memcached_server_push(memc, servers);

    if (rc == MEMCACHED_SUCCESS)
        fprintf(stderr, "Added server successfully\n");
    else
        fprintf(stderr, "Couldn't add server: %s\n", memcached_strerror(memc, rc));

    for(x= 0; x < 3; x++)
    {
        key_length[x] = strlen(keys[x]);
        value_length[x] = strlen(values[x]);

        rc= memcached_set(memc, keys[x], key_length[x], values[x],
            value_length[x], (time_t)0, (uint32_t)0);
        if (rc == MEMCACHED_SUCCESS)
            fprintf(stderr, "Key %s stored successfully\n", keys[x]);
        else
            fprintf(stderr, "Couldn't store key: %s\n", memcached_strerror(memc, rc));
    }

    rc= memcached_mget(memc, keys, key_length, 3);

    if (rc == MEMCACHED_SUCCESS)
    {
        while ((return_value= memcached_fetch(memc, return_key, &return_key_length,
            &return_value_length, &flags, &rc)) != NULL)
        {
            if (rc == MEMCACHED_SUCCESS)
            {
                fprintf(stderr, "Key %s returned %s\n", return_key, return_value);
            }
        }
    }

    return 0;
}

```

Running the above application:

```

shell> memc_multi_fetch
Added server successfully
Key huey stored successfully
Key dewey stored successfully
Key louie stored successfully
Key huey returned red
Key dewey returned blue
Key louie returned green

```

14.5.3.1.5. libmemcached Behaviors

The behavior of `libmemcached` can be modified by setting one or more behavior flags. These can either be set globally, or they can be applied during the call to individual functions. Some behaviors also accept an additional setting, such as the hashing mechanism used when selecting servers.

To set global behaviors:

```

memcached_return
    memcached_behavior_set (memcached_st *ptr,
                            memcached_behavior flag,
                            uint64_t data);

```

To get the current behavior setting:

```

uint64_t
    memcached_behavior_get (memcached_st *ptr,
                            memcached_behavior flag);

```

Behavior	Description
<code>MEMCACHED_BEHAVIOR_NO_BLOCK</code>	Caused <code>libmemcached</code> to use asynchronous I/O.
<code>MEMCACHED_BEHAVIOR_TCP_NODELAY</code>	Turns on no-delay for network sockets.
<code>MEMCACHED_BEHAVIOR_HASH</code>	Without a value, sets the default hashing algorithm for keys to use MD5. Other valid values include <code>MEMCACHED_HASH_DEFAULT</code> , <code>MEMCACHED_HASH_MD5</code> , <code>MEMCACHED_HASH_CRC</code> , <code>MEMCACHED_HASH_FNV1_64</code> , <code>MEMCACHED_HASH_FNV1A_64</code> , <code>MEMCACHED_HASH_FNV1_32</code> , and <code>MEMCACHED_HASH_FNV1A_32</code> .
<code>MEMCACHED_BEHAVIOR_DISTRIBUTION</code>	Changes the method of selecting the server used to store a given value. The default method is <code>MEMCACHED_DISTRIBUTION_MODULA</code> . You can enable consistent hashing by setting <code>MEMCACHED_DISTRIBUTION_CONSISTENT</code> . <code>MEMCACHED_DISTRIBUTION_CONSISTENT</code> is an alias for the value <code>MEMCACHED_DISTRIBUTION_CONSISTENT_KETAMA</code> .
<code>MEMCACHED_BEHAVIOR_CACHE_LOOKUPS</code>	Cache the lookups made to the DNS service. This can improve the performance if you are using names instead of IP addresses for individual hosts.
<code>MEMCACHED_BEHAVIOR_SUPPORT_CAS</code>	Support CAS operations. By default, this is disabled because it imposes a performance penalty.
<code>MEMCACHED_BEHAVIOR_KETAMA</code>	Sets the default distribution to <code>MEMCACHED_DISTRIBUTION_CONSISTENT_KETAMA</code> and the hash to <code>MEMCACHED_HASH_MD5</code> .
<code>MEMCACHED_BEHAVIOR_POLL_TIMEOUT</code>	Modify the timeout value used by <code>poll()</code> . You should supply a <code>signed int</code> pointer for the timeout value.
<code>MEMCACHED_BEHAVIOR_BUFFER_REQUESTS</code>	Buffers IO requests instead of them being sent. A get operation, or closing the connection will cause the data to be flushed.
<code>MEMCACHED_BEHAVIOR_VERIFY_KEY</code>	Forces <code>libmemcached</code> to verify that a specified key is valid.
<code>MEMCACHED_BEHAVIOR_SORT_HOSTS</code>	If set, hosts added to the list of configured hosts for a <code>memcached_st</code> structure will be placed into the host list in sorted order. This will break consistent hashing if that behavior has been enabled.
<code>MEMCACHED_BEHAVIOR_CONNECT_TIMEOUT</code>	In non-blocking mode this changes the value of the timeout during socket connection.

14.5.3.1.6. `libmemcached` Command-line Utilities

In addition to the main C library interface, `libmemcached` also includes a number of command line utilities that can be useful when working with and debugging `memcached` applications.

All of the command line tools accept a number of arguments, the most critical of which is `servers`, which specifies the list of servers to connect to when returning information.

The main tools are:

- `memcat` — display the value for each ID given on the command line:

```
shell> memcat --servers=localhost hwkey
Hello world
```

- `memcp` — copy the contents of a file into the cache, using the file names as the key:

```
shell> echo "Hello World" > hwkey
shell> memcp --servers=localhost hwkey
shell> memcat --servers=localhost hwkey
Hello world
```

- `memrm` — remove an item from the cache:

```
shell> memcat --servers=localhost hwkey
Hello world
shell> memrm --servers=localhost hwkey
shell> memcat --servers=localhost hwkey
```

- `memslap` — test the load on one or more `memcached` servers, simulating get/set and multiple client operations. For example, you can simulate the load of 100 clients performing get operations:

```
shell> memslap --servers=localhost --concurrency=100 --flush --test=get
memslap --servers=localhost --concurrency=100 --flush --test=get Threads connecting to servers 100
Took 13.571 seconds to read data
```

- `memflush` — flush (empty) the contents of the `memcached` cache.

```
shell> memflush --servers=localhost
```

14.5.3.2. Using MySQL and `memcached` with Perl

The `Cache::Memcached` module provides a native interface to the Memcache protocol, and provides support for the core functions offered by `memcached`. You should install the module using your hosts native package management system. Alternatively, you can install the module using CPAN:

```
root-shell> perl -MCPAN -e 'install Cache::Memcached'
```

To use `memcached` from Perl through `Cache::Memcached` module, you first need to create a new `Cache::Memcached` object that defines the list of servers and other parameters for the connection. The only argument is a hash containing the options for the cache interface. For example, to create a new instance that uses three `memcached` servers:

```
use Cache::Memcached;

my $cache = new Cache::Memcached {
    'servers' => [
        '192.168.0.100:11211',
        '192.168.0.101:11211',
        '192.168.0.102:11211',
    ],
};
```

Note

When using the `Cache::Memcached` interface with multiple servers, the API automatically performs certain operations across all the servers in the group. For example, getting statistical information through `Cache::Memcached` returns a hash that contains data on a host by host basis, as well as generalized statistics for all the servers in the group.

You can set additional properties on the cache object instance when it is created by specifying the option as part of the option hash. Alternatively, you can use a corresponding method on the instance:

- `servers` or method `set_servers()` — specifies the list of the servers to be used. The servers list should be a reference to an array of servers, with each element as the address and port number combination (separated by a colon). You can also specify a local connection through a UNIX socket (for example `/tmp/sock/memcached`). You can also specify the server with a weight (indicating how much more frequently the server should be used during hashing) by specifying an array reference with the `memcached` server instance and a weight number. Higher numbers give higher priority.
- `compress_threshold` or method `set_compress_threshold()` — specifies the threshold when values are compressed. Values larger than the specified number are automatically compressed (using `zlib`) during storage and retrieval.
- `no_rehash` or method `set_norehash()` — disables finding a new server if the original choice is unavailable.
- `readonly` or method `set_readonly()` — disables writes to the `memcached` servers.

Once the `Cache::Memcached` object instance has been configured you can use the `set()` and `get()` methods to store and retrieve information from the `memcached` servers. Objects stored in the cache are automatically serialized and deserialized using the `Storable` module.

The `Cache::Memcached` interface supports the following methods for storing/retrieving data, and relate to the generic methods as shown in the table.

<code>Cache::Memcached</code> Function	Equivalent to
<code>get()</code>	Generic <code>get()</code>
<code>get_multi(keys)</code>	Gets multiple <code>keys</code> from memcache using just one query. Returns a hash reference of key/value pairs.
<code>set()</code>	Generic <code>set()</code>
<code>add()</code>	Generic <code>add()</code>

Cache::Memcached Function	Equivalent to
<code>replace()</code>	Generic <code>replace()</code>
<code>delete()</code>	Generic <code>delete()</code>
<code>incr()</code>	Generic <code>incr()</code>
<code>decr()</code>	Generic <code>decr()</code>

Below is a complete example for using `memcached` with Perl and the `Cache::Memcached` module:

```

root-shell>! /usr/bin/perl
use Cache::Memcached;
use DBI;
use Data::Dumper;

# Configure the memcached server
my $cache = new Cache::Memcached {
    'servers' => [
        'localhost:11211',
    ],
};

# Get the film name from the command line
# memcached keys must not contain spaces, so create
# a key name by replacing spaces with underscores
my $filename = shift or die "Must specify the film name\n";
my $filmkey = $filename;
$filmkey =~ s/ /_/;

# Load the data from the cache
my $filmdata = $cache->get($filmkey);

# If the data wasn't in the cache, then we load it from the database
if (!defined($filmdata))
{
    $filmdata = load_filmdata($filename);
    if (defined($filmdata))
    {
# Set the data into the cache, using the key
        if ($cache->set($filmkey,$filmdata))
        {
            print STDERR "Film data loaded from database and cached\n";
        }
        else
        {
            print STDERR "Couldn't store to cache\n";
        }
    }
    else
    {
        die "Couldn't find $filename\n";
    }
}
else
{
    print STDERR "Film data loaded from Memcached\n";
}

sub load_filmdata
{
    my ($filename) = @_ ;

    my $dsn = "DBI:mysql:database=sakila;host=localhost;port=3306";
    $dbh = DBI->connect($dsn, 'sakila','password');

    my ($filmbase) = $dbh->selectrow_hashref(sprintf('select * from film where title = %s',
                                                    $dbh->quote($filename)));

    if (!defined($filename))
    {
        return (undef);
    }

    $filmbase->{stars} =
        $dbh->selectall_arrayref(sprintf('select concat(first_name," ",last_name) ' .
                                        'from film_actor left join (actor) ' .
                                        'on (film_actor.actor_id = actor.actor_id) ' .
                                        'where film_id=%s',
                                        $dbh->quote($filmbase->{film_id})));

    return($filmbase);
}

```

The example uses the Sakila database, obtaining film data from the database and writing a composite record of the film and actors to memcache. When calling it for a film that does not exist, you should get this result:

```
shell> memcached-sakila.pl "ROCK INSTINCT"
Film data loaded from database and cached
```

When accessing a film that has already been added to the cache:

```
shell> memcached-sakila.pl "ROCK INSTINCT"
Film data loaded from Memcached
```

14.5.3.3. Using MySQL and memcached with Python

The Python `memcache` module interfaces to `memcached` servers, and is written in pure python (i.e. without using one of the C APIs). You can download and install a copy from [Python Memcached](#).

To install, download the package and then run the Python installer:

```
python setup.py install
running install
running bdist_egg
running egg_info
creating python_memcached.egg-info
...
removing 'build/bdist.linux-x86_64/egg' (and everything under it)
Processing python_memcached-1.43-py2.4.egg
creating /usr/lib64/python2.4/site-packages/python_memcached-1.43-py2.4.egg
Extracting python_memcached-1.43-py2.4.egg to /usr/lib64/python2.4/site-packages
Adding python-memcached 1.43 to easy-install.pth file

Installed /usr/lib64/python2.4/site-packages/python_memcached-1.43-py2.4.egg
Processing dependencies for python-memcached==1.43
Finished processing dependencies for python-memcached==1.43
```

Once installed, the `memcache` module provides a class-based interface to your `memcached` servers. Serialization of Python structures is handled by using the Python `cPickle` or `pickle` modules.

To create a new `memcache` interface, import the `memcache` module and create a new instance of the `memcache.Client` class:

```
import memcache
memc = memcache.Client(['127.0.0.1:11211'])
```

The first argument should be an array of strings containing the server and port number for each `memcached` instance you want to use. You can enable debugging by setting the optional `debug` parameter to 1.

By default, the hashing mechanism used is `crc32`. This provides a basic module hashing algorithm for selecting among multiple servers. You can change the function used by setting the value of `memcache.serverHashFunction` to the alternate function you want to use. For example:

```
from zlib import Adler32
memcache.serverHashFunction = Adler32
```

Once you have defined the servers to use within the `memcache` instance, the core functions provide the same functionality as in the generic interface specification. A summary of the supported functions is provided in the following table.

Python <code>memcache</code> Function	Equivalent to
<code>get()</code>	Generic <code>get()</code>
<code>get_multi(keys)</code>	Gets multiple values from the supplied array of <code>keys</code> . Returns a hash reference of key/value pairs.
<code>set()</code>	Generic <code>set()</code>
<code>set_multi(dict [, expiry [, key_prefix]])</code>	Sets multiple key/value pairs from the supplied <code>dict</code> .
<code>add()</code>	Generic <code>add()</code>
<code>replace()</code>	Generic <code>replace()</code>
<code>prepend(key, value [, expiry])</code>	Prepends the supplied <code>value</code> to the value of the existing <code>key</code> .
<code>append(key, value [, expiry])</code>	Appends the supplied <code>value</code> to the value of the existing <code>key</code> .
<code>delete()</code>	Generic <code>delete()</code>

Python <code>memcache</code> Function	Equivalent to
<code>delete_multi(keys [, expiry [, key_prefix]])</code>	Deletes all the keys from the hash matching each string in the array <code>keys</code> .
<code>incr()</code>	Generic <code>incr()</code>
<code>decr()</code>	Generic <code>decr()</code>

Note

Within the Python `memcache` module, all the `*_multi()` functions support an optional `key_prefix` parameter. If supplied, then the string is used as a prefix to all key lookups. For example, if you call:

```
memc.get_multi(['a', 'b'], key_prefix='users:')
```

The function will retrieve the keys `users:a` and `users:b` from the servers.

An example showing the storage and retrieval of information to a `memcache` instance, loading the raw data from MySQL, is shown below:

```
import sys
import MySQLdb
import memcache

memc = memcache.Client(['127.0.0.1:11211'], debug=1);

try:
    conn = MySQLdb.connect (host = "localhost",
                            user = "sakila",
                            passwd = "password",
                            db = "sakila")
except MySQLdb.Error, e:
    print "Error %d: %s" % (e.args[0], e.args[1])
    sys.exit (1)

popularfilms = memc.get('top5films')

if not popularfilms:
    cursor = conn.cursor()
    cursor.execute('select film_id,title from film order by rental_rate desc limit 5')
    rows = cursor.fetchall()
    memc.set('top5films',rows,60)
    print "Updated memcached with MySQL data"
else:
    print "Loaded data from memcached"
    for row in popularfilms:
        print "%s, %s" % (row[0], row[1])
```

When executed for the first time, the data is loaded from the MySQL database and stored to the `memcached` server.

```
shell> python memc_python.py
Updated memcached with MySQL data
```

The data is automatically serialized using `cPickle/pickle`. This means when you load the data back from `memcached`, you can use the object directly. In the example above, the information stored to `memcached` is in the form of rows from a Python DB cursor. When accessing the information (within the 60 second expiry time), the data is loaded from `memcached` and dumped:

```
shell> python memc_python.py
Loaded data from memcached
2, ACE GOLDFINGER
7, AIRPLANE SIERRA
8, AIRPORT POLLOCK
10, ALADDIN CALENDAR
13, ALI FOREVER
```

The serialization and deserialization happens automatically, but be aware that serialization of Python data may be incompatible with other interfaces and languages. You can change the serialization module used during initialization, for example to use JSON, which will be more easily exchanged.

14.5.3.4. Using MySQL and `memcached` with PHP

PHP provides support for the Memcache functions through a PECL extension. To enable the PHP `memcache` extensions, you must build PHP using the `--enable-memcache` option to `configure` when building from source.

If you are installing on a RedHat based server, you can install the `php-pecl-memcache` RPM:

```
root-shell> yum --install php-pecl-memcache
```

On Debian based distributions, use the `php-memcache` package.

You can set global runtime configuration options by specifying the values in the following table within your `php.ini` file.

Configuration option	Default	Description
<code>memcache.allow_failover</code>	1	Specifies whether another server in the list should be queried if the first server selected fails.
<code>memcache.max_failover_attempts</code>	20	Specifies the number of servers to try before returning a failure.
<code>memcache.chunk_size</code>	8192	Defines the size of network chunks used to exchange data with the <code>memcached</code> server.
<code>memcache.default_port</code>	11211	Defines the default port to use when communicating with the <code>memcached</code> servers.
<code>memcache.hash_strategy</code>	standard	Specifies which hash strategy to use. Set to <code>consistent</code> to allow servers to be added or removed from the pool without causing the keys to be remapped to other servers. When set to <code>standard</code> , an older (modula) strategy is used that potentially uses different servers for storage.
<code>memcache.hash_function</code>	crc32	Specifies which function to use when mapping keys to servers. <code>crc32</code> uses the standard CRC32 hash. <code>fnv</code> uses the FNV-1a hashing algorithm.

To create a connection to a `memcached` server, you need to create a new `Memcache` object and then specifying the connection options. For example:

```
<?php
$cache = new Memcache;
$cache->connect('localhost',11211);
?>
```

This opens an immediate connection to the specified server.

To use multiple `memcached` servers, you need to add servers to the `memcache` object using `addServer()`:

```
bool Memcache::addServer ( string $host [, int $port [, bool $persistent
                        [, int $weight [, int $timeout [, int $retry_interval
                        [, bool $status [, callback $failure_callback
                        ]]]]] ] )
```

The server management mechanism within the `php-memcache` module is a critical part of the interface as it controls the main interface to the `memcached` instances and how the different instances are selected through the hashing mechanism.

To create a simple connection to two `memcached` instances:

```
<?php
$cache = new Memcache;
$cache->addServer('192.168.0.100',11211);
$cache->addServer('192.168.0.101',11211);
?>
```

In this scenario the instance connection is not explicitly opened, but only opened when you try to store or retrieve a value. You can enable persistent connections to `memcached` instances by setting the `$persistent` argument to true. This is the default setting, and will cause the connections to remain open.

To help control the distribution of keys to different instances, you should use the global `memcache.hash_strategy` setting. This sets the hashing mechanism used to select. You can also add an additional weight to each server, which effectively increases the number of times the instance entry appears in the instance list, therefore increasing the likelihood of the instance being chosen over other instances. To set the weight, set the value of the `$weight` argument to more than one.

The functions for setting and retrieving information are identical to the generic functional interface offered by `memcached`, as shown in this table.

PECL <code>memcache</code> Function	Equivalent to
<code>get()</code>	Generic <code>get()</code>

PECL <code>memcache</code> Function	Equivalent to
<code>set()</code>	Generic <code>set()</code>
<code>add()</code>	Generic <code>add()</code>
<code>replace()</code>	Generic <code>replace()</code>
<code>delete()</code>	Generic <code>delete()</code>
<code>increment()</code>	Generic <code>incr()</code>
<code>decrement()</code>	Generic <code>decr()</code>

A full example of the PECL `memcache` interface is provided below. The code loads film data from the Sakila database when the user provides a film name. The data stored into the `memcached` instance is recorded as a `mysqli` result row, and the API automatically serializes the information for you.

```
<?php
$memc = new Memcache;
$memc->addServer('localhost', '11211');
?>

<html xmlns="http://www.w3.org/1999/xhtml" xml:lang="en" lang="en">
<head>
<meta http-equiv="Content-Type" content="text/html; charset=utf-8" />
<title>Simple Memcache Lookup</title>
</head>
<body>
<form method="post">
<p><b>Film</b>: <input type="text" size="20" name="film"></p>
<input type="submit">
</form>
<hr/>
<?php
    echo "Loading data...\n";
$value = $memc->get($_REQUEST['film']);
if ($value)
{
    printf("<p>Film data for %s loaded from memcache</p>", $value['title']);
    foreach (array_keys($value) as $key)
    {
        printf("<p><b>%s</b>: %s</p>", $key, $value[$key]);
    }
}
else
{
    $con = new mysqli('localhost', 'sakila', 'password', 'sakila') or
        die("<h1>Database problem</h1>" . mysqli_connect_error());
    $result = $con->query(sprintf('select * from film where title = "%s"', $_REQUEST['film']));
    $row = $result->fetch_array(MYSQLI_ASSOC);
    $memc->set($row['title'], $row);
    printf("<p>Loaded %s from MySQL</p>", $row['title']);
}
?>
```

With PHP, the connections to the `memcached` instances are kept open as long as the PHP and associated Apache instance remain running. When adding a removing servers from the list in a running instance (for example, when starting another script that mentions additional servers), the connections will be shared, but the script will only select among the instances explicitly configured within the script.

To ensure that changes to the server list within a script do not cause problems, make sure to use the consistent hashing mechanism.

14.5.3.5. Using MySQL and `memcached` with Ruby

There are a number of different modules for interfacing to `memcached` within Ruby. The `Ruby-MemCache` client library provides a native interface to `memcached` that does not require any external libraries, such as `libmemcached`. You can obtain the installer package from <http://www.deveiate.org/projects/RMemCache>.

To install, extract the package and then run `install.rb`:

```
shell> install.rb
```

If you have RubyGems, you can install the [Ruby-MemCache](#) gem:

```
shell> gem install Ruby-MemCache
Bulk updating Gem source index for: http://gems.rubyforge.org
Install required dependency io-reactor? [Yn] y
Successfully installed Ruby-MemCache-0.0.1
Successfully installed io-reactor-0.05
Installing ri documentation for io-reactor-0.05...
Installing RDoc documentation for io-reactor-0.05...
```

To use a `memcached` instance from within Ruby, create a new instance of the `MemCache` object.

```
require 'memcache'
memc = MemCache::new '192.168.0.100:11211'
```

You can add a weight to each server to increase the likelihood of the server being selected during hashing by appending the weight count to the server host name/port string:

```
require 'memcache'
memc = MemCache::new '192.168.0.100:11211:3'
```

To add servers to an existing list, you can append them directly to the `MemCache` object:

```
memc += ["192.168.0.101:11211"]
```

To set data into the cache, you can just assign a value to a key within the new cache object, which works just like a standard Ruby hash object:

```
memc["key"] = "value"
```

Or to retrieve the value:

```
print memc["key"]
```

For more explicit actions, you can use the method interface, which mimics the main `memcached` API functions, as summarized in the following table.

Ruby <code>MemCache</code> Method	Equivalent to
<code>get()</code>	Generic <code>get()</code>
<code>get_hash(keys)</code>	Get the values of multiple <code>keys</code> , returning the information as a hash of the keys and their values.
<code>set()</code>	Generic <code>set()</code>
<code>set_many(pairs)</code>	Set the values of the keys and values in the hash <code>pairs</code> .
<code>add()</code>	Generic <code>add()</code>
<code>replace()</code>	Generic <code>replace()</code>
<code>delete()</code>	Generic <code>delete()</code>
<code>incr()</code>	Generic <code>incr()</code>
<code>decr()</code>	Generic <code>decr()</code>

14.5.3.6. Using MySQL and `memcached` with Java

The `com.danga.MemCached` class within Java provides a native interface to `memcached` instances. You can obtain the client from <http://whalin.com/memcached/>. The Java class uses hashes that are compatible with `libmemcached`, so you can mix and match Java and `libmemcached` applications accessing the same `memcached` instances. The serialization between Java and other interfaces will not be compatible. If this is a problem, use JSON or a similar nonbinary serialization format.

On most systems you can download the package and use the `jar` directly. On OpenSolaris, use `pkg` to install the `SUNWmem-cached-java` package.

To use the `com.danga.MemCached` interface, you create a `MemCachedClient` instance and then configure the list of servers by configuring the `SocketIOPool`. Through the pool specification you set up the server list, weighting, and the connection parameters to optimized the connections between your client and the `memcached` instances that you configure.

Generally you can configure the `memcached` interface once within a single class and then use this interface throughout the rest of

your application.

For example, to create a basic interface, first configure the `MemCachedClient` and base `SockIOPool` settings:

```
public class MyClass {
    protected static MemCachedClient mcc = new MemCachedClient();
    static {
        String[] servers =
            {
                "localhost:11211",
            };
        Integer[] weights = { 1 };
        SockIOPool pool = SockIOPool.getInstance();
        pool.setServers( servers );
        pool.setWeights( weights );
    }
}
```

In the above sample, the list of servers is configured by creating an array of the `memcached` instances that you want to use. You can then configure individual weights for each server.

The remainder of the properties for the connection are optional, but you can set the connection numbers (initial connections, minimum connections, maximum connections, and the idle timeout) by setting the pool parameters:

```
pool.setInitConn( 5 );
pool.setMinConn( 5 );
pool.setMaxConn( 250 );
pool.setMaxIdle( 1000 * 60 * 60 * 6 );
```

Once the parameters have been configured, initialize the connection pool:

```
pool.initialize();
```

The pool, and the connection to your `memcached` instances should now be ready to use.

To set the hashing algorithm used to select the server used when storing a given key you can use `pool.setHashingAlg()`:

```
pool.setHashingAlg( SockIOPool.NEW_COMPAT_HASH );
```

Valid values are `NEW_COMPAT_HASH`, `OLD_COMPAT_HASH` and `NATIVE_HASH` are also basic modular hashing algorithms. For a consistent hashing algorithm, use `CONSISTENT_HASH`. These constants are equivalent to the corresponding hash settings within `libmemcached`.

Java <code>com.danga.MemCached</code> Method	Equivalent to
<code>get()</code>	Generic <code>get()</code>
<code>getMulti(keys)</code>	Get the values of multiple <code>keys</code> , returning the information as Hash map using <code>java.lang.String</code> for the keys and <code>java.lang.Object</code> for the corresponding values.
<code>set()</code>	Generic <code>set()</code>
<code>add()</code>	Generic <code>add()</code>
<code>replace()</code>	Generic <code>replace()</code>
<code>delete()</code>	Generic <code>delete()</code>
<code>incr()</code>	Generic <code>incr()</code>
<code>decr()</code>	Generic <code>decr()</code>

14.5.3.7. Using the MySQL `memcached` UDFs

The `memcached` MySQL User Defined Functions (UDFs) enable you to set and retrieve objects from within MySQL 5.0 or greater.

To install the MySQL `memcached` UDFs, download the UDF package from http://tangent.org/586/Memcached_Functions_for_MySQL.html. You will need to unpack the package and run `configure` to configure the build process. When running `configure`, use the `--with-mysql` option and specify the location of the `mysql_config` command. Note that you must be running :

```
shell> tar zxf memcached_functions_mysql-0.5.tar.gz
shell> cd memcached_functions_mysql-0.5
shell> ./configure --with-mysql-config=/usr/local/mysql/bin/mysql_config
```

Now build and install the functions:

```
shell> make
shell> make install
```

You may want to copy the MySQL `memcached` UDFs into your MySQL plugins directory:

```
shell> cp /usr/local/lib/libmemcached_functions_mysql* /usr/local/mysql/lib/mysql/plugins/
```

Once installed, you must initialize the function within MySQL using `CREATE` and specifying the return value and library. For example, to add the `memc_get()` function:

```
mysql> CREATE FUNCTION memc_get RETURNS STRING SONAME "libmemcached_functions_mysql.so";
```

You must repeat this process for each function that you want to provide access to within MySQL. Once you have created the association, the information will be retained, even over restarts of the MySQL server. You can simplify the process by using the SQL script provided in the `memcached` UDFs package:

```
shell> mysql <sql/install_functions.sql
```

Alternatively, if you have Perl installed, then you can use the supplied Perl script, which will check for the existence of each function and create the function/library association if it has not already been defined:

```
shell> utils/install.pl --silent
```

The `--silent` option installs everything automatically. Without this option, the script will ask whether you want to install each of the available functions.

The interface remains consistent with the other APIs and interfaces. To set up a list of servers, use the `memc_servers_set()` function, which accepts a single string containing and comma-separated list of servers:

```
mysql> SELECT memc_servers_set('192.168.0.1:11211,192.168.0.2:11211');
```

Note

The list of servers used by the `memcached` UDFs is not persistent over restarts of the MySQL server. If the MySQL server fails, then you must re-set the list of `memcached` servers.

To set a value, use `memc_set()`:

```
mysql> SELECT memc_set('myid', 'myvalue');
```

To retrieve a stored value:

```
mysql> SELECT memc_get('myid');
```

The list of functions supported by the UDFs, in relation to the standard protocol functions, is shown in the following table.

MySQL <code>memcached</code> UDF Function	Equivalent to
<code>memc_get()</code>	Generic <code>get()</code>
<code>memc_get_by_key(master_key, key, value)</code>	Like the generic <code>get()</code> , but uses the supplied master key to select the server to use.
<code>memc_set()</code>	Generic <code>set()</code>
<code>memc_set_by_key(master_key, key, value)</code>	Like the generic <code>set()</code> , but uses the supplied master key to select the server to use.
<code>memc_add()</code>	Generic <code>add()</code>
<code>memc_add_by_key(master_key, key, value)</code>	Like the generic <code>add()</code> , but uses the supplied master key to select the server to use.
<code>memc_replace()</code>	Generic <code>replace()</code>
<code>memc_replace_by_key(master_key, key, value)</code>	Like the generic <code>replace()</code> , but uses the supplied master key

MySQL <code>memcached</code> UDF Function	Equivalent to
	to select the server to use.
<code>memc_prepend(key, value)</code>	Prepend the specified <code>value</code> to the current value of the specified <code>key</code> .
<code>memc_prepend_by_key(master_key, key, value)</code>	Prepend the specified <code>value</code> to the current value of the specified <code>key</code> , but uses the supplied master key to select the server to use.
<code>memc_append(key, value)</code>	Append the specified <code>value</code> to the current value of the specified <code>key</code> .
<code>memc_append_by_key(master_key, key, value)</code>	Append the specified <code>value</code> to the current value of the specified <code>key</code> , but uses the supplied master key to select the server to use.
<code>memc_delete()</code>	Generic <code>delete()</code>
<code>memc_delete_by_key(master_key, key, value)</code>	Like the generic <code>delete()</code> , but uses the supplied master key to select the server to use.
<code>memc_increment()</code>	Generic <code>incr()</code>
<code>memc_decrement()</code>	Generic <code>decr()</code>

The respective `*_by_key()` functions are useful when you want to store a specific value into a specific `memcached` server, possibly based on a differently calculated or constructed key.

The `memcached` UDFs include some additional functions:

- `memc_server_count()`

Returns a count of the number of servers in the list of registered servers.

- `memc_servers_set_behavior(behavior_type, value)`, `memc_set_behavior(behavior_type, value)`

Set behaviors for the list of servers. These behaviors are identical to those provided by the `libmemcached` library. For more information on `libmemcached` behaviors, see [Section 14.5.3.1, “Using libmemcached”](#).

You can use the behavior name as the `behavior_type`:

```
mysql> SELECT memc_servers_behavior_set("MEMCACHED_BEHAVIOR_KETAMA",1);
```

- `memc_servers_behavior_get(behavior_type)`, `memc_get_behavior(behavior_type, value)`

Returns the value for a given behavior.

- `memc_list_behaviors()`

Returns a list of the known behaviors.

- `memc_list_hash_types()`

Returns a list of the supported key-hashing algorithms.

- `memc_list_distribution_types()`

Returns a list of the supported distribution types to be used when selecting a server to use when storing a particular key.

- `memc_libmemcached_version()`

Returns the version of the `libmemcached` library.

- `memc_stats()`

Returns the general statistics information from the server.

14.5.3.8. `memcached` Protocol

Communicating with a `memcached` server can be achieved through either the TCP or UDP protocols. When using the TCP protocol you can use a simple text based interface for the exchange of information.

14.5.3.8.1. Using the TCP text protocol

When communicating with `memcached` you can connect to the server using the port configured for the server. You can open a connection with the server without requiring authorization or login. As soon as you have connected, you can start to send commands to the server. When you have finished, you can terminate the connection without sending any specific disconnection command. Clients are encouraged to keep their connections open to decrease latency and improve performance.

Data is sent to the `memcached` server in two forms:

- Text lines, which are used to send commands to the server, and receive responses from the server.
- Unstructured data, which is used to receive or send the value information for a given key. Data is returned to the client in exactly the format it was provided.

Both text lines (commands and responses) and unstructured data are always terminated with the string `\r\n`. Because the data being stored may contain this sequence, the length of the data (returned by the client before the unstructured data is transmitted) should be used to determine the end of the data.

Commands to the server are structured according to their operation:

- **Storage commands:** `set`, `add`, `replace`, `append`, `prepend`, `cas`

Storage commands to the server take the form:

```
command key [flags] [exptime] length [noreply]
```

Or when using compare and swap (`cas`):

```
cas key [flags] [exptime] length [casunique] [noreply]
```

Where:

- `command` — the command name.
 - `set` — Store value against key
 - `add` — Store this value against key if the key does not already exist
 - `replace` — Store this value against key if the key already exists
 - `append` — Append the supplied value to the end of the value for the specified key. The `flags` and `exptime` arguments should not be used.
 - `prepend` — Append value currently in the cache to the end of the supplied value for the specified key. The `flags` and `exptime` arguments should not be used.
 - `cas` — Set the specified key to the supplied value, only if the supplied `casunique` matches. This is effectively the equivalent of change the information if nobody has updated it since I last fetched it.
- `key` — the key. All data is stored using a the specific key. The key cannot contain control characters or whitespace, and can be up to 250 characters in size.
- `flags` — the flags for the operation (as an integer). Flags in `memcached` are transparent. The `memcached` server ignores the contents of the flags. They can be used by the client to indicate any type of information. In `memcached` 1.2.0 and lower the value is a 16-bit integer value. In `memcached` 1.2.1 and higher the value is a 32-bit integer.
- `exptime` — the expiry time, or zero for no expiry.
- `length` — the length of the supplied value block in bytes, excluding the terminating `\r\n` characters.
- `casunique` — is a unique 64-bit value of an existing entry. This will be used to compare against the existing value. You should use the value returned by the `gets` command when issuing `cas` updates.
- `noreply` — tells the server not to reply to the command.

For example, to store the value `abcdef` into the key `xyzkey`, you would use:

```
set xyzkey 0 0 6\r\nabcdef\r\n
```

The return value from the server will be one line, specifying the status or error information. For more information, see [Table 14.2, “memcached Protocol Responses”](#).

- **Retrieval commands:** `get`, `gets`

Retrieval commands take the form:

```
get key1 [key2 ... keyn]
gets key1 [key2 ... keyn]
```

You can supply multiple keys to the commands, with each requested key separated by whitespace.

The server will respond with an information line of the form:

```
VALUE key flags bytes [casunique]
```

Where:

- `key` — the key name.
- `flags` — the value of the flag integer supplied to the `memcached` server when the value was stored.
- `bytes` — the size (excluding the terminating `\r\n` character sequence) of the stored value.
- `casunique` — the unique 64-bit integer that identifies the item.

The information line will immediately be followed by the value data block. For example:

```
get xyzkey\r\n
VALUE xyzkey 0 6\r\n
abcdef\r\n
```

If you have requested multiple keys, an information line and data block will be returned for each key found. If a requested key does not exist in the cache, no information is returned.

- **Delete commands:** `delete`

Deletion commands take the form:

```
delete key [time] [noreply]
```

Where:

- `key` — the key name.
- `time` — the time in seconds (or a specific Unix time) for which the client wishes the server to refuse `add` or `replace` commands on this key. All `add`, `replace`, `get`, and `gets` commands will fail during this period. `set` operations will succeed. After this period, the key will be deleted permanently and all commands will be accepted.

If not supplied, the value is assumed to be zero (delete immediately).

- `noreply` — tells the server not to reply to the command.

Responses to the command will either be `DELETED` to indicate that the key was successfully removed, or `NOT_FOUND` to indicate that the specified key could not be found.

- **Increment/Decrement:** `incr`, `decr`

The increment and decrement commands change the value of a key within the server without performing a separate `get/set` sequence. The operations assume that the currently stored value is a 64-bit integer. If the stored value is not a 64-bit integer, then the value is assumed to be zero before the increment or decrement operation is applied.

Increment and decrement commands take the form:

```
incr key value [noreply]
decr key value [noreply]
```

Where:

- `key` — the key name.
- `value` — an integer to be used as the increment or decrement value.
- `noreply` — tells the server not to reply to the command.

The response will be:

- `NOT_FOUND` — the specified key could not be located.
- `value` — the new value of the specified key.

Values are assumed to be unsigned. For `decr` operations the value will never be decremented below 0. For `incr` operations, the value will be wrap around the 64-bit maximum.

- **Statistics commands: `stats`**

The `stats` command provides detailed statistical information about the current status of the `memcached` instance and the data it is storing.

Statistics commands take the form:

```
STAT [name] [value]
```

Where:

- `name` — is the optional name of the statistics to return. If not specified, the general statistics are returned.
- `value` — a specific value to be used when performing certain statistics operations.

The return value is a list of statistics data, formatted as follows:

```
STAT name value
```

The statistics are terminated with a single line, `END`.

For more information, see [Section 14.5.4, “Getting memcached Statistics”](#).

For reference, a list of the different commands supported and their formats is provided below.

Table 14.1. memcached Command Reference

Command	Command Formats
<code>set</code>	<code>set key flags exptime length, set key flags exptime length noreply</code>
<code>add</code>	<code>add key flags exptime length, add key flags exptime length noreply</code>
<code>replace</code>	<code>replace key flags exptime length, replace key flags exptime length noreply</code>
<code>append</code>	<code>append key length, append key length noreply</code>
<code>prepend</code>	<code>prepend key length, prepend key length noreply</code>
<code>cas</code>	<code>cas key flags exptime length casunique, cas key flags exptime length casunique noreply</code>
<code>get</code>	<code>get key1 [key2 ... keyn]</code>
<code>gets</code>	
<code>delete</code>	<code>delete key, delete key noreply, delete key expiry, delete key expiry noreply</code>
<code>incr</code>	<code>incr key, incr key noreply, incr key value, incr key value noreply</code>
<code>decr</code>	<code>decr key, decr key noreply, decr key value, decr key value noreply</code>
<code>stat</code>	<code>stat, stat name, stat name value</code>

When sending a command to the server, the response from the server will be one of the settings in the following table. All response values from the server are terminated by `\r\n`:

Table 14.2. memcached Protocol Responses

String	Description
STORED	Value has successfully been stored.
NOT_STORED	The value was not stored, but not because of an error. For commands where you are adding a or updating a value if it exists (such as <code>add</code> and <code>replace</code>), or where the item has already been set to be deleted.
EXISTS	When using a <code>cas</code> command, the item you are trying to store already exists and has been modified since you last checked it.
NOT_FOUND	The item you are trying to store, update or delete does not exist or has already been deleted.
ERROR	You submitted a non-existent command name.
CLIENT_ERROR error-string	There was an error in the input line, the detail is contained in <code>errorstring</code> .
SERVER_ERROR error-string	There was an error in the server that prevents it from returning the information. In extreme conditions, the server may disconnect the client after this error occurs.
VALUE keys flags length	The requested key has been found, and the stored <code>key</code> , <code>flags</code> and data block will be returned, of the specified <code>length</code> .
DELETED	The requested key was deleted from the server.
STAT name value	A line of statistics data.
END	The end of the statistics data.

14.5.4. Getting memcached Statistics

The `memcached` system has a built in statistics system that collects information about the data being stored into the cache, cache hit ratios, and detailed information on the memory usage and distribution of information through the slab allocation used to store individual items. Statistics are provided at both a basic level that provide the core statistics, and more specific statistics for specific areas of the `memcached` server.

This information can prove be very useful to ensure that you are getting the correct level of cache and memory usage, and that your slab allocation and configuration properties are set at an optimal level.

The stats interface is available through the standard `memcached` protocol, so the reports can be accessed by using `telnet` to connect to the `memcached`. Alternatively, most of the language API interfaces provide a function for obtaining the statistics from the server.

For example, to get the basic stats using `telnet`:

```
shell> telnet localhost 11211
Trying ::1...
Connected to localhost.
Escape character is '^]'.
stats
STAT pid 23599
STAT uptime 675
STAT time 1211439587
STAT version 1.2.5
STAT pointer_size 32
STAT rusage_user 1.404992
STAT rusage_system 4.694685
STAT curr_items 32
STAT total_items 56361
STAT bytes 2642
STAT curr_connections 53
STAT total_connections 438
STAT connection_structures 55
STAT cmd_get 113482
STAT cmd_set 80519
STAT get_hits 78926
STAT get_misses 34556
STAT evictions 0
STAT bytes_read 6379783
STAT bytes_written 4860179
STAT limit_maxbytes 67108864
STAT threads 1
END
```

When using Perl and the `Cache::Memcached` module, the `stats()` function returns information about all the servers cur-

rently configured in the connection object, and total statistics for all the `memcached` servers as a whole.

For example, the following Perl script will obtain the stats and dump the hash reference that is returned:

```
use Cache::Memcached;
use Data::Dumper;

my $memc = new Cache::Memcached;
$memc->set_servers(\@ARGV);

print Dumper($memc->stats());
```

When executed on the same `memcached` as used in the `Telnet` example above we get a hash reference with the host by host and total statistics:

```
$VAR1 = {
  'hosts' => {
    'localhost:11211' => {
      'misc' => {
        'bytes' => '2421',
        'curr_connections' => '3',
        'connection_structures' => '56',
        'pointer_size' => '32',
        'time' => '1211440166',
        'total_items' => '410956',
        'cmd_set' => '588167',
        'bytes_written' => '35715151',
        'evictions' => '0',
        'curr_items' => '31',
        'pid' => '23599',
        'limit_maxbytes' => '67108864',
        'uptime' => '1254',
        'rusage_user' => '9.857805',
        'cmd_get' => '838451',
        'rusage_system' => '34.096988',
        'version' => '1.2.5',
        'get_hits' => '581511',
        'bytes_read' => '46665716',
        'threads' => '1',
        'total_connections' => '3104',
        'get_misses' => '256940'
      },
      'sizes' => {
        '128' => '16',
        '64' => '15'
      }
    }
  },
  'self' => {},
  'total' => {
    'cmd_get' => 838451,
    'bytes' => 2421,
    'get_hits' => 581511,
    'connection_structures' => 56,
    'bytes_read' => 46665716,
    'total_items' => 410956,
    'total_connections' => 3104,
    'cmd_set' => 588167,
    'bytes_written' => 35715151,
    'curr_items' => 31,
    'get_misses' => 256940
  }
};
```

The statistics are divided up into a number of distinct sections, and then can be requested by adding the type to the `stats` command. Each statistics output is covered in more detail in the following sections.

- General statistics, see [Section 14.5.4.1, “memcached General Statistics”](#).
- Slab statistics (`slabs`), see [Section 14.5.4.2, “memcached Slabs Statistics”](#).
- Item statistics (`items`), see [Section 14.5.4.3, “memcached Item Statistics”](#).
- Size statistics (`sizes`), see [Section 14.5.4.4, “memcached Size Statistics”](#).

14.5.4.1. memcached General Statistics

The output of the general statistics provides an overview of the performance and use of the `memcached` instance. The statistics returned by the command and their meaning is shown in the following table.

The following terms are used to define the value type for each statistics value:

- `32u` — 32-bit unsigned integer
- `64u` — 64-bit unsigned integer
- `32u32u` — Two 32-bit unsigned integers separated by a colon
- `String` — Character string

Statistic	Description	
<code>pid</code>	<code>32u</code>	Process id of the <code>memcached</code> instance.
<code>uptime</code>	<code>32u</code>	Uptime (in seconds) for this <code>memcached</code> instance.
<code>time</code>	<code>32u</code>	Current time (as epoch).
<code>version</code>	<code>string</code>	Version string of this instance.
<code>pointer_size</code>	<code>string</code>	Size of pointers for this host specified in bits (32 or 64).
<code>rusage_user</code>	<code>32u:32u</code>	Total user time for this instance (seconds:microseconds).
<code>rusage_system</code>	<code>32u:32u</code>	Total system time for this instance (seconds:microseconds).
<code>curr_items</code>	<code>32u</code>	Current number of items stored by this instance.
<code>total_items</code>	<code>32u</code>	Total number of items stored during the life of this instance.
<code>bytes</code>	<code>64u</code>	Current number of bytes used by this server to store items.
<code>curr_connections</code>	<code>32u</code>	Current number of open connections.
<code>total_connections</code>	<code>32u</code>	Total number of connections opened since the server started running.
<code>connection_structures</code>	<code>32u</code>	Number of connection structures allocated by the server.
<code>cmd_get</code>	<code>64u</code>	Total number of retrieval requests (<code>get</code> operations).
<code>cmd_set</code>	<code>64u</code>	Total number of storage requests (<code>set</code> operations).
<code>get_hits</code>	<code>64u</code>	Number of keys that have been requested and found present.
<code>get_misses</code>	<code>64u</code>	Number of items that have been requested and not found.
<code>evictions</code>	<code>64u</code>	Number of valid items removed from cache to free memory for new items.
<code>bytes_read</code>	<code>64u</code>	Total number of bytes read by this server from network.
<code>bytes_written</code>	<code>64u</code>	Total number of bytes sent by this server to network.
<code>limit_maxbytes</code>	<code>32u</code>	Number of bytes this server is allowed to use for storage.
<code>threads</code>	<code>32u</code>	Number of worker threads requested.

The most useful statistics from those given here are the number of cache hits, misses, and evictions.

A large number of `get_misses` may just be an indication that the cache is still being populated with information. The number should, over time, decrease in comparison to the number of cache `get_hits`. If, however, you have a large number of cache misses compared to cache hits after an extended period of execution, it may be an indication that the size of the cache is too small and you either need to increase the total memory size, or increase the number of the `memcached` instances to improve the hit ratio.

A large number of `evictions` from the cache, particularly in comparison to the number of items stored is a sign that your cache is too small to hold the amount of information that you regularly want to keep cached. Instead of items being retained in the cache, items are being evicted to make way for new items keeping the turnover of items in the cache high, reducing the efficiency of the cache.

14.5.4.2. `memcached` Slabs Statistics

To get the `slabs` statistics, use the `stats slabs` command, or the API equivalent.

The slab statistics provide you with information about the slabs that have created and allocated for storing information within the cache. You get information both on each individual slab-class and total statistics for the whole slab.

```
STAT 1:chunk_size 104
STAT 1:chunks_per_page 10082
STAT 1:total_pages 1
STAT 1:total_chunks 10082
STAT 1:used_chunks 10081
STAT 1:free_chunks 1
STAT 1:free_chunks_end 10079
STAT 9:chunk_size 696
STAT 9:chunks_per_page 1506
STAT 9:total_pages 63
```

```
STAT 9:total_chunks 94878
STAT 9:used_chunks 94878
STAT 9:free_chunks 0
STAT 9:free_chunks_end 0
STAT active_slabs 2
STAT total_malloced 67083616
END
```

Individual stats for each slab class are prefixed with the slab ID. A unique ID is given to each allocated slab from the smallest size up to the largest. The prefix number indicates the slab class number in relation to the calculated chunk from the specified growth factor. Hence in the example, 1 is the first chunk size and 9 is the 9th chunk allocated size.

The different parameters returned for each chunk size and the totals are shown in the following table.

Statistic	Description
chunk_size	Space allocated to each chunk within this slab class.
chunks_per_page	Number of chunks within a single page for this slab class.
total_pages	Number of pages allocated to this slab class.
total_chunks	Number of chunks allocated to the slab class.
used_chunks	Number of chunks allocated to an item..
free_chunks	Number of chunks not yet allocated to items.
free_chunks_end	Number of free chunks at the end of the last allocated page.
active_slabs	Total number of slab classes allocated.
total_malloced	Total amount of memory allocated to slab pages.

The key values in the slab statistics are the `chunk_size`, and the corresponding `total_chunks` and `used_chunks` parameters. These given an indication of the size usage of the chunks within the system. Remember that one key/value pair will be placed into a chunk of a suitable size.

From these stats you can get an idea of your size and chunk allocation and distribution. If you are storing many items with a number of largely different sizes, then you may want to adjust the chunk size growth factor to increase in larger steps to prevent chunk and memory wastage. A good indication of a bad growth factor is a high number of different slab classes, but with relatively few chunks actually in use within each slab. Increasing the growth factor will create fewer slab classes and therefore make better use of the allocated pages.

14.5.4.3. memcached Item Statistics

To get the `items` statistics, use the `stats items` command, or the API equivalent.

The `items` statistics give information about the individual items allocated within a given slab class.

```
STAT items:2:number 1
STAT items:2:age 452
STAT items:2:evicted 0
STAT items:2:outofmemory 0
STAT items:27:number 1
STAT items:27:age 452
STAT items:27:evicted 0
STAT items:27:outofmemory 0
```

The prefix number against each statistics relates to the corresponding chunk size, as returned by the `stats slabs` statistics. The result is a display of the number of items stored within each chunk within each slab size, and specific statistics about their age, eviction counts, and out of memory counts. A summary of the statistics is given in the following table.

Statistic	Description
number	The number of items currently stored in this slab class.
age	The age of the oldest item within the slab class, in seconds.
evicted	The number of items evicted to make way for new entries.
outofmemory	The number of items for this slab class that have triggered an out of memory error (only value when the <code>-M</code> command line option is in effect).

Item level statistics can be used to determine how many items are stored within a given slab and their freshness and recycle rate. You can use this to help identify whether there are certain slab classes that are triggering a much larger number of evictions than others.

14.5.4.4. memcached Size Statistics

To get size statistics, use the `stats sizes` command, or the API equivalent.

The size statistics provide information about the sizes and number of items of each size within the cache. The information is returned as two columns, the first column is the size of the item (rounded up to the nearest 32 byte boundary), and the second column is the count of the number of items of that size within the cache:

```
96 35
128 38
160 807
192 804
224 410
256 222
288 83
320 39
352 53
384 33
416 64
448 51
480 30
512 54
544 39
576 10065
```

Caution

Running this statistic will lock up your cache as each item is read from the cache and its size calculated. On a large cache, this may take some time and prevent any set or get operations until the process completes.

The item size statistics are useful only to determine the sizes of the objects you are storing. Since the actual memory allocation is relevant only in terms of the chunk size and page size, the information will only be useful during a careful debugging or diagnostic session.

14.5.5. memcached FAQ

Questions

- [14.5.5.1](#): How does an event such as a crash of one of the `memcached` servers handled by the `memcached` client?
- [14.5.5.2](#): Are there any, or are there any plans to introduce, a framework to hide the interaction of `memcached` from the application, i.e., within hibernate?
- [14.5.5.3](#): What's a recommended hardware config for a `memcached` server? Linux or Windows?
- [14.5.5.4](#): How expensive is it to establish a `memcache` connection? Should those connections be pooled?
- [14.5.5.5](#): How will the data will be handled when the `memcached` server is down?
- [14.5.5.6](#): Can `memcached` be run on a Windows environment?
- [14.5.5.7](#): What is the max size of an object you can store in `memcache` and is that configurable?
- [14.5.5.8](#): Is it true `memcached` will be much more effective with db-read-intensive applications than with db-write-intensive applications?
- [14.5.5.9](#): What are best practices for testing an implementation, to ensure that it is an improvement over the MySQL query cache, and to measure the impact of `memcached` configuration changes? And would you recommend keeping the configuration very simple to start?
- [14.5.5.10](#): Can MySQL actually trigger/store the changed data to `memcached`?
- [14.5.5.11](#): So the responsibility lies with the application to populate and get records from the database as opposed to being a transparent cache layer for the db?
- [14.5.5.12](#): `memcached` is fast - is there any overhead in not using persistent connections? If persistent is always recommended, what are the downsides (e.g. locking up)?
- [14.5.5.13](#): Is compression available?
- [14.5.5.14](#): File socket support for `memcached` from the localhost use to the local `memcached` server?
- [14.5.5.15](#): What are the advantages of using UDFs when the `get/sets` are manageable from within the client code rather than the

db?

- [14.5.5.16](#): Is `memcached` typically a better solution for improving speed than MySQL Cluster and/or MySQL Proxy?
- [14.5.5.17](#): What speed trade offs is there between `memcached` vs MySQL Query Cache? Where you check `memcached`, and get data from MySQL and put it in `memcached` or just make a query and results are put into MySQL Query Cache.
- [14.5.5.18](#): Does the `-L` flag automatically sense how much memory is being used by other `memcached`?
- [14.5.5.19](#): Is the data inside of `memcached` secure?
- [14.5.5.20](#): Can we implement different types of `memcached` as different nodes in the same server - so can there be deterministic and non deterministic in the same server?
- [14.5.5.21](#): How easy is it to introduce `memcached` to an existing enterprise application instead of inclusion at project design?
- [14.5.5.22](#): Can `memcached` work with ASPX?
- [14.5.5.23](#): If I have an object larger than a MB, do I have to manually split it or can I configure `memcached` to handle larger objects?
- [14.5.5.24](#): How does `memcached` compare to nCache?
- [14.5.5.25](#): Doing a direct telnet to the `memcached` port, is that just for that one machine, or does it magically apply across all nodes?
- [14.5.5.26](#): Is `memcached` more effective for video and audio as opposed to textual read/writes
- [14.5.5.27](#): We are caching XML by serialising using `saveXML()`, because PHP cannot serialise DOM objects; Some of the XML is variable and is modified per-request. Do you recommend caching then using XPath, or is it better to rebuild the DOM from separate node-groups?
- [14.5.5.28](#): Do the memcache UDFs work under 5.1?
- [14.5.5.29](#): How are auto-increment columns in the MySQL database coordinated across multiple instances of `memcached`?
- [14.5.5.30](#): If you log a complex class (with methods that do calculation etc) will the get from Memcache re-create the class on the way out?

Questions and Answers

14.5.5.1: How does an event such as a crash of one of the `memcached` servers handled by the `memcached` client?

There is no automatic handling of this. If your client fails to get a response from a server then it should fall back to loading the data from the MySQL database.

The client APIs all provide the ability to add and remove `memcached` instances on the fly. If within your application you notice that `memcached` server is no longer responding, you can remove the server from the list of servers, and keys will automatically be redistributed to another `memcached` server in the list. If retaining the cache content on all your servers is important, make sure you use an API that supports a consistent hashing algorithm. For more information, see [Section 14.5.2.4](#), “`memcached` Distribution Types”.

14.5.5.2: Are there any, or are there any plans to introduce, a framework to hide the interaction of `memcached` from the application, i.e., within hibernate?

There are lots of projects working with `memcached`. There is a Google Code implementation of Hibernate and `memcached` working together. See <http://code.google.com/p/hibernate-memcached/>.

14.5.5.3: What's a recommended hardware config for a `memcached` server? Linux or Windows?

`memcached` is only available on Unix/Linux, so using a Windows machine is not an option. Outside of this, `memcached` has a very low processing overhead. All that is required is spare physical RAM capacity. The point is not that you should necessarily deploy a dedicated `memcached` server. If you have web, application, or database servers that have spare RAM capacity, then use them with `memcached`.

If you want to build and deploy a dedicated `memcached` servers, then you use a relatively low-power CPU, lots of RAM and one or more Gigabit Ethernet interfaces.

14.5.5.4: How expensive is it to establish a memcache connection? Should those connections be pooled?

Opening the connection is relatively inexpensive, because there is no security, authentication or other handshake taking place before you can start sending requests and getting results. Most APIs support a persistent connection to a `memcached` instance to reduce the latency. Connection pooling would depend on the API you are using, but if you are communicating directly over TCP/IP, then connection pooling would provide some small performance benefit.

14.5.5.5: How will the data will be handled when the `memcached` server is down?

The behavior is entirely application dependent. Most applications will fall back to loading the data from the database (just as if they were updating the `memcached`) information. If you are using multiple `memcached` servers, you may also want to remove a server from the list to prevent the missing server affecting performance. This is because the client will still attempt to communicate the `memcached` that corresponds to the key you are trying to load.

14.5.5.6: Can memcached be run on a Windows environment?

No. Currently `memcached` is available only on the Unix/Linux platform. There is an unofficial port available, see <http://www.codeplex.com/memcachedproviders>.

14.5.5.7: What is the max size of an object you can store in memcache and is that configurable?

The default maximum object size is 1MB. If you want to increase this size, you have to re-compile `memcached`. You can modify the value of the `POWER_BLOCK` within the `slabs.c` file within the source.

14.5.5.8: Is it true `memcached` will be much more effective with db-read-intensive applications than with db-write-intensive applications?

Yes. `memcached` plays no role in database writes, it is a method of caching data already read from the database in RAM.

14.5.5.9: What are best practices for testing an implementation, to ensure that it is an improvement over the MySQL query cache, and to measure the impact of `memcached` configuration changes? And would you recommend keeping the configuration very simple to start?

The best way to test the performance is to start up a `memcached` instance. First, modify your application so that it stores the data just before the data is about to be used or displayed into `memcached`. Since the APIs handle the serialization of the data, it should just be a one line modification to your code. Then, modify the start of the process that would normally load that information from MySQL with the code that requests the data from `memcached`. If the data cannot be loaded from `memcached`, default to the MySQL process.

All of the changes required will probably amount to just a few lines of code. To get the best benefit, make sure you cache entire objects (for example, all the components of a web page, blog post, discussion thread, etc.), rather than using `memcached` as a simple cache of individuals rows of MySQL tables. You should see performance benefits almost immediately.

Keeping the configuration very simple at the start, or even over the long term, is very easy with `memcached`. Once you have the basic structure up and running, the only addition you may want to make is to add more servers into the list of servers used by your clients. You don't need to manage the `memcached` servers, and there is no complex configuration, just add more servers to the list and let the client API and the `memcached` servers make the decisions.

14.5.5.10: Can MySQL actually trigger/store the changed data to memcached?

Yes. You can use the MySQL UDFs for `memcached` and either write statements that directly set the values in the `memcached` server, or use triggers or stored procedures to do it for you. For more information, see [Section 14.5.3.7, "Using the MySQL memcached UDFs"](#)

14.5.5.11: So the responsibility lies with the application to populate and get records from the database as opposed to being a transparent cache layer for the db?

Yes. You load the data from the database and write it into the cache provided by `memcached`. Using `memcached` as a simple database row cache, however, is probably inefficient. The best way to use `memcached` is to load all of the information from the database relating to a particular object, and then cache the entire object. For example, in a blogging environment, you might load the blog, associated comments, categories and so on, and then cache all of the information relating to that blog post. The reading of the data from the database will require multiple SQL statements and probably multiple rows of data to complete, which is time consuming. Loading the entire blog post and the associated information from `memcached` is just one operation and doesn't involve using the disk or parsing the SQL statement.

14.5.5.12: `memcached` is fast - is there any overhead in not using persistent connections? If persistent is always recommended, what are the downsides (e.g. locking up?)

If you don't use persistent connections when communicating with `memcached` then there will be a small increase in the latency of opening the connection each time. The effect is comparable to use non-persistent connections with MySQL.

In general, the chance of locking or other issues with persistent connections is minimal, because there is very little locking within `memcached`. If there is a problem then eventually your request will timeout and return no result so your application will need to

load from MySQL again.

14.5.5.13: Is compression available?

Yes. Most of the client APIs support some sort of compression, and some even allow you to specify the threshold at which a value is deemed appropriate for compression during storage.

14.5.5.14: File socket support for `memcached` from the localhost use to the local memcached server?

You can use the `-s` option to `memcached` to specify the location of a file socket. This automatically disables network support.

14.5.5.15: What are the advantages of using UDFs when the get/sets are manageable from within the client code rather than the db?

Sometimes you want to be able to update the information within `memcached` based on a generic database activity, rather than relying on your client code. For example, you may want to update status or counter information in `memcached` through the use of a trigger or stored procedure. For some situations and applications the existing use of a stored procedure for some operations means that updating the value in `memcached` from the database is easier than separately loading and communicating that data to the client just so the client can talk to `memcached`.

In other situations, when you are using a number of different clients and different APIs, you don't want to have to write (and maintain) the code required to update `memcached` in all the environments. Instead, you do this from within the database and the client never gets involved.

14.5.5.16: Is `memcached` typically a better solution for improving speed than MySQL Cluster and/or MySQL Proxy?

Both MySQL Cluster and MySQL Proxy still require access to the underlying database to retrieve the information. This implies both a parsing overhead for the statement and, often, disk based access to retrieve the data you have selected.

The advantage of `memcached` is that you can store entire objects or groups of information that may require multiple SQL statements to obtain. Restoring the result of 20 SQL statements formatted into a structure that your application can use directly without requiring any additional processing is always going to be faster than building that structure by loading the rows from a database.

14.5.5.17: What speed trade offs is there between `memcached` vs MySQL Query Cache? Where you check `memcached`, and get data from MySQL and put it in `memcached` or just make a query and results are put into MySQL Query Cache.

In general, the time difference between getting data from the MySQL Query Cache and getting the exact same data from `memcached` is very small.

However, the benefit of `memcached` is that you can store any information, including the formatted and processed results of many queries into a single `memcached` key. Even if all the queries that you executed could be retrieved from the Query Cache without having to go to disk, you would still be running multiple queries (with network and other overhead) compared to just one for the `memcached` equivalent. If your application uses objects, or does any kind of processing on the information, with `memcached` you can store the post-processed version, so the data you load is immediately available to be used. With data loaded from the Query Cache, you would still have to do that processing.

In addition to these considerations, keep in mind that keeping data in the MySQL Query Cache is difficult as you have no control over the queries that are stored. This means that a slightly unusual query can temporarily clear a frequently used (and normally cached) query, reducing the effectiveness of your Query Cache. With `memcached` you can specify which objects are stored, when they are stored, and when they should be deleted giving you much more control over the information stored in the cache.

14.5.5.18: Does the `-L` flag automatically sense how much memory is being used by other memcached?

No. There is no communication or sharing of information between `memcached` instances.

14.5.5.19: Is the data inside of `memcached` secure?

No, there is no security required to access or update the information within a `memcached` instance, which means that anybody with access to the machine has the ability to read, view and potentially update the information. If you want to keep the data secure, you can encrypt and decrypt the information before storing it. If you want to restrict the users capable of connecting to the server, your only choice is to either disable network access, or use IPTables or similar to restrict access to the `memcached` ports to a select set of hosts.

14.5.5.20: Can we implement different types of `memcached` as different nodes in the same server - so can there be deterministic and non deterministic in the same server?

Yes. You can run multiple instances of `memcached` on a single server, and in your client configuration you choose the list of servers you want to use.

14.5.5.21: How easy is it to introduce `memcached` to an existing enterprise application instead of inclusion at project design?

In general, it is very easy. In many languages and environments the changes to the application will be just a few lines, first to attempt to read from the cache when loading data and then fall back to the old method, and to update the cache with information once the data has been read.

`memcached` is designed to be deployed very easily, and you shouldn't require significant architectural changes to your application to use `memcached`.

14.5.5.22: Can `memcached` work with ASPX?

There are ports and interfaces for many languages and environments. ASPX relies on an underlying language such as C# or Visual-Basic, and if you are using ASP.NET then there is a C# `memcached` library. For more information, see .

14.5.5.23: If I have an object larger than a MB, do I have to manually split it or can I configure `memcached` to handle larger objects?

You would have to manually split it. `memcached` is very simple, you give it a key and some data, it tries to cache it in RAM. If you try to store more than the default maximum size, the value is just truncated for speed reasons.

14.5.5.24: How does `memcached` compare to nCache?

The main benefit of `memcached` is that is very easy to deploy and works with a wide range of languages and environments, including .NET, Java, Perl, Python, PHP, even MySQL. `memcached` is also very lightweight in terms of systems and requirements, and you can easily add as many or as few `memcached` servers as you need without changing the individual configuration. `memcached` does require additional modifications to the application to take advantage of functionality such as multiple `memcached` servers.

14.5.5.25: Doing a direct telnet to the memcached port, is that just for that one machine, or does it magically apply across all nodes?

Just one. There is no communication between different instances of `memcached`, even if each instance is running on the same machine.

14.5.5.26: Is memcached more effective for video and audio as opposed to textual read/writes

`memcached` doesn't care what information you are storing. To `memcached`, any value you store is just a stream of data. Remember, though, that the maximum size of an object you can store in `memcached` without modifying the source code is 1MB, so its usability with audio and video content is probably significantly reduced. Also remember that `memcached` is a solution for caching information for reading. It shouldn't be used for writes, except when updating the information in the cache.

14.5.5.27: We are caching XML by serialising using `saveXML()`, because PHP cannot serialise DOM objects; Some of the XML is variable and is modified per-request. Do you recommend caching then using XPath, or is it better to rebuild the DOM from separate node-groups?

You would need to test your application using the different methods to determine this information. You may find that the default serialization within PHP may allow you to store DOM objects directly into the cache.

14.5.5.28: Do the memcache UDFs work under 5.1?

Yes.

14.5.5.29: How are auto-increment columns in the MySQL database coordinated across multiple instances of memcached?

They aren't. There is no relationship between MySQL and `memcached` unless your application (or, if you are using the MySQL UDFs for `memcached`, your database definition) creates one.

If you are storing information based on an auto-increment key into multiple instances of `memcached` then the information will only be stored on one of the `memcached` instances anyway. The client uses the key value to determine which `memcached` instance to store the information, it doesn't store the same information across all the instances, as that would be a waste of cache memory.

14.5.5.30: If you log a complex class (with methods that do calculation etc) will the get from Memcache re-create the class on the way out?

In general, yes. If the serialization method within the API/language that you are using supports it, then methods and other information will be stored and retrieved.

14.6. MySQL Proxy

The MySQL Proxy is an application that communicates over the network using the MySQL Network Protocol and provides communication between one or more MySQL servers and one or more MySQL clients. In the most basic configuration, MySQL Proxy

simply passes on queries from the client to the MySQL Server and returns the responses from the MySQL Server to the client.

Because MySQL Proxy uses the MySQL network protocol, any MySQL compatible client (include the command line client, any clients using the MySQL client libraries, and any connector that supports the MySQL network protocol) can connect to the proxy without modification.

In addition to the basic pass-through configuration, the MySQL Proxy is also capable of monitoring and altering the communication between the client and the server. This interception of the queries enables you to add profiling, and the interception of the exchanges is scriptable using the Lua scripting language.

By intercepting the queries from the client, the proxy can insert additional queries into the list of queries sent to the server, and remove the additional results when they are returned by the server. Using this functionality you can add informational statements to each query, for example to monitor their execution time or progress, and separately log the results, while still returning the results from the original query to the client.

The proxy allows you to perform additional monitoring, filtering or manipulation on queries without you having to make any modifications to the client and without the client even being aware that it is communicating with anything but a genuine MySQL server.

Warning

MySQL Proxy is currently an Alpha release and should not be used within production environments.

Important

MySQL Proxy is compatible with MySQL 5.0.x or later. Testing has not been performed with Version 4.1. Please provide feedback on your experiences via the [MySQL Proxy Forum](#).

14.6.1. MySQL Proxy Supported Platforms

MySQL Proxy is currently available as a pre-compiled binary for the following platforms:

- Linux (including RedHat, Fedora, Debian, SuSE) and derivatives.
- Mac OS X
- FreeBSD
- IBM AIX
- Sun Solaris
- Microsoft Windows (including Microsoft Windows XP, and Microsoft Windows Server 2003)

Other Unix/Linux platforms not listed should be compatible by using the source package and building MySQL Proxy locally.

System requirements for the MySQL Proxy application are the same as the main MySQL server. Currently MySQL Proxy is compatible only with MySQL 5.0.1 and later. MySQL Proxy is provided as a standalone, statically linked binary. You do not need to have MySQL or Lua installed.

14.6.2. Installing MySQL Proxy

You have three choices for installing MySQL Proxy:

- Pre-compiled binaries are available for a number of different platforms. See [Section 14.6.2.1, “Installing MySQL Proxy from a binary distribution”](#).
- You can install from the source code if you want to build on an environment not supported by the binary distributions. See [Section 14.6.2.2, “Installing MySQL Proxy from a source distribution”](#).
- The latest version of the MySQL proxy source code is available through a development repository is the best way to stay up to date with the latest fixes and revisions. See [Section 14.6.2.3, “Installing MySQL Proxy from the Subversion repository”](#).

14.6.2.1. Installing MySQL Proxy from a binary distribution

If you download the binary packages then you need only to extract the package and then copy the `mysql-proxy` file to your desired location. For example:

```
shell> tar zxf mysql-proxy-0.5.0.tar.gz
shell> cp ./mysql-proxy-0.5.0/sbin/mysql-proxy /usr/local/sbin
```

14.6.2.2. Installing MySQL Proxy from a source distribution

If you have downloaded the source package then you will need to compile the MySQL Proxy before using it. To build you will need to have the following installed:

- libevent 1.x or higher (1.3b or later is preferred)
- lua 5.1.x or higher
- glib2 2.6.0 or higher
- pkg-config
- MySQL 5.0.x or higher developer files

Note

On some operating systems you may need to manually build the required components to get the latest version. If you are having trouble compiling MySQL Proxy then consider using one of the binary distributions.

Once these components are installed, you need to configure and then build:

```
shell> tar zxf mysql-proxy-0.5.0.tar.gz
shell> cd mysql-proxy-0.5.0
shell> ./configure
shell> make
```

If you want to test the build, then use the `check` target to `make`:

```
shell> make check
```

The tests try to connect to `localhost` using the `root` user. If you need to provide a password, set the `MYSQL_PASSWORD` environment variable:

```
shell> MYSQL_PASSWORD=root_pwd make check
```

You can install using the `install` target:

```
shell> make install
```

By default `mysql-proxy` is installed into `/usr/local/sbin/mysql-proxy`. The Lua example scripts are copied into `/usr/local/share`.

14.6.2.3. Installing MySQL Proxy from the Subversion repository

The MySQL Proxy source is available through a public Subversion repository and is the quickest way to get hold of the latest releases and fixes.

To build from the Subversion repository, you need the following components already installed:

- Subversion 1.3.0 or higher
- [libtool](#) 1.5 or higher
- [autoconf](#) 2.56 or higher
- [automake](#) 1.9 or higher
- [libevent](#) 1.x or higher (1.3b or later is preferred)
- [lua](#) 5.1.x or higher
- [glib2](#) 2.4.0 or higher

- `pkg-config`
- MySQL 5.0.x or higher developer files

To checkout a local copy of the Subversion repository, use `svn`:

```
shell> svn co http://svn.MySQL.com/svnpublic/mysql-proxy/ mysql-proxy
```

The above command will download a complete version of the Subversion repository for `mysql-proxy`. The main source files are located within the `trunk` subdirectory. The configuration scripts need to be generated before you can configure and build `mysql-proxy`. The `autogen.sh` script will generate the configuration scripts for you:

```
shell> sh ./autogen.sh
```

The script creates the standard `configure` script, which you can then use to configure and build with `make`:

```
shell> ./configure
shell> make
shell> make install
```

If you want to create a standalone source distribution, identical to the source distribution available for download:

```
shell> make distcheck
```

The above will create the file `mysql-proxy-0.5.0.tar.gz` within the current directory.

14.6.3. MySQL Proxy Command-Line Options

To start `mysql-proxy` you can just run the command directly. However, for most situations you will want to specify at the very least the address/host name and port number of the backend MySQL server to which the MySQL Proxy should pass on queries.

You can get a list of the supported command-line options using the `--help-all` command-line option. The majority of these options set up the environment, either in terms of the address/port number that `mysql-proxy` should listen on for connections, or the onward connection to a MySQL server. A full description of the options is shown below:

- `--help-all` — show all help options.
- `--help-admin` — show options for the admin-module.
- `--help-proxy` — Show options for the proxy-module.
- `--admin-address=host:port` — specify the host name (or IP address) and port for the administration port. The default is `localhost:4041`.
- `--proxy-address=host:port` — the listening host name (or IP address) and port of the proxy server. The default is `localhost:4040`.
- `--proxy-read-only-backend-address=host:port` — the listening host name (or IP address) and port of the proxy server for read-only connections. The default is for this information not to be set.
- `--proxy-backend-addresses=host:port` — the host name (or IP address) and port of the MySQL server to connect to. You can specify multiple backend servers by supplying multiple options. Clients are connected to each backend server in round-robin fashion. For example, if you specify two servers A and B, the first client connection will go to server A; the second client connection to server B and the third client connection to server A.
- `--proxy-skip-profiling` — disables profiling of queries (tracking time statistics). The default is for tracking to be enabled.
- `--proxy-fix-bug-25371` — gets round an issue when connecting to a MySQL server later than 5.1.12 when using a MySQL client library of any earlier version.
- `--proxy-lua-script=file` — specify the Lua script file to be loaded. Note that the script file is not physically loaded and parsed until a connection is made. Also note that the specified Lua script is reloaded for each connection; if the content of the Lua script changes while `mysql-proxy` is running then the updated content will automatically be used when a new connection is made.
- `--daemon` — starts the proxy in daemon mode.

- `--pid-file=file` — sets the name of the file to be used to store the process ID.
- `--version` — show the version number.

The most common usage is as a simple proxy service (i.e. without addition scripting). For basic proxy operation you must specify at least one `proxy-backend-addresses` option to specify the MySQL server to connect to by default:

```
shell> mysql-proxy
--proxy-backend-addresses=MySQL.example.com:3306
```

The default proxy port is `4040`, so you can connect to your MySQL server through the proxy by specifying the host name and port details:

```
shell> mysql --host=localhost --port=4040
```

If your server requires authentication information then this will be passed through natively without alteration by `mysql-proxy`, so you must also specify the authentication information if required:

```
shell> mysql --host=localhost --port=4040 \
--user=username --password=password
```

You can also connect to a read-only port (which filters out `UPDATE` and `INSERT` queries) by connecting to the read-only port. By default the host name is the default, and the port is `4042`, but you can alter the host/port information by using the `-proxy-read-only-address` command-line option.

For more detailed information on how to use these command line options, and `mysql-proxy` in general in combination with Lua scripts, see [Section 14.6.5, “Using MySQL Proxy”](#).

14.6.4. MySQL Proxy Scripting

You can control how MySQL Proxy manipulates and works with the queries and results that are passed on to the MySQL server through the use of the embedded Lua scripting language. You can find out more about the Lua programming language from the [Lua Website](#).

The primary interaction between MySQL Proxy and the server is provided by defining one or more functions through an Lua script. A number of functions are supported, according to different events and operations in the communication sequence between a client and one or more backend MySQL servers:

- `connect_server()` — this function is called each time a connection is made to MySQL Proxy from a client. You can use this function during load-balancing to intercept the original connection and decide which server the client should ultimately be attached to. If you do not define a special solution, then a simple round-robin style distribution is used by default.
- `read_handshake()` — this function is called when the initial handshake information is returned by the server. You can capture the handshake information returned and provide additional checks before the authorization exchange takes place.
- `read_auth()` — this function is called when the authorization packet (user name, password, default database) are submitted by the client to the server for authentication.
- `read_auth_result()` — this function is called when the server returns an authorization packet to the client indicating whether the authorization succeeded.
- `read_query()` — this function is called each time a query is sent by the client to the server. You can use this to edit and manipulate the original query, including adding new queries before and after the original statement. You can also use this function to return information directly to the client, bypassing the server, which can be useful to filter unwanted queries or queries that exceed known limits.
- `read_query_result()` — this function is called each time a result is returned from the server, providing you have manually injected queries into the query queue. If you have not explicitly inject queries within the `read_query()` function then this function is not triggered. You can use this to edit the result set, or to remove or filter the result sets generated from additional queries you injected into the queue when using `read_query()`.

The table below describes the direction of flow of information at the point when the function is triggered.

Function	Supplied Information	Direction
<code>connect_server()</code>	None	Client to Server
<code>read_handshake()</code>	Handshake packet	Server to Client

Function	Supplied Information	Direction
<code>read_auth()</code>	Authorization packet	Client to Server
<code>read_auth_result()</code>	Authorization response	Server to Client
<code>read_query()</code>	Query	Client to Server
<code>read_query_result()</code>	Query result	Server to Client

By default, all functions return a result that indicates that the data should be passed on to the client or server (depending on the direction of the information being transferred). This return value can be overridden by explicitly returning a constant indicating that a particular response should be sent. For example, it is possible to construct result set information by hand within `read_query()` and to return the resultset directly to the client without ever sending the original query to the server.

In addition to these functions, a number of built-in structures provide control over how MySQL Proxy forwards on queries and returns the results by providing a simplified interface to elements such as the list of queries and the groups of result sets that are returned.

14.6.4.1. Proxy Scripting Sequence During Query Injection

The figure below gives an example of how the proxy might be used when injecting queries into the query queue. Because the proxy sits between the client and MySQL server, what the proxy sends to the server, and the information that the proxy ultimately returns to the client do not have to match or correlate. Once the client has connected to the proxy, the following sequence occurs for each individual query sent by the client.

1. The client submits one query to the proxy, the `read_query()` function within the proxy is triggered. The function adds the query to the query queue.
2. Once manipulation by `read_query()` has completed, the queries are submitted, sequentially, to the MySQL server.
3. The MySQL server returns the results from each query, one result set for each query submitted. The `read_query_result()` function is triggered for each result set, and each invocation can decide which result set to return to the client

For example, you can queue additional queries into the global query queue to be processed by the server. This can be used to add statistical information by adding queries before and after the original query, changing the original query:

```
SELECT * FROM City;
```

Into a sequence of queries:

```
SELECT NOW();
```

```
SELECT * FROM City;
SELECT NOW();
```

You can also modify the original statement, for example to add `EXPLAIN` to each statement executed to get information on how the statement was processed, again altering our original SQL statement into a number of statements:

```
SELECT * FROM City;
EXPLAIN SELECT * FROM City;
```

In both of these examples, the client would have received more result sets than expected. Regardless of how you manipulate the incoming query and the returned result, the number of queries returned by the proxy must match the number of original queries sent by the client.

You could adjust the client to handle the multiple result sets sent by the proxy, but in most cases you will want the existence of the proxy to remain transparent. To ensure that the number of queries and result sets match, you can use the MySQL Proxy `read_query_result()` to extract the additional result set information and return only the result set the client originally requested back to the client. You can achieve this by giving each query that you add to the query queue a unique ID, and then filter out queries that do not match the original query ID when processing them with `read_query_result()`.

14.6.4.2. Internal Structures

There are a number of internal structures within the scripting element of MySQL Proxy. The primary structure is `proxy` and this provides an interface to the many common structures used throughout the script, such as connection lists and configured backend servers. Other structures, such as the incoming packet from the client and result sets are only available within the context of one of the scriptable functions.

Attribute	Description
<code>connection</code>	A structure containing the active client connections. For a list of attributes, see <code>proxy.connection</code> .
<code>servers</code>	A structure containing the list of configured backend servers. For a list of attributes, see <code>proxy.backends</code> .
<code>queries</code>	A structure containing the queue of queries that will be sent to the server during a single client query. For a list of attributes, see <code>proxy.queries</code> .
<code>PROXY_VERSION</code>	The version number of MySQL Proxy, encoded in hex. You can use this to check that the version number supports a particular option from within the Lua script. Note that the value is encoded as a hex value, so to check the version is at least 0.5.1 you compare against <code>0x00501</code> .

`proxy.connection`

The `proxy.connection` object is read only, and provides information about the current connection.

Attribute	Description
<code>thread_id</code>	The thread ID of the connection.
<code>backend_ndx</code>	The ID of the server used for this connection. This is an ID valid against the list of configured servers available through the <code>proxy.backends</code> object.

`proxy.backends`

The `proxy.backends` table is partially writable and contains an array of all the configured backend servers and the server metadata (IP address, status, etc.). You can determine the array index of the current connection using `proxy.connection["backend_ndx"]` which is the index into this table of the backend server being used by the active connection.

The attributes for each entry within the `proxy.backends` table are shown in this table.

Attribute	Description
<code>address</code>	The host name/port combination used for this connection
<code>connected_clients</code>	The number of clients currently connected.
<code>state</code>	The status of the backend server. See Section 14.6.4.2, “Internal Structures” [1184]

`proxy.queries`

The `proxy.queries` object is a queue representing the list of queries to be sent to the server. The queue is not populated automatically, but if you do not explicitly populate the queue then queries are passed on to the backend server verbatim. Also, if you do not populate the query queue by hand, then the `read_query_result()` function is not triggered.

The following methods are supported for populating the `proxy.queries` object.

Function	Description
<code>append(id,packet)</code>	Appends a query to the end of the query queue. The <code>id</code> is an integer identifier that you can use to recognize the query results when they are returned by the server. The packet should be a properly formatted query packet.
<code>prepend(id,packet)</code>	Prepends a query to the query queue. The <code>id</code> is an identifier that you can use to recognize the query results when they are returned by the server. The packet should be a properly formatted query packet.
<code>reset()</code>	Empties the query queue.
<code>len()</code>	Returns the number of query packets in the queue.

For example, you could append a query packet to the `proxy.queries` queue by using the `append()`:

```
proxy.queries:append(1,packet)
```

proxy.response

The `proxy.response` structure is used when you want to return your own MySQL response, instead of forwarding a packet that you have received a backend server. The structure holds the response type information, an optional error message, and the result set (rows/columns) that you want to return.

Attribute	Description
<code>type</code>	The type of the response. The type must be either <code>MYSQLD_PACKET_OK</code> or <code>MYSQLD_PACKET_ERR</code> . If the <code>MYSQLD_PACKET_ERR</code> , then you should set the value of the <code>mysql.response.errmsg</code> with a suitable error message.
<code>errmsg</code>	A string containing the error message that will be returned to the client.
<code>resultset</code>	A structure containing the result set information (columns and rows), identical to what would be returned when returning a results from a <code>SELECT</code> query.

When using `proxy.response` you either set `proxy.response.type` to `proxy.MYSQLD_PACKET_OK` and then build `resultset` to contain the results that you want to return, or set `proxy.response.type` to `proxy.MYSQLD_PACKET_ERR` and set the `proxy.response.errmsg` to a string with the error message. To send the completed resultset or error message, you should return the `proxy.PROXY_SEND_RESULT` to trigger the return of the packet information.

An example of this can be seen in the `tutorial-resultset.lua` script within the MySQL Proxy package:

```
if string.lower(command) == "show" and string.lower(option) == "querycounter" then
    ---
    -- proxy.PROXY_SEND_RESULT requires
    --
    -- proxy.response.type to be either
    -- * proxy.MYSQLD_PACKET_OK or
    -- * proxy.MYSQLD_PACKET_ERR
    --
    -- for proxy.MYSQLD_PACKET_OK you need a resultset
    -- * fields
    -- * rows
    --
    -- for proxy.MYSQLD_PACKET_ERR
    -- * errmsg
    proxy.response.type = proxy.MYSQLD_PACKET_OK
    proxy.response.resultset = {
        fields = {
            { type = proxy.MYSQL_TYPE_LONG, name = "global_query_counter", },
            { type = proxy.MYSQL_TYPE_LONG, name = "query_counter", },
        },
        rows = {
            { proxy.global.query_counter, query_counter }
        }
    }

    -- we have our result, send it back
    return proxy.PROXY_SEND_RESULT
elseif string.lower(command) == "show" and string.lower(option) == "myerror" then
    proxy.response.type = proxy.MYSQLD_PACKET_ERR
    proxy.response.errmsg = "my first error"

    return proxy.PROXY_SEND_RESULT
```

proxy.response.resultset

The `proxy.response.resultset` structure should be populated with the rows and columns of data that you want to return. The structure contains the information about the entire result set, with the individual elements of the data shown in the table below.

Attribute	Description
<code>fields</code>	The definition of the columns being returned. This should be a dictionary structure with the <code>type</code> specifying the MySQL data type, and the <code>name</code> specifying the column name. Columns should be listed in the order of the column data that will be returned.
<code>flags</code>	A number of flags related to the resultset. Valid flags include <code>auto_commit</code> (whether an automatic commit was triggered), <code>no_good_index_used</code> (the query executed without using an appropriate index), and <code>no_index_used</code> (the query executed without using any index).
<code>rows</code>	The actual row data. The information should be returned as an array of arrays. Each inner array should contain the column data, with the outer array making up the entire result set.
<code>warning_count</code>	The number of warnings for this result set.
<code>affected_rows</code>	The number of rows affected by the original statement.
<code>insert_id</code>	The last insert ID for an auto-incremented column in a table.
<code>query_status</code>	The status of the query operation. You can use the <code>MYSQLD_PACKET_OK</code> or <code>MYSQLD_PACKET_ERR</code> constants to populate this parameter.

For an example of the population of this table, see [Section 14.6.4.2, “Internal Structures” \[1183\]](#).

Proxy Return State Constants

The following constants are used internally by the proxy to specify the response to send to the client or server. All constants are exposed as values within the main `proxy` table.

Constant	Description
<code>PROXY_SEND_QUERY</code>	Causes the proxy to send the current contents of the queries queue to the server.
<code>PROXY_SEND_RESULT</code>	Causes the proxy to send a result set back to the client.
<code>PROXY_IGNORE_RESULT</code>	Causes the proxy to drop the result set (nothing is returned to the client).

As constants, these entities are available without qualification in the Lua scripts. For example, at the end of the `read_query_result()` you might return `PROXY_IGNORE_RESULT`:

```
return proxy.PROXY_IGNORE_RESULT
```

Packet State Constants

The following states describe the status of a network packet. These items are entries within the main `proxy` table.

Constant	Description
<code>MYSQLD_PACKET_OK</code>	The packet is OK.
<code>MYSQLD_PACKET_ERR</code>	The packet contains error information.
<code>MYSQLD_PACKET_RAW</code>	The packet contains raw data.

Backend State/Type Constants

The following constants are used either to define the status of the backend server (the MySQL server to which the proxy is connected) or the type of backend server. These items are entries within the main `proxy` table.

Constant	Description
<code>BACKEND_STATE_UNKNOWN</code>	The current status is unknown.
<code>BACKEND_STATE_UP</code>	The backend is known to be up (available).
<code>BACKEND_STATE_DOWN</code>	The backend is known to be down (unavailable).
<code>BACKEND_TYPE_UNKNOWN</code>	Backend type is unknown.

Constant	Description
BACKEND_TYPE_RW	Backend is available for read/write.
BACKEND_TYPE_RO	Backend is available only for read-only use.

Server Command Constants

The following values are used in the packets exchanged between the client and server to identify the information in the rest of the packet. These items are entries within the main `proxy` table. The packet type is defined as the first character in the sent packet. For example, when intercepting packets from the client to edit or monitor a query you would check that the first byte of the packet was of type `proxy.COM_QUERY`.

Constant	Description
COM_SLEEP	Sleep
COM_QUIT	Quit
COM_INIT_DB	Initialize database
COM_QUERY	Query
COM_FIELD_LIST	Field List
COM_CREATE_DB	Create database
COM_DROP_DB	Drop database
COM_REFRESH	Refresh
COM_SHUTDOWN	Shutdown
COM_STATISTICS	Statistics
COM_PROCESS_INFO	Process List
COM_CONNECT	Connect
COM_PROCESS_KILL	Kill
COM_DEBUG	Debug
COM_PING	Ping
COM_TIME	Time
COM_DELAYED_INSERT	Delayed insert
COM_CHANGE_USER	Change user
COM_BINLOG_DUMP	Binlog dump
COM_TABLE_DUMP	Table dump
COM_CONNECT_OUT	Connect out
COM_REGISTER_SLAVE	Register slave
COM_STMT_PREPARE	Prepare server-side statement
COM_STMT_EXECUTE	Execute server-side statement
COM_STMT_SEND_LONG_DATA	Long data
COM_STMT_CLOSE	Close server-side statement
COM_STMT_RESET	Reset statement
COM_SET_OPTION	Set option
COM_STMT_FETCH	Fetch statement
COM_DAEMON	Daemon (MySQL 5.1 only)
COM_ERROR	Error

MySQL Type Constants

These constants are used to identify the field types in the query result data returned to clients from the result of a query. These items are entries within the main `proxy` table.

Constant	Field Type
MYSQL_TYPE_DECIMAL	Decimal
MYSQL_TYPE_NEWDECIMAL	Decimal (MySQL 5.0 or later)

Constant	Field Type
<code>MYSQL_TYPE_TINY</code>	Tiny
<code>MYSQL_TYPE_SHORT</code>	Short
<code>MYSQL_TYPE_LONG</code>	Long
<code>MYSQL_TYPE_FLOAT</code>	Float
<code>MYSQL_TYPE_DOUBLE</code>	Double
<code>MYSQL_TYPE_NULL</code>	Null
<code>MYSQL_TYPE_TIMESTAMP</code>	Timestamp
<code>MYSQL_TYPE_LONGLONG</code>	Long long
<code>MYSQL_TYPE_INT24</code>	Integer
<code>MYSQL_TYPE_DATE</code>	Date
<code>MYSQL_TYPE_TIME</code>	Time
<code>MYSQL_TYPE_DATETIME</code>	Datetime
<code>MYSQL_TYPE_YEAR</code>	Year
<code>MYSQL_TYPE_NEWDATE</code>	Date (MySQL 5.0 or later)
<code>MYSQL_TYPE_ENUM</code>	Enumeration
<code>MYSQL_TYPE_SET</code>	Set
<code>MYSQL_TYPE_TINY_BLOB</code>	Tiny Blob
<code>MYSQL_TYPE_MEDIUM_BLOB</code>	Medium Blob
<code>MYSQL_TYPE_LONG_BLOB</code>	Long Blob
<code>MYSQL_TYPE_BLOB</code>	Blob
<code>MYSQL_TYPE_VAR_STRING</code>	Varstring
<code>MYSQL_TYPE_STRING</code>	String
<code>MYSQL_TYPE_TINY</code>	Tiny (compatible with <code>MYSQL_TYPE_CHAR</code>)
<code>MYSQL_TYPE_ENUM</code>	Enumeration (compatible with <code>MYSQL_TYPE_INTERVAL</code>)
<code>MYSQL_TYPE_GEOMETRY</code>	Geometry
<code>MYSQL_TYPE_BIT</code>	Bit

14.6.4.3. Capturing a connection with `connect_server()`

When the proxy accepts a connection from a MySQL client, the `connect_server()` function is called.

There are no arguments to the function, but you can use and if necessary manipulate the information in the `proxy.connection` table, which is unique to each client session.

For example, if you have multiple backend servers then you can set the server to be used by that connection by setting the value of `proxy.connection.backend_ndx` to a valid server number. The code below will choose between two servers based on whether the current time in minutes is odd or even:

```
function connect_server()
    print("--> a client really wants to talk to a server")
    if (tonumber(os.date("%M")) % 2 == 0) then
        proxy.connection.backend_ndx = 2
        print("Choosing backend 2")
    else
        proxy.connection.backend_ndx = 1
        print("Choosing backend 1")
    end
    print("Using " .. proxy.backends[proxy.connection.backend_ndx].address)
end
```

In this example the IP address/port combination is also displayed by accessing the information from the internal `proxy.backends` table.

14.6.4.4. Examining the handshake with `read_handshake()`

Handshake information is sent by the server to the client after the initial connection (through `connect_server()`) has been made. The handshake information contains details about the MySQL version, the ID of the thread that will handle the connection information, and the IP address of the client and server. This information is exposed through a Lua table as the only argument to the

function.

- `mysqld_version` — the version of the MySQL server.
- `thread_id` — the thread ID.
- `scramble` — the password scramble buffer.
- `server_addr` — the IP address of the server.
- `client_addr` — the IP address of the client.

For example, you can print out the handshake data and refuse clients by IP address with the following function:

```
function read_handshake( auth )
  print("<-- let's send him some information about us")
  print("  mysqld-version: " .. auth.mysqld_version)
  print("  thread-id      : " .. auth.thread_id)
  print("  scramble-buf   : " .. string.format("%q", auth.scramble))
  print("  server-addr    : " .. auth.server_addr)
  print("  client-addr    : " .. auth.client_addr)

  if not auth.client_addr:match("^127.0.0.1:") then
    proxy.response.type = proxy.MYSQLD_PACKET_ERR
    proxy.response.errmsg = "only local connects are allowed"

    print("we don't like this client");

    return proxy.PROXY_SEND_RESULT
  end
end
```

Note that you have to return an error packet to the client by using `proxy.PROXY_SEND_RESULT`.

14.6.4.5. Examining the authentication credentials with `read_auth()`

The `read_auth()` function is triggered when an authentication handshake is initiated by the client. In the execution sequence, `read_auth()` occurs immediately after `read_handshake()`, so the server selection has already been made, but the connection and authorization information has not yet been provided to the backend server.

The function accepts a single argument, an Lua table containing the authorization information for the handshake process. The entries in the table are:

- `username` — the user login for connecting to the server.
- `password` — the password, encrypted, to be used when connecting.
- `default_db` — the default database to be used once the connection has been made.

For example, you can print the user name and password supplied during authorization using:

```
function read_auth( auth )
  print("  username      : " .. auth.username)
  print("  password     : " .. string.format("%q", auth.password))
end
```

You can interrupt the authentication process within this function and return an error packet back to the client by constructing a new packet and returning `proxy.PROXY_SEND_RESULT`:

```
proxy.response.type = proxy.MYSQLD_PACKET_ERR
proxy.response.errmsg = "Logins are not allowed"
return proxy.PROXY_SEND_RESULT
```

14.6.4.6. Accessing authentication information with `read_auth_result()`

The return packet from the server during authentication is captured by `read_auth_result()`. The only argument to this function is the authentication packet returned by the server. As the packet is a raw MySQL network protocol packet, you must access the first byte to identify the packet type and contents. The `MYSQLD_PACKET_ERR` and `MYSQLD_PACKET_OK` constants can be used to identify whether the authentication was successful:

```
function read_auth_result( auth )
  local state = auth.packet:byte()
```

```

if state == proxy.MYSQLD_PACKET_OK then
    print("<-- auth ok");
elseif state == proxy.MYSQLD_PACKET_ERR then
    print("<-- auth failed");
else
    print("<-- auth ... don't know: " .. string.format("%q", auth.packet));
end
end

```

14.6.4.7. Manipulating Queries with `read_query()`

The `read_query()` function is called once for each query submitted by the client and accepts a single argument, the query packet that was provided. To access the content of the packet you must parse the packet contents manually.

For example, you can intercept a query packet and print out the contents using the following function definition:

```

function read_query( packet )
    if packet:byte() == proxy.COM_QUERY then
        print("we got a normal query: " .. packet:sub(2))
    end
end

```

This example checks the first byte of the packet to determine the type. If the type is `COM_QUERY` (see [Section 14.6.4.2, "Internal Structures" \[1185\]](#)), then we extract the query from the packet and print it out. The structure of the packet type supplied is important. In the case of a `COM_QUERY` packet, the remaining contents of the packet are the text of the query string. In this example, no changes have been made to the query or the list of queries that will ultimately be sent to the MySQL server.

To modify a query, or add new queries, you must populate the query queue (`proxy.queries`) and then execute the queries that you have placed into the queue. If you do not modify the original query or the queue, then the query received from the client is sent to the MySQL server verbatim.

When adding queries to the queue, you should follow these guidelines:

- The packets inserted into the queue must be valid query packets. For each packet, you must set the initial byte to the packet type. If you are appending a query, you can append the query statement to the rest of the packet.
- Once you add a query to the queue, the queue is used as the source for queries sent to the server. If you add a query to the queue to add more information, you must also add the original query to the queue or it will not be executed.
- Once the queue has been populated, you must set the return value from `read_query()` to indicate whether the query queue should be sent to the server.
- When you add queries to the queue, you should add an ID. The ID you specify is returned with the result set so that you identify each query and corresponding result set. The ID has no other purpose than as an identifier for correlating the query and result-set. When operating in a passive mode, during profiling for example, you want to identify the original query and the corresponding resultset so that the results expect by the client can be returned correctly.
- Unless your client is designed to cope with more result sets than queries, you should ensure that the number of queries from the client match the number of results sets returned to the client. Using the unique ID and removing result sets you inserted will help.

Normally, the `read_query()` and `read_query_result()` function are used in conjunction with each other to inject additional queries and remove the additional result sets. However, `read_query_result()` is only called if you populate the query queue within `read_query()`.

14.6.4.8. Manipulating Results with `read_query_result()`

The `read_query_result()` is called for each result set returned by the server only if you have manually injected queries into the query queue. If you have not manipulated the query queue then this function is not called. The function supports a single argument, the result packet, which provides a number of properties:

- `id` — the ID of the result set, which corresponds to the ID that was set when the query packet was submitted to the server when using `append(id)` on the query queue.
- `query` — the text of the original query.
- `query_time` — the number of microseconds required to receive the first row of a result set.
- `response_time` — the number of microseconds required to receive the last row of the result set.

- `resultset` — the content of the result set data.

By accessing the result information from the MySQL server you can extract the results that match the queries that you injected, return different result sets (for example, from a modified query), and even create your own result sets.

The Lua script below, for example, will output the query, followed by the query time and response time (i.e. the time to execute the query and the time to return the data for the query) for each query sent to the server:

```
function read_query( packet )
    if packet:byte() == proxy.COM_QUERY then
        print("we got a normal query: " .. packet:sub(2))

        proxy.queries:append(1, packet )

        return proxy.PROXY_SEND_QUERY
    end
end

function read_query_result(inj)
    print("query-time: " .. (inj.query_time / 1000) .. "ms")
    print("response-time: " .. (inj.response_time / 1000) .. "ms")
end
```

You can access the rows of returned results from the resultset by accessing the rows property of the resultset property of the result that is exposed through `read_query_result()`. For example, you can iterate over the results showing the first column from each row using this Lua fragment:

```
for row in inj.resultset.rows do
    print("injected query returned: " .. row[1])
end
```

Just like `read_query()`, `read_query_result()` can return different values for each result according to the result returned. If you have injected additional queries into the query queue, for example, then you will want to remove the results returned from those additional queries and only return the results from the query originally submitted by the client.

The example below injects additional `SELECT NOW()` statements into the query queue, giving them a different ID to the ID of the original query. Within `read_query_result()`, if the ID for the injected queries is identified, we display the result row, and return the `proxy.PROXY_IGNORE_RESULT` from the function so that the result is not returned to the client. If the result is from any other query, we print out the query time information for the query and return the default, which passes on the result set unchanged. We could also have explicitly returned `proxy.PROXY_IGNORE_RESULT` to the MySQL client.

```
function read_query( packet )
    if packet:byte() == proxy.COM_QUERY then
        proxy.queries:append(2, string.char(proxy.COM_QUERY) .. "SELECT NOW()" )
        proxy.queries:append(1, packet )
        proxy.queries:append(2, string.char(proxy.COM_QUERY) .. "SELECT NOW()" )

        return proxy.PROXY_SEND_QUERY
    end
end

function read_query_result(inj)
    if inj.id == 2 then
        for row in inj.resultset.rows do
            print("injected query returned: " .. row[1])
        end
        return proxy.PROXY_IGNORE_RESULT
    else
        print("query-time: " .. (inj.query_time / 1000) .. "ms")
        print("response-time: " .. (inj.response_time / 1000) .. "ms")
    end
end
```

For further examples, see [Section 14.6.5, “Using MySQL Proxy”](#).

14.6.5. Using MySQL Proxy

There are a number of different ways to use MySQL Proxy. At the most basic level, you can allow MySQL Proxy to pass on queries from clients to a single server. To use MySQL proxy in this mode, you just have to specify the backend server that the proxy should connect to on the command line:

```
shell> mysql-proxy --proxy-backend-addresses=sakila:3306
```

If you specify multiple backend MySQL servers then the proxy will connect each client to each server in a round-robin fashion. For example, imagine you have two MySQL servers, A and B. The first client to connect will be connected to server A, the second to server B, the third to server C. For example:

```
shell> mysql-proxy \
  --proxy-backend-addresses=narcissus:3306 \
  --proxy-backend-addresses=nostromo:3306
```

When you have specified multiple servers in this way, the proxy will automatically identify when a MySQL server has become unavailable and mark it accordingly. New connections will automatically be attached to a server that is available, and a warning will be reported to the standard output from `mysql-proxy`:

```
network-mysqld.c.367: connect(nostromo:3306) failed: Connection refused
network-mysqld-proxy.c.2405: connecting to backend (nostromo:3306) failed, marking it as down for ...
```

Lua scripts enable a finer level of control, both over the connections and their distribution and how queries and result sets are processed. When using an Lua script, you must specify the name of the script on the command line using the `--proxy-lua-script` option:

```
shell> mysql-proxy --proxy-lua-script=mc.lua --proxy-backend-addresses=sakila:3306
```

When you specify a script, the script is not executed until a connection is made. This means that faults with the script will not be raised until the script is executed. Script faults will not affect the distribution of queries to backend MySQL servers.

Note

Because the script is not read until the connection is made, you can modify the contents of the Lua script file while the proxy is still running and the script will automatically be used for the next connection. This ensures that MySQL Proxy remains available because it does not have to be restarted for the changes to take effect.

14.6.5.1. Using the Administration Interface

The `mysql-proxy` administration interface can be accessed using any MySQL client using the standard protocols. You can use the administration interface to gain information about the proxy server as a whole - standard connections to the proxy are isolated to operate as if you were connected directly to the backend MySQL server. Currently, the interface supports a limited set of functionality designed to provide connection and configuration information.

Because connectivity is provided over the standard MySQL protocol, you must access this information using SQL syntax. By default, the administration port is configured as 4041. You can change this port number using the `--admin-address` command-line option.

To get a list of the currently active connections to the proxy:

```
mysql> select * from proxy_connections;
+----+-----+-----+-----+
| id | type  | state | db   |
+----+-----+-----+-----+
| 0  | server | 0     |     |
| 1  | proxy  | 0     |     |
| 2  | server | 10    |     |
+----+-----+-----+-----+
3 rows in set (0.00 sec)
```

To get the current configuration:

```
mysql> select * from proxy_config;
+-----+-----+
| option                    | value |
+-----+-----+
| admin.address             | :4041 |
| proxy.address             | :4040 |
| proxy.lua_script          | mc.lua |
| proxy.backend_addresses[0] | mysql:3306 |
| proxy.fix_bug_25371       | 0     |
| proxy.profiling           | 1     |
+-----+-----+
6 rows in set (0.01 sec)
```

14.6.6. MySQL Proxy FAQ

Questions

- **14.6.6.1:** Is the system context switch expensive, how much overhead does the lua script add?
- **14.6.6.2:** How do I use a socket with MySQL Proxy? Proxy change logs mention that support for UNIX sockets has been added.

- [14.6.6.3](#): Can I use MySQL Proxy with all versions of MySQL?
- [14.6.6.4](#): If MySQL Proxy has to live on same machine as MySQL, are there any tuning considerations to ensure both perform optimally?

- [14.6.6.13](#): Can MySQL Proxy be used on slaves and intercept binlog messages?
- [14.6.6.14](#): MySQL Proxy can handle about 5000 connections, what is the limit on a MySQL server?
- [14.6.6.15](#): How does MySQL Proxy compare to DBSlayer ?
- [14.6.6.16](#): I currently use SQL Relay for efficient connection pooling with a number of apache processes connecting to a MySQL server. Can MySQL proxy currently accomplish this. My goal is to minimize connection latency while keeping temporary tables available.
- [14.6.6.17](#): The global namespace variable example with quotas does not persist after a reboot, is that correct?
- [14.6.6.18](#): I tried using MySQL Proxy without any Lua script to try a round-robin type load balancing. In this case, if the first database in the list is down, MySQL Proxy would not connect the client to the second database in the list.
- [14.6.6.19](#): Would the Java-only connection pooling solution work for multiple web servers? With this, I'd assume you can pool across many web servers at once?
- [14.6.6.20](#): Is the MySQL Proxy an API ?
- [14.6.6.21](#): If you have multiple databases on the same box, can you use proxy to connect to databases on default port 3306?
- [14.6.6.22](#): Will Proxy be deprecated for use with connection pooling once MySQL 6.x comes out? Or will 6.x integrate proxy more deeply?
- [14.6.6.23](#): In load balancing, how can I separate reads from writes?
- [14.6.6.24](#): We've looked at using MySQL Proxy but we're concerned about the alpha status - when do you think the proxy would be considered production ready?
- [14.6.6.25](#): Will the proxy road map involve moving popular features from lua to C? For example Read/Write splitting
- [14.6.6.26](#): Are these reserved function names (e.g., `error_result`) that get automatically called?
- [14.6.6.27](#): Can you explain the status of your work with `memcached` and MySQL Proxy?
- [14.6.6.28](#): Is there any big web site using MySQL Proxy ? For what purpose and what transaction rate have they achieved.
- [14.6.6.29](#): So the authentication when connection pooling has to be done at every connection? What's the authentication latency?
- [14.6.6.30](#): Is it possible to use the MySQL proxy w/ updating a Lucene index (or Solr) by making TCP calls to that server to update?
- [14.6.6.31](#): Isn't MySQL Proxy similar to what is provided by Java connection pools?
- [14.6.6.32](#): Are there tools for isolating problems? How can someone figure out if a problem is in the client, in the db or in the proxy?
- [14.6.6.33](#): Can you dynamically reconfigure the pool of MySQL servers that MySQL Proxy will load balance to?

- [14.6.6.34](#): Given that there is a `connect_server` function, can a Lua script link up with multiple servers?
- [14.6.6.35](#): Adding a proxy must add latency to the connection, how big is that latency?
- [14.6.6.36](#): In the quick poll, I see "Load Balancer: read-write splitting" as an option, so would it be correct to say that there are no scripts written for Proxy yet to do this?
- [14.6.6.37](#): Is it "safe" to use `LuaSocket` with proxy scripts?
- [14.6.6.38](#): How different is MySQL Proxy from DBCP (Database connection pooling) for Apache in terms of connection pooling?
- [14.6.6.39](#): Do you have make one large script and call at proxy startup, can I change scripts without stopping and restarting (interrupting) the proxy?

Questions and Answers

14.6.6.1: Is the system context switch expensive, how much overhead does the lua script add?

Lua is fast and the overhead should be small enough for most applications. The raw packet-overhead is around 400 microseconds.

14.6.6.2: How do I use a socket with MySQL Proxy? Proxy change logs mention that support for UNIX sockets has been added.

Just specify the path to the socket:

```
--proxy-backend-addresses=/path/to/socket
```

However it appears that `--proxy-address=/path/to/socket` does not work on the front end. It would be nice if someone added this feature.

14.6.6.3: Can I use MySQL Proxy with all versions of MySQL?

MySQL Proxy is designed to work with MySQL 5.0 or higher, and supports the MySQL network protocol for 5.0 and higher.

14.6.6.4: If MySQL Proxy has to live on same machine as MySQL, are there any tuning considerations to ensure both perform optimally?

MySQL Proxy can live on any box: application, db or its own box. MySQL Proxy uses comparatively little CPU or RAM, so additional requirements or overhead is negligible.

14.6.6.5: Do proxy applications run on a separate server? If not, what is the overhead incurred by Proxy on the DB server side?

You can run the proxy on the application server, on its own box or on the DB-server depending on the use-case

14.6.6.6: Can MySQL Proxy handle SSL connections?

No, being the man-in-the-middle, Proxy can't handle encrypted sessions because it cannot share the SSL information.

14.6.6.7: What is the limit for `max-connections` on the server?

Around 1024 connections the MySQL Server may run out of threads it can spawn. Leaving it at around 100 is advised.

14.6.6.8: As the script is re-read by proxy, does it cache this or is it looking at the file system with each request?

It looks for the script at client-connect and reads it if it has changed, otherwise it uses the cached version.

14.6.6.9: With load balancing, what happen to transactions ? Are all queries sent to the same server ?

Without any special customization the whole connection is sent to the same server. That keeps the whole connection state intact.

14.6.6.10: Can I run MySQL Proxy as a daemon?

Starting from version 0.6.0, the Proxy is launched as a daemon by default. If you want to avoid this, use the `-D` or `--no-daemon` option. To keep track of the process ID, the daemon can be started with the additional option `--pid-file=file`, to save the PID to a known file name. On version 0.5.x, the Proxy can't be started natively as a daemon

14.6.6.11: What about caching the authorization info so clients connecting are given back-end connections that were established with identical authorization information, thus saving a few more round trips?

There is an option that provides this functionality `--proxy-pool-no-change-user`.

14.6.6.12: Could MySQL Proxy be used to capture passwords?

The MySQL network protocol does not allow passwords to be sent in clear-text, all you could capture is the encrypted version.

14.6.6.13: Can MySQL Proxy be used on slaves and intercept binlog messages?

We are working on that. See <http://jan.kneschke.de/2008/5/30/mysql-proxy-rbr-to-sbr-decoding> for an example.

14.6.6.14: MySQL Proxy can handle about 5000 connections, what is the limit on a MySQL server?

See your `max-connections` settings. By default the setting is 150, the proxy can handle a lot more.

14.6.6.15: How does MySQL Proxy compare to DBSLayer ?

DBSLayer is a REST->MySQL tool, MySQL Proxy is transparent to your application. No change to the application is needed.

14.6.6.16: I currently use SQL Relay for efficient connection pooling with a number of apache processes connecting to a MySQL server. Can MySQL proxy currently accomplish this. My goal is to minimize connection latency while keeping temporary tables available.

Yes.

14.6.6.17: The global namespace variable example with quotas does not persist after a reboot, is that correct?

Yes. if you restart the proxy, you lose the results, unless you save them in a file.

14.6.6.18: I tried using MySQL Proxy without any Lua script to try a round-robin type load balancing. In this case, if the first database in the list is down, MySQL Proxy would not connect the client to the second database in the list.

This issue is fixed in version 0.7.0.

14.6.6.19: Would the Java-only connection pooling solution work for multiple web servers? With this, I'd assume you can pool across many web servers at once?

Yes. But you can also start one proxy on each application server to get a similar behaviour as you have it already.

14.6.6.20: Is the MySQL Proxy an API ?

No, MySQL Proxy is an application that forwards packets from a client to a server using the MySQL network protocol. The MySQL proxy provides a API allowing you to change its behaviour.

14.6.6.21: If you have multiple databases on the same box, can you use proxy to connect to databases on default port 3306?

Yes, MySQL Proxy can listen on any port. Providing none of the MySQL servers are listening on the same port.

14.6.6.22: Will Proxy be deprecated for use with connection pooling once MySQL 6.x comes out? Or will 6.x integrate proxy more deeply?

The logic about the pooling is controlled by the lua scripts, you can enable and disable it if you like. There are no plans to embed the current MySQL Proxy functionality into the MySQL Server.

14.6.6.23: In load balancing, how can I separate reads from writes?

There is no automatic separation of queries that perform reads or writes to the different backend servers. However, you can specify to `mysql-proxy` that one or more of the 'backend' MySQL servers are read-only.

```
$ mysql-proxy \  
--proxy-backend-addresses=10.0.1.2:3306 \  
--proxy-read-only-backend-addresses=10.0.1.3:3306 &
```

In the next releases we will add connection pooling and read/write splitting to make this more useful. See also [MySQL Load Balancer](#).

14.6.6.24: We've looked at using MySQL Proxy but we're concerned about the alpha status - when do you think the proxy would be considered production ready?

We are on the road to the next feature release: 0.7.0. It will improve the performance quite a bit. After that we may be able to enter the beta phase.

14.6.6.25: Will the proxy road map involve moving popular features from lua to C? For example Read/Write splitting

We will keep the high-level parts in the Lua layer to be able to adjust to special situations without a rebuild. Read/Write splitting sometimes needs external knowledge that may only be available by the DBA.

14.6.6.26: Are these reserved function names (e.g., `error_result`) that get automatically called?

Only functions and values starting with `proxy.` * are provided by the proxy. All others are provided by you.

14.6.6.27: Can you explain the status of your work with `memcached` and MySQL Proxy?

There are some ideas to integrate proxy and `memcache` a bit, but no code yet.

14.6.6.28: Is there any big web site using MySQL Proxy ? For what purpose and what transaction rate have they achieved.

Yes, [gaiaonline](#). They have tested MySQL Proxy and seen it handle 2400 queries per second through the proxy.

14.6.6.29: So the authentication when connection pooling has to be done at every connection? What's the authentication latency?

You can skip the round-trip and use the connection as it was added to the pool. As long as the application cleans up the temporary tables it used. The overhead is (as always) around 400 microseconds.

14.6.6.30: Is it possible to use the MySQL proxy w/ updating a Lucene index (or Solr) by making TCP calls to that server to update?

Yes, but it isn't advised for now.

14.6.6.31: Isn't MySQL Proxy similar to what is provided by Java connection pools?

Yes and no. Java connection pools are specific to Java applications, MySQL Proxy works with any client API that talks the MySQL network protocol. Also, connection pools do not provide any functionality for intelligently examining the network packets and modifying the contents.

14.6.6.32: Are there tools for isolating problems? How can someone figure out if a problem is in the client, in the db or in the proxy?

You can set a debug script in the proxy, which is an exceptionally good tool for this purpose. You can see very clearly which component is causing the problem, if you set the right breakpoints.

14.6.6.33: Can you dynamically reconfigure the pool of MySQL servers that MySQL Proxy will load balance to?

Not yet, it is on the list. We are working on a administration interface for that purpose.

14.6.6.34: Given that there is a `connect_server` function, can a Lua script link up with multiple servers?

The proxy provides some tutorials in the source-package, one is `examples/tutorial-keepalive.lua`.

14.6.6.35: Adding a proxy must add latency to the connection, how big is that latency?

In the range of 400microseconds

14.6.6.36: In the quick poll, I see "Load Balancer: read-write splitting" as an option, so would it be correct to say that there are no scripts written for Proxy yet to do this?

There is a proof of concept script for that included. But its far from perfect and may not work for you yet.

14.6.6.37: Is it "safe" to use `LuaSocket` with proxy scripts?

You can, but it is not advised as it may block.

14.6.6.38: How different is MySQL Proxy from DBCP (Database connection pooling) for Apache in terms of connection pooling?

Connection Pooling is just one use-case of the MySQL Proxy. You can use it for a lot more and it works in cases where you can't use DBCP (like if you don't have Java).

14.6.6.39: Do you have make one large script and call at proxy startup, can I change scripts without stopping and restarting (interrupting) the proxy?

You can just change the script and the proxy will reload it when a client connects.

Chapter 15. MySQL Enterprise Monitor

Note

MySQL Enterprise subscription, MySQL Enterprise Monitor, MySQL Replication Monitor, and MySQL Query Analyzer are only available to commercial customers. To learn more, see: <http://www.mysql.com/products/enterprise/features.html>.

The MySQL Enterprise Monitor serves as an automated assistant for MySQL database administrators. This service is designed to help administrators with their day-to-day tasks by monitoring MySQL servers and identifying potential problems. These features are designed to save the database administrator's time and effort by providing the information you need through a simplified interface.

An extension of existing MySQL Enterprise services, MySQL Enterprise Monitor monitors enterprise database environments and provides expert advice on how customers can tighten security and optimize the performance and uptime of their MySQL servers.

MySQL Enterprise Monitor helps administrators:

- Intelligently stay up to date with releases and bug fixes
- Know what's going on with their system
- Manage day-to-day database maintenance tasks
- Improve the performance of their system
- Manage and prevent crises

The MySQL Enterprise Monitor was designed to tackle the job of managing the performance of any number of MySQL database servers, regardless of their physical or geographical location. Although MySQL Enterprise Monitor can easily track just a handful of MySQL servers, the service is specifically designed to greatly curtail the time it takes to get a handle on the availability and performance levels of many database servers at once.

The MySQL Enterprise Monitor does this by providing a web-based interface — called the Enterprise Dashboard — that serves as the portal for viewing information about your MySQL database servers. MySQL professionals can manage all their servers by group or individually if need be.

The Enterprise Dashboard web interface does not have to be installed on individual desktops, but is instead available from a centrally located machine that serves as the main location for the Monitoring and Advisory service.

15.1. An Overview of the Service

The MySQL Enterprise Monitor is a collection of components that work together to monitor and help administer your MySQL server installations. This service includes server management agents, advisors, and a central MySQL Enterprise Service Manager, all working in tandem with the MySQL Enterprise to keep your MySQL servers secure and up to date. All of this is controlled through the MySQL Enterprise Dashboard — a lightweight web-based interface that gives you complete control of your MySQL servers from any location.

Figure 15.1. MySQL Enterprise Monitor Architecture

The service is made up of a number of components, including the Monitor Agent (MySQL Enterprise Monitor Agent), the Service Manager (MySQL Enterprise Service Manager), the Enterprise Dashboard, the Repository and the Advisors.

15.1.1. The Service Architecture

The MySQL Enterprise Monitor is powered by a distributed web-based application that is deployed within the confines of the corporate firewall. The Enterprise Dashboard provides the interface to the server data, advisor notifications, live information and communication with the MySQL Enterprise Update Service.

Subscribers are kept up to date about the latest releases of the MySQL server or issues that may affect their specific implementation of MySQL by using the MySQL Enterprise Update Service. This same mechanism is used to notify MySQL Enterprise Monitor users of updates to the application or to the MySQL Advisors and Rules. The various components are described below.

- **Monitor Agent**

Monitor Agents are the foot soldiers of the MySQL Enterprise Monitor; they monitor each MySQL server. Running as a Windows service or Unix daemon, the Agent uses a combination of MySQL specific commands, SQL queries, and custom scripts to collect and report MySQL server or operating system (OS) specific data. The Monitor Agent initiates a “heartbeat” to the Service Manager on a regular basis to ensure specific MySQL server and OS level data collections are current.

In the overall architecture, the Monitor Agent is the only component of the MySQL Enterprise Monitor that establishes or maintains a connection with the monitored MySQL Server. As with any MySQL client, the Monitor Agent is authenticated on the monitored MySQL server and requires a user name and password to establish a connection.

In addition, the MySQL Enterprise Monitor Agent also provides a proxy service that allows for information about queries to be captured and reported as part of the Query Analyzer functionality. The MySQL Enterprise Monitor Agent accepts client connections and forwards the SQL statements on to the server and returns the results. In the background, the agent is collecting information about the query execution, row counts, times and other data so that queries and their execution can be monitored.

- **Service Manager**

The Service Manager is the heart and soul of the MySQL Enterprise Monitor. It is built on a collection of Java services hosted on a single Windows or Unix server. The Service Manager interacts with all of the Monitor Agents under its domain to collect MySQL server and OS level data for each of the monitored MySQL servers.

The Service Manager performs many duties including:

- Enterprise Dashboard, the main interface to the MySQL Enterprise Service Manager.
- Autodiscovery of monitored MySQL Servers.

- Creation and management of Monitor Agent tasks.
- Storage of data collections from Monitor Agents.
- Monitoring of key MySQL server and OS level metric data collections.
- Reporting MySQL best practice events and violations.
- Providing MySQL expert advice for MySQL best practice violations.
- Autodiscovery of replication topology (Not available for all subscription levels)

- **The Repository**

The Repository is built on MySQL 5.0.x and is used to store MySQL server and OS level data collections for each of the monitored MySQL Servers. This information is used by the Service Manager to evaluate and report the health and status of the monitored MySQL environment(s).

- **The Enterprise Dashboard**

The MySQL Enterprise web client provides the graphical user interface (GUI) for the MySQL Enterprise Monitor. This interface is the primary means of monitoring the state of your MySQL servers, identifying rule violations and providing advice on how best to address and correct any underlying issues.

This interface also provides an easy means of configuring advisors, adding users, creating notification groups, and receiving updates from MySQL Enterprise.

15.1.2. Service Features

The key features of the MySQL Enterprise Monitor can be summarized as follows:

- Group-level or Server-level management options
- Enterprise Dashboard for managing all MySQL Servers from a consolidated console
- Monitoring page for “at a glance” global health check of key systems
- MySQL-provided Advisors and Advisor Rules for enforcing MySQL Best Practices
- Advisor Rule Scheduling for unattended operations
- Customizable Thresholds and Alerts for identifying Advisor Rule violations
- User-Defined Advisor Rules
- Event/Alert History browser for researching advisor-specific events and annotations
- Query Analyzer functionality allowing you to monitor the execution times, row counts and other data about queries executed on your MySQL server.

These features are presented through the MySQL Enterprise Dashboard which is made up of six main pages:

- The **MONITOR** page comprises:
 - The **SERVER TREE**: Easily navigate monitored servers
 - The **GRAPHING**: This capability is built in so you can quickly assess critical functions such as activity, performance metrics, and number of connections
 - The **HEAT CHART**: Color-coded buttons provide key operating system and database metrics
- The **ADVISORS** page

This page shows the advisors that are currently scheduled. There are advisors for a variety of topics such as security and indexing. Users can add, edit, or create their own advisors.

- The **EVENTS** page

This page shows rule violations, indicating the server, severity, and time of occurrence. A number of filter options are available, allowing various views of events.

- The **GRAPHS** page

Use this page to view all the available graphs and to adjust the scale of the graphs, for a more or less detailed view as the situation requires.

- The **QUERY ANALYZER** page

- The **REPLICATION** page

Use this page to keep track of your masters and their slaves (Not available for all subscription levels)

- The **SETTINGS** page

On this page you configure servers, users, email addresses, and notification groups. Entering a user name and password for MySQL Enterprise provides automatic updates.

15.1.3. Security

Using the Tomcat/Apache web server for the user interface allows an administrator to configure the web server to meet any security regulations. The MySQL Enterprise Monitor architecture is designed to be as secure as possible, even when monitoring systems outside of the local network.

Communications between the MySQL Enterprise Monitor Agent and MySQL Enterprise Service Manager can be protected by Secure Socket Layer (SSL) encryption and server and agent can use SSL certificates to provide authentication and prevent spoofing.

The MySQL Enterprise Monitor Agent is like a web browser—it is an HTTP client application that initiates all communication with the MySQL Enterprise Service Manager. If the server requires action from the agent, it must wait until the agent next initiates contact and sends its request in a response. This means you do not need to open an inbound port on the machine on which the agent is running because it does not listen for requests. However, an outbound port must be open for the agent to contact the MySQL Enterprise Service Manager.

As an additional security feature, each Agent can have a separate Advisory Service login which minimizes exposure should any one agent be compromised.

15.2. Conventions Used in This Document

This document uses certain typographical conventions:

- *Text in this style* is used for SQL statements; database, table, and column names; program listings and source code; and environment variables. Example: “To reload the grant tables, use the `FLUSH PRIVILEGES` statement.”
- *Text in this style* indicates input that you type in examples.
- *Text in this style* indicates the names of executable programs and scripts, examples being `mysql` (the MySQL command line client program) and `mysqld` (the MySQL server executable).
- *Text in this style* is used for variable input for which you should substitute a value of your own choosing.
- File names and directory names are written like this: “The global `my.cnf` file is located in the `/etc` directory.”
- Character sequences are written like this: “To specify a wildcard, use the ‘`%`’ character.”
- *Text in this style* is used for emphasis.
- **Text in this style** is used in table headings and to convey especially strong emphasis.

When commands are shown that are meant to be executed from within a particular program, the prompt shown preceding the command indicates which command to use. For example, `shell>` indicates a command that you execute from your login shell or from the command line in Windows:

```
shell> type a shell command here
```

The “shell” is your command interpreter. On Unix, this is typically a program such as `sh`, `csh`, or `bash`. On Windows, the equivalent program is `command.com` or `cmd.exe`, typically run in a console window.

When you enter a command or statement shown in an example, do not type the prompt shown in the example.

Sometimes, what appears on one line in a console window cannot be represented in the documentation on a single line. In cases such as this the character ‘`»`’ is used. For example:

```
Please specify the directory where the MySQL Enterprise Monitor Â»
will be installed.
```

Where Unix commands are concerned, the continuation character ‘`\`’ is used. Doing this allows commands to be copied and pasted to the command line verbatim. For example:

```
shell> /opt/mysql/enterprise/agent/bin/mysql-monitor-agent -f \
/opt/mysql/enterprise/agent/etc/mysql-monitor-agent.ini
```

SQL keywords are not case sensitive and may be written in either case. This document uses uppercase.

In syntax descriptions, square brackets (‘`[`’ and ‘`]`’) indicate optional words or clauses. For example, in the following statement, `IF EXISTS` is optional:

```
DROP TABLE [IF EXISTS] tbl_name
```

When a syntax element consists of a number of alternatives, the alternatives are separated by vertical bars (‘`|`’). When one member from a set of choices *may* be chosen, the alternatives are listed within square brackets (‘`[`’ and ‘`]`’):

```
TRIM([[BOTH | LEADING | TRAILING] [remstr] FROM] str)
```

When one member from a set of choices *must* be chosen, the alternatives are listed within braces (‘`{`’ and ‘`}`’):

```
{DESCRIBE | DESC} tbl_name [col_name | wild]
```

An ellipsis (‘`...`’) indicates the omission of a section of a statement, typically to provide a shorter version of more complex syntax. For example, `INSERT ... SELECT` is shorthand for the form of `INSERT` statement that is followed by a `SELECT` statement.

An ellipsis can also indicate that the preceding syntax element of a statement may be repeated. In the following example, multiple `reset_option` values may be given, with each of those after the first preceded by commas:

```
RESET reset_option [,reset_option] ...
```

Commands for setting shell variables are shown using Bourne shell syntax. For example, the sequence to set the `CC` environment variable and run the `configure` command looks like this in Bourne shell syntax:

```
shell> CC=gcc ./configure
```

If you are using `csh` or `tcsh`, you must issue commands somewhat differently:

```
shell> setenv CC gcc
shell> ./configure
```

Throughout this document the term ‘`Unix`’ is used to describe any Unix or Unix-like operating system. For an up-to-date list of operating systems supported by the MySQL Enterprise Monitor please see the [MySQL Enterprise web site](#).

15.3. Installation and Upgrades

Note

MySQL Enterprise subscription, MySQL Enterprise Monitor, MySQL Replication Monitor, and MySQL Query Analyzer are only available to commercial customers. To learn more, see: <http://www.mysql.com/products/enterprise/features.html>.

This chapter describes the process of installing the MySQL Enterprise Monitor on all operating systems. A working installation requires the installation of a MySQL Enterprise Service Manager, the MySQL Enterprise Advisors and one or more MySQL Enterprise Monitor Agents. Simply described, the agent inspects the MySQL server it is monitoring, reports to the Service Manager, and the results are interpreted by the advisors and displayed in the MySQL Enterprise Dashboard for viewing in a web browser.

One Monitor Agent is installed for each MySQL server that is being monitored. The Monitor Agent usually runs on the same machine that hosts the monitored MySQL server but it may run on any machine that has access to both the monitored MySQL server and the MySQL Enterprise Dashboard. The agent reports its findings to the Service Manager and these results are interpreted by Advisors and displayed in the dashboard. The end user opens a web browser to view the information presented in the dashboard. The Service Manager and dashboard run on the same machine and both have access to a local MySQL server installed as part of the MySQL Enterprise Monitor. This server is known as the repository and provides storage for the data provided by the agent.

Installation is a three step process:

1. Install and start the Service Manager on the monitoring system.
2. Configure the Service Manager and install the Advisors.
3. Install and start the Monitor Agent to monitor the targeted MySQL server.

Installation Requirements

The Service Manager is available for Windows, Mac OS X, and a variety of Unix and Linux operating systems.

Note

The Mac OS X Service Manager is only supported on Intel architecture. However, the Mac OS X agent is supported for both Intel and the PowerPC.

To install the MySQL Enterprise Monitor on Windows requires approximately 260 MB of space and approximately 450 MB on Unix, Linux and Mac OS X. The installer checks that there is enough free space on the destination disk. However, disk space usage will increase with time since the repository stores historical data.

The minimum recommended requirements for the service manager are at least a 2GHz CPU and at least 1GB of RAM. If you are monitoring a large number of services, then there will be an increased load on the server manager. Running the service manager on a machine that is already running other tasks is only recommended if you are monitoring a small number of agents. For monitor five or more agents simultaneously, you should dedicate a machine to the process.

For more information, see [Section 15.4.4, “Choosing Suitable MySQL Enterprise Service Manager Hardware Configurations”](#).

The Monitor Agent is available for a wide range of operating systems. For an up-to-date list please see the [MySQL Enterprise web site](#). The agent can be used to monitor any MySQL server from version 4.0.x through 6.0.x.

15.3.1. User Roles

Prior to installation you will need to have at hand credentials for access to the MySQL server you plan to monitor and also your MySQL Enterprise credentials. *During* installation and when first logging in, you will set up a variety of users with different roles and credentials. This can become confusing. This section outlines the various users associated with the MySQL Enterprise Monitor and gives a brief description of their roles.

15.3.1.1. Existing Users

The **MySQL Enterprise user** – These are the credentials you use to log in to the MySQL Enterprise web site. You will need them in order to acquire the Advisor files and receive updates and, if necessary, acquire a product key.

The **MySQL user** – For Monitor Agents to report the status of a MySQL server they must have privileges on that server. To perform all functions an agent must have `SHOW DATABASES`, `REPLICATION CLIENT`, `SUPER`, `CREATE`, and `SELECT` privileges. In short, the Monitor Agent needs to have read access to all data. Details about this account are given in [Section 15.3.3.1, “Creating a MySQL User Account for the Monitor Agent”](#).

15.3.1.2. User Created During Installation

The **Repository user** – This user is the only user in the `user` table in the `mysql` database in the bundled MySQL server. To avoid confusion with monitored MySQL servers, this server is referred to throughout this document as the *repository*. The repository user can log in from `localhost` using the password specified during installation and has all privileges on all databases. These credentials are used to create the repository and its tables and to record data in them. During installation the default value for the user name for this role is `service_manager`. No default password is specified. You can use these credentials to manage the repository from the command line or when using a program such as MySQL Administrator.

During installation the file `configuration_report.txt` is created. Reference this file for the credentials of the repository manager. After the MySQL Enterprise Service Manager is installed, look for this file in the following directories:

- Windows – `C:\Program Files\MySQL\Enterprise\Monitor`
- Unix – `/opt/mysql/enterprise/monitor`
- Mac OS X – `/Applications/mysql/enterprise/monitor`

15.3.1.3. Users Created on First Log-in

The **Root user** – This user is the administrator of the dashboard. The first time you log in to the dashboard you must log in as this user. The default user name for this user is `admin`. There is no default password for this user.

The **Agent user** – The Monitor Agent needs to report the status of the MySQL server it is monitoring. For this reason it needs to log in to the dashboard. The default user name for this user is `agent`. There is no default password for this user.

Note

The Monitor Agent has two roles in the MySQL Enterprise Monitor; it must have access to the dashboard and to the MySQL server it is monitoring. For a description of the agent as a MySQL user see [Section 15.3.1.1, “Existing Users”](#).

15.3.2. Service Manager Installation

The MySQL Enterprise Service Manager is the core element of the MySQL Enterprise Monitor. The installation process for this element is completely self-contained, but the installation includes the following components:

- Apache Tomcat
- MySQL Server
- Java VM

Note

After installation you can determine the version number of the various components by entering `http://server_name:18080/main?command=list_versions` into the web browsers address bar.

During installation, versions of MySQL and Tomcat will be installed onto the machine. The installer automatically provides default network ports that are different from standard installation for these applications. You can change the ports during installation.

During installation, default values are shown for user names and ports. This is for your convenience only; you may choose different values. The installer detect ports that are already in use and allows you to select different ports.

Warning

The MySQL Enterprise Service Manager version 2.0 requires agents using 2.0 or higher.

All the installations share the same basic configuration parameters that you will be asked to confirm during installation. Before you start your installation, please review the section on these common parameters, then proceed to section specific to your installation platform. For details of the common parameters, see [Section 15.3.2.1, “Service Manager Installation Common Parameters”](#). For information on installation under Windows, see [Section 15.3.2.2, “Service Manager Installation on Windows”](#), for Mac OS X see [Section 15.3.2.3, “Service Manager Installation on Mac OS X”](#), and for Unix/Linux, see [Section 15.3.2.4, “Service Manager Installation on Unix”](#).

15.3.2.1. Service Manager Installation Common Parameters

All installations of the Service Manager install the Tomcat and MySQL applications using the same basic set of parameters. The defaults provided by the installation process are designed to be unique so that they do not interfere with existing installations of either product. However, you should check these parameters before installation to ensure that you do not experience any problems.

The common parameters are divided into those applying to the Tomcat server, and the MySQL server (Repository Configuration):

- **Tomcat Server Options**
 - Tomcat Server port — the default port that the Tomcat server will use when listening for connections. If you change this option, then the port that you need to use when connecting to the Service Manager must be modified accordingly. The default value is 18080.

Note

If you are not currently running a web server on port 80 you may find it more convenient to use the well known port rather than 18080. Since port 80 is the default for a web server, you can then open the dashboard without specifying a port.

- Tomcat Shutdown port —the port used by the management scripts that is used to shut the Tomcat server down when you need to stop the Service Manager. The default value is 18005.
- Tomcat SSL Port — the standard port used to connect to the Service Manager when you want to use Secure Sockets Layer (SSL) encrypted communication. The default value is 18443.
- **Repository Configuration (MySQL Server)**
 - Repository Username — the user name created and used to store information within the MySQL server to hold the information used by the Service Manager. In normal use, you should not need to use or modify this information, but it may be required if you have a support issue. The default value is `service_manager`.
 - Repository User password — the password to be used for the Repository Username. This should be set to a secure password so that the repository data is secure.

The information that you configure during installation will always be recorded within the `configuration_report.txt` file within the installation directory for the Service Manager.

Caution

Because the information stored within the `configuration_report.txt` file is in plain text, the Repository user name and password information are also exposed within this file. Make sure that the installation directory and file are secure that they can only be accessed by those users who would need to use the information.

15.3.2.2. Service Manager Installation on Windows

On Windows the installation modes are `win32` and `unattended` only. `unattended` mode is especially useful if you are doing multiple installations. For more information on this topic see [Section 15.3.4, “Unattended Installation”](#).

Note

In order to install the Service Manager as a Windows service, you must do the installation as a privileged user.

On Windows Vista, if user account control is on, an operating system dialog box requests confirmation of the installation.

To install the Service Manager on Windows, find the executable file named `mysqlmonitor-version-windows-installer.exe` (where `version` represents the three-part version number).

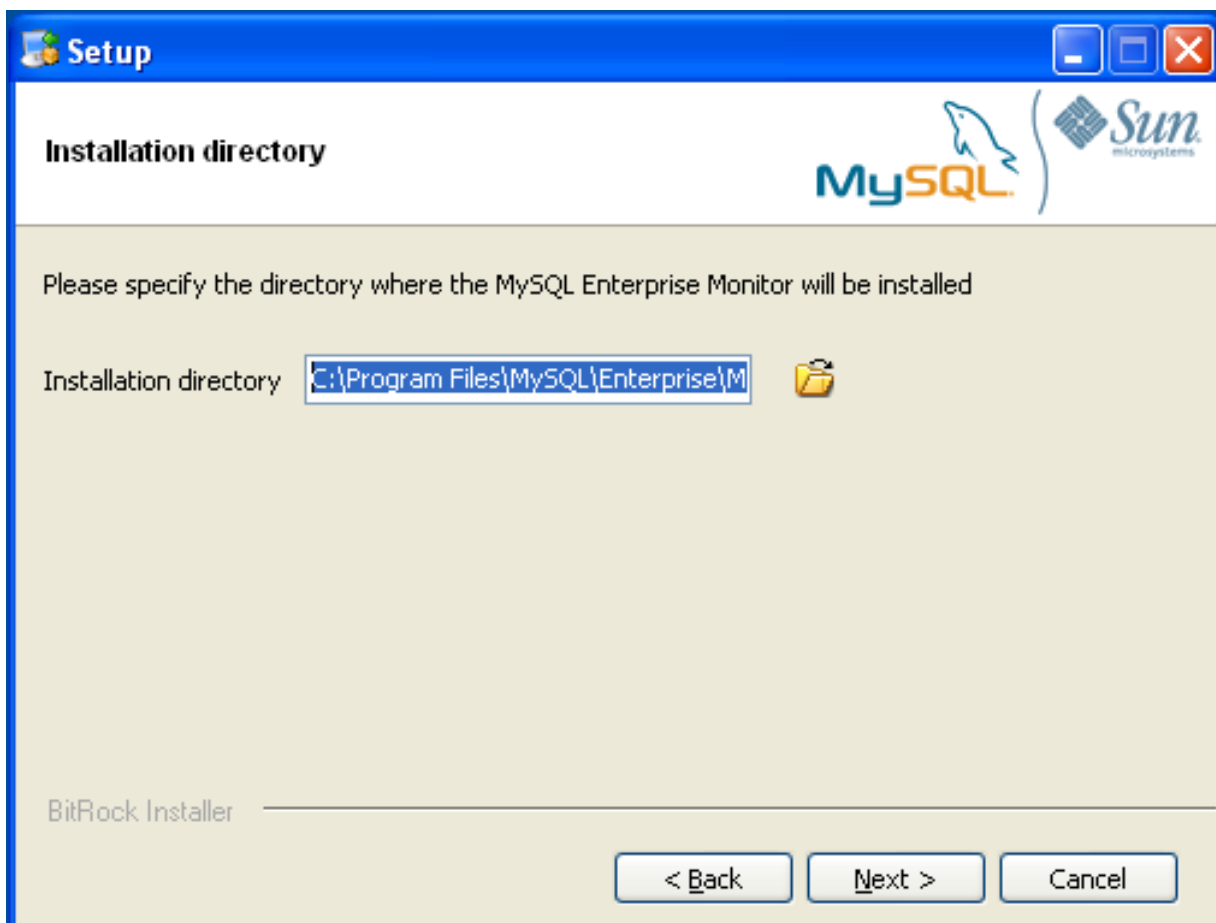

1. Double click on the MySQL Monitor installer. You should be presented with the Language Selection prompt. Select the language to use for the installer and then click OK.

Figure 15.2. MySQL Enterprise Monitor: Installing Monitor on Windows: Language Selection

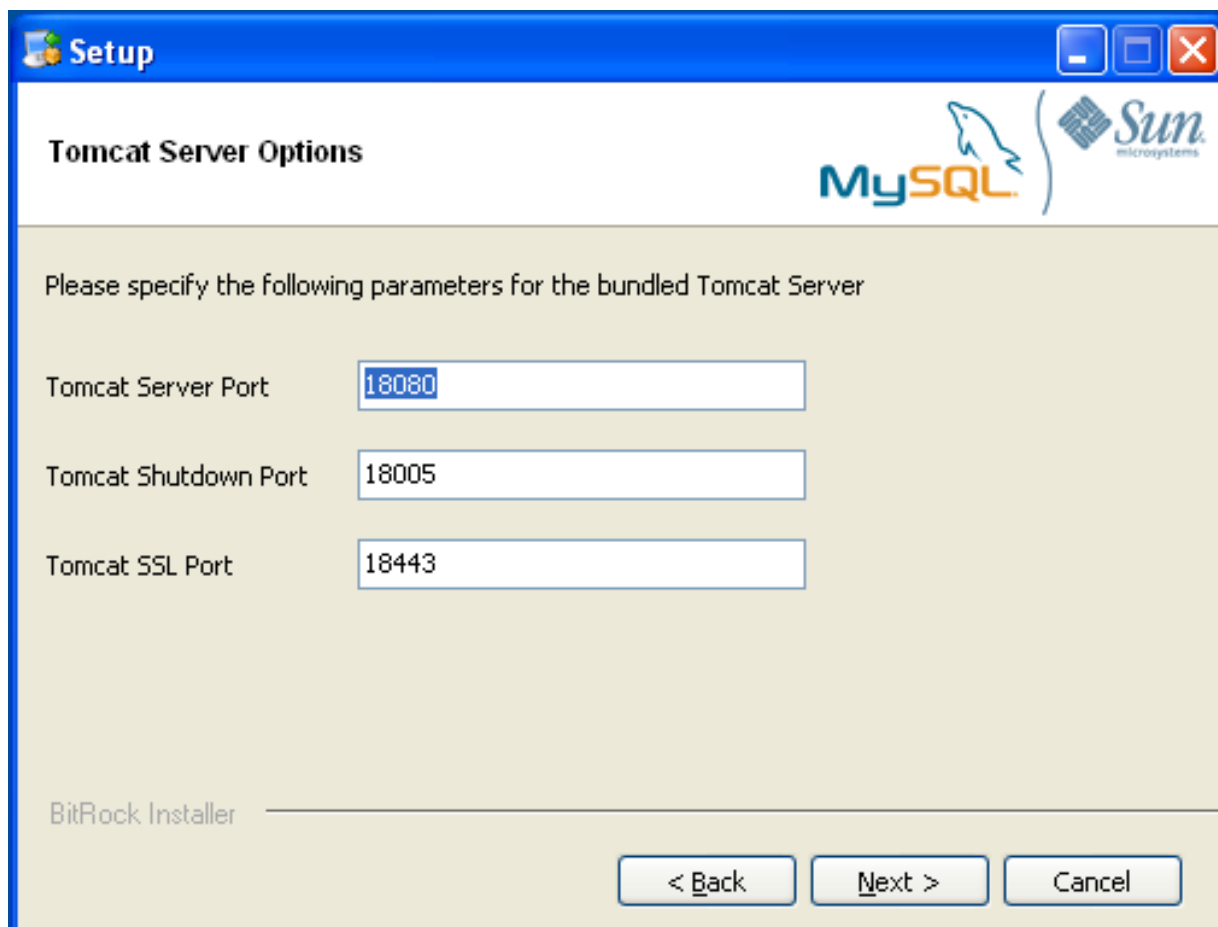

2. With the installation language selected, the remainder of the installation sets up the installation location and the main configuration parameters required by MySQL Enterprise Service Manager. Click NEXT to continue.
3. Select the installation directory where you want the MySQL Enterprise Service Manager components installed. By default on Windows the directory is `C:\Program Files\MySQL\Enterprise\Monitor`. You click the button next to the installation directory field to select a directory using the File chooser, or type the directory manually. Click NEXT to continue.

Figure 15.3. MySQL Enterprise Monitor: Installing Monitor on Windows: Installation Directory

4. Configure the options that set the network ports used by the Tomcat server. For more information, see [Section 15.3.2.1, "Service Manager Installation Common Parameters"](#). Click NEXT to continue.

Figure 15.4. MySQL Enterprise Monitor: Installing Monitor on Windows: Tomcat Server Options

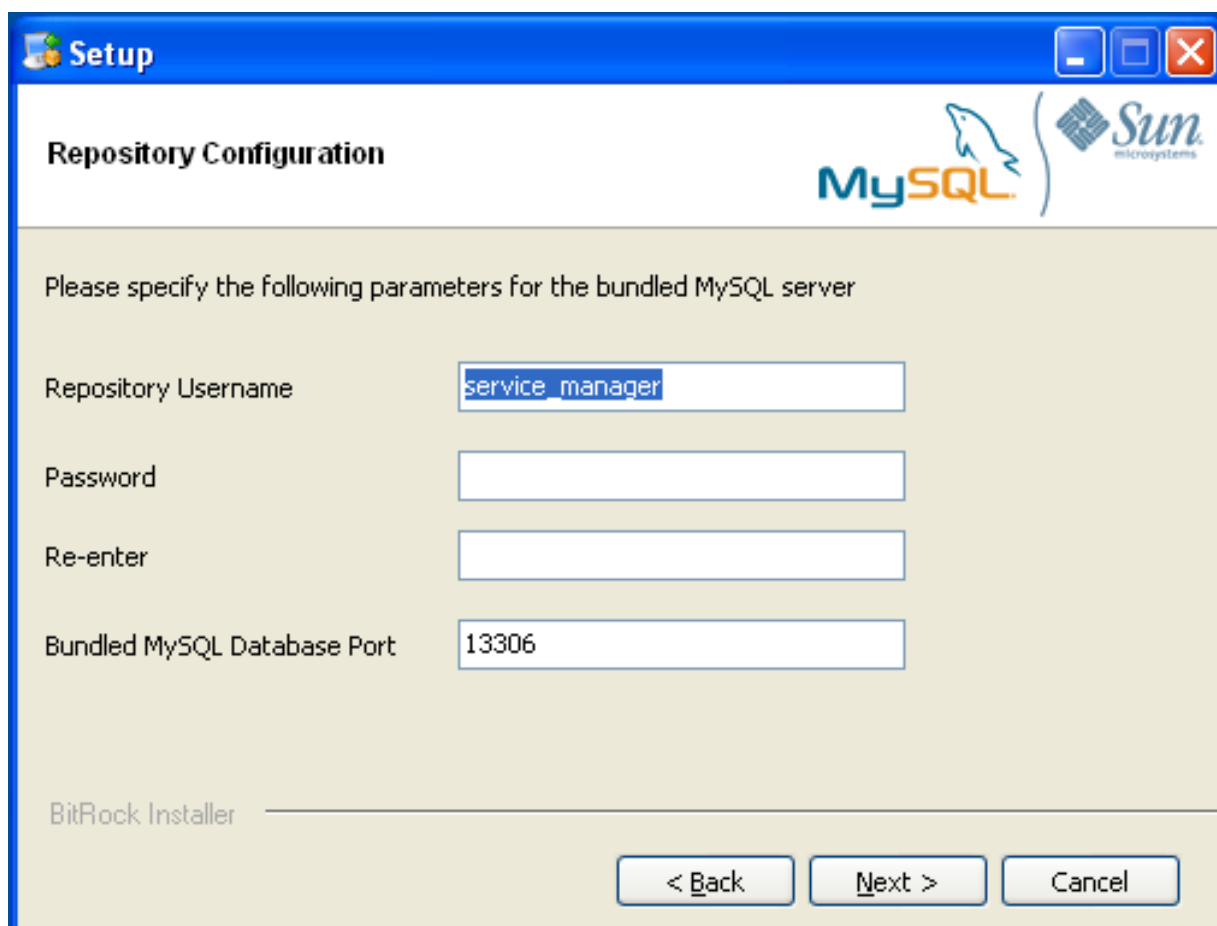

5. Configure the repository settings, setting the user name, password and port used to communicate with the bundled MySQL server that will be used to store the information and statistics for your installation. For more information, see [Section 15.3.2.1, "Service Manager Installation Common Parameters"](#). Click NEXT to continue.

Note

If the Windows firewall is enabled you will be asked to unblock ports for Apache/Tomcat and the MySQL server.

Figure 15.5. MySQL Enterprise Monitor: Installing Monitor on Windows: Repository Configuration

6. You will be provided with information and a warning about the configuration options and how they are stored in the `configuration_report.txt` file, and its location. Take a note of the full path to this file in case you need to look up the information later. Click NEXT to continue.
7. You should now be prompted to start the installation process. Click NEXT to continue.
8. Once the installation has been completed, you will be provided with the information on how to uninstall MySQL Enterprise Service Manager. Click NEXT to continue.
9. To complete the installation and set up your MySQL Enterprise Service Manager, you will need to login to the Dashboard. You can do this automatically by checking the box on the final window before clicking FINISH. This checkbox is selected by default. If you do not want to run the Dashboard at this time, uncheck the box and click FINISH.

For instructions on starting the MySQL Enterprise Monitor services under Windows, see [Section 15.3.2.5, “Starting/Stopping the MySQL Enterprise Monitor Service on Windows”](#).

15.3.2.3. Service Manager Installation on Mac OS X

On Mac OS X there are three installation modes `osx`, `text`, and `unattended`. For more information on this topic see [Section 15.3.4, “Unattended Installation”](#). The `text` mode installation for Mac OS X is identical to `text` installation under Unix. For `text` mode installation instructions see [Section 15.3.2.4, “Service Manager Installation on Unix”](#).

Installing the MySQL Enterprise Service Manager on Mac OS X requires an existing installation of Java. The minimum required version is 1.5.0_7. If this version is not installed on your machine you can download it from Apple. This version of Java requires Mac OS X version 10.4.5 as a minimum, so you may need to upgrade your operating system in order to install it.

For reasons of backwards compatibility, Mac OS X is usually installed with multiple versions of Java. When installing in `osx` mode, version 1.5.0_7 must be the default version. Upon installation, Java 1.5.0_7 sets itself as the default so this is usually not a problem.

If you have changed the default you can reset it or you may install the MySQL Enterprise Service Manager in `text` mode, setting the environment variables to point to the correct version of Java. To install in `text` mode, find the `installbuilder` file in the

`Contents/MacOS` directory immediately below the `mysqlmonitor-version-osx-installer.app` directory. Installing the MySQL Enterprise Service Manager in `text` mode is identical to the procedure described in Section 15.3.2.4, “Service Manager Installation on Unix” with the minor differences noted above.

To install using the GUI (osx) installation, follow these instructions:

1. Double click on the MySQL Monitor installer. You should be presented with the Language Selection prompt. Select the language to use for the installer and then click OK.

Figure 15.6. MySQL Enterprise Monitor: Installing Monitor on OS X: Language Selection

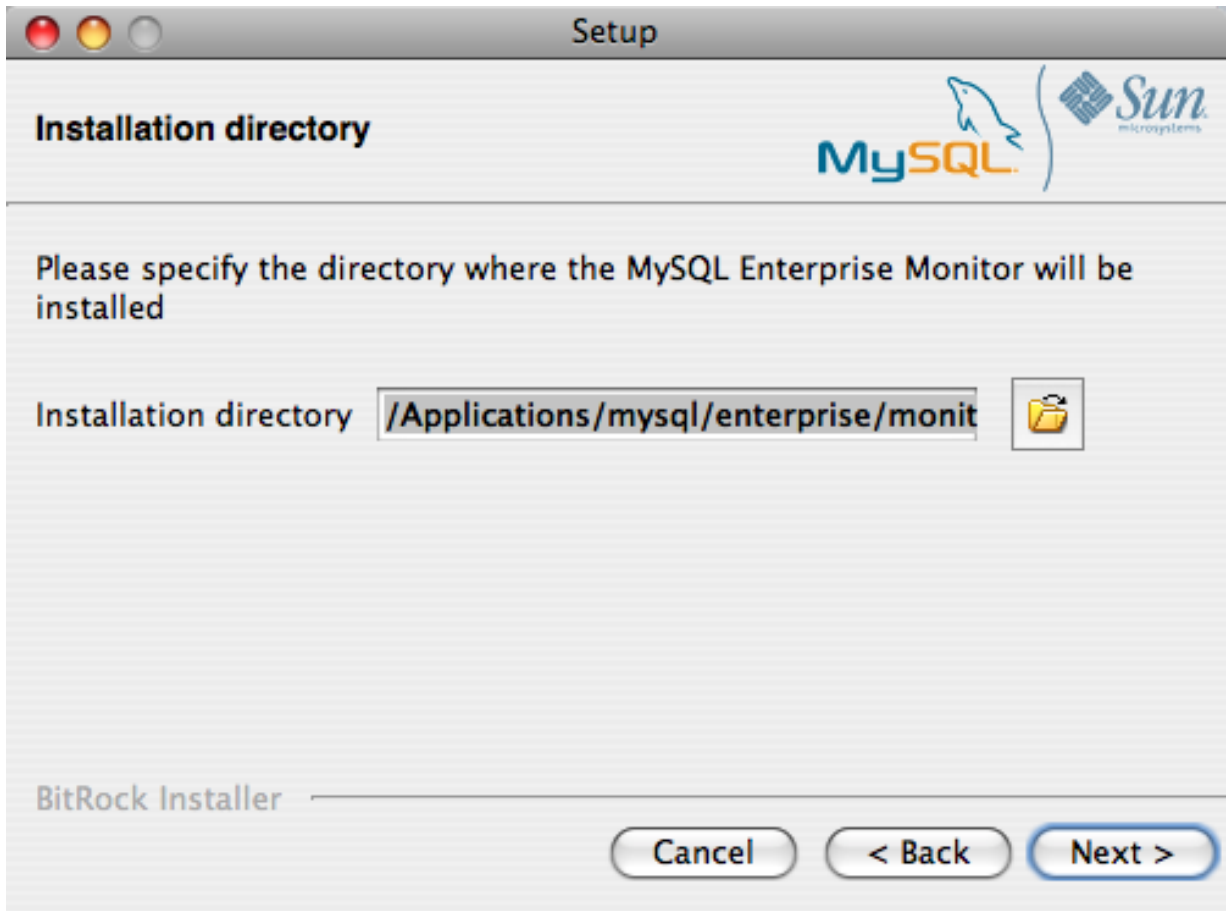

2. If you have multiple Java installations on your machine, you will be asked to choose which Java to use with your MySQL Enterprise Service Manager installation. Choose the Java version you want to use (1.5.0 or later is required), and click OK.

Figure 15.7. MySQL Enterprise Monitor: Installing Monitor on OS X: Java Selection

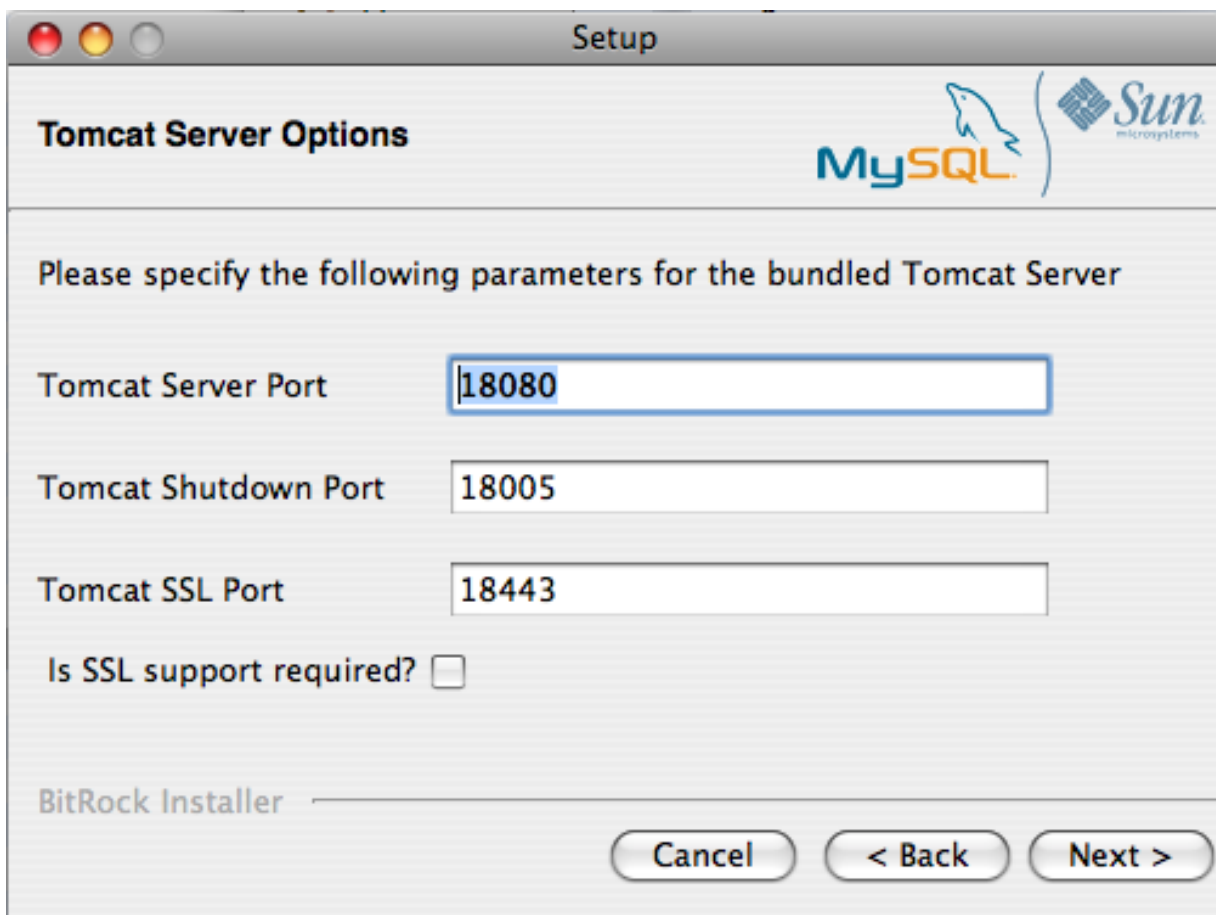

3. With the installation language and Java version selected, the remainder of the installation sets up the installation location and the main configuration parameters required by MySQL Enterprise Service Manager. Click NEXT to continue.
4. Select the installation directory where you want the MySQL Enterprise Service Manager components installed. By default on Mac OS X the directory is `/Applications/mysql/enterprise/monitor`. You click the button next to the installation directory field to select a directory using the File chooser, or type the directory manually. Click NEXT to continue.

Figure 15.8. MySQL Enterprise Monitor: Installing Monitor on OS X: Installation Directory

5. Configure the options that set the network ports used by the Tomcat server. For more information, see [Section 15.3.2.1, “Service Manager Installation Common Parameters”](#). Click NEXT to continue.

Figure 15.9. MySQL Enterprise Monitor: Installing Monitor on OS X: Tomcat Server Options

6. Configure the repository settings, setting the user name, password and port used to communicate with the bundled MySQL server that will be used to store the information and statistics for your installation. For more information, see [Section 15.3.2.1, "Service Manager Installation Common Parameters"](#). Click NEXT to continue.

Figure 15.10. MySQL Enterprise Monitor: Installing Monitor on OS X: Repository Configuration

Setup

Repository Configuration

MySQL Sun
microsystems

Please specify the following parameters for the bundled MySQL server

Repository Username:

Cancel < Back Next >

7. You will be provided with information and a warning about the configuration options and how they are stored in the `configuration_report.txt` file, and its location. Take a note of the full path to this file in case you need to look up the information later. Click NEXT to continue.
8. You should now be prompted to start the installation process. Click NEXT to continue.
9. Once the installation has been completed, you will be provided with the information on how to uninstall MySQL Enterprise Service Manager. Click NEXT to continue.
10. To complete the installation and set up your MySQL Enterprise Service Manager, you will need to login to the Dashboard. You can do this automatically by checking the box on the final window before clicking FINISH. This checkbox is selected by default. If you do not want to run the Dashboard at this time, uncheck the box and click FINISH.

Your installation should now be complete. To continue with the configuration of MySQL Enterprise Service Manager, see [Section 15.3.2.7, “MySQL Enterprise Service Manager Configuration Settings and Advisor Installation”](#).

15.3.2.4. Service Manager Installation on Unix

To install the Service Manager find the file named `mysqlmonitor-version-installer.bin` (where *version* indicates the version number, the OS, and the architecture). Ensure that this file is executable by typing:

```
shell> chmod +x mysqlmonitor-version-installer.bin
```

To install to the default directory (`/opt/mysql/enterprise/monitor`) you need to be logged in as `root`. Installing as an unprivileged user installs to the `/home/user_name/mysql/enterprise/monitor/` directory.

What follows describes installation from the command line. You may install the Service Manager graphically by running the installer from within a windows manager. In both cases the steps are identical. You may also install the Service Manager in `unattended` mode. This is especially useful if you are doing multiple installations. For more information on this topic see [Section 15.3.4, “Unattended Installation”](#).

1. Begin installation by typing:

```
shell> ./mysqlmonitor-version-installer.bin
```

2. First choose the language for the installation:

```
Language Selection
Please select the installation language
[1] English
[2] Japanese
Please choose an option [1] :
```

3. Throughout the installation process you will be asked the configuration questions for different options. Default values are shown between square brackets; to use the default press **Enter**. Otherwise, enter the new value and press **Enter**:

First, select the directory where you want MySQL Enterprise Service Manager to be installed. The default is `/opt/mysql/enterprise/monitor/`. Make sure that the location you choose has enough space to hold the installation files and the database information that will be created when MySQL Enterprise Service Manager is running.

```
Please specify the directory where the MySQL Enterprise Service Manager
will be installed.
Installation directory [/opt/mysql/enterprise/monitor/]:
```

4. Now set the Tomcat Server options. For more details on these parameters, see [Section 15.3.2.1, “Service Manager Installation Common Parameters”](#).

```
-----
Tomcat Server Options
Please specify the following parameters for the bundled Tomcat Server
Tomcat Server Port [18080]:
Tomcat Shutdown Port [18005]:
Tomcat SSL Port [18443]:
```

You will also be asked if SSL support is required. SSL support allows your agents and monitor to communicate with each other using SSL. Using SSL means that the data exchanged by the agent and MySQL Enterprise Service Manager are secure and can be used to monitor servers securely, or to monitor agents over a public connection.

You can enable SSL by pressing **Y** when prompted during installation:

```
Is SSL support required?          [y/N]:
```

5. Set the repository (embedded MySQL server) configuration options. For more details on these parameters, see [Section 15.3.2.1, “Service Manager Installation Common Parameters”](#).

```
-----
Repository Configuration
Please specify the following parameters for the bundled MySQL server
Repository Username [service_manager]:
Password :
Re-enter :
Bundled MySQL Database Port [13306]:
```

6. Before the final installation process, you will be provided with the location of the file that contains a copy of all of the settings. Be sure to follow the instructions and store this report in a secure location. There is no password recovery feature.

```
-----
Configuration Report
Note:
The settings you specified will be saved here:
/opt/mysql/enterprise/monitor/configuration_report.txt
```

```
IMPORTANT: This configuration report includes passwords stored in plain text; it
is intended to help you install and configure your agents. We strongly advise
you to secure or delete this text file immediately after installation.
```

```
Press [Enter] to continue :
```

7. You will now be asked to confirm the installation process.

```
Setup is now ready to begin installing MySQL Enterprise Monitor
on your computer.
```

```
Do you want to continue? [Y/n]: Y
```

```
Please wait while Setup installs MySQL Enterprise Monitor
on your computer.
```

The installation process may take a few minutes to complete. Upon completion you should see:

```
Completed installing files
```

```
Setup has completed installing MySQL Enterprise files on your computer
```

```
Uninstalling the MySQL Enterprise files can be done by invoking:
```

```
/opt/mysql/enterprise/monitor/uninstall
```

```
To complete the installation, launch the MySQL Enterprise Dashboard and complete
the initial setup and product activation information. Refer to the readme file
for additional information and a list of known issues.
```

```
Press [Enter] to continue :
```

8. Finally, you will be given the opportunity to read a supplied [Readme](#) file that is supplied with the installation. The [Readme](#) contains important information about how to use and start your MySQL Enterprise Service Manager.

```
-----
Setup has finished installing MySQL Enterprise Monitor on your computer.
```

```
View Readme File [Y/n]: n
```

Once the [Readme](#) file has been displayed, or if you did not elect to read the file, the installation provides information about how to continue with your installation.

```
Info: To access the MySQL Enterprise Monitor please visit the
following page: http://localhost:18080/Auth.action
```

```
Press [Enter] to continue :
```

The Enterprise Dashboard will not start up automatically if you perform a [text](#) mode installation. For more information on starting and stopping MySQL Enterprise Service Manager, see [Section 15.3.2.6, “Starting/Stopping the MySQL Enterprise Monitor Service on Unix and Mac OS X”](#).

15.3.2.5. Starting/Stopping the MySQL Enterprise Monitor Service on Windows

You can choose to start up the MySQL Enterprise Service Manager on installation. The installed services are called:

- MySQL Enterprise Tomcat
- MySQL Enterprise MySQL

You can stop or start the services from the Microsoft Management Console Services window. Look for the [MySQL Enterprise Tomcat](#) and the [MySQL Enterprise MySQL](#) entries.

Note

On Windows Vista, starting these services requires administrative privileges — you must be logged in as an administrator. To start or stop a service right click it and choose the [RUN AS ADMINISTRATOR](#) menu option. The same restric-

tion applies to using the menu options discussed in the following and to starting the services from the command line. To open an administrator `cmd` window right click the `cmd` icon and choose the `RUN AS ADMINISTRATOR` menu option.

To start or stop a service, right click it and choose from the options in the pop-up menu.

There is also a menu entry for starting and stopping the services. Navigate to the `Program, MySQL, MySQL Enterprise Monitor, Services` entry to stop or start the services.

You can also stop or start a service from the command line. To start the Tomcat service type:

```
shell> sc start MySQLEnterpriseTomcat
```

or:

```
shell> net start MySQLEnterpriseTomcat
```

To stop this service type:

```
shell> sc stop MySQLEnterpriseTomcat
```

or:

```
shell> net stop MySQLEnterpriseTomcat
```

In similar fashion, you may stop or start the MySQL server from the command line. The service name is `MySQLEnterpriseMySQL`.

You may also start, stop, and restart a specific service or both services using the `mysqlmonitorctl.bat` file. To execute this file, go to the command line and navigate to the `C:\Program Files\MySQL\Enterprise\Monitor` directory. Typing `mysqlmonitorctl.bat help` produces the following output:

```
usage: mysqlmonitorctl.bat help
mysqlmonitorctl.bat (start|stop|restart|install|uninstall)
mysqlmonitorctl.bat (start|stop|restart) tomcat
mysqlmonitorctl.bat (start|stop|restart) mysql

help      - this screen
start     - start the service(s)
stop      - stop the service(s)
restart   - restart or start the service(s)
install   - install the service(s)
uninstall - uninstall the service(s)
```

To stop a specific service, pass the argument `tomcat` or `mysql` in addition to the status change argument. If you wish to change the status of both services, do not specify a service name. You may also uninstall the services using this batch file.

Configuration of the dashboard begins immediately after the Service Manager is installed. To continue a Windows installation skip the next section and go to [Section 15.3.2.7, "MySQL Enterprise Service Manager Configuration Settings and Advisor Installation"](#).

15.3.2.6. Starting/Stopping the MySQL Enterprise Monitor Service on Unix and Mac OS X

The services incorporated into the MySQL Enterprise Service Manager are:

- The MySQL Server
- The Apache/Tomcat Server

Should you need to stop, start, or restart the MySQL Enterprise Service Manager call the `mysqlmonitorctl.sh` file located in the `/opt/mysql/enterprise/monitor/` directory on Unix or the `/Applications/mysql/enterprise/monitor/` on Mac OS X. To see all the available options navigate to the appropriate directory and type:

```
shell> /opt/mysql/enterprise/monitor/mysqlmonitorctl.sh help
```

Executing this script produces the following output:

```
usage: ./mysqlmonitorctl.sh help
./mysqlmonitorctl.sh (start|stop|status|restart)
./mysqlmonitorctl.sh (start|stop|status|restart) mysql
./mysqlmonitorctl.sh (start|stop|status|restart) tomcat
```

```

help      - this screen
start     - start the service(s)
stop      - stop the service(s)
restart   - restart or start the service(s)
status    - report the status of the service

```

Using this script you can stop, start, or restart all the Service Manager components. To do this make a call to `mysqlmonitorctl.sh start` from your start-up script.

To start the service:

```

shell> ./mysqlmonitorctl.sh start
./mysqlmonitorctl.sh : mysql started
nohup: redirecting stderr to stdout
Starting mysqld daemon with databases from /opt/mysql/enterprise/monitor/mysql/data/
Using CATALINA_BASE:   /opt/mysql/enterprise/monitor/apache-tomcat
Using CATALINA_HOME:   /opt/mysql/enterprise/monitor/apache-tomcat
Using CATALINA_TMPDIR: /opt/mysql/enterprise/monitor/apache-tomcat/temp
Using JRE_HOME:        /opt/mysql/enterprise/monitor/java

```

If you try to start the service and it is already running, you will be warned that the services are already running:

```

shell> ./mysqlmonitorctl.sh start
./mysqlmonitorctl.sh : mysql (pid 18403) already running
./mysqlmonitorctl.sh : tomcat (pid 18480) already running

```

To stop the service:

```

shell> ./mysqlmonitorctl.sh stop
Using CATALINA_BASE:   /Applications/mysql/enterprise/monitor/apache-tomcat
Using CATALINA_HOME:   /Applications/mysql/enterprise/monitor/apache-tomcat
Using CATALINA_TMPDIR: /Applications/mysql/enterprise/monitor/apache-tomcat/temp
Using JRE_HOME:        /System/Library/Frameworks/JavaVM.framework/Versions/1.5.0/Home
Stopping tomcat service .. [ OK ]
STOPPING server from pid file /Applications/mysql/enterprise/monitor/mysql/data/mysqld.pid
090209 15:37:09 mysqld ended

```

The `restart` command is equivalent to executing a `stop` and then `start` operation.

This script can also be used to check the status of the Tomcat web server or the MySQL repository.

```

shell> ./mysqlmonitorctl.sh status
MySQL Network MySQL is running
MySQL Network Tomcat is running

```

Configuration of the dashboard begins immediately after the MySQL Enterprise Service Manager is installed.

15.3.2.7. MySQL Enterprise Service Manager Configuration Settings and Advisor Installation

The Enterprise Dashboard is the web-based interface to the Service Manager so the procedure for starting the dashboard is identical for all platforms. From the dashboard you can configure the settings necessary for receiving updates from MySQL Enterprise and for the initial installation of the Advisors.

If you installed the Service Manager using a graphical interface, you have the option of launching the dashboard on the final installation screen (as long as the LAUNCH MYSQL ENTERPRISE MONITOR NOW checkbox is checked).

Otherwise, you can view the dashboard by typing `http://localhost:18080/Auth.action` into the address bar of your web browser. If you are unsure of the host name and port to use, check the `configuration_report.txt` file.

Under Windows it is also possible to open the dashboard by choosing the `MySQL` menu item and finding the `MySQL Enterprise Monitor` entry. Under this entry choose `Start Service Manager`.

15.3.2.7.1. Initial Dashboard Log-in

If this is the first time that you have attempted to log in to the dashboard you should see a screen similar to the following:

Figure 15.11. MySQL Enterprise Monitor: Initial dashboard log-in

Welcome to the MySQL Enterprise Dashboard Setup.
Before proceeding, you must complete the form below.

Enterprise Credentials and Subscription Information

To enable this application, please provide a MySQL Enterprise Product Key or your MySQL Enterprise credentials
When you press "complete setup", your Enterprise credentials will be validated at enterprise.mysql.com. These credentials will that you may update your credentials or Product Key at any time on the Settings page.

Email Address (MySQL Enterprise Login)

Enterprise Password (MySQL Enterprise Password)

Confirm Password

- OR -

MySQL Enterprise Product Key

Advisor .jar File (recommended)

Create Administrator	Configure Agent Credentials
Username <input type="text" value="admin"/>	Username <input type="text" value="agent"/>
Password <input type="password"/>	Password <input type="password"/>
Confirm Password <input type="password"/>	Confirm Password <input type="password"/>

Use this screen to perform the following tasks:

- Install the Advisors
- Set up your MySQL Enterprise credentials
- Create a user name and password for the dashboard administrator
- Create a user name and password for the Monitor Agent

If you have been provided with a [MySQL Enterprise Product Key](#) and an Advisors file click the BROWSE button and locate these files. The advisor file bears the name, `AdvisorScript-version.jar` and the product key, `Subscription-level_date.xml`. If you do not allow Internet access from the dashboard you must install the advisors in this way. It is strongly recommended that you install the Advisors at this point, but you may do so later. For instructions on doing this see, [Section 15.3.2.7.3, "Installing Advisors After Initial Log-in"](#). If the product key that you provide is invalid a notification appears and you will be unable to import the advisors.

Note

If you are activating the MySQL Enterprise Monitor using a product key *do not* enter your MySQL credentials; entering both produces an error message.

If you have Internet access from the dashboard, activate MySQL Enterprise Monitor by supplying your MySQL Enterprise credentials. Enter your email address as the [MySQL Enterprise Login](#) and enter and confirm your MySQL Enterprise password. If you specify incorrect credentials, you receive the error message, “Unable to connect to verify credentials.”

In the **CREATE ADMINISTRATOR** section of this screen, enter credentials for the dashboard administrator. This creates the [root user](#) described in [Section 15.3.1.3, “Users Created on First Log-in”](#). Make note of the user name and password as these credentials are required for any future login.

In the **CONFIGURE AGENT CREDENTIALS** section of this screen enter the credentials for the agent. This is the [agent user](#) also described in [Section 15.3.1.3, “Users Created on First Log-in”](#). The agent needs to log in in order to report its findings. Make note of the agent's credentials; this information is required when installing the agent.

When all the settings have been specified, click the COMPLETE SETUP button. If you log in successfully you should see a message displaying the number of graphs and advisors that have been imported. This number varies depending upon your subscription level.

If importation of the advisor files fails, you will see the message:

```
Unable to import Advisor Jar. You may download the jar manually from the Enterprise Portal and import it from the 'Check For Updates' page.
```

In this case you may download the advisor file from the Enterprise website and install it as described in [Section 15.3.2.7.3, “Installing Advisors After Initial Log-in”](#).

15.3.2.7.2. Setting the Timezone and Locale

If this is the first time that you have launched the dashboard you are asked to set your time zone and locale. Choose the appropriate values from the drop-down list boxes. Setting the time zone ensures that you have an accurate time reference for any notifications from the MySQL Enterprise Advisors.

Warning

It is especially important that the time zone be set correctly as this may also affect the way the graphs display. For this reason, also ensure that the time reported by the operating system is correct. To change the time zone or locale see [Section 15.6.2, “User Preferences”](#).

The locale chosen determines the user's default language when logging in to the Dashboard. Note that this will override the default browser settings whenever this specific user logs in.

After specifying your time zone and locale, the dashboard opens on the [Monitor](#) page. For a detailed examination of the [Monitor](#) Screen see, [Section 15.5, “MySQL Enterprise Dashboard”](#).

15.3.2.7.3. Installing Advisors After Initial Log-in

The Advisors interpret the data sent by the Monitor Agents and display the results in the dashboard. A minimal set of Advisors are preinstalled with the Service Manager. To obtain the full set of Advisors and get the most value from the MySQL Enterprise Monitor, you must download Advisors from MySQL Enterprise.

If you did not install the Advisors when you first logged in to the MySQL Enterprise Dashboard, open the dashboard, find the [Advisors](#) tab, and choose the [Check for Updates](#) link. Doing this downloads the latest version of the Advisors from the MySQL Enterprise web site. In order to install the advisors in this fashion you must specify your MySQL Enterprise credentials. Find instructions for doing this in [Section 15.6.1, “Global Settings”](#).

If you do not allow Internet access from the dashboard, you must install the Advisors from a local file. To do this you need an advisor file bearing the name, [AdvisorScript-version.jar](#). If you don't already have this file, you can find it on the MySQL Enterprise downloads page. Download the Advisors file to a location that is accessible from the dashboard. Use the BROWSE button to find the Advisors file and then choose IMPORT to load the advisors.

15.3.2.7.4. Upgrading and Updating Advisors

The process for upgrading advisors is exactly the same as the initial installation. Advisors are updated by choosing the UPDATE button on the [Check for Updates](#) page. If you do not have Internet access from the dashboard you can import the Advisors from a local file as described in [Section 15.3.2.7.3, “Installing Advisors After Initial Log-in”](#).

Note

You may choose to upgrade your MySQL Enterprise Monitor subscription level at any time.

15.3.2.7.5. Outgoing Email Settings

Alert notification via email is a key component of the MySQL Enterprise Monitor Advisor solution. For this reason you may want to immediately configure an SMTP account for at least one recipient.

To do this choose the [Settings](#) tab and go to the [Global Settings](#) screen by clicking the appropriate link. Here you can configure the email settings. These settings apply to the currently logged-in user.

Find the [Outgoing Email Settings](#) on the left of this page.

Figure 15.12. MySQL Enterprise Monitor: Outgoing email settings

Outgoing Email Settings

Enable Email Notifications
From Address (ex. "MySQL Dashboard" <name@domain.com>)

SMTP Server

SMTP Server Login

Disable JavaMail TLS/SSL

Update Password On Save

SMTP Server Password **Confirm Password**

On Save, Send Test Email Message to (optional)

Ensure that the [Enable Email Notifications](#) checkbox is checked and enter information as appropriate.

The default value for the SMTP port is 25. If your mail server runs on a different port simply specify it, separating it from the server name using a colon. For example, if your mail server runs on port 587 enter `email.myserver.com:587` into the **SMTP SERVER** text box.

Note

An email server must be available for sending email alerts.

The SMTP client uses Transport Layer Security (TLS) if the SMTP server supports it.

If your SMTP server incorrectly indicates that it supports TLS, check the **DISABLE JAVAMAIL TLS/SSL** check box.

The email settings page is dealt with in more detail in [Section 15.6, "The Settings Page"](#).

15.3.3. Monitor Agent Installation

A MySQL Enterprise Monitor Agent monitors a MySQL server and sends data to the Advisors. These data are interpreted and displayed in the dashboard. The Monitor Agent is installed on all platforms using the steps described in the next section.

Warning

The MySQL Enterprise Service Manager version 2.0 or higher requires agents with a version number of 2.0 or higher.

15.3.3.1. Creating a MySQL User Account for the Monitor Agent

Before setting up an agent to monitor a MySQL server you need to ensure that there is a user account for the agent on that server.

The privileges required for this user account vary depending on the information you wish to gather using the MySQL Enterprise Monitor Agent. The following privileges allow the Monitor Agent to perform its assigned duties without limitation:

- **SHOW DATABASES:** Allows the MySQL Enterprise Monitor Agent to gather inventory about the monitored MySQL server.
- **REPLICATION CLIENT:** Allows the MySQL Enterprise Monitor Agent to gather Replication master/slave status data. This privilege is only needed if the MySQL Replication Advisor Rules are employed.
- **SELECT:** Allows the MySQL Enterprise Monitor Agent to collect statistics for table objects.
- **SUPER:** Allows the MySQL Enterprise Monitor Agent to execute `SHOW ENGINE INNODB STATUS` in order to collect data about InnoDB tables.
- **PROCESS:** When monitoring a MySQL server running MySQL 5.1.24 or above with InnoDB, the **PROCESS** privilege is required to execute `SHOW ENGINE INNODB STATUS`.
- **INSERT:** Required to create the UUID required by the agent.
- **CREATE:** Allows the MySQL Enterprise Monitor Agent to create tables. During discovery, the agent creates the table `inventory` within the `mysql` database that is used to the UUID for the server. Without this table, the agent cannot determine the UUID of the server and therefore use this when sending information to MySQL Enterprise Service Manager.

For example, the following `GRANT` statement will give the agent the required `SELECT`, `REPLICATION CLIENT`, `SHOW DATABASES` and `SUPER` rights:

```
GRANT SELECT, REPLICATION CLIENT, SHOW DATABASES, SUPER, PROCESS
ON *.*
TO 'mysqluser'@'localhost'
IDENTIFIED BY 'agent_password';
```

For security reasons, you may wish to limit the `CREATE` and `INSERT` privileges to the agent so that it can only create tables within the `mysql` database:

```
GRANT CREATE, INSERT
ON mysql.*
TO 'mysqluser'@'localhost'
IDENTIFIED BY 'agent_password';
```

To enable replication discovery to work, you should also grant the `SELECT` privilege on the `mysql.inventory` table for each user with replication privileges on the corresponding replication master. This is required to let the MySQL Enterprise Monitor Agent read the replication master UUID. For example:

```
GRANT SELECT
ON mysql.inventory
TO 'replicationuser'@'%'
IDENTIFIED BY 'replication_password';
```

If the agent is unable to access the information from the table then a warning containing this information will be written to the agent log.

Note

You may want to disable logging for the grant statement to prevent the grant information being replicated to the slaves. If this is the case, execute the statement `SET SQL_LOG_BIN=0` before you execute the above `GRANT` statement.

In a typical configuration, the agent runs on the same machine as the MySQL server it is monitoring so the host name will be `loc-`

localhost. However, this will change if the agent is running on a machine other than the one that hosts the monitored MySQL server. In this case, change *localhost* to the appropriate value. For more information about remote monitoring see [Section 15.3.3.6.4, “Configuring an Agent to Monitor a Remote MySQL Server”](#).

15.3.3.2. Installing the Agent on Microsoft Windows

To install the MySQL Enterprise Monitor Agent on Windows, double-click the `mysqlmonitoragent-version-windows-installer.exe` (where *version* indicates the three-part version number) installer.

Note

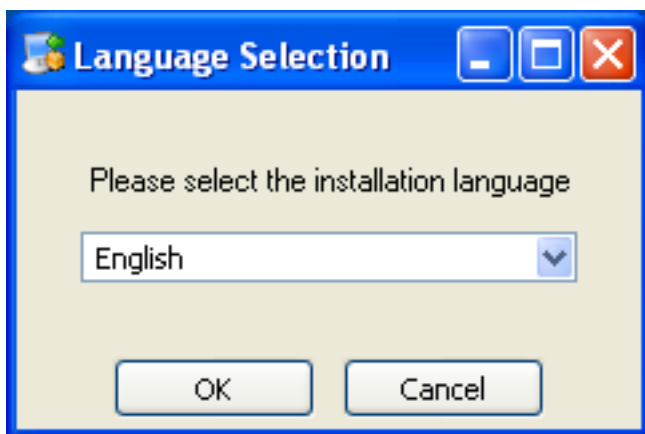

In order to install the agent as a Windows service, you must do the installation as a privileged user.

On Windows Vista, if user account control is on, an operating system dialog box requests confirmation of the installation.

You may also install the Monitor Agent in *unattended* mode. This is especially useful if you are doing multiple installations. For more information on this topic see, [Section 15.3.4, “Unattended Installation”](#).

1. First, select the language for the MySQL Enterprise Monitor Agent installation. Click OK to continue installation.

Figure 15.13. MySQL Enterprise Monitor: Installing Agent on Windows: Language Selection

2. Click NEXT to start the installation process.
3. Select the installation directory. The default installation directory is `C:\Program Files\MySQL\Enterprise\Agent`. Select the installation directory, or type the new directory location. Click NEXT to continue the installation process.

Figure 15.14. MySQL Enterprise Monitor: Installing Agent on Windows: Installation Directory

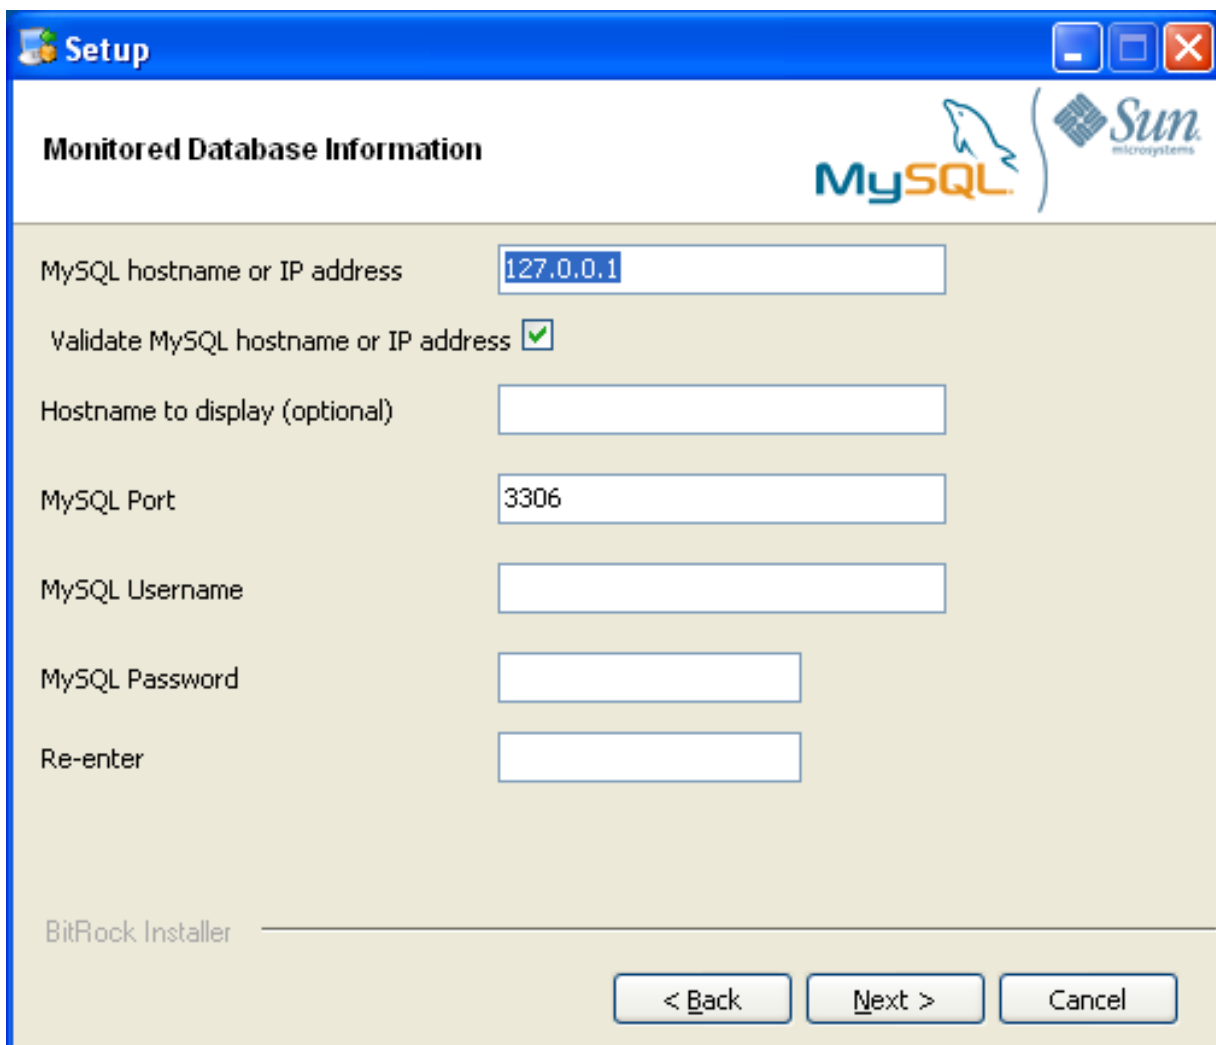

4. You need to specify the information about the MySQL server that you want to monitor. You must enter the IP address or host name of the host you want to monitor, and the port, user name and password that you will use to connect to the MySQL server. If you want to confirm that the MySQL server is currently reachable using the information, ensure that the **VALIDATE MYSQL HOST NAME OR IP ADDRESS** checkbox is selected.

Note

Currently, on Windows, the service agent only includes support for connecting to the server to be monitored via TCP/IP, so if the server has been started with `--skip-networking` it cannot be monitored.

If the MySQL server to be monitored has been started using the command option `--bind-address` then the server will only listen for connections on the IP address specified, that is, the IP address of the MySQL server. If the service agent has been started using TCP/IP networking and the default address of 127.0.0.1 it will not be able to connect to the server to be monitored. Also, if "localhost" is specified as the host name during agent configuration, a connection will not be established, as the server will be listening for connections on the address specified with the `--bind-address` option, not 127.0.0.1.

Figure 15.15. MySQL Enterprise Monitor: Installing Agent on Windows: Monitored Database Information

The screenshot shows a Windows-style window titled "Setup" with a blue header bar. The main content area is titled "Monitored Database Information" and features the MySQL and Sun Microsystems logos in the top right corner. The configuration fields are as follows:

MySQL hostname or IP address	<input type="text" value="127.0.0.1"/>
Validate MySQL hostname or IP address	<input checked="" type="checkbox"/>
Hostname to display (optional)	<input type="text"/>
MySQL Port	<input type="text" value="3306"/>
MySQL Username	<input type="text"/>
MySQL Password	<input type="password"/>
Re-enter	<input type="password"/>

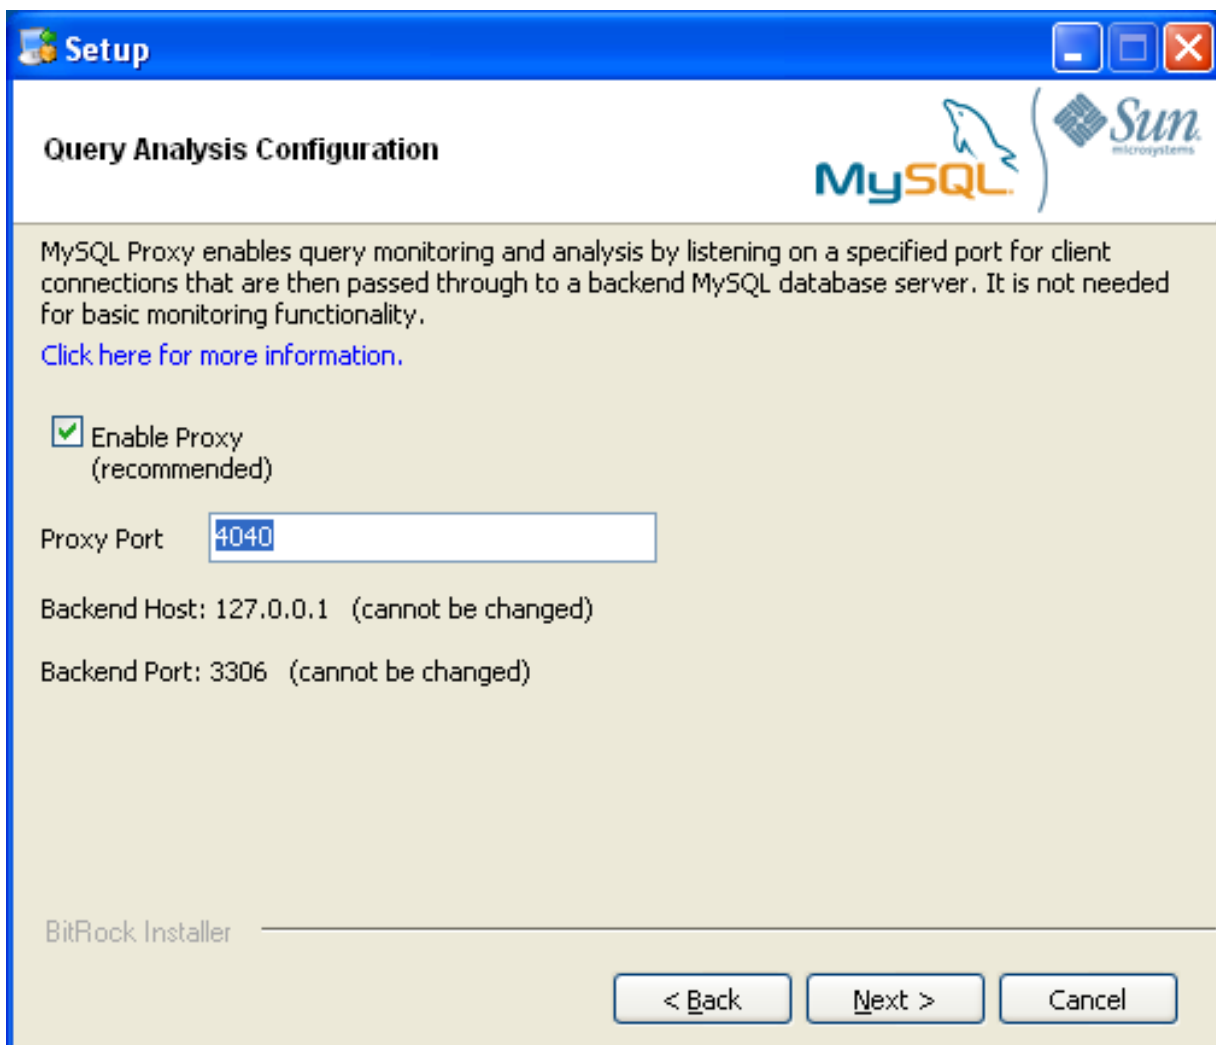

At the bottom left, it says "BitRock Installer". At the bottom right, there are three buttons: "< Back", "Next >", and "Cancel".

Click NEXT to continue the installation.

5. If you want to use Query Analyzer, then you need to enable the MySQL Enterprise Monitor Agent Proxy. The Proxy is enabled by default. If you disable the Proxy during installation, you will need to enable it later before you are able to use Query Analysis. For more information on Query Analyzer, see [Section 15.10, "The Query Analyzer Page"](#).

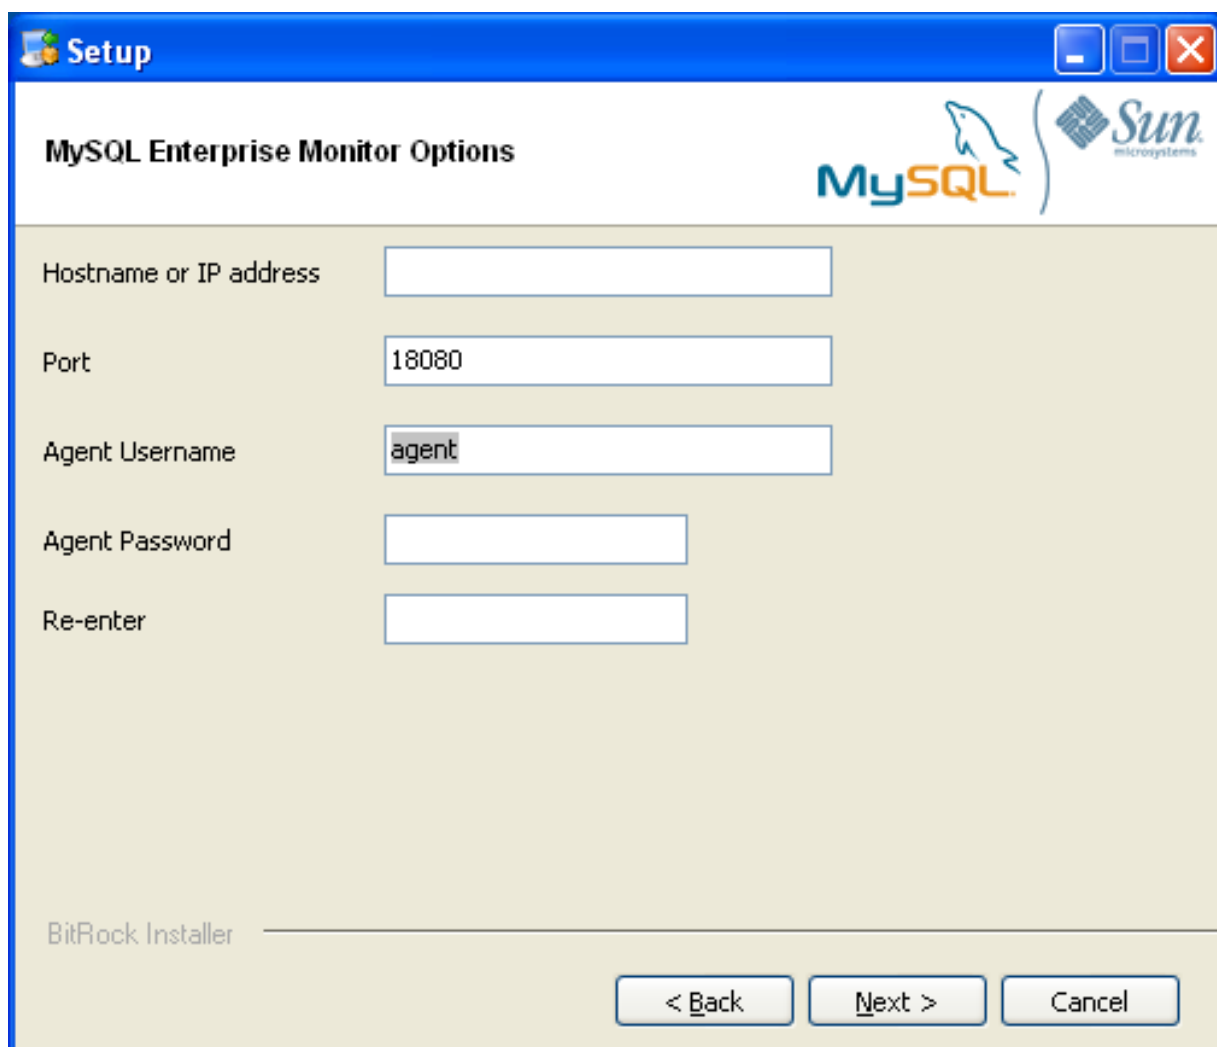

When Proxy is enabled, MySQL Enterprise Monitor Agent listens on a network port for client applications, and forwards the connections to the backend MySQL server. You can change the port number that MySQL Enterprise Monitor Agent listens for connections. The default port is 4040.

Figure 15.16. MySQL Enterprise Monitor: Installing Agent on Windows: Query Analyzer Configuration

6. The MySQL Enterprise Service Manager that you want to use must be configured during installation. The host name, port and agent authentication information must be entered. If you have already installed MySQL Enterprise Service Manager then you can locate the information in the installation report file created during installation. Enter the required information and then click NEXT to continue.

Figure 15.17. MySQL Enterprise Monitor: Installing Agent on Windows: MySQL Enterprise Service Manager Options

7. You will be provided with a Configuration Report containing the information that you have entered during the installation. Check the information provided in the report. If you see a problem, use BACK to go back to the configuration screen and change the information. If the information is correct, click NEXT to continue.
8. You are given a final opportunity to change the installation parameters. Click NEXT to start the installation process.
9. Once the agent has been installed, you will get a confirmation message. Click NEXT to finalize the installation.
10. You can start the MySQL Enterprise Monitor Agent automatically now the installation has been completed. To allow the agent to be started, leave the checkbox selected. To start the agent separately, uncheck the checkbox. Click FINISH to exit the installation.

Once the Monitor Agent is installed, it needs to be started. For information on how to start and stop the Agent, see [Section 15.3.3.5.1, “Starting/Stopping the Agent on Windows”](#).

15.3.3.3. Installing the Agent on Mac OS X

To install the MySQL Enterprise Monitor Agent on Mac OS X, decompress the `mysqlmonitoragent-version-installer.app.zip` and then run the `mysqlenterpriseagent-version-installer` application.

1. First, select the language for the MySQL Enterprise Monitor Agent installation. Click OK to continue installation.

Figure 15.18. MySQL Enterprise Monitor: Installing Agent on Mac OS X: Language Selection

2. Click NEXT to start the installation process.
3. Select the installation directory. The default installation directory is `C:\Program Files\MySQL\Enterprise\Agent`. Select the installation directory, or type the new directory location.

You also need to select the method that the agent will use to communicate with the MySQL server. You can choose either to use a TCP/IP (network) connection, or a Socket (local) connection. Choose the connection method, and click NEXT.

Note

The service agent always associates “localhost” with the TCP/IP address 127.0.0.1, not the MySQL socket. This is in contrast to the MySQL Command Line Tool, which connects via the MySQL socket by default on Unix, if the host-name “localhost” is specified.

If the MySQL server you wish to monitor has been started with the `--skip-networking` command option then you will not be able to connect to it via TCP/IP, as the server will not listen for TCP/IP connections. In this case the service agent will need to be configured to use the MySQL socket. This can be done during installation by selecting “socket” rather than “TCP/IP” and then specifying the MySQL socket name. This can also be configured after installation by editing the `agent-instance.ini` configuration file, for further information on this refer to [Section 15.3.3.6.2, “MySQL Server \(agent-instance.ini\) Configuration”](#).

If the MySQL server to be monitored has been started using the command option `--bind-address` then the server will only listen for connections on the IP address specified, that is, the IP address of the MySQL server. If the service agent has been started using TCP/IP networking and the default address of 127.0.0.1 it will not be able to connect to the server to be monitored. Also, if “localhost” is specified as the host name during agent configuration, a connection will not be established, as the server will be listening for connections on the address specified with the `--bind-address` option, not 127.0.0.1.

Figure 15.19. MySQL Enterprise Monitor: Installing Agent on Mac OS X: Installation Directory

4. You need to specify the information about the MySQL server that you want to monitor. The configuration information you enter will depend on the connection method selected in the previous screen.
 - If you chose TCP/IP as the connection method, you must enter the IP address or host name of the host you want to monitor, and the port, user name and password that you will use to connect to the MySQL server. If you want to confirm that the MySQL server is currently reachable using the information, ensure that the **VALIDATE MYSQL HOST NAME OR IP ADDRESS** checkbox is selected.

Cancel < Back Next >

- If you chose Socket as the connection method, you must enter the full path name to the Unix socket created by your MySQL server, and the user name and password that will be used to authenticate with the server. Typical values include `/tmp/mysql.sock` and `/var/mysql/mysql.sock`.

Figure 15.21. MySQL Enterprise Monitor: Installing Agent on Mac OS X: Monitored Database Information

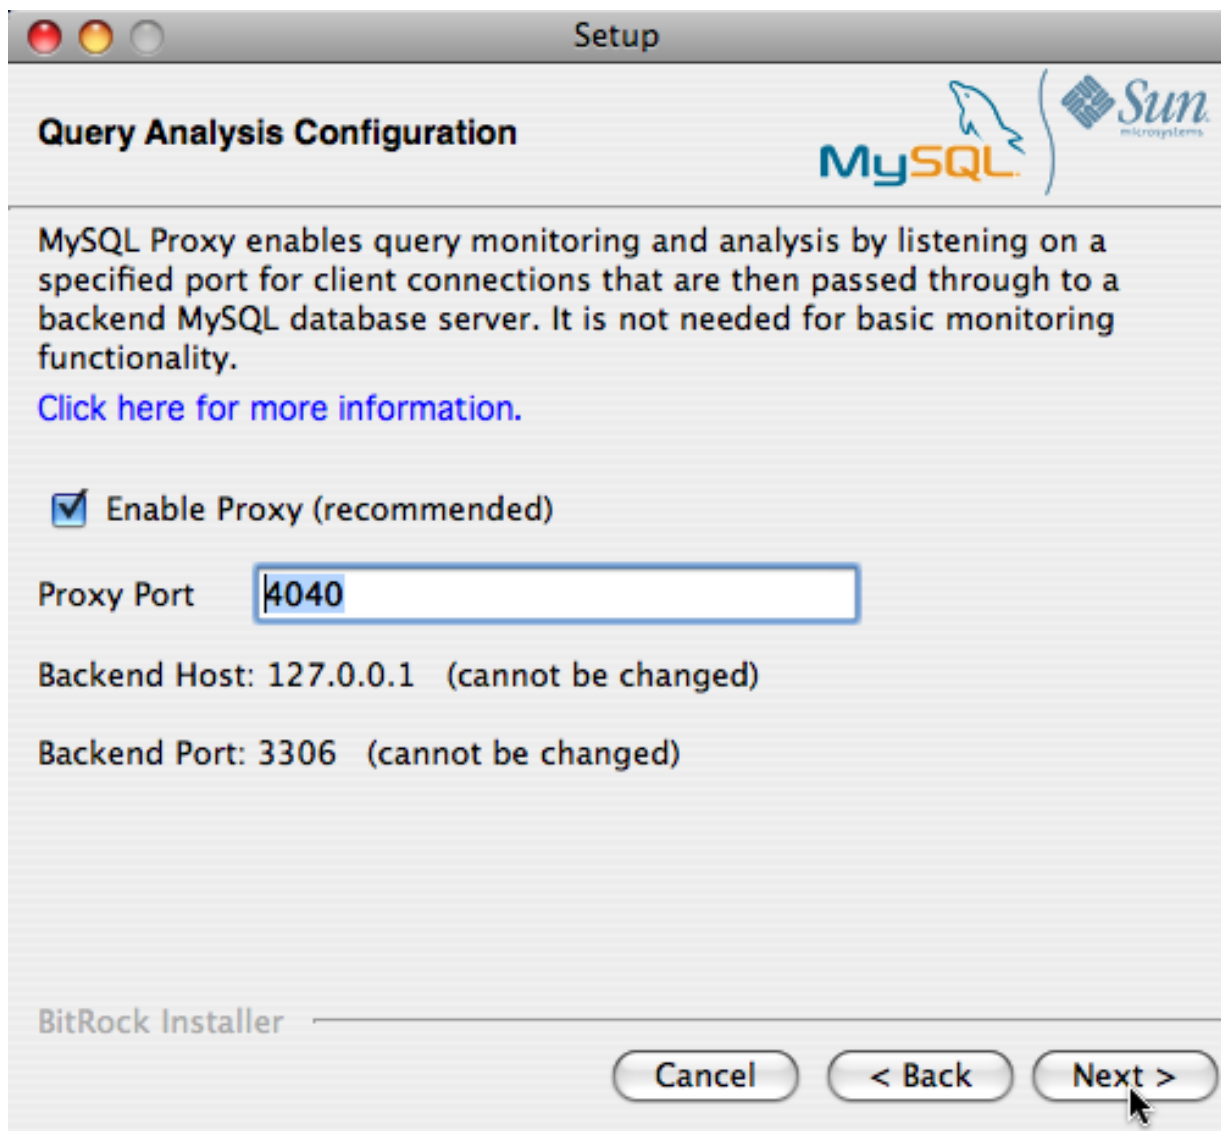

Click NEXT to continue the installation.

5. If you want to use Query Analyzer, then you need to enable the MySQL Enterprise Monitor Agent Proxy. The Proxy is enabled by default. If you disable the Proxy during installation, you will need to enable it later before you are able to use Query Analysis. For more information on Query Analyzer, see [Section 15.10, “The Query Analyzer Page”](#).

When Proxy is enabled, MySQL Enterprise Monitor Agent listens on a network port for client applications, and forwards the connections to the backend MySQL server. You can change the port number that MySQL Enterprise Monitor Agent listens for connections. The default port is 4040.

Figure 15.22. MySQL Enterprise Monitor: Installing Agent on Mac OS X: Query Analyzer Configuration

6. The MySQL Enterprise Service Manager that you want to use must be configured during installation. The host name, port and agent authentication information must be entered. If you have already installed MySQL Enterprise Service Manager then you can locate the information in the installation report file created during installation. Enter the required information and then click NEXT to continue.

Figure 15.23. MySQL Enterprise Monitor: Installing Agent on Mac OS X: MySQL Enterprise Service Manager Options

The screenshot shows a 'Setup' window for 'MySQL Enterprise Monitor Options'. The window has a title bar with three colored buttons (red, yellow, grey) and the text 'Setup'. Below the title bar, the text 'MySQL Enterprise Monitor Options' is displayed on the left, and the MySQL and Sun Microsystems logos are on the right. The main area contains five input fields: 'Hostname or IP address' (empty), 'Port' (18080), 'Agent Username' (agent), 'Agent Password' (empty), and 'Re-enter' (empty). At the bottom, there are three buttons: 'Cancel', '< Back', and 'Next >'. The text 'BitRock Installer' is visible in the bottom left corner.

7. You will be provided with a Configuration Report containing the information that you have entered during the installation. Check the information provided in the report. If you see a problem, use BACK to go back to the configuration screen and change the information. If the information is correct, click NEXT to continue.
8. You are given a final opportunity to change the installation parameters. Click NEXT to start the installation process.
9. Once the agent has been installed, you will get a confirmation message. Click NEXT to finalize the installation.
10. You can start the MySQL Enterprise Monitor Agent automatically now the installation has been completed. To allow the agent to be started, leave the checkbox selected. To start the agent separately, uncheck the checkbox. Click FINISH to exit the installation.

Once the Monitor Agent is installed, it needs to be started. For information on how to start and stop the Agent, see [Section 15.3.3.5.2, "Starting/Stopping the Agent on Mac OS X"](#).

15.3.3.4. Installing the Monitor Agent on Unix

As a prerequisite for installing the MySQL Enterprise Monitor Agent on Linux systems you must have the Linux Standards Base (LSB) initialization functions installed.

To install the agent navigate to the directory that contains the file, `mysqlmonitoragent-version-installer.bin` (where *version* indicates the three-part version number, the OS, and the architecture). Ensure that this file is executable by typing:

```
shell> chmod +x mysqlmonitoragent-version-installer.bin
```

To install to the default directory (`/opt/mysql/enterprise/agent`) you need to be logged in as `root`. Installing as an unprivileged user installs to the `/home/user_name/mysql/enterprise/agent` directory.

Note

If you install the agent as an unprivileged user, it will not automatically start up on rebooting.

What follows describes installation from the command line. You may install the Monitor Agent graphically by running the installer from within a windows manager. In both cases the steps are identical. You may also install the Monitor Agent in `unattended` mode. This is especially useful if you are doing multiple installations. For more information on this topic see [Section 15.3.4, “Unattended Installation”](#).

Begin installation from the command line by typing:

```
shell> ./mysqlmonitoragent-version-installer.bin --mode text
```

The various options are shown in what follows. Default values are indicated by square brackets; to select them press ENTER. Otherwise enter a value of your choosing.

1. First, you must select the Language you want to use during the installation process:

```
Language Selection
Please select the installation language
[1] English
[2] Japanese
Please choose an option [1] :
```

2. Next, specify the directory where you want the agent installed:

```
-----
Welcome to the MySQL Enterprise Monitor Agent Setup Wizard.
-----
Please specify the directory where MySQL Enterprise Monitor Agent will be installed
Installation directory [/opt/mysql/enterprise/agent]:
```

3. Specify the MySQL server that you want to monitor. First, you must specify whether you want to use a TCP/IP or socket-based connection to communicate with the MySQL Server:

```
How will the agent connect to the database it is monitoring?

[1] TCP/IP
[2] Socket
Please choose an option [1] :
```

If you select TCP/IP, then you will be asked to enter the TCP/IP address and port number:

```
-----
Monitored Database Information
IMPORTANT: The agent user account specified below requires special MySQL privileges.
Visit the following URL for more information:
https://enterprise.mysql.com/docs/monitor/2.0/en/mem-install.html#mem-agent-rights
MySQL hostname or IP address [127.0.0.1]:

Validate MySQL hostname or IP address [Y/n]:

MySQL Port [3306]:
```

If you select Socket, then you will be asked to provide the path name to the MySQL socket. Typical values are `/tmp/mysql.sock`, `/var/lib/mysql.sock`, or `/var/run/mysql.sock`.

```
-----
Monitored Database Information
IMPORTANT: The agent user account specified below requires special MySQL privileges.
```

Visit the following URL for more information:
<https://enterprise.mysql.com/docs/monitor/2.0/en/mem-install.html#mem-agent-rights>
 MySQL Socket []:

Note

The service agent always associates “localhost” with the TCP/IP address 127.0.0.1, not the MySQL socket. This is in contrast to the MySQL Command Line Tool, which connects via the MySQL socket by default on Unix, if the host-name “localhost” is specified.

If the MySQL server you wish to monitor has been started with the `--skip-networking` command option then you will not be able to connect to it via TCP/IP, as the server will not listen for TCP/IP connections. In this case the service agent will need to be configured to use the MySQL socket. This can be done during installation by selecting “socket” rather than “TCP/IP” and then specifying the MySQL socket name. This can also be configured after installation by editing the `agent-instance.ini` configuration file, for further information on this refer to [Section 15.3.3.6.2, “MySQL Server \(agent-instance.ini\) Configuration”](#).

If the MySQL server to be monitored has been started using the command option `--bind-address` then the server will only listen for connections on the IP address specified, that is, the IP address of the MySQL server. If the service agent has been started using TCP/IP networking and the default address of 127.0.0.1 it will not be able to connect to the server to be monitored. Also, if “localhost” is specified as the host name during agent configuration, a connection will not be established, as the server will be listening for connections on the address specified with the `--bind-address` option, not 127.0.0.1.

- Specify the user credentials for the MySQL server that you want to monitor:

```
MySQL Username []: service_agent
MySQL Password :
Re-enter :
```

- Select whether you want to enable Query Analyzer. If you disable the Query Analyzer during installation, you will need to manually edit the configuration file to re-enable the Query Analyzer functionality. If you enable Query Analysis (Proxy), you must specify the port on which the agent will listen for queries.

```
-----
Query Analyzer Configuration
MySQL Proxy enables query monitoring and analysis by listening on a specified port for client connections that are

Use SSL? [y/N]:
Agent Username [agent]:
Agent Password :
Re-enter :
-----

```

7. Before installation starts, you will be provided with a summary of the installation settings that you have specified:

```

Here are the settings you specified:
Installation directory: /opt/mysql/enterprise/agent
Monitored MySQL Database:
-----
Hostname or IP address: 127.0.0.1
Port: 3306
MySQL username: mysql_user
MySQL password: password
Query Analyzer Configuration
-----
Proxy Enabled: yes
Proxy Port: 4040
MySQL Enterprise Manager:
-----
Hostname or IP address: 192.168.0.197
Tomcat Server Port: 18080
Tomcat SSL Port: 18443
Use SSL: 0
Agent username: agent
Press [Enter] to continue :
-----
Setup is now ready to begin installing MySQL Enterprise Monitor Agent on your computer.
Do you want to continue? [Y/n]: y

```

8. The installer will copy the necessary files and create the configuration file required to run the agent:

```

-----
Please wait while Setup installs MySQL Enterprise Monitor Agent on your computer.

Installing
0% _____ 50% _____ 100%
#####
-----
Info to start MySQL Agent

The MySQL agent was successfully installed. To start the MySQL Agent please
invoke:
/opt/mysql/enterprise/agent/etc/init.d/mysql-monitor-agent start
Press [Enter] to continue :
-----
Setup has finished installing MySQL Enterprise Monitor Agent on your computer.

```

9. Finally, you can read the supplied [README](#) file when prompted. The file is provided within the [share/doc/README_en.txt](#) file within the agent installation directory if you would like to read this file separately.

For information on starting the agent, see [Section 15.3.3.5.3, “Starting/Stopping the Agent on Unix”](#).

15.3.3.5. Starting/Stopping the MySQL Enterprise Monitor Agent

The MySQL Enterprise Monitor Agent can be started and stopped at any time. When not running, information about the current status of your server will not be available, and MySQL Enterprise Service Manager will provide a warning if an agent and the MySQL server that it monitors is unavailable.

■ Warning

If you are using Query Analyzer, then turning off the agent will prevent your applications from communicating with the MySQL server. See [Section 15.10, “The Query Analyzer Page”](#).

15.3.3.5.1. Starting/Stopping the Agent on Windows

You have the option of starting the Monitor Agent from the final installation screen. Otherwise you can do this by going to the [Start Menu](#) and under [Programs](#) find [MySQL](#) and then the [MySQL Enterprise Monitor Agent](#) entry. Simply select the [Start MySQL Enterprise Monitor Agent](#) option.

Note

On Windows Vista, starting the agent requires administrative privileges — you must be logged in as an administrator. To start or stop the agent right click the menu item and choose the [RUN AS ADMINISTRATOR](#) menu option. The same restriction applies to starting the agent from the command line. To open an administrator [cmd](#) window right-click the [cmd](#) icon and choose the [RUN AS ADMINISTRATOR](#) menu option.

Warning

To report its findings, the agent needs to be able to connect to the dashboard through the port specified during installation. The default value for this port is [18080](#); ensure that this port is not blocked. If you need help troubleshooting the agent installation see, [Section 15.3.3.7, “Troubleshooting the Agent”](#).

Alternately, you can start the agent from the command line by entering:

```
shell> sc start MySQLEnterpriseMonitorAgent
```

or:

```
shell> net start MySQLEnterpriseMonitorAgent
```

You can also start the agent by issuing the command, [agentctl.bat start](#). Stop the agent by passing the argument, [stop](#). This batch file is found in the [Agent](#) directory.

For confirmation that the service is running you can open the Microsoft Management Console Services window. To do this go to the Control Panel, find [Administrative Tools](#) and click on the link to [Services](#). Locate the service named [MySQL Enterprise Monitor Agent](#) and look under the [STATUS](#) column.

You may also start the agent from this window rather than from the [Start](#) menu or the command line. Simply right click [MySQL Enterprise Monitor Agent](#) and choose [Start](#) from the pop-up menu. Starting the agent from this window opens an error dialog box if the agent cannot connect to the MySQL server it is monitoring. No error is displayed if the agent is unable to connect to the MySQL Enterprise Service Manager.

The pop-up menu for starting the agent also offers the option of stopping the agent. To stop the agent from the command line you only need type:

```
shell> sc stop MySQLEnterpriseMonitorAgent
```

or:

```
shell> net stop MySQLEnterpriseMonitorAgent
```

Note

[MySQLEnterpriseMonitorAgent](#) is the default name of the Monitor Agent service. If you have added an additional agent as described in [Section 15.3.3.6.2, “MySQL Server \(agent-instance.ini\) Configuration”](#), replace [MySQLEnterpriseMonitorAgent](#) with the appropriate agent name.

15.3.3.5.2. Starting/Stopping the Agent on Mac OS X

The script to start the agent on Mac OS X is located in the [/Applications/mysql/enterprise/agent/etc/init.d](#) directory. To start the agent navigate to this directory and at the command line type:

```
shell> ./mysql-monitor-agent start
```

To stop the agent, use the [stop](#) command:

```
shell> ./mysql-monitor-agent stop
```

If the agent cannot be stopped because the `pid` file that contains the agent's process ID cannot be found, you can use `kill` to send a `TERM` signal to the running process:

```
shell> kill -TERM PID
```

If you are running more than one agent on a specific machine, you must also specify the path to the `ini` file when you are stopping the agent. Executing `mysql-monitor-agent stop` without an `ini` file will only stop the agent associated with the default `ini` file.

For more information about creating additional agents see, [Section 15.3.3.6.2, “MySQL Server \(agent-instance.ini\) Configuration”](#).

To verify that the agent is running use the following command:

```
shell> ./mysql-monitor-agent status
```

The resulting message indicates whether the agent is running or not. If the agent is not running, use the following command to view the last ten entries in the agent log file:

```
shell> tail /Applications/mysql/enterprise/agent/log/mysql-monitor-agent.log
```

For further information on troubleshooting the agent see [Section 15.3.3.7, “Troubleshooting the Agent”](#).

Installation creates the directory `/Applications/mysql/enterprise/agent` with the settings stored in the `mysql-monitor-agent.ini` file located directly below this directory in the `etc` directory. The `log` directory is also located immediately below the `agent` directory.

To see all the command-line options available when running the service agent, navigate to the `/Applications/mysql/enterprise/agent/etc/init.d` directory and execute `mysql-monitor-agent help`. You should see the message:

```
Usage: ./mysql-monitor-agent {start|stop|restart|status} [ini-file-name]
```

The `ini-file-name` option only needs to be used if the `ini` file is not installed to the default location or you have changed the name of the `ini` file. You will need to use this option if you are installing more than one agent on the same machine. Pass the full path to the `ini` file. For example, after navigating to the `/Applications/mysql/enterprise/agent/etc/init.d` directory, issue the command:

```
shell> ./mysql-monitor-agent start /Applications/mysql/enterprise/agent/etc/new-mysql-monitor-agent.ini
```

If you installed the agent as `root`, on reboot the `mysql-monitor-agent` daemon will start up automatically. If you installed the agent as an unprivileged user, you must manually start the agent on reboot or write a script to perform this task. Likewise, if you have added an additional agent as described in [Section 15.3.3.6.2, “MySQL Server \(agent-instance.ini\) Configuration”](#), and you wish to start this agent on reboot, create a system initialization script appropriate to your operating system. To determine whether the agent is running or not navigate to the `init.d` directory and issue the command `./mysql-monitor-agent status`.

Warning

To report its findings, the agent needs to be able to connect to the dashboard through the port specified during installation. The default value for this port is `18080`; ensure that this port is not blocked. If you need help troubleshooting the agent installation see, [Section 15.3.3.7, “Troubleshooting the Agent”](#).

15.3.3.5.3. Starting/Stopping the Agent on Unix

When installation is finished, you can start the service agent from the command line by typing:

```
shell> /opt/mysql/enterprise/agent/etc/init.d/mysql-monitor-agent start
```

For a non-root installation the command would be:

```
shell> /home/<user name>/mysql/enterprise/agent/etc/init.d/mysql-monitor-agent start
```

To stop the agent, use the `stop` command:

```
shell> ./mysql-monitor-agent stop
```

If the agent cannot be stopped because the `pid` file that contains the agent's process ID cannot be found, you can use `kill` to send a `TERM` signal to the running process:

```
shell> kill -TERM PID
```

If you are running more than one agent on a specific machine, you must also specify the path to the `ini` file when you are stopping the agent. Executing `mysql-monitor-agent stop` without an `ini` file will only stop the agent associated with the default `ini` file. Likewise, when checking the status of an agent specify its `ini` file.

For more information about creating additional agents see, [Section 15.3.3.6.2, “MySQL Server \(agent-instance.ini\) Configuration”](#).

To verify that the agent is running use the following command:

```
shell> ./mysql-monitor-agent status
```

The resulting message indicates whether the agent is running or not. If the agent is not running, use the following command to view the last ten entries in the agent log file:

```
shell> tail /opt/mysql/enterprise/agent/log/mysql-monitor-agent.log
```

For further information on troubleshooting the agent see [Section 15.3.3.7, “Troubleshooting the Agent”](#).

Installation creates the directory `/opt/mysql/enterprise/agent` with the settings stored in the `mysql-monitor-agent.ini` file located directly below this directory in the `etc` directory. The `log` directory is also located immediately below the `agent` directory.

To see all the command-line options available when running the service agent, navigate to the `/opt/mysql/enterprise/agent/etc/init.d` directory and execute `mysql-monitor-agent help`. You should see the message:

```
Usage: ./mysql-monitor-agent {start|stop|restart|status} [ini-file-name]
```

The `ini-file-name` option only needs to be used if the `ini` file is not installed to the default location or you have changed the name of the `ini` file. You will need to use this option if you are installing more than one agent on the same machine. Pass the full path to the `ini` file. For example, after navigating to the `/opt/mysql/enterprise/agent/etc/init.d` directory, issue the command:

```
shell> ./mysql-monitor-agent start /opt/mysql/enterprise/agent/etc/new-mysql-monitor-agent.ini
```

If you installed the agent as `root`, on reboot the `mysql-monitor-agent` daemon will start up automatically. If you installed the agent as an unprivileged user, you must manually start the agent on reboot or write a script to perform this task. Likewise, if you have added an additional agent as described in [Section 15.3.3.6.2, “MySQL Server \(agent-instance.ini\) Configuration”](#), and you wish to start this agent on reboot, create a system initialization script appropriate to your operating system. To determine whether the agent is running or not navigate to the `init.d` directory and issue the command `./mysql-monitor-agent status`.

Warning

To report its findings, the agent needs to be able to connect to the dashboard through the port specified during installation. The default value for this port is `18080`; ensure that this port is not blocked. If you need help troubleshooting the agent installation see, [Section 15.3.3.7, “Troubleshooting the Agent”](#).

15.3.3.6. Advanced Agent Configuration

The MySQL Enterprise Monitor Agent is configured through files located within the `etc` directory within the directory where you installed the agent.

Configuration is stored in multiple files, according to a predetermined file and directory layout. The primary configuration file contains specific information about the agent and how the agent communicates with MySQL Enterprise Service Manager. The main configuration is located within the `mysql-monitor-agent.ini` file.

Additional configuration files contain information about the MySQL server that is being monitored. You can configure which directory is used for storing this information within the `mysql-monitor-agent.ini` file. The default location is the `etc/instances` directory within the MySQL Enterprise Monitor Agent directory.

The server you want to monitor should have a directory within the specified location, optionally using the name of the server you are monitoring, and within that directory, an `agent-instance.ini` file. This file contains the configuration information for

connecting to the MySQL server, including the host name, port, user credentials and display name.

You can see an example of the file layout of the `etc` directory:

```
./init.d
./init.d/mysql-monitor-agent
./instances
./instances/agent
./instances/agent/agent-instance.ini
./mysql-monitor-agent.ini
```

For more information on the configuration of the `mysql-monitor-agent.ini` file, see [Section 15.3.3.6.1, “MySQL Enterprise Monitor Agent \(`mysql-monitor-agent.ini`\) Configuration”](#). For details on the content of the individual MySQL instance configuration files, see [Section 15.3.3.6.2, “MySQL Server \(`agent-instance.ini`\) Configuration”](#).

15.3.3.6.1. MySQL Enterprise Monitor Agent (`mysql-monitor-agent.ini`) Configuration

The `mysql-monitor-agent.ini` files contains the base configuration information for the MySQL Enterprise Monitor Agent. The file sets the core information about the supported functionality for the entire agent.

You can see a sample of the configuration file below:

```
# WARNING - the UUID defined below must be unique for each agent.
#
# To use this .ini file as a template for configuring additional
# agents, do not simply copy and start a new agent without first
# modifying the UUID.
#
# Refer to the documentation for more detailed information and
# instructions.
#
# Version: 20080718_230416_r7011

[mysql-proxy]

plugins=proxy,agent
agent-mgmt-hostname = http://agent:password@monitor-server:18080/heartbeat
mysql-instance-dir= etc/instances
agent-item-files = share/mysql-proxy/items/quan.lua,share/mysql-proxy/items/items-mysql-monitor.xml
proxy-address=:4040
proxy-backend-addresses = 127.0.0.1:3306
proxy-lua-script = share/mysql-proxy/quan.lua

agent-uuid = 8770ead5-3632-4b29-a413-4a7c92437e26
log-file = mysql-monitor-agent.log
pid-file=/Applications/mysql/enterprise/agent/mysql-monitor-agent.pid
```

Note

Do not copy the agent configuration information from one machine to another without changing the `agent-uuid`. Each agent instance must have a unique agent id.

The main configuration information must be located within the `[mysql-proxy]` section of the configuration file. The main configurable parameters within this file are:

- `plugins` — configures the plugins to be used by the agent. When monitoring servers you must have the `agent` plugin configured. If you want to support Query Analyzer then you must also have the `proxy` module enabled. Plugins should be specified as a comma separated list of plugin names.

If you selected to support Query Analyzer during installation of the agent, the default value will be `proxy,agent`. If you disabled Query Analysis during installation, the default value will be `agent`.

- `log-level` — sets the logging level of the agent. The default level is `message`.

Valid values for `log-level` are as follows:

- `debug` — provides detailed information about what the agent is doing and the information being provided by the agent to the MySQL Enterprise Service Manager.
- `critical` — lists critical messages highlighting problems with the agent.
- `error` — lists error messages.
- `warning` — provides only warning messages generated by the agent.
- `message` — provides information about the agent and basic processing information.

- `info` — provides messages used for informational purposes.

Warning

Be careful when setting the `log-level` to `debug`. Doing this will rapidly increase the size of your `mysql-monitor-agent.log` file. To avoid disk space problems, put the log files on a different drive from your MySQL server and the MySQL Enterprise Dashboard.

It is strongly recommended that you use a `log-level` of `critical` or `error` in a production server. Use the higher-levels to provide more detailed information only for debugging problems with your agent.

Under Windows, if you restart the agent from the command line after setting the `log-level` to `debug`, extensive debug information is displayed to the console as well as to the log file.

- `agent-mgmt-hostname` — sets the URL to use when reporting information. This value will be automatically set to your MySQL Enterprise Service Manager during installation.
 - `mysqld-instance-dir` — sets the directory where the configuration files that specify the MySQL servers to be monitored can be located.
 - `agent-item-files` — sets the information that is provided up to the MySQL Enterprise Service Manager when the agent is reporting status information. You should leave this item with the default setting of the `share/mysql-proxy/items/quant.lua` (which provides Query Analyzer data) and `share/mysql-proxy/items/items-mysql-monitor.xml` (which provides the core agent monitoring data).
 - `proxy-address` — sets the address and/or port number for the proxy to listen to for connections. The setting is used when employing Query Analysis as the address/port that you must configure your application to use in place of your normal MySQL server. By default this item is set during installation. The default value is 4040. If you want to support a different local host name/IP address and port, specify the host name and the port number, separated by a colon.
 - `proxy-backend-addresses` — sets the host name and port number to be used when communicating the backend MySQL server when employing query analyzer. This is the MySQL server where packets from the client are sent when communicating with the proxy on the host name/port set by the `proxy-address`.
 - `proxy-lua-script` — sets the Lua script to be used by the proxy when forwarding queries. To use Query Analyzer, this parameter should be set to `share/mysql-proxy/quant.lua`. This is the default value.
 - `agent-uuid` — sets the UUID (Universally Unique ID) of the agent. This value should be unique for all agents communicating with the same server, as the UUID is used to uniquely ID the agent within MySQL Enterprise Service Manager
- If you are setting up multiple hosts and copying the configuration between hosts, make sure that the `agent-uuid` is unique. You can have the agent create a new UUID by leaving this configuration property blank.
- `log-file` — sets the location of the log file used to record information about the agent when it is running. If you do not specify a full path name, then the log file location is considered to be relative to the installation directory of the agent.
 - `pid-file` — sets the location of the file used to record the Process ID of the agent. This is used by the script that shuts down the agent to identify the process to be shutdown. The default value is the `mysql-monitor-agent.pid` file within the base installation directory as created by the agent installer.

A number of optional parameters are also configurable within the `mysql-monitor-agent.ini` file:

- `backlog-threshold` — determines the amount of time that the agent will collect information after detecting that the service manager is down. The default value for this option is 600 seconds. In cases where there is a short network outage no information will be lost. If the outage is longer than the value of `backlog-threshold` older data is dropped as the new data is acquired.

A setting of 600 seconds means that excessive memory usage is avoided should there be a long outage. In most circumstances, there is no need to change this option. To set `backlog-threshold` to a value other than the default, add a line with the information specifying the number of seconds.

Warning

Setting this option to a value higher than the default can exhaust memory.

15.3.3.6.2. MySQL Server (`agent-instance.ini`) Configuration

For the MySQL server that you want to monitor, you must create an `agent-instance.ini` within the directory specified by the `mysqld-instance-dir` configuration parameter within the main `mysql-monitor-agent.ini` file.

The `agent-instance.ini` file contains the host name and user credentials for connecting to the MySQL server that you want the agent to monitor. The format of the file is as follows:

```
# WARNING - the displayname defined below must be unique for each
# MySQL server being monitored.
#
# To use this .ini file as a template for configuring additional
# instances to monitor, do not simply copy and start a new agent
# without first modifying the displayname.
#
# Refer to the documentation for more detailed information and
# instructions.
#
# Version: 20080718_230416_r7011

[mysqld]
hostname = 127.0.0.1
port      = 3306
user      = root
password =
```

The individual configuration parameters can be defined as follows:

- `hostname` — the host name of the MySQL server that you want to monitor.
- `port` — the TCP/IP port of the MySQL server that you want to monitor.
- `user` — the user to use when connecting to the MySQL server that you want to monitor.
- `password` — the corresponding password to use when connecting to the MySQL server that you want to monitor.

It is also possible to configure the agent to use sockets. This can be done during installation by selecting “socket” rather than “TCP/IP” from the menu and then specifying the socket name. This can also be configured after installation by editing the `agent-instance.ini` configuration file, and adding the line:

```
socket = /full/path/to/mysql.sock
```

15.3.3.6.3. Monitoring Multiple MySQL Servers

You can monitor multiple MySQL servers (either on the same machine, or across different machines) using two different methods:

- By using a single agent instance to monitor multiple MySQL servers. You can use this method if you want to monitor multiple servers, but do not want or need to support Query Analysis on the additional servers.
- By using multiple copies of the MySQL Enterprise Monitor Agent to monitor each server individually. Using this method requires additional overhead to monitor each server, while also allowing you to supply Query Analysis data.

Using a Single Agent Instance

To use a single agent to monitor multiple instances, you can create additional directories and configuration files within the `instances` directory for the agent. For example, you can see the default structure of the agent configuration directory:

```
./init.d
./init.d/mysql-monitor-agent
./instances
./instances/agent
./instances/agent/agent-instance.ini
./mysql-monitor-agent.ini
```

Within the `instances` directory, you can add further directories, one for each monitored server. Each additional directory must have a suitable `agent-instance.ini` file containing the connection information for the new MySQL server instance. For example, the following structure demonstrates an agent monitoring four MySQL servers:

```
./init.d
./init.d/mysql-monitor-agent
./instances
./instances/agent
./instances/agent/agent-instance.ini
./instances/mysql2
./instances/mysql2/agent-instance.ini
./instances/mysql-rep
```

```
./instances/mysql-rep/agent-instance.ini
./instances/mysql-backup
./instances/mysql-backup/agent-instance.ini
./mysql-monitor-agent.ini
```

To add another MySQL monitored server, follow these steps:

1. Make sure that the MySQL instance that you want to monitor has a suitable user to use for connecting to the server. For more information, see [Section 15.3.3.1, “Creating a MySQL User Account for the Monitor Agent”](#).
2. Copy an existing configuration directory and configuration files to the new directory:

```
shell> cp -R etc/instances/agent etc/instances/mysql2
```

3. Edit the configuration file within the new directory, for example `mysql2/agent-instance.ini`, and set the `user`, `password` and either the `hostname` and `port`, or `socket` parameters.
4. Restart the agent:

```
shell> mysql-monitor-agent restart
```

Using Multiple Agent Instances

To use multiple agents to monitor multiple MySQL servers you need to create a new configuration structure for both the agent and the MySQL server instances you need to monitor, including the binaries and configuration files, and then update the configuration to set the corresponding parameters to monitor the new server. Using this method allows you to enable query analysis by redirecting requests to the target server using the built-in proxy service within the agent.

For example, the directory structure below shows the configuration directory for two agents monitoring a single MySQL server each:

```
./init.d
./init.d/mysql-monitor-agent
./instances
./instances/agent
./instances/agent/agent-instance.ini
./instances-second/agent
./instances-second/agent/agent-instance.ini
./mysql-monitor-agent.ini
./mysql-second-agent.ini
```

The `mysql-monitor-agent.ini` file contains the configuration for the first agent, with the MySQL servers monitored defined within the `instances` directory. The `mysql-second-agent.ini` file contains the configuration information for the second agent, with the MySQL servers monitor defined within the `instances-second` directory.

To set up multiple agents:

1. Make sure that the MySQL instance that you want to monitor has a suitable user to use for connecting to the server. For more information, see [Section 15.3.3.1, “Creating a MySQL User Account for the Monitor Agent”](#).
2. You need to generate a new UUID for the new agent:

```
shell> mysql-monitor-agent --agent-generate-uuid
ee9296d7-f7cd-4fee-8b26-ead884ebf398
2009-03-05 11:49:37: (critical) shutting down normally
```

Keep a record of the UUID to update the configuration file.

Note, the agent should not be running when the UUID is generated.

3. Copy the main agent configuration file, `mysql-monitor-agent.ini`:

```
shell> cp mysql-monitor-agent.ini mysql-second-agent.ini
```

4. Edit the new configuration file, changing the following settings:

- Change the `mysql-d-instance-dir` to the new directory that will contain the individual MySQL server configuration files.

- Change the `proxy-address` to a different value than the first agent configuration.
 - Change the `proxy-backend-addresses` to specify the IP address and MySQL port number for the MySQL server.
 - Change the `agent-uuid` to the new value obtained in an earlier step.
 - Change the `log-file` parameter to specify a different file to use when logging errors and problems. You cannot log to the same file from two different agents.
 - Change the `pid-file` parameter to specify the file that will be used to store the process ID of the agent.
5. Copy an existing configuration directory and configuration files to the new directory:

```
shell> cp -R etc/instances etc/instances-second
```

6. Edit the configuration file, `instances/second/agent/agent-instance.ini` within the new directory, and set the `user`, `password` and either the `hostname` and `port`, or `socket` parameters.
7. With multiple instances, you must start each agent individually, specifying the location of the main configuration file. For example, to start the original (default) service:

```
shell> mysql-monitor-agent start /opt/mysql/monitor/agent/etc/mysql-monitor-agent.ini
```

To start the second instance:

```
shell> mysql-monitor-agent start /opt/mysql/monitor/agent/etc/mysql-second-agent.ini
```

15.3.3.6.4. Configuring an Agent to Monitor a Remote MySQL Server

Typically, the agent runs on the same machine as the MySQL server it is monitoring. Fortunately, this is not a requirement. If you want to monitor a MySQL server running on an operating system for which there is no agent available, you can install the agent on a machine other than the one hosting the MySQL server.

The process for installing an agent to monitor a MySQL server on a remote machine is identical to the process described in [Section 15.3.3, “Monitor Agent Installation”](#). Follow the directions given there, being careful to specify the correct IP address or host name for the MySQL Enterprise Service Manager and likewise for the MySQL server — since the agent is not running on the same machine as the MySQL server, it cannot be the default, `localhost`.

Don't forget that the agent must be given rights to log in to the MySQL server from a host other than `localhost` and that the port used by the MySQL server, typically `3306` must be open for remote access. For more information about the database credentials required by agents see, [Section 15.3.3.1, “Creating a MySQL User Account for the Monitor Agent”](#).

The agent also needs to be able to log in to the MySQL Enterprise Service Manager, typically using port `18080`, so ensure that the appropriate port is open.

Note

Monitoring a MySQL server from a remote machine affects how information is displayed in the dashboard. The `OS` and `CPU` information applies to the machine on which the agent is running not the machine hosting the monitored server. For more information on this topic see [Section 15.5, “MySQL Enterprise Dashboard”](#).

If your subscription level entitles you to replication autodiscovery, do **not** use remote monitoring with replication slaves or masters. The agent must be installed on the same machine as the server you are monitoring in order for discovery to work properly. For more information, see [Section 15.11, “The Replication Page”](#).

15.3.3.6.5. Monitoring Outside the Firewall with an SSH Tunnel

If you run an SSH server on the machine that hosts the MySQL Enterprise Service Manager and an SSH client on the machine that hosts the agent, you can create an SSH tunnel so that the agent can bypass your firewall. First, you need to make an adjustment to the `hostname` value specified in the `[mysql-proxy]` section of the `.ini` file. (For more information about the contents and location of the `.ini` file see [Section 15.3.3.6.1, “MySQL Enterprise Monitor Agent \(`mysql-monitor-agent.ini`\) Configuration”](#).) Stop the agent and change the `hostname` value as shown in the following:

```
hostname = http://agent_name:password@localhost:18080/heartbeat
```

Replace the `agent_name` and `password` with suitable values. Likewise replace port `18080` if you are not running the dashboard on this port. Use `localhost` for the host name, since the agent is connecting through an SSH tunnel.

Next, execute the following command on the machine where the agent is running:

```
shell> ssh -L 18080:Dashboard_Host:18080 -l user_name -N Dashboard_Host
```

When prompted, enter the password for `user_name`.

If you are not running the MySQL Enterprise Service Manager on port 18080, substitute the appropriate port number. Likewise, replace `Dashboard_Host` with the correct value. `user_name` represents a valid operating system user on the machine that hosts the MySQL Enterprise Service Manager.

Be sure to restart the agent so that the new value for the `hostname` takes effect. For instructions on restarting the agent see:

- Under Windows see, [Section 15.3.3.5.1, “Starting/Stopping the Agent on Windows”](#).
- Under Unix see, [Section 15.3.3.5.3, “Starting/Stopping the Agent on Unix”](#).
- Under Mac OS X see, [Section 15.3.3.5.2, “Starting/Stopping the Agent on Mac OS X”](#).

15.3.3.6.6. Generating a new UUID

In Unix go to the command line and type:

```
shell> /opt/mysql/enterprise/agent/bin/mysql-monitor-agent --agent-generate-uuid
```

In Mac OS X go to the command line and type:

```
shell> /Applications/mysql/enterprise/agent/bin/mysql-monitor-agent --agent-generate-uuid
```

This should display a line similar to the following:

```
ee9296d7-f7cd-4fee-8b26-ead884ebf398
```

Paste this line into the `[mysql-proxy]` section of the `ini` file for the `agent-uuid` parameter.

Ensure that the newly created file `mysql-service-agent-3307.ini`, is in the `C:\Program Files\MySQL\Enterprise\Agent` directory.

Navigate to this directory and execute `mysql-service-agent -uf mysql-service-agent-3307.ini`. Doing this generates a new UUID and inserts it into the configuration file.

15.3.3.7. Troubleshooting the Agent

The first step in troubleshooting the agent is finding out whether it is running or not. To do this see:

- Windows – [Section 15.3.3.5.1, “Starting/Stopping the Agent on Windows”](#)
- Unix – [Section 15.3.3.5.3, “Starting/Stopping the Agent on Unix”](#)
- Mac OS X – [Section 15.3.3.5.2, “Starting/Stopping the Agent on Mac OS X”](#)

If incorrect credentials are specified for the agent login to the MySQL server that it is monitoring, then the agent will not run on start-up. Log in to the monitored MySQL server and check the agent's credentials. Compare the values of the `Host`, `User`, and `Password` fields in the `mysql.user` table with the values shown in the `[mysqld]` section of the `etc/instances/mysql/agent-instance.ini`. If incorrect credentials are specified in the `ini` file, simply correct them and restart the agent. Remember, changes to the `ini` file do not take effect until the agent is restarted.

The agent will not start up if incorrect credentials are specified for the service manager login. Using incorrect credentials for logging in to the service manager creates an entry in the agent log file. For the location of this log file see [Agent Log and PID Files](#).

If the agent starts up but no server appears in the dashboard, check the `hostname` specified in the `[mysql-proxy]` portion of the `mysql-monitor-agent.ini` file. Incorrect credentials, IP address, or port will all cause the MySQL server to fail to appear in the dashboard. Also, ensure that the port specified in this file is not blocked on the machine hosting the MySQL Enterprise Service Manager.

An easy way to confirm that the agent can log in to the service manager is to type `http://Dashboard_Host:18080/`

heartbeat into the address bar of your web browser, substituting the appropriate host name and port. When the HTTP authentication dialog box opens, enter the agent user name and password. If you log in successfully, you should see the following message:

```
<exceptions>
<error>E1031: Agent payload parameter NULL.</error>
</exceptions>
```

Note

Despite the fact that the preceding listing shows an error, you have logged in successfully. This error appears *because* you have logged in but with no “payload”.

If you can log in successfully in the way described above and the agent is running, then there are errors in the `mysql-monitor-agent.ini` file. Compare the host name, port, agent name, and password found in the `ini` file with the values you entered into the address bar of your web browser.

If HTTP authentication fails then you are using incorrect credentials for the agent. Attempting to log in to the service manager using incorrect credentials creates an entry in the agent log file. For the location of this log file see [Agent Log and PID Files](#).

If no HTTP authentication dialog box appears, and you are unable to connect at all, then you may have specified an incorrect host name or port. Confirm the values you entered against those described as the `Application hostname and port:` in the `configuration_report.txt` file. Failure to connect could also indicate that the port is blocked on the machine hosting the MySQL Enterprise Service Manager.

To check if a blocked port is the problem, temporarily bring down your firewall. If the agent is then able to connect, open up the port specified during installation and restart the agent. If necessary you can monitor outside the firewall using an SSH tunnel. For more information, see [Section 15.3.3.6.5, “Monitoring Outside the Firewall with an SSH Tunnel”](#).

You can also check the agent error log file to help determine any problems. An error such as the following might indicate a blocked port:

```
(critical) connection to merlin-server
'http://agent:test@172.11.1.1:18080/heartbeat' failed:
"connect() timed out!" error.
```

For the location of the agent error log file see, [Agent Log and PID Files](#).

Setting the `log-level` entry in your `ini` file is also a good debugging technique. For more information on this subject see, [Section 15.3.3.6.1, “MySQL Enterprise Monitor Agent \(mysql-monitor-agent.ini\) Configuration”](#).

Running the agent from the command line sometimes displays errors that fail to appear in the log file or on the screen when the agent is started from a menu option. To start the agent from the command line see the instructions given at the start of this section.

If you have more than one agent running on the same machine, the `UUID` must be unique and the `log-file` and `pid-file` values must be different. For more information, see [Section 15.3.3.6.2, “MySQL Server \(agent-instance.ini\) Configuration”](#).

If the agent is not running on the same machine that hosts the MySQL server it is monitoring, then you must ensure that the correct `host` is specified for the agent account. The correct port, typically 3306, must also be open for remote login. For more information about remote monitoring see, [Section 15.3.3.6.4, “Configuring an Agent to Monitor a Remote MySQL Server”](#).

15.3.4. Unattended Installation

It is possible to install the MySQL Enterprise Monitor without any direct user interaction. This is done by passing the command-line option `--mode unattended` to the installation file.

Using this mode and other command-line parameters means the user will not be prompted for input during installation. This is especially useful when doing multiple installations of the MySQL Enterprise Monitor.

However, rather than passing numerous parameters from the command line, it is usually more convenient to save your options in a text file and invoke the installer using the `optionfile` option. This is a more reusable and less error-prone solution.

Before attempting an unattended installation, it is recommended that you install the MySQL Enterprise Monitor interactively at least once. Failing this, as a minimum, read the regular installation instructions since some tasks still remain after an unattended installation; you must configure the MySQL Enterprise settings, import the advisors, and start up all the services/daemons.

15.3.4.1. Command-Line Options

To view the available options for the monitor installer or for the agent installer, at the command line type the executable file name along with the `help` option.

15.3.4.1.1. MySQL Enterprise Service Manager Options

The following listing shows the command line options for the MySQL Enterprise Service Manager.

```
--help                Display the list of valid options
--version             Display product information
--optionfile <optionfile> Installation option file
                        Default:
--mode <mode>        Installation mode
                        (Windows)Default: win32
                        (Unix)Default: gtk
                        (Mac OS X)Default: osx
                        (Windows)Allowed: win32 unattended
                        (Unix)Allowed: gtk text xwindow unattended
                        (Mac OS X)Allowed: osx text unattended
```

Note

The default modes are different for different operating systems. The values allowed also differ. There is no `text` installation mode under Windows.

```
--debugtrace <debugtrace> Debug filename
                        Default:
--installer-language <installer-language> Language selection
                        Default:
                        Allowed: en jp
--installdir <installdir> Installation directory
                        (Windows)Default:C:\Program »
                        Files\MySQL\Enterprise\Monitor
                        (Unix)Default:/opt/mysql/enterprise/monitor/
                        (Mac OS X)Default:/Applications/mysql/enterprise/monitor/
--tomcatport <tomcatport> Tomcat Server Port
                        Default: 18080
--tomcatshutdownport <tomcatshutdownport> Tomcat Shutdown Port
                        Default: 18005
--tomcatsslport <tomcatsslport> Tomcat SSL Port
                        Default: 18443
--usessl <usessl>      Should communication between the Dashboard »
                        and Service Manager be encrypted?
                        Default: 0
--adminuser <adminuser> Repository Username
                        Default: service_manager
--adminpassword <adminpassword> Password
                        Default:
```

Warning

The repository user name and password are stored in unencrypted form in the `config.properties` file. To locate this file on your operating system see [The config.properties File](#).

```
--dbport <dbport>      Bundled MySQL Database Port
                        Default: 13306
```

The monitor installation options are the same for all operating systems except as noted in the preceding listing.

15.3.4.1.2. MySQL Enterprise Monitor Agent Options

To view all the options available for an unattended *agent* installation, invoke the agent installer file passing in the `help` option. (Under Windows you must redirect the output to a file as shown in [Section 15.3.4.1, “Command-Line Options”](#)). You should see a listing similar to the following:

```
--help                Display the list of valid options
--version             Display product information
                        Default:
--optionfile <optionfile> Installation option file
                        Default:
--mode <mode>        Installation mode
```

```
(Windows)Default: win32
(Unix)Default: gtk
(Mac OS X)Default: osx
(Windows)Allowed: win32 unattended
(Unix)Allowed: gtk text xwindow unattended
(Mac OS X)Allowed: osx text unattended
```

Note
